Notice

Clinical chemistry is an ever-changing field. Standard safety precautions must be followed, but as new research and clinical experience broaden our knowledge, changes in treatment and drug therapy may become necessary or appropriate. Readers are advised to check the most current product information provided by the manufacturer of each drug to be administered to verify the recommended dose, the method and duration of administration, and contraindications. It is the responsibility of the treating physician, relying on experience and knowledge of the patient, to determine dosages and the best treatment for each individual patient. Neither the Publisher nor the editor assume any liability for any injury and/or damage to persons or property arising from this publication.

PREFACE

Although Dr. Norbert Tietz has retired from active practice, his name and legacy continues on in his textbooks and in this Fourth Edition of *Clinical Guide to Laboratory Tests*. It has been 11 years since the publication of the last edition. The field of laboratory medicine has exploded with new tests and procedures since the publication of the last edition. The fourth edition highlights four new sections. **Section I**, written by Sol Green, contains preanalytical factors that affect clinical laboratory data including patient status, collection factors, processing and centrifugation, and specimen transportation. This section also generically describes the dozens of blood collection tubes used in modern phlebotomy. **Section VI**, written by C. Mark Lu, consists of an updated catalog of the hundreds of immunophenotyping markers measured by flow cytometry and immunohistochemistry. Part I contains Cluster of Differentiation or “CD” antigens and other immunophenotypic markers, while Part II consists of immunophenotypic markers of hematopoietic and lymphoid neoplasms. **Section VII**, written by Steve Wong and Paul Jannetto, consists of tests useful in the emerging field of pharmacogenetics and pharmacogenomics. Part I consists of Phase I liver drug metabolizing enzymes, Part II consists of Phase II liver drug metabolizing enzymes, Part III consists of drug transporters, and Part IV consists of drug receptor targets. **Section VIII**, written by John Halsey, lists the tests useful for allergy detection. Table VIII-1 lists the various allergens that are commonly tested such as pollens, molds and yeasts, mites, animal proteins, foods, insects, parasites, drugs, and occupational and miscellaneous allergens.

In addition to these new sections, each of the sections from the third edition has been greatly expanded. **Section II** consists of nearly 700 entries of the general clinical laboratory tests, with dozens of new entries and the elimination of many tests that are now obsolete. All entries have been reviewed and updated by contributors largely new to this series. For selected clinical chemistry tests, we have added new data on reference intervals for random urine concentrations, expressed as per gram of creatinine. This is the result of a large database generated by Larry Bond, Bill Ottinger, and Carl Garber for Quest Laboratories. **Section III** on molecular diagnostics tests written by Greg Tsongalis has been greatly expanded to reflect the many changes that this field has undergone in the last decade. In addition to a summary of molecular diagnostic techniques, tests cover the areas of infectious disease, bacteriology, cancer, genetic diseases, and identity testing. **Section IV** consists of therapeutic drugs written by Kiang-Teck Jerry Yeo, Hong Kee Lee, Joyce Liu Flanagan, and Catherine Hammett Stabler, and has been combined with Drugs of Abuse Testing, written by Larry Brousard. As in the previous edition, therapeutic ranges are combined with pharmacokinetic parameters. **Section V**, written by Yvette McCarter, Susan Sharp, Diane Halstead, and Jaber Aslanzadeh, consists of antimicrobial susceptibility tests and combined entries for over 150 microbiology tests for the identification of bacteriological, spirochetal, mycoplasmal, chlamydial, rickettsial, fungal, parasitic, and viral diseases. Tests include cultures, serologies, and special procedures.

Throughout the sections, we have listed the references immediately after each entry to make this guide more user-friendly. Although this book has become a mainstay for clinical laboratories, it was also written for medical practitioners. Thus this book is a *Clinical Guide* to Laboratory Tests. We would like to acknowledge David Stein of Elsevier for his proof-reading assistance.

Alan H.B. Wu
July, 2005

DISCLAIMER

Reference ranges are valuable guides for the clinician, but they should not be regarded as absolute indicators of health and disease. Reference intervals should be used with caution, since values for healthy individuals often overlap significantly with values for persons afflicted with disease. In addition, laboratory values may vary significantly because of differences in methodology and mode of standardization. This is especially true for immunological tests, which use antibodies that may have different characteristics. As a result, laboratory values in individual institutions may differ from those listed in this manual.

Doses for drugs listed as part of the protocol for laboratory tests, as well as their therapeutic and toxic ranges, are those commonly accepted on the basis of present knowledge. The constant acquisition of new knowledge makes it necessary to confirm and compare information supplied in this manual with data furnished by manufacturers. It should also be considered that there are significant differences in drug response among individuals.

This page intentionally left blank

INSTRUCTIONS

The following tables provide the content of each of the eight main sections of this book. Below each subsection title is a general description of the contents for each entry. In all sections, specific information related to a particular test method lines up opposite that method. The test index lists test names or diseases from all sections alphabetically. Where appropriate, cross-references are given to other entries. Thin lines serve as guides; double lines separate complete test entries. Cited references are listed below each entry. At the end of the book there is a separate index for disease and keywords.

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION I, PHLEBOTOMY TUBES

| TUBE TYPE/ MATERIAL | STOPPER COLOR | ADDITIVE/PRESERVATIVE | GENERAL USE |
|---|---|---|---|
| Intended use of tube and material used to make the tube (glass or plastic). | Colors are standardized across the phlebotomy industry. | Chemicals added to perform certain functions (e.g., anticoagulation). | Specific areas within laboratory medicine where the tube is most commonly used. |

| RECOMMENDED HANDLING CONDITIONS (E.G., MIXING, G FORCE, AND SPIN TIME) | SPECIMEN STABILITY | REMARKS |
|---|---|---|
| Handling conditions necessary to ensure optimum stability of test analyte and accuracy of result. Centrifugation speed listed are relative multiples of the gravitational force, g. | General stability information relative to the intended analyte. | Important notes for optimum use of phlebotomy tube. |

This page intentionally left blank

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION I, PREANALYTICAL FACTORS AFFECTING CLINICAL LABORATORY TEST RESULTS

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|--|---|---|--|
| Factors listed are patient status, collection procedure, processing and centrifugation, specimen transportation and instrument/method and collection tube compatibility. | These errors are diet, exercise, medication, disease state/patient demographics, body position, endogenous substances, patient identification, tourniquet and draw technique, order of draw, draw volume, mixing, inappropriate use of gel tubes, serum clotting time, centrifugation conditions, common modes of transport, and invalidated preanalytical phase. | The result of the various sources of error or variability listed. | Specific remarks, outcomes, and procedures for the various sources of error or variability are listed. |

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION II, GENERAL CLINICAL TESTS AND SECTION VIII, ALLERGY TESTING

| TEST NAME AND METHOD | SPECIMEN REQUIREMENTS | REFERENCE INTERVAL, CONVENTIONAL [INTERNATIONAL RECOMMENDED UNITS] | CHEMICAL INTERFERENCES AND IN VIVO EFFECTS |
|---|---|--|---|
| <p>Test Name (Synonyms, abbreviations), references related to entire entry.</p> <p><i>Method</i></p> <p>Important assay conditions; test doses and pretest instructions.</p> | <p>Specimen (anticoagulant). Collection times, storage information, special instructions.</p> | <p>Generally accepted values are listed. Units in brackets usually conform to the SI system (Système International d'Unités). However, units recommended by the International Union of Pure and Applied Chemistry (IUPAC) and the Commission on World Standards of the World Association of Societies of Pathology (COWS of WASP) are used when these units have found wider acceptance in the clinical laboratories and offer advantages over SI units.</p> <p>Factors for converting conventional units to international units are placed between the two ranges and are placed only in the first line of a column of values.</p> <p>Values that line up with a specific procedure were determined using that method. Where appropriate, data are stratified by age and sex, and toxic concentrations are noted where appropriate. Values without designations are ranges for the adult population.</p> <p>Units for the reference range either follow the value or appear at the top of the column of values.</p> | <p>Substances and conditions listed are known to interfere with the test procedure(s).</p> <p>V = <i>in vivo</i> effects</p> <p>C = chemical interferences</p> <p>Arrows indicate an increase (↑) or decrease (↓) in value. Abbreviations preceding an arrow indicate the body fluid. For key to abbreviations, see <i>Abbreviations</i>.</p> |

General comments: Information that pertains to an *entire* entry (test procedure or analyte) begins on the first line of the entry, regardless of the column in which it appears. Related information lines up across the page; thin lines serve as guides. Double lines separate entries. When the name of an entry refers to a group of analytes (e.g., complement components), the individual analytes are also listed in column 1 but are indented.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>This column lists clinical conditions that manifest a change in the concentration of the analyte or test result.</p> <p>Arrows indicate an increase or a decrease in value. Abbreviations preceding an arrow indicate the specimen; two or more arrows indicate a more pronounced effect.</p> | <p>This column contains general information pertinent to the use of the test procedure. Only information that has specific importance and is not general knowledge is referenced.</p> |
| | |

This page intentionally left blank

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION III, MOLECULAR DIAGNOSTICS

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| <p>Disorder, Organism, or Test Name (Synonyms, abbreviations), references related to entire entry.</p> <p>Individual disorder name when group is main heading</p> <p><i>Method</i></p> | <p>Specimen. Special instructions for patient preparation and specimen collection and processing.</p> | <p>This column contains general and clinical information pertinent to the use of the test procedure. Only information that has specific importance and is not general knowledge is referenced. The affected target gene is also identified.</p> |

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION IV, THERAPEUTIC DRUGS AND DRUGS OF ABUSE

| REFERENCE (THERAPEUTIC) | | | |
|---|--|--|--|
| TEST NAME AND METHOD | SPECIMEN | INTERVAL, CONVENTIONAL [INTERNATIONAL RECOMMENDED UNITS] | KINETIC VALUES |
| <p>Test Name (Synonyms, abbreviations), references related to entire entry.</p> <p><i>Method</i></p> <p><i>Molecular weight.</i></p> | Specimen (anticoagulant). Collection times, storage information, special instructions. | The most widely used therapeutic and toxic intervals for the drugs are listed. | This column contains specific information about the pharmacokinetic parameters of individual drugs. Parameters such as half-life ($t_{1/2}$) volume of distribution (V_d), clearance (Cl_T), fraction protein bound (PB), free fraction (F), and time to maximum drug concentrations (T_{max}) are listed when well-established values are available. Where available, the enzymes responsible for metabolism are listed. This information is to be used with pharmacogenetic data given in Section VII. |

**FACTORS INFLUENCING
DRUG DISPOSITION****REMARKS AND INTERFERENCES**

The column identifies the normal route of drug elimination. Directional arrows indicate changes in the analyte's clearance rate and half-life (\uparrow lengthened, \downarrow shortened, \rightarrow unchanged). Conditions responsible for these changes, such as chronological age, treatment protocols, or disease states are identified. Drugs that are known to cause interactions are also identified. The mechanism of excretion and the effect of dialysis on the removal of the drug are also listed.

This column contains general information pertinent to the effective use of the drug and factors affecting its laboratory measurement. Only information that has specific importance and is not general knowledge is referenced.

Also listed in this column are substances and conditions known to interfere with the test procedure(s) as well as side effects known to be associated with the use of the drug.

This page intentionally left blank

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION V, MICROBIOLOGY

| TEST NAME OR METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| <p>Test Name or Organism (Synonyms, abbreviations), references related to entire entry.</p> <p><i>Method</i></p> <p>Special tests used to detect the same entity.</p> | <p>Specimen. Special instructions for patient preparation and specimen collection and pro- cessing.</p> | <p>Column contains general and clinical information pertinent to the use of the test procedure. Only information that has specific importance and is not general knowledge is referenced.</p> |

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION VI, IMMUNOPHENOTYPING MARKERS

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (kDa) |
|--|---------------------------------|-------------------------------------|
| Specific cluster of differentiation (CD) antigen | Common protein name of antigen. | Estimated to the nearest whole kDa. |

| KNOWN NORMAL DISTRIBUTION | REMARKS |
|---|--|
| Distribution within normal and cancerous tissues. | General and clinical information pertinent to the CD antigen or immunophenotypic marker. |

QUICK REFERENCE TO INFORMATION CONTAINED IN THE *CLINICAL GUIDE TO LABORATORY TESTS*—SECTION VII, PHARMACOGENOMICS

| ENZYME NAME | SUBSTRATE | INHIBITORS | INDUCERS | SELECTED MUTATIONS |
|--|---|--|--|---|
| Name of the enzyme involved in the metabolism. | Drugs that are metabolized by the enzyme. | Other drugs that act as inhibitors of the enzyme, thereby decreasing activity. | Other drugs that act as inducers of the enzyme, thereby increasing activity. | Common mutations and polymorphisms that may have an impact on individual drug concentrations. |

| PREVALENCE OF VARIANT ALLELE (% , RACE) | NUCLEOTIDE CHANGE | CLINICAL EFFECT (ENZYME ACTIVITY) |
|--|--|--|
| The reported prevalence of the variant allele broken down by race. Reference number 22 is used unless otherwise specified. | Specific nucleotide substitution and location of substitution on the DNA of the variant allele compared with the wild type allele. | The <i>in vivo</i> and <i>in vitro</i> effect (if any) that the particular nucleotide change has on the enzyme activity. |

SECTION I

PREANALYTICAL ASPECTS OF CLINICAL TESTING

Preanalytical Factors Affecting Clinical Laboratory Test Results

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------------------------|--|--|
| Patient Status | Diet | Variation in results based on diet | Metabolic products of food can increase in venous blood. Glucose, lipids, and catecholamines may show variation because of postabsorptive hormonal effects. Caffeine can elevate concentrations of catecholamine and plasma renin. ¹ Glucose and lipid profiles require fasting specimens for accurate results. Specimens for chemistry analysis should be collected 12 hours after the last meal. ¹ |
| | Exercise | Variation in results after heavy exercise | Physical activity can have different effects on analyte concentrations, depending on whether it represents isometric or isotonic activity. This is the result of volume shifts between the vascular and interstitial compartments, volume loss by sweating, and changes in hormone concentrations. ² Differences can be observed in blood chemistry values that occur after heavy exercise (e.g., proteinuria, LD isoenzymes, and elevations in creatine kinase [CK], CK-MB, and testosterone). |
| | Medication | Variation in results because of timing of blood collection or interference from medication | Therapeutic drug monitoring (TDM) specimen collection should be scheduled according to the time of the last dose. Hepatotoxic drugs can elevate liver function enzymes. Medications affecting plasma volume can affect protein concentrations, complete blood cell count (CBC), blood urea nitrogen (BUN), iron, and calcium concentrations, whereas other medications can interfere with some analytical methods. ³ Drug/drug interactions in vivo can influence the concentration of some drugs by interfering with the volume of distribution and metabolism. |
| | Disease state/patient demographics | Disease state, patient demographics, and stress can affect laboratory results | Since geriatric, oncology, or other hematological patients can have fragile veins, it is preferable to use a winged blood collection set. The preferable site for venipuncture may be the dorsal part of the hand or wrist area when veins in the antecubital area are not acceptable. Pediatric patients have small veins. Collecting blood from these types of patients can lead to traumatic collection and collapsed veins causing vessel wall injury and hemolysis. Hemolysis caused by turbulent blood flow results in the release of intracellular contents. ⁴ The use of partial draw vacuum tubes or an aspirated syringe draw may prevent fragile veins from collapsing and may minimize hemolysis. |

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------------------------|--------|---------------------------|
|-------------------------|--------------------------------------|--------|---------------------------|

Patient Status—CONT

Patient age, body weight, sex, and ethnicity affect analytical results. Physiological variation of veins in obese patients may be difficult to palpate and visualize. Probing with the needle should be avoided because this may lead to erroneous test results and may damage the vein, artery, nerves, and tendons. It is recommended to use a longer needle or select another site. If no other site is available, consider the dorsal part of the hand or wrist.

Patient anxiety can affect laboratory results. It has been observed to increase secretion of hormones, such as catecholamines and cortisol. Stress is also associated with increased concentrations of albumin, glucose, fibrinogen, insulin, lactate, and cholesterol. Hyperventilation results in respiratory alkalosis with depressed PO₄ and elevated potassium.

| | | |
|---------------|--|---|
| Body position | Increased variability based on body position | Hospital inpatients usually have blood collected while lying down. For outpatients, blood is usually collected with the patient in a blood collection chair or on an examination table. When collecting blood in a home situation, the phlebotomist should ask patients who are not bedridden to sit in a chair that reclines backward as protection from falling if they faint. The position of a patient before and during venipuncture has an effect on laboratory test results. Changing from a supine position to sitting or standing causes constriction of the blood vessels. Changing from sitting to supine causes shifting of water and electrolytes into tissue causing hemoconcentration, affecting serum/plasma levels of total protein, albumin, lipids, and cells to increase. The plasma portion of the patient's blood is filtered into the tissue, resulting in lower plasma volume and elevation of protein concentrations, blood cell counts, BUN, iron, and calcium within the blood. ⁵ |
|---------------|--|---|

| PREANALYTICAL FACTOR | SOURCE OF ERROR | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------|--------|---------------------------|
| | OR VARIABILITY | | |

Patient Status—CONT

| | | |
|-----------------------|-----------------------------------|---|
| Endogenous substances | Lipemia, icterus, enzyme activity | <p>Lipemic samples: Lipemia is difficult to control by the laboratory. Lipemic specimens occur in nonfasting blood or in patients with hyperlipidemia or receiving total par-enteral nutrition (TPN) therapy. Severe hyperlipidemia can result in erroneous results by the displacement of plasma volume and subsequent short sampling. Depending on the extent of lipemia, it can interfere with spectrophotometric, turbidimetric measurements and some immunoassays. It is desirable to collect blood from patients after a period of fasting for many laboratory assays. However, for some patients it may be necessary to pretreat the blood before analysis by ultracentrifugation or enzymatic cleavage to remove lipids.⁶</p> <p>Icterus: Visible icterus in the serum occurs when serum bilirubin is >25 mg/L.⁷ Bilirubin interferes with several colorimetric assays (e.g., albumin by 2-(4-hydroxyphenylazo) benzoic acid [HABA], cholesterol using ferric chloride reagents, glucose assays based on <i>o</i>-toluidine, and biuret total protein methods). In each case, results are elevated but can be corrected by use of appropriate blanking procedures or dual wavelength methods.</p> <p>Endogenous enzyme activity: Homogeneous immunoassays can be influenced by endogenous enzyme activity that is the same as the enzyme label in the reaction (e.g., alkaline phosphatase). These may be removed by washing as in heterogenous immunoassays.⁸</p> <p>Heterophile antibodies: Heterophile antibody interferences can occur in both types of immunoassay (homogeneous and heterogenous). Heterophile or endogenous antispecies antibodies can bind the assay antibody such that the signal is compromised. Example: Human anti-mouse antibody (HAMA) will bind to mouse immunoglobulin coating latex microparticles in turbidimetric inhibition assays, with agglutination resulting in falsely elevated signal.⁸ HAMA is commonly neutralized by including excess mouse immunoglobulin in the reagent.</p> |
|-----------------------|-----------------------------------|---|

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------------------------|--------|---------------------------|
|-------------------------|--------------------------------------|--------|---------------------------|

Patient Status—CONT

| | | | |
|--|--|--|--|
| | | | Metabolites and other proteins: Some proteins and metabolites of drugs can bind nonspecifically with some polyclonal antibodies in immunoassays, causing erroneous results. Example: Rheumatoid factor reacts with the Fc portion of antibody-antigen complexes. In antibody assays with solid-phase adsorbed antigen, this can lead to cross-linking of nonreactive immunoglobulin G (IgG) with subsequent increased signal. ⁸ |
|--|--|--|--|

| | | | |
|------------|---|--------------------------------|--|
| Collection | Patient Identification Wrist band, tube label, bar codes | Incorrect, missing, unreadable | Incorrect identification can lead to wrong patient results, delay in patient results, and patient redraw. To avoid these situations, ask for the patient's name, confirm with appropriate identification, match the name with the requisition, correctly label the tubes at the bedside, and ensure that the requisition accompanies the tubes to the laboratory. ⁹ |
|------------|---|--------------------------------|--|

| | | | |
|------------|---|-------------------------------|--|
| Collection | Tourniquet and Draw Technique Quality of phlebotomy, placement, and duration | Improper phlebotomy technique | <p>Single-use and latex-free tourniquets are preferred products. Determine if latex sensitivity precautions are necessary.</p> <p>The tourniquet should be placed about 3 to 4 inches above the venipuncture site.¹⁰ Elevations in the concentration of plasma constituents can result when the tourniquet is left on for longer than 1 minute. Hemoconcentration can increase proteins, potassium, and packed cell volume.</p> <p>Traumatic draw as a result of vessel wall injury can cause elevations in CK, myoglobin, and potassium.</p> <p>Blood collections from peripheral catheters may cause hemolysis as a result of circuitous blood flow between the vein and blood collection tube. Use of partial draw tubes will decrease turbulence and specimen hemolysis. Hemolysis rates are higher in acute care settings (e.g., emergency and labor/delivery departments), where peripheral catheter collections are more prevalent. Hemolysis can interfere with results from all laboratory disciplines, especially colorimetric assays.^{11–13}</p> <p>Blood collection near the site of infusion may cause elevations of electrolytes and/or other infusion fluids.¹⁴</p> <p>Decentralization of phlebotomy can double hemolysis rates, specimen rejection rates, and the number of redraws.^{1,15,16}</p> <p>Excessive fist clenching can result in elevations in potassium.¹⁷</p> |
|------------|---|-------------------------------|--|

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------------------------|-------------------------|--|
| Collection—CONT | | | |
| | Order of Draw | Incorrect order of draw | <p>Improper order of blood collection tube draw can result in incorrect test results. The National Committee for Clinical Laboratory Standards (NCCLS) recommends the following order of draw for glass or plastic tubes¹⁰: blood culture tubes; coagulation tubes; serum tube with or without clot activator, with or without gel; heparin tube with or without gel plasma separator; EDTA tube and glycolytic inhibitor. Glass serum tubes may be drawn before the coagulation tube. If using a wingset, a discard tube must be drawn before the coagulation tube. The discard tube should be a coagulation or nonadditive tube. In addition, an institution can validate its own order of draw.¹⁸</p> <p>Blood culture specimens should be collected first to prevent contamination from other tubes. Potassium EDTA drawn before a serum tube can cause elevated potassium values. Heparin tubes collected before serum and additive tubes before citrate may effect clotting.</p> |

| | | | |
|------------|-------------|---|---|
| Collection | Draw Volume | Incorrect filling of collection tubes will cause an altered blood to additive ratio | <p>Underfilling: Inappropriate tube storage conditions prior to blood collection (excessive temperature and/or humidity), as well as tubes used after their expiration date can affect tube vacuum. Blood collection at high altitude can affect draw volume. Premature tube removal from tube holders, vein collapse, and inadequate transfer of blood collected with a syringe to blood collection tubes may also result in suboptimal sample volume, thus altering the correct blood to additive ratio in the tube. Underfilling blood collection tubes can affect red blood cell (RBC) morphology and lipids in EDTA tubes¹⁹⁻²² and binding of electrolytes and troponin to heparin in some plasma tubes. CK and aminoglycoside values are affected in serum, and erroneous results have been observed in some immunoassays in serum tubes as a result of elevated concentrations of clot activator and/or silicone in blood collection tubes.²³ The anticoagulant to blood ratio for coagulation is usually 9:1. Inadequate filling of the evacuated tube may cause divergence from this ratio, leading to inaccurate results (i.e., the effect of altered sodium citrate concentration on prothrombin time.²⁴</p> |
|------------|-------------|---|---|

