IN NO EVENT SHALL NETAPP BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

NetApp reserves the right to change any products described herein at any time, and without notice. NetApp assumes no responsibility or liability arising from the use of products described herein, except as expressly agreed to in writing by NetApp. The use or purchase of this product does not convey a license under any patent rights, trademark rights, or any other intellectual property rights of NetApp.

The product described in this manual may be protected by one or more U.S.A. patents, foreign patents, or pending applications.

RESTRICTED RIGHTS LEGEND: Use, duplication, or disclosure by the government is subject to restrictions as set forth in subparagraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause at DFARS 252.277-7103 (October 1988) and FAR 52-227-19 (June 1987).

Trademark information

IBM, the IBM logo, and [ibm.com](http://www.ibm.com) are trademarks or registered trademarks of International Business Machines Corporation in the United States, other countries, or both. A complete and current list of other IBM trademarks is available on the Web at <http://www.ibm.com/legal/copytrade.shtml>

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

NetApp; the NetApp logo; the Network Appliance logo; Bycast; Cryptainer; Cryptoshred; DataFabric; Data ONTAP; Decru; Decru DataFort; FAServer; FilerView; FlexCache; FlexClone; FlexShare; FlexVol; FPolicy; gFiler; Go further, faster; Manage ONTAP; MultiStore; NearStore; NetCache; NOW(NetApp on the Web); ONTAPI; RAID-DP; SANscreen; SecureShare; Simulate ONTAP; SnapCopy; SnapDrive; SnapLock; SnapManager; SnapMirror; SnapMover; SnapRestore; SnapValidator; SnapVault; Spinnaker Networks; Spinnaker Networks logo; SpinAccess; SpinCluster; SpinFlex; SpinFS; SpinHA; SpinMove; SpinServer; SpinStor; StorageGRID; StoreVault; SyncMirror; Topio; vFiler; VFM; and WAFL are registered trademarks of NetApp, Inc. in the U.S.A. and/or other countries. Network Appliance, Snapshot, and The evolution of storage are trademarks of NetApp, Inc. in the U.S.A. and/or other countries and registered trademarks in some other countries. The StoreVault logo, ApplianceWatch, ApplianceWatch PRO, ASUP, AutoSupport, ComplianceClock, DataFort, DataMotion, FlexScale, FlexSuite, Lifetime Key Management, LockVault, NOW, MetroCluster, OpenKey, ReplicatorX, SecureAdmin, Shadow Tape, SnapDirector, SnapFilter, SnapMigrator, SnapSuite, TechOnTap, Virtual File Manager, VPolicy, and Web Filer are trademarks of NetApp, Inc. in the U.S.A. and other countries. Get Successful and Select are service marks of NetApp, Inc. in the U.S.A.

All other brands or products are trademarks or registered trademarks of their respective holders and should be treated as such.

NetApp is a licensee of the CompactFlash and CF Logo trademarks.

NetApp NetCache is certified RealSystem compatible.

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe on any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, N.Y. 10504-1785
U.S.A.

For additional information, visit the web at:
<http://www.ibm.com/ibm/licensing/contact/>

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law:

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM web sites are provided for convenience only and do not in any manner serve as an endorsement of those web sites. The materials at those web sites are not part of the materials for this IBM product and use of those web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

If you are viewing this information in softcopy, the photographs and color illustrations may not appear.

About the Data ONTAP Commands: Manual Page Reference, Volume 2

The *Commands: Manual Page Reference* document is a compilation of all the manual (man) pages for Data ONTAP commands, special files, file formats and conventions, and system management and services. It is provided in two volumes, each of which includes a complete index of all man pages in both volumes.

Manual pages are grouped into sections according to standard UNIX naming conventions and are listed alphabetically within each section. The following tables list the types of information for which Data ONTAP provides manual pages and the reference volume in which they can be found.

Contents of Volume 1

Manual page section	Section titles	Information related to
1	Commands	Storage system administration

Contents of Volume 2

Manual page section	Section titles	Information related to
4	Special Files	Formatting of media
5	File Formats and Conventions	Configuration files and directories
8	System Management and Services	Protocols, service daemons, and system management tools

Manual pages can also be viewed from the FilerView main navigational page or displayed at the storage system command line.

Terminology

Storage systems that run Data ONTAP are sometimes also referred to as *filers*, *appliances*, *storage appliances*, or *systems*. The name of the graphical user interface for Data ONTAP (*FilerView*) reflects one of these common usages.

The na prefix for manual page names

All Data ONTAP manual pages are stored on the storage system in files whose names are prefixed with the string "na_" to distinguish them from client manual pages. The prefixed names are used to refer to storage system manual pages from other manual pages and sometimes appear in the NAME field of the manual page, but the prefixes do not need to be part of commands.

Viewing manual pages in FilerView

To view a manual page in FilerView, complete the following steps:

1. Go to the following URL:

`http://filename/na_admin`

filename is the name (fully qualified or short) of your storage system or the IP address of the storage system.

2. Click the manual pages icon.

For more information about FilerView, see the *System Administration Guide* or FilerView Help.

Viewing manual pages at the command line

To view a manual page for a command at your storage system command line (console), enter the following:

```
man command
```

Note: Data ONTAP commands are case sensitive.

To see a list of all commands from the storage system command line, enter a question mark (?) after the host prompt.

Manual pages about using manual pages

Useful manual pages about using manual pages are the help(1) and the man(1) manual pages. You can use the `man help` command to view information about how to display the manual page for a particular command. You can use the `man man` command to view information about how to use the `man` command.

Manual Pages by Section in This Volume and Complete Index of Both Volumes

Manual Pages By Section

Section 4: Special Files

Using device files such as tape.

[[Section 1](#) | **Section 4** | [Section 5](#) | [Section 8](#) | [Complete Index](#)]

[tape](#) information on the tape interface

Section 5: File Formats and Conventions

Formats for human-readable configuration files, such as those found in `/etc` on the root volume.

[[Section 1](#) | [Section 4](#) | **Section 5** | [Section 8](#) | [Complete Index](#)]

auditlog	contains an audit record of recent administrative activity
backuplog	captures significant events during file system backup/recovery activities.
boot	directory of Data ONTAP executables
cifs_homedir.cfg	configuration file for CIFS home directories
cifs_nbalias.cfg	configuration file for CIFS NetBIOS aliases
clone	Log of clone activities
cloned_tapes	list of nonqualified tape drives attached to the filer
crash	directory of system core files
dgateways	default gateways list
dumpdates	data base of file system dump times
exports	directories and files exported to NFS clients
fsecurity	Definition file for an fsecurity job
ftpusers	file listing users to be disallowed ftp login privileges
group	group file
hosts	host name data base
hosts.equiv	list of hosts and users with rsh permission
httpd.access	authentication controls for HTTP access
httpd.group	names of HTTP access groups and their members
httpd.hostprefixes	configuration of HTTP root directories for virtual hosts
httpd.log	Log of HTTP
httpd.mimetypes	map of file suffixes to MIME ContentType
httpd.passwd	file of passwords required for HTTP access
httpd.translations	URL translations to be applied to incoming HTTP requests

messages	record of recent console messages
ndmpdlog	The ndmpdlog provides a detailed description of the activities of all active NDMP sessions.
netgroup	network groups data base
networks	network name data base
nsswitch.conf	configuration file for name service switch
nvfail_rename	Internet services
passwd	password file
psk.txt	pre-shared authentication key file
qual_devices	table of qualified disk and tape devices
quotas	quota description file
rc	system initialization command script
registry	registry database
resolv.conf	configuration file for domain name system resolver
rmtab	remote mounted file system table
serialnum	system serial number file
services	Internet services
shadow	shadow password file
sis	Log of Advanced Single Instance Storage (SIS) activities
sm	network status monitor directory
snapmirror	Log of SnapMirror Activity
snapmirror.allow	list of allowed destination filers
snapmirror.conf	volume and qtree replication schedules and configurations
stats_preset	stats preset file format
symlink.translations	Symbolic link translations to be applied to CIFS path lookups
syslog.conf	syslogd configuration file
tape_config	directory of tape drive configuration files
treecompare	Log of treecompare activities
usermap.cfg	mappings between UNIX and Windows NT accounts and users
zoneinfo	time zone information files

Section 8: System Management and Services

Protocols and service daemons, such as **rshd** and **snmpd**, and system management tools, such as **autosupport** and **syslogd**.

[[Section 1](#) | [Section 4](#) | [Section 5](#) | **[Section 8](#)** | [Complete Index](#)]

autosupport	notification daemon
cifs	Common Internet File System (CIFS) Protocol
cli	Data ONTAP command language interpreter (CLI)
dns	Domain Name System
http	HyperText Transfer Protocol
nfs	Network File System (NFS) Protocol
nis	NIS client service
pcnfsd	(PC)NFS authentication request server
protocolaccess	Describes protocol access control
rmt	remote magtape protocol module
rquotad	remote quota server
rshd	remote shell daemon
snmpd	snmp agent daemon
syslogd	log system messages

Man Page Complete Index

acpadmin (1)	Commands for managing Alternate Control Path Administrator.
aggr (1)	commands for managing aggregates, displaying aggregate status, and copying aggregates
arp (1)	address resolution display and control
auditlog (5)	contains an audit record of recent administrative activity
autosupport (8)	notification daemon
backup (1)	manages backups
backuplog (5)	captures significant events during file system backup/recovery activities.
bmc (1)	commands for use with a Baseboard Management Controller (BMC)
boot (5)	directory of Data ONTAP executables
bootfs (1)	boot file system accessor command (ADVANCED)
cdpd (1)	view the neighbors of the storage controller that are discovered using Cisco Discovery Protocol(CDP) v1 and associated statistics
cf (1)	controls the takeover and giveback operations of the filers in a cluster
charmap (1)	command for managing per-volume character maps
cifs (1)	summary of cifs commands
cifs (8)	Common Internet File System (CIFS) Protocol
cifs_access (1)	modify share-level access control or Windows machine account access
cifs_adupdate (1)	update the filer's account information on the Active Directory server
cifs_audit (1)	Configure CIFS auditing.
cifs_broadcast (1)	display a message on user workstations
cifs_changefilerpwd (1)	schedules a domain password change for the filer
cifs_comment (1)	display or change CIFS server description

cifs_domaininfo (1)	display domain type information
cifs_help (1)	display help for CIFS-specific commands
cifs_homedir (1)	Manage CIFS home directory paths.
cifs_homedir.cfg (5)	configuration file for CIFS home directories
cifs_lookup (1)	translate name into SID or vice versa
cifs_nbalias (1)	Manage CIFS NetBIOS aliases.
cifs_nbalias.cfg (5)	configuration file for CIFS NetBIOS aliases
cifs_prefdc (1)	configure and display CIFS preferred Domain Controller information
cifs_resetdc (1)	reset CIFS connection to Domain Controller
cifs_restart (1)	restart CIFS service
cifs_sessions (1)	information on current CIFS activity
cifs_setup (1)	configure CIFS service
cifs_shares (1)	configure and display CIFS shares information
cifs_sidcache (1)	clears the CIFS SID-to-name map cache
cifs_stat (1)	print CIFS operating statistics
cifs_terminate (1)	terminate CIFS service
cifs_testdc (1)	test the Filer's connection to Windows NT domain controllers
cifs_top (1)	display CIFS clients based on activity
cli (8)	Data ONTAP command language interpreter (CLI)
clone (1)	Manages file and sub-file cloning
clone (5)	Log of clone activities
cloned_tapes (5)	list of nonqualified tape drives attached to the filer
config (1)	command for configuration management
crash (5)	directory of system core files
date (1)	display or set date and time
dd (1)	copy blocks of data
df (1)	display free disk space
dgateways (5)	default gateways list
disk (1)	RAID disk configuration control commands
disk_fw_update (1)	update disk firmware
disktest (1)	Disk Test Environment
dln (1)	Administer Dynamically Loadable Modules
dns (1)	display DNS information and control DNS subsystem
dns (8)	Domain Name System
download (1)	install new version of Data ONTAP
dump (1)	file system backup
dumpdates (5)	data base of file system dump times
echo (1)	display command line arguments
ems (1)	Invoke commands to the ONTAP Event Management System
enable (1)	DEPRECATED, use na_license(1) instead

environ (1)	DEPRECATED, please use the na_environment(1) command instead.
environment (1)	display information about the filer's physical environment
exportfs (1)	exports or unexports a file system path, making it available or unavailable, respectively, for mounting by NFS clients.
exports (5)	directories and files exported to NFS clients
fcadmin (1)	Commands for managing Fibre Channel adapters.
fcdiag (1)	Diagnostic to assist in determining source of loop instability
fcpl (1)	Commands for managing Fibre Channel target adapters and the FCP target protocol.
fcstat (1)	Fibre Channel stats functions
fctest (1)	test Fibre Channel environment
file (1)	manage individual files
filestats (1)	collect file usage statistics
flexcache (1)	commands for administering FlexCache volumes
floppyboot (1)	describes the menu choices at the floppy boot prompt
fpolicy (1)	configure file policies
fsecurity (1)	Summary of fsecurity commands
fsecurity (5)	Definition file for an fsecurity job
fsecurity_apply (1)	Creates a security job based on a definition file and applies it to the file system.
fsecurity_cancel (1)	Cancels outstanding fsecurity jobs
fsecurity_help (1)	Displays a description and usage information for fsecurity commands
fsecurity_remove-guard (1)	Removes the Storage-Level Access Guard from a volume or qtree
fsecurity_show (1)	Displays the security settings on files and directories
fsecurity_status (1)	Displays the status of outstanding fsecurity jobs
ftp (1)	display FTP statistics
ftpd (1)	file transfer protocol daemon
ftpusers (5)	file listing users to be disallowed ftp login privileges
group (5)	group file
halt (1)	stop the filer
help (1)	print summary of commands and help strings
hostname (1)	set or display filer name
hosts (5)	host name data base
hosts.equiv (5)	list of hosts and users with rsh permission
http (8)	HyperText Transfer Protocol
httpd.access (5)	authentication controls for HTTP access
httpd.group (5)	names of HTTP access groups and their members
httpd.hostprefixes (5)	configuration of HTTP root directories for virtual hosts
httpd.log (5)	Log of HTTP
httpd.mimetypes (5)	map of file suffixes to MIME ContentType

httpd.passwd (5)	file of passwords required for HTTP access
httpd.translations (5)	URL translations to be applied to incoming HTTP requests
httpstat (1)	display HTTP statistics
ifconfig (1)	configure network interface parameters
ifinfo (1)	display driver-level statistics for network interfaces
ifstat (1)	display device-level statistics for network interfaces
igroup (1)	Commands for managing initiator groups
ipsec (1)	manipulates the ipsec SP/SA/certificate Databases and displays ipsec statistics
ipspace (1)	ipspace operations
iscsi (1)	manage iSCSI service
iswt (1)	manage the iSCSI software target (ISWT) driver
keymgr (1)	key and certificate management
license (1)	license Data ONTAP services
lock (1)	manage lock records
logger (1)	record message in system logs
logout (1)	allows a user to terminate a telnet session.
lun (1)	Commands for managing luns
man (1)	locate and display reference manual pages
maxfiles (1)	increase the number of files the volume can hold
memerr (1)	print memory errors
messages (5)	record of recent console messages
mt (1)	magnetic tape positioning and control
nbtstat (1)	displays information about the NetBIOS over TCP connection
ndmpcopy (1)	transfers directory trees between filers using NDMP
ndmpd (1)	manages NDMP service
ndmpdlog (5)	The ndmpdlog provides a detailed description of the activities of all active NDMP sessions.
ndp (1)	control/diagnose IPv6 neighbor discovery protocol
netdiag (1)	perform network diagnostics
netgroup (5)	network groups data base
netstat (1)	show network status
networks (5)	network name data base
nfs (1)	manage Network File System service
nfs (8)	Network File System (NFS) Protocol
nfsstat (1)	display NFS statistics
nis (1)	display NIS information
nis (8)	NIS client service
nsswitch.conf (5)	configuration file for name service switch
nvfail_rename (5)	Internet services

options (1)	display or set filer options
orouted (1)	old network routing daemon
partner (1)	access the data on the partner in takeover mode
passwd (1)	modify the system administrative user's password
passwd (5)	password file
pcnfsd (8)	(PC)NFS authentication request server
ping (1)	send ICMP ECHO_REQUEST packets to network hosts
ping6 (1)	send ICMPv6 ECHO_REQUEST packets to network hosts
pktt (1)	controls on-filer packet tracing
portset (1)	Commands for managing portsets
priority (1)	commands for managing priority resources.
priv (1)	control per-connection privilege settings
protocolaccess (8)	Describes protocol access control
psk.txt (5)	pre-shared authentication key file
qtree (1)	create and manage qtrees
qual_devices (5)	table of qualified disk and tape devices
quota (1)	control filer disk quotas
quotas (5)	quota description file
rc (5)	system initialization command script
rdate (1)	set system date from a remote host
rdfile (1)	read a WAFL file
reallocate (1)	command managing reallocation of files, LUNs, volumes and aggregates
reboot (1)	stop and then restart the filer
registry (5)	registry database
resolv.conf (5)	configuration file for domain name system resolver
restore (1)	file system restore
rlm (1)	commmands for use with a Remote LAN Module (RLM)
rmc (1)	commmands for use with a remote management controller
rmt (8)	remote magtape protocol module
rmtab (5)	remote mounted file system table
route (1)	manually manipulate the routing table
routed (1)	network RIP and router discovery routing daemon
rquotad (8)	remote quota server
rshd (8)	remote shell daemon
rshstat (1)	prints the information about active rsh sessions.
rtsold (1)	router solicitation daemon
san (1)	Glossary for IBM specific SAN terms
sasadmin (1)	Commands for managing Serial Attached SCSI (SAS) adapters.
sasstat (1)	Commands for managing Serial Attached SCSI (SAS) adapters.
savecore (1)	save a core dump

sectrace (1)	manages permission tracing filters
secureadmin (1)	command for secure administration of the appliance.
serialnum (5)	system serial number file
services (5)	Internet services
setup (1)	update filer configuration
sftp (1)	display SFTP (SSH File Transfer Protocol) statistics.
shadow (5)	shadow password file
shelfchk (1)	verify the communication of environmental information between disk shelves and the filer
sis (1)	Advanced Single Instance Storage (SIS) management.
sis (5)	Log of Advanced Single Instance Storage (SIS) activities
sm (5)	network status monitor directory
snap (1)	manage snapshots
snaplock (1)	compliance related operations.
snapmirror (1)	volume, and qtree mirroring
snapmirror (5)	Log of SnapMirror Activity
snapmirror.allow (5)	list of allowed destination filers
snapmirror.conf (5)	volume and qtree replication schedules and configurations
snapvault (1)	disk-based data protection
snmp (1)	set and query SNMP agent variables
snmpd (8)	snmp agent daemon
software (1)	Install or upgrade Data ONTAP
source (1)	read and execute a file of filer commands
stats (1)	command for collecting and viewing statistical information
stats_preset (5)	stats preset file format
storage (1)	Commands for managing the disks and SCSI and Fibre Channel adapters in the storage subsystem.
symlink.translations (5)	Symbolic link translations to be applied to CIFS path lookups
sysconfig (1)	display filer configuration information
syslog.conf (5)	syslogd configuration file
syslogd (8)	log system messages
sysstat (1)	report filer performance statistics
tape (4)	information on the tape interface
tape_config (5)	directory of tape drive configuration files
timezone (1)	set and obtain the local timezone
traceroute (1)	print the route packets take to network host
traceroute6 (1)	print the route IPv6 packets take to a network node
treecompare (5)	Log of treecompare activities
ups (1)	controls the monitoring of UPS' (Uninterruptable Power Supply'(s))
uptime (1)	show how long system has been up

useradmin (1)	Administer file access controls
usermap.cfg (5)	mappings between UNIX and Windows NT accounts and users
version (1)	display Data ONTAP version
vfiler (1)	vfiler operations
vif (1)	manage virtual network interface configuration
vlan (1)	manage VLAN interface configuration
vol (1)	commands for managing volumes, displaying volume status, and copying volumes
vscan (1)	control virus scanning for files on the filer
wcc (1)	manage WAFL credential cache
wrfile (1)	write a WAFL file
ypcat (1)	print values from a NIS database
ypgroup (1)	display the group file entries cached locally from the NIS server if NIS is enabled
ypmatch (1)	print matching values from a NIS database
ypwhich (1)	display the NIS server if NIS is enabled
zoneinfo (5)	time zone information files

tape

NAME

na_tape - information on the tape interface

DESCRIPTION

The Data ONTAP system supports up to 64 local tape drives (tape drives connected directly to the system). The tape drive interface follows a UNIX-like device name allowing use of a **rewind**, **norewind** or **unload/reload** device. The device name can be the classic *cstnd* format, or of the format *c.name.d* where:

c
describes the rewind/unload characteristic of the device. Use **r** to specify the **rewind** device, use **nr** to specify the **norewind** device, or use **ur** to specify the **unload/reload** device. The **norewind** device will not rewind when the tape device is closed. The **unload/reload** device is used with sequential tape loaders and will unload the current tape volume and attempt to load the next tape volume (note that the server will wait up to one minute for the next volume to become ready before aborting the reload of the next volume). The rewind device will rewind the tape volume to beginning-of-tape on close.

st
the **st** portion of the device name is always present in the classic format, and is one of the options in the *name* format. It specifies that you are requesting a SCSI tape device.

n
the alias number (in decimal) of the tape drive to use. The **st** and *n* parameters together - **stn** constitute a tape "alias". See the **storage alias** command for information about tape aliases and device addresses.

d
the density (or format) to use for tape write operations. Consists of one of the four letters **l** (low), **m** (medium), **h** (high) or **a** (advanced).

name
specifies a tape alias, an electrical name or an IEEE World-Wide Name (WWN) corresponding to the device. The electrical-name and WWN formats only can contain an optional device LUN (SCSI Logical UNit) parameter expressed as **Llun**. See the **storage alias** command for further information about the format of the *name* parameter.

Each tape device is automatically associated with an alias. If an alias assignment does not already exist at the first discovery of a tape device, the system will create an alias for it. FC devices receive WWN aliases, and SCSI devices receive electrical aliases by default. The alias will remain associated with the WWN or electrical name -- even through boot -- until the alias is changed.

The **storage alias** and **storage unalias** commands (q.v.) allow the user to preassign electrical or WWN addresses to aliases (the devices do not have to exist yet), or to adjust the aliases after automatic assignment. A WWN alias allows an FC device that has been moved from one FC adapter or switch port to another to be located by the system without further intervention. An electrical-name alias allows a particular address to be persistently allocated to the alias.

EXAMPLES

The density specifications for an Exabyte 8505 8mm drive:

```
l Exabyte 8200 format, no compression
m Exabyte 8200 format with compression
h Exabyte 8500 format, no compression
a Exabyte 8500 format with compression
```

Examples of tape drive names:

```
nrst01
nr.st0.1
r.9a.1l1.a
ur.switch1:5.h
nr.WWN[1:23:456789:012345].m
```

The **sysconfig -t** command displays the tape drives on your system, the device alias associated with each tape device, and the device's available density settings. The following is an example of the output from a **sysconfig** command on a system with one tape device attached:

toaster> **sysconfig -t**

```
Tape drive (0.6) Exabyte 8505 8mm
rst01 - rewind device, format is: EXB-8200 2.5GB
nrst01 - no rewind device, format is: EXB-8200 2.5GB
urst01 - unload/reload device, format is: EXB-8200 2.5GB
rst0m - rewind device, format is: EXB-8200C (w/compression)
nrst0m - no rewind device, format is: EXB-8200C (w/compression)
urst0m - unload/reload device, format is: EXB-8200C (w/compression)
rst0h - rewind device, format is: EXB-8500 5.0GB
nrst0h - no rewind device, format is: EXB-8500 5.0GB
urst0h - unload/reload device, format is: EXB-8500 5.0GB
rst0a - rewind device, format is: EXB-8500C (w/compression)
nrst0a - no rewind device, format is: EXB-8500C (w/compression)
urst0a - unload/reload device, format is: EXB-8500C (w/compression)
```

The **storage show tape** command shows the electrical or WWN name associated with the device and the corresponding alias:

toaster> **storage show tape**

```
Tape Drive: 0.6
Description: Exabyte 8505 8mm
Serial Number: IE71E024
World Wide Name:
Alias Name(s): st0
Device State: available
```

tape

auditlog

NAME

na_auditlog - contains an audit record of recent administrative activity

SYNOPSIS

<logdir>/auditlog

<logdir> is /etc/log for filers and /logs for NetCache appliances.