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------------------------|--|---|
| Collection—CONT | | | Overfilling: An appropriate safety transfer device should be used when transferring blood. Inappropriate transfer of blood from syringe collection to a blood collection tube can result in overfilling blood collection tubes beyond manufacturers' recommended draw volume, causing inadequate anticoagulation, fibrin formation, microclots, platelet clumping, and increased instrument maintenance. It could also lead to a biohazard risk if the tube stopper pops off because of overfilling the tube. |
| | | | Liquid additives in blood collection tubes will add a dilution factor compared with dry additives. For example, liquid K ₃ EDTA causes a dilution of approximately 1% to 2% compared with dry EDTA additive tubes, decreasing white blood cells (WBCs), RBCs, platelets, hematocrit (Hct), and hemoglobin. Therefore institutions should standardize on a single type of EDTA tube, either liquid or dry, to minimize analytical variability. |
| | Mixing | Incorrect number of specimen inversions | Insufficient mixing can cause microclots in blood collection tubes affecting Hct, hemoglobin, and clotting times and causing fibrin formation, leading to instrument probe and/or fluid path obstruction and increased instrument down time. There is greater potential for microclots and platelet clumping with dry additives, which are highly dependent on proper mixing of specimens. |
| | | Excessive inversions or agitation of specimens | Mixing is obtained by gentle inversions of the tube 180 degrees. One inversion is usually defined as gently inverting a specimen upside down and then back right side up. Vigorous inversions may cause foaming or hemolysis. Hemolysis occurs when plasma hemoglobin exceeds 200 mg/L. Hemolysis can cause erroneous test results in nearly all laboratory disciplines (chemistry, hematology, coagulation, and microbiology). Lactate dehydrogenase (LD) and potassium are the most sensitive indicators of hemolysis. Other tests affected by hemolysis are alanine aminotransferase (ALT), aspartate transaminase (AST), hemoglobin, iron, and T ₄ . ²⁵ |

| PREANALYTICAL FACTOR | SOURCE OF ERROR OR VARIABILITY | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------------|--------------------------------------|---|--|
| Collection—CONT | | | |
| | Inappropriate Use of Gel Tubes | Inappropriate blood collection tube for specific analytes | Almost all analytes are stable in gel tubes; however, only some blood collection tube manufacturers validated their use for TDM testing. Analyte stability in gel tubes is dependent on several factors. These include the composition of the gel, gel surface area, volume of sample, time the sample is on the gel, temperature of the specimen, and the chemical structure of the analyte. Hydrophilic analytes are usually stable when specimens are stored in gel tubes for several days at 4° C. Some hydrophobic analytes such as amitriptyline, phenytoin, and progesterone can be underestimated when specimens are stored on the gel over time. Laboratory policies can allow accurate testing of these hydrophobic analytes through monitoring the length of time from specimen collection to analysis and specimen storage temperature, as well as using rejection criteria for short draws and enforcing policies eliminating add-on testing of these tests. Each laboratory should evaluate analyte stability in specimens collected in gel tubes in their laboratory environment before implementing usage. |
| Processing and Centrifugation | Serum Clotting Time | Insufficient clotting time | Serum should be clotted before centrifugation. ²⁶ Clot formation is usually complete within 30 to 60 minutes at room temperature (20 to 25° C). However, some serum tubes may contain a clot activator allowing shorter clotting times. Thrombin presence in collection tubes can usually clot the specimen in as little as 5 minutes. Inadequate clotting time can cause a problem for many instruments because of latent fibrin formation, which may cause instrument probe clogging as well as erroneous results. |
| | | Prolonged contact time with cells before separation | Prolonged contact time of serum/plasma with cells leads to the exchange of compounds in and out of the cell. Serum or plasma should be separated within 2 hours from the time of draw. Particularly critical increases in potassium can be observed. ^{27,28} Contact time of less than 2 hours is also recommended for adrenocorticotrophic hormone (ACTH), cortisol, catecholamines, and lactic acid testing. ²⁹⁻³³ Prolonged cell contact time causing decreases in glucose and increases in CO ₂ results from cellular metabolism. Albumin, alkaline phosphatase, ALT, bilirubin, calcium, cholesterol, CK, creatinine, magnesium, phosphorus, sodium, total protein, triglycerides, T ₃ , T ₄ , urea nitrogen, and uric acid are unaffected at room temperature for as long as 48 hours. ³⁴ |

| PREANALYTICAL FACTOR | SOURCE OF ERROR | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------|--------|---------------------------|
| | OR VARIABILITY | | |

Processing and Centrifugation—CONT

| | | | |
|--|--------------------------------------|---|---|
| | Centrifugation Conditions | Inappropriate RCF, centrifuge time, and temperature | Recommendations for centrifugation vary according to blood collection tube type, manufacturer, and centrifuge type (swing bucket versus fixed angle). Excessive centrifugation g force (RCF), >3000 g, may cause cell lysis and slight elevations in LD and potassium. Inadequate g force (RCF), <1000 g or less than 10 minutes, may cause incomplete barrier formation in gel tubes or cell contamination of the specimen. Most clinical specimens should be centrifuged at room temperature. ³⁵ Overuse of fixed angle centrifugation can cause rotor heating and affect gel integrity. Platelet poor plasma is required for coagulation testing. Centrifuges should be periodically calibrated. Blood collection tubes should be kept closed at all times. ³⁵ |
| | | Recentrifugation of gel tubes | Recentrifugation of gel tubes may cause serum/plasma under the gel barrier to express up through the gel and mix with the specimen above the gel barrier. ³⁴ Significant elevations in potassium can be observed when gel tubes are recentrifuged after 24 hours. ³⁶ |

| | | | |
|------------------------------------|--|---|---|
| Specimen Transportation | Common Modes of Transport Pneumatic tube, hand carry, ground transport courier, shipment | Excessive time from draw to analysis, excessive vibration, elevated or decreased temperature, and exposure to light | Excessive transport time to analysis can result in hemolysis and elevated LD and potassium values. Most general chemistry tests are stable longer when specimens are centrifuged immediately after blood collection in gel separator tubes or are aliquoted before transport. Transport tubes (double gel) may help during stressed conditions such as specimen centrifugation at low g forces (<1300 g), use of fixed angle centrifuges, minimal spin time, and excessive transport times. These conditions are more prevalent at outpatient drawing stations where specimens should not be transported unspun unless they reach the laboratory with serum/plasma separation within 2 hours of collection. ³⁵ Respinning gel tubes in a core laboratory can cause increased potassium levels (see Centrifugation Conditions). ³⁶ Collection devices containing additives such as sodium fluoride can prevent changes in glucose and concentrations of other analytes over long transport times. Exposure to light can affect bilirubin, vitamin A and B ₆ , beta-carotene, and porphyrins. These specimens should be protected with aluminum foil, an amber container, or equivalent. ³⁵ |
|------------------------------------|--|---|---|

| PREANALYTICAL FACTOR | SOURCE OF ERROR | RESULT | REMARKS/OUTCOME/PROCEDURE |
|-------------------------|--------------------|--------|---------------------------|
| | OR VARIABILITY | | |

Specimen Transportation—CONT

Vibration from some pneumatic tube transport systems can activate platelets affecting prothrombin time (PT) and activated partial thromboplastin time (APTT) testing.³⁷ Excessive vibration can also cause hemolysis and elevations in LD and potassium.³⁸ Excessive specimen vibration of arterial blood gas syringes can cause elevations in Po₂ values.³⁹

Serum tubes exposed to elevated temperature can affect cryoglobulins, which precipitate at <37° C. Temperatures >56° C will denature proteins, and heated centrifugation can affect gel integrity (see Centrifugation Conditions). Chilling (2 to 8° C) of whole blood specimens is not recommended for whole blood beyond 2 hours.⁴⁰⁻⁴¹ It is contraindicated for potassium testing because it causes leakage of potassium from the cells as a result of inhibition of glycolysis. Chilling specimens is required for catecholamines, ammonia, lactic acid, pyruvate, gastrin, and parathyroid hormone (PTH) testing.⁴²

Blood collection tubes should be stored and transported in a vertical position to promote complete clot formation and reduce stopper contamination, specimen agitation, and potential hemolysis. Uncontrolled transport conditions can cause inaccurate analytical results. Monitoring patient population results (inpatient versus outpatient), tracking time and temperature from blood collection to analysis, in-servicing proper handling and transport conditions, and establishment of specimen acceptance criteria can help. Cracked or leaking containers allow for contamination of the specimen. Ensure that blood specimens are securely covered and placed in leak-proof plastic bags or lockable rigid containers before transport.

| PREANALYTICAL FACTOR | SOURCE OF ERROR | | REMARKS/OUTCOME/PROCEDURE |
|---|---------------------------------|---|--|
| | OR VARIABILITY | RESULT | |
| Instrument/Method and Collection Tube Compatibility | Invalidated preanalytical phase | Interference between tube additives, environmental conditions, and analytical methodology | Although some blood collection tube manufacturers collaborate with diagnostic manufacturers to ensure compatibility between blood collection tubes and assay reagents, validation of the preanalytical phase and blood collection tubes is crucial. Laboratory environmental variation combined with the growing number of clinical laboratory tests, methodologies, increased assay sensitivity, decreased sample volume, different sample aspiration depths, and different types of blood collection tubes increase the risk of erroneous test results throughout the preanalytical phase. Poor compliance with manufacturers' recommendations, such as short draws, affects the blood to additive ratio in blood collection tubes, increasing the possibility of preanalytical error. |

Phlebotomy Tubes

| TUBE TYPE/ MATERIAL | STOPPER COLOR | ADDITIVE/PRESERVATIVE | GENERAL USE |
|---|------------------|--|---|
| Serum/glass | Red or pink | Silicone coating prevents RBCs from adhering to tube walls | General chemistry, blood bank, and serology |
| Serum/plastic | Red or pink | Silica clot activator/silicone coating | General chemistry, blood bank, and serology |
| Serum/glass with gel and clot activator | Red/gray or gold | Silica clot activator/silicone coating/gel | General chemistry and serology |

*Analyte stability is dependent on time, temperature, transport, processing, and storage conditions. Consult the manufacturer, CLSI, or equivalent standards' body for stability recommendations and/or limitations. If necessary, conduct an evaluation to establish specific claims. Whenever changing any manufacturer's blood collection tube type, size, or storage condition for a particular laboratory assay, the laboratory personnel should review the tube manufacturer's data and their own data to establish/verify the reference range for a specific instrument/reagent system. Based on such information, the laboratory can then decide whether a change is appropriate.

| RECOMMENDED HANDLING CONDITIONS (E.G., MIXING, G FORCE, AND SPIN TIME) | SPECIMEN STABILITY* | REMARKS |
|--|---|---|
| No mixing is required for glass serum tubes because glass is a natural clot activator. Allow specimens to clot at room temperature for 30 to 60 minutes before centrifugation. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 7 days at 4° C when serum is aliquoted from the clot. | Silicone coatings may interfere with some immunoassays. |
| For proper additive performance, invert plastic tubes with clot activator 5 to 10 times. Allow specimens to clot at room temperature for 30 to 60 minutes before centrifugation. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 7 days at 4° C when serum is aliquoted from the clot. | Silicone coatings may interfere with some immunoassays. Silica is added to plastic tubes to simulate glass clotting because without this addition clotting time would be prolonged. Tubes with clot activator should not be used as discard tubes for coagulation studies. |
| For proper additive performance, invert serum tubes 5 to 6 times. Allow specimens to clot at room temperature for 30 to 60 minutes before centrifugation. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 7 days at 4° C. | Silicone coatings may interfere with some immunoassays. Silica is added to activate clotting and decrease clotting time. A thixotropic gel is included in these tubes and is present at the tube bottom. The density of this material causes it to move upward during centrifugation to the serum-clot interface, where it forms a barrier separating serum from the clot. Many instruments are configured to sample serum directly from the collection tube, eliminating the need for transfer to another container. Transport tubes contain an additional quantity of gel barrier. This additional material produces a thicker barrier between the serum and cells that may be more stable for shipping from a phlebotomy site to a testing site. |

|--------------------------------|-------|---|-------------------|

| | | | |
|--|---|---------------------|-------------------|
| Plasma/glass with gel Plasma/plastic with gel | Green/gray or light green or green or green/light brown | Lithium heparin/gel | General chemistry |
|--|---|---------------------|-------------------|

| RECOMMENDED HANDLING CONDITIONS (E.G., MIXING, G FORCE, AND SPIN TIME) | SPECIMEN STABILITY* | REMARKS |
|--|--|---|
| For proper additive performance, invert serum tubes 5 to 10 times. Allow specimens to clot at room temperature for 30 to 60 minutes before centrifugation. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 7 days at 4° C. | Silicone may interfere with some immunoassays. Silica is added to plastic tubes to simulate glass clotting because without this addition clotting time would be prolonged. A thixotropic gel is present at the tube bottom. The density of this material causes it to move upward during centrifugation to the serum-clot interface, where it forms a barrier separating serum from the clot. Serum may be aspirated directly from the collection tube, eliminating the need for transfer to another container. Tubes with clot activator should not be used as discard tubes for coagulation studies. |
| For proper additive performance, invert heparin additive tubes 5 to 10 times. Centrifugation conditions range from 1000 to 3000 g for 10 to 15 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 2 hours at room temperature. | Plasma specimens do not require clotting before centrifugation and offer faster turnaround time than serum. Plasma obtained in heparin tubes should be tested or removed from the tube within 2 hours of collection. Do not use tubes containing lithium heparin for lithium measurement. Tubes containing sodium heparin are not recommended for sodium analysis. Lithium heparin may also be used in blood collection syringes for whole blood critical care testing (may contain either reduced or balanced lithium heparin). ⁴³ Do not use ammonium heparin tubes for ammonia measurement. |
| For proper additive performance, invert all filled additive tubes 5 to 10 times. Centrifugation conditions range from 1000 to 3000 g for 10 to 15 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 2 hours at room temperature. | Heparin activates antithrombins, thus blocking the coagulation cascade and producing a whole blood/plasma sample. A gel barrier is present at the tube bottom. The density of this material causes it to move upward during centrifugation to the plasma-cell interface, where it forms a barrier separating plasma from cells. Supernatant plasma may be aspirated directly from the collection tube, eliminating the need for manual transfer to another container. |

|--|--|---|
| <p>For proper additive performance, invert filled additive tubes 8 to 10 times. Centrifugation conditions range from 1000 to 2500 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations.</p> | <p>Analyte stability varies depending on preanalytical conditions such as sample handling.</p> | <p>For molecular diagnostic testing (e.g., HIV and hepatitis C virus [HCV] viral load testing) and screening nucleic acid test, genotyping blood bank assays, such as but not limited to polymerase chain reaction (PCR) and/or branched DNA (bDNA) amplification techniques, or other procedures, an undiluted plasma specimen is required as determined by the laboratory. Standard centrifugation conditions to generate plasma for testing do not completely sediment all cells. Accordingly, cell-based metabolism, as well as natural degradation <i>ex vivo</i>, may affect plasma analyte concentration/activities beyond acellular changes. Blood samples should be centrifuged within 2 hours of collection.</p> |
| <p>These tubes are used in the collection of blood specimens for whole blood testing that requires no centrifugation. For proper additive performance, invert filled additive tubes 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations.</p> | <p>Routine hematology testing should be conducted within 6 hours of collection, keeping the sample at room temperature.⁴³</p> | <p>EDTA is used for a wide range of hematology tests, genetic testing, immunosuppressants, HbA1c, RBC folate, and other selected tests. K₂EDTA, K₃EDTA, Na₂EDTA and serum tubes may be used for routine immunohematology testing such as red cell grouping, Rh typing, and antibody screens.⁴⁴ The common types of EDTA used in blood collection tubes are Na₂EDTA, K₃EDTA and K₂EDTA. K₃EDTA is available in both liquid and dry forms. Solubility of EDTA varies. Potassium EDTA is more soluble than the sodium form and liquid EDTA is more soluble than dry. However, liquid K₃EDTA causes a sample dilution of approximately 1-2% of blood. K₃EDTA causes largest amount of RBC shrinkage at increasing EDTA concentrations; therefore K₂EDTA is recommended by NCCLS and International Committee for Standardization in Hematology (ICSH) for blood cell counting and sizing. Other comparative studies using liquid K₃EDTA and the dry form of K₂EDTA have demonstrated either acceptable agreement,⁴⁵ no marked differences at optimal conditions,⁴⁶ or minimal differences that are not clinically significant.⁴⁷ Errors include EDTA-induced platelet-specific antibodies, platelet clumping (pseudothrombocytopenia, EDTA-induced polymorphonuclear leukocyte (PMN), agglutination in vitro, spurious leukopenia, and pseudogranulocytopenia.</p> |

|---|--|---|
| These tubes are used in the collection of blood specimens for whole blood testing that requires no centrifugation. For proper additive performance, invert tubes 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | Routine hematology testing should be conducted within 6 hours of collection, keeping the sample at room temperature. ⁴³ | Blood collection tubes containing liquid K ₃ EDTA additive dilute specimens approximately 1% to 2% compared with dry EDTA additives, resulting in a negative bias between the two blood collection tube types. Therefore institutions should standardize on either dry EDTA or liquid and avoid use of both tube types. |
| For proper additive performance, invert tubes 8 to 10 times. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | | Various glycolytic inhibitors are available including: potassium oxalate/NaF, EDTA/NaF, sodium heparin/NaF, and iodoacetate. Fluoride and iodoacetate inhibit glycolysis, whereas oxalate, EDTA, and heparin are anticoagulants used to provide plasma specimens. Gray top tubes can also be used for lactate and alcohol determinations. |
| For proper additive performance, invert tubes 5 to 10 times. Allow specimens to clot at room temperature for 30 to 60 minutes before centrifugation. Centrifugation conditions range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | | Fluoride inhibits glycolysis. Appropriate additive mixing is critical in serum samples due to the absence of an anticoagulant. These tubes can also be used for lactate and alcohol determinations. |
| For proper additive performance, invert tubes 8 to 10 times. Centrifugation conditions after clot formation range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | Most analytes 7 days at 4° C, when serum is aliquoted from the clot. | Tube inversions ensure complete clotting usually in 5 minutes. |
| For proper additive performance, invert tubes three or four times. Vigorous mixing may cause platelet activation. Centrifuge at 1500 to 2500 g for 15 minutes; plasma should contain fewer than 10,000 platelets/mL plasma. Conditions may vary depending on tube manufacturer recommendations. | | For clot-based chromogenic and immunological coagulation assays. NCCLS recommends 0.105 to 0.109 mol/L sodium citrate (~3.2% sodium citrate). See NCCLS documents for specimen handling and specific assay recommendations. |
| For proper additive performance, invert tubes three or four times. Vigorous mixing may cause platelet activation. |--|------------------------|---|
| For proper additive performance, invert tubes three or four times. Vigorous mixing may cause platelet activation. Centrifuge at 1500 to 2500 <i>g</i> for 15 minutes; plasma should contain fewer than 10,000 platelets/mL plasma. Conditions may vary depending on tube manufacturer recommendations. | | The citrate, theophylline, adenosine, and dipyridamole (CTAD) tube is used for the collection and transport of specimens for hemostasis testing. The CTAD solution is a mixture of sodium citrate, theophylline, adenosine, and dipyridamole. The purpose of the additive is to anticoagulate the specimen and to minimize in vitro platelet activation. CTAD tubes must be protected from artificial and natural light during storage because dipyridamole is light sensitive. Accumulated light exposure in excess of 12 hours can cause additive inactivation. CTAD may result in longer clotting times compared with citrate because of minimization of platelet activation and subsequent neutralization of heparin. |
| For proper additive performance, invert tube six to eight times. Conditions may vary depending on tube manufacturer recommendations. | | ESR determination by Westergren method. |
| For proper additive performance, invert tube 6 to 8 times. Conditions may vary depending on tube manufacturer recommendations. | | ESR determination by Westergren method. |
| For proper additive performance, invert tube 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | | The ACT tube is an in vitro diagnostic reagent system used in screening coagulation defects of whole blood, with the exception of platelets (in certain instances) and factor VII (proconvertin). The inert additive siliceous earth provides contact activation resulting in a shortening of the coagulation time and thus creating a uniquely sensitive screening method for detecting coagulation disorders, exclusive of factor VII and platelet deficiencies. As such, the ACT has shown itself to be a simple, sensitive, and reliable test for clotting activity. |
| For proper additive performance, invert tubes 8 to 10 times. Centrifugation conditions range from 1000 to 3000 <i>g</i> for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | | Some manufacturers' tubes are tested and certified for lead level. Some manufacturers may use special stoppers to eliminate most trace metal contamination. |

|---|---|---|
| For proper additive performance, invert tubes 8 to 10 times. Centrifugation conditions after clot formation range from 1000 to 3000 g for 10 minutes. Conditions may vary depending on tube manufacturer recommendations. | | Some manufacturers may use special stoppers to eliminate most trace metal contamination. |
| For proper additive performance, invert filled tubes 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | | For blood culture specimens in microbiology. |
| For proper additive performance, invert filled tubes 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | | For blood bank studies, human leukocyte antigen (HLA) phenotyping, DNA, and paternity testing. |
| For proper additive performance, invert filled tubes 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | | For blood bank studies, HLA phenotyping, DNA, and paternity testing. |
| After blood collection, gently invert tube 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | DNA profile may remain stable in situ for up to 14 days at 18 to 25° C, 4 weeks at 2 to 8° C, 10 weeks at –20° C, and 10 months at –70/–80° C. | For the collection of whole blood for the isolation of genomic DNA. Molecular test methods that require intact genomic DNA from whole blood. These test methods include, but are not limited to, PCR and Southern blot analysis. |
| After blood collection, gently invert tube 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | RNA profile may remain stable for several days. Stability increases at 4° C and can be further prolonged after freezing. Contact the manufacturer for specific information on stability conditions. | For the collection of whole blood and stabilization of the cellular RNA profile. The RNA tube contains an additive that stabilizes cellular RNA and prepares the sample for RNA purification. Methods include, but are not limited to, reverse transcriptase PCR (RT-PCR) and Northern blot analysis. In stabilized blood, RNA rapidly degrades significantly within hours after blood collection. Furthermore, certain species of RNA, through the process of gene induction, increase once the blood is collected. Both RNA degradation and in vitro gene induction can lead to an underestimation or overestimation of in vivo gene transcript number. |
| Conditions may vary depending on tube manufacturer recommendations. | Less than 2 hours at room temperature post-collection. Refrigerate specimen if there is a delay of more than 2 hours. Specimen should be at room temperature before testing is performed. ⁴⁸ | Can be used for automated chemistry on dedicated urinalysis instruments and microscopic analysis of sediments. |

|---|--|---|
| Shake tubes vigorously to ensure complete dissolution of the preservative. Centrifuge at 600 g for 5 minutes in a swing bucket centrifuge. Conditions may vary depending on tube manufacturer recommendations. | Specimens not tested or preserved within 1 to 2 hours of collection should be refrigerated. Stable up to 72 hours at room temperature. | Urinalysis preservative tube can be used for automated chemistry urinalysis and sediment analysis. Without the presence of a preservative, the bacteria continue to be metabolically active and reproduce, causing changes in the urine chemistry components measured in a routine urinalysis. Because of the instability of bilirubin and urobilinogen in urine when exposed to room temperature and light, testing should be performed as soon as possible. Specimens should be stored in darkness or collected in amber tubes or amber 24-hour containers. |
| Mix by inverting 8 to 10 times. Conditions may vary depending on tube manufacturer recommendations. | Specimen preserved for 48 hours at room temperature. | Culture and sensitivity for bacteria. Bacteria quantification of clean-voided midstream collected urine is widely used as an aid in evaluating a patient for urinary tract infections. Urine frequently supports the proliferation of bacteria, which may multiply at the same rate as in the nutrient broth. Therefore urine delayed in transit and left at room temperature for an extended period may lead to a false result. As a means of preventing growth of the microorganisms from sources exogenous to the bladder, refrigeration or culturing within 2 hours of micturition is recommended. Timed specimens should be refrigerated between collections. The microbial load in urine from a given patient may be influenced by the time of collection and fluid intake. |
| For proper additive performance, invert filled additive tubes 8 to 10 times. Tubes must be filled to ensure the proper blood to additive ratio. Conditions may vary depending on tube manufacturer recommendations. | Specimens can be stored up to 4 hours before analysis. | Skin puncture blood specimens for hematologic determinations, WBC, RBC, hemoglobin (Hgb), Hct, reticulocyte, white cell differential count, mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), mean corpuscular volume (MCV), and platelet count. As with any skin puncture blood system, “milking” the skin puncture site may cause hemolysis and adversely affect the accuracy of the determinations. Some microcollection tubes may contain silicone to facilitate easy removal of the specimen from the container. |

SECTION II

GENERAL CLINICAL TESTS

| TEST NAME AND METHOD | SPECIMEN REQUIREMENTS | REFERENCE INTERVAL, CONVENTIONAL [INTERNATIONAL RECOMMENDED UNITS] | CHEMICAL INTERFERENCES AND IN VIVO EFFECTS |
|---|--|---|---|
| ABO and Rh Typing ¹⁻⁷ | Erythrocytes. | Not applicable. | The presence of fibrin strands, paraproteins, or plasma expanders in serum or Wharton's jelly in cord blood samples may cause pseudoagglutination. Cold-reacting autoantibodies, weakened antigen expression (e.g., variant A genes) or altered antigens (e.g., acquired B phenotype) can give discrepant results. Hematopoietic stem cell transplantation or the presence of transfused red blood cells may give unexpected results. |
| Testing for minor blood group antigens such as Kell, Duffy, and others is known as red cell phenotyping. | Clotted blood collected in plain (red stopper) tube without silicon gel ⁸ or EDTA-anticoagulated blood (pink or lavender top tube). Local laboratory requirements may vary. | | |
| <i>Agglutination tests using slide, tube, gel card, or microplate formats for ABO, Rh typing.</i> | Store at 4° C. Stable for 5-7 days. | | |

DIAGNOSTIC INFORMATION

REMARKS

Urinary excretion of acetaldehyde during period of elevated blood level has been suggested but not documented.²

↑ Diabetic ketoacidosis, prolonged excessive insulin administration in diabetics, prolonged fasting (so-called ketotic hypoglycemia, most common in children aged 1-6 yr), severe carbohydrate restriction with normal fat intake (weight-reducing diets), anorexia nervosa,¹² persistent vomiting, glycogen storage diseases I, III, and VI, branched-chain ketonuria, methylmalonic aciduria, exercise in untrained subjects,¹ pregnancy,¹ stress,¹² postanesthesia.¹³

↑ States with (1) markedly increased metabolic rate (high fever, severe thyrotoxicosis, active acromegaly); (2) excess of growth hormone, corticotropin, glucocorticoids, hyperinsulinism; or (3) excess of catecholamines causing hyperglycemia, decreased insulin secretion, and increased production of ketone bodies. These conditions (1, 2, and 3) are especially important when diabetes mellitus coexists.