DESCRIPTION

If the option **auditlog.enable** is on, the system logs all input to the system at the console/telnet shell and via rsh to the auditlog file. The data output by commands executed in this fashion is also logged to auditlog. Administrative servlet invocations (via HTTP, typically from FilerView) and API calls made via the ONTAPI interface are also logged to the auditlog. A typical message is:

Wed Feb 9 17:34:09 GMT [rshd_0:auditlog]: root:OUT:date: Wed Feb 9 17:34:09 GMT 2000

This indicates that there was an rsh session around Wed Feb 9 17:34:09 GMT which caused the **date** command to be executed. The user performing the command was root. The type of log is data output by the system as indicated by the **OUT** keyword.

Commands typed at the filer's console or executed by rsh are designated by the **IN** keyword as in:

Wed Feb 9 17:34:03 GMT [rshd_0:auditlog]: :IN:rsh shell: RSH INPUT COMMAND is date

The start and end of an rsh session are specially demarcated as in

Wed Feb 9 17:34:09 GMT [rshd_0:auditlog]: root:START:rsh shell:orbit.eng.mycompany.com

and

Wed Feb 9 17:34:09 GMT [rshd_0:auditlog]: root:END:rsh shell:

The maximum size of the auditlog file is controlled by the **auditlog.max_file_size** option. If the file gets to this size, it is rotated (see below).

Every Saturday at 24:00, <logdir>/auditlog is moved to <logdir>/auditlog.0, <logdir>/auditlog.0 is moved to <logdir>/auditlog.1, and so on. This process is called rotation. Auditlog files are saved for a total of six weeks, if they do not overflow.

If you want to forward audit log messages to a remote syslog log host (one that accepts syslog messages via the BSD Syslog protocol specified in RFC 3164), modify the filer's /etc/syslog.conf file to forward messages from the filer's "local7" facility to the remote host. Do this by adding a line like:

```
local7.*
    @1.2.3.4
```

auditlog

to `/etc/syslog.conf`. An IP address has been used here, but a valid DNS name could also be used. Note that using a DNS name can fail if the filer is unable to resolve the name given in the file. If that happens, your messages will not be forwarded.

On the log host, you'll need to modify the syslog daemon's configuration file to redirect syslog message traffic from the "local7" facility to the appropriate configuration file. That is typically done by adding a line similar to the one shown above for the filer:

local7.*

`/var/logs/filer_auditlogs`

Then restart the daemon on the log host, or send an appropriate signal to it. See the documentation for your log host's syslog daemon for more information on how to make that configuration change.

FILES

<logdir>/auditlog

auditlog file for current week. **<logdir>/auditlog.[0-5]** auditlog files for previous weeks

`na_syslog.conf(5)`

backuplog

NAME

na_backuplog - captures significant events during file system backup/recovery activities.

SYNOPSIS

/etc/log/backup

DESCRIPTION

Filer captures significant dump/restore-related events and the respective times at which they occur. All events are recorded in one-line messages in **/etc/log/backup**.

The following are the events filer monitors:

Start

Dump/restore starts.

Restart

Restart of a dump/restore.

End

Dump/restore completes successfully.

Abort

The operation aborts.

Error

Dump/restore hits an unexpected event.

Options

Logs the options as users specify.

Tape_open

Output device is opened successfully.

Tape_close

Output device is closed successfully.

Phase_change

As dump/restore completes a stage.

Dump specific events:

Snapshot

When the snapshot is created or located.

backuplog

Base_dump

When a valid base dump entry is located.

Logging events:

Start_logging Logging begins.

Stop_logging

Logging ends.

Each event record is in the following format:

TYPE TIME_STAMP IDENTIFIER EVENT (EVENT_INFO)

TYPE

Either dmp(dump), rst(restore) or log events.

TIME_STAMP

Shows date and time at which event occurs.

IDENTIFIER

Unique ID for the dump/restore.

EVENT

The event name.

EVENT_INFO

Event specific information.

A typical event record message looks like:

dmp Thu Apr 5 18:54:56 PDT 2001 /vol/vol0/home(5) Start (level 0, NDMP)

In the particular example:

TYPE

= **dmp**

TIME_STAMP

= **Thu Apr 5 18:54:56 PDT 2001**

IDENTIFER

= **/vol/vol0/home(5)**

EVENT

= **Start**

EVENT_INFO

= **level 0, NDMP**

All event messages go to **/etc/log/backup**. On every Sunday at 00:00, **backup** is roated to **backup.0** and **backup.0** is moved to **backup.1** and so on. Up to 6 log files(spanning up to 6 weeks) are kept.

The registry option **backup.log.enable** controls the enabling and disabling of the logging with values **on** and **off** respectively. The functionality is enabled by default. (See `na_options(1)` for how to set options.)

FILES

/etc/log/backup

backup log file for current week. **/etc/log/backup.[0-5]** backup log files for previous weeks

SEE ALSO

`na_options(1)`

boot

boot

NAME

na_boot - directory of Data ONTAP executables

SYNOPSIS

/etc/boot

DESCRIPTION

The **boot** directory contains copies of the executable files required to boot the filer. The **download** command (see `na_download(1)`) copies these files from **/etc/boot** into the filer's boot block, from which the system boots.

FILES

/etc/boot

directory of Data ONTAP executables. Files are placed in `/etc/boot` after the tar or `setup.exe` has decompressed them. These files vary from release to release.

SEE ALSO

`na_download(1)`

cifs_homedir.cfg

NAME

na_cifs_homedir.cfg - configuration file for CIFS home directories

SYNOPSIS

`/etc/cifs_homedir.cfg`

DESCRIPTION

The configuration file `/etc/cifs_homedir.cfg` is used to configure home directory paths for users which access the filer using the CIFS network protocol.

EXAMPLE

This is a sample `/etc/cifs_homedir.cfg` file with one CIFS home directory path. The filer will look for a CIFS home directory for user "Bill" by appending the user's name to the path. From the example below, the filer will provide user "Bill" a CIFS home directory at `/vol/userVol/users/Bill` if that directory exists.

```
#
# This file contains the path(s) used by the filer to determine if a
# CIFS user has a home directory. See the System Administrator's Guide
# for a full description of this file and a full description of the
# CIFS homedir feature.
#
# There is a limit to the number of paths that may be specified.
# Currently that limit is 1000.
# Paths must be entered one per line.
#
# After editing this file, use the console command "cifs homedir load"
# to make the filer process the entries in this file.
#
# Note that the "#" character is valid in a CIFS directory name.
# Therefore the "#" character is only treated as a comment in this
# file if it is in the first column.
#
# Two example path entries are given below.
# /vol/vol0/users1
# /vol/vol1/users2
#
# Actual path entries follow this line.
/vol/userVol/users
```

EFFECTIVE

Any changes take effect after running the 'cifs homedir load' command.

cifs_homedir.cfg

PERSISTENCE

Changes are persistent across system reboots.

FILES

`/etc/cifs_homedir.cfg`

SEE ALSO

`na_cifs_homedir(1)`

cifs_nbalias.cfg

NAME

na_cifs_nbalias.cfg - configuration file for CIFS NetBIOS aliases

SYNOPSIS

`/etc/cifs_nbalias.cfg`

DESCRIPTION

The configuration file `/etc/cifs_nbalias.cfg` is used to configure NetBIOS aliases for the filer. A NetBIOS alias allows the filer to be accessed by a CIFS client using an alternate name for the filer.

EXAMPLE

This is a sample `/etc/cifs_nbalias.cfg` file with one NetBIOS alias.

```
#
# This file contains NetBIOS aliases used by the filer.
# See the System Administrator's Guide for a full
# description of this file.
#
# There is a limit to the number of aliases that may be specified.
# Currently that limit is 200.
#
# Aliases must be entered one per line.
#
# After editing this file, use the console command "cifs nbalias load"
# to make the filer process the entries in this file.
#
# Note that the "#" character is valid in a CIFS NetBIOS alias.
# Therefore the "#" character is only treated as a comment in this
# file if it is in the first column.
#
# Actual NetBIOS alias name(s) for the filer follow this line.
FILERALIAS01
```

EFFECTIVE

Any changes take effect once CIFS services are restarted

PERSISTENCE

Changes are persistent across system reboots.

cifs_nbalias.cfg

FILES

/etc/cifs_nbalias.cfg

SEE ALSO

na_cifs_nbalias(1)

clone

NAME

na_clone - Log of clone activities

SYNOPSIS

/etc/log/clone

DESCRIPTION

The **clone** log file contains a log of clone activities for the filer. The file lives in **/etc/log** on the root volume.

Every Sunday at midnight, **/etc/log/clone** is moved to **/etc/log/clone.0**; **/etc/log/clone.0** is moved to **/etc/log/clone.1**; and so on. The suffix can go up to 5, so the old **/etc/log/clone.5** will be deleted. Clone activities are saved for a total of seven weeks.

Each entry of the **/etc/log/clone** file is a single line containing the following space-separated fields.

```
timestamp Volume:vol-name event_info
```

The following is a description of each field.

timestamp

Displayed in **ctime()** format, e.g. Fri Jul 17 20:41:09 GMT 2008. Indicates the time this event was recorded.

vol-name

The volume name on which clone operation is performed:

event_info

The event which is being logged. These are the current event types with their operation info:

Clone Start ID:<clone-id> Clone File:<clone-file> Source File:<source-file> Total Blocks:<total-blocks>

Corresponds to "clone start" command.

Clone End ID:<clone-id> Clone File:<clone-file> Source File:<source-file> <end-reason> Total Blocks:<totalblocks> Blocks Copied: <blocks-copied>

Corresponds to clone operation has been completed successfully, unsuccessfully or stopped by user.

Clone Stop ID:<clone-id> Clone File:<clone-file> Source File:<source-file>

Corresponds to "clone stop" command.

Clone Restart Successful/Failed ID:<clone-id> Clone File:<clone-file> Source File:<source-file> Total Blocks:<total-blocks>

clone

Corresponds to "clone restart" operation.

Clone Boot <info>

Corresponds to reboot and provides the information about clone boot work on the volume, whether it is completed successfully or failed with error.

EXAMPLE

A clone operation started with source file as f1 and clone file as f1_1. then the clone operation was stopped by user. The clone log file should have the following entries:

```
Tue Oct 21 09:03:18 GMT 2008 Volume: vol1 [sid: 0] Clone Start ID: 1, Clone File: f1_1, Source File: f1, Total Blocks: 786432
Tue Oct 21 09:03:24 GMT 2008 Volume: vol1 [sid: 0] Clone Stop ID: 1, Clone File: f1_1, Source File: f1
Tue Oct 21 09:03:26 GMT 2008 Volume: vol1 [sid: 0] Clone End ID: 1, Clone File: f1_1, Source File: f1 (Clone operation aborted by user), Total Blocks: 786432,Blocks Copied: 0
Tue Oct 21 09:11:17 GMT 2008 Volume: vol2 [sid: 0] Clone Restart Successful. ID: 2, Clone File: f2, Source File: f2_1, Total Blocks: 50
```

FILES

/etc/log/clone

Clone log file for current week.

/etc/log/clone.[0-5]

Clone log files for previous weeks.

SEE ALSO

na_clone(1)

cloned_tapes

NAME

na_cloned_tapes - list of nonqualified tape drives attached to the filer

SYNOPSIS

/etc/cloned_tapes

DESCRIPTION

If you attach a tape drive that IBM has not tested with the filer, enter information about the tape drive in the **/etc/cloned_tapes** file. This file enables the filer to register the drive as a clone of a qualified drive.

If the filer boots with a nonqualified tape drive and the **/etc/cloned_tapes** file does not exist, the filer creates a sample file, when the first "mt" command for the tape is executed.

Each entry in the **/etc/cloned_tapes** file corresponds to one tape drive. Specify the entry in one of the following formats:

clone_vendor_id clone_product_id EMULATES vendor_id product_id

clone_product_id EMULATES product_id

The "storage show tape supported" command provides a list the product_id and vendor_id values of qualified drives.

EXAMPLE

The following entry in the **/etc/cloned_tapes** file enables the filer to register the Quantum DLT9000 tape drive, which has not been tested with the filer, as a clone of the Quantum DLT7000 tape drive:

QUANTUM DLT9000 EMULATES QUANTUM DLT7000

SEE ALSO

na_storage(1)

crash

crash

NAME

na_crash - directory of system core files

SYNOPSIS

/etc/crash

DESCRIPTION

If a filer crashes, it creates a core file in the **crash** directory. The core files are very useful for finding and fixing bugs in Data ONTAP, so please notify IBM Service and Support of any core files on your filer.

See `na_savecore(1)` for more details about how core files are saved.

FILES

/etc/crash/core.*
saved core files **/etc/crash/core.*-small** compact core file.

/etc/crash/bounds
suffix for next core file

/etc/crash/minfree
free KB in FS to maintain after savecore

SEE ALSO

`na_savecore(1)`

dgateways

NAME

na_dgateways - default gateways list

SYNOPSIS

/etc/dgateways

DESCRIPTION

The use of */etc/dgateways* file has been deprecated. Either add a static default gateway in */etc/rc* or enable router discovery in **routed** to discover multiple default gateways.

The */etc/dgateways* file is used by the old **routed** command to construct a set of potential default gateways. The file comprises a series of lines, each in the following format:

gateway metric

gateway is the name or address of a gateway to be used as a potential default gateway.

metric is a metric indicating the preference weighting of the gateway. 1 is the value to use for highest preference, 15 for the least. If no value is specified, *metric* will default to the value 1.

There can be a maximum of 128 valid entries in the */etc/dgateways* file - additional ones will be ignored, with an error message being displayed. Duplicate gateway names or addresses are not allowed - only the first one encountered in the file will be added by **routed** to the default gateway table, and the additional ones will produce error messages.

EXAMPLE

Here are typical lines from the */etc/dgateways* file:

```
main_router    1
backup_router  2
```

SEE ALSO

na_rc(5),

NOTES

The use of */etc/dgateways* file has been deprecated.

dumpdates

NAME

na_dumpdates - data base of file system dump times

SYNOPSIS

/etc/dumpdates

DESCRIPTION

The **dump** command (see `na_dump(1)`) uses */etc/dumpdates* to keep track of which subtrees have been dumped and when. Each line in **dumpdates** contains the subtree dumped, the dump level, and the creation date of the snapshot used by **dump**. There is only one entry per subtree at a given dump level. **dumpdates** may be edited to change any of the fields, if necessary.

EXAMPLE

This shows the dumpdate file for a system on which **/home** and **/export** are backed up using **dump**.

```

/home      0 Tue Nov  2 10:56:27 1993
/export    0 Tue Nov  2 13:51:17 1993
/export    1 Tue Nov  5 18:31:17 1993
/home      1 Tue Nov  5 18:45:27 1993

```

FILES

/etc/dumpdates

SEE ALSO

`na_dump(1)`

exports

NAME

na_exports - directories and files exported to NFS clients

SYNOPSIS

/etc/exports

DESCRIPTION

The */etc/exports* file contains a list of export entries for all file system paths that Data ONTAP exports automatically when NFS starts up. The */etc/exports* file can contain up to 10,240 export entries. Each export entry can contain up to 4,096 characters, including the end-of-line character. To specify that an export entry continues onto the next line, you must use the line continuation character "\".

An export entry has the following syntax:

Each export entry is a line in the following format:

```
pathname -option[,option ] ...
```

The following list describes the fields in an export entry:

pathname

path name of a file or directory to be exported.

option

the export option specifying how a file or directory is exported.

You can specify an option in one of the following formats:

actual=path

Specifies the actual path to use when a NFS client attempts to mount the original path. This option is useful for moving mount points without reconfiguring the clients right away. Note that while the exported pathname need not exist, the pathname given as a parameter to **actual** must exist. Note: NFSv4 clients will not see an exported path using the **actual** option unless the export path is only one level deep and is not **/vol**.

anon=uid|name If a request comes from user ID of 0 (root user ID on the client), use *uid* as the effective user ID unless the client host is included in the **root** option. The default value of *uid* is 65534. To disable root access, set *uid* to 65535. To grant root access to all clients, set *uid* to 0. The user ID can also be specified by a name string corresponding to an entry in */etc/passwd*.

nosuid

Disables **setuid** and **setgid** executables and **mknod** commands on the file system path. Unless the file system is a root partition of a diskless NFS client, you should set the **nosuid** option to prevent NFS client users from creating **setuid** executables and device nodes that careless or cooperating NFS server users could use to gain root access.

exports

ro | **ro=hostname**[:*hostname*]...

A *pathname* can be either exported **ro** to all hosts or to a set of specified hosts.

rw | **rw=hostname**[:*hostname*]...

A *pathname* can be either exported **rw** to all hosts or to a set of specified hosts. If no access modifiers are provided, then the default is **rw**.

root=hostname[:*hostname*]...

Give **root** access only to the specified hosts. Note that there is no **-root** option, i.e., this option always takes at least one hostname as a parameter.

sec=secflavor[:*secflavor*]...

Allow access to the mounted directory only using the listed security flavors. If no **sec** directive is provided, then the default of **sys** is applied to the export. The **sec** directive may appear multiple times in a rule, which each appearance setting the context of the following directives: **anon**, **nosuid**, **ro**, **root**, and **rw**. The contexts apply in order. If only one security context is provided in an export, then it applies regardless of where it appears in the export. Note that any given *secflavor* **can only appear once in an export rule**.

The supported security flavors are:

sys

for Unix(tm) style security based on uids and gids

krb5

for Kerberos(tm) Version 5 authentication.

krb5i

for Kerberos(tm) Version 5 integrity service

krb5p

for Kerberos(tm) Version 5 privacy service

The Kerberos(tm) authentication service verifies the identity of the users accessing the filer on all accesses, and also verifies to the client that the responses are from the filer. The integrity service provides a strong assurance that the messages have not been tampered with. The privacy service ensures that messages intercepted on the wire cannot be read by any other party. The integrity and privacy services both include authentication. The default security flavor is **sys**.

The security flavor of **none** can also be applied to an export. If the client uses this flavor, then all requests get the effective UID of the anonymous user. Also, if a request arrives with a security context which is not present in the export, and **none** is allowed, then that request is treated as if it arrived with the flavor of **none**.

HOSTNAMES

A host is allowed to mount an export if it has either **ro** or **rw** access permissions.

A hostname is described as:

[-][machine name|netgroup|machine IP|subnet|DNS domain]

Where, '-' indicates that the host is to be denied access.

A machine name is an alphanumeric string.

A netgroup is also an alphanumeric string and describes a group of machine names. If NIS is not enabled, then each netgroup must be defined in the */etc/netgroup* file. If NIS is enabled, then each netgroup may either be in a NIS mapping or defined in the */etc/netgroup* file.

If a netgroup occurs in both NIS and */etc/netgroup*, then the ordering given in */etc/nsswitch.conf* determines which definition is used.

A netgroup can be differentiated from a hostname by prepending an '@' to the name. When an entry begins with an '@', ONTAP treats it as netgroup and not a hostname. When an entry does not begin with '@', the handling depends on the setting of the option **nfs.netgroup.strict**.

If **nfs.netgroup.strict** is set, then the '@' determines whether an entry is either a netgroup or a hostname. In this case, when an entry appears without a prepended '@', it is assumed to be a hostname, i.e., it cannot be a netgroup.

If **nfs.netgroup.strict** is not set, then an entry with '@' will still only denote a netgroup, but the absence of the '@' does not determine that an entry is a host.

The use of the **nfs.netgroup.strict** option eliminates spurious netgroup lookups (which can be helpful to performance). If it is not used, backwards compatibility with export specifications in which netgroups are not specified with an '@' is retained.

For IPv4, a machine IP is in dotted decimal format (AAA.BBB.CCC.DDD), and for IPv6, machine IP is of the form [AAAA:BBBB:CCCC:DDDD::FFFF].

A subnet is in the forms:

IP_address/num_bits

The IP_address field is a subnet number. It can be a IPv4 or IPv6 address in the format specified above. The num_bits field specifies the size of the subnet by the number of leading bits of the netmask.

"[network] subnet [netmask] netmask" The subnet field is the subnet number. The netmask field is the netmask. Note that the keywords *net_work* and *netmask* are optional.

A DNS domain starts with a '.' and is alphanumeric.

If there is a machine name and a netgroup with the same name, then the hostname is assumed to be the name of a machine.

In UNIX, it is illegal to export a directory that has an exported ancestor in the same file system. Data ONTAP does not have this restriction. For example, you can export both the */vol/vol0* directory and the */vol/vol0/home* directory. In determining permissions, the filer uses the longest matching prefix.

DUPLICATE DETECTION

Neither the same path nor the same file handle can be advertised for exports. We restrict the path names to make mounts unique and the file handle restriction makes per NFS request checking also be unique.

As the `/etc/exports` file is parsed and the same path is determined to be used for exporting, then the last instance of the export rule is stored in memory. Note that different path names may evaluate to the same advertised path:

/home

/vol/vol0/home

/vol/vol0/home/ontap/..

The addition of **actual** complicates the rules for determining what gets exported. If an export uses **-actual**, then neither the advertised path nor the actual storage path may be duplicated in memory.

ACCESS RULES

There is no set ordering of options, but as the **ro** and **rw** options interact, there is a strict interpretation of these options:

- 1) **-rw** is the default if **-ro**, **-ro=**, **-rw**, and **-rw=** are all not present.
- 2) If only **-rw=** is present, **ro** is *not* the default for all other hosts. This rule is a departure from pre-6.5 semantics.
- 3) **-ro,ro=** and **-rw,rw=** are errors.
- 4) **-ro=A,rw=A** is an error
- 5) **-ro=A,rw=-A** is an error
- 6) **-ro=-A,rw=A** is an error
- 7) The position of **-rw**, **-rw=**, **-ro**, and **-ro=** in the options does not have any significance
- 8) **-ro** trumps **-rw**
- 9) **-ro=** trumps **-rw**
- 10) **-rw=** trumps **-ro**
- 11) A specific host name in either **-ro=** or **-rw=** overrides a grouping in the other access specifier.
- 12) **-ro=** trumps **-rw=**
- 13) Left to right precedence, which determines '-' and the order we go across the wire.

Note, "A trumps B" means that option A overrides option B.

ACCESS RULES EXAMPLES

Given the following netgroups:

farm pets (alligator,,) **livestock** workers

pets (dog,,) (cat,,) (skunk,,) (pig,,) (crow,,)

livestock
(cow,,) (pig,,) (chicken,,) (ostrich,,)

workers
(dog,,) (horse,,) (ox,,) (mule,,)

predators
(coyote,,) (puma,,) (fox,,) (crow,,)

We can illustrate the access rules thusly:

/vol/vol0 -anon=0

All hosts have **rw** access, and root at that.

/vol/vol0 -root=horse,rw

All hosts have **rw** access, but only horse has root access.

/vol/vol0 -anon=0,rw=horse

Only horse has access and it is **rw**. Note the departure from the prior rule format, in which all other hosts would by default have **ro** access.

/vol/vol0 -anon=0,ro,rw=horse

All hosts have **ro** access, except horse, which has **rw** access.

/vol/vol1 -ro=@workers,rw=@farm:canary /vol/vol1 -rw=@farm:canary,ro=@workers

All hosts in the netgroup **farm** have **rw** access, except dog, horse, ox, and mule. All of which have **ro** access. In addition, canary has **rw** access to the export. Note that both lines are identical with respect to determining access rights.

/vol/vol2 -ro=@pets,rw

All hosts have **rw** access, except for dog, cat, skunk, pig, and crow, all of which have **ro** access.

/vol/vol2 -ro=-@pets,rw

All hosts have **rw** access, except for dog, cat, skunk, pig, and crow, all of which have no access at all.

By rule #9, all members of the netgroup **pets** are denied **rw** access. By negation, all members of the netgroup **pets** are denied **ro** access.

exports

/vol/vol2 -ro,rw=@pets:canary

All hosts have **ro** access, except for canary, dog, cat, skunk, pig, and crow, all of which have **rw** access.

/vol/vol2 -ro,rw=-@pets:canary

All hosts have **ro** access, except for canary which has **rw** access.

/vol/vol2 -ro,rw=@pets:@farm:canary

All hosts have **ro** access, except for canary and all hosts in the netgroups pets and farm, which all have **rw** access.

/vol/vol2 -ro,rw=-@pets:@farm:canary

All hosts have **ro** access, except for all hosts in the netgroup farm, excluding all hosts in the netgroup pets, which have **rw** access. The host canary also has **rw** access.

If the host cat wants to write to /vol/vol2, by rule #10, we first check the **-rw=** access list. By rule #13, we check for access in order of **-@pets**, **@farm**, and finally canary. We match cat in the netgroup pets and therefore cat is denied **rw** access. It will however be granted **ro** access.

/vol/vol2 -ro,rw=@farm:-@pets:canary

Effectively, all hosts have **ro** access, except for canary and all hosts in the netgroup farm, which all have **rw** access.