In diabetic ketoacidosis (DKA) β -hydroxybutyrate (BOHB), the predominant ketone, is a better indicator of clinical state than acetoacetate. The BOHB/AcAc ratio is normally 3:1. This ratio will increase to 6:1 or 12:1 during ketoacidosis, particularly if there is associated decreased tissue perfusion, metabolic acidosis, and tissue catabolism. All of these will favor reductive metabolism and hence BOHB production. Acetoacetate may increase during therapy for DKA because BOHB is oxidatively metabolized to acetoacetate.¹⁴

Hemolysis causes discoloration of test tablets or sticks. Failure to crush Acetest tablets before use with serum may give falsely low results. Moisture reduces sensitivity of Acetest tablets. The lower limit of detection is ~ 10 mg/dL [1.0 mmol/L] with Acetest tablets.⁸

In some cases of diabetes mellitus with elevated blood ketone levels, no ketone bodies appear in the urine.

False-positive results may be seen with highly pigmented urine specimens and in those preserved with 8-hydroxyquinoline.⁸ Detection of urinary ketones may be used to verify compliance with a weight-reducing regimen.¹⁵

Limits of detection: 5-10 mg/dL [0.5-1.0 mmol/L] acetoacetic acid.⁴

β -Hydroxybutyrate (the predominant ketone) is not measured by reagent strip methods. Acetone is measured only by Chem-strip reagent strip and the Acetest tablet.

Two methods can be used to differentiate false-positive results caused by free sulfhydryl groups from true positive results: (1) add 1 drop of glacial acetic acid to the "positive" test pad (color is removed from false-positive results); (2) monitor the reaction constantly (true positive results develop a purple color with Acetest that intensifies as long as 60 sec; false-positive results develop a purple color that fades, usually completely, within 30 sec).¹⁶

Quantitative determination of acetoacetate in plasma is only rarely necessary for the workup of metabolic disorders.

↑ Diabetic or fasting ketoacidosis, 2-propanol poisoning (acetone is a major product of 2-propanol metabolism), starvation, severe carbohydrate restriction

Nitroprusside tests are as much as 10-20 times more sensitive to acetoacetate than to acetone. They do not measure β -hydroxybutyric acid. Strongly positive acetone with normal anion gap, bicarbonate, and plasma glucose suggests rubbing alcohol (isopropanol) intoxication.⁹

Acetest is better suited for serial dilutions in serum because it is formulated with lactose for better color differentiation.²

Limits of detection:

Acetest: 20-25 mg acetone/dL [3.4-4.3 mmol/L] of urine

Chemstrip: 40-70 mg acetone/dL [6.9-12.0 mmol/L] of urine

False-negative results may occur with improper specimen handling, which allows acetone to volatilize or be consumed by bacterial action.

The ketone test pad on Multistix reagent strips does not measure acetone.^{4,10}

Moisture will adversely affect results obtained from Acetest tablets by reducing sensitivity.

| Acetonitrile concentrations in air up to 500 ppm [12.2 mmol/L] cause irritation of mucous membranes. Higher concentrations produce weakness, nausea, convulsions, and death. Urine SCN ⁻ concentration is not significantly elevated after exposure to 160 ppm [3.9 mmol/L] for 4 hr. In biological monitoring, preexposure levels should be established because smokers show elevated concentrations of metabolites. The onset of symptoms is delayed due to metabolic conversion to cyanide. Most poisonings have occurred from fingernail glue remover. | | Acetonitrile is not measured in blood and urine, but the metabolites cyanide and thiocyanate are. |
| ↑ Sickle cell anemia ⁸ | | Because intraindividual variation in acetylcholinesterase activity is high and the enzyme activity is sensitive to a variety of genetic, physiological, and disease-related factors, use of this assay to diagnose organophosphate poisoning is problematic. Acetylcholinesterase activity may be useful in monitoring exposure to organophosphates, but the clinical diagnosis is usually based on the cholinergic toxidrome. ¹¹ |
| ↓ Organophosphate toxicity; paroxysmal nocturnal hemoglobinuria; during relapse of megaloblastic anemia (returns to normal with therapy) ⁹ ; pyridostigmine therapy for myasthenia gravis in parallel with clinical improvement. ¹⁰ | | Erythrocyte cholinesterase recovers more slowly than serum cholinesterase and is thus a more sensitive indicator of chronic organophosphorus poisoning. ¹² Recovery is best determined by looking for a plateau in erythrocyte cholinesterase activity and not simply by returning to the reference range. ¹³ |

| DIAGNOSTIC INFORMATION | REMARKS |
|-------------------------------|---|
| AF ↑ Open neural tube defects | <p>Polyacrylamide gel EP of amniotic fluid for acetylcholinesterase is more specific than α-fetoprotein (AFP) determinations and may be used in combination with AFP. Erythrocyte cholinesterase can also be increased in ventral wall defects, omphalocele, other birth defects, and miscarriages. Contamination with fetal serum caused cross-reactivity and false-positive reactions. Inhibition and immunoassay are more specific than EP for determination of true acetylcholinesterase activity.</p> <p>Because of the variability of the assay, a range of 4.0-8.0 mU/mL [4.0-8.0 U/L] has been proposed. To reliably distinguish normal from affected individuals, separate acetylcholinesterase from other cholinesterases by electrophoresis.⁵</p> |

Whole blood (no anti-coagulant; draw into tubes containing an activator). Perform test immediately at bedside at 37° C.

Varies depending on the methodology and the type of surgical/cardiac procedure or therapy.

In general, the accepted goal during cardiopulmonary bypass surgery is ~400-500 sec.

↑ Contamination from a line that contains heparin (especially if drawn from central venous pressure [CVP] line)

Hypothermia, hemodilution, and platelet number and function may affect the ACT.

Mild exposure to acrylonitrile results in eye irritation, headache, nausea, and weakness. Severe cases may result in asphyxia and death. The monomer is carcinogenic. In biological monitoring, preexposure levels should be established because smokers show elevated concentrations of metabolites.

Acrylonitrile is not measured in blood or urine; instead, the metabolite cyanide is measured in blood and thiocyanate in urine. Toxicity is due to cyanide formation in vivo.

Kinetic values

$t_{1/2}$: 8 hr

Test is mostly used as "point of care" to monitor high-dose heparin as an anticoagulant during cardiac surgery (extracorporeal circulation), angioplasty, and hemodialysis.

Because different methodologies and a number of variables may affect the ACT, this test is not standardized.

The ACT is also used to determine the dose of protamine sulfate to reverse the heparin effect on completion of the procedure.

| | | | |
|---|---|---|---|
| Activated Partial Thromboplastin Time (APTT)^{1,2} | Plasma (blue top tube with 3.2% citrate). Centrifuge and remove plasma immediately. Plasma is stable for 1 hr at 4° C, 4 hr on ice, or for 28 days if frozen. | Reference range varies with the reagent-instrument combination used. In general: lower limit of normal 20-25 sec, upper limit <35 sec. Note: The PTT is normally prolonged in newborns/infants. The PTT gradually decreases into the adult range by 6 mo. | ↑ Extraneous heparin Traumatic venipuncture may contaminate specimen with tissue thromboplastin and shorten APTT. A difficult draw may also interfere with PTT used for heparin monitoring by neutralizing the heparin effect in sample due to release of PF4 from platelets. |

Activins, like inhibins, belong with transforming growth factor β superfamily. Activins are dimers of two β -subunits and hence have three forms: β A- β A (activin A), β B- β B (activin B), and β A- β B (activin AB). Several organs express activin, including gonads, ovary, testis, placenta, brain, pituitary, thyroid, adrenal cortex, bone marrow, liver, and pancreas. However, the contribution of activin A synthesized by these organs to the serum level of activin A is not completely clarified. Activin A may function as a growth factor or a cytokine and have an autocrine or paracrine role to regulate cell growth.

The majority of circulating activin A is bound by α 2-macroglobulin and follistatin; the latter is a monomeric glycoprotein structurally unrelated to activins. These binding protein are considered to modulate the biological functions of activin A.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>P ↑ Addison's disease (>1000 pg/mL; >220 pmol/L), congenital adrenal hyperplasia, pituitary-dependent Cushing's disease, ectopic ACTH-producing tumors, Nelson's syndrome</p> | <p>ACTH is unstable in blood, and proper handling of specimen is important.¹² Most commercial RIAs are insensitive and non-specific, measuring intact ACTH, precursor molecules, and ACTH fragments. The highly sensitive IRMA recognizes intact ACTH only. RIA is recommended for investigating ectopic ACTH-producing tumors because some of these tumors secrete ACTH precursors and fragments as well as intact ACTH. Immunoradiometric assays are generally more sensitive (and precise) than RIA and are preferred for investigating disorders of the hypothalamic-pituitary-adrenal system.</p> |
| <p>P ↓ Secondary adrenocortical insufficiency, adrenal carcinoma, adenoma, hypopituitarism</p> | <p>Pregnancy, menstrual cycle, and stress increase secretion. Nyctohemeral rhythm (sleep-wake cycle): highest levels prevail between 6:00 and 8:00 AM (soon after rising) and lowest levels between 9:00 and 10:00 PM (on retiring to bed), although there may be significant oscillations throughout the day. Periodicity is abolished in all types of hypercortisolism except in occasional cases of adrenal tumors. For meaningful comparisons, blood samples should be drawn at the same time each day, preferably in the early morning. Additional samples taken in the late evening may be helpful in cases of Cushing's syndrome. Sequential assays are useful in monitoring response to therapy.</p> |
| <p>AF ↓ Anencephalic fetuses</p> | <p>ACTH in amniotic fluid may be of fetal origin. The relatively high concentration of ACTH in the normal fetus may reflect immaturity of hypothalamic regulation.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Test is used to assess hypothalamic-pituitary-adrenal axis. No response or inadequate response may be due to a hypothalamic lesion or pituitary ACTH deficiency.</p> | <p>Test is also called the insulin-induced hypoglycemia test or insulin tolerance test. In normal individuals, the stress of insulin-induced hypoglycemia induces pituitary ACTH secretion; cortisol is measured as an indicator of ACTH response. Test should be performed only if adrenal responsiveness to ACTH can be assumed or has been demonstrated using the cosyntropin (Cortrosyn) stimulation test. (See <i>Adrenocorticotrophic Hormone Stimulation Test, Rapid</i>.)</p> <p>In insulin-resistant patients, give dose of 0.15-0.3 U/kg. For effective ACTH challenge, clinical manifestations of hypoglycemia must be present; if not, repeat dose within 45 min to 1 hr. Risk of the test is serious hypoglycemia. Test is contraindicated in convulsive disorders, ischemic heart disease, or cerebrovascular disease. See <i>Insulin Tolerance Test</i>.</p> |
| <p><i>Primary adrenal insufficiency</i> (Addison's disease): No or inadequate response</p> | <p>In primary adrenal insufficiency, administer 2 mg dexamethasone to prevent adrenal crisis. This stimulation test is not useful in the differential diagnosis of Cushing's syndrome.</p> |
| <p><i>Secondary adrenal insufficiency</i> (hypopituitarism): Delayed but normal response (gradual staircase increase over 2-3 days)</p> | <p>Adrenal hemorrhages have been reported to occur following ACTH administration to patients with Cushing's syndrome.</p> |
| <p><i>Congenital adrenal hyperplasia due to 21-hydroxylase and 17-hydroxylase deficiency</i>: Increased urinary 17-KGS and 17-KS; little or no change in 17-OHCS or serum cortisol.</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>This is a screening test only. A normal (positive) response rules out primary and overt secondary adrenal insufficiency, but a partial ACTH deficiency is not excluded. A subnormal response indicates decreased adrenal reserve and a diagnosis of insufficiency, either primary to adrenal failure (e.g., Addison's disease) or secondary to pituitary disease or suppression by steroid medications. To distinguish primary and secondary insufficiency, the prolonged ACTH test and plasma ACTH measurements may be performed. See <i>Adrenocorticotrophic Hormone Stimulation Test</i>, <i>Prolonged Infusion</i> and <i>Adrenocorticotrophic Hormone</i>.</p> <p>In adrenal hyperplasia there is a threefold to fivefold increase; in adrenal carcinoma there is little or no response.</p> | <p>A normal response does not rule out partial secondary adrenal insufficiency in patients who cannot maintain sufficient basal ACTH to respond to stress or hypoglycemia. In these cases, the pituitary can be tested with metyrapone or with insulin-induced hypoglycemia. See <i>Metyrapone Stimulation Test</i> and <i>Adrenocorticotrophic Hormone Stimulation Test (after Insulin)</i>.</p> <p>Total cortisol measurements sensitive to serum protein concentrations.⁴</p> |
| <p>S ↑ Hepatobiliary and pancreatic disease, elevation parallels ALP; malignancy⁸; pregnancy, AAP peaks at term.</p> <p>S ↓ Abortion</p> | <p>AAP is also known as microsomal aminopeptidase, in contrast to LAP, which is a cytosolic aminopeptidase.</p> <p>Electrophoresis can separate isoenzymes according to tissue origin. Tissues with significant activity are liver, kidney, pancreas, and small intestine. A serum isoform has been noted in subjects on anticonvulsant drugs and abusers of alcohol.⁹ Normal serum contains only the liver isoenzyme, whereas normal urine contains only the kidney isoenzyme. The kidney isoenzyme originates from the brush border membranes of the proximal renal tubule.⁴ Urinary output of soluble forms of AAP is increased by diuresis.¹⁰ The serum enzyme appears in the urine only in the presence of proteinuria. Urine enzyme activity is most useful when expressed <i>per g creatinine</i> rather than as a concentration (per liter) or as output per hour.¹¹</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| ↑↑ Acute liver cell necrosis of any cause, severe shock, right heart failure, acute anoxia (e.g., status asthmaticus), extensive trauma, left heart failure | ALT is present in very high amounts in liver and kidney and in smaller amounts in skeletal muscle and the heart. Its intracellular location is predominantly cytosolic. There is a mitochondrial isoenzyme, but its half-life in serum is very short. Trace amounts are present in skin, pancreas, spleen, and lung. Activity in erythrocytes is approximately six times the activity in serum. |
| ↑ Cirrhosis, obstructive jaundice, liver tumors, extensive myocardial infarction, myositis, myocarditis, muscular dystrophy; occasionally in hemolytic disease, preeclampsia, moderate muscle trauma, fatty liver, chronic alcohol abuse, filariasis, severe burns, severe pancreatitis, chronic hepatitis | An ALT level that remains high after an attack of acute hepatitis suggests lack of resolution of the disease and high risk for development of chronic hepatitis. ^{6,7} Elevated ALT levels are more often due to obesity (particularly in males) or alcohol abuse than to viral hepatitis. ⁸ Although ALT correlates to body mass index, it correlates better to abdominal fat accumulation. ⁴ Several studies have suggested basing reference limits for ALT on values found in normal body weight individuals. In such studies, reference limits are typically much lower (30 U/L in men, 19 U/L in women). ⁹ In blunt abdominal trauma in children, ALT >250 U/L is a good predictor of liver injury. ¹⁰ Values are reported to be higher in Hispanics than in other Caucasians. ^{11,12} |
| ↓ Pyridoxal phosphate deficiency | Modern methods incorporate pyridoxal phosphate in the reagent with the result that levels are found ~25% higher than formerly. In some patients on renal dialysis, values may show greater increases. |

| <p>S ↑ Any condition causing dehydration</p> | <p>Albumin is the protein of greatest concentration found in plasma, comprising ~55-60% of the serum protein. Its structure is relatively resistant to denaturation. Other members of the albumin superfamily include vitamin D-binding protein, α-fetoprotein, and afamin. Synthesis is hepatic and is primarily regulated by the colloid osmotic pressure of the interstitial fluid surrounding hepatocytes. Catabolism occurs in nearly all organs, allowing albumin to serve as a source of free amino acids for the body. Approximately 100 variant forms are known. However, with the exception of the syndrome of familial dysalbuminemic hyperthyroxinemia, these are not typically associated with significant alterations in function.¹⁷ The rare condition of analbuminemia, in which serum albumin is almost totally lacking, is usually associated with few symptoms.²¹</p> |
| <p>S ↓ <i>Acute phase reaction and chronic inflammation:</i> Infection, surgery, trauma, chronic inflammatory diseases, critical illness, malignancy</p> | <p>Albumin has been demonstrated to serve several functions. It provides the majority of the intravascular oncotic pressure and also contributes to the regulation of fluid concentrations in tissues. It has an important role in the binding and transport of endogenous substances and medications. Hypoalbuminemia can affect free drug concentrations of medications that are highly albumin-bound. There is evidence that albumin has antioxidant activity,¹⁷ may promote wound healing, has a heparin-like anticoagulant effect,¹¹ and serves as a buffer for acid-base homeostasis.²¹</p> |
| <p><i>Decreased hepatic synthesis:</i> Acute and chronic liver disease, amyloidosis, chronic illness, malabsorption, fasting, protein-calorie malnutrition, diabetes mellitus, decreased growth hormone levels, hypothyroidism, hypoadrenalism, carcinoid syndrome, malignancy, disorders associated with a hypergammaglobulinemia,¹⁷ congenital analbuminemia</p> | <p>Antialbumin antibodies are commonly found with hepatic dysfunction and are typically IgA in type.¹¹</p> |
| <p><i>Increased loss:</i> Nephrotic syndrome/renal dysfunction, thermal burns, exfoliative dermatitis, protein-losing enteropathies, trauma, internal exudate formation, gastrointestinal and lymphatic fistulae, repeated thoracentesis or paracentesis</p> | <p>Ischemia-modified albumin, in which the metal binding capacity of albumin has decreased due to exposure to ischemic events, is a biological marker of myocardial ischemia.²²</p> |
| <p><i>Increased catabolism:</i> Conditions including therapy with some antimetabolites, radiation treatment, familial hypercatabolic hypoproteinemia, tumors, extensive thermal burns</p> | <p>MW: 66,460 t_{1/2}: 18-20 days</p> |
| <p><i>Plasma volume expansion:</i> Pregnancy, oral contraceptives, congestive heart failure</p> | <p>Urinary protein excretion varies throughout the course of a 24-hr period and can be affected by factors such as administered medications.²³</p> |
| <p>U ↑ <i>Functional or benign:</i> Strenuous exercise/exertion, exposure to cold temperatures, congestive heart failure, substantial fever, postural (orthostatic) proteinuria, pregnancy</p> | <p>Orthostatic (postural) proteinuria can be suspected when a first morning urine sample obtained immediately after rising does not show evidence of proteinuria, whereas a second sample obtained ≥ 2 hr after upright activity is positive.</p> |
| <p><i>Pathological proteinuria:</i> Renal include nephrotic syndrome, nephrosclerosis, amyloidosis and multiple myeloma, glomerulonephritis (acute and chronic), lupus nephritis, infection/pyelonephritis, preeclampsia, diabetic nephropathy,</p> | |

DIAGNOSTIC INFORMATION

REMARKS

↑ Is a risk factor for progression to proteinuria and chronic renal failure in both insulin-dependent and non-insulin-dependent diabetic patients.¹⁸ Can also be found in nondiabetic individuals, particularly those who are hypertensive, and is a risk factor for cardiovascular disease and mortality in both nondiabetic hypertensive individuals and diabetic patients.¹⁸⁻²⁰ Any condition associated with increased urinary albumin concentrations can yield a false-positive result for microalbuminuria.

Microalbuminemia (MA) is most often detected in diabetic individuals who are active smokers, have HbA1c concentrations of >8.0%, and have retinopathy.¹⁸ Evidence suggests that even at urinary albumin concentrations less than those defined as diagnostic of MA, a continuous relationship between the rate of urinary albumin excretion and adverse clinical outcomes exists.^{18,25} Regression of MA occurs in some individuals over time.¹⁸

Medications that act on the renin-angiotensin system may delay onset of renal and cardiovascular disease, making screening for MA important in the care of diabetic patients.¹⁸

| <i>Enzymatic</i> | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Drug hepatotoxicity, hepatocellular damage, obstructive jaundice,⁶ infection, inflammation, and malignancy.</p> <p>ADH is claimed to be a highly sensitive marker for liver anoxia with centrilobular damage.⁴</p> | <p>ADH is a hepatic cytoplasmic enzyme predominantly located in the centrilobular region. When significantly increased, ADH may sometimes be detected as a sixth band on LDH isoenzyme electrophoresis.⁷ ADH isoenzymes specific for liver, gastric mucosa, and kidney have been identified.</p> <p>ADH is actually a family of closely related enzymes with considerable polymorphism⁸ that may influence ethanol elimination rates.⁹</p> <p>ADH activity is responsible for the metabolic conversion of methanol and ethylene glycol to toxic compounds. Such conversion is inhibited by the administration of ethanol or 4-methylpyrazole.</p> |

Highest elevated activities are observed in progressive muscular dystrophy (Duchenne). Lower elevated activities are found in dermatomyositis, polymyositis, and limb-girdle dystrophy. The increase in activities becomes less as muscle mass declines. Aldolase increases have also been observed in myocardial infarction, viral hepatitis, cirrhosis, and obstructive jaundice, prostate tumors, and chronic leukemias.

Creatine kinase (CK) generally provides sufficient diagnostic information; thus aldolase monitoring is not routinely recommended. Increased aldolase activities, in the presence of normal CK activities, have been observed in patients with eosinophilic fasciitis.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ <i>Primary aldosteronism</i> due to aldosterone-secreting adenoma (Conn's syndrome); pseudopriary aldosteronism (bilateral adrenal hyperplasia); <i>secondary aldosteronism</i> in laxative abuse, diuretic abuse, cardiac failure, cirrhosis of the liver with ascites formation, nephrotic syndrome, idiopathic cyclic edema, Bartter's syndrome, hypovolemia due to hemorrhage and transudation, renal juxtaglomerular hyperplasia with potassium wastage and retarded growth, hemangiopericytomas of the kidney that produce renin, renal hypertension during malignant phase, thermal stress, pregnancy, mid and late luteal phases of menstruation, after 10 days of starvation, and in chronic obstructive lung disease</p> <p>A diagnosis of primary aldosteronism may be made (1) by demonstrating suppressed plasma renin activity that cannot be stimulated following sodium restriction (see <i>Aldosterone Stimulation Test [after Sodium Restriction]</i>) or administration of a diuretic (see <i>Furosemide Stimulation Test, Rapid</i>); and (2) by demonstrating a lack of suppression of aldosterone following saline infusion (see <i>Aldosterone Suppression Test [after Saline Infusion]</i>) or treatment with a mineralocorticoid (see <i>Fludrocortisone Suppression Test</i> and <i>Deoxycorticosterone Suppression Test</i>). Differentiation of hyperplasia from adenoma as the cause of primary aldosteronism can be made by adrenal venous aldosterone sampling. In hyperplasia both adrenals secrete high levels of aldosterone, whereas in adenoma the contralateral adrenal will be suppressed.</p> <p>↓ <i>Without hypertension</i>: Addison's disease, isolated aldosterone deficiency, syndrome of hypoaldosteronism due to renin deficiency</p> <p>↓ <i>With hypertension</i>: Excess secretion of deoxycorticosterone, corticosterone, or 18-hydroxydeoxycorticosterone; Turner's syndrome (25% of cases); diabetes mellitus; acute alcoholic intoxication (increased during hangover)</p> | <p>If an upright sample is collected, patient should be upright (standing or seated) for at least 2 hr. Normal secretion depends on multiple factors, including the renin-angiotensin system, potassium, ACTH, magnesium, and sodium. In normal subjects and patients with aldosteronism, there is a significant overlap. The plasma aldosterone level is reduced with age. Also, responses of aldosterone to dietary sodium restriction, upright position, angiotensin II, and potassium are greatly reduced. The decline of aldosterone with age is probably due to the suppression of renin.</p> <p>Urine specimens should not be acidified with strong mineral acids.</p> |

↑ Disorders with increased bone formation, Paget's disease (total or bone alkaline phosphatase is best marker), high-turnover osteoporosis, primary and secondary hyperparathyroidism, renal osteodystrophy, hyperthyroidism, osteomalacia, metastatic bone disease, recent bone fractures, acromegaly, children during bone growth, adults >50 yr, menopause

↓ Pregnancy, growth hormone deficiency, hypothyroidism, hypoparathyroidism

BAP, produced by the osteoblast, is a marker of bone formation. Bone, liver, and kidney are isoforms of the same gene product, the tissue-nonspecific gene. BAP is a more sensitive and specific marker of bone formation than total alkaline phosphatase. Consequently, it is more useful in mild metabolic bone diseases such as osteoporosis and early metabolic bone disease. However, because most therapies for osteoporosis and other metabolic bone diseases are antiresorptive, they are usually monitored with collagen telopeptides or cross-links (see *Collagen Cross-Linked Telopeptides and Pyridinium Cross-Links*). Because bone formation and resorption are coupled, formation markers respond to antiresorption therapies, although the response (plateau at 6-12 mo) is delayed compared with resorption markers.

Two methods have been developed using monoclonal antibodies against BAP: an IRMA-measuring mass, and an immunoabsorption assay measuring enzyme activity. These immunoassays exhibit 7-17% cross-reactivity with the liver isoforms. Consequently, current methods overestimate BAP in patients with liver disease with increased concentrations of the liver isoform.

BAP shows the least within-subject variability of bone markers due to its long half-life and the greater reproducibility of serum bone markers. It has several advantages over osteocalcin, the other noteworthy marker of bone formation. Unlike osteocalcin, BAP exhibits little diurnal variation due to its much longer half-life (1-3 days) in vivo. BAP is more useful in patients with impaired renal function. It is more stable in vitro. BAP measurements may not accurately reflect bone formation in patients with liver disease (cross-reactivity of liver isoform), in osteomalacia (mineralizing defect), and with increased concentrations of 1,25(OH)₂D (increases synthesis of BAP).

↑ *Bone isoenzyme*: Increased bone formation, Paget's disease, bone growth in children, healing of bone fractures, osteomalacia and osteoporosis, postmenopausal osteoporosis, osteomalacia of primary, secondary, and tertiary hyperparathyroidism; nutritional deficiency, e.g., vitamin D rickets, vitamin D-resistant rickets, anticonvulsant-induced iatrogenic rickets, renal tubular acidosis rickets, malabsorption syndrome, osteomalacia; osteosarcoma of bone, metastatic carcinoma of prostate, breast with osteoblastic bone formation, secondary osteoblastic regeneration of healing following successful therapy of osteolytic metastatic bone cancer, lymphoma, leukemia of bone marrow; storage diseases, e.g., Gaucher's disease and Niemann-Pick; bone regeneration following osteoporosis and osteomalacia of Cushing's or chronic adrenal steroids; hyperthyroidism, renal osteodystrophy (uremic bone disease or renal rickets).

↓ Osteopenia due to genetic hypophosphatasemia, cretin hypothyroidism, chronic nutritional deficiency, e.g., magnesium and zinc; vitamin B12 deficiency, pernicious anemia.

↑ *Liver I isoenzyme* (enhanced biosynthesis): Hepatic congestion and decreased clearance of the enzyme, vasculitis, pregnancy

↑ *Liver II isoenzyme* (intracellular enzyme): Parenchymal cell damage

↑ *Biliary ALP*: Cholestasis (high molecule mass lipoprotein-X, ALP)

↑ *Intestinal ALP*: Some patients with intestinal disease, some individuals of blood type O or B (particularly after meals); intestinal variant ALP

↑ *Placental ALP*: Appears in maternal serum, especially during the third trimester

See *Alkaline Phosphatase, Bone*.

Various procedures are utilized to assess ALP isoenzymes:

Heat stability after 56° C for 10 min,

Placenta 90% stable

Regan 90% stable

Liver 50% stable

Intestinal 50% stable

Bone 10% stable

This technique has important shortcomings because sharp demarcation of heat stability of the ALP isoenzymes does not occur. Presence of very heat-stable isoenzymes (see above) or significant intestinal isoenzyme will alter the heat stability index of the serum. Quantification is difficult when intestinal, placenta, or high concentrations of liver and bone are present. Failure to accurately control the temperature significantly alters findings.

Chemical inhibition: Urea, L-phenylalanine, and other chemicals have been used to differentially inhibit isoenzymes of alkaline phosphatase. Precise quantification of isoenzymes with chemical inhibition has been difficult and is not widely used.

Electrophoresis: Polyacrylamide or agarose gel methods have been used to separate the main ALP isoenzyme groups. An agarose gel technique has been shown to be useful in the detection of bone and liver metastases.⁹ The separation of liver and bone is inadequate for precise quantification. Consequently this labor-intensive technique has not been widely used.

Isoelectric focusing^{6,7}: IEF has the capability of distinguishing up to 12 ALP isoenzymes/isoforms: biliary, hepatocytic, hepatic reticuloendothelial cell, vascular bed, bone, pulmonary alveolar cells, neutrophil, fetal intestinal (adrenal?), germ cells (testis and ovary), placental or activated T lymphocyte, renal, and intestinal.

↑ *Unidentified isoenzymes*: Frequently of neoplastic origin (e.g., Regan or Nagao isoenzymes). Heat stability and electrophoretic migration of these isoenzymes are similar to those of placental isoenzyme.

*Wheat germ lectin precipitation of bone ALP*⁸
This assay was commercialized by Roche outside the U.S. Lectin precipitates ~90% of bone ALP but <5% of nonbone ALP. The robustness of the method has been questioned including lot-to-lot variation in lectin and its stability, the quantitative precipitation of the bone isoenzyme, and coprecipitation of biliary isoenzyme. The method has not been widely used in the U.S.

|---|--|----------|--|
| Alloantibodies (Atypical, unexpected), Antibody Identification, Red Blood Cell (RBC) [e.g., anti-K (Kell), anti-Jka (Kidd), anti-Fya (Duffy) ¹⁻⁷] | Serum or plasma (EDTA). Store at 4° C for 1 wk or up to 6 mo at -30° C. | Negative | |
| Indirect antiglobu- lin test | For pretransfusion test- ing, specimen age must comply with AABB Standards for Blood and Transfusion Ser- vices. ¹ | | Abnormalities in serum composition such as dys- proteinemia and presence of foreign substances (plasma expanders, silicon gel, sodium caprylate, a stabilizer used in albumin preparations) may cause interferences. |
| <i>Agglutination/he- molysis of type O RBCs of known antigen type using tube, gel, or mi- croplate formats.</i> | | | Some clinically significant antibodies (e.g., those against the Duffy and Kidd blood group antigens) may react only with test eryth- rocytes homozygous for the corresponding antigen. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>Alloantibodies are a result of exposure to foreign erythrocytes by transfusion, pregnancy, or transplantation.</p> | <p>For alloantibody identification, three antigen positive RBCs must demonstrate reactivity to “rule in” the presence of the antibody (probability is 95% that the antibody is present). Three antigen-negative RBCs must demonstrate no reactivity to exclude the presence of an antibody to other antigens (probability is 95% that an antibody to other antigens is not present).</p> |
| <p>Reactivity in the testing system is dependent on the specificity of the antibody, the titer of the antibody, the antigen profile of the RBCs used for identification, and the test methodology used.</p> | <p>Reaction media may include saline, albumin, low ionic strength solution, or polyethylene glycol, with the addition of antihuman globulin reagent. Procedures including treatment with enzymes or sulfhydryl reagents, adsorption, or neutralization may be done before the application of a detection system such as agglutination.</p> |
| <p>Alloantibodies may be of donor origin, as in the passenger lymphocyte syndrome following hematopoietic stem cell or organ transplantation.⁹</p> | <p>Alloantibodies due to transfusions or pregnancy may be demonstrable for years after the antigen exposure.¹⁰</p> |
| | <p>Passively acquired antibodies are usually demonstrable for 4-6 wk, although they may be detectable for up to 6 months.</p> |

Alloantibodies (Atypical, unexpected), Antibody Identification, Red Blood Cell (RBC)—CONT

Treatment of red cells with proteolytic enzymes such as ficin or papain may enhance antibody reactivity (e.g., antibodies against Rh, Kidd blood group antigens).

Duffy, M, N, S, and some other blood group antigens are weakened or destroyed by proteolytic enzymes, whereas sulfhydryl reagents like dithiothreitol have the same effect on Kell and Lutheran blood group antigens, among others. Treatment of test erythrocytes with these agents will result in a decrease in the reactivity of the corresponding antibody.

Anti-D may be detected in D-negative individuals following RHIG administration.

Infrequently, other alloantibodies may be passively transferred, e.g., from intravenous immunoglobulin preparations.

DIAGNOSTIC INFORMATION

REMARKS

Autoantibodies may mask the presence of alloantibodies. Autoantibody activity may be removed by adsorbing the serum with pretransfusion autologous erythrocytes to detect underlying alloantibodies. Autoantibodies may be warm or cold reactive and should be tested at appropriate temperatures.

Alloadsorption studies, rather than autoadsorptions, are performed in recently (<3 mo) transfused patients because transfused erythrocytes may carry antigens that may react with and remove important alloantibodies.

| Primarily used in prenatal testing to determine alloantibody reactivity in maternal serum, to assess the risk for hemolytic disease of the newborn (HDN). | Precision of the test is poor; technical variables affect results. Previous sample (stored frozen) should be tested in parallel with the current sample. |
| Titration studies are occasionally of value in antibody identification or in the separation of multiple antibody specificities. | <p>Titration studies are performed without enhancement media.</p> <p>Titration studies for anti-D antibody are widely used as a guide for noninvasive or invasive interventions in pregnancies at high risk for HDN. Titers between 8 and 32 are frequently considered “significant” or “critical,” i.e., may warrant invasive fetal monitoring.⁸</p> <p>Whereas a very low titer, especially one that does not increase with gestation, correlates in general with a low risk of HDN, close follow up with the obstetric team is recommended. Values for critical titers may vary according to the laboratory that performs the test and have not been well established for non-Rh antibodies.⁹</p> |

S ↑ Renal failure, dialysis dementia, Hodgkin’s disease, cystic fibrosis; >100 mcg/L [3.7 $\mu\text{mol/L}$] indicates possible toxicity and >200 mcg/L [7.4 $\mu\text{mol/L}$] usually shows clinical symptoms of toxicity.

B ↑ Pregnancy, leukemias, liver and bile duct disorders

B ↓ Gastric ulcers, pernicious anemia, diabetes, skin diseases except psoriasis

P, U, Sw ↑ Cystic fibrosis

$\text{Al}(\text{OH})_3$ is used in medicine as a gastric antacid and as a phosphate-binding agent in dialysis patients. Al accumulates in patients with renal failure; massive accumulation from long-term intermittent dialysis against high-aluminum dialysate leads to dialysis encephalopathy and vitamin D-resistant osteomalacia. Prolonged IV feeding of preterm infants with Al-containing solutions associated with impaired neurologic function.¹¹ Role of Al in Alzheimer’s disease remains controversial.¹² Al affects bone formation and remodeling and inhibits hemoglobin synthesis.¹³ Occupational exposure does not increase serum Al.¹⁴ There are circadian changes of blood Al in normal individuals with highest levels at 9:00 AM and

| <p>↓ Lead poisoning,⁵ hereditary tyrosinemia,⁶ and ALAD deficiency⁷</p> | <p>Decreased activity of ALAD is a sensitive test for subclinical lead poisoning but has largely been supplanted by direct measurement of blood lead. The enzyme is prone to inactivation during handling of Ercs and the approximate threefold biological variation in normal ALAD values also decreases the test's utility. However, ALAD can be used to follow effectiveness of Pb chelation therapy. Activation of ALAD activity in vitro⁵ can help distinguish Pb poisoning from ALAD deficiency and hereditary tyrosinemia. In the latter disorder, it is endogenous succinylacetone that inhibits ALAD and causes increased urine ALA. Hereditary tyrosinemia is associated with neuropathic symptoms similar to those in the acute porphyrias.⁶</p> |
| <p>6. Sassa S, Kappas A: Hereditary tyrosinemia and the heme biosynthetic pathway—profound inhibition of delta-aminolevulinic acid dehydratase activity by succinylacetone, <i>J Clin Invest</i> 71:625-634, 1983.</p> <p>7. ↑ Pancreatitis⁴ (usually >6%); in some patients with diabetic ketoacidosis, renal insufficiency, duodenal perforation, following extracorporeal circulation, large doses of corticosteroids, hyperemesis of pregnancy, toxemia of pregnancy, after abdominal surgery, pancreatic cancer, myeloma and light-chain disease, and marked hemoglobinuria. Some patients with pancreatitis and macroamylasemia have a normal ratio.^{2,3}

Subtle ↑ is an early renal change in diabetes mellitus⁵ and gentamycin toxicity.⁶

↓ Macroamylasemia

Ratio is significantly lower for persons <30 yr but otherwise remains constant for both sexes, up to 80 yr.⁷

Ratio is dependent on technique of amylase assay; therefore reference interval must be confirmed for particular methodology.^{7,8}

The ratio is calculated as:

$$\frac{\text{Urine amylase}}{\text{Serum amylase}} \times \frac{\text{Serum creatinine}}{\text{Urine creatinine}} \times 100$$

The units used for either test in serum and urine must be the same, e.g., U/L for amylase and mg/dL (or μmol/L) for creatinine. A timed collection of urine is not needed because the rate (mL/min) of urine excretion cancels in the above equation. The change in clearance in some nonpancreatic diseases is probably due to competitive interference of amylase absorption in the tubules by nonspecific proteins with low molecular weights similar to that of amylase.⁴

This test is no longer routinely used in pancreatic disease because clinical experience has not supported earlier publications. It is still useful in the diagnosis of macroamylasemia.

|---|--|--|--|
| Amylase Isoenzymes and Isoforms (1,4- α -D-glucanohydrolase; EC 3.2.1.1) ¹ | Serum. Analyze promptly or store. See <i>Amylase</i> . | Depending on the method, up to three P-type and three S-type isoenzymes have been demonstrated with routine techniques (See <i>Remarks</i>). Total S-type accounts for 45-70% (x: 57%) of total activity; the remainder is P-type. Values differ with method. P-type reaches a maximum value in the fourth decade and then declines. | Storage of serum can result in quantitative changes in the isoenzyme patterns observed. Persulfate used to polymerize acrylamide gel can destroy the enzymes. ⁷ |
| <i>EP</i> , ² <i>IEF</i> , ² <i>selective inhibition</i> , ³ <i>RIA</i> , ⁴ <i>immunochemical</i> , ^{2,5} <i>immunoinhibition</i> ⁶ | Urine. Amylase is very unstable in acid urine. Adjust pH to alkaline range before storage. | Patterns are essentially the same as for serum except for macroamylase complexes that do not appear in urine. P-type isoamylase is proportionally higher in urine. Reference ranges are much wider than in serum because of the wide variation in diuresis. See also <i>Macroamylase</i> . | Improper handling and prolonged storage can produce deamidation products of amylase that exhibit anomalous mobilities on some electrophoretic or isoelectric focusing procedures. ¹ |
| | Ascitic or pleural fluids. Stability similar to serum. Store at 4° C. | Ascitic and pleural fluid isoamylase activity identical to, or slightly less than, serum activity | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Identification of increased S- or P-type isoenzymes is not pathognomonic for a specific disease, although the detection of increased P-type is diagnostically superior to demonstration of elevated total amylase for acute pancreatitis. Abnormal serum salivary amylase is usually present in parotitis but also appears in serum of patients with some types of bronchogenic or serous ovarian tumors and in a variety of abdominal diseases.¹ S-type isoamylase occurs in mumps. If, however, mumps causes pancreatitis, a P-type isoamylase may also be present. Increased P-type isoamylase occurs in diabetic ketoacidosis due either to hyperglycemia or to an associated pancreatitis. S/P ratio is elevated in diabetes possibly because of glomerular changes.⁸ S-type isoamylase increases after rupture of the esophagus or of an ectopic pregnancy.</p> <p>Amylase isoenzyme determinations are helpful in excluding pancreatic causes in postsurgical hyperamylasemia.</p> <p>Increased P3 amylase has been suggested as an indicator for poor prognosis following acute pancreatitis.⁷</p> | <p>There are two main amylase isoenzymes (P- and S-type), but multiple isoenzymes and isoforms exist because of genetic variants and posttranslational modifications. Up to 17 bands have been observed with high-resolution techniques. Ovarian and bronchogenic tumors produce an amylase that is probably an isoform similar to the S-type isoenzyme.¹</p> <p>Observations are highly method dependent.¹ Methods employing the salivary amylase inhibitor from wheat germ or immunoassay with the monoclonal antibody⁶ obviate the need for electrophoresis to distinguish S- from P-type amylase (See <i>Amylase</i>).</p> <p>The P-type isoamylase undergoes faster urinary clearance than the S-type isoamylase. The ratio of P-type/S-type urinary clearance is in the range 2.1-6.1 using the monoclonal antibody assay.⁹ Note that urinary elevations occur later than serum changes in acute pancreatitis (See <i>Amylase, serum</i>). In heavy proteinuria due to primary glomerulopathies, the ratio of P-type/S-type urinary clearance is decreased to the range 0.2-2.2. On remission, the ratio reverts to normal.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Inhaled aniline is rapidly absorbed by the lungs, leading to systemic toxicity. Aniline also is efficiently absorbed through the skin and GI tract. The absorbed compound oxidizes hemoglobin iron to produce methemoglobinemia and is oxidized by the cytochrome P-450 system to <i>p</i>-aminophenol, conjugates of which are excreted in the urine. Exposure to 7-53 ppm aniline vapor for several hours may cause slight symptoms, and concentrations >100-160 ppm produce are toxic. As little as 1 g of ingested aniline can be fatal to humans, but the mean lethal dose is 5-30 g (HSDB 2000).³</p> | <p>Aniline measurement in blood is not helpful in monitoring exposure or toxicity. Aniline toxicity is monitored by measuring methemoglobin.</p> <p>Less than 1% of an absorbed dose of aniline is excreted unchanged in the urine. From 15-60% is oxidized to <i>p</i>-aminophenol, which is excreted in the urine as glucuronide and sulfate conjugates; 89% of the absorbed dose is excreted within 24 hr of exposure.</p> <p>Acetaminophen may increase urinary <i>p</i>-aminophenol concentrations, but in therapeutic doses the contribution does not exceed the toxic threshold.</p> |

↑ *Metabolic acidosis*: Uremia with increase in phosphate, negatively charged amino acids, and sulfate; ketoacidosis (diabetic, alcoholic, and starvation) with increase in β -hydroxybutyrate and acetoacetate; lactic acidosis in shock, muscular exercise, or lactic acid syndrome; salicylate, methanol, ethylene glycol, and paraldehyde poisoning; severe dehydration (increase in plasma protein concentration); great-est increases in anion gap seen in organic acidosis.

The anion gap is normal in hyperchloremic acidosis (e.g., due to gastrointestinal loss of HCO_3^-) and in some forms of renal tubular acidosis.

↓ Hypokalemia, hypocalcemia; hypomagnesemia; rhabdomyolysis; increase in proteins with less negative charge (hypergammaglobulinemia), decrease in negatively charged proteins (hypoalbuminemia), increase in positively charged proteins (myeloma).

Various dilutional states, disorders associated with hyperviscosity, SIADH

Anion gap is a mathematical approximation of the difference between the unmeasured cations and anions in serum.

The anion gap is also useful for quality control of laboratory results for Na^+ , K^+ , Cl, and total CO_2 .

Changes in methodologies, mainly to ISEs, require a reevaluation of the reference range. For sera from patients with hyperlipemia or severe hyperproteinemia, the solvent exclusion effect will affect the results differently, depending on the specific method used, e.g., direct or indirect potentiometry. Therefore the reference interval may be higher or lower than that given here.

Using the Beckman ASTRA analyzer, Winter et al⁵ found an anion gap of 3-11 mmol/L. Dinovo et al⁶ conducted a similar study and suggested a reference interval for the anion gap of 5-14 mmol/L.

|---|--|----------|---|

1. Technical manual committee, Brecher ME, editors: *Technical manual*, ed 14, Bethesda, MD, 2002, American Association of Blood Banks.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>A positive antibody screen should be evaluated by an antibody identification panel.</p> <p>Reactivity in the testing system is dependent on the specificity of the antibody, the titer of the antibody, the antigen profile of the RBCs used for identification, and the test methodology used.</p> | <p>For alloantibody identification, three antigen-positive RBCs must demonstrate reactivity to “rule in” the presence of the antibody (probability is 95% that the antibody is present). Three antigen-positive RBCs must demonstrate no reactivity to exclude the presence of an antibody to that antigen (probability is 95% that an antibody to this antigen is not present).</p> <p>Autoantibodies may mask the presence of alloantibodies. Autoantibody activity may be removed by adsorbing the serum with pretransfusion autologous erythrocytes to detect alloantibodies. Autoantibodies may be warm or cold reactive and should be tested at appropriate temperatures. Note that use of a posttransfusion sample is not recommended because transfused erythrocytes may carry antigen that may react with and remove important alloantibody.</p> <p>See <i>Antibody Screen, RBC</i>.</p> |
| <p>Positive tests may occur after immunization, during pregnancy, or after transfusion with RBCs having antigens foreign to the recipient. Positive test may occur in the presence of RBC autoantibodies.</p> <p>Drugs may stimulate antibodies, some with Rh-like specificity.</p> <p>Positive test indicates the presence of one or more atypical antibodies, i.e., alloantibody, to foreign erythrocyte antigens. Allogeneic erythrocyte transfusion and pregnancy are the most frequent sources for these erythrocyte antigens.</p> | <p>Primary response (to first antigen exposure) requires 20-120 days; antibody is largely IgM with a small quantity of IgG. Secondary response requires 1-14 days; antibody is mostly IgG.</p> <p>Some antibody activity (e.g., anti-Jk^a, anti-E) becomes so weak as to be undetectable but increases rapidly after secondary stimulation with the same antigen.</p> <p>See also <i>Alloantibodies (Atypical, Unexpected), Immunoglobulin G (IgG)</i>.</p> |
| <p>Autoantibodies are generally seen in infectious diseases such as infectious mononucleosis or primary atypical pneumonia; collagen vascular disease, especially SLE; and lymphoproliferative diseases such as CLL and lymphocytic lymphomas. Cold autoantibodies may produce cold agglutinin disease, whereas warm autoantibodies may produce a warm autoimmune hemolytic anemia.</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Anticentromere antibodies occur in a variant of scleroderma known as CREST syndrome (calcinosis, Raynaud's phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia).¹</p> | <p>Anticentromere antibodies react with protein antigens associated with the centromere, including CENP-A, -B, and -C that vary in size from 17-80 to 140 kDa, respectively. These autoantibodies occur in up to 96% of patients with CREST syndrome and may antedate the development of symptoms in this disease.²</p> |
| <p>↑ <i>Inappropriate increase (with respect to plasma osmolality) in syndromes of excessive ADH production (SIADH):</i> Acute intermittent porphyria, Guillain-Barré syndrome, brain tumor (primary or metastatic), vascular and infectious diseases of the brain, pneumonia, pulmonary tuberculosis, tuberculous meningitis, nephrogenic diabetes insipidus</p> | <p>Higher secretion occurs at night; in erect posture; with pain, stress, or exercise; with increased plasma osmolality (e.g., hypertonic saline infusion); and with decrease in effective blood volume or arterial pressure. Lower secretion occurs in recumbency, hypoosmolality, volume expansion, and hypertension. Action of ADH on the kidney is inhibited by lithium, calcium, and demeclocycline. Significant deterioration of ADH occurs with prolonged storage. Plasma samples should not be left at room temperature.</p> |
| <p>↑↑↑ Systemic neoplasm (ectopic ADH)</p> | <p>It is important to distinguish SIADH from other conditions that cause dilutional hyponatremia: congestive heart failure, renal insufficiency, glucocorticoid deficiency, hypothyroidism, and drugs that stimulate ADH (e.g., chlorpropamide, thiazide diuretics). Patients with SIADH usually show decreased plasma sodium and plasma osmolality, high urine osmolality relative to plasma osmolality, urine sodium that is neither high nor low, and a reduced ability to excrete a water load. See <i>Water Loading Antidiuretic Hormone Suppression Test</i>.</p> |
| <p>↓ Central diabetes insipidus, psychogenic polydipsia, nephrotic syndrome</p> | |
| <p>To differentiate ADH deficiency (central diabetes insipidus) from renal resistance to ADH (nephrogenic diabetes insipidus) or excess water intake (psychogenic polydipsia), perform dynamic tests.⁶ See <i>Water Deprivation Antidiuretic Hormone Stimulation Test</i>.</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| Antihistone antibodies occur in patients with drug-induced LE but are also found in patients with idiopathic LE. ¹ Drug-induced LE patients usually do not have antibodies to dsDNA. | Antihistone antibodies in patients with drug-induced LE react with H2A-H2B dimer. Patients with idiopathic LE also have antihistone antibodies that react with these antigens and with other classes of histones. ² Commercial EIAs do not identify antihistone antibodies with H2A-H2B reactivity exclusively, and the results cannot be relied on to distinguish drug-induced from idiopathic LE. |
| Anti-Jo 1 antibodies occur in patients with myositis with a frequency that approaches 20%. ¹ | Jo-1 protein is a member of the amino-acyl tRNA synthetase family. Anti-Jo1 antibodies are specific for myositis but occur in a minority of patients with this CTD. Myositis is a heterogeneous disease, and anti-Jo-1 antibodies identify a subset of patients who frequently have symmetrical polyarthritis and pulmonary fibrosis. ² |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Tests for autoantibodies to specific nuclear antigens are performed to define the specificities of antibodies present in sera that test positive on the generic ANA test.¹</p> | <p>Several of the specific antinuclear autoantibodies have strong associations with individual CTDs or are prognostic indicators.^{1,2} Tests for any of the antibodies listed below are not useful if the test for generic ANA is negative.</p> |

The test for generic ANA is the most commonly performed screening test for autoantibodies in patients suspected of having a connective tissue disease (CTD). ANAs occur in both systemic and organ-specific autoimmune diseases. A positive ANA is common in CTD, especially lupus erythematosus for which a positive ANA is a diagnostic criterion. Positive ANAs occur with variable frequency in other CTDs, including rheumatoid arthritis, scleroderma, Sjogren syndrome, mixed connective tissue disease, CREST syndrome, and myositis. A positive ANA result (≥ 160 titer or ≥ 3 U) is consistent with the diagnosis of a CTD and indicates an increased likelihood of finding a specific autoantibody on second order testing.¹

Anti-self-reactivity is an essential feature of the immune system, and low levels of autoantibodies to nuclear antigens are not necessarily an indication of disease. Weakly positive results occur in up to 20% of healthy women aged >40 yr. For purposes of testing in a diagnostic algorithm, it is not indicated to test for specific autoantibodies in sera that give weakly reactive ANA results. IFA and EIA methods are comparable for diagnostic purposes in most clinical situations. Patterns of nuclear fluorescence observed by IFA are not specific for common autoantibodies except centromere (CREST syndrome). As an indicator of disease activity it is not useful to repeat the test for generic ANA in patients with known diagnoses of CTD.²

DIAGNOSTIC INFORMATION

REMARKS

Measurement of antiphospholipid antibodies is useful in the evaluation of patients with thrombosis or possible antiphospholipid syndrome (APS), including patients with unexplained thrombosis, recurrent pregnancy loss (usually in the second or third trimester) or thrombocytopenia. APS may account for up to 20% of cases of deep venous thrombosis and up to 33% of strokes in patients <50 y. The diagnosis of APS requires the demonstration of positive or strongly positive tests for IgG or IgM antiphospholipid antibodies on 2 or more occasions at least 6 wk apart in an immunoassay for β_2 -glycoprotein 1 dependent antibodies.¹

Antiphospholipid antibodies react in vitro with a non-covalent complex formed from negatively charged phospholipid and β_2 -glycoprotein 1.¹ Several anionic phospholipids, including cardiolipin and phosphatidylserine, have been used as reagents in immunoassays to detect these auto antibodies. Accordingly, the antibodies may be named with reference to the phospholipid antigen, e.g. anticardiolipin antibodies. Antiphospholipid antibodies have specificity for one or more of the 5 antigenic domains of β_2 -glycoprotein 1, a 37 kDa protein. These antibodies produce prolongation of phospholipid dependent coagulation tests in vitro, so called lupus anticoagulant activity; and they promote binding of β_2 -glycoprotein 1 to platelets and endothelial cells which may promote thrombosis in vivo.²

Hereditary α_2 -antiplasmin deficiency is associated with a severe bleeding tendency (homozygous) or mild or asymptomatic disorder (heterozygous).