If the host cat wants to write to /vol/vol2, by rule #10, we first check the **-rw=** access list. By rule #13, we check for access in order of **@farm**, **-@pets**, and finally canary. We match cat in the netgroup farm, by expansion, and therefore cat is granted **rw** access.

/vol/vol2a -rw=@pets:-@workers,ro=@livestock

By rule #12, cow, pig, chicken, and ostrich all have **ro** access.

By rule #13, dog, cat, and skunk all have **rw** access.

By negation, horse, ox, and mule have no **rw** access and by rule #2, they have no access at all.

/vol/vol2a -rw=-@workers:pets,ro=@livestock

By rule #12, cow, pig, chicken, and ostrich all have **ro** access.

By rule #13, negation, and rule #2, dog, horse, ox, and mule have no access.

cat and skunk have **rw** access.

/vol/vol3 -ro=@pets,rw=@farm:lion

All hosts in the netgroup farm have **rw** access, except for all hosts in the netgroup pets, which all have **ro** access. In addition, the host lion has **rw** access.

If the host `cat` wants to write to `/vol/vol3`, by rule #12, we first check the `-ro=` access list. We match `cat` in the netgroup `pets` and therefore we deny `rw` access.

`/vol/vol4 -ro=10.56.17/24,rw=10.56/16`

All hosts in the subnet `10.56/16` have `rw` access, except those in the subnet `10.56.17/24`, which have `ro` access.

`/vol/vol1`

`-ro=[A1C0:4C34:5D32:6F34::1]/64,\ \ rw=[BA32:235C:5D24:23F::32]`

All hosts in the subnet `A1C0:4C34:5D32:6F34::1/64` have `ro` access and the host whose IPv6 address is `BA32:235C:5D24:23F::32` has `rw` access.

`/vol/vol17`

`-ro=10.56.17/24,rw=10.56.17.5:10.56.17.6:farm`

All hosts in the subnet `10.56.17/24` have `ro` access, except, by rule #11, for `10.56.17.5` and `10.56.17.6`, which have `rw` access. If the hosts in the netgroup `farm` are on the `10.56.17/24` subnet, they have `ro` access, else they have `rw` access. Rule #11 allows for specific hosts to be excluded from a range provided by a group. Since it makes no sense to compare netgroups to subnets, we do not allow exceptions by groups.

`/vol/vol19`

`-ro=10.56.17.9:.frogs.fauna.mycompany.com,\ \ rw=.fauna.mycompany.com`

All hosts in the subdomain `.fauna.mycompany.com` get `rw` access, except those in the subdomain `Note` that we determine this result from rule #12 and not rule #11; we do not evaluate if one grouping construct is a subset of another. If `10.56.17.9` is in the subdomain `.fauna.mycompany.com`, then by rule #11, it gets `ro` access.

`/vol/vol21 -ro=10.56.17.9,rw=-pets:farm:skunk`

Rule #11 interacts with rules #5 and #6 in an interesting way, if a host is mentioned in an export by either name or IP, then it appears that it will always be granted the access given by whether it is in `-ro=` or `-rw=`. However, rule #13 still applies. Thus, `10.56.17.9` always gets `ro` access, but in this case by rule #13, `skunk` is denied access to the mount. Since `skunk` is a member of the netgroup `pets`, and `pets` is denied `rw` access by negation, `skunk` is denied access.

`/vol/vol5`

`-ro=.farm.mycompany.com,sec=krb5,rw,anon=0`

If the `secflavor` is `sys`, then all hosts in the DNS subdomain of `.farm.mycompany.com` are granted `ro` access. If the `secflavor` is `krb5`, then all hosts are granted `rw` access.

`/vol/vol6 -sec=sys:none,rw,sec=krb5:krb5i:k4b5p,rw,anon=0`

If the `secflavor` is `sys` or `none`, then all hosts are granted `rw` access, but effectively all `root` access is blocked. If the `secflavor` is from one of the secure `krb5`, `krb5i`, or `krb5p`, then `rw` and effectively `root` access are both granted.

UPGRADING

Exports defined prior to ONTAP 6.5 contain a different option, **-access**, which defined which hosts were permitted to mount an export. With the newer finer grained options, and by allowing more flexibility such as netgroups in the options, **-access** has been removed as an option.

Another significant change is that **-ro** is no longer the default if **-rw=** is present as an option.

During the upgrade process, the */etc/exports* file is converted to the newer format.

The rules for upgrading to the new format are:

- 1) **-root=** options stay the same
- 2) No access list => **-rw**
- 3) **-access=X** => **-rw=X**
- 4) **-ro** => **-ro**
- 5) **-access=X,ro** => **-ro=X**
- 6) **-rw=X** => **-rw=X**

This is more secure than the change **-rw=X,ro**.

Remember from Access Rule #2, **-ro** is never a default.

If the less restrictive form is desired, then the option needs to be manually changed. Note that if an export file has a mix of old and new style options, the more secure new style option of **-rw=X** can not be differentiated from the less secure option of **-rw=X(ro)** with the implicit **ro** modifier. To solve this problem, we always interpret **-rw=X** in the most secure format.

- 7) **-access=Y,rw=X** => **-rw=X,ro=(Y-X)**

There is a potential to remove write access here, but we keep the most secure translation.

In all cases, we preserve ordering inside an option.

UPGRADE EXAMPLES

/vol/vol0 -anon=0

By rule #2, this becomes:

/vol/vol0 -rw,anon=0

/vol/vol3 -ro By rule #4, this becomes:

/vol/vol3 -ro

/vol/vol0/home -rw=dog:cat:skunk:pig:mule By rule #6, this becomes:

```
/vol/vol0/home -rw=dog:cat:skunk:pig:mule
```

Note that by the access rules given above, all other hosts are denied **ro** access.

Since the upgrade code does not know about netgroups and netgroups used to not be allowed inside the **-rw** host list, this could be rewritten as:

```
/vol/vol0/home -rw=@pets
```

Also, if the security style is desired to be the older style, this could be further rewritten as:

```
/vol/vol0/home -ro,rw=@pets
```

```
/vol/vol1  
-access=pets:workers:alligator:mule,\\ rw=dog:cat:skunk:pig:horse:ox:mule
```

By rule #7, this becomes:

```
/vol/vol1  
-ro=pets:workers:alligator,\\ rw=dog:cat:skunk:pig:horse:ox:mule
```

This can be rewritten as:

```
/vol/vol1  
-ro=pets:workers:alligator,\\ rw=pets:workers
```

And should be:

```
/vol/vol1 -ro=alligator,rw=@pets:@workers
```

AUTOMATIC EDITING

The */etc/exports* file is changed by ONTAP for any of the following conditions:

vol create

A default entry is added for the new volume. If an admin host had been defined during the setup process, access is restricted to that host, otherwise all hosts have access to the new volume.

vol rename

All entries which have either a pathname or an **-actual** pathname which matches the old volume name are changed to be that of the new volume name.

vol destroy

All entries which have either a pathname or an **-actual** pathname which matches the old volume name are removed from the file.

upgrade

During every invocation of **exportfs -a**, the exports file is checked for old style formatting. If this style is found, the exports file is upgraded to follow the current formatting.

Please note that when we upgrade exports which contain subnets, we always rewrite the subnets in the compact format of **IP_address/num_bits**.

If the option **nfs.export.auto-update** is disabled, then the automatic updates for the **vol** commands will not take place. Instead the need for manual updates is syslogged.

ACCESS CACHE

A new feature in ONTAP 6.5 is the access cache, which allows netgroups to appear in **-ro=**, **-rw=**, and **-root=** options. Each time a request arrives from a host, it refers to an exported path. To avoid lengthy delays, we first check for that host and path in the cache to determine if we will accept or reject the request. If there is cache miss, we reject the request and do name resolution in another thread. On the next request, we should get a cache hit (i.e., the hit or miss depends on network traffic).

The time that a entry lives in the cache is determined by the two options:

nfs.export.neg.timeout

dictates how long an entry which has been denied access lives

nfs.export.pos.timeout

dictates how long an entry which has been granted access lives

There are several ways that the cache can be flushed:

exportfs -f

Flushes the entire access cache.

exportfs -f pathname

Flushes the cache for the longest leading prefix match for the path.

Also, any command which alters an export entry will result in the access cache for that export being flushed. E.g., **exportfs -au**, **exportfs -a**, **exportfs -io -rw /vol/vol1**, etc.

As the access cache is designed to eliminate name service lookups, entries inside it can become stale when the name services are modified. For example, if a netgroup is changed or a DNS server is found to have corrupt maps. If the access cache is found to have stale data, then either parts of it or all of it must be flushed. If the stale data applies to only a few exports, then each may be flushed with the **exportfs -f pathname** command. The entire cache may be cleared with the **exportfs -f** command.

Note that the same effect may be had by using commands to reload the exports table. In prior versions of ONTAP, either the **exportfs -au; exportfs -a** command sequence or a simple **exportfs -a** command was commonly used to clear away exports issues. While these can be used to clear the access cache, they can also result in extra work and lead to very small windows when an export is unavailable.

TROUBLESHOOTING

All mount requests, and NFS requests, come across the wire with an IP address and not the hostname. In order for an address to be converted to a name, a reverse lookup must be performed. Depending on the contents and ordering in */etc/nsswitch.conf*, DNS, NIS, and/or */etc/hosts* may be examined to determine the mapping.

A common problem with reverse DNS lookups is the existence of a mapping from name to IP, but not IP to name. Note: Data ONTAP cannot resolve a IPv6 address to multiple hostnames (including aliases), when doing a reverse host name lookup.

The option **nfs.mountd.trace** can be turned on to help debug access requests. Note that as this option can be very verbose and it writes to the syslog, care should be taken to only enable it while trying to resolve an access problem.

Another useful tool is to use **exportfs -c** to check for access permissions.

DEPRECATED FEATURES

All exported pathnames which do not begin with a leading `"/vol/"` or `"/etc/"` pathname are being deprecated.

WARNINGS

Exporting the root volume as `/` can be misleading to some automounters.

fsecurity

NAME

na_fsecurity - Definition file for an fsecurity job

DESCRIPTION

The fsecurity definition files describe an fsecurity job, which is used as input to the na_fsecurity_apply(1) command, and contains a list of tasks that will be run against the file system. This file can have any convenient name, and can be stored in any convenient location in the local volumes. The name of the file is given as a parameter to the na_fsecurity_apply(1) command.

SYNTAX

The definition file can be located anywhere in the file system, in either ASCII or Unicode format. The first line is always the file's signature, with task definitions on each subsequent line.

The file signature is currently *cb56f6f4*, and it will be updated when new versions of the file are supported. It is important that this is the only value on the line, including spaces.

Each task is a comma-separated list of values that are defined as follows:

```
type,subtype,"path",propagation mode,"security definition"
```

type

1 - Security Descriptor Definition Language (SDDL)

subtype

0 - Standard

1 - Storage-Level Access Guard (Guard)

path

The path to the target file system object, in double-quotes.

propagation mode

0 - Propagate inheritable permissions to all subfolders and files

1 - Do not allow permissions on this file or folders to be replaced (**Not implemented**)

2 - Replace existing permissions on all subfolders and files with inheritable permissions

security definition

The security definition that will be applied to the specified **path**. The format is described by the **type** field, and is always enclosed in double-quotes.

For more information about SDDL syntax and proper formatting of the security description value, see "Security Descriptor String Format" at the following URL:
<http://msdn2.microsoft.com/en-us/library/aa379567.aspx>

NOTE This file can also be generated by the **secedit** utility. For more information about how to obtain it, contact technical support.

EXAMPLE

This is a sample fsecurity definition file which propagates a security descriptor down the /vol/vol0/qtree hierarchy. The definition allows Everyone full control, and the second line sets a Guard security descriptor which denies the ability to Write.

```
cb56f6f4
1,0,"/vol/vol0/qtree",0,"D:(A;CIOI;0x1f01ff;;;Everyone) "
1,1,"/vol/vol0/qtree",0,"D:(D;CIOI;0x000002;;;Everyone) "
```

EFFECTIVE

Any changes take effect after running the `na_fsecurity_apply(1)` command.

PERSISTENCE

Changes are persistent across system reboots.

SEE ALSO

`na_fsecurity(1)`

ftputers

NAME

na_ftputers - file listing users to be disallowed ftp login privileges

SYNOPSIS

/etc/ftputers

DESCRIPTION

The `/etc/ftputers` file is an ASCII file that lists users for whom ftp login privileges are disallowed. Each ftpuser entry is a single line of the form:

`user_name`

where `user_name` is the user's login name.

By default there is no `/etc/ftputers` file, and therefore ftp login privileges are allowed to all users.

EFFECTIVE

Any changes take effect immediately

PERSISTENCE

Changes are persistent across system reboots.

group

NAME

na_group - group file

SYNOPSIS

/etc/group

DESCRIPTION

The **/etc/group** database contains information for each group in the following form:

groupname:password:gid:user-list

The following list describes the required fields:

groupname

The name of the group.

password

The group's password, in an encrypted form. This field may be empty.

gid

An integer representing the group; each group is assigned a unique integer.

user-list

The user list is a comma-separated list of users allowed in the group.

EXAMPLE

Here is a sample group file:

```
project:asderghuIoiyw:12:dan,dave
myproject::11:steve,jerry
```

SEE ALSO

na_quota(1), na_cifs_setup(1)

hosts

NAME

na_hosts - host name data base

SYNOPSIS

/etc/hosts

DESCRIPTION

The **hosts** file contains information regarding the known hosts on the network. For each host an entry should be present with the following information:

Internet-address official-host-name aliases

When both IPv4 and IPv6 addresses are configured for a particular host, there will be a separate entry in the file for each address. Items are separated by any number of blanks and/or tab characters. A ‘#’ indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. The maximum line length is 1022 characters. There is no way to continue an entry past the end of the line.

This file may be created from the official host data base maintained at the Network Information Control Center (NIC), though local changes may be required to bring it up to date regarding unofficial aliases and/or unknown hosts.

IPv4 network addresses are specified in the conventional ‘.’ (dot) notation. IPv6 addresses are specified in any of the conventional forms i.e., the colon delimited compressed form or the mixed IPv6 and IPv4 notation. Host names may contain any alphanumeric character, but not field delimiters, newline, or comment characters.

FILES

/etc/hosts

SEE ALSO

na_nis(8)

hosts.equiv

NAME

na_hosts.equiv - list of hosts and users with rsh permission

SYNOPSIS

/etc/hosts.equiv

DESCRIPTION

The **hosts.equiv** file contains a list of hosts on which you can enter a filer command through the remote shell protocol (**rsh**).

Hosts specified in this file are considered the trusted hosts of the filer.

It is also possible to use **hosts.equiv** for other protocols such as ssh (both interactive and non-interactive) and telnet. Additionally, access to ONTAPI (ONTAP management APIs) over HTTP and HTTPS can use **hosts.equiv** authentication by setting the filer option `httpd.admin.hostsequiv.enable`.

Each line in **hosts.equiv** has the following format:

```
hostname [ username ]
+@netgroup [ username ]
```

If the host on which you enter the filer command is a UNIX host, the user name is optional. If the host on which you enter the filer command is a PC, you must enter the user name for that PC in the */etc/hosts.equiv* file.

We can also specify a group of hosts using **netgroup**. Hence all hosts in that netgroup are allowed to access the filer.

If you do not specify a user name for a UNIX host, you must be root on that host to execute a filer command through **rsh**.

If multiple users on the same host should have access to the filer through **rsh**, enter each user name on a separate line.

EXAMPLE

The following **hosts.equiv** file allows both **root** and **joe_smith** to enter filer commands through **rsh** on a UNIX host named **adminhost**. It also allows **joe_smith** to enter filer commands through **rsh** from all hosts in netgroup **ourhosts**:

```
adminhost
adminhost joe_smith
+@ourhosts joe_smith
```

hosts.equiv

na_options(1)

httpd.access

NAME

na_httpd.access - authentication controls for HTTP access

SYNOPSIS

`/etc/httpd.access`

DESCRIPTION

The HTTP daemon can apply authentication controls to individual users or groups on a per directory basis. The file `/etc/httpd.access` specifies the following items for each access-controlled tree:

the path to the tree

the authority required to authenticate access to the tree

the lists of users or groups who are permitted access when authenticated

The syntax is the same as the access control syntax used by NCSA and Apache. However, the `httpd.access` file only supports a subset of directives supported by NCSA and Apache. You can copy an existing NCSA or Apache access to the filer without editing or reformatting.

SYNTAX

The supported directives are:

```
<Directory directory_name>
```

```
</Directory>
```

```
AuthName Title phrase
```

```
require user user_id[, user_id,...] require group group_id[, group_id,...]
```

where *Title phrase* is a word or phrase that is passed to the authentication dialog as a title for the dialog that prompts the user for a password.

EXAMPLES

The following example restricts access to the file `/home/htdocs/private/bob` so that only user `dole` can access it, after supplying the required password. The authentication dialog is titled “My private stuff.”

```
<Directory /home/htdocs/private/bob> AuthName My private stuff
```

```
<Limit GET>
```

```
require user dole
```

```
</Limit>
```

```
</Directory>
```

The `<Limit GET>` and `</Limit>` directives are not supported, but are retained for format consistency with NCSA and Apache. The filer just ignores them.

The following example restricts access to the directory tree **/home/htdocs/private/conspiracy** to the group “guyinblack”, which consists of the users whose IDs are cancer, deepthroat, mrx, and skinner. The authentication dialog is titled “Area 51.”

```
<Directory /home/htdocs/private/conspiracy> AuthName Area 51
<Limit GET>
require group guyinblack
</Limit GET>
</Directory>
```

In this example, “guyinblack” is defined by the following entry in **/etc/httpd.group**:

```
guyinblack: cancer deepthroat mrx skinner
```

The following example requires the client to provide a Windows Domain username and password to access the directory tree **/home/htdocs/win**. The authentication dialog is “Windows(tm) Authentication” This authentication dialog, typed exactly as presented here, is required to enforce NTLM authentication.

```
<Directory /home/htdocs/win>
AuthName Windows(tm) Authentication </Directory>
```

If this authentication control is used the Filer must have CIFS running, and either be a member of a Windows Domain or be using Local User authentication.

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

SEE ALSO

na_httpd.group(5).

BUGS

Only the directives listed above are supported; other directives that may appear in NCSA or Apache access files are ignored.

httpd.group

NAME

na_httpd.group - names of HTTP access groups and their members

SYNOPSIS

/etc/httpd.group

DESCRIPTION

The file declares the names of groups and the user IDs of the members of each group, for use by the HTTP daemon in executing the access controls declared in **/etc/httpd.access**.

SYNTAX

group_id1:user_id1 [user_id2 ...]

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

SEE ALSO

na_httpd.access(5).

httpd.hostprefixes

NAME

na_httpd.hostprefixes - configuration of HTTP root directories for virtual hosts

SYNOPSIS

`/etc/httpd.hostprefixes`

DESCRIPTION

The **httpd.hostprefixes** file maps virtual hosts used in HTTP to corresponding root directories. The same configuration file is used for both IP virtual hosts (defined by the IP address used for connecting to the server) and HTTP virtual hosts (defined by the **Host:** header used in HTTP requests).

Each virtual host has a corresponding subdirectory within the directory specified by the option **httpd.rootdir**. This subdirectory is called the virtual host root directory. Clients connected to a virtual host can only access files within the virtual host root directory.

In the **httpd.hostprefixes** file, each line consists of a virtual host root directory followed by the names and IP addresses of a virtual host. If you specify an IP address, the virtual host root directory is associated with the given virtual host for IP-level virtual hosting. If you specify a name, the virtual host root directory is associated with the virtual host with that name, using HTTP-level virtual hosting. If the filer can resolve that name to an IP address, which is used for an IP-level host alias (see the **alias** option in `na_ifconfig(1)`), the filer uses that IP address in the same way as it would if you specified the IP address in the **httpd.hostprefixes** file.

If the `/etc/httpd.hostprefixes` file is edited, it is read again by the HTTP server after the changes are saved.

SETUP

1. Enable **httpd.enable** and set HTTP Root directory **httpd.rootdir**
2. Configure network interface with HTTP Virtual Host Addresses. For example, to add the 207.68.156.50 as HTTP Virtual Host address to the network interface e0a, enter the following command:

```
toaster> ifconfig e0a alias 207.68.156.50
```

NOTE: In Data ONTAP 7.3 and later releases, VH interface is no longer supported for HTTP Virtual Hosting.

3. Edit `/etc/httpd.hostprefixes` file and map the Virtual Host addresses to respective subdirectories within the directory specified by the option **httpd.rootdir**. For example, to map the Virtual Host address 207.68.156.50 specified in Step 2 above to the **httpdir1** subdirectory within **httpd.rootdir**, add the following entry to the `/etc/httpd.hostprefixes` file:

```
/httpdir1 207.68.156.50
```

4. Test HTTP virtual host setup by sending HTTP request to the Virtual Host address added and mapped in Step 2 and 3 above.

EXAMPLE

This example maps requests sent to **www.customer1.com** to the **customer1** subdirectory of **httpd.rootdir** and requests directed at a host with IP address 207.68.156.58 to the subdirectory **customer2**.

```
/customer1 www.customer1.com  
/customer2 207.68.156.58
```

If the command

```
toaster> ifconfig e0a alias www.customer1.com
```

had been issued before the configuration file was read, requests destined for the IP address of **www.customer1.com** would also be mapped to the **/customer1** subdirectory, regardless any the **Host:** header they included.

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

SEE ALSO

na_options(1)

httpd.log

NAME

na_httpd.log - Log of HTTP

SYNOPSIS

/etc/log/httpd.log

DESCRIPTION

The HTTP server logs an entry for every file retrieved via HTTP. This log, written to **/etc/log/httpd.log**, is stored in the "Common Log Format," which is used by many WorldWide Web servers.

Each entry in **/etc/log/httpd.log** consists of one line with seven fields. The fields are, in order:

address

The IP address of the HTTP client requesting the file.

rfc931

This field is always "-".

authuser

This field is always "-".

date

The time and date the request was is reported in the format "[Day/Mon/Year:HH:MM:SS]", which is logged in universal time (GMT) rather than the local time zone.

request

A quoted string is recorded for the method (request type) and file involved in the request.

result

The status code for the request, as defined in RFC 1945, the HTTP protocol specification. (See below.)

bytes

The size of the file in bytes.

Possible values for *result* codes include:

200

Success: the requested file was transmitted.

302 Redirected (see **/etc/httpd.translations**).

304

Not modified (client cache used).

- 400** Bad request.
- 401** Unauthorized request.
- 403** Access to file prohibited.
- 404** File not found.
- 503** HTTP server disabled.

The size of the log file can be restricted by the option **httpd.log.max_file_size**.

SEE ALSO

na_httpd.translations(5)
RFC 1945, "Hypertext Transfer Protocol -- HTTP/1.0"

BUGS

Some Web servers report size statistics differently for result codes other than 200. For example, a file size of 0 is often reported for result code 304 (Not modified).

The log file grows automatically and is never reset. It is your responsibility to rotate files and empty the log files regularly.

httpd.mimetypes

NAME

na_httpd.mimetypes - map of file suffixes to MIME ContentType

SYNOPSIS

/etc/httpd.mimetypes

DESCRIPTION

For HTTP/1.0 and higher protocols, a MIME header is returned in the reply of every GET request. This header includes a "Content-Type" field, whose contents is determined by examining the suffix of the file being transmitted.

The **/etc/httpd.mimetypes** file contains the mapping of filename suffixes to MIME Content-Type. The format of each line is: suffix, Content-Type. Comments are introduced with a "#".

The filer is not shipped with the **/etc/httpd.mimetypes** file. Instead, the filer's system files include a sample file named **/etc/httpd.mimetypes.sample**. Before you start using HTTP, make a copy of **/etc/httpd.mimetypes.sample** and name the copy **/etc/httpd.mimetypes**.

If the file **/etc/httpd.mimetypes** is not installed, the HTTP server looks for the file **/etc/httpd.mimetypes.sample** as a fallback.

EXAMPLE

```
# map .ps files to PostScript type:  
ps application/postscript
```

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

httpd.passwd

NAME

na_httpd.passwd - file of passwords required for HTTP access

SYNOPSIS

/etc/httpd.passwd

DESCRIPTION

The password file containing the encrypted form of the password that an HTTP client must supply to have access to a file in a controlled-access directory tree, as declared in **/etc/httpd.access**.

The password is encrypted in the regular UNIX style. User of NCSA or Apache can use their **htpasswd** program to generate the user_id:passwd pair.

The HTTP access control does not use the existing CIFS password database on the filer because in http basic authentication, in each request for protected pages, the value of *passwd* is sent over the network in clear text, and without encryption would compromise the user's password.