Acquired α_2 -antiplasmin deficiency may be seen in liver disease, DIC, thrombolytic therapy, nephrotic syndrome, amyloidosis, or cancer.

Antiplasmin is a component of the fibrinolytic system and serves mainly as a physiologic inhibitor of plasmin. Hereditary deficiency of antiplasmin is rare and is classified as type I (quantitative: decreased antigen and functional levels) and type II (qualitative: normal antigen levels but decreased functional levels).

Homozygotes have severe hemorrhagic manifestations. Heterozygotes, typically with a 30-50% reference range, may have a mild bleeding disorder.

α_2 -Antiplasmin levels increase with age. Estrogen from oral contraceptives or pregnancy may also increase plasma concentrations.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Anti-Scl 70 antibodies occur in patients with scleroderma (systemic sclerosis) with a frequency that approaches 60% when tests are performed by EIA. ¹ | Scl-70 (topoisomerase 1) is a 70 kDa protein antigen. Anti-Scl 70 autoantibodies are specific for scleroderma and are associated with extensive cutaneous disease and an increased risk of interstitial pulmonary fibrosis. ² |
| Anti-Sm antibodies occur in patients with LE. The frequency of finding anti-Sm antibodies varies with technique, approaching 30% when tests are performed by EIA. ¹ | Sm is a small nuclear ribonucleoprotein comprising several protein antigens that vary in size from 11-26 kDa complexed to snRNAs. The proteins are designated B, B', D, E, F, and G. Most commercial EIAs do not test specifically for anti-Sm but detect anti-Sm in combination with anti-U1RNP (so-called Sm/RNP reactivity). Specific anti-Sm reactivity is inferred from the finding of a positive result for Sm/RNP with a negative result for U1RNP. |
| Anti-SSA/Ro antibodies occur in patients with CTDs, including Sjogren syndrome, lupus erythematosus (LE), and rheumatoid arthritis. ¹ | SSA/Ro is a saline extractable nuclear antigen comprising protein antigens of 52 and 60 kDa. Presence of anti-SSA/Ro is associated with an increased risk of neonatal LE and congenital complete heart block in infants born to mothers with LE. ² Anti-SSA/Ro is also associated with features of extraglandular inflammation, including vasculitis, purpura, cytopenias, and adenopathy in patients with LE and other CTDs. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| Anti-SSB/La antibodies occur in patients with CTDs, including Sjogren syndrome and LE. Anti-SSB/La antibodies are somewhat less common than anti-SSA/Ro in these diseases. ¹ | SSB/La is a saline extractable nuclear antigen comprising a 47 kDa protein antigen. This autoantibody is rarely found in the absence of anti-SSA/Ro. |

↓ Hereditary deficiency, consumption (thrombosis, DIC, surgery), decreased production (liver disease, L-asparaginase treatment), proteinuria (nephrotic syndrome), and elevated estrogen levels (oral contraceptives, pregnancy).

Antithrombin deficiency, hereditary or acquired, may be associated with an increased risk of thrombosis. Hereditary deficiency is classified as type I quantitative (antigenic) and type II qualitative (functional). Different methods are available to measure antigenic or functional deficiency.

The functional assays may be chromogenic or, less commonly, clot based. These assays are based on the reaction with either thrombin or factor Xa (different susceptibility to interferences from thrombin inhibitors such as hirudin). The antigenic assay is immunological (ELISA, immunoelectrophoresis, latex agglutination).

A screening functional assay (activity) can be done first; if abnormal, a follow-up antigenic assay can then distinguish between type I and II deficiencies.

Because of the many acquired causes of decreased antithrombin levels, an abnormal antithrombin should be repeated, ideally when known conditions of decreased AT (e.g., liver disease) are no longer present. Correlation with family history and testing of relatives may also be informative. Of note, patients with antithrombin deficiency may demonstrate heparin resistance.

↑ Acute phase reacting protein. Increased in inflammation, infection, tissue injury or necrosis, rheumatic diseases, and some malignancies. Also increased with estrogen (oral contraceptives⁷; pregnancy, especially third trimester, when levels can be two times normal⁸) and hepatic inflammation.⁹

α_1 -Antitrypsin is normally the major constituent of the α_1 -band on routine serum protein electrophoresis. It is an antiprotease that belongs to the serpin family of proteins, which includes α_1 -antichymotrypsin, α_2 -antiplasmin, plasminogen activator I, thyroxine-binding globulin, cortisol-binding globulin,

DIAGNOSTIC INFORMATION

REMARKS

↓ Deficiency states (hereditary). Manifestations include pulmonary emphysema by third or fourth decade of life, COPD, especially in smokers,³ hepatic disease (hepatitis, cholestasis, eventual cirrhosis or hepatocellular carcinoma) particularly beginning in childhood,^{3,10,11} and ulcerative neutrophilic cutaneous panniculitis.³

Decreased values can also be caused by excessive catabolism as occurs with idiopathic respiratory distress syndrome of infancy,^{12,13} neonatal hepatitis syndrome,^{12,14} and severe pancreatic^{12,15} or liver disease. Levels are also low with the nephrotic syndrome if inflammation is absent. Consequently, phenotyping studies are recommended to confirm a suspected hereditary deficiency.

angiotensinogen, protease nexin I, kallistatin, and leukocyte inhibitor.³ The inhibitory activity of α_1 -AT is against the serine proteases, including neutrophil elastase, cathepsin G, and proteinase 3 released from neutrophil leukocytes during phagocytosis.³ Most of the serum α_1 -AT is hepatic in origin, although it is also produced by other cell types, such as neutrophils, monocytes, and enterocytes.^{3,16} Because of its relatively small molecular size, it diffuses readily and is found in nearly all body fluids.¹²

More than 75 allelic variants of α_1 -AT are known that are identifiable in serum.¹⁻³ The gene for α_1 -AT is on the q arm of chromosome 14.³ More than 90% of clinically significant cases of α_1 -AT deficiency are caused by the Pi*ZZ mutation.³ A single amino acid substitution (Gly³⁴² to Lys³⁴²) appears to be the cause of the Z mutation.^{3,17} Genetic deficiency is associated with liver disease, especially in children (neonatal hepatitis syndrome and infantile cirrhosis),^{14,18} an increased risk of hepatocellular carcinoma,^{3,19} and with chronic lung disease in adults (emphysema, COPD, and chronic bronchitis, especially in smokers).²⁰

Therapeutic measures include avoidance of smoking, hepatic transplantation, and exogenous α_1 -AT.

Serum or plasma left in contact with leukocytes contaminated with bacteria may show fragmentation of this protein and on assay may give spuriously high or low values.

Indications for quantitation include a visibly diminished α_1 -band on serum protein electrophoresis, pulmonary emphysema by the third or fourth decade of life, COPD, hepatic disease in childhood, and ulcerative neutrophilic cutaneous panniculitis.

| Anti-U1RNP antibodies occur with varying frequencies in patients with several of the CTDs, especially LE and mixed connective tissue disease (MCTD). ¹ | U1RNP is a small nuclear ribonucleoprotein that contains 22, 33, and 70 kDa protein antigens complexed with U1snRNA. When found in isolation (anti-dsDNA and anti-Sm antibodies are undetectable), presence of anti-U1RNP suggests the diagnosis of MCTD. MCTD resembles LE but less frequently has renal involvement. ² |

| | |
|---|--|
| ↑ Familial hyperalphalipoproteinemia, familial cholesteryl ester transfer protein (CETP) deficiency. | Measurement of apo A-I, the major protein component of HDL particles, is useful for characterizing low HDL cholesterol concentrations in individuals and families. Apo A-I measurement may also be useful for assessing CHD risk, although there is debate as to whether apo A-I is better than HDL-cholesterol measurement. |
| ↓ Familial hypoalphalipoproteinemia, apo A-I variants (e.g., apo A-I Milano), fish eye disease, familial lecithin-cholesterol acyltransferase (LCAT) deficiency, Tangier disease, familial apo A-I deficiency (with or without apo CIII/apo A-IV deficiency), coronary heart disease, hepatocellular disorders, cholestasis, nephrotic syndrome, chronic renal failure, and malignancy. | Intraindividual variability in apo A-I measurement averages 7-8%. Apo A-I methods should be standardized using WHO/IFCC international reference materials. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ Hyperapobetalipoproteinemia (normal LDL-C and elevated apo B), familial combined hyperlipidemia, familial hypercholesterolemia, familial defective apo B-100, polygenic (sporadic) hypercholesterolemia, coronary heart disease, diabetes, hypothyroidism, nephrotic syndrome, chronic renal failure, hepatic obstruction, hepatic disease, and Cushing's syndrome.</p> <p>↓ Abetalipoproteinemia, hypobetalipoproteinemia, homozygous hypobetalipoproteinemia, hyperthyroidism, malnutrition, intestinal malabsorption, infection, and inflammation.</p> | <p>Apo B exists in two major forms, apo B-48 (synthesized in the intestine) and apo B-100 (synthesized in the liver). The assays commonly in use by clinical laboratories recognize both forms of apo B. Apo B is required for binding of LDL particles to the LDL receptor. Apo B measurement is useful to identify various lipoprotein abnormalities in individuals and families. Many studies indicate that apo B is a better marker for CHD risk than LDL cholesterol. The ratio of apo B/apo A-I also appears superior to the total cholesterol/HDL cholesterol ratio.</p> <p>One apo B molecule is present on each LDL, IDL, and VLDL particle, and therefore apo B concentration reflects the total number of atherogenic particles in the circulation. Apo B measurement is particularly useful in identifying individuals who have an increased number of small, dense LDL but normal LDL cholesterol concentrations and are at increased risk of CHD.</p> <p>Intraindividual variability in apo B measurement is ~8-10%. Apo B methods should be standardized using WHO/IFCC international reference materials.</p> |

Bloody stools containing fetal hemoglobin indicate intrinsic fetal hemorrhage, whereas bloody stools containing Hb A (adult) usually indicate swallowing of maternal blood at parturition.

The test is based on the fact that fetal hemoglobin is more resistant than adult hemoglobin to denaturation with alkali. Bloody stools caused by intrinsic hemorrhage are usually passed 1 day after birth, whereas those caused by ingestion of maternal blood are usually passed within 12 hr after birth. The test can be modified by adding the water and sodium hydroxide directly to a blood-stained diaper. More sensitive spectrophotometric methods may be advantageous.

|--|--|
| <p>↑ Acute viral hepatitis, toxic hepatitis, cirrhosis, diseases with secondary hepatic involvement (e.g., pulmonary disease, diabetes, congestive cardiac failure), post-GI surgical procedures such as cholecystectomy and gastrectomy, neoplastic diseases, and liver metastases</p> <p>↓ Genetic deficiency of ASAL, mentally deficient patients with argininosuccinic aciduria,² and some autoimmune chronic hepatitis associated with antibodies to ASAL.⁵</p> | <p>ASAL is more sensitive than ALT or AST in detecting hepatocellular disease.^{1,3} Genetic assays now exist for detecting deficiency of this and other urea cycle enzymes.^{6,7}</p> |

| | |
|--|--|
| <p>Symptoms of acute As poisoning are severe gastric pain, vomiting, and diarrhea, as well as convulsions, cardiovascular collapse, coma, and death. Symptoms of chronic As poisoning are diarrhea, pigmentation and scaling of skin, hyperkeratosis of palms and soles, hepatomegaly, hair loss, peripheral neuropathy, and Mees lines. Hematological changes in chronic arsenic poisoning include anemia, leukopenia, thrombocytopenia, basophilic stippling, disturbed erythropoiesis and myelopoiesis. Epidemiological studies suggest that arsenic is carcinogenic in humans. Experimental corroboration in animals is lacking.</p> | <p>Arsenic is found in house and garden pesticides.</p> <p>As is used as an antiparasitic agent in veterinary medicine and to treat trypanosomiasis and amebiasis in some countries. It occurs naturally in the environment and in food. As³⁺ is more toxic than As⁵⁺. Industrial exposure in the manufacture of brass, bronze, ceramics, dye, wood products, and paint may result in As intoxication. As trioxide can induce remission in patients with acute promyelocytic leukemia who have relapsed after other therapies.</p> <p>Urine is the preferred specimen if symptoms are present or in cases of acute exposure. Urine, hair, and nail clippings should be assayed in cases of chronic exposure.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>Surface contamination of hair or nails may not be completely removed by washing. Cutting washed hair into 1-cm segments and analyzing each group of segments separately can give a reliable indication of As concentration in hair versus time of exposure. Concentrations in urine or hair after acute exposure are a function of time.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| Serum–Asc albumin gradient (SAAG) ≥ 1.1 g/dL implies portal hypertension. Low Chol implies cirrhosis. | Of patients with ascites, 75% have hepatic cirrhosis, 10% have malignancies, and 5% have congestive heart failure. |
| Low Asc protein increases risk of SBP and portends a worse prognosis once it develops. ² Elevated ANC is strongly associated with SBP. | |
| Infected Asc almost always has pH < 7.35 or 0.1 units less than arterial pH. | |
| DPL with \uparrow RBC or WBC suggests intraabdominal injury. | |
| 2. Filik L, Unal S: Clinical and laboratory features of spontaneous bacterial peritonitis, <i>East Afr Med J</i> 81:474-479, 2004. | |
| <p>$\uparrow\uparrow$ Fulminant forms of acute hepatitis, especially viral hepatitis</p> <p>\uparrow Liver cell necrosis or injury of any cause, including cholestatic and obstructive jaundice, chronic hepatitis, drug-induced injury to the liver; alcoholic hepatitis (AST usually $>$ ALT); viral and chronic hepatitis (ALT $>$ AST in most cases; those in whom AST $>$ ALT have poor prognosis)¹¹; hepatic metastases and hepatoma; infectious mononucleosis; necrosis or trauma to heart or skeletal muscle; inflammatory disease of heart or skeletal muscle; after acute MI, AST $>$ ALT; severe exercise, heart failure, severe burns, Forbes' disease (children, not adults), heat stroke (mean is 20-fold normal), hypothyroidism (40-90% of cases), intestinal obstruction (may indicate infarction of small intestine), lactate acidosis, legionnaires' disease, malignant hyperthermia, postcommissurotomy syndrome, polymyalgia rheumatica, typhoid fever, thalassemia major, von Gierke's disease, and toxic shock syndrome.¹²</p> | <p>The enzyme is distributed in all body tissues, but greatest activity occurs in liver, heart, and skeletal muscle and in erythrocytes. Minimal activity occurs in skin, kidney, and pancreas.</p> <p>In blunt abdominal trauma in children, AST > 450 U/L is a good predictor of liver injury.¹³ After severe liver injury in adults, AST peaks within 24 hr and then rapidly decreases during the next 4 days. Elevations prolonged past 4 days should be investigated for a cause.¹⁴</p> <p>IgA-AST complexes are frequently found in association with liver malignancies.¹⁵</p> <p>Serum AST activity is increased on the average by $\sim 30\%$ by the addition of pyridoxal-5'-phosphate (P-5'-P) to the reagent or specimen. This increase can be even more striking for patients on chronic hemodialysis. AST values that are abnormal because of heart or liver disease are increased by preincubation of serum with P-5'-P; the effect on the heart enzyme is greater than on the liver enzyme.¹⁶ Note that addition of P-5'-P to reagent systems increases the "blank" reaction.</p> |
| Usually normal after IM injections, moderate exercise | See also <i>Aspartate Aminotransferase, Mitochondrial</i> . |
| Increased or normal in cirrhosis, neurological disease, cerebral infarction or hemorrhage, acute pancreatitis, renal infarction, hemolytic anemia, hemophilia, malnutrition, and obesity | |

↑↑ Acute liver disease, myocardial infarction; increase reflects severity of disease, organ damage, and prognosis.

The release and clearance of mAST are slower than for cAST; after infarction, mAST values reach a peak in serum later than do cAST values, and abnormal values persist longer.

↑ Chronic alcohol abuse, alcoholic hepatitis, fulminant viral hepatitis, myocardial infarction, severe heart failure, and liver injury.

Isoenzymes of AST are cAST (cytosolic form) and mAST (mitochondrial). In human liver and most other organs, mAST represents 80% of the total, but in serum it is usually <10%.¹

Most immunological methods measure residual catalytic activity of serum mAST after precipitation of cAST with specific antibody. An alternative approach involves digestion of cAST by proteinase K, which does not inactivate mAST.⁹ The kinetic assay for total AST is optimized for cAST, although substrate requirements for mAST are much higher. Furthermore, mAST is activated to a greater degree by P-5'P than is cAST, so that omission of P-5'P from reagent will underestimate the contribution of mAST to total AST activity. Alcohol can lead to expression of mAST on the surface of hepatocytes,¹⁰ a mechanism that may be responsible for the greater percentage increase in mAST in alcoholic liver disease.¹¹

↑ Congestive heart failure, cardiovascular disease with elevated cardiac filling pressure, asymptomatic cardiac volume overload, atrial pacing, paroxysmal atrial tachycardia.⁴

ANH is an endogenous antihypertensive agent secreted from the cardiac atria. This hormone enhances salt and water excretion, blocks aldosterone and renin secretion, inhibits the action of angiotensin II and vasopressin, and inhibits smooth muscle contraction. Its net effect is to decrease blood volume and reduce blood pressure.

Side-by-side studies have shown that ANP and NT-proANH are not as useful for congestive heart failure as are B-type natriuretic peptide or NT-proBNP.⁴

See *B-type natriuretic peptide and NT-proBNP*.

4. Doust JA, Glasziou PP, Pietrzak E, et al: A systematic review of the diagnostic accuracy of natriuretic peptides for heart failure, *Arch Intern Med* 164:1978-1984, 2004.

Increased concentrations of BNP and NT-proBNP occur in patients with HF.⁶ They are also increased in asymptomatic left ventricular dysfunction (LVD), arterial and pulmonary hypertension, cardiac hypertrophy, valvular heart disease, arrhythmia, and acute coronary syndrome.⁷ NPs are useful for prognosis for guiding and monitoring HF therapy.⁸ However, BNP and NT-proBNP are increased in a variety of cardiac diseases; thus the clinician has to be conscious in interpreting results. In the management of cardiology patients, clinicians need to know (1) the form of the biomarker, (2) the immunoassays used are lacking standardization, (3) the discrimination limits are dependent on age, gender, and biological variation, (4) the diagnostic time window (admission or serial sampling to obtain peak value), (5) the clinical setting (used by the general practitioner, ED, CCU, etc.), (6) the diagnostic use (early

BNP has biologic effects similar to those of atrial natriuretic peptide (ANP) and is stored mainly in the myocardium of the cardiac ventricles. Blood levels of BNP are elevated in hypervolemic states such as CHF and hypertension.⁶

Natriuretic peptides (NPs) are secreted to regulate fluid volume, blood pressure, and electrolyte balance. They have activity in both the central and peripheral nervous systems. ANP was the first described in 1981.³ BNP was discovered 7 yr later in the porcine brain.¹² However, in humans, the main source of circulatory BNP is the heart ventricles. Other members of the NP family include C-type natriuretic peptide (CNP) and urodilatin. Although these hormones are not produced by myocardium, they are released with ANP and BNP in patients with volume overload, hypertension, and hyponatremia.

DIAGNOSTIC INFORMATION

REMARKS

and/or late, rule-in, rule-out, definitive for ACS, CHF, LVD [diastolic or systolic dysfunction], asymptomatic LVD, etc.), prognostic use (importance of increased level at admission, peak-value, risk stratification), or for therapeutic guidance (titration of therapies of the biomarkers used), (7) possible confounding diseases, and (8) biological variability. The BV indicate a change of 130% for BNP and 90% for NT-proBNP is necessary before results of serially collected data can be considered statistically significant.^{9,10}

There are no primary reference materials to standardize BNP assays, and different antibodies are used that detect different forms of NPs.

Clinical laboratory testing in the setting of CHF focuses on several goals: (1) to determine the cause of diagnostic symptoms, (2) to estimate the degree of severity of heart failure, (3) to estimate the risk of disease progression and risk, and (4) to screen for less symptomatic disease.¹¹

The NPs should be tested to (1) to confirm HF in patients presenting with ambiguous clinical features or confounding pathology etiologies, such as chronic obstructive pulmonary disease, (2) to assist/improve the diagnostic accuracy for HF, and (3) assist in ruling out HF with a normal NP. However, plasma NPs testing in patients with obvious HF (e.g., NYHA class IV) is not necessary. The NPs are “not a stand-alone diagnostic test”; it must be used and interpreted with regard to the clinical presentation, specifically pertaining to the age and gender of the patient.

ANP and BNP are released in response to atrial/ventricular stretch from volume overload, wall tension, and myocardial stretching. Blood NPs increase in all diseases with volume overload, including renal and liver diseases, as well as some endocrine disorders (e.g., Cushing’s, primary hyperaldosteronism).¹³ NPs increase cardiac output by decreasing systemic and pulmonary vascular resistance. Additionally, NPs reduce production of renin and aldosterone by increasing renal blood flow, GFR, and urine output. Overall, NPs regulate blood pressure and volume status. They also have direct effects on the myocardium interstitium.

BNP synthesis mostly relies primarily on gene expression and initial up-regulation of mRNA.

DIAGNOSTIC INFORMATION

REMARKS

Toxicity from beryllium exposure is latent; symptoms develop from inhalation of or contact with Be salts or metal dust. Potentially reversible symptoms of acute toxicity include eye ulcers and inflammation of the lungs, airways, and skin. Other acute responses are hyperemia, edema, hemorrhage with mild edema of the brain, liver inflammation, and focal hemorrhage of the spleen. Chronic inhalation will lead to berylliosis. Beryllium can enter the bloodstream through the lungs and will cause cellular death in tissues in which it accumulates. Beryllium toxicity has been associated with an increased incidence of pulmonary cancers.

Beryllium exposure is an industrial hazard for workers in metal extraction and refining plants; exposure to Be may occur near rocket bases or nuclear plants, or where coal is burned extensively. Urinary excretion is variable in exposed workers and does not correlate well with beryllium disease. Be disease diagnosed on history of exposure, finding of noncaseating granulomas in lung, and T lymphocytes sensitized to Be obtained from blood or lavage fluid.⁵

↑ Compensated respiratory acidosis, metabolic alkalosis

↓ Metabolic acidosis, compensated respiratory alkalosis

See also *Carbon Dioxide, Total*.