SYNTAX

```
user_id1:encrypted_passwd1  
used_id2:encrypted_passwd2  
...
```

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

SEE ALSO

na_httpd.access(5).

httpd.translations

NAME

na_httpd.translations - URL translations to be applied to incoming HTTP requests

SYNOPSIS

/etc/httpd.translations

DESCRIPTION

The HTTP daemon supports four URL translation rules to filter incoming HTTP requests. The HTTP daemon applies each rule in succession, stopping at the first successful **Redirect**, **Pass**, or **Fail** rule:

Map *template result*

Any request which matches *template* is replaced with the *result* string given.

Redirect *template result*

Any request which matches *template* is redirected to the *result* URL. Note that this must be a full URL, e.g., beginning with "http:".

Pass *template* [*result*]

Any request which matches *template* is granted access, and no further rule processing occurs. An optional *result* can be used in place of the matching URL.

Fail *template*

Any request which matches *template* is denied access. Rule processing stops after a matched **Fail**.

Both templates and results may contain wildcards (a star "*" character). The wildcard behaves like a shell wildcard in the *template* string, matching zero or more characters, including the slash ("/") character. In the *result* string, a wildcard causes text from the corresponding match in the *template* string to be inserted into the result.

EXAMPLE

This example redirects CGI queries to **cgi-host**, prevents accesses to **/usr/forbidden**, and maps requests for images to a local image directory:

```
#
# Example URL translations
#
Redirect /cgi-bin/* http://cgi-host/*
Fail /usr/forbidden/*
Map /image-bin/* /usr/local/http/images/*
```

EFFECTIVE

Any changes take effect within 5 minutes

PERSISTENCE

Changes are persistent across system reboots.

messages

NAME

na_messages - record of recent console messages

SYNOPSIS

/etc/messages

DESCRIPTION

The default behavior of the filer **syslogd** daemon (see [na_syslogd\(8\)](#)) is to print all logging messages of priority **info** or higher to the console, and to the **messages** file. A typical message is:

Fri Jun 10 14:31:37 PDT 2005 [rc]: Data ONTAP Release 7.1 boot complete.

Every Saturday at 24:00, **/etc/messages** is moved to **/etc/messages.0**, **/etc/messages.0** is moved to **/etc/messages.1**, and so on. Message files are saved for a total of six weeks.

FILES

/etc/messages

messages file for current week **/etc/messages.[0-5]** messages file for previous weeks

SEE ALSO

[na_syslog.conf\(5\)](#)

ndmpdlog

NAME

na_ndmpdlog - The ndmpdlog provides a detailed description of the activities of all active NDMP sessions.

SYNOPSIS

/etc/log/ndmpdlog.yyyymmdd

DESCRIPTION

The NDMP debug log provides a detailed description of the activities of all active NDMP sessions. See **na_ndmpd (1)** for a detailed description of how NDMP logging is enabled and disabled and the various options associated with the control of logging. All events are recorded in multi-line entries and are sent to the filer console and/or the **/etc/log/ndmpdlog.yyyymmdd** files depending on how logging has been configured with the **ndmpd debug** command.

The information in the ndmpdlog is a trace of the NDMP protocol messages as defined in the various versions of the NDMP Protocol Specification. Data ONTAP supports versions 2, 3 and 4 of the protocol. At least a cursory knowledge of the NDMP Protocol is required to analyze the ndmpdlog. Describing the protocol is beyond the scope of this manpage. Descriptions of the three supported versions of the protocol can be found at **www.ndmp.org**.

If logging to files is enabled, a new log file is created each day. The last part of the log file name is the date for which the log file applies. If NDMP sessions are active at the time a new daily log file is created, information for the existing sessions will continue to be logged to the file which was active at the time the sessions were created. Information for any new sessions will be logged in the new log file. Up to 9 daily log files are retained on the system. A log file for a particular day may not exist if no NDMP activity occurred on that day. Log files over 8 days old are automatically deleted by Data ONTAP.

The log has a multi-column, multi-line format.

The three columns contain:

Date

The time of the messages displayed in the timezone specified by the **timezone** command.

Session

The NDMP session number for the messages in [ndmpd:<session>] format.

Message

The contents of the messages.

The information for each message occupies multiple lines in the log. At a high level, there are two types of log entries: those representing request/reply pairs and those representing log/notify messages. Note that there is only one entry for a request/reply pair. Some of the information is placed in the log as the message is received by the filer and other information is placed in the log as the reply is being sent to the NDMP client. Also note that the debug level must be set to the appropriate level with the **ndmpd**

debug command as described in `na_ndmpd(1)` for the following information to be displayed.

The log entry for each request/reply message begins with the following 2 lines:

NDMP message type:

The high-level message type such as

NDMP_DATA_START_BACKUP
or NDMP_TAPE_OPEN.

NDMP message replysequence:

The replysequence is the sequence number from the request message with which the reply is associated.

The log entry for each log/notify message begins with the following line:

Message <message type> sent

The high-level message type such as

NDMP_NOTIFY_DATA_ABORT
or NDMP_LOG_MESSAGE.

The above information is followed by the NDMP message header.

Message header:

The message header contains information such as sequence numbers, a numerical representation of the message type, and an error field representing the success or failure of receiving and decoding the message. The fields correspond to the fields in the NDMP message header as defined in the NDMP Protocol Specifications.

The header information is followed by the request/reply information or the log/notify information.

Request/Reply information including the Error code: Contains the remainder of the information about the request and reply for the message and possibly some other state information associated with the request/reply. An **Error code:** field is displayed for all reply message log entries. This is the overall status of the execution of the request and is a key piece of information when diagnosing problems. The contents of the rest of the log entry varies widely depending on the message being logged. It is beyond the scope of this manpage to describe the details for the dozens of different messages which are part of the NDMP protocol. Refer to the NDMP Protocol Specifications as well as the NDMP Extension Specifications available from IBM to decode these fields in the logs.

Log/Notify information:

Contains the remainder of the information about the log/notify message. As for the request/reply information, see the NDMP Protocol Specifications as well as the NDMP Extension Specifications to decode these fields in the logs.

VFILER CONSIDERATIONS

The log files are stored in the `/etc/log` directory of the vfiler's root volume.

FILES

/etc/log/ndmpdlog.yyyymmdd
daily ndmpd log file

SEE ALSO

na_ndmpd(1).

netgroup

NAME

na_netgroup - network groups data base

SYNOPSIS

/etc/netgroup

DESCRIPTION

netgroup defines network wide groups used for access permission checking during remote mount request processing. Each line defines a group and has the format:

groupname member-list

Each element in member-list is either another group name or a triple of the form:

(hostname, username, domainname)

The *hostname* entry must be fully qualified if the specified host is not in the local domain.

The filer can also use the **netgroup** NIS map.

Since the filer uses netgroups only in **/etc/exports** (see *na_exports(5)*), the *username* entry is ignored. The *domainname* field refers to the domain in which the netgroup entry is valid. It must either be empty or be the local domain; otherwise the netgroup entry is ignored. An empty entry allows a single **/etc/netgroup** file to be used for filers in multiple domains.

A group definition can be at most 4096 bytes even when ‘\’s are used to extend the definition over several lines. The maximum nesting level when group names are used in the *member-lists* of other groups is 1000.

Modifications to the **/etc/netgroup** file may take upto 60 seconds to take effect.

EXAMPLE

This is a typical **netgroup** file:

```
trusted_hosts (adminhost,,) (zeus,,) (thor,,) (minerva,,)
```

```
untrusted_hosts
  (sleepy,,) (dopey,,) (grumpy,,) (sneezy,,)
```

```
all_hosts
  trusted_hosts untrusted_hosts
```

With this **netgroup** file it might make sense to modify **/etc/exports** to export / on the filer only to *trusted_hosts*, but to export **/home** to *all_hosts*.

FILES

/etc/netgroup

/etc/exports

directories and files exported to NFS clients

/etc/hosts

host name data base

SEE ALSO

na_nis(8)

BUGS

The only place that netgroups can be used are in the options of the **exportfs** command (see *exportfs(1)*) and **/etc/exports**.

The **/etc/netgroup** configuration does not failover. Thus, the **/etc/netgroup** files on the active and backup filer must be kept consistent manually.

networks

NAME

na_networks - network name data base

SYNOPSIS

/etc/networks

DESCRIPTION

The **networks** file contains information regarding the known networks which comprise the Internet. For each network a single line should be present with the following information:

official-network-name network-number aliases

Items are separated by any number of blanks and/or tab characters. A “#” indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file. This file is normally created from the official network data base maintained at the Network Information Control Center (NIC), though local changes may be required to bring it up to date regarding unofficial aliases and/or unknown networks.

Network number may be specified in the conventional “.” (dot) notation or as a 32 bit integer. Numbers may be specified in decimal (default), octal or hexadecimal. A number is interpreted as octal if it starts with the digit "0". A hexadecimal number must begin with "0x" or "0X." Network names may contain any printable character other than a field delimiter, newline, or comment character.

FILES

/etc/networks

nsswitch.conf

NAME

na_nsswitch.conf - configuration file for name service switch

SYNOPSIS

`/etc/nsswitch.conf`

DESCRIPTION

The name service switch configuration file contains the preferred order in which name services will be contacted for name resolution by the filer. For each map, the name services to be used and the lookup order is specified in this file. Currently four name services are supported. They are local files in the /etc directory, NIS, LDAP, and DNS. The maps or "databases" that are supported are hosts, passwd, shadows, group, and netgroups (LDAP is currently supported in the passwd, group, and netgroups map). Each line has the form:

map: order of name services

For example:

hosts: files nis dns ldap

passwd: files nis ldap

When trying to resolve a name, the services are contacted one by one, as per the order specified, until the name is successfully resolved. A name resolution failure occurs when no service can successfully resolve the name. When enumerating a map, enumeration happens over all the services specified for the map.

FILES

`/etc/nsswitch.conf`

SEE ALSO

na_setup(1)

nvfail_rename

NAME

na_nvfail_rename - Internet services

SYNOPSIS

/etc/services

DESCRIPTION

The **services** file contains information mapping between port numbers and service names. This file exists purely for reference purposes and is not currently used by Data ONTAP. Modifying entries in this file will have no effect on the filer. Removing entries will not disable ports or services. For information on how to change which port numbers a service uses (if possible), see the relevant manual page for that service. Such changes will not update the **services** file.

Each line contains a service name followed by a port number, a ‘/’, and a protocol, for example 20/tcp. Legal protocol names are ‘tcp’ and ‘udp’. Port numbers are decimal numbers in the range of 0 to 65535. A service name may contain any printable character other than the comment character (i.e. no spaces, tabs, newlines, or ‘#’).

Items are separated by any number of blanks and/or tab characters. A ‘#’ indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.

FILES

/etc/nvfail_rename

SEE ALSO

na_vol(1)

passwd

NAME

na_passwd - password file

SYNOPSIS

/etc/passwd

DESCRIPTION

The **passwd** file contains basic information about each user's account. It contains a one-line entry for each authorized user, of the form:

username:password:uid:gid:gc_{os}_field:home_directory:login_shell

Required Fields:

username

The user's login name, not more than eight characters.

password

The user's password, in an encrypted form that is generated by the UNIX passwd function. However, if the encrypted password is stored in **/etc/shadow**, (see *shadow(5)*), the password field of **/etc/passwd** is empty.

uid

A unique interger assigned by the UNIX administrator to represent the user's account; its value is usually between 0 and 32767.

gid

An interger representing the group to which the user has been assigned. Groups are created by the UNIX system administrator; each is assigned a unique integer whose value is generally between 0 and 32767.

gc_{os}-field

The user's real name. The name may be of any length; it may include capital letters as well as lower case, and may include blanks. The name may be empty.

home_directory The user's home directory. The home directory field may be empty.

login-shell

The default shell launched at login. This field may be empty.

EXAMPLE

passwd

Here is a sample passwd file when the /etc/shadow does not exist:

```
root:bDPu/ys5PBoYU:0:1:Operator:/:/bin/csh
dave:Qs5I6pBb2rJDA:1234:12:David:/u/dave:/bin/csh
dan:MNRWdsW/srMfE:2345:23:Dan:
jim:HNRYuuiumFferx::::
```

If the system keeps the passwords in the /etc/shadow, the file

/etc/passwd would be exactly the same but the password field would be empty.

```
root::0:1:Operator:/:/bin/csh
dave::1234:12:David:/u/dave:/bin/csh
dan::2345:23:Dan:
jim:::::
```

SEE ALSO

na_pcnfsd(8), na_cifs_access(1), na_cifs_setup(1)

psk.txt

NAME

na_psk.txt - pre-shared authentication key file

SYNOPSIS

/etc/psk.txt

DESCRIPTION

The **psk.txt** file contains an pre-shared key that authenticates the specified machine For each machine a single line should be present with the following information:

Internet-address authentication-key

Items are separated by any number of blanks and/or tab characters. authentication-key is specified as an ascii text. Network addresses are specified in the conventional “.” (dot) notation.

FILES

/etc/hosts

SEE ALSO

na_ipsec(1),

qual_devices

NAME

na_qual_devices - table of qualified disk and tape devices

SYNOPSIS

`/etc/qual_devices`

DESCRIPTION

The **qual_devices** file names storage devices qualified for use with Data ONTAP. This is a read-only file and must not be modified.

Disk and tape drives listed in this file are qualified for use with a Data ONTAP system. This file is read by the dynamic qualification process which is invoked to authenticate devices not listed in the internal tables of a particular Data ONTAP release. The dynamic qualification process may be invoked at system startup, cluster takeover, or when a new device is detected.

WARNING

Do not modify or remove this file. However, it may be replaced with an updated version containing identification data for additionally qualified devices supplied by IBM.

NOTES

Each line in the file contains identification strings for a qualified device.

QUALIFICATION ERRORS

A qualification error will occur when Data ONTAP is unable to locate identification information for one or more storage devices detected by the system. To resolve qualification errors, verify the existence of `/etc/qual_devices` and ensure it represents the latest version available from IBM. Periodic console messages will be generated when a qualification error is present. All qualification errors **MUST** be resolved for continued system operation.

quotas

NAME

na_quotas - quota description file

SYNOPSIS

/etc/quotas

DESCRIPTION

The `/etc/quotas` file describes disk quotas that go into effect when quotas are enabled. All quotas are established on a per-volume basis. If a volume name is not specified in an entry of the `/etc/quotas` file, the entry applies to the root volume.

The following sample `/etc/quotas` file describes different kinds of quotas:

```
# Quota Target      type      disk  files thold  sdisk  sfile
# -----
mhoward             user      500M  50K
lfine               user@/vol/home  500M
tracker            user      -      -
stooges            group@/vol/vol0  750M  75K
/vol/vol0/export   tree     750M  75K
mhoward            user@/vol/vol0/export  50M  5K
stooges            group@/vol/vol0/export  100M  10K
*                  user@/vol/home     100M  10K      90M   90M   9K
*                  group@/vol/vol0    500M  70K
*                  tree              500M  50K
*                  user@/vol/vol0/export  20M  2K
*                  group@/vol/vol0/export  200M  20K      150M
*                  tree@/vol/home     500M  50K
corp\bill           user      -      -      100M
corp\joe, fin\joe  user      200M  40K      160M
corp\sue, sue      user      100M  20K
corp\ann           user      100M  -      90M
QUOTA_TARGET_DOMAIN corp
# The following entry will become corp\jim
jim                 user      200M  -      -
# The following entry will become corp\beth
beth               user      120M  50K      -
QUOTA_TARGET_DOMAIN
QUOTA_PERFORM_USER_MAPPING ON
# If corp\sam maps to usam, the following entry will become
# corp\sam, usam ....
corp\sam           user      50M
# If umary maps to corp\mary, the following entry will become
# umary, corp\mary user ...
umary              user      300M
QUOTA_PERFORM_USER_MAPPING OFF
```

The first non-comment line in the file restricts the user mhoward to 500 MB of disk space and 51,200 files in the root volume. The second line restricts the user lfine to 500 MB of disk space in the home volume, but places no restriction on the number of files he can have. You can leave the file limit blank to indicate that no limit is imposed but you cannot omit the value for disk space. The third line places no restriction on either disk usage or file usage by using a limit field of "-". This may be useful for tracking usage on a per-user or per-group basis without imposing any usage limits.

The next two lines restrict the stooges group and the /vol/vol0/export qtree to 750 MB and 76,800 files each in the root volume.

The fifth column of the /etc/quotas file contains a value for the warning threshold. If an attempt to allocate space for the quota target causes the quota target's disk space usage to exceed the warning threshold value, a warning message is logged on the filer's console. Additionally, an SNMP trap is emitted indicating the condition. The disk space allocation will succeed if no other quota limits are exceeded. The value is specified in bytes.

The sixth column specifies a soft disk limit, while the seventh column specifies a soft file limit. They are analogous to the (hard) limits specified in the third and fourth columns, but behave more similarly to the threshold value: when a soft limit is exceeded, a warning message is logged to the filer's console. Additionally, an SNMP trap is emitted indicating the condition. Lastly, when the quota target's usage returns below the soft limit, a warning message and SNMP trap is also generated.

An entry in the /etc/quotas file may extend over several lines, but the last five columns (hard limits, warning threshold, and soft limit values) must be on the same line of the quota file.

A user is specified by one of the following values:

- a unix user name, which must appear in the password database (either in the /etc/passwd file on the filer, or in the password NIS map if NIS is enabled on the filer and is being used for the password database);

- a numerical unix user ID;

- the pathname of a file owned by that user;

- a Windows account name, which consists of the domain name and the account name separated by a backslash (if the domain name or the account name contain spaces or other special characters, then the entire name must be enclosed in quotes);

- the text form of a Windows SID that represents a Windows account;

- a comma separated list of any of the above items that are to be considered one user quota target (the list can extend to multiple lines, but the last item must be on the same line as the quota type, disk limit, file limit and warning threshold values).

A group is specified by one of the following values:

- a unix group name, which must appear in the group database (either in the /etc/group file on the filer, or in the group NIS map if NIS is enabled on the filer and is being used for the group database);

a numerical group ID;

the pathname of a file owned by that group.

The user or group identifier for a user or group quota can be followed by an **@/vol/volume** string, which specifies the volume to which the quota applies. If the string is omitted, the quota applies to the root volume.

A quota of type **tree** can only be applied to a qtree, which is a directory in the root directory of a specified volume. A qtree is created with the **qtree create** command.

User and group quotas can be created inside a qtree, so that the user's or group's use of space or files within that qtree is restricted. This is done by specifying the type as **user@tree** or **group@tree** where *tree* is the name of the qtree. In the example above, we first limit overall usage in the qtree `/vol/vol0/export` and then we restrict the user `mhoward` to 50 MB and 5,120 files under the `/vol/vol0/export` tree. Similarly, the group `stooges` has been limited to 100 MB of disk space and 10,240 files under the `/vol/vol0/export` tree.

In any operation that creates files or writes to them, all applicable quotas must be satisfied. For example, the user `mhoward` can write to a file in the `/vol/vol0/export` tree if all of these requirements are met:

his total disk usage in the root volume does not exceed 500 MB

his total number of files in the root volume does not exceed 51,200

his usage within the `/vol/vol0/export` tree does not exceed 50 MB

his number of files within the `/vol/vol0/export` tree does not exceed 5,120

the space already in use in the `/vol/vol0/export` tree does not exceed 750 MB

the number of files in the `/vol/vol0/export` tree does not exceed 768,000

The asterisk (*) in the `/etc/quotas` file specifies a default user, group, or tree quota depending on the type. Any user, group, or qtree that is not specifically mentioned in the `/etc/quotas` file is subject to the limits of the default user, group, or tree. Default user or group quotas can be specified on either a per qtree basis or a per volume basis.

Default tree quotas can be specified on a per volume basis. The tree identifier for a qtree quota can be followed by an **@/vol/volume** string, which specifies the volume to which the quota applies. If the string is omitted, the quota applies to the root volume.

Hard disk limits, hard file limits, warning threshold, soft disk limits, and soft file limits in the last five columns of the `/etc/quotas` file end in "K", "M", or "G". "K" indicates kilobytes (or kilofiles). That is, it multiplies the limit by 1,024. Similarly, "M" denotes megabytes (or megafiles) and "G" denotes gigabytes (or gigafiles). The unit specifiers are not case sensitive so lower-case letters may be used. The default for the disk limits and warning threshold is kilobytes.

The **QUOTA_TARGET_DOMAIN** *domain* directive can be used to change a user quota target that is a unix name to a user quota target that is a Windows account. It will prepend the *domain* and a backslash to subsequent user quota targets that are unix user names. It will continue to prepend the unix user name names with the domain name until either the end of the `/etc/quotas` file or another

QUOTA_TARGET_DOMAIN directive is encountered.

The **QUOTA_PERFORM_USER_MAPPING** [**ON** | **OFF**] directive, when **ON**, will use the filer's user name mapping support to map user quota targets that are unix user names to their corresponding Windows account names and consider both as one user quota target. It will also map user quota targets that are Windows account names to their corresponding unix user names and consider both as one user quota target. The setting remains until either the end of the `/etc/quotas` file is reached or another **QUOTA_PERFORM_USER_MAPPING** directive is encountered. If the directive is omitted or if the directive is **OFF**, no user name mapping is done.

SEE ALSO

`na_usermap.cfg(5)`

rc

NAME

na_rc - system initialization command script

SYNOPSIS

/etc/rc

DESCRIPTION

The command script */etc/rc* is invoked automatically during system initialization. Since the filer has no local editor, */etc/rc* must be edited from an NFS client with root access to */etc*. Alternately, you can use the **setup** command to generate a new */etc/rc* file without using NFS.

EXAMPLE

This is a sample */etc/rc* file as generated by **setup**:

```
#Auto-generated by setup Tue Jun 2 21:23:52 GMT 1994
hostname toaster.mycompany.com
ifconfig e0 `hostname`-0
ifconfig e1a `hostname`-1
route add default MyRouterBox 1
routed on
timezone Atlantic/Bermuda
savecore
```

FILES

/etc/rc

SEE ALSO

na_nfs(1), na_setup(1), na_timezone(1)

registry

NAME

na_registry - registry database

SYNOPSIS

/etc/registry

DESCRIPTION

The file **/etc/registry** stores a variety of persistent information for ONTAP. For example, the **options** command uses this file to save option values, eliminating the need to manually add lines to the **/etc/rc** file.

Do not edit this file directly; if you do, some aspects of ONTAP will not operate correctly. Several backups of the registry database exist and are automatically used if the original registry becomes unusable. In particular, **/etc/registry.lastgood** is a copy of the registry as it existed after the last successful boot.

If you back up the configuration files in the **/etc** directory, the **/etc/registry** file should be included. After restoring all the configuration files, a reboot will be required to complete the restore (for example, in order to reload the registry, and to re-execute **/etc/rc**).

ERRORS

If the **/etc/rc** file contains an explicit "options" statement whose value conflicts with the value of the option stored in the registry, you will see an error message at boot time like this:

```
** Option cifs.show_snapshot is being set to "true" in /etc/rc, and this
** conflicts with a value - "off" - loaded from the registry.
** Commands in /etc/rc always override the registry at boot time,
** so the value of cifs.show_snapshot is now "true".
```

Similarly, if you execute the "options" statement interactively, and the **/etc/rc** file contains an explicit "options" statement for the same option, you may see an error message such as this:

```
** Option autosupport.enable is being set to "off", but this conflicts
** with a line in /etc/rc that sets it to "on".
** Options are automatically persistent, but the line in /etc/rc
** will override this persistence, so if you want to make this change
** persistent, you will need to change (or remove) the line in /etc/rc.
```

By removing the explicit options statements from **/etc/rc**, you can eliminate these warnings about inconsistencies between **/etc/rc** and the registry.

/etc/registry.lastgood (second-level backup)

resolv.conf

NAME

na_resolv.conf - configuration file for domain name system resolver

SYNOPSIS

/etc/resolv.conf

DESCRIPTION

The resolver configuration file contains information that is read by the resolver routines. The file is designed to be human readable and contains a list of keywords with values that provide various types of resolver information. Semicolon (;) or pound (#) starts comment. So, any character after ';' or '#' is ignored until the next line. Lines in bad formats are ignored entirely.

The different configuration options are:

nameserver *address*

This specifies the Internet address (in dot notation) of a name server that the resolver should query. Up to 3 name servers may be listed, one per keyword. If there are multiple servers, the resolver queries them in the order listed. When a query to a name server on the list times out, the resolver will move to the next one until it gets to the bottom of the list. It will then restart from the top retrying all the name servers until a maximum number of retries are made.

search *domain-list*

This specifies the search list for host-name lookup. The search list is normally determined from the local domain name; by default, it begins with the local domain name, then successive parent domains that have at least two components in their names. This may be changed by listing the desired domain search path following the **search** keyword with spaces or tabs separating the names. Most resolver queries will be attempted using each component of the search path in turn until a match is found. Note that this process may be slow and will generate a lot of network traffic if the servers for the listed domains are not local, and that queries will time out if no server is available for one of the domains.

The search list is currently limited to six domains with a total of 256 characters.

The keyword and value must appear on a single line, and the keyword (e.g. **nameserver**) must start the line. The value follows the keyword, separated by white space.

FILES

/etc/resolv.conf

SEE ALSO

na_rc(5), RFC 1034, RFC 1035

rmtab

NAME

na_rmtab - remote mounted file system table

SYNOPSIS

/etc/rmtab

DESCRIPTION

/etc/rmtab maintains the list of client mount points between server reboots. The list of client mount points can be obtained by using the **MOUNTPROC_DUMP** remote procedure call, or by using the UNIX *showmount(1)* command. When the server successfully executes a mount request from a client, the server appends a new entry to the file. When the client issues an unmount request, the corresponding entry is marked as unused. When the server reboots, unused entries are deleted from the file.

BUGS

Entries may become stale if clients crash without sending an unmount request. The file may be removed before rebooting the server in which case the server will lose information about any active client mount entries on reboot.

serialnum

NAME

na_serialnum - system serial number file

SYNOPSIS

/etc/serialnum

DESCRIPTION

The file **/etc/serialnum** should contain the serial number of your machine.

If **/etc/serialnum** does not exist, it is an indication that your machine could not obtain the serial number from the hardware. In this case you need to enter the serial number manually. The serial number is found on the back of the machine in the lower right hand corner. You should see a tag that says:

NetworkAppliance SN: xxxx

Use a text editor to create **/etc/serialnum** and put the machine's serial number in it. The file should contain a single line that only has the serial number. The file is used to help IBM's customer service group process your autosupport email more efficiently.

FILES

/etc/serialnum

WARNINGS

A warning is issued to the console if **/etc/serialnum** contains a different value other than the hardware serial number in which case it is automatically overwritten with the hardware serial number. Also if the hardware serial number and **/etc/serialnum** do not exist, then a warning is issued to the console.

services

NAME

na_services - Internet services

SYNOPSIS

/etc/services

DESCRIPTION

The **services** file contains information mapping between port numbers and service names. This file exists purely for reference purposes and is not currently used by Data ONTAP. Modifying entries in this file will have no effect on the filer. Removing entries will not disable ports or services. For information on how to change which port numbers a service uses (if possible), see the relevant manual page for that service. Such changes will not update the **services** file.

Each line contains a service name followed by a port number, a “/”, and a protocol, for example 20/tcp. Legal protocol names are “tcp” and “udp”. Port numbers are decimal numbers in the range of 0 to 65535. A service name may contain any printable character other than the comment character (i.e. no spaces, tabs, newlines, or “#”).

Items are separated by any number of blanks and/or tab characters. A “#” indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines which search the file.

FILES

/etc/services

SEE ALSO

na_hosts(5)

shadow

NAME

na_shadow - shadow password file

SYNOPSIS

/etc/shadow

DESCRIPTION

The **shadow** file provides more secure storage for the user's password (which would otherwise be in **/etc/passwd**). When the password field of an entry in **/etc/passwd** is empty, **/etc/shadow** must contain a corresponding entry with the same user name but a non-empty encrypted password.

username:password:

The following list explains the required fields:

username

The user's login name, not more than eight characters.

password

The user's password, in an encrypted form that is generated by the UNIX passwd function.

There can be other fields in the **/etc/shadow** file following the ":" after the **password**.

EXAMPLE

Here is a sample shadow password file entry:

```
dave:Qs5I6pBb2rJDA:
```

SEE ALSO

na_pcnfsd(8), na_nsswitch.conf(5)

sis

NAME

na_sis - Log of Advanced Single Instance Storage (SIS) activities

SYNOPSIS

/etc/log/sis

DESCRIPTION

The **sis** log file contains a log of SIS activities for this filer. The file lives in **/etc/log** on the root volume.

Every Sunday at midnight, **/etc/log/sis** is moved to **/etc/log/sis.0**; **/etc/log/sis.0** is moved to **/etc/log/sis.1**; and so on. The suffix can go up to 5, so the old **/etc/log/sis.5** will be deleted. SIS activities are saved for a total of seven weeks.

Each entry of the **/etc/log/sis** file is a single line containing the following space-separated fields.

```
timestamp path session-ID event_info
```

The following is a description of each field.

timestamp

Displayed in **ctime()** format, e.g. Fri Jul 17 20:41:09 GMT 2008. Indicates the time this event was recorded.

path

The full path to a SIS volume as shown below

```
/vol/volume_name
```

session-ID

The session ID is as shown below:

```
[sid: 1220249325]
```

event_info

The event which is being logged. Some events may have extra information in parentheses. The current event types are:

Sis Restart

When a SIS operation resumes from a checkpoint. The event is augmented within parenthesis with the stage from which it is restarting.(Restarting from [- | gathering | sorting | saving_pass1 | saving_pass2 checking | checking_pass1 | checking_pass2])

Begin (*operation information*)

When a SIS operation is first kicked off, there can be multiple reasons which trigger it. The event is augmented with the following additional information in parenthesis.

schedule : If the SIS operation is kicked off as per the configured or default schedule.

sis start scan : Corresponds to "sis start -s", when we are instructed to scan the entire file system for duplicated blocks.

sis check : If we are specifically instructed to perform fingerprint database checking.

sis start snapvault : If the snapvault initiated the SIS operation.

sis start : When the SIS operation is kicked off to perform deduplication based on the changelogs.

Undo

Corresponds to "sis undo" command.

Stage (amount_processed)

An event is logged at the end of each stage along with the amount of processing that was done in that stage. The different stages can be Sort, Dedup Pass1, Dedup Pass2 and Verify. Note the Verify event is logged at the start of sis check operation. The events for each are shown below :

```
Thu Sep 01 10:31:05 GMT 2008 /vol/dense_vol [sid: 12] Sort (2560 fp entries)
Thu Sep 22 10:33:03 GMT 2008 /vol/dense_vol [sid: 12] Dedup Pass1 (0 dup entries)
Thu Oct 13 10:35:00 GMT 2008 /vol/dense_vol [sid: 12] Dedup Pass2 (2559 dup entries)
Thu Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 12] Verify
```

End (processed_size KB)

When a long-running SIS operation (either Begin or Undo) completes successfully. The size of data processed is included in the event.

Error (Error_message)

If a SIS operation aborts or fails to start, the cause of the error is indicated.

Config (schedule_string)

When a "sis config" command successfully set or modified the SIS schedule on a volume. The new schedule string is logged with the event.

Enable

When the SIS is enabled on a volume.

Disable

When the SIS is disabled on a volume.

Stats (statistics string)

When each changelog is processed ,statistics are logged with this event.

Info (operation information)

Some of the operations that are logged within parenthesis in the **Info** event are :

sis start : This corresponds to the event when user issues the sis operation based on changelogs.

sis check : When a sis check operation starts to perform fingerprint database checking.

sis start scan : This information is logged when a "sis start -s" command is issued.

sis start schedule : When a sis operation starts based on its schedule.

operation pending : The maximum number of sis operations running is 8. If a sis operation is issued or scheduled when this upper limit is already reached, it gets queued as a pending operation and prints this message in **Info** event.

starting pending operation : A sis operation is queued when 8 sis operations are already running. This message is logged when later on system becomes free and the pending operation starts its execution at the time of schedule start.

EXAMPLE

On the successful completion of such a sis start -s operation, the log file should have the following entries:

```
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Info (sis start scan)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Begin (sis start scan)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Sort (0 fp entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Dedup Pass1 (0 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Dedup Pass2 (0 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 11] Stats (blks gathered 0,finger
prints sorted 0,dups found 0,new dups found 0,blks deduped 0,finger prints checked 0,finger
prints deleted 0)
Tue Jul 12 02:02:05 GMT /vol/dense_vol [sid: 11] End (0 KB)
```

On the successful completion of a sis start operation, the log file should have the following entries:

```
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Info (sis start)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Begin (sis start)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Sort (0 fp entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Dedup Pass1 (0 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Dedup Pass2 (0 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 9] Stats (blks gathered 0,finger
prints sorted 0,dups found 0,new dups found 0,blks deduped 0,finger prints checked
0,finger prints deleted 0)
Tue Jul 12 02:02:05 GMT 2008 /vol/dense_vol [sid: 9] End (0 KB)
```

A SIS operation initiated by schedule and based on change log is the most common case. In this case a pending operation has started its execution. On the successful completion of such an operation, the log file should have the following entries:

```
Tue Jul 12 02:01:03 GMT 2008 /vol/dense_vol [sid: 0] Info (starting pending operation)
Tue Jul 12 02:01:03 GMT 2008 /vol/dense_vol [sid: 0] Begin (schedule)
Tue Jul 12 02:01:04 GMT 2008 /vol/dense_vol [sid: 0] Sort (128000 fp entries)
Tue Jul 12 02:01:04 GMT 2008 /vol/dense_vol [sid: 0] Dedup Pass1 (0 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 0] Dedup Pass2 (127999 dup entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 0] Stats (blks gathered 0,finger prints sorted 0,dups found
0,new dups found 127999,blks deduped 127541,finger prints checked 0,finger prints deleted 0)
Tue Jul 12 02:02:22 GMT 2008 /vol/dense_vol [sid: 0] End (2356080 KB)
```

The log file will have following entries if sis start operation starts from a checkpoint corresponding to saving_pass2 stage :

sis

```
Thu Sep 18 03:32:23 GMT 2008 /vol/dense_vol [sid: 15] Sis Restart (Restarting from saving_pass2 stage )
Thu Sep 18 03:32:23 GMT 2008 /vol/dense_vol [sid: 15] Begin (sis start)
Thu Sep 18 03:32:23 GMT 2008 /vol/dense_vol [sid: 15] Backup Pass2 (130559 dup entries)
Thu Sep 18 03:32:30 GMT 2008 /vol/dense_vol [sid: 15] Stats (blks gathered 0,finger prints sorted 0,dups found 0,new dups found 130559,blks deduped 130091,finger prints checked 0,finger prints delet...
Thu Sep 18 03:32:30 GMT 2008 /vol/dense_vol [sid: 15] End (52240 KB)
```

On the successful completion of such a sis check operation, the log file should have the following entries: (sis check)

```
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 14] Info (sis check)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 14] Begin (sis check)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 14] Verify
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 14] Merge(0 stale entries)
Tue Jul 12 02:01:05 GMT 2008 /vol/dense_vol [sid: 14] Stats (blks gathered 0,finger
prints sorted 0,dups found 0,new dups found 0,blks deduped 0,finger prints
checked 0,finger prints deleted 0)
Tue Jul 12 02:02:05 GMT 2008 /vol/dense_vol [sid: 14] End (0 KB)
```

If a SIS operation aborts, the Error event will replace the End event.

```
Fri Jul 15 00:40:31 GMT 2008 /vol/dense_vol [sid: 18] Begin(schedule)
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 18] Error (Volume is full)
```

The Undo is the only other long-running event, similar to the Begin event, is terminated by either End or Error.

```
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 19] Undo
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 19] End (34670 KB)
```

The Enable, Disable and Config events are only logged when they complete successfully.

```
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 20] Enable
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 20] Disable
Fri Jul 15 18:58:26 GMT 2008 /vol/dense_vol [sid: 20] Config (sun-sat@0-23)
```

FILES

/etc/log/sis

SIS log file for current week.

/etc/log/sis.[0-5] SIS log files for previous weeks.

SEE ALSO

na_sis(1)

sm

NAME

na_sm - network status monitor directory

SYNOPSIS

/etc/sm

DESCRIPTION

The network status monitor provides information about the status of network hosts to clients such as the network lock manager. The network status monitor keeps its information in the **/etc/sm** directory.

The **/etc/sm/state** file contains an integer that is incremented each time the filer is booted.

The **/etc/sm/monitor** file contains a list of network hosts the filer is monitoring.

The **/etc/sm/notify** file contains a list of network hosts that made an NLM lock request to the filer. Each time the filer reboots, it tries to notify the hosts of its new state information. You can remove this file if you want the filer to stop notifying the hosts in this file.

BUGS

If the filer cannot resolve a host name in the **/etc/sm/notify** file or if a host in the **/etc/sm/notify** file does not exist on the network any more, the filer logs an error message each time it tries to contact the host. The error message is similar to the following:

```
[sm_recover]: get RPC port for failed
```

To stop the error messages, remove the **/etc/sm/notify** file.

snapmirror

NAME

na_snapmirror - Log of SnapMirror Activity

SYNOPSIS

/etc/log/snapmirror

DESCRIPTION

The SnapMirror log file contains a log of SnapMirror activity for this filer. The file lives in **/etc/log** on the root volume of both the source and destination filers. When the option **snapmirror.log.enable** is set to **on**, all the SnapMirror activities will be recorded in this log file. See `na_options(1)` for details regarding how to enable and disable this option. Every Sunday at 00:00, **/etc/log/snapmirror** is moved to **/etc/log/snapmirror.0**, **/etc/log/snapmirror.0** is moved to **/etc/log/snapmirror.1**, and so on. The suffix can go up to 5. This process is called rotation. SnapMirror log entries are saved for a total of six weeks.

Each entry of the **/etc/log/snapmirror** file is a single line consisting of space-separated fields. All log entries begin with a type field and a timestamp field. The final field may be enclosed by parentheses, in which case it may contain spaces. The timestamp field contains a fixed number of spaces, and as such can be parsed as five space-delimited fields. Which fields appear, and in what order they appear in, is determined by the type field of log entry (which is the first field).

Following is a description of each field.

type Indicate the type of the entry, which also determines the format of the rest of the entry. It can be one of the following values:

log

log facility activity

Format: *type timestamp event_info...*

sys

system-wide activity

Format: *type timestamp event_info...*

tgt

snapvault target activity

Format: *type timestamp volume target event_info...*

src

source activity

Format: *type timestamp source destination event_info...*

dst
destination activity

Format: *type timestamp source destination event_info...*

cmd
user command activity

Format: *type timestamp source destination event_info...*

scn
replication check source activity

Format: *type timestamp source destination event_info...*

chk
replication check destination activity.

Format: *type timestamp source destination event_info...*

vol
volume-wide activity

Format: *type timestamp volume event_info...*

slk
softlock addition-deletion activity

Format: *type timestamp softlock event_info...*

timestamp

Displayed in **ctime()** format, e.g. Fri Jul 17 20:41:09 GMT. Indicates the time this event is recorded.

volume Specifies the name of the volume to which this entry applies.

target This is the name and type of the target for this entry. Targets are volume-wide actions, typically snapshot creations. It is displayed as two colonseparated fields, as follows:

target_type:target_name

The target name may be an empty string.

source This is the name of the source filer and the volume name or qtree path to be mirrored. The name is specified as two colon-separated fields, as follows:

host:path

This field may be '-' when not applicable for the event.

destination

This is the name of the destination filer and the volume name or qtree path of the destination. The name is specified as two colon-separated fields, same as in the *source* field.

This field may be '-' when not applicable for the event.

event_info

This field contains the event which is being logged. Some events may have extra information in parentheses.

Request (*IP address | transfer type*) A transfer request has been sent (destination) or received (source). On source side, the IP address of the destination filer that made the request is included in parentheses. On destination side, the transfer type is included in the parentheses.

Start The beginning of a transfer.

Start (Snapshots to check=#num, level={data|checksum}, {check|fix}, {quick|full} mode)

The beginning of a replication check or fix session. The session options are included in the parentheses. All options appear on the destination side log but only the "snapshots to check" option appears in source side log.

Restart (@ num KB)

The beginning of a restarted transfer.

End (num KB done)

The completion of a transfer. The total size of the transfer in KB is included in the parentheses.

End (src_only=num_1, dst_only=num_2, mismatch=num_3) The completion of a replication check or fix session. The summary of the session is included in the parentheses. The summary is present only on the destination side logs. Source side logs will not contain any summary information.

Abort (error msg)

A transfer is aborted. The error message is included in the parentheses.

Defer (reason)

Indicates a transfer is deferred because of a resource limitation. The reason for the deferment is included in the parentheses.

Wait_tape

A SnapMirror tape operation is waiting for next tape.

New_tape

A SnapMirror tape operation continued the operation with the new tape.

Sync_start

The start of synchronous mirroring mode for the SnapMirror relationship specified by this log entry.

Sync_end (reason)

The end of synchronous mirroring mode for the SnapMirror relationship specified by this log entry. The reason for dropping out of synchronous mode is included in the parentheses.

Quiesce_start

The beginning of quiesce process.

Quiesce_end

The completion of quiesce process.

Quiesce_failed (*reason*)

The failure of quiesce process. The reason for failure is included in the parentheses.

Rollback_start

The beginning of a rollback process for a qtree SnapMirror or SnapVault.

Rollback_end

The completion of a rollback process for a qtree SnapMirror or SnapVault.

Rollback_failed (*reason*)

The failure of a rollback process for a qtree SnapMirror or SnapVault. The reason for failure is included in the parentheses.

Coalesce_start (*snapshot*)

The beginning of a coalesce process for a SnapVault qtree. The base snapshot for the coalesce operation is included in the parentheses.

Coalesce_end

The completion of a coalesce process for a SnapVault qtree.

Coalesce_failed (*reason*)

The failure of a coalesce process for a SnapVault qtree. The reason for failure is included in the parentheses.

Target_start

The beginning of a SnapVault target.

Target_end

The completion of a SnapVault target.

Target_failed (*reason*)

The failure of a SnapVault target. The reason for failure is included in the parentheses.

Start_logging

SnapMirror log was enabled.

End_logging

SnapMirror log was disabled.

SnapMirror_on (*cause*)

SnapMirror was enabled on this host. The operation or process that caused SnapMirror to become enabled is specified in the parentheses.

SnapMirror_off (*cause*)

SnapMirror was disabled on this host. The operation or process that caused SnapMirror to become disabled is specified in the parentheses.

SnapVault_on (*cause*)

SnapVault was enabled on this host. The operation or process that caused SnapVault to become enabled is specified in the parentheses.

SnapVault_off (*cause*)

SnapVault was disabled on this host. The operation or process that caused SnapVault to become disabled is specified in the parentheses.

Resume_command

User issued **snapmirror resume** command.

Break_command

User issued **snapmirror break** command.

Release_command

User issued **snapmirror release** command.

Abort_command**Abort_command** (*type*)

User issued **snapmirror abort** command. The *type* will only be present if the abort was issued with additional options which changed the type of the abort.

Resync_command (*common snapshot*)

User issued **snapmirror resync** command. The common snapshot for the resync operation is included in the parentheses.

Restore_resync_command (*common snapshot*) User issued **snapvault restore -r** command. The common snapshot for the resync operation is included in the parentheses.

Migrate_command

User issued **snapmirror migrate** command.

Request_check (*snapshot_name*)

A request for single snapshot during replication check session. This is source side log entry. Each snapshot being checked in a replication check session will have its entry. Name of snapshot is included in the parentheses.

Checking_snapshot *source snapshot_name (timestamp, cpcount=num_2, snapid=id) to dest_snapshot_name (timestamp, cpcount=count, snapid=id)* The beginning of a single snapshot comparison during replication check. It is logged on both source and destination.

Abort_check

replication check session for SnapMirror or SnapVault aborted. Reason of abort is included in the parentheses.

Abort_check_command

User issued replication **check abort** command. Corresponding log file entry appears with **cmd** *type*.

Data_differ (*{block blk_num in file_path | VBN vbn}*)

Replication check found a data block mismatch. Either the block number and the inode path or Volume Block Number (VBN) is included in the parentheses.

Unique_in_src (*entry_type* for *entry_path*) Replication check found an entry only present in the *source*. The entry type and entry path are included in the parentheses.

Unique_in_dst (*entry_type* for *entry_path*) Replication check found an entry only present in the *destination*. The entry type and entry path are included in the parentheses.

Size_differ (*path*)

Replication check found a file size mismatch in specified inode. The inode path is included in the parentheses.

Type_differ (*path*)

Replication check found a inode type mismatch. The inode path is included in the parentheses.

UID_differ (*path*)

Replication check found a user ID mismatch for specified inode. The inode path is included in the parentheses.

GID_differ (*path*)

Replication check found a group ID mismatch for specified inode. The inode path is included in the parentheses.

Perm_differ (*path*)

Replication check found a permission or dosbit mismatch for specified inode. The inode path is included in the parentheses.

Atime_differ (*path*)

Replication check found a mismatch in the last access time for specified inode. The inode path is included in the parentheses.

Mtime_differ (*path*)

Replication check found a mismatch in the last modification time for specified inode. The inode path is included in the parentheses.

Ctime_differ (*path*)

Replication check found a mismatch in the last size/status change time for specified inode. The inode path is included in the parentheses.

Crttime_differ (*path*)

Replication check found a mismatch in the creation time for specified inode. The inode path is included in the parentheses.

Rdev_differ (*path*)

Replication check found a device number mismatch for specified inode. The inode path is included in the parentheses.

DOSbits_differ (*path*)

Replication check found a DOS bits mismatch for specified inode. The inode path is included in the parentheses.

ACL_differ (*path*)

Replication check found an NT or NFS V4 ACL mismatch for specified inode. The inode path is included in the parentheses.

Hardlink_differ (*path*)

Replication check found a hardlink for specified inode, but the inode on *destination* doesn't match between the links. The inode path is included in the parentheses.

Qtree_oplock_differ (*path*)

Replication check found oplock setting mismatch for a qtree. The qtree path is included in the parentheses.

Qtree_security_differ (*path*)

Replication check found security setting mismatch for a qtree. The qtree path is included in the parentheses.

Hole_uses_disk_space (*path*)

Replication check found unnecessary disk usage for specified inode, this however is not a mismatch. The inode path is included in the parentheses.

Convert_command

User issued **snapmirror convert** command.

Older_snapshot

Updating from a snapshot which is older than the current base snapshot.

Snapshot_delete (*snapshot name*)

A snapshot is deleted from this volume. The snapshot name is included in the parentheses.

Snapshot_replace (*snapshot name*)

A SnapVault snapshot has been replaced after a SIS operation with a newer snapshot of the same name. The snapshot name is included in the parentheses.

FILED_REBOOTED

The filer is rebooted.

WORM_LOG_FAIL (*reason*)

Write to WORM log file failed. The reason for failure is included in the parentheses.

WORM_LOG_FAILURE_RECOVER_START

The beginning of the recovery of the failed WORM log entries.

WORM_LOG_FAILURE_RECOVER_END

The end of the recovery of the failed WORM log entries.

Softlock_add (*operation*)

A softlock is added. The operation that added the softlock is included in the parentheses.

Softlock_add_pending (*operation*)

A softlock is added as a pending softlock. The operation that added the softlock is included in the parentheses.

Softlock_delete (*operation*)

A softlock is deleted. The operation that deleted the softlock is included in the parentheses.

Softlock_delete_pending (*operation*) A pending softlock is deleted. The operation that deleted it is included in the parentheses.

Softlock_mark_pending (*operation*)

A softlock is marked as pending. The operation that marked it is included in the parentheses.

EXAMPLES

A typical entry in `/etc/log/snapmirror` looks like:

```
dst Fri Jul 17 22:50:18 GMT filer1:srcvol filer2:dstvol Request (Update)
```

The above example shows an update request recorded by the destination side for a SnapMirror relationship from filer:srcvol to filer2:dstvol that happened at the recorded time.