Bicarbonate can be determined directly by titration, but this is rarely done. Bicarbonate is generally calculated using the Henderson-Hasselbalch equation or a nomogram based on this equation.

$$\text{HCO}_3^- = \text{Total CO}_2 - \text{H}_2\text{CO}_3$$

Small amounts of CO_3^{2-} and carbamino compounds present in plasma are customarily included in this fraction.

The HCO_3^- is the largest fraction contributing to the total carbon dioxide. Therefore both parameters change usually in the same direction.

The standard bicarbonate is the concentration of bicarbonate in whole blood at 38° C equilibrated at a PCO_2 of 40 mm Hg [5-32 kPa] with the blood Hb fully oxygenated.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ GI bacterial overgrowth associated with stasis, ileal dysfunction (disease, bypass, or surgical resection)</p> <p>The bile acid breath test does not differentiate bacterial overgrowth from ileal damage or resection. This creates clinical difficulties because bacterial overgrowth may be superimposed on ileal damage in conditions such as Crohn's disease, lymphoma, and radiation enteritis. False-negative results have been described in 30-40% of patients with culture-proven overgrowth.⁵ An alternative version of the test uses ursodeoxycholic acid conjugated to <i>p</i>-aminobenzoic acid and measures urinary excretion of hippurate. Results of the two versions are often discordant in bacterial overgrowth, suggesting that use of both methods may be helpful.⁶</p> | <p>This is a rapid, simple outpatient procedure in which values are elevated 10-fold with increased bacterial bile acid deconjugation. Fecal radioactivity measurement permits separation of bile acid malabsorption from bacterial overgrowth and will also identify patients with a negative breath test despite bile acid malabsorption.¹</p> <p>The ¹⁴C-D-xylose breath test is the test of choice to detect bacterial overgrowth.⁵ See <i>¹⁴C-D-Xylose Breath Test</i>.</p> |

Determination of the ratio of cholyglycine to chenodeoxycholyglycine may be of diagnostic value because ~80% of patients with hepatocellular disease have a ratio <1, whereas ~80% of patients with cholestatic disease have a ratio >1.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| AF ↑ Erythroblastosis, maternal infectious hepatitis, maternal sickle cell crisis | Positive interference by moderate amounts of hemoglobin can be mathematically corrected. ² |
| S ↑ Intrahepatic and extrahepatic biliary tree obstruction, hepatocellular damage (especially late in the disease process), cholestasis (for drugs causing cholestasis, see Table II-5), Dubin-Johnson syndrome, Rotor's syndrome | <p>The portion of bilirubin detected with traditional methods consists of conjugated and δ-bilirubin, and a small fraction of unconjugated bilirubin. Typically, 70-90% of conjugated and δ-bilirubin react directly. The proportion of unconjugated bilirubin that reacts directly is increased by exposure to light,¹⁷ alkaline pH, presence of detergent or other surfactants,¹⁸ and varies widely from one method to another in proficiency surveys,¹⁹ probably related to matrix effects.²⁰</p> <p>Normal adults have very low conjugated bilirubin levels, usually <0.1 mg/dL [<1.7 μmol/L] (lower limit of detection).</p> <p><i>Vitros</i>: Because conjugated bilirubin measured by this method does not include the δ-fraction as does the direct bilirubin, conjugated bilirubin is a better indicator than direct bilirubin during the resolving phase of hepatic and cholestatic disorders.²⁰</p> |
| S ↑ Hemolytic disorders or those associated with breakdown of hemoglobin such as large resolving hematomas; convalescent phase of acute hepatitis and sepsis; transient neonatal hyperbilirubinemia, Gilbert's syndrome, Criglar-Najjar syndrome, and ineffective erythropoiesis as seen in B ₁₂ and folate deficiencies and cirrhosis. ^{12,13} | Unconjugated bilirubin is measured by the same slide (by differential light absorption) as conjugated bilirubin but is not reported by many laboratories and is used only in the calculation of δ -bilirubin. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>S ↑ Hepatobiliary disorders; may remain elevated after conjugated and unconjugated bilirubin have returned to normal. Thus conjugated bilirubin is a better indicator during resolution of disease than direct or total bilirubin.¹⁴</p> | <p>This derived test (total bilirubin minus conjugated plus unconjugated bilirubin) should not be calculated on neonatal patients (<14 days).</p> <p>δ-Bilirubin is a form of bilirubin that is covalently bound to albumin. It has a longer half-life than other forms of bilirubin; thus it remains elevated during the convalescent phases of hepatic disorders when the conjugated and unconjugated bilirubin have already begun to decline or have returned to normal.²¹</p> |

|---|---|
| <p>Clinical use in detecting bladder cancer recurrence. Monitoring sensitivity of 57-83% and specificity of 68-72% for BTA <i>stat</i> and sensitivity of 66-78% and specificity of 50-75% for BTA TRAK.¹</p> <p>Positive result or elevated values observed with renal stones, nephritis, urinary tract infections, cystitis, renal cancer, and recent bladder or urinary tract trauma, including cystoscopy.</p> | <p>The antigen in bladder tumor–associated antigen detected in the BTA <i>stat</i> and TRAK assays is human complement factor H–related protein (hCFHrp), which has similarity to human complement factor H (hCFH), also detected in the assays. hCFH functions in the alternative complement pathway by interacting with complement factor C3b to prevent cell lysis. Bladder tumor–associated antigen may allow tumor cells to evade the host immune system.</p> <p>The qualitative point-of-care BTA <i>stat</i> assay (Bion Diagnostic Sciences, Inc., Cortlandt Manor, NY) is an immunochromatographic assay utilizing two monoclonal antibodies to hCFHrp. The quantitative BTA TRAK assay has an EIA format. Both tests have FDA-approved indications for use as an aid in the management of bladder cancer patients in conjunction with cystoscopy.</p> |

↑ Platelet function disorder, both hereditary (Glanzmann's thrombasthenia, Bernard-Soulier syndrome, storage pool disorder) and acquired (uremia, paraprotein, drugs), von Willebrand's disease, thrombocytopenia, and vascular abnormalities such as Ehlers-Danlos syndrome.

The bleeding time measures overall platelet function. It is neither a sensitive nor a specific test, and its use has overall declined with time.

The BT is subject to many variables (constant blood pressure, length of incision, blotting technique). Only experienced individuals should perform the test; ideally the same individual/team should do the test for consistency.

Although the BT time may be informative in evaluating a patient with a bleeding history, it should not be used as a perioperative screening test in an individual without a history of bleeding.

The original BT was known as the Duke BT, in which the earlobe was pierced. Subsequent modifications include the Ivy BT and the template methods (Surgicutt and Simplate). In both methods a blood pressure cuff is used on the upper arm and inflated to 40 mm Hg to increase capillary pressure in the forearm, and either a puncture wound (Ivy) or a linear incision (template) is made in the forearm.⁵

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ TBV</p> <p>Polycythemia vera, pulmonary disease, severe starvation, acidosis, thyrotoxicosis, vasodilatation, cardiac failure, overhydration, renal insufficiency, congenital cardiac disorders, pregnancy, recumbent posture, athletes</p> | <p>Determination of TBV by laboratory methods is rarely indicated in clinical medicine, including hemapheresis.³ Usually estimation from nomograms or mathematical formulas suffices.</p> |
| <p>↓ TBV</p> <p>Hemorrhage, burns, severe anemia, pheochromocytoma, chronic infection, chronic azotemia, vomiting, diarrhea, dehydration, salt deficiency, diabetes, starvation, old age, bed rest, exercise, cold, standing, apprehension, obesity (fat is relatively avascular)</p> | <p>If accurate determination of the TBV is critical, calculation from the sum of measured red cell and plasma volumes is the recommended method. In this approach a disproportionate high white cell count may underestimate the true TBV.</p> <p>The alternative method of calculating TBV from RCV and Hct uses a correction factor (0.9) to account for the mean Hct difference between whole-body and venous Hct.</p> |

$$TBV = \frac{RCV}{0.9 \times Hct}$$

The Hct difference in individuals varies widely around this mean, both in healthy persons and in disease states, most notably in splenomegaly (↑) and, to some extent, in severe anemia (↓). At Hct >55% [>0.55], this method underestimates TBV. When TBV is based on total body water or lean body mass (instead of body weight), there is no difference between the values for obese and lean persons.

| | |
|--|---|
| <p>Orally administered borate is rapidly distributed throughout body water, is not metabolized, and has an elimination half-life of 21 hr.</p> <p>Dermal absorption of borate is minimal and significantly less than dietary exposure.²</p> | <p>Boric acid and sodium borate are used in cleaning agents, preservatives, and fungicides. Serum boric acid levels correlate poorly with development of symptoms in acute, single ingestions.³</p> <p>The NOAEL and LOAEL for borate are 55 and 7 mg/kg/day, respectively.</p> <p>See Table II-6.</p> |

Ozelik H, Glendon G: *BRCA1* and *BRCA2*: genes that predispose to breast and ovarian cancer. In Diamandis EP, Fritsche HA, Lilja H, et al, editors: *Tumor markers. Physiology, pathobiology, technology, and clinical applications*, Washington DC, 2002, AACC Press.

DIAGNOSTIC INFORMATION

REMARKS

BRCA1 and *BRCA2* are tumor suppressor genes that function in DNA damage repair and transcriptional regulation. *BRCA1* and *BRCA2* are located on chromosomes 17q21 and 13q12.3, respectively, and are inherited in an autosomal-dominant fashion.¹ Germline mutations in these genes result in a predisposition to breast and ovarian cancers, and these mutations account for the majority of families with hereditary susceptibility to breast and ovarian cancer. *BRCA2* is associated with male breast cancer and may be associated with prostate and pancreas cancers.^{2,3}

Hereditary breast cancer accounts for 5-10% of all breast cancer cases, and approximately 10% of epithelial ovarian cancers are related to genetic mutations. *BRCA1* and *BRCA2* mutation carriers have an estimated lifetime risk of breast cancer ranging from 55-85% compared with a lifetime risk of 13% in the general population. Founder mutations, exhibiting specific patterns, have been identified in the Ashkenazi Jewish population and in other populations including those in Iceland and the Netherlands.^{1,2,4}

Candidates for *BRCA1* and *BRCA2* testing include probands at high risk for *BRCA1* or *BRCA2* cancer-predisposing mutations or at-risk relatives of an individual with an identified mutation. Genetic counseling for risk assessment and test interpretation, taking into account family history, is part of the pretesting and posttesting process.^{4,5} Typically, testing is performed on genomic DNA isolated from peripheral blood lymphocytes. Testing for mutations in *BRCA1* and *BRCA2* includes sequence analysis and mutation analysis. Comprehensive analysis (Myriad Genetics, Inc., Salt Lake City, UT) includes full *BRCA1* and *BRCA2* gene sequencing and detection of five genomic rearrangements of the *BRCA1* gene. Mutation-specific analysis (single and multisite) can include testing for specific familial mutations if a deleterious familial mutation is known or for population-specific mutations such as the three common mutations associated with Ashkenazi Jewish ancestry. Sites performing testing can be found at www.genetests.org.^{2,5,6}

|--|--|--|--------------------|--|
| C-Peptide ¹⁻⁵ | Serum, fasting. Store at −70° C. Stable for 30 days when frozen. | 0.78-1.89 ng/mL ² × 0.333* | [0.26-0.63 nmol/L] | ↑ V Chloroquine, danazol, ethinyl estradiol, oral contraceptives |
| RIA | | *Conversion factor based on MW of C-peptide of 3000. | | |
| Immunometric assays "Chemiluminescent" | | 0.9-4.3 ng/mL | 0.28-1.42 nmol/L | ↓ Proinsulin (some assays) ↓ EDTA (15-20%) ↓ Hemolysis |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>A high fasting breath H_2 level and an increase of at least 12 ppm [12×106] within 30 min after lactulose challenge are indicative of bacterial overgrowth in the small intestine. The increase must precede the colonic response.</p> | <p>Bacterial overgrowth is defined as a jejunal culture yielding at least 105 organisms/mL.</p> <p>No antibiotics, laxatives, or enemas for 1 wk before the test.</p> |
| <p>False-positive tests can be expected in patients without overgrowth if there is accelerated gastric emptying and rapid transit of substrate to the cecum. Therefore avoid laxatives. False-negative breath tests are observed in patients receiving antibiotics and in nonhydrogen producers.</p> | <p>The test meal consists of meat and rice taken the evening before the test. Avoid foods high in fiber.</p> <p>The test originally used a glucose challenge and was reported to have a sensitivity of 93% and specificity of 78%.¹ More recent studies show sensitivities of 20-58%, specificities of 36-91%, and PPV from 63-75%.³⁻⁶ The test is questionable for routine diagnosis. The lactulose is diagnostically similar but is much easier to perform.</p> |
| <p>↑ Insulinoma, pancreas or β-cell transplants, ingestion of oral hypoglycemic drugs, renal failure, non-insulin-dependent (type II) diabetes mellitus</p> | <p>A strong correlation exists between serum levels of insulin and C-peptide. However, C-peptide is biologically inactive. Insulin does not cross-react in C-peptide assays; proinsulin may cross-react but typically contributes <1% to the C-peptide values.</p> |
| <p>↓ Factitious hypoglycemia due to insulin administration, radical pancreatectomy, insulin-dependent (type I) diabetes mellitus</p> | <p>A molar ration of C-peptide/insulin >5 in the peripheral circulation is probably due to the longer half-life of C-peptide over that of insulin in circulation (20 min vs. 5-10 min) and to the fact that C-peptide is not significantly metabolized by the liver. Unlike insulin, the majority of C-peptide is degraded in the kidney and partially excreted in the urine.</p> |
| <p>Other applications are (1) to assess β-cell function and endogenous insulin secretion in the presence of exogenous insulin or when circulating insulin antibodies preclude measurement of insulin, and (2) to facilitate the interpretation of peripheral insulin levels when hepatic insulin extraction may be variable.</p> | <p>Both C-peptide and insulin should be in same units (i.e., pmol/L) for ratio calculation.</p> |
| <p>Measurements of C-peptide before and after glucagon stimulation may be of value in assessing insulin treatment in diabetes mellitus. (See also <i>C-Peptide Stimulation Test</i>.)</p> | |

| DIAGNOSTIC INFORMATION | | REMARKS | |
|---|--|---|--|
| This test is useful when continuous assessment of β -cell function is desirable or frequent blood sampling is not practical. | | Urine C-peptide values correlate well with fasting serum levels but not with insulin secretory rate. ⁷ | |
| In subjects with diabetes mellitus, those with values >1.8 ng/mL [>0.60 nmol/L] after glucagon stimulation can often be managed without insulin treatment. | | Determines insulin secretory reserve, can help distinguish patients with T1DM from T2DM because T1DM patients will usually have low or undetectable C-peptide levels after stimulation. | |

DIAGNOSTIC INFORMATION

REMARKS

↑ Acute phase reacting protein. Rapid, marked increases occur with inflammation, infection, trauma and tissue necrosis, malignancies, and autoimmune diseases.^{2,3} Unlike other acute phase (AP) proteins, such as α 1-antitrypsin and haptoglobin, CRP is essentially unaffected by hormones (whether endogenous, as in pregnancy, or exogenous).⁷ CRP values increase very quickly and dramatically in response to stimuli, and then decrease substantially with resolution of the disorder.² Because concentrations typically increase more markedly than do those of other AP proteins, CRP is exceptionally useful in assessing the acute phase response.

Levels of CRP do not increase consistently in viral or spirochetal infections. Consequently, in the absence of other causes, very high levels may be indicative of a bacterial infection.⁸⁻¹⁰ The CRP response has been found to be particularly helpful in the neonatal period in the diagnosis of bacterial sepsis.⁸ In patients with bacterial meningitis, very high initial levels may also be predictive of neurological sequelae.¹¹ Sequential levels are valuable to monitor response to antimicrobial therapy.¹¹ Similarly, because levels are increased initially after surgery but decrease rapidly in the absence of bacterial infection, sequential levels are useful to monitor for postoperative infection.¹²

CRP levels are valuable in the clinical assessment of chronic inflammatory disorders such as rheumatoid arthritis,¹³ systemic lupus erythematosus,¹⁴ vasculitis syndromes, and inflammatory bowel disease.¹⁵ Therapeutic nonsteroidal antiinflammatory medications decrease the CRP response.¹⁶

↓ No deficiency states have been identified.¹⁵

C-reactive protein (CRP) is a member of the pentraxin protein family.² Hepatic secretion is stimulated in response to inflammatory cytokines such as interleukin 6 (IL-6).² CRP is believed to have a role in the innate immune response. CRP activates the complement system, binds to Fc receptors, and serves as an opsonin for some microorganisms.² In a calcium-dependent mechanism, it has been shown to bind pathogens such as *Haemophilus influenzae*, *Leishmania donovani*, and the C-polysaccharide of the pneumococcal cell wall.² Evidence suggests that CRP may also have a role in the clearance of nuclear antigens and damaged cell membranes.^{2,18}

It binds phosphatidylcholine on damaged cell membranes,^{2,17} exposed chromatin,^{2,18} and small nuclear ribonucleoproteins (snRNPs), which may be involved in autoimmunity.^{2,19} CRP is actively transported into cell nuclei.² Studies in mice have demonstrated a protective effect against the development of autoimmunity^{2,20} and the lethal effects of infection.^{2,21}

High sensitivity measurements of CRP are useful in assessing vascular inflammation and cardiovascular risk stratification.³ Studies indicate that CRP may be involved in the atherogenesis,³⁹³ and elevated levels can decrease endothelial cell expression and activity of nitric oxide synthase.^{3,21} CRP level has been shown to be an independent risk factor for atherosclerotic disease, and increases predicted are associated with increased cardiovascular morbidity and mortality in patients with coronary artery disease.³

There is a good correlation with the erythrocyte sedimentation rate (ESR), but CRP appears and disappears earlier than changes in ESR.

Acute exposure from inhalation (industrial settings) results in acute respiratory symptoms including pulmonary edema, proliferative interstitial pneumonia, and cardiovascular collapse; permanent lung damage may occur. Cd can be ingested from food stored or prepared in cadmium-plated containers. Acute poisoning from ingestion results in a sudden onset of violent GI symptoms within 30 min after eating. Chronic ingestion results in severe osteomalacia and Fanconi-like renal dysfunction. OSHA recommends three laboratory tests to monitor exposure to cadmium: whole blood cadmium, urine cadmium, and urine β_2 -microglobulin (β_2 -M). (See Table II-12, for 1999 revised standard.)

Cd accumulates in tissue, concentrating primarily in the kidney and liver. More than 95% of blood Cd is in erythrocytes. Smokers have higher blood cadmium levels than nonsmokers. See Table II-12 for OSHA-recommended action levels for workers exposed to cadmium.

See Table II-6.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Medullary thyroid carcinoma (MTC); C-cell hyperplasia; in some patients with carcinoma of lung, breast, or pancreas; Z-E syndrome; pernicious anemia; chronic renal failure; pseudohypoparathyroidism; tumors of APUD cells; carcinoid syndrome; alcoholic cirrhosis; patients with pancreatitis and thyroiditis.</p> <p>Elevations may be observed in pregnancy and benign diseases of the lung. Calcitonin may also be ectopically produced by numerous cancers, particularly those of a neuroendocrine nature.⁹</p> <p>Test is useful in monitoring response to therapy and predicting recurrences of disease in individuals with medullary thyroid carcinoma; it is also useful as a screening test for family members of patients with medullary carcinoma (20% of these cancers have a familial pattern).^{10,11}</p> | <p>Calcitonin is a peptide hormone produced by the perifollicular C cells of the thyroid gland. Its physiologic function is as an antagonist of parathyroid hormone to inhibit osteoclastic bone activity and to decrease serum calcium. It is a 32-amino acid chain with an MW of 3400.</p> <p>Values for healthy subjects vary depending on the particular immunoassay used. CT levels decrease gradually with age but increase during pregnancy and lactation. Values in serum are higher than in plasma. Clinically the test is useful as a tumor marker for MTC, especially in following patients with the disease or screening asymptomatic relatives of MTC patients. About 10% of cases appear as a component of multiple endocrine neoplasia (MEN) type IIA or IIB. Some patients may have normal or borderline elevated basal calcitonin values; in these cases provocative agents such as pentagastrin or calcium may be used to stimulate calcitonin secretion and demonstrate the abnormalities [see <i>Calcitonin Stimulation Test (after Calcium Infusion)</i> and <i>Calcitonin Stimulation Test (after Penta-gastrin)</i>].</p> |
| <p>↑ Medullary thyroid carcinoma (MTC)</p> | <p>Test is not needed for patients with diagnostically high basal calcitonin (CT). It is most useful in screening family members of patients with familial medullary carcinoma. In patients with MTC, maximum responses usually occur within 2 min after pentagastrin injection; a 5- to 36-fold increase in calcitonin over basal values is typically produced. In patients with elevated calcitonin levels and nonthyroidal malignancies, responses after pentagastrin are not as vigorous.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|--|
| | <p>For the detection and management of MTC, pentagastrin is considered by some to be the provocative agent of choice. Side effects of pentagastrin (e.g., nausea, headache, epigastric and chest discomfort) are common but usually very brief. A few patients with MTC, however, do not respond to pentagastrin, and a calcium infusion test—alone or in combination with pentagastrin—may also be needed. [See <i>Calcitonin Stimulation Test (after Calcium Infusion)</i>.] In some cases it may be necessary to carry out these stimulation tests over a period of months or years to confirm or rule out a diagnosis.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Medullary thyroid carcinoma, pseudohypoparathyroidism</p> | <p>Regardless of age, increase in calcitonin (CT) in response to Ca infusion is greater in men than in women, but basal levels of CT and the response to Ca wane with age in both sexes. The 4-hr calcium infusion test (15 mg Ca/kg) can be unpleasant for patients (e.g., causing fatigue, nausea, vomiting) and is no longer routinely used. A 10-min calcium infusion test (3 mg/kg) is also available, but the 1-min infusion is commonly employed. This short test is relatively free of side effects. A combined calcium-pentagastrin infusion test is considered by some to be more effective and reliable than either pentagastrin or calcium infusion alone.</p> |
| <p>↑ Primary hyperparathyroidism, PTH-producing tumors, excess intake of vitamin D, various malignancies (elevations may be seen even when total Ca is normal)</p> <p>↓ Primary hypoparathyroidism (both Ca fractions), pseudohypoparathyroidism, vitamin D deficiency, magnesium deficiency; after transfusions with blood containing anions that complex free Ca (e.g., citrate); after major surgery, trauma, sepsis, burns, pancreatitis, multiple organ failure; after hemodialysis with low-calcium dialysate; alkalemia or increases in ionic strength (e.g., increased Na)</p> <p>See also <i>Calcium, Total</i>.</p> | <p>Test is useful in determining the “physiologically active” or free Ca level in patients with altered proteins (chronic renal failure, nephrotic syndrome, malabsorption, multiple myeloma) and in disturbances of acid-base metabolism. Ionized Ca values reflect Ca metabolism better than total Ca values, and many clinicians prefer CaI over total Ca for evaluating Ca abnormalities. A significant decrease in CaI regardless of total Ca level may lead to an increase in neuromuscular irritability and thus to tetany.</p> <p>Differences in specimen preparation and electrode selectivity are probably responsible for differences in reported reference ranges. Heparin itself causes a 0.04 mg/dL [0.01 mmol/L] decrease in CaI for each unit added per milliliter of blood. Adjusting the pH of the specimen to pH 7.4 at the time of measurement is not necessary if the specimen is collected anaerobically.</p> <p>Various formulas are available for calculating CaI using total calcium, total protein, and albumin values. However, these formulas may not apply in some situations; their use is discouraged.¹⁴</p> |