A typical Replication check session in `/etc/log/snapmirror` on destination looks like:

```
chk Wed Jan 19 01:07:39 GMT woolf:/vol/voll milton:/vol/voll Request (check)
chk Wed Jan 19 01:07:39 GMT woolf:/vol/voll milton:/vol/voll Start (Snapshots to check = 2, level= data, check, full)
chk Wed Jan 19 01:07:39 GMT woolf:/vol/voll milton:/vol/voll Checking_snapshot milton(0033587346)_voll.5 (Jan 18...
chk Wed Jan 19 01:07:48 GMT woolf:/vol/voll milton:/vol/voll Checking_snapshot nightly.0 (Jan 18 00:00, cpcount =...
chk Wed Jan 19 01:07:57 GMT woolf:/vol/voll milton:/vol/voll End (src_only = 0, dst_only = 0, mismatch = 0)
```

A typical Replication check session in `/etc/log/snapmirror` on source looks like:

```
scn Wed Jan 19 00:58:27 GMT woolf:/vol/voll milton:/vol/voll Request (172.29.19.15)
scn Wed Jan 19 00:58:27 GMT woolf:/vol/voll milton:/vol/voll Start (Snapshots to check = 2)
scn Wed Jan 19 00:58:27 GMT woolf:/vol/voll milton:/vol/voll Request_check (milton(0033587346)_voll.5)
scn Wed Jan 19 00:58:27 GMT woolf:/vol/voll milton:/vol/voll Checking_snapshot milton(0033587346)_voll.5 (Jan 18...
scn Wed Jan 19 00:58:36 GMT woolf:/vol/voll milton:/vol/voll Request_check (nightly.0)
scn Wed Jan 19 00:58:36 GMT woolf:/vol/voll milton:/vol/voll Checking_snapshot nightly.1 (Jan 18 00:00, cpcount =...
scn Wed Jan 19 00:58:45 GMT woolf:/vol/voll milton:/vol/voll End
```

A typical softlock logging in `/etc/log/snapmirror` looks like:

```
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011e.054.filer1:vol3 Softlock_add (Transfer)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (Transfer)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (Revert)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (Release)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (Clean_softlocks)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_add (RSM_forward)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (RSM_forward)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete (Snapmirror_destinations)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_delete_pending (Transfer)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_add_pending (Transfer)
slk Wed May 10 03:06:15 GMT state.softlock.voll.0000011b.054.filer1:vol3 Softlock_mark_pending (Transfer)
```

FILES

`/etc/log/snapmirror`

SnapMirror log file for current week.

`/etc/log/snapmirror.[0-5]`

SnapMirror log files for previous weeks.

SEE ALSO

`na_snapvault(1)`

snapmirror.allow

NAME

na_snapmirror.allow - list of allowed destination filers

SYNOPSIS

`/etc/snapmirror.allow`

DESCRIPTION

The `/etc/snapmirror.allow` file provides for one of two ways for controlling SnapMirror access to a source filer.

The **snapmirror.access** option is the preferred method for controlling snapmirror access on a snapmirror source filer. See `na_options(1)` and **na_protocolaccess (8)** for information on setting the option. If the option **snapmirror.access** is set to "legacy", the **snapmirror.allow** file defines the access permissions.

The **snapmirror.allow** file exists on the source filer used for SnapMirror. It contains a list of allowed destination filers to which you can replicate volumes or qtrees from that filer.

The file format is line-based. Each line consists of the hostname of the allowed destination filer.

The **snapmirror.checkip.enable** option controls how the allow check is performed. When the option is **off**, which is the default, the entries in the allow file must match the hostname of the destination filer as reported by the **hostname** command. When the option is **on**, the source filer resolves the names in the **snapmirror.allow** to IP addresses and then checks for a match with the IP address of the requesting destination filer. In this mode, literal IPv4 addresses (e.g. 123.45.67.89), literal IPv6 addresses (e.g. fe:dc:ba:98:76:54:32:10) and fully qualified names (e.g. toaster.acme.com) may be valid entries in the allow file.

Note that the allow file entry must map to the IP address of the originating network interface on the destination filer. For example, if the request comes from the IP address of a Gbit Ethernet interface e10 which is given the name "toaster-e10", then the allow file must contain "toaster-e10" or "toaster-e10.acme.com" so the name resolves to the correct IP address.

A local snapmirror, between two volumes or qtrees on the same filer, does not require an entry in the allow file.

EXAMPLE

The following **snapmirror.allow** file on a filer allows filers named **toaster** and **fridge** to replicate volumes or qtrees from it:

```
toaster
fridge
```

snapmirror.conf

NAME

na_snapmirror.conf - volume and qtree replication schedules and configurations

SYNOPSIS

/etc/snapmirror.conf

DESCRIPTION

The **/etc/snapmirror.conf** file exists on the filer containing the mirror used for SnapMirror.

There are two types of lines in the configuration file: lines that define mirror relationships and lines that define connections to source filers to be used in the relationship definitions. Relationship definition lines are used to define the mirror relationships for destination volumes on this filer. Connection definition lines are optional and are used to specify specific network connections to the source volume and allow the specification of dual paths to the source volume.

Each relationship line of the file specifies the volume or qtree to be replicated, arguments for the replication, and the schedule for updating the mirror. You may only have one line for each destination volume or qtree. The maximum number of relationship entries supported is limited to 712. Any entry after this limit is ignored.

Each relationship entry of the **/etc/snapmirror.conf** file is a single line containing space-separated fields. The entry has this format:

source destination arguments schedule

If the *source* or *destination* field contains one or more space characters (on account of it including a qtree name with space(s)), then the field must be enclosed in double quotes. If the field value itself contains one or more double quotes, then each of these double quotes must be escaped by preceding it with an additional double quote.

The following list describes the fields in each entry:

source This is the name of the source host, and the volume name, or the path of the qtree to be mirrored. The name is specified as two colon-separated fields, as follows:

host:volname

host:/vol/volume/qtree

Note that the *host* field is not necessarily the hostname of the filer (unlike the first field of the *destination* entry). You can specify a network resolvable name, IP address or connection name. The *host* field can be considered a definition of how to reach the source over the network.

destination

This is the hostname (must match the result of the `hostname` command) of the destination filer and the name of the destination volume or the path of the destination qtree. The name is specified as two colon-separated fields, as follows:

name:volume

name:/vol/volume/qtrees

The *name* field must match the hostname of the destination filer (use the *hostname(1)* function to check this).

arguments

These are a comma-separated list of arguments for the transfer. To specify no arguments, enter a dash (“-”) in this field. Each argument is specified as a *key* and a *value* pair, as follows:

key=value

Currently, there are the following argument keys:

cksum This controls which checksum algorithm is used to protect the data transmitted by SnapMirror. Currently supported values are "none", "crc32c", and "crc32c_header_only". The value "crc32c_header_only" has been added only for volume SnapMirror and is not supported for synchronous SnapMirror and qtrees SnapMirror.

kbs

The *value* for this argument specifies the maximum speed (in kilobytes per second) at which SnapMirror data is transferred over the network. The **kbs** setting is used to throttle network bandwidth consumed, disk I/O, and CPU usage. By default, the filer transfers the data as fast as it can. The throttle value is not used while synchronously mirroring.

tries The *value* for this argument specifies the maximum number of attempts that the destination will make to complete a scheduled snapmirror update. A retry will be attempted on the first minute after the previous attempt was abandoned. Notice that retries are only attempted for retry-able errors, and that some errors do not count as a retry. The **tries** setting is used to limit the number of retries, for instance to assure that backup transfers are started within a designated backup window, or else abandoned entirely until the next scheduled update. The syntax is "tries=N" or "tries=unlimited", where N is greater or equal to 0, and N is less or equal to 1000000000. If this *value* is set to 0, the transfer is never started. If no try count is specified, the default is "unlimited". Manually started transfers are never retried irrespective of the the *value* of this argument.

restart

This controls the behavior of the SnapMirror scheduler with respect to restartability. If *value* is set to **always**, then an interrupted transfer will always restart, if it has a restart checkpoint and the conditions are the same as before the transfer was interrupted. If *value* is set to **never**, then an interrupted transfer will never restart, even if it has a restart checkpoint. By default, SnapMirror behaves like the **always** case, unless it has passed the next scheduled transfer time, in which case it will begin that scheduled transfer instead of restarting.

ignore_atime

The *value* for this argument can be **enable** or **disable**. This option only applies to Qtree SnapMirror relationships. When the value is **enable**, SnapMirror will ignore files which have only their access times changed for incremental transfers. When the value is **disable**, SnapMirror will transfer metadata for all modified files. If not specified, the default is **disable**.

outstanding (deprecated)

This argument controls the performance versus synchronicity trade-off for synchronous mirrors. The *value* for this argument is a number followed by the suffixes: **ops** (operations), **ms** (milliseconds) or **s** (seconds). Setting a value less than 10s configures the mirror to run in fully synchronous mode. Setting a value greater than or equal to 10s configures the mirror to run in semi-synchronous mode. This argument is ignored for asynchronous mirrors. Please note that this is a deprecated option. Use the `schedule` field to specify the synchronous mode for the mirror.

wsize This sets the TCP window size to use for the connection. Due to how TCP negotiates window sizes, the size of the receive window will initially be large and gradually work its way down to the size specified.

visibility_interval

The *value* for this argument is a number optionally followed by the suffixes: **s** (seconds), **m** (minutes) or **h** (hours). If a suffix is not specified, *value* is interpreted as seconds. This argument controls the amount of time before an automatic snapshot is created on the source volume that is synchronously mirrored. The *value* is the number of seconds between automatically created snapshots. The default value is 3 minutes. A small number here can negatively affect the performance of the mirror. This argument is ignored for asynchronous mirrors.

compression

The *value* for this argument can be **enable** or **disable**. This argument can only be used when a connection definition is used for the relationship entry. Using this argument without a connection definition will throw an error message. When the value is **enable**, SnapMirror will compress/decompress the data that is transferred between the source and destination filer. If not specified, the default is **disable**.

connection_mode

The *value* for this argument can be **inet** or **inet6**.

When the value is **inet6**, the connection between the primary and secondary will be established using IPv6 addresses only. If there is no IPv6 address configured for the primary, then the connection will fail. When the value is **inet**, the connection between the primary and secondary will be established using IPv4 addresses only. If there is no IPv4 address configured on the primary, then the connection will fail. When this argument is not specified, then the connection will be tried using both IPv6 and IPv4 addresses. **inet6** mode will have higher precedence than **inet** mode. If a connection request using **inet6** mode fails, SnapMirror will retry the connection using **inet** mode.

This argument is not meaningful when an IP address is specified instead of a hostname. If the IP address format and connection mode doesn't match, the operation prints an error message and aborts.

schedule

This is the schedule used by the destination filer for updating the mirror.

It informs the SnapMirror

scheduler when transfers will be initiated. The `schedule` field can contain

the word **sync** to specify fully synchronous mirroring, **semi-sync** to specify semi-synchronous mirroring, or a cron-style specification of when to update the mirror. The cron-style schedule contains four space-separated fields:

minute hour day-of-month day-of-week

Each field consists of one or more numbers or ranges. If a field contains more than one value, the values are separated from each other by a comma. A field consisting solely of an asterisk (“*”) is the same as a field enumerating all possible legal values for that field. A field consisting solely of a dash (“-”) represents a null value; any *schedule* with a dash in one of its fields will never run any scheduled transfers. Values in a field can take any of the following forms:

number

first-last

first-last/step

A value with a dash in it specifies a range; it is treated as containing all the values between *first* and *last*, inclusive. A range value with a slash specifies skips of *step* size in the range. For example, the value of the entry “0-23/4” would be the same as that of the entry “0,4,8,12,16,20”.

minute Which minutes in each hour to update on. Values are from 0 to 59.

hour Which hours in the day to update on. Values are from 0 to 23.

day-of-month

Which days in the month to update on. Values are from 1 to 31.

day-of-week

Which days in the week to update on. Values are from 0 (Sunday) to 6 (Saturday).

Whenever the current time matches all the specified *schedule* fields, a transfer from the *source* to the *destination* will be invoked.

The other type of line allowed in this file is a *connection definition* line. These lines define an alternate name for the source filer that can be used as the source host in the relationship lines. They are used to describe more specifically the parameters for the connection(s) to the source filer. SnapMirror supports the multi path specification for both asynchronous and synchronous mirrors.

Each connection definition is a single line giving a name to one or two pairs of IP addresses along with a mode of operation for the connection. The lines are specified in the following format:

name = *mode*(*source_ip_addr1* , *dest_ip_addr1*) (*source_ip_addr2* , *dest_ip_addr2*)

name This is the name of the connection you would like to define. This name is to be used as the source filer in relationship definitions.

mode The mode is optional and specifies the mode in which two IP address pairs will be used. Two modes are allowed multiplexing and failover mode and are specified by using the **multi** and **failover** keywords. If not specified, multiplexing mode is used.

The multiplexing mode causes snapmirror to use both paths at the same time. If one should fail, it will switch to use the remaining path only and use both again should the failing path be repaired.

Failover mode causes snapmirror to use the first path as the desired path and only use the second path should problems arise with the first path.

source_ip_addr1

source_ip_addr2 dest_ip_addr1 dest_ip_addr2 These are resolvable network names or IP addresses that define a path through the network between the source and the destination. The source addresses are the IP addresses of interfaces to use on the source and respectively for the destination. The pairing denotes a path from source to destination.

EXAMPLES

The following **snapmirror.conf** entry indicates that filer fridge's qtree **home**, in volume **vol2** will mirror qtree **home**, in volume **vol1** from the filer toaster. Transfer speed is set at a maximum rate of 2,000 kilobytes per second. The four asterisks mean transfers to the mirror are initiated every minute, if possible. (If a previous transfer is in progress at the minute edge, it will continue; a new transfer will be initiated at the first minute edge after the transfer has completed.)

```
toaster:/vol/vol1/home fridge:/vol/vol2/home kbs=2000 * * * *
```

The following **snapmirror.conf** entry is similar to the above example, except that it shows how qtree names with spaces and double quotes can be specified. This entry indicates that filer fridge's qtree **x y"z** in volume **vol2** will mirror qtree **x y"z** in volume **vol1** from the filer toaster.

```
"toaster:/vol/vol1/x y"z" "fridge:/vol/vol2/x y"z" kbs=2000 * * * *
```

The following **snapmirror.conf** entry indicates that filer myfiler1's volume **home_mirror** will mirror volume **home** via the myfiler0-gig interface. (The myfiler0-gig interface is whatever IP address myfiler1 can resolve that name to. In this case, it might be a gigabit ethernet link on filer myfiler0.) The mirror is updated at 9:30 a.m., 1:30 p.m., and 7:30 p.m., Monday through Friday. The asterisk means that the data replication schedule is not affected by the day of month; it is the same as entering numbers 1 through 31 (comma-separated) in that space. The dash in the *arguments* field indicates that both the **kbs** and **restart** arguments are set to default.

```
myfiler0-gig:home myfiler1:home_mirror - 30 9,13,19 * 1,2,3,4,5
```

The following **snapmirror.conf** entry makes transfers every half hour, with the first at 8:15 a.m., and the last at 6:45 p.m. The asterisks mean that the data replication schedule is not affected by the day of month or week; in other words, this series of transfers are initiated every day.

```
filer1:build filer2:backup - 15,45 8,9,10,11,12,13,14,15,16,17,18 * *
```

The following **snapmirror.conf** entry, between the **docs** qtree on dev and **docs_bak** on icebox, is kicked off on every Sunday, at 12:00 midnight.

```
dev:/vol/dept/docs icebox:/vol/backup/docs_bak - 0 0 * 0
```

The following **snapmirror.conf** entry, between the **home** and **backup** volume on icebox, is kicked off once every half-past the hour between 7:30 a.m. and 9:30 p.m., and once at midnight.

```
icebox:home icebox:backup - 30 0,7-21 * *
```

The following **snapmirror.conf** entry, between the **db** volumes on fridge-gig dev and icebox, is kicked off on every five minutes, starting at 0. (Note that fridge-gig is just a network interface name. In this case, it could be a gigabit ethernet link on fridge.)

```
fridge-gig:db icebox:db - 0-55/5 * * *
```

This can be extended to use the multiple path options and synchronous mirroring.

```
fridge-con = failover(fridge-gig,icebox-gig) (fridge-slow,icebox-slow)
fridge-con:db icebox:db - sync
```

This can further be extended to use Network compression for Asynchronous Volume SnapMirror transfers.

```
fridge-con = multipath(fridge-gig,icebox-gig) (fridge-slow,icebox-slow)
fridge-con:db icebox:db compression=enable * * * *
```

This changes the relationship into synchronous mode and the connection specifies that we should use a gigabit ethernet path for the mirroring where only if that connection fails, use a slower network connection. Even if you would like to use one path from source to destination, it is a good idea to specify a connection line in your configuration file. This can reduce problems seen with name resolution affects on the relationship configuration line.

CONCURRENT STREAM LIMITS

The number of concurrent replication streams are limited for each ONTAP platform. This limitation is put in order to restrict the overuse of resources and bandwidth on the source and destination of the streams. These limits do not scale with the capabilities of the platform, e.g. cpu, memory, networking, etc. The following tables give the maximum number of concurrent transfers that each platform may allow.

Personality: Default

```
=====
# Model      Maximum #
#           Transfers #
=====
| N3700      8          |
=====
```

The above platform has the same maximum concurrent transfer limit for each transfer type.

stats_preset

NAME

na_stats_preset - stats preset file format

SYNOPSIS

/etc/stats/preset

DESCRIPTION

The **stats** utility supports preset queries, using the **-p** argument. A preset includes the statistics to be gathered, and the format for display. Using presets not only saves typing when entering commands from the CLI, it also allows greater flexibility in formatting the data than is possible on the command line. Each preset is described in an XML file, stored in the appliance directory **/etc/stats/preset**. The name of each preset file is *pre_setname.xml*.

PRESET FILE FORMAT

Preset Element

The main element of a preset file is a single **preset**. The preset consists of attributes, plus one or objects that should be included in the preset. A simple preset to display all information from the **system** object using the default formats might be:

```
<?xml VERSION = "1.0" ?>
<preset>
<object name="system">
</object> </preset>
```

Preset Attributes

The following attributes are available for the **preset** element.

orientation

Output orientation, "row" or "column", see **-r/-c** command line options.

outfile

Output file. See **-o** command line option. When used with a **stats start** and **stats stop** pair this option is only active with **stats stop**. In such pairs the same preset is typically used with both commands, although this is not mandatory.

interval

Interval between output. See **-i** command line option.

icount Number of outputs when using interval output. See **-n** command line option.

print_header

Whether or not to print a output header. Default: true

stats_preset

print_object_names

In row output, whether or not to include object names in the output. Default: true

print_instance_names

In column output, whether or not to include instance names as a column in the output. Default: true

print_footer

After printing a set of counters print a footer string. Default: false. In multiple-count outputs the footer is printed after each iteration.

pre_header

A header string that is printed prior to data headers. Default: none

use_regex

Allow extended regular expressions for instance and counter names. Default: false

print_zero_values

Determines whether counters with zero values should be displayed. The default setting displays all counters, except for counters that are flagged as not-zero-printing by default. The allowed values are **default**, **true** and **false**. This option only affects row output.

column_delimiter

In column output, the text to print between each column, changing the default TAB spacing.

catenate_instances

In column output, whether or not to catenate all instance counters into a long line, or to split the output so that each instance goes on its own line. Default: false

The following example specifies a preset with column output, that displays values each second:

```
<?xml VERSION = "1.0" ?>
<preset orientation="column" interval="1" > ...
</preset>
```

Objects

The **object** element specifies an object that is to be used in the preset. It has attributes, as listed below, and optional counters and instances.

The following example shows a preset using the **system** and **volume** objects:

```
<?xml VERSION = "1.0" ?>
<preset>
<object name="system">
...
</object>
<object name="volume">
...
</object>
</preset>
```

The following table lists object attributes.

name

Object name. If "*" is used, this means all objects. This attribute is mandatory

Object counters and instances

Each object may list which instances and/or which counters are to be used in the preset, using the **instance** and **counter** elements. If no instances or counters are listed then all instances, all counters are assumed.

Counters may be listed for an object, or for an instance. If a counter is listed for an object then it applies to all instances of the object in the preset. If a counter is listed for an instance then it only applies to that instance.

The following example shows a case where counter "global_counter" is being used for all instances, but "counter_0" is only being used for a specific instance.

```
<?xml VERSION = "1.0" ?>
<preset>
<object name="OBJNAME">
<instance name="instance0"> <counter name="counter_0"> </counter">
</instance>

<counter name="global_counter"> </counter>
</object>
</preset>
```

See below for more information on the syntax for counters and instances.

Counters

Object counters are specified with the **counter** element. The required attribute "name" specifies the counter name, or "*" may be used to indicate all counters for an object.

A counter also has the following elements:

title Title to be used in column headers.

width Column width in output, in characters.

The following example shows a column named "disk_io" formatted in a column 8 characters wide, with a column header of "Disk I/O":

```
<counter name="disk_io">
<title>Disk I/O</title>
<width>8</width>
</counter">
```

Instances

Object instance are specified with the **instance** element. The required attribute "name" attribute specifies the instance name.

An instance has the following optional elements:

counter

An instance-specific counter. The element may occur multiple times.

Note that if no counters are listed for an instance then the default set of counters for the preset will be used. This is either counters listed at the object level, or all counters for the object.

The following example shows an instance with two counters:

```
<instance name="instance0">
<counter name="counter0"> <title>Cnt0</title>
</counter">
<counter name="counter1"> <title>Cnt1</title>
</counter">
</instance">
```

EXAMPLE

The following example shows a preset with output similar to the **sysstat** command. It might be invoked as:

stats show -p sysstat -i 1

```
<?xml VERSION = "1.0" ?>
<!-- This preset is similar to the tradition 'sysstat' command, using column output -->
<preset orientation="column"
print_instance_names="false" catenate_instances="true" > <object name="system">
<counter name="cpu_busy"> <width>4</width>
<title>CPU</title>
</counter>
<counter name="nfs_ops"> <width>6</width>
<title>NFS</title>
</counter>
<counter name="cifs_ops"> <width>6</width>
<title>CIFS</title>
</counter>
<counter name="http_ops"> <width>6</width>
<title>HTTP</title>
</counter>
<counter name="net_data_recv"> <width>8</width>
<title>Net in</title> </counter>
<counter name="net_data_sent"> <width>8</width>
<title>Net out</title> </counter>
<counter name="disk_data_read"> <width>8</width>
<title>Disk read</title> </counter>
<counter name="disk_data_written"> <width>8</width>
<title>Disk write</title> </counter>
</object>
</preset>
```

symlink.translations

NAME

na_symlink.translations - Symbolic link translations to be applied to CIFS path lookups

SYNOPSIS

/etc/symlink.translations

DESCRIPTION

When the CIFS server encounters a symbolic link (also called a "symlink," or "soft link"), it attempts to follow the link. If the symlink target is a path that starts with a "/", the filer must interpret the rest of the path relative to the root of the file system. On the filer, there is no way to know how NFS clients (which must be used to create the symlinks) might have mounted filesystems, so there is no reliable way to follow such absolute, or "rooted" symlinks. The **symlink.translations** file enables you to use absolute symlinks by mapping them to CIFS-based paths.

The entries in this file are similar to the `httpd.translations` file. There are two formats for file entries, as follows:

Map *template result*

Widelink *template [@qtree] result*

Any request that matches *template* is replaced with the *result* string given. Note that the result path for a "Map" entry must point to a destination within the share to which the client is connected. This is because the client has only been authenticated to that share; therefore access is limited to the same share for security reasons. A result path for a "Widelink" entry may point anywhere, thus the name "wide symlink" or widelink for short. Widelinks have these limitations-- the filer share on which the symlink resides must be enabled for wide symlinks, the CIFS client must support Microsoft's Dfs protocol, and the destination must be able to function as a Dfs leaf node. By using Dfs requests, the filer causes the client to authenticate with the destination and thus enforces security. To enable a filer share for "wide symlinks", use the "cifs shares -change" filer console command.

Both templates and results might (and usually do) contain wildcards (a star "*" character). The wildcard behaves like a shell wildcard in the *template* string, matching zero or more characters, including the slash ("/") character. In the *result* string, a wildcard causes text from the corresponding match in the *template* string to be inserted into the result.

The entries are examined in the order they appear in the file until a match is found or the lookup fails.

EXAMPLES

This example maps absolute symlinks that start with `"/u/home"` to go to the filer path `"/vol/vol2/home"`. Also, symlinks starting with `"/u"` go to `"/vol/vol0"`. Note that you should put the more restrictive entries first to avoid premature mapping since the matches are done in order.

```
#
# Example Map symlink translations
#
Map /u/home/* /vol/vol2/home/*
Map /u/* /vol/vol0/*
```

The next example maps absolute symlinks that start with "/u/docs/" to go to the filer path "\\filer\engr\tech pubs". Note that widelink result paths use CIFS pathname syntax (backslashes are separators, spaces in path components are allowed, and so on).

```
#
# Example Widelink symlink translation
#
Widelink /u/docs/* \\filer\engr\tech pubs\*
```

The next example maps absolute symlinks that start with "/u/joe". Note that depending on how NFS mounts are set up, it is possible that there could be several absolute symlinks pointing to "/u/joe" which need to have differing destinations. The qtree in which a symlink resides can optionally be used to distinguish destinations. Thus, following an absolute symlink starting with "/u/joe" in qtree /vol/vol1/mixed takes the client to "\\filer\home\joe", while symlinks in other qtrees take the client to "\\filer\test tools\joe".

```
#
# Example Widelink symlink translations #
Widelink /u/joe/* @/vol/vol1/mixed \\filer\home\joe\* Widelink /u/joe/* \\filer\test tools\joe\*
```

Note that there is no theoretical reason why a wide symlink can't point to another filer or indeed any NT server, though it may be difficult to imagine the translated link making sense to the Unix client which created the original symlink.

```
#
# More Widelink examples
#
Widelink /u/joe/* @/vol/vol1/mixed \\myfiler2\users2\joe\*
Widelink /u/joe/* \\joe-PC\Program Files\*
```

syslog.conf

NAME

na_syslog.conf - syslogd configuration file

DESCRIPTION

The **syslog.conf** file is the configuration file for the **syslogd** daemon (see `na_syslogd(8)`). It consists of lines with two fields separated by tabs or spaces:

```
selector
  action
```

The *selector* field specifies the types of messages and priorities to which the line applies. The *action* field specifies the action to be taken if a message the **syslogd** daemon receives matches the selection criteria.