| | | | | S ↓ V Albuterol, alprostadil, aminoglycosides (e.g., gentamicin), asparaginase, barbiturates in elderly, calcitonin, carbamazepine, carbenoxolone, carboplatin, corticosteroids; diuretics (initial effect) including acetazolamide, ethacrynic acid, furosemide, ergocalciferol, gastrin, glucagons, glucose, indapamide, insulin, isoniazid, laxatives (excessive use), magnesium salts, methicillin, phenytoin, phosphates, plicamycin, saline (effect of isotonic solution in hypercalcemia), tetracycline (in pregnancy) |
| | | | | S ↓ C Fluorides, oxalate, protein (with AAS unless added to standards), sulfates |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>S ↑ Primary and tertiary hyperparathyroidism, malignant disease with bone involvement (in particular metastatic carcinoma of the breast, lung, kidney, multiple myeloma, lymphomas, and leukemia), malignant diseases without bone involvement (particularly in squamous cell carcinoma of lung, carcinoma of kidney), malignant neoplasms of esophagus, pancreas, bladder; malignant neoplasm of liver, polycythemia vera, pheochromocytoma (associated parathyroid hyperplasia), sarcoidosis, vitamin D intoxication, milk-alkali syndrome, Paget's disease with immobilization, thyrotoxicosis, acromegaly, diuretic phase of acute tubular necrosis, "idiopathic" hypercalcemia of infancy, dehydration (e.g., from vomiting, diarrhea, alcohol), familial hypocalciuric hypercalcemia, iatrogenic hypercalcemia</p> <p>S ↓ Idiopathic, surgical, or congenital hypoparathyroidism; pseudohypoparathyroidism; vitamin D deficiency (in particular nutritional malabsorption); chronic renal failure; magnesium deficiency; prolonged anticonvulsant therapy; acute pancreatitis; hyperphosphatemia; massive blood transfusion; leprosy; anterior pituitary hypofunction; cystinosis; osteomalacia (advanced disease); proximal and distal renal tubular disease; alcoholism; hepatic cirrhosis; hypoalbuminemia; neonatal prematurity; inadequate nutrition</p> | <p>The lowest values are observed at 2:00-4:00 AM and the highest at 8:00 PM. Concentrations of Ca vary with age and are highest in the neonatal period. There is a gradual decrease of Ca levels in males >50 yr. Upright position for 15 min causes an increase of 4-7% in Ca level (minimal change in ionized calcium, CaI). Total serum Ca level is altered by changes in protein concentration. A change of 1 g/dL [10 g/L] of protein (albumin) corresponds to a parallel change in total Ca concentration of ≤ 0.8 mg/dL [≤ 0.2 mmol/L]. False elevations of serum Ca are caused by venous stasis during collection and by prolonged storage of blood. Use carefully prepared syringes, containers, and glassware for blood collection because Ca soaps adhere to glass. Repeated determinations of serum Ca should be made for diagnosis of hyperparathyroidism; at times the total Ca is normal and the CaI is elevated. Tetany may occur if total serum Ca is < 6.0-7.0 mg/dL [1.50-1.75 mmol/L]; in both metabolic and respiratory alkalemia, tetany may occur with normal serum total Ca level (but low CaI).</p> <p>See also <i>Parathyroid Hormone</i> and Figure II-3.</p> |

| AAS | Feces | 420-560 mg/day $\times 0.025$ [10.5-14.0 mmol/day] | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>U ↑ Increased exposure to sunlight, hyperparathyroidism, osteolytic bone metastases (carcinoma, sarcoma), myeloma; osteoporosis (especially after immobilization, in Cushing's syndrome, in acromegaly), vitamin D intoxication (hypercalciuria occurs in many cases before serum Ca increases), distal renal tubular acidosis, idiopathic hypercalciuria, thyrotoxicosis, Paget's disease, Fanconi's syndrome, hepatolenticular degeneration, schistosomiasis, sarcoidosis, malignant neoplasm of breast or bladder, osteitis deformans, immobilization</p> <p>U ↓ Hypoparathyroidism, pseudohypoparathyroidism, rickets, osteomalacia, all cases in which serum Ca is low (other than renal disease), many cases of nephrosis, acute nephritis, malignant neoplasm in bone, osteoblastic metastases, hypothyroidism, celiac sprue disease, steatorrhea, hypocalciuric hypercalcemia</p> | <p>Values in both healthy and sick individuals span a wide range. Calcium and protein intake and phosphate excretion alter urinary Ca excretion. Urine Ca decreases in late normal pregnancy. About one third of hyperparathyroid patients have normal urine output. Test has little practical value in differential diagnosis.</p> <p>The rate of Ca excretion can also be expressed as a calcium/creatinine ratio. In healthy individuals with constant muscle mass, urinary Ca (mg/dL)/Cr (mg/dL) is usually 0.14 [$\text{Ca}(\text{mmol/L})/\text{Cr}(\text{mmol/L}) = < 0.40$]. Values > 0.57 (mmol/L units) or > 0.20 (mg/dL units) suggest hypercalciuria.</p> <p>In cases of hypercalciuria, e.g., Ca > 350 mg/day [> 8.75 mmol/day], some investigators collect a 2-hr urine sample after a 12-hr fast to determine whether a decrease in dietary Ca changes the hypercalciuria. In absorptive hypercalciuria (i.e., too much Ca from GI absorption), values < 20 mg Ca/2 hr [< 0.50 mmol/2 hr] are found. In nonabsorptive hypercalciuria, > 30 mg Ca/2 hr [> 0.75 mmol/2 hr] suggests some other problem such as hyperparathyroidism.¹³</p> |
| See <i>Calcium, Ionized</i> . | <p>Values correlate very closely with serum ionized Ca concentrations. CSF does not reflect serum Ca changes in hypoparathyroidism. Increases in total and ionized CSF calcium appear in conditions in which the CSF protein is also increased.</p> |
| | <p>Values for fecal excretion assume an average Ca intake of 700 mg/day [17.5 mmol/day] and net absorption of 20-40%.</p> |

In hyperparathyroidism, no response.

A marked decrease will be observed in hypercalcemia secondary to sarcoidosis, vitamin D intoxication, breast cancer and myeloproliferative disorders, hypercalcemia due to immobilization, and Addison's disease. Patients with metastatic tumors or nonmetastatic malignant disease show a variable response.

Correction of hypercalcemia generally rules out primary hyperparathyroidism. Because fluid retention may produce some decrease in serum Ca, correction for protein concentration should be made. Because of the general availability of other diagnostic tests such as PTH and vitamin D metabolites, this test is rarely used.

S ↑ In ~80% of women with metastatic breast cancer. Test may be useful to predict recurrence of disease and to evaluate response to therapy. The clinical sensitivity is 0.60, the specificity 0.87, and the positive predictive value 0.91. In addition to breast cancer, elevated concentrations also found in pancreas, lung, ovarian, colorectal, and liver cancers and in benign liver and breast diseases.^{1,3-5}

CA 15-3 is a mucin-type high-molecular-weight glycoprotein, localized to the apical side of alveoli and ducts of mammary glands, and is present as a circulating antigen. The test utilizes two antibodies (Fujirebio Diagnostics, Inc., Malvern, PA), 115D8 raised against antigens of human milk fat-globule membranes and DF3 prepared against a membrane-enriched fraction from a human breast cancer cell line. CA 15-3 FDA indications are for serial testing in conjunction with other clinical and diagnostic procedures as an aid in the early detection of recurrence in previously treated stage II and III breast cancer patients and for monitoring response to therapy in metastatic breast cancer patients. Considered equivalent to the CA 27.29 mucin marker.

S ↑ In approximately 75% of women with metastatic breast cancer. Test may be useful to predict recurrence of disease and to evaluate response to therapy.^{1,3} The clinical sensitivity is 57.7%, the specificity 97.9%, the positive predictive value 83.3%, and the negative predictive value 92.6% for detecting recurrence in patients with stage II and III disease. In addition to breast cancer, elevated concentrations also found in pancreas, lung, ovarian, colorectal, and liver cancers and in benign liver and breast diseases.⁴

CA 27.29 (BR 27.29) is a mucin-type high-molecular-weight glycoprotein, localized to the apical side of alveoli and ducts of mammary glands, and is present as a circulating antigen. The competitive CA 27.29 assay utilizes the B27.29 monoclonal antibody generated against the 20 amino acid tandem repeat backbone of the MUC-1 mucin core. The B27.29 reactive sequence overlaps with one of the two antibodies (DF3) in the CA 15-3 tumor marker assay.²

CA 27.29 FDA indications are for serial testing in conjunction with other clinical and diagnostic procedures as an aid in the early detection of recurrence in previously treated stage II and III breast cancer patients and for monitoring response to therapy in metastatic breast cancer patients. CA 27.29 is considered equivalent to the CA 15-3 mucin marker.

A greater percentage of patients with metastatic gastric carcinoma demonstrate elevated levels of TAG 72 compared with CEA or CA 19-9. Increased levels are not observed in benign gastric disease but are seen in >50% of patients with gastric cancers.¹ Although useful for monitoring gastric carcinoma after treatment, sensitivity is improved combining CA 72-4, CEA, and CA 19.9.²

TAG-72 is a high-molecular-weight (MW 220-1000 kDa), mucin-like, tumor-associated antigen. It is assayed with two monoclonal antibodies, CC49 prepared against highly purified TAG-72 and B72-3, which is directed against a membrane fraction from a human breast cancer cell line. The antigen is found primarily in adenocarcinomas of the gastrointestinal tract and in ovary and breast tissues. Assays do not have FDA approval for clinical use.

↑ Serous, endometrial, clear-cell, and undifferentiated ovarian carcinoma, adenocarcinoma of the endometrium or fallopian tube, some nongynecological malignancies, certain nonmalignant conditions (pregnancy, menstruation, peritoneal or pleural inflammation, ovarian cysts, endometriosis), and other cancers including those of the uterus, colorectal, liver, and lung. This test is approved by the FDA as an aid in monitoring response to therapy for patients with epithelial ovarian cancer. CA 125 was initially approved as an aid in the detection of residual ovarian cancer in women who have undergone first-line therapy and are considered for diagnostic second-look procedures. However, second-look laparotomy is now considered to be controversial. Because of lack of sensitivity and specificity, CA 125 is not approved by the FDA or recommended for screening.¹⁻³

CA 125 is a high-molecular-weight glycoprotein (MW 200,000 to >1,000,000). It was first detected with a monoclonal antibody derived from a papillary serous-cyst adenocarcinoma of the ovary. The CA 125 antigen was found to be produced by epithelial ovarian carcinoma cell lines but not by normal cells. The CA 125 II sandwich assay utilized the CA 125 and M11 monoclonal antibodies.

CA 125 is present in normal endometrial tissue and in serous and mucinous uterine fluids. It does not enter the circulation except in instances of destruction of natural barriers. Serum levels may double during menses, especially with endometriosis. Higher serum levels can be found in the first trimester of pregnancy. Increased levels may also be observed in 1% of healthy controls, 6% of patients with certain nonmalignant conditions, and in some patients with nongynecological malignancies.

In both ovarian and endometrial malignancies, a persistently increasing CA 125 value may be associated with progressive malignant disease and poor therapeutic response, whereas a declining CA 125 value indicates a favorable prognosis and good therapeutic response. Elevated CA 125 is also a predictor of the presence of an intraperitoneal tumor or a recurrence. Normal levels do not rule out recurrence or the presence of extensive tumor.^{1,2}

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| In primary aldosteronism, plasma aldosterone remains high and plasma renin activity remains low after captopril. | Occasional patients with essential hypertension (EH) have high aldosterone levels, and many with EH have low renin. The ratio of aldosterone to PRA after captopril (>50 in primary aldosteronism, <50 in EH) provides the best discrimination. |
| Symptoms of exposure are typical of cholinergic toxins and include blurred vision, salivation, sweating, nausea, vomiting, and convulsions. | This insecticide (Sevin) is a carbamate derivative that inhibits cholinesterase enzymes. Because the insecticide is rapidly metabolized to 1-naphthol, measurement of the parent compound is not helpful. 1-naphthol is excreted primarily in conjugated forms in the urine. Occasionally, phenolic metabolites may be detected in urine as long as 2-3 days after significant pesticide absorption. ² |
| <p>↑ All forms of gastrointestinal cancer and other adenocarcinomas. Most frequently elevated marker in pancreatic cancer (sensitivity 70-95%). Amount of elevation has no relation to tumor mass, but test can be used to monitor the course of disease.</p> <p>Elevations are also seen in acute and chronic pancreatitis, cholangitis, and cirrhosis.¹⁻³</p> | <p>CA 19-9 is a derivative of the Lewis blood group. Individuals with blood group Le^{a-b-} do not synthesize CA 19-9 (5-10% of the population). CA 19-9 is a high-molecular-weight glycoprotein (MW 1,000,000). CA 19-9 alone is the preferred test for patients with pancreatic cancer; CEA is the preferred test for patients with colorectal cancer. Also useful for monitoring in gastric cancer. CA 19-9 is approved for use by the FDA for serial testing as an aid in monitoring patients with pancreatic cancer who have measurable CA 19-9 results over the course of their disease.¹⁻³</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Respiratory acidosis, especially compensated, caused by poor gas exchange (emphysema, pneumonia, cardiac failure with pulmonary congestion, cystic fibrosis) or depression of respiratory center; generalized respiratory disease; metabolic alkalosis, e.g., after severe vomiting in pyloric stenosis, hypokalemic states, excessive alkali intake.</p> | <p>Arteriovenous difference varies with the metabolic activity of the organ or tissue from which the venous blood is obtained. Therefore arterial blood is preferred for many studies.</p> |
| <p>↓ Compensated respiratory alkalosis, metabolic acidosis in diabetes mellitus, renal glomerular or tubular failure, renal tubular acidosis, and intestinal loss of alkali with coexisting increase in Cl^- and normal anion gap (in acidosis due to most other obscure causes, the chloride is normal or low and anion gap is increased), ureteric transplantation into ileum or colon, hypotension, dehydration or other states with poor tissue perfusion.</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ <i>Respiratory acidosis (hypercapnia)</i>: Increased PCO_2 in inspired air (e.g., rebreathing air); decreased alveolar ventilation due to diseases of the lungs and bronchial tree, foreign body in the airways, allergic laryngeal edema, asthmatic shock, chronic bronchitis, pulmonary tuberculosis or emphysema, chronic obstructive lung disease; disturbances in respiratory control center (e.g., brain tumor, depression of the respiratory center by drugs like opiates and barbiturates); disturbances in neuromuscular apparatus of breathing (e.g., poliomyelitis, curare intoxication, severe electrolyte disturbances, acute intermittent porphyria, severe hypothyroidism); myopathy; cardiac disease; metabolic alkalosis (with compensatory hypoventilation). PCO_2 values >80 mm Hg [>10.64 kPa] may cause narcosis.</p> | <p>Respiratory conditions will primarily affect the PCO_2, whereas metabolic disturbances are first reflected in the HCO_3.</p> |
| <p>↓ <i>Respiratory alkalosis (hypocapnia)</i>: Increased alveolar ventilation caused by mechanical artificial ventilation or by stimulation of the respiratory center due to one or more of the following factors: hypoxia, salicylates, anxiety, hyperthermia, head injury with damage to respiratory center.</p> | <p>With the patient in a sitting or standing position, the values are slightly lower (2–4 mm Hg; 0.27–0.53 kPa) than in the supine position. The difference between arterial blood and peripheral venous blood varies considerably, depending on the skin temperature, length of stasis, and muscular activity.</p> <p>Sources of error are exposure of the blood to air and acid formation by metabolic processes in the erythrocytes and leukocytes during storage. Glycolysis and oxidative metabolism increase PCO_2 by 5 mm Hg/hr [0.67 kPa/hr] at 37°C and 0.5 mm Hg/hr [0.07 kPa/hr] at $2\text{--}4^\circ\text{C}$. PCO_2 values measured at 37°C must be corrected to the actual body temperature because PCO_2 increases with increase of temperature. See nomogram, Figure II-2. The bicarbonate concentration can be computed by the PCO_2 and the pH (see Figure II-1).</p> |

Acute exposure causes irritation to eyes, skin, and mucous membranes. Chronic exposure may result in headache, polyneuritis, emotional disturbances, psychosis, atherosclerosis, coronary heart disease, hypertension, central scotoma, red-green color blindness, anorexia, weight loss, Parkinson-like syndrome, fatigue, anemia, blood and protein in the urine, and liver damage.

Exposure is usually by inhalation of vapor or absorption of liquid CS_2 through the skin.

Carbon disulfide is a metabolite of disulfiram and other thio-carbamates.²

Levels are slightly higher in smokers than in nonsmokers. In malignant disease, elevated values are related to the stage and extent of the disease. Increased values have been observed in cancer of the colon, rectum, lung, breast, liver, pancreas, stomach, and ovary. Lesser elevations have been reported in benign liver disease (hepatitis, cirrhosis), benign gastric and intestinal disease (polyposis, ulcerative colitis), benign breast disease, pulmonary infection, emphysema, and renal failure. CEA is useful in monitoring patients with colon, breast, and gastric cancers. Preoperative concentrations of CEA correlate with prognosis and development of metastasis in colorectal cancer and serial measurements have a sensitivity of ~80% and a specificity of ~70% for detecting recurrence. CEA should not be used for screening/early detection of malignant disease.¹⁻³

CEA is a tumor-associated, oncofetal antigen observed in embryonic and fetal tissues. The CEA family is a heterogeneous group of cell-surface glycoproteins, and up to 36 different glycoproteins have been identified. Because of structural similarities CEA is classified as a member of the immunoglobulin gene super g family. CEA has a molecular mass of ~200 kDa and a high carbohydrate content (50-60%). Because of the heterogeneity of CEA and differences in antibodies, numerical values will differ with different assay techniques. It is essential that the same method be used for longitudinal monitoring. Concordance between methods may be very poor in specimens with elevated values. Factors cannot be applied to convert values from one method to those of another.

| U ↑ Carnosinemia, high-meat diet (especially poultry) | Carnosine is present in the skeletal muscles of almost all animals. |
| ↑ Liver disease, diabetes mellitus, hypothyroidism, high dietary intake, essential hyperlipemia, pregnancy, subacute thyroiditis, hyperlipoproteinemia (types I, IIA, and IIB), myxedema, chronic nephritis, nephrotic syndrome | β-Carotene is a precursor of vitamin A and has received attention as a preventive agent for certain cancers, although most recent trials have not demonstrated benefit and some report harmful primary endpoints. ⁸ Its level does not always reflect vitamin A status and varies with dietary intake. High values can be used to rule out steatorrhea, but low-normal levels lack specificity. Total serum carotenoids, normally 60-200 mcg/dL [0.60-2.00 mg/L], vary with dietary intake and can be measured photometrically after extraction into hexane-ethanol. Excessive dietary intakes are not toxic but can cause hypercarotenemia and carotenoderma in the nasolabial folds, hands, and feet; color of the sclera is unaffected. Carotenemia can be confused with jaundice. β-Carotene may be administered to reduce the severity of photosensitivity reactions in patients with erythropoietic protoporphyria (EPP). ⁹ |
| ↓ High fever, rheumatoid arthritis, liver disease, acquired immune deficiency syndrome (AIDS), Tangier disease, small bowel disease, Zollinger-Ellison syndrome, Whipple's disease, enteritis, pancreatitis, pancreatic cancer, cystic fibrosis, malabsorption with excess loss of fat or vitamin A; levels <30 mcg/dL [$<0.56 \mu\text{mol/L}$] in severe malabsorption. | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ In catecholamine-secreting neurochromaffin tumors such as pheochromocytoma, paraganglioma, and neuroblastoma (neuroblastoma is not associated with increased epinephrine); anxiety, intense physical activity.</p> <p>↓ Autonomic neuropathy including diabetes, parkinsonism; orthostatic hypotension.</p> | <p>HPLC with electrochemical detection methods are prone to interference by several drugs. If possible, the patient should discontinue all drugs at least 1 wk before testing. The preferred specimen is a 24-hr urine collection. Shorter, timed collections (e.g., 12 hr) or random spot urines collected during an acute hypertensive episode have also been suggested, provided the catecholamine excretion is normalized to creatinine excretion. HPLC methods with tandem mass spectrometry are free of interferences from drugs and drug metabolites.</p> <p>Exercise, stress, smoking, and pain induce physiologic increase of catecholamines. Excretion levels are significantly lower during the night. E and NE excretion increase during the luteal phase of the menstrual cycle, then decrease to a minimum during the ovulatory period. Similar changes occur in vanillylmandelic acid (VMA).</p> <p>Simultaneous determination of homovanillic acid (HVA) and VMA may be helpful for the diagnosis of neural crest tumors. Measurements of VMA and catecholamines in urine are more specific (fewer false-positive results) but less sensitive (more false-negative results) than urine metanephrines for pheochromocytoma. Increased dopamine is particularly characteristic of neuroblastoma.</p> <p>The measurement of plasma free metanephrines is recommended as the initial screening test for pheochromocytoma (high diagnostic sensitivity and specificity). See <i>Metanephrines, Fractionated</i>.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>In pheochromocytoma there is a higher level of NE than E in plasma.¹³</p> | <p>Most assays measure only free catecholamines, but a few measure both free and conjugated types. Free amines are more closely associated with tumor load than are conjugated amines. Conditions of sampling are important and should be standardized. The collection of samples with metabisulfite or glutathione is sometimes recommended to prevent oxidation of catecholamines. Blood catecholamines are raised by many variables, including the stress of venipuncture and upright posture. Ideally blood should be collected through an indwelling venous catheter after 30 min of rest in a supine position.</p> <p>The use of epinephrine, norepinephrine, or dopamine must be discontinued for ≥ 12 hr before specimen collection. Discontinue drugs that are known to stimulate the release of catecholamines for 3-7 days. Patients should not eat, use tobacco, or drink caffeinated beverages for at least 4 hr before collection.</p> <p>Plasma catecholamines (total) are often >1000 pg/mL in patients with pheochromocytoma but may be less (or even normal) in normotensive patients between acute attacks. This test is frequently used in subjects with high suspicion for the disease but who have urine results that are borderline or normal. Pharmacologic tests to suppress or stimulate catecholamine release may be considered if measurements of catecholamines and metabolites fail to provide a diagnosis. (See <i>Clonidine Suppression Test</i>.) Plasma catecholamines have also been utilized for tumor localization by selective venous sampling. Measurements of plasma norepinephrine are useful in diagnosing patients with orthostatic hypotension. Failure to increase the supine norepinephrine concentration on standing suggests a sympathetic nervous system disorder.</p> <p>This is not the preferred test for detection of pheochromocytoma as plasma catecholamines may not be consistently increased. This test may be useful in patients whose plasma or urine metanephrine concentrations do not exclude the diagnosis.</p> |

DIAGNOSTIC INFORMATION

REMARKS

12. Rosano TG: Liquid-chromatographic evaluation of age-related changes in the urinary excretion of free catecholamines in pediatric patients, *Clin Chem* 30:301-303, 1984.
13. Shapiro B, Fig LM: Management of pheochromocytoma, *Endocrine Metab Clin North Am* 18:443-481, 1989.

CD40 ligand has been shown to be useful for risk stratification of patients with acute coronary syndrome. In the Opus-TIMI16 Trial, increased CD40 ligand was associated with a higher incidence of death or nonfatal myocardial infarction.³ In the CAPTURE trial, patients with high CD40 ligand who were treated with abciximab (glycoprotein IIb/IIIa inhibitor) had a lower incidence of death or myocardial infarction than patients with high CD40l who were not treated.⁴ The highest odds ratio was obtained when CD40 ligand was combined with other markers such as placental growth factor.⁵

CD40 is a receptor found on leukocytes, endothelial and smooth muscle cells, and platelets. CD40 ligand is a soluble protein ligand that is shed from activated leukocytes and platelets. Given the role of platelets and monocytes in the pathophysiology of acute coronary syndromes, CD40 ligand has been suggested as a marker for risk stratification.

S ↑ Acute phase reacting protein. Increased in inflammation, infection, tissue injury, cardiovascular disease, and some malignancies. Elevations of ceruloplasmin occur very gradually, typically peaking in 4-20 days.¹¹

Pregnancy: levels may increase to approximately double the baseline values during the third trimester.⁶

S ↓ Hepatolenticular degeneration (Wilson's disease). Autosomal-recessive disease involving copper metabolism. A lack of, or a defective copper transporting P-type ATPase (ATP7B) results in impaired incorporation of copper into apoceruloplasmin and subsequent impairment of biliary excretion.¹² Affected individuals experience hepatic copper accumulation, hepatic and neurological disease.¹³

Ceruloplasmin (CP), an α_2 -globulin, is a member of the multicopper oxidase family of proteins. This serum ferroxidase contains ~95% or more of the plasma copper.¹⁶ It has a role in both iron and copper metabolism.