The *selector* field is encoded as a *facility*, a period (“.”), and a *level*, with no intervening white-space. Both the *facility* and the *level* are case insensitive.

The *facility* describes the part of the system generating the message, and is one of the following keywords: **auth**, **cron**, **daemon**, **kern** and **local7**. Here’s a short description of each *facility* keyword:

kern

Messages generated by the filer kernel.

daemon

System daemons, such as the **rshd** daemon (see `na_rshd(8)`), the routing daemon (see `na_routed(1)`), the SNMP daemon (see `na_snmpd(8)`), etc.

auth

The authentication system, e.g. messages logged for Telnet sessions.

cron

The system’s internal cron facility.

local7

The system’s audit logging facility. All messages coming from the audit logging facility are logged at level debug.

The *level* describes the severity of the message, and is a keyword from the following ordered list (higher to lower): **emerg**, **alert**, **crit**, **err**, **warning**, **notice**, **info**, and **debug**.

Here is a short description of each *level* keyword:

emerg

A panic condition that results in the disruption of normal service.

alert

A condition that should be corrected immediately, such as a failed disk.

crit

Critical conditions, such as hard disk errors.

err

Errors, such as those resulting from a bad configuration file.

warning

Warning messages.

notice

Conditions that are not error conditions, but that may require special handling.

info

Informational messages, such as the hourly uptime message (see `na_uptime(1)`).

debug

Debug messages used for diagnostic purposes. These messages are suppressed by default.

If a received message matches the specified *facility* and is of the specified *level* (or a higher *level*), the action specified in the *action* field will be taken.

Multiple *selectors* may be specified for a single *action* by separating them with semicolon (“;”) characters. It is important to note, however, that each *selector* can modify the ones preceding it.

Multiple *facilities* may be specified for a single *level* by separating them with comma (“,”) characters.

An asterisk (“*”) can be used to specify all *facilities* (except local7) or all *levels*.

The special *level* **none** disables a particular *facility*.

The *action* field of each line specifies the action to be taken when the *selector* field selects a message. There are four forms:

A pathname (beginning with a leading slash).

Selected messages are appended to the specified file.

A hostname (preceded by an at (“@”) sign).

Selected messages are forwarded to the **syslogd** daemon on the named host.

/dev/console. Selected messages are written to the console.

An asterisk. Selected messages are written to the console.

Blank lines and lines whose first non-blank character is a pound (“#”) character are ignored.

It is recommended that all **/etc/syslog.conf** files include the line

syslog.conf

```
*.info /etc/messages
```

so that all messages are logged to the /etc/messages file.

EXAMPLES

A configuration file might appear as follows:

```
# Log all kernel messages, and anything of level err or
# higher to the console.
*.err;kern.* /dev/console

# Log anything of level info or higher to /etc/messages.
*.info /etc/messages

# Also log the messages that go to the console to a remote
# loghost system called adminhost.
*.err;kern.* @adminhost

# Also log the messages that go to the console to the local7
# facility of another remote loghost system called adminhost2
# at level info.
*.err;kern.* local7.info@adminhost2

# The /etc/secure.message file has restricted access.
auth.notice /etc/secure.message
```

Also see the sample configuration file in **/etc/syslog.conf.sample**

FILES

/etc/syslog.conf

The **syslogd** configuration file. **/etc/syslog.conf.sample** Sample **syslogd** configuration file.

BUGS

The effects of multiple selectors are sometimes not intuitive. For example “daemon.crit,*.err” will select “daemon” facility messages at the level of “err” or higher, not at the level of “crit” or higher.

na_messages(5)

tape_config

NAME

tape_config - directory of tape drive configuration files

SYNOPSIS

`/etc/tape_config`

DESCRIPTION

The **tape_config** directory contains IBM-approved tape configuration files. These files allow Data ONTAP to recognize a tape drive and to properly set its various parameters without the tape drive parameters being built into Data ONTAP. Only IBM-approved tape configuration files should be placed into the **tape_config** directory.

The **tape_config** directory of the latest release of Data ONTAP contains tape configuration files for tape drives that are configured exclusively with tape configuration files. Other approved files may be added to the directory by the user as tape qualifications are completed by IBM and configuration files become available.

To use configuration files shown in this page -- if your version of Data ONTAP does not already support the tape drive(s) -- first verify that the configuration file is approved for your version of Data ONTAP. Then copy the desired file(s) to the **/etc/tape_config** directory. The file(s) may be renamed if necessary. When an attached tape drive is accessed, Data ONTAP detects the presence of files in the directory and install the parameters for the tape drive.

SEE ALSO

`na_cloned_tapes(5)`

NOTES

External tape configuration files do not override built-in tape drive parameters. If the tape drive is already supported by Data ONTAP, remove the corresponding tape configuration file.

If a tape drive is represented in `tape_config` directory, remove any reference from the `/etc/cloned_tapes` file that attempts to cause the drive to use the parameters of another drive.

The command **storage show tape supported** displays all tape drives that are currently supported directly within Data ONTAP. If any tape drives are connected to the system, the command will also any show tape drives specified by tape configuration files.

treecompare

NAME

na_treecompare - Log of treecompare activities

SYNOPSIS

`/etc/log/treecompare`

DESCRIPTION

The **treecompare** log file contains a log of treecompare activities for this filer. The file lives in `/etc/log` on the root volume.

Every Sunday at midnight, `/etc/log/treecompare` is moved to `/etc/log/treecompare.0`; `/etc/log/treecompare.0` is moved to `/etc/log/treecompare.1`; and so on. The suffix can go up to 5, so the old `/etc/log/treecompare.5` will be deleted. Treecompare activities are saved for a total of seven weeks.

Each entry of the `/etc/log/treecompare` file is a single line containing the following space-separated fields.

```
timestamp tree1 tree2 event_info
```

The following is a description of each field.

timestamp

Displayed in **ctime()** format, e.g. Fri Jul 17 20:41:09 GMT. Indicates the time this event was recorded.

tree1 The name of the host1 and the full path for tree1 as shown below:

```
host1:tree1_path
```

tree2 The name of the host2 and the full path for tree2 as shown below:

```
host2:tree2_path
```

event_info

The event which is being logged. Some events may have extra information in parentheses. The existing event types are:

Start (cmp_level={data|checksum}, {compare|ignore} NT ACL)

The beginning of a treecompare session. The command options are included in the parentheses.

End (tree1_only=num_1, tree2_only=num_2, mismatch=num_3) The completion of a treecompare session. The summary of the session is included in the parentheses.

Abort (error_msg)

A treecompare operation was aborted. The error message is included in the parentheses.

Data_differ (block *blk_num* in *file_name*) Found a data block mismatch. The block number and the file name are included in the parentheses.

Unique_in_tree1 (*entry_type* for *entry_path*) Found an entry only present in the first tree. The entry type and entry path are included in the parentheses.

Unique_in_tree2 (*entry_type* for *entry_path*) Found an entry only present in the second tree. The entry type and entry path are included in the parentheses.

Size_differ (*file_name*)

Found a file size mismatch. The file name is included in the parentheses.

Type_differ (*entry_name*)

Found a directory entry type mismatch. The entry name is included in the parentheses.

UID_differ (*entry_name*)

Found a user ID mismatch for a directory entry. The entry name is included in the parentheses.

GID_differ (*entry_name*)

Found a group ID mismatch for a directory entry. The entry name is included in the parentheses.

Perm_differ (*entry_name*)

Found a permission mismatch for a directory entry. The entry name is included in the parentheses.

Atime_differ (*entry_name*)

Found a mismatch in the last access time for a directory entry. The entry name is included in the parentheses.

Mtime_differ (*entry_name*)

Found a mismatch in the last modification time for a directory entry. The entry name is included in the parentheses.

Ctime_differ (*entry_name*)

Found a mismatch in the last size/status change time for a directory entry. The entry name is included in the parentheses.

Crttime_differ (*entry_name*)

Found a mismatch in the creation time for a directory entry. The entry name is included in the parentheses.

Rdev_differ (*entry_name*)

Found a device number mismatch for a directory entry. The entry name is included in the parentheses.

DOSbits_differ (*entry_name*)

Found a DOS bits mismatch for a directory entry. The entry name is included in the parentheses.

ACL_differ (*entry_name*)

Found an NT ACL mismatch for a directory entry. The entry name is included in the parentheses.

Hardlink_differ (*entry_name*)

Found a hardlink for a directory entry, but the inode on tree2 doesn't match between the links. The entry name is included in the parentheses.

Skip (*attr_type* for *entry_name*)

Skipped the comparison of an unsupported attribute type for a directory entry. The attribute type and the entry name are included in the parentheses.

Inode_Num_differ (*entry_name*)

Found an inode number mismatch for a directory entry. The entry name is included in the parentheses.

Inode_Gen_differ (*entry_name*)

Found an inode generation number mismatch for a directory entry. The entry name is included in the parentheses.

Inode_Tid_differ (*entry_name*)

Found an inode tree id mismatch for a directory entry. The entry name is included in the parentheses.

CIFS_reserve_differ (*entry_name*)

Found a cifs space reservation mismatch for a directory entry. The entry name is included in the parentheses.

HOLES_reserve_differ (*entry_name*)

Found a holes space reservation mismatch for a directory entry. The entry name is included in the parentheses.

BLOCK_reserve_differ (*entry_name*)

Found a block space reservation mismatch for a directory entry. The entry name is included in the parentheses.

QT_oplock_differ (*entry_name*)

Found oplock setting mismatch for a qtree. The entry name is included in the parentheses.

QT_security_differ (*entry_name*)

Found security setting mismatch for a qtree. The entry name is included in the parentheses.

QT_reserve_differ (*entry_name*)

Found space reservation setting mismatch for a qtree. The entry name is included in the parentheses.

EXAMPLE

A typical treecompare session in `/etc/log/treecompare` looks like:

```
Tue Jun 24 00:05:20 GMT fridge:/vol/src1/.snapshot/snap1/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Start (cmp_level = data, compare NT ACL)
Tue Jun 24 00:05:44 GMT fridge:/vol/src1/.snapshot/snap1/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 End (tree1_only = 0, tree2_only = 0, mismatch = 0)
```

This example shows a treecompare session which used comparison level *data* and did compare NT ACLs. At the end of the session, the summary shows no mismatches were found.

The next example shows a log with several mismatches.

```
Tue Jun 24 00:07:31 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Start (cmp_level = checksum, ignore NT ACL)
Tue Jun 24 00:07:32 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Atime_differ (.)
Tue Jun 24 00:07:32 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
```

```

dst4/.snapshot/snap1/qt1 Atime_differ (./subd1)
Tue Jun 24 00:07:42 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Atime_differ (./subd1/dfile2)
Tue Jun 24 00:07:42 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Mtime_differ (./subd1/dfile2)
Tue Jun 24 00:07:42 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Size_differ (./subd1/dfile2)
Tue Jun 24 00:07:42 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Data_differ (block 0 in ./subd1/dfile2)
Tue Jun 24 00:07:51 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 Data_differ (block 1000 in ./subd1/dfile2)
Tue Jun 24 00:07:52 GMT fridge:/vol/src1/.snapshot/snap2/qt1 toaster:/vol/
dst4/.snapshot/snap1/qt1 End (tree1_only = 0, tree2_only = 0, mismatch = 7)

```

FILES

/etc/log/treecompare

Treecompare log file for current week.

/etc/log/treecompare.[0-5] Treecompare log files for previous weeks.

SEE ALSO

usermap.cfg

NAME

na_usermap.cfg - mappings between UNIX and Windows NT accounts and users

SYNOPSIS

/etc/usermap.cfg

DESCRIPTION

The **usermap.cfg** file explicitly maps Windows NT users to the correct UNIX account and UNIX users to the correct Windows NT account. Each line in **/etc/usermap.cfg** has the format:

```
[ IP-qual: ] [ NT-domain \ ] NTUser [ direction ] [ IP-qual: ] UnixUser
```

Lines are processed sequentially.

The following table describes the variables in the **usermap.cfg** file description.

IP-qual

An IP qualifier that the filer uses to match a user. You use an IP qualifier to narrow a match. *IP-qual* can be a regular IP address, a host name, a network name, or a network name with a subnet specified in dot notation.

NT-domain

Specifies the domain to match or the domain to use for a mapped UNIX account. The default is the domain in which the filer is installed.

NTUser

Any user-type account name. If the name contains a space, put the name in quotation marks.

direction

Restricts the direction of the mapping. By default, mappings are bidirectional. The three valid direction symbols are as follows: "*=>*" means NT to UNIX mapping only; "*=<*" means UNIX to NT mapping only; "*==*" means bidirectional mapping (use this to explicitly indicate a bidirectional mapping).

The **usermap.cfg** file format uses the following symbol conventions. An asterisk (*) matches any name. The null string ("") matches no name and rejects any user. You can use either spaces or tabs as separators.

Windows NT names are case-insensitive and can contain nonASCII characters within the character set in the current code page. Windows NT user names can contain spaces, in which case you must enclose the name in quotation marks. UNIX user names are case-sensitive and must be in ASCII.

This manpage is not encyclopedic. Please refer to online documentation and the System Administrator's Guide for further information.

EXAMPLES

The following **usermap.cfg** file ...

```
"Bob Garg" == bobg
mktg\Roy => nobody
engr\Tom => ""
uguest <= *
*\root => ""
```

maps NT user *Bob Garg* to UNIX user *bobg* and vice versa,

allows *mktg\Roy* to login, but only with the privileges of UNIX user *nobody*,

disallows login by NT user *engr\Tom*,

maps all other UNIX names to NT user *uguest*,

and disallows NT logins using the name *root* from all domains.

zoneinfo

NAME

na_zoneinfo - time zone information files

SYNOPSIS

`/etc/zoneinfo`

DESCRIPTION

The directory `/etc/zoneinfo` contains time zone information files used by the **timezone** command (see `na_timezone(1)`). They are in standard Unix time zone file format as described below.

The time zone information files begin with bytes reserved for future use, followed by six four-byte signed values, written in a "standard" byte order (the high-order byte of the value is written first). These values are, in order:

tzh_ttisgmtcnt

The number of GMT/local indicators stored in the file.

tzh_ttisstdcnt

The number of standard/wall indicators stored in the file.

tzh_leapcnt

The number of leap seconds for which data is stored in the file.

tzh_timecnt

The number of "transition times" for which data is stored in the file.

tzh_typecnt

The number of "local time types" for which data is stored in the file (must not be zero).

tzh_charcnt

The number of characters of "time zone abbreviation strings" stored in the file.

The above header is followed by **tzh_timecnt** four-byte signed values, sorted in ascending order. These values are written in "standard" byte order. Each is used as a transition time at which the rules for computing local time change. Next come **tzh_timecnt** one-byte unsigned values; each one tells which of the different types of "local time" types described in the file is associated with the same-indexed transition time. These values serve as indices into an array of structures that appears next in the file; these structures are written as a four-byte signed **tt_gmttoff** member in a standard byte order, followed by a one-byte signed **tt_isdst** member and a one-byte unsigned **tt_abbrind** member. In each structure, **tt_gmttoff** gives the number of seconds to be added to GMT, **tt_isdst** tells whether this time is during a Daylight Savings Time period and **tt_abbrind** serves as an index into the array of time zone abbreviation characters that follow the structure(s) in the file.

Then there are **tzh_leapcnt** pairs of four-byte values, written in standard byte order; the first value of each pair gives the time at which a leap second occurs; the second gives the *total* number of leap seconds to be applied after the given time. The pairs of values are sorted in ascending order by time.

Then there are **tz_h_ttisstdcnt** standard/wall indicators, each stored as a one-byte value; they tell whether the transition times associated with local time types were specified as standard time or wall clock time. A local time transition specified in standard time ignores any offset due to Daylight Savings Time. On the other hand, a time specified in wall clock time takes the prevailing value of Daylight Savings Time in to account.

Finally there are **tz_h_ttisgmtcnt** GMT/local indicators, each stored as a one-byte value; they tell whether the transition times associated with local time types were specified as GMT or local time.

SEE ALSO

na_timezone(1)

autosupport

NAME

na_autosupport - notification daemon

SYNOPSIS

Data ONTAP is capable of sending automated notification to Customer Support at IBM and/or to other designated addressees in certain situations. The notification contains useful information to help them solve or recognize problems quickly and proactively. The system can also be configured to send a short alert notification containing only the reason for the alert to a separate list of recipients. This notification is sent only for critical events that might require some corrective action and can be useful for Administrators with alphanumeric pagers that can accept short email messages.

DESCRIPTION

The autosupport mechanism will use SMTP if there are any (user configured) destination email addresses set in the **autosupport.to** option. If **autosupport.support.enable** is **on** then autosupports will also be sent to IBM. Autosupports sent to IBM may be transmitted by SMTP or by HTTP as specified in the **autosupport.support.transport** option.

If SMTP is used then the autosupport mechanism contacts a mail host that is listening on the SMTP port (25) to send email. A list of up to 5 mailhosts can be specified by using the **autosupport.mailhosts** option, and they will be accessed in the order specified until one of them answers as a mailhost. It will then send email through the successful mailhost connection to the destination email address specified in the **autosupport.to** option. Note that the **autosupport.to** option only allows 5 email address. To send to more than 5 recipients, create a local alias, or distribution list, and add that as the recipient.

If **autosupport.support.enable** is **on** then a copy of the autosupport message is also sent to IBM as follows:

If **autosupport.support.transport** is **smtp** then the copy of the autosupport is emailed to the destination specified in **autosupport.support.to** and the same mailhost picking algorithm is used as above.

If **autosupport.support.transport** is **http** then a direct connection to the location specified in **autosupport.support.url** is made and the autosupport is transmitted to IBM via HTTP POST.

The autosupport mechanism is triggered automatically once a week by the kernel to send information before backing up the messages file. It can also be invoked to send the information through the **options** command. Autosupport mail will also be sent on events that require corrective action from the System Administrator. And finally, the autosupport mechanism will send notification upon system reboot from disk.

To accommodate multiple delivery methods and destinations and to preserve time dependent values, the outgoing autosupport messages are now spooled in **/etc/log/autosupport**. Autosupport processing will attempt to deliver all (currently undelivered) messages until the **autosupport.retry.count** has been reached or until subsequent autosupport messages "fill the spool" such that the oldest (undelivered) messages are forced to be dropped. The spool size is currently 40 messages.

The subject line of the mail sent by the autosupport mechanism contains a text string to identify the reason for the notification. The subject also contains a relative prioritization of the message, using syslog severity levels from DEBUG to EMERGENCY (see `na_syslog.conf(5)`). The messages and other information in the notification should be used to check on the problem being reported.

The **setup** command tries to configure autosupport as follows:

If a **mailhost** is specified, it adds an entry for **mailhost** to the `/etc/hosts` file.

Setup also queries for `autosupport.from` information.

OPTIONS

Autosupport features are manipulated through the **options** command (see `na_options(1)`). The available options are as follows:

autosupport.cifs.verbose

If **on**, includes CIFS session and share information in autosupport messages. If **off**, those sections are omitted. The default is **off**.

autosupport.content

The type of content that the autosupport notification should contain. Allowable values are **complete** and **minimal**. The default value is **complete**. The **minimal** option allows the delivery of a "sanitized" and smaller version of the autosupport, at the cost of reduced support from IBM. Please contact IBM if you feel you need to use the **minimal** option. The **complete** option is the traditional (and default) form of autosupport. If this option is changed from **complete** to **minimal** then all previous and pending autosupport messages will be deleted under the assumption that **complete** messages should not be transmitted.

autosupport.doit

Triggers the autosupport daemon to send an autosupport notification immediately. A text word entered as the option is sent in the notification subject line and should be used to explain the reason for the notification.

autosupport.enable

Enables/disables the autosupport notification features (see `na_autosupport(8)`). The default is **on** to cause autosupport notifications to be sent. This option will override the **autosupport.support.enable** option.

autosupport.from

Defines the user to be designated as the sender of the notification. The default is **postmaster@your.domain**. Email replies from IBM will be sent to this address.

autosupport.local.nht_data.enable

Enables/disables the NHT data autosupport to be sent to the recipients listed in the **autosupport.to** option. NHT data is the binary, internal log data from each disk drive, and in general, is not parsable by other than IBM. There is no customer data in the NHT autosupport. The default for this option is **off**.

autosupport.local.performance_data.enable

Enables/disables performance data autosupport to be sent to the recipients listed in **autosupport.to**. The performance autosupport contains hourly samples of system performance counters, and in general is only useful to IBM. The default is **off**.

autosupport.mailhost

Defines the list of up to 5 mailhost names. Enter the host names as a comma-separated list with no spaces in between. The default is an empty list.

autosupport.minimal.subject.id

Defines the type of string that is used in the identification portion of the subject line when **autosupport.content** is set to **minimal**. Allowable values are **systemid** and **hostname**. The default is **systemid**.

autosupport.noteto

Defines the list of recipients for the autosupport short note email. Up to 5 mail addresses are allowed. Enter the addresses as a comma-separated list with no spaces in between. The default is an empty list to disable short note emails.

autosupport.nht_data.enable

Enables/disables the generation of the Health Trigger (NHT) data autosupport. Default is **off**

autosupport.performance_data.enable

Enables/disables hourly sampling of system performance data, and weekly creation of a performance data autosupport. The default is **on**.

autosupport.retry.count

Number of times to try resending the mail before giving up and dropping the mail. Minimum is 5; maximum is 4294967295 ; The default is **15** .

autosupport.retry.interval

Time in minutes to delay before trying to send the autosupport again. Minimum is 30 seconds, maximum is 1 day. Values may end with 's', 'm' or 'h' to indicate seconds, minutes or hours respectively, if no units are specified than input is assumed to be in seconds. The default value is **4m**.

autosupport.support.enable

Enables/disables the autosupport notification to IBM The default is **on** to cause autosupport notifications to be sent directly to IBM as described by the **autosupport.support.transport** option. This option is superseded (overridden) by the value of **autosupport.enable**.

autosupport.support.proxy

Allows the setting of an http based proxy if **autosupport.support.transport** is **https** or **http**. The default for this option is the empty string, implying no proxy is necessary.

autosupport.support.to

This option is read only; it shows where autosupport notifications to IBM are sent if **autosupport.support.transport** is **smtp**.

autosupport.support.transport

Allows setting the type of delivery desired for autosupport notifications that are destined for IBM. Allowed values are **https**, **http** (for direct web based posting) or **smtp** (for traditional email). The default value is **https**. Note that **http** and **https** may (depending on local network configuration) require that the **autosupport.support.proxy** option be set correctly. Also **smtp** requires that **autosupport.mailhosts** be configured correctly before autosupport delivery can be successful.

autosupport.support.url

This option is read only; it shows where autosupport notifications to IBM are sent if **autosupport.support.transport** is **https** or **http**.

autosupport.throttle

Enables autosupport throttling (see `na_autosupport(8)`). When too many autosupports are sent in too short a time, additional messages of the same type will be dropped. Valid values for this option are **on** or **off**. The default value for this option is **on**.

autosupport.to

Defines the list of recipients for the autosupport email notification. Up to 5 mail addresses are allowed. Enter the addresses as a comma-separated list with no spaces in between. The default is an empty list. Note that it is no longer necessary to use the standard IBM autosupport email address in this field to direct autosupport messages to IBM. Please use **autosupport.support.enable** instead.

autosupport.partner.to

Defines the list of recipients for the autosupport email notification that will receive all messages that are or will be sent to the standard IBM autosupport email address. Up to 5 mail addresses are allowed. Enter the addresses as a comma-separated list with no spaces in between. To disable, clear this list. The default is an empty list.

CONTENTS

A complete autosupport will contain the following information. Note that some sections are configurable, and/or available depending on what features are licensed. The order given is the general order of appearance in the autosupport message itself.

Generation date and timestamp

Software Version

System ID

Hostname

SNMP contact name (if specified)

SNMP location (if specified)

Partner System ID (if clustered)

Partner Hostname (if clustered)

Cluster Node Status (if clustered)

Console language type

WAFL_check logs

TYPES

The following types of autosupport messages, with their associated severity, can be generated automatically. The autosupport message text is in bold, and the LOG_XXX value is the syslog severity level. Note that text inside of square brackets ([]) is descriptive and is not static for any given autosupport message of that type.

CLUSTER CONSIDERATIONS

The autosupport email messages from a filer in a cluster are different from the autosupport email messages from a standalone filer in the following ways:

The subject in the autosupport email messages from a filer in a cluster reads, “Cluster notification,” instead of “System notification.”

The autosupport email messages from a filer in a cluster contains information about its partner, such as the partner system ID and the partner host name.

In takeover mode, if you reboot the live filer, two autosupport email messages notify the email recipients of the reboot: one is from the live filer and one is from the failed filer.

The live filer sends an autosupport email message after it finishes the takeover process.

cifs

NAME

na_cifs - Common Internet File System (CIFS) Protocol

DESCRIPTION

The filer supports the **CIFS** protocol, which is documented in an Internet Engineering Task Force (IETF) InternetDraft specification titled "A Common Internet File System (CIFS/1.0) Protocol."

CIFS is a file sharing protocol intended to provide an open cross-platform mechanism for client systems to request file services from server systems over a network. it is based on the standard Server Message Block (SMB) protocol widely in use by personal computers and workstations running a wide variety of operating systems.

RFC 1001, RFC 1002

cli

NAME

na_cli - Data ONTAP command language interpreter (CLI)

DESCRIPTION

The Data ONTAP CLI is a command language interpreter that executes commands from the Data ONTAP console. You can access the console with a physical connection, through telnet, or through the Remote LAN Manager (RLM). The commands can also be executed using rsh and ssh protocols.

You can concatenate commands together on the same line by separating the commands with semi-colons, (;).

Quoting

The quoting rules in the Data ONTAP CLI are unusual. There is no **escape** character like the backslash; however there are the following special characters:

&	(ampersand)	- unicode indicator
#	(pound sign)	- comment indicator
;	(semicolon)	- command separator
'	(single quote)	- parameter wrapper
"	(double quote)	- parameter wrapper
	(space)	- parameter separator
	(tab)	- parameter separator

When special characters are part of a command argument, the argument needs to be surrounded by quotes or the character will be treated as a special character. A single quote character needs to be surrounded by double quote characters and a double quote character needs to be surrounded by single quote characters. The other special characters can be surrounded by either single or double quotes.

EXAMPLES

The following examples show quote usage:

```
qtree create /vol/test_vol/'qtree 1'
```

The qtree **qtree 1** is created.

```
qtree create /vol/test_vol/'qtree#1'
```

The qtree **qtree#1** is created.

```
qtree create /vol/test_vol/"qtree'1"
```

The qtree **qtree'1** is created.

```
qtree create /vol/test_vol/'hello''''''1'
```

cli

The qtree **hello''1** is created.

cifs shares add jふxp /vol/test_vol/home

Creates a share with a Japanese character; whereas

cifs shares add "jふxp" /vol/test_vol/home

Creates the share **jふxp**.

sysconfig; version

Executes the **sysconfig** and **version** commands.

dns

NAME

na_dns - Domain Name System

DESCRIPTION

Domain Name Service provides information about hosts on a network. This service has two parts: a resolver which requests information and a nameserver which provides it.

Data ONTAP supports only the resolver. When the filer needs to resolve a host address, it first looks at the **/etc/nsswitch.conf** (see `na_nsswitch.conf(5)`) file to get the order in which various name services are to be consulted. If the name services before DNS fail in their lookup and DNS is enabled, then the DNS name server is contacted for address resolution.

DNS can be enabled on the filer by running the **setup** command (see `na_setup(1)`) or by manually editing the configuration files as described below. If DNS is enabled by running the **setup** command, then the DNS domain name needs to be entered.

Enabling DNS without the setup command:

1. Create the **/etc/resolv.conf** file (see `na_resolv.conf(5)`) with up to 3 nameservers. Each line contains the keyword **nameserver** followed by the IP address of the server. For example:

```
nameserver 192.9.200.1
nameserver 192.9.201.1
nameserver 192.9.202.1
```

2. Edit the **/etc/rc** file (see `na_rc(5)`) to make sure that the option specifying the DNS domain name is set and the option to enable DNS is on. For example:

```
options dns.domainname mycompany.com
options dns.enable on
```

3. Reboot the filer for these changes to take effect. If the above options commands are also entered from the console, the reboot can be avoided.

Enabling DNS with the setup command:

At setup time, one can choose to enable DNS when prompted to do so. **setup** then queries for the Internet addresses of up to three DNS nameservers.

VFILER CONSIDERATIONS

When run from a vfiler context, (e.g. via the **vfiler run** command), **dns** displays DNS information about the concerned vfiler.

dns

na_resolv.conf(5), **RFC1034**, **RFC1035**

http

NAME

na_http - HyperText Transfer Protocol

DESCRIPTION

The filer supports the **HTTP/1.0** protocol, which is documented in the Internet Engineering Task Force (IETF) **RFC 1945** titled "HyperText Transfer Protocol --HTTP/1.0."

HTTP is the primary Internet protocol used for transferring documents on the World Wide Web. It is a simple ASCII text request/response protocol. An HTTP request consists of a **method**, a target Web address or **URL** (Uniform Resource Locator), a protocol version identifier, and a set of **headers**. The method specifies the type of operation. For example, the **GET** method is used to retrieve a document. The **POST** method is used to submit a form. Headers contain additional information to the request in the form of simple name-value pairs. The HTTP header section is similar to Multipurpose Internet Mail Extensions (MIME).

The GET method is the most commonly used HTTP method. GET is used to retrieve a single resource, for example, an HTML document, image file, or other type of object, or part of it. By appending an **If-modified-since** header to the GET request, the document is retrieved conditionally, based on whether it has been modified since the date specified in the header.

An HTTP response consists of a protocol version identifier, a status code, a text response status line, response headers, and the contents of the requested document.

Access for http can be restricted by the **options httpd.access** command. Please see na_protocolaccess(8) for details.

EXAMPLES

The following is an example of use of the **GET** method:

```
GET http://www.somesite.com/ HTTP/1.0
If-modified-since: Fri, 31 Dec 1999 15:45:12 GMT
```

SEE ALSO

na_httpd.hostprefixes(5),

na_httpd.mimetypes(5), na_httpstat(1), na_protocolaccess(8)

nfs

NAME

na_nfs - Network File System (NFS) Protocol

DESCRIPTION

The filer supports versions 2, 3, and 4 of the **NFS** protocol, which are documented in RFC's 1094, 1813, and 3530 respectively.

NFS is a widely used file sharing protocol supported on a broad range of platforms. The protocol is designed to be stateless, allowing easy recovery in the event of server failure. Associated with the NFS protocol are two ancillary protocols, the **MOUNT** protocol and the **NLM** protocol. The **MOUNT** protocol provides a means of translating an initial pathname on a server to an NFS filehandle which provides the initial reference for subsequent NFS protocol operations. The **NLM** protocol provides file locking services, which are stateful by nature, outside of the stateless NFS protocol.

NFS is supported on both TCP and UDP transports. Support for TCP and UDP is enabled by default. Either one can be disabled by setting the **nfs.tcp.enable** or **nfs.udp.enable** options using the **options** command.

SEE ALSO

na_nfsstat(1), na_exports(5),

nis

NAME

na_nis - NIS client service

DESCRIPTION

The NIS client service provides information about hosts, user passwords, user groups and netgroups on a network. In NIS terminology, each of the above is referred to as the map and the specific information being looked up is called the key. For example, the hosts map is like the `/etc/hosts` file; it provides a translation from host names to IP addresses. The NIS service typically has two parts: a client component which requests information and a name server which provides it.

Data ONTAP supports only the NIS client. When the filer needs to resolve a key in a given map, it looks at the `/etc/nsswitch.conf` (see `na_nsswitch.conf(5)`) file to figure out the order in which the various databases should be consulted. For example, in case of the hosts map the lookup order may be **file, nis, dns**. This means that the filer will first consult the `/etc/hosts` file. If the host name is not found in the local file, it will then try the NIS service. If the host name is still not found, then it will attempt a DNS lookup.

The NIS client can be enabled on the filer by running the **setup** command (see `na_setup(1)`) or by manually editing the configuration files as described below. If NIS is enabled by running the **setup** command, then the NIS domain name needs to be entered.

Enabling NIS without the setup command:

1. Edit the `/etc/rc` file (see `na_rc(5)`) to make sure that the option specifying the NIS domain name is set and the option to enable NIS is on. For example:

```
options nis.domainname mycompany.com
options nis.enable on
```

2. Reboot the filer for these changes to take effect. If the above options commands are also entered from the console, the reboot can be avoided. If the options are entered via the console only, they are not saved across a reboot.

Enabling NIS with the setup command:

At setup time, one can choose to enable NIS when prompted to do so. **setup** then queries for the NIS domain name.

SEE ALSO

`na_nsswitch.conf(5)`.

pcnfsd

NAME

na_pcnfsd - (PC)NFS authentication request server

DESCRIPTION

pcnfsd provides a personal computer NFS client with the authentication services. This release supports versions 1 and 2 of the PCNFS protocol.

When **pcnfsd** receives an authentication request, it will register the user by validating the user name and password and returning the corresponding UID and primary GID pair, and the secondary group set for PCNFS version 2.

It will look up the user in the **/etc/shadow** file, or the **passwd.adjunct** NIS map, if present, to find the user's password. It will look up the user in the **/etc/passwd** file, or the **passwd.byname** NIS map, to find the user's UID and primary GID, and to find the user's password if there is no **/etc/shadow** file or **passwd.adjunct** NIS map.

For a PCNFS version 2 request, it will scan the **/etc/group** file, or the **group.byname** NIS map, to find all the groups of which the user is a member. It will look up the user in the **auto.home** NIS map, if NIS is enabled, to find the user's home directory; if NIS is not enabled, no home directory will be returned.

FILES

/etc/passwd

This file should be in the format used on many flavors of UNIX (SunOS 4.x and later, 4.4BSD, System V Release 4 and later, and others).

/etc/group

This file should be in the format used on many flavors of UNIX (SunOS 4.x and later, 4.4BSD, System V Release 4 and later, and others).

/etc/shadow

This file should be in the format used on many flavors of UNIX (SunOS 5.x and later, System V Release 4 and later, and others).

SEE ALSO

na_nis(8)

BUGS

When the call fails, **pcnfsd** doesn't fake by setting the UID and the GID to acceptable values. Passwords that have been encrypted using Kerberos are not supported.

protocolaccess

NAME

na_protocolaccess - Describes protocol access control

DESCRIPTION

Protocol access control defines a method to restrict access to the filer on a protocol-by-protocol basis. For example, the command **options rsh.access host=admin** restricts access to rsh to a host named admin. Access can be restricted by host name, IP address, and/or network interface name.

USAGE

The syntax is as follows:

```
options protocol.access access_spec [ AND | OR [ ( ) access_spec [ ] ] ... ]
```

protocol is currently one of the following: rsh, telnet, ssh, httpd, httpd.admin, snmp, ndmpd, snapmirror, or snapvault.

access_spec is composed of keywords and their values. Currently the following keywords and values are defined:

```
host [=|!=] host spec
netgroup [=|!=] netgroup spec
if [=|!=] network interface spec
all
none
legacy
*
```

host spec is a comma separated list consisting of either a host name, an IP address, or an IP address with a netmask. Valid host name is a string and cannot contain the following characters: "=", "(", ")", "!", "*", and ",". IP address can be either an IPv4 address or IPv6 address. An IPv4 address is of the format *aa.bb.cc.dd*. If the IP address contains a netmask, then the format is: *aa.bb.cc.dd/mm* where *mm* represents the number of bits from the left. An IPv6 address is of the format *aaaa:bbbb:cccc:ddd:eee:fff:ggg:hhh*. If the IPv6 address contains a prefixlen, then the format is: *aaaa:bbbb:cccc:ddd:eee:fff:ggg:hhh/mm* where *mm* represents the number of bits from the left.

network interface spec is a comma separated list of one or more network interface names. Valid network interface names can be obtained from the **ifconfig -a** command.

netgroup spec is a comma separated list consisting of names of one or more netgroups(group of hosts).

The access specs may be and'ed and or'ed by the keywords **AND** and **OR** respectively. The keywords **AND** and **OR** are not case-sensitive.

Operational precedence is from left to right. Parentheses may be used to force operational order.

The keyword *all* is used to allow access to all. The keyword *none* is used to allow access to none. The *legacy* keyword is used to specify previous behavior. For example, the legacy behavior of telnet is to use `trusted.hosts`, while the legacy behavior of rsh is to allow all.

The *access spec* can be a "*" which matches all. This is the same as the *all* keyword. If the *access spec* is a "-", then all access is denied. This is the same as the *none* keyword.

The difference between setting the host value to an IP address or a host name becomes apparent when the matching occurs. IP addresses are matched before the connection is made. If access is denied, the connection is not made and the client times out. Therefore, specifying the IP address lessens the impact of denial of service attacks. Host names are matched after the connection is made, and therefore the client is informed that access is denied.

If `httpd.admin.access` is not set to *legacy*, then `trusted.hosts` is ignored for httpd.admin. If `telnet.access` is not set to *legacy*, then `trusted.hosts` is ignored for telnet. If `snapmirror.access` is not set to *legacy*, then the `/etc/snapmirror.allow` file is ignored for snapmirror destination checking.

EXAMPLES

Here are some protocol access control examples:

Allow an NDMP server to accept control connection request from any client.

```
options ndmpd.access legacy
```

Allow remote shell access for only one host named gnesha.zo.

```
options rsh.access "host = gnesha.zo"
```

Allow access for Telnet subnet 10.42.69.

```
options telnet.access host=10.42.69.1/24
```

Allow access for Telnet to all hosts with prefix matching 3FFE:81D0:107:2082

```
options telnet.access host=3FFE:81D0:107:2082::1/64
```

Allow ssh access for hosts abc and xyz when on network interface e0.

```
options ssh.access "host=abc,xyz AND if=e0"
```

Allow access to SNMP for network interfaces e0, e1, and e2.

```
options snmp.access if=e0,e1,e2
```

Do not allow access to HTTPD for network interface e3.

```
options httpd.access "if != e3"
```

Allow access to administrative HTTPD from for two hosts.

options httpd.admin.access host=champagne,tequilla

Disallow all access to Telnet.

options telnet.access "host=-"

Set httpd.admin to use previous trusted.hosts access

options httpd.admin.access legacy

Point SnapMirror to the (deprecated) `/etc/snapmirror.allow` file to check access to sources from other filers.

options snapmirror.access legacy

Allow a SnapVault server to accept any client requests.

options snapvault.access all

Allow telnet access for all hosts in the netgroups `admin_hosts` and `it_hosts`. Both netgroups `admin_hosts` and `it_hosts` are defined in `/etc/netgroup`.

options telnet.access "netgroup = admin_hosts,it_hosts"

Allow telnet access for all hosts except those in the netgroup `admin_hosts`. Netgroup `admin_hosts` is defined in `/etc/netgroup`.

options telnet.access "netgroup != admin_hosts"

Note: quotes are needed around access specifications that include blanks.

SEE ALSO

`na_snmpd(8)`, `na_netgroup(5)`

rmt

NAME

na_rmt - remote magtape protocol module

SYNOPSIS

/etc/rmt

DESCRIPTION

/etc/rmt is a special command that can be used by remote computers to manipulate a magnetic tape drive over a network connection; for example, the UNIX **dump** and **restore** commands often can either use */etc/rmt* to access a remote tape, or have **rdump** and **rrestore** variants that can do so. */etc/rmt* is normally run by the **rshd** daemon (see `na_rshd(8)`) as a result of a remote machine making a request to **rshd** to do so.

The */etc/rmt* command accepts requests specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. This protocol is provided by **rmt** commands on many UNIX systems, although UNIX systems may support more commands and may give more different error codes.

All responses are in ASCII and in one of two forms. Successful commands have responses of:

Anumber\n

number is an ASCII representation of a decimal number. Unsuccessful commands are responded to with:

Error-number\n*error-message*\n

error-number is one of:

2 (ENOENT)

The tape device specified in an open request did not have a valid syntax.

6 (ENXIO)

The tape device specified in an open request does not exist.

5 (EIO)

An I/O error occurred when performing the request.

25 (ENOTTY)

An invalid tape operation was specified in a “perform special tape operation” request.

error-message is a (UNIX-style) error string for the error specified by *error-number*.

The protocol is comprised of the following commands, which are sent as indicated - no spaces are supplied between the command and its arguments, or between its arguments, and \n indicates that a newline should be supplied:

Odevice\nmode\n

Open the specified *device* using the indicated *mode*. *device* is a tape name of the form described in `na_tape(4)` and *mode* is an ASCII representation of a decimal number specifying how the tape is to be opened:

- 0** read-only
- 1** write-only
- 2** read-write

If a device had already been opened, it is closed before a new open is performed.

Cdevice\n

Close the currently open device. The *device* specified is ignored.

Lwhence\noffset\n

Performs no operation, and returns the value of *offset*; UNIX-style **lseek** operations are ignored on IBM filer tape devices, just as they are on tape devices on many UNIX systems.

Wcount\n

Write data onto the open device. If *count* exceeds the maximum data buffer size (64 kilobytes), it is truncated to that size. **/etc/rmt** then reads *count* bytes from the connection, aborting if a premature end-of-file is encountered. The response value is the number of bytes written if the write succeeds, or -1 if the write fails.

Rcount\n

Read *count* bytes of data from the open device. If *count* exceeds the maximum data buffer size (64 kilobytes), it is truncated to that size. **/etc/rmt** then attempts to read *count* bytes from the tape and responds with **Acount-read\n** if the read was successful; otherwise an error in the standard format is returned. If the read was successful, the data read is then sent.

Ioperation\ncount\n

Perform a special tape operation on the open device using the specified parameters. The parameters are interpreted as ASCII representations of the decimal values. *operation* is one of:

- 0** write end-of-file marker
- 1** forward space *count* files
- 2** backward space *count* files
- 3** forward space *count* tape blocks

rmt

4 backward space *count* tape blocks

5 rewind the tape

6 rewind and unload the tape

The return value is the *count* parameter when the operation is successful.

Any other command causes **/etc/rmt** to close the connection.

DIAGNOSTICS

All responses are of the form described above.

rquotad

NAME

na_rquotad - remote quota server

DESCRIPTION

The filer supports the remote quota service that allows NFS clients to determine their quota allocation on the server.

SEE ALSO

na_quota(1)

BUGS

The rquota protocol doesn't support group or tree quotas.

rshd

NAME

na_rshd - remote shell daemon

DESCRIPTION

The filer has UNIX-compatible remote shell capability that enables you to execute certain filer commands from a UNIX command line or shell script. It also enables you to use a remote shell application on a PC to run filer commands.

The value of **rsh.access** controls access to the filer, and is set by **options rsh.access**. See [na_protocolaccess\(8\)](#) for more details. This value is checked prior to the authentication mechanisms discussed below.

The **/etc/hosts.equiv** file controls authentication to the filer remote shell. The hosts and users (on those hosts) listed in the **/etc/hosts.equiv** file are automatically authenticated. This means that the filer accepts remote shell commands via rsh from these hosts and users.

An alternative authentication mechanism for rshd is to have the client use rsh with a **-l** option that specifies the **admin_name** and password in the form of **-l admin_name:password**. Both the **admin_name** and password are created with the filer's **useradmin** command.

EXAMPLE

The following example shows how to run the **version** command from a trusted host named *adminhost* through a remote shell:

```
adminhost% rsh -l root toaster version
```

The following example shows how to run the **sysconfig -r** command with a password *rpass42* from an untrusted host named *ahost* through a remote shell:

```
ahost% rsh -l root:rpass42 toaster sysconfig -r
```

To see a list of filer commands that can be executed, enter:

```
adminhost% rsh -l root toaster "?"
```

SEE ALSO

snmpd

NAME

na_snmpd - snmp agent daemon

DESCRIPTION

The filer supports an SNMP version 1 (RFC 1157) compatible agent that provides support for both the MIB-II (RFC 1213) management information base for TCP/IP based internets as well as a Data ONTAP Custom MIB.

A number of user configurable options for the SNMP agent can be set and queried from the console using the **snmp** command (see na_snmp(1)).

Due to weak authentication in SNMP version 1, SetRequest commands that allow the remote setting of configuration variables have been disabled.

Access for snmp can be restricted by the **options snmp.access** command. Please see na_protocolaccess(8) for details.

MIB-II

Under MIB-II, information is accessible for the **system, interfaces, at, ip, icmp, tcp, udp** and **snmp** MIBII groups. The transmission and egp groups are not supported.

The **coldStart, linkDown, linkUp** and **authenticationFailure** traps are implemented. Traps are configured using the **snmp** command.

DATA ONTAP CUSTOM MIB

The Data ONTAP Custom MIB provides a means to obtain detailed information about many aspects of filer operation via SNMP.

The following is a summary of the top-level groups in the Custom MIB and the information they contain:

product

Product-level information such as the software version string and system ID.

sysStat

System-level statistics such as CPU uptime, idle time and aggregate kilobytes received and transmitted on all network interfaces.

nfs

Statistics like those displayed by the **nfsstat** command (see na_nfsstat(1)), including statistics for each client if per-client NFS statistics have been enabled using the **nfs.per_client_stats.enable** option (see na_options(1)). The per-client NFS statistics are indexed by client IP addresses.

snmpd

quota

Information related to disk quotas, including the output of the quota report command (see `na_quota(1)`). To access quota information, quotas must be turned on.

filesystems

Information related to the file system, including the equivalent of the **maxfiles** and **df** commands, and some of the information from the **snap list** command (see `na_maxfiles(1)`, `na_snap(1)`).

raid

Information on RAID equivalent to the output of the **sysconfig -r** command (see `na_sysconfig(1)`).

CLUSTER CONSIDERATIONS

In takeover mode, SNMP agents can continue to access the MIBs on both filers in a cluster. However, the counters reported by SNMP are combined counters from both filers. For example, in takeover mode, the SNMP agent can report the number of packets sent or received by both filers, but you cannot determine from the number how many packets are sent or received on each filer.

You can have an application on the network management station set an alarm when a filer has been taken over. The SNMP variable to check is the **netapp.netapp1.sysStat.cf.cfSettings** variable. If this variable is set to **thisNodeDead**, the filer has been taken over.

syslogd

NAME

na_syslogd - log system messages

DESCRIPTION

The **syslogd** daemon logs system messages to the console, log files and other remote systems as specified by its configuration file, **/etc/syslog.conf**. The **syslogd** daemon reads its configuration file when it starts up during the boot procedure, or within 30 seconds after the **/etc/syslog.conf** file is modified. For information on the format of the configuration file, see `na_syslog.conf(5)`.

If **/etc/syslog.conf** does not exist the **syslogd** daemon will output all log messages of priority **info** or higher to the console and to the file **/etc/messages**. To prevent **/etc/messages** from getting too large, the **syslogd** daemon will rotate the contents of **/etc/messages** through the files **/etc/messages.0** through **/etc/messages.5**. This rotation is done once a week. So the log messages of the current week will be saved in the file **/etc/messages** and the message logs of the six weeks prior to that are saved in the files **/etc/messages.0** through **/etc/messages.5**.

To prevent large numbers of repeated messages being logged, the **syslogd** daemon will follow the first instance of a repeated message with the number of times the message was repeated. If a message is repeated over a long time period, the **syslogd** daemon will wait for increasingly longer intervals before logging the number of repeats. The repeat notification interval starts at 30 seconds and moves quickly to 20 minutes.

FILES

/etc/syslog.conf

The configuration file. **/etc/syslog.conf.sample** A sample configuration file.

/etc/messages

Message log file for current week.

/etc/messages.[0-5]

Message log for prior weeks.

CLUSTER CONSIDERATIONS

In takeover mode, the failed filer logs syslog messages to its own **/etc/messages** file and to the **/etc/messages** file on the live filer. The live filer logs its syslog messages only to its own **/etc/messages** file.

Because the **/etc/messages** file on the live filer contains syslog messages from two filers, the filer uses filer names in the syslog messages to indicate the filer from which the syslog message originated.

For example, if **toaster1** takes over **toaster2**, a message from **toaster2** is logged to the **/etc/messages** file on **toaster1**, and the message can be similar to the following:

syslogd

```
Wed May 6 18:57:52 GMT [toaster2/toaster1]: raid_disk_admin]: Volume vol7 has been added to the system.
```

If the name of the failed filer is unknown, the string “partner” is printed instead of a filer name.