Immunonephelometric methods may measure both the inactive apo-CP and serum CP; consequently, assessment of oxidase activity may be useful for clinical diagnosis.¹⁷

Epidemiological evidence suggests that CP may be an independent risk factor for cardiovascular disease, possibly due to oxidative alteration of low density lipoprotein.⁴

Indications for quantitation include evaluation of the acute phase response and assessment for possible Wilson's disease,

| <p>No adverse effects from industrial exposure have been reported. Nausea, diarrhea, and torsades de pointes have been reported in patients receiving naturopathic therapy for cancer.^{3,4}</p> | <p>The serum level of cesium may be influenced by platelet destruction during the clotting process. Increased K levels facilitate Cs excretion. Hemolysis will increase serum or plasma Cs because erythrocytes have 6.5 times higher levels of Cs than does plasma. Cesium chloride blocks the inward-rectifying potassium channel.⁵</p> |
| <p>S ↑ Dehydration, renal tubular acidosis, acute renal failure, diabetes insipidus, metabolic acidosis associated with prolonged diarrhea with loss of NaHCO_3, salicylate intoxication, respiratory alkalosis, some cases of primary hyperparathyroidism, following head injury associated with hypothalamic stimulation or damage, adrenocortical hyperfunction</p> | <p>Except in emergencies, the specimen should be collected when the patient is in a fasting state. There is a slight decrease in chloride ions after meals. Factors similar to those provoking hyponatremia also cause hyperchloremia. In bromide intoxication, Br^- replaces Cl^-. The resulting hypochloremia may not be detected because some laboratory methods are nonspecific.</p> |
| <p>S ↓ Excessive sweating, prolonged vomiting from any cause or gastric suction, persistent gastric secretion, salt-losing nephritis, Addisonian crisis, metabolic acidosis associated with increase in organic anions, aldosteronism, potassium depletion associated with alkalosis, respiratory acidosis, cerebral salt wasting after head injury, water intoxication and other conditions with expansion of the extracellular fluid volume, acute intermittent porphyria, SIADH</p> | <p>Direct ISE measurements do not give the volume displacement error in specimens with high lipid or protein content, as indirect ISE and flame measurements do.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| CSF ↑ Any condition with elevated serum chloride | |
| CSF ↓ Any condition with decreased serum Cl level, tuberculous meningitis, other bacterial meningitides (nonspecific, test reflects systemic hypochloremia) | |
| F ↑ Severe diarrhea (up to 500 mmol of chloride can be lost in 24 hr), congenital chloridorrhea (very rare condition), idiopathic proctocolitis, ileostomy | |
| Sw ↑ Cystic fibrosis (in 98% of patients), untreated adrenal insufficiency, familial hypoparathyroidism, familial ectodermal dysplasia with sensorineural deafness, nephrogenic diabetes insipidus, hypothyroidism, fucosidosis, G6PD deficiency, mucopolysaccharidosis, hereditary nephrogenic diabetes, familial cholestasis, alcoholic pancreatitis, some cases of renal disease. ¹¹ Most of these conditions are rare and are clinically distinct from cystic fibrosis. | <p>The sweat test with iontophoretic stimulation is considered the most reliable single test in the diagnosis of cystic fibrosis. Test becomes positive between 3 and 5 wk in most affected infants. Test may be normal in patients with salt depletion, e.g., during periods of hot weather. Additional electrolyte studies prevent misinterpretations. Sweat conductivity performs comparable to sweat chloride concentration in diagnosing CF.^{12,13}</p> <p>Sweat chloride increases by 10 mmol/L during a lifetime.</p> <p>Skin lesions or rash can cause increase in values.</p> <p>At least 75 mg of sweat should be collected.¹⁴</p> |
| Sal ↑ Cystic fibrosis | Results obtained with the saliva test are inconsistent and not as reliable as those obtained with the sweat test. |
| Sal ↓ Congestive heart failure, adrenocortical hyperfunction | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Chlorinated hydrocarbons show varying degrees of toxicity, but all are CNS depressants and with prolonged exposure produce liver and kidney damage. Some of the chlorinated hydrocarbons are suspected carcinogens.</p> | <p>The chlorinated hydrocarbons are widely used solvents and are absorbed by inhalation or cutaneously. Dichloromethane is metabolized in part to CO with resulting elevation of carboxyhemoglobin concentration. Trichloroethane, trichloroethylene, and tetrachloroethylene are partially metabolized to trichloroethanol and trichloroacetic acid, both of which can be monitored by GLC.²</p> |

|--|---|
| <p>↑ Patients with pancreatic exocrine and celiac disease (up to 8500 pg/mL [8500 ng/L]). CCK values are also of possible interest in fatty food intolerance, gastric ulcer, postgastrectomy states, and irritable bowel syndromes. There is no defined clinical diagnostic purpose for this test.</p> | <p>There are various stimulating agents and protocols.⁶ Variation in reference ranges among laboratories is large.</p> <p>CCK, like gastrin, exists in several different molecular forms; unlike gastrin, a sulfated form occurs naturally and is required for biological activity. Cholecystokinin and pancreozymin are not different substances but are the same hormone with a dual action.</p> <p>The CCK half-life in vivo has been reported as 2.5 min or 5-7 min. Because CCK is responsible for a number of important actions on the GI tract, notably gall bladder contraction and pancreatic enzyme secretion, disturbances in its secretion or actions may be important in various clinical disorders of these organs (e.g., pancreatic insufficiency, celiac disease, Z-E syndrome). Levels of CCK increase following ingestion of a test meal; responses are more rapid in patients with duodenal ulcers and diabetes than in healthy subjects.</p> |

| | | | INTERFERENCES AND IN VIVO EFFECTS |
| Chorionic Gonadotropin (hCG) ¹⁻⁴ | Urine; freshly voided first-morning specimen preferred. Centrifuge at 900g for 10 min. Store at 2-8° C for up to 48 hr. | Negative; pregnancy is detected 8-14 days after first missed menstrual period. | False-positive results: Menotropins (pergonal, LH with FSH), chorionic gonadotropin (Follutein) |
| <i>Qualitative</i> | | | U ↑ Proteinuria, hema- turia, gross bacterial con- tamination, detergents |
| <i>Agglutination inhibition (slide or tube tests)</i> | | | Variable effects of phe- nothiazines have been re- ported. |
| <i>Immunometric assay</i> | Urine (see above) or serum. Store serum at 2-8° C for up to 24 hr. Otherwise, freeze at -20° C. | Negative; pregnancy is detected in urine 1 wk after implantation or 4-5 days before first missed men- strual period. | |

DIAGNOSTIC INFORMATION

REMARKS

Human chorionic gonadotropin (hCG) is composed of two non-covalently bound glycoprotein subunits, α and β . Sera from normal pregnant women contain hCG in many forms, including intact (92-98%), α -subunit (0-7%), β -subunit (0-3%), and partially degraded (e.g., nicked hCG and β -core fragments). Urine from early pregnancy contains mostly β -core fragments (~50%) and to a lesser degree intact hCG (~35%) and nicked hCG (~10%).^{6,7} hCG assays measure only the intact molecule. Assays specific for the β -subunit may be used for those situations in which subunit production should be monitored. (See *Chorionic Gonadotropin, β -Subunit*.)

Sensitivity of the agglutination inhibition tube assay⁸: >150 mU/mL [>150 U/L]

Slide tests are more rapid but less sensitive than tube tests for the detection of pregnancy. Neither test is sensitive enough to detect ectopic or abnormal intrauterine pregnancies. Cross-reactions with LH (as in menopause, mid-cycle LH peak) may give false-positive values. These tests are infrequently used and have been replaced by more sensitive immunometric assays.

Home pregnancy test kits are commonly used. Most kits use an immunometric technique; detection limits in urine are ~50 mU/mL [50 U/L], making these tests suitable for detecting hCG just after the first missed menstrual period.⁸ Home tests require 2-30 min to perform.

Sensitivity of the qualitative *laboratory immunometric assay*: 25-50 mU/mL [25-50 U/L]

Assay is rapid (3-15 min) and specific for the intact hCG. The assay has good correlation with positive, negative, equivocal results of quantitative serum hCG.⁹ The rapidity and simplicity of the test make it most useful on an emergency basis for determining pregnancy in patients with pelvic pain. However, this test may miss the diagnosis of very early or abnormal pregnancy.

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|--|
| | <p>Sensitivity of the quantitative immunometric assay: 1-2 mU/mL [1-2 U/L]; assay time: 0.2-1 hr</p> <p>Test is specific for intact hCG and has little or no cross-reactivity with LH. It is used to diagnose very early pregnancy (6-8 days after conception) and estimate gestational age. This sensitive test may also be used to detect ectopic hCG-producing tissue.</p> <p>Because there is considerable variability in hCG concentration among gravid women, a single value cannot be used to date the gestational stage accurately. Nor can a single determination be used to determine fetal viability. Serial determinations may be helpful when abnormal pregnancy is suspected.¹⁰ In normal intrauterine pregnancy, hCG rapidly increases, with a doubling time of 1.5 days during weeks 2-5. In ectopic pregnancy or spontaneous abortion, hCG concentrations increase more slowly or decrease.¹¹</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Choriocarcinoma, hydatidiform mole, and nontrophoblastic cancers, particularly germ cell tumors of the ovary and testes. In germ cell tumors, both β-hCG and AFP are elevated; the increase and decrease reflect the course of the disease. Detection of increased levels facilitates initial diagnosis, but during recurrence, only one of the two markers may be elevated. Using multivariate analysis, the combination of LDH and β-hCG levels and the total number of metastatic sites predicts whether there will be a response to the therapy. During therapy, a decrease in level is a good prognostic indicator. Increases are also observed in 100% of trophoblastic tumors, 70% of men with nonseminomatous testicular tumors, and 10% with seminomas.⁶⁻¹⁰</p> <p>Values up to 50 mU/mL [50 U/L] may occur in pregnant women during the first week following conception. Maximum values (up to 290,000 mU/mL [290,000 U/L]) are reached by the second or third month, and then there is a gradual decrease to values as low as 4000 mU/mL [4000 U/L].</p> | <p>The β-subunit of hCG is a sialoglycoprotein that contains 180 amino acids and has an MW of 25,000-30,000. The first 150 amino acids have an 80% homology with luteinizing hormone. hCG is synthesized by trophoblastic cells of the developing blastocysts and later by syncytiotrophoblastic cells. The biological half-life ($t_{1/2}$) is 12-36 hr.</p> <p>Serial determinations in neoplasms that produce hCG indicate both a response to treatment by surgery or chemotherapy and recurrences. In some tumors variable amounts of free α- or β-subunits of the hormone have been identified.¹¹ Increased concentration of hCG is also found in patients without tumors but with a variety of benign diseases with enhanced cellular proliferation. The detection limit for serum is 1-3 mU/mL [1-3 U/L].</p> <p>Most assays for β-hCG are designed to measure the intact hCG molecule and the free β-hCG molecule. When hCG is assayed as a tumor marker, a method measuring total β-subunits (free and intact) must be used.</p> |
| S ↓ Threatened abortion, ectopic pregnancy | |
| AF ↑ Severe erythroblastosis fetalis (some reports) | |
| CSF ↑ Spinal fluid dysgerminomas and meningeal carcinomatosis | <p>The pattern of change in hCG levels in amniotic fluid mimics that observed in maternal serum. The mean concentration of hCG in the maternal peripheral circulation at term is 40-100 times higher than in the amniotic fluid, which in turn is at least 10-fold greater than that measured in umbilical blood.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↓ Pregnancy, diabetic children</p> <p>Toxicity is mostly from occupational exposure in electroplating, welding, steelmaking, leather tanning, photography, dyeing, and chemical manufacture operations. Exposure of the skin results in dermatitis and ulceration. Ingestion results in vertigo, abdominal pain, vomiting, anuria, convulsions, shock, or coma.</p> | <p>Chromium as Cr^{3+} is a required cofactor in the initiation of the action of insulin in peripheral tissues (GTF; glucose tolerance factor). Reduced Cr intake can be an aggravating factor in the disturbed glucose tolerance of marasmic infants, maturity-onset diabetic patients, and some elderly persons. Metallic chromium is not allergenic or toxic, but Cr^{3+} and Cr^{6+} are toxic in excess, although carcinogenic effects are thought to be due to Cr^{6+}. Cr^{6+} is more toxic than Cr^{3+}.</p> <p>Glucose intolerance and neuropathy due to chromium deficiency have been documented in patients receiving Cr-deficient IV solutions for long periods.</p> |

|---|--|
| <p>↑ Carcinoid tumors, pheochromocytomas, neuroblastomas, small cell lung cancers, hyperparathyroid adenomas, pituitary tumors, prostate cancers, pancreatic islet tumors including multiple endocrine neoplasia (MEN) I and II syndromes, pancreatic islet cell syndromes including insulinomas, glucagonomas, somatostatinomas, Zollinger-Ellison syndrome, Verner-Morrison syndrome, pancreatic polypeptide-producing tumors, and nonfunctioning neuroendocrine tumors. Concentrations correlate with tumor burden.</p> <p>Nontumor-associated increases include renal insufficiency, liver disease, atrophic gastritis, inflammatory bowel disease, and stress.^{2,3}</p> | <p>Chromogranin A (CgA) is a 48-kDa acidic glycoprotein that is part of a family of proteins found in neuroendocrine cells and in neuronal cells in the central and peripheral nervous system, thus explaining their role in neuroendocrine tumors. On stimulation, CgA, in addition to peptide hormones and neuropeptides, is released from the secretory granules of neuroendocrine cells. CgA can be processed by neuroendocrine cells into a number of bioactive peptides that may differ by cell type. N-terminal peptides have vasodilatory functions, whereas mid- and C-terminal peptides have autocrine or paracrine inhibitory functions.</p> <p>CgA is used as an aid in the diagnosis and monitoring of carcinoid tumors, pheochromocytoma, neuroblastoma, endocrine pancreatic tumors, and small cell lung cancers. May be useful in nonfunctioning neuroendocrine tumors that do not secrete other hormones.¹⁻³</p> <p>Several non-FDA-approved commercial assays for CgA are available that are primarily in use outside the United States. These assays have different formats (ELISA, RIA), types of antibodies, standards, and units. Assays measure different forms of the molecule and therefore give different results and differ in clinical performance.^{3,5}</p> |
| <p>S ↑ Acute pancreatitis, chronic renal failure can also be found with gastric or pancreatic cancer¹⁰ and junctional epidermolysis bullosa.¹¹</p> <p>S ↓ Chronic pancreatitis, late cystic fibrosis</p> | <p>Fecal chymotrypsin tests provide a noninvasive method to evaluate for suspected pancreatic exocrine insufficiency. They can also be used to monitor adequacy of treatment. Evidence suggests that assays of fecal elastase-1 concentrations may be more sensitive for the diagnosis of moderate and severe disease.⁹ Direct, invasive functional assays like the pancreozymin-secretin test are frequently considered the “gold standard” and can be used to provide definitive diagnosis.⁹</p> |

| ↓ In kidney stone formers | Citrate in urine is a principal inhibitor of kidney stone formation. Citrate combines with calcium in the tubular lumen to form a soluble complex (thereby reducing the concentration of free calcium available to combine with oxalate) and also appears to inhibit the process of crystal agglomeration, in which individual calcium oxalate crystals combine to form a stone. Hypocitraturia is considered a risk factor for kidney stone formation and occurs in isolation in stone formers or in association with hypercalciuria, hyperoxaluria, or hyperuricosuria. ⁶ |

| <p>S ↓ <i>Congenital</i>: Inherited deficiency of C1q, C1r, or C1s</p> <p><i>Acquired</i>: Reflects complement consumption resulting from activation by immune complexes, cryoglobulinemia, or other autoimmune process, severe malnutrition, and lymphopenia. C1 function is decreased in serum from patients with acquired but not hereditary angioedema. Hypocomplementemic urticarial vasculitis (HUVS) and SLE may be associated with autoantibodies to the collagen-like region of C1q.¹⁰</p> <p>S ↑ <i>Acquired</i>: Acute phase response</p> | <p>The complement system, as a component of the innate immune response, comprises >30 individual proteins located in plasma or on cellular surfaces.¹⁹</p> <p>The C1 molecular complex consists of one C1q subunit, two C1r subunits, and two C1s subunits held together by Ca^{2+} ions. Most of the circulating C1 is produced by intestinal epithelial cells, although mononuclear phagocytes and fibroblasts also make active C1.⁴ The functional assay measures the hemolytic activity of intact C1. The C1H_{50} is defined as the reciprocal of the dilution that lyses 50% of the cells.</p> |
| <p>S ↓ <i>Congenital</i>: Inherited deficiency of C1q, hypogammaglobulinemia</p> <p><i>Acquired</i>: Complement consumption resulting from immune complexes, autoimmune processes, cryoglobulinemia, HUVS, and lymphopenia</p> <p>S ↑ <i>Acquired</i>: Increased C1q levels have been associated with kala-azar (<i>Leishmania donovani</i> infection).¹¹</p> | <p>C1q, the recognition unit for the classical pathway, binds to immunoglobulin in immune complexes ($\text{IgM} > \text{IgG}_3 > \text{IgG}_1 > \text{IgG}_2$, but not IgA, IgE, or IgG₄). C1q is therefore used in tests for the presence of immune complexes. Nonimmunological activators of C1q include DNA, IgG bound to staphylococcal protein A, complexes of C-reactive protein with polysaccharide, membranes of subcellular organelles (mitochondria), some enveloped viruses, monosodium urate crystals (in gout), and lipid A of bacterial lipopolysaccharide.²⁰⁻²⁴</p> |
| <p>S ↓ <i>Congenital</i>: Inherited deficiency of C1q, linked to immune complex disease with and without recurrent infections</p> <p><i>Acquired</i>: C1q is often low in patients with hypogammaglobulinemia; the decrease is thought to be caused by hypercatabolism of C1q rather than by primary deficiency. Other causes for low C1q are complement consumption resulting from formation of immune complexes, cryoglobulinemia or other autoimmune processes, hypocomplementemic urticarial vasculitis syndrome (HUVS), and lymphopenia.</p> | <p>The C1q molecule is made up of 18 polypeptide chains: six A chains (MW 26,500 each), six B chains (MW 26,500 each), and six C chains (MW 24,000 each), arranged into six subunits of three chains each (1A:1B:1C).²⁵ The N-terminal ends have collagen-like amino acid sequences that form a single "stalk," whereas the C-terminal ends are globular and spread out from each other in a configuration that resembles a bouquet of flowers. The binding sites for immunoglobulin Fc are in these globular heads, whereas the collagen-like tail portion reacts with C1q receptors.</p> <p>C1q is produced by epithelial cells, primarily in the intestine but also in the lung and other tissues.²⁶ The $t_{1/2}$ of C1q in the circulation is ~40 hr, with a fractional catabolic rate of 2.7-2.8% of the plasma pool per hour and a synthesis rate of 140-190 mg/kg body wt./hr. Approximately 50-75% of the C1q is in the intravascular space.²⁷</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>S ↓ <i>Congenital</i>: C1r deficiency is associated with SLE-like disease, renal disease, recurrent infections, and rheumatoid arthritis. C1r-deficient patients may also have low C1s.</p> | <p>This test measures the function of C1q in a hemolytic assay using sensitized sheep erythrocytes (EA), serial dilutions of the test serum or plasma, and serum depleted by affinity chromatography of C1q (but not other complement components). C1q function is lost rapidly when serum is heated $>37^{\circ}\text{C}$ and is irreversibly destroyed by heating at 56°C for 30 min. Serum samples that have not been collected or stored properly may have low C1q function.</p> |
| <p><i>Acquired</i>: Immune complex diseases, autoimmune processes, bacterial and viral infections, and severe trauma and burns. Activation of the classical pathway leads to rapid binding of C1INH to the C1r and C1s enzymes and clearance of C1r-C1INH and C1s-C1INH complexes.</p> | <p>Under physiological conditions, C1r forms dimers (C1r₂) that associate with C1q and dimers of C1s to form C1qr₂s₂. C1r is a serine protease that remains inactive in the C1qr₂s₂ complex but is converted to an active enzyme C1r when C1q binds to an immune complex or other activator. The substrates of C1r are other C1r molecules and C1s. When cleaved by C1r, C1s also becomes an active serine esterase. C1r and C1s share a high degree of homology and presumably evolve from gene duplication. C1r and C1s are inactivated in serum by C1-esterase inhibitor (C1-INH), to which they covalently bind, and the C1r-C1INH and C1s-C1INH complexes are subsequently removed from the circulation. Serum C1s is synthesized by epithelial cells of the intestine and bladder and to some extent by fibroblasts, monocytes, and macrophages in other tissues.²⁸ The binding of C1INH to C1r masks the antigenic site of C1r recognized by many antisera used for the detection and quantitation of C1r, thus making the C1r “invisible” to detection by immunochemical means.²⁹</p> |
| <p>S ↓ <i>Congenital</i>: C1s deficiency (rare), associated with SLE-like disease, renal disease, recurrent infections, and rheumatoid arthritis. C1s deficiency is usually linked to C1r deficiency.</p> | <p>In serum, C1s forms calcium-dependent dimers that associate with C1r dimers and C1q to form macromolecular C1qr₂s₂. C1s is a serine esterase that remains inactive in the C1qrs complex but is converted to its active form when cleaved by C1r. The substrates of C1s are C4 and C2, which combine to form the classical pathway C3 convertase (C4b2a). C1s is inactivated by C1-esterase inhibitor (C1INH), leading to C1s-C1INH complexes that are cleared from the circulation. Serum C1s is synthesized by epithelial cells of the intestine and bladder and to some extent by fibroblasts, monocytes, and macrophages in other tissues.²⁸</p> |
| <p>S ↓ <i>Congenital</i>: C2 deficiency is the most common complement deficiency in Caucasian populations (the frequency of the C2 null gene is 0.01, incidence of deficiency is 1 in 10,000). Type I C2 deficiency is a defect in synthesis of C2 protein, and little or no C2 is detectable in the circulation. Type II C2 defi-</p> | <p>C2 is a proenzyme that becomes active after cleavage by C1s. The larger fragment (C2a) combines with C4b to form the enzyme site of C3 and C5 convertases, and the smaller fragment (C2b) may be further cleaved to produce the kinin-like activity in angioedema patients.³⁰</p> |

DIAGNOSTIC INFORMATION

REMARKS

ciency is a defect in C2 protein secretion and is associated with low levels of protein in the circulation.¹¹ Heterozygous individuals have half-normal levels. C2-deficient patients may be asymptomatic or may present with SLE-like disease, renal disease, rheumatoid arthritis, and recurrent infections (usually with *Streptococcus pneumoniae*, *Staphylococcus pneumoniae*, and *Haemophilus influenzae*).¹²

Acquired: Hereditary and acquired angioedema patients have low C2 and low C4 because of uncontrolled expression of C1 activity. C2 is also decreased in patients with immune complex diseases, bacteremia, viremia, autoimmune disorders, severe trauma, burns, and severe malnutrition.

S ↑ *Congenital:* Patients with deficiencies of C1q, C1r, or C1s often have elevated C2, C4, and C1INH levels and functions.¹³

Acquired: Acute phase response

C2 is synthesized by hepatocytes and by monocytes and macrophages in blood and other tissues.²⁸ The genes for C2 are linked to those of factor B and C4 in the HLA domain on chromosome 6, and there are multiple alleles giving rise to different C2 isotypes in the population. The most common of these, C2 C, is found in ~96% of the population.³¹

The hemolytic activity of C2 is extremely heat sensitive and can be destroyed by heating serum at 50° C for 30 min. Loss of C2 activity can occur on improper handling or storage of the specimen. The hemolytic assay for C2 function uses sensitized sheep erythrocytes precoated with C1 and C4. The C2H₅₀ is the reciprocal of the dilution of test material that lyses 50% of the cells in 1 mL of the assay mixture.

S ↑ *Congenital:* Presence of more than four C4 alleles. Deficiency of C1q, C1r, or C1s is associated with increases in C2, C4, and C1 INH.

Acquired: Acute phase reaction, certain malignancies

S ↓ *Congenital:* Total C4 deficiency is rare, but partial C4 deficiency is common (see *Remarks*). Partial and complete C4 deficiency and certain C4 haplotypes have been associated with immune complex diseases, SLE, autoimmune thyroiditis, and juvenile dermatomyositis.¹⁴⁻¹⁶ Onset of SLE in C-deficient patients is often early (preteens) and tends to be somewhat less severe than that in patients with normal complement; ANA titers may be negative in these patients. Infections associated with C4 deficiency include bacterial or viral meningitis, *Streptococcus* and *Staphylococcus* sepsis, and pneumonia.

C4 is a glycoprotein, MW 205,000, that participates in the classical pathway of activation. Precursor C4 is synthesized as a single polypeptide chain that is posttranslationally cleaved into three disulfide-linked chains (a, b, and g). C4 is produced primarily by hepatocytes but can also be made by other cell types (monocytes, fibroblasts, macrophages). Complement activation produces several C4 split products that have different biological activities: C4a is a weak anaphylatoxin, C4b is part of the enzyme that cleaves C3, C4b, iC4b, and C4d are opsonins that bind to CR1, CR3, and CR2 receptors, respectively. C4c is an inactive product found in the fluid phase.

The fragments of C4, C4a, and C4d can be measured by RIA, rocket electrophoresis, or ELISA techniques. These fragments provide very sensitive measures of in vivo complement activation. Activation of as little as 1% of the classical pathway can be detected by comparing the ratio of C4a or C4d with C4 in the plasma. By measuring fragments of factor B, C3, and C5, one can determine which pathway has been activated and to what extent. Previous objections to using complement mea-

| <p><i>Acquired:</i> Hereditary and acquired angioedema, complement activation resulting from immune complex diseases, decreased synthesis (liver disease), increased consumption in glomerulonephritis, SLE, rheumatoid arthritis, respiratory distress syndrome, autoimmune hemolytic anemia, cryoglobulinemia, and sepsis.</p> | <p>Measurements to follow a patient's disease progress were related only to C4 and C3 levels, which are relatively insensitive because most patients with inflammation also mount an acute-phase response that can mask complement consumption. Use of complement split-product measurements should make it much easier and more accurate to monitor trends and predict flares in a patient's disease.</p> |
| | <p>There are two separate genes for C4: C4A and C4B. They are class III MHC genes located near the genes for C2, factor B, and 21-hydroxylase on the short arm of chromosome 6. There are many different alleles of C4A and C4B, which were identified previously as C4F (fast) and C4S (slow) by their electrophoretic mobility and as the Chido (C4B) and Rodgers (C4A) blood group antigens.³² Null alleles that produce no protein are common. Sixty-nine to 76% of Caucasians express all four alleles, 13-24.5% express three alleles, and ~10% express only two alleles. Expression of only one or no alleles is rare.</p> |
| <p>S ↓ <i>Congenital:</i> Factor D deficiency is very rare. AH₅₀ is abnormal, but CH₅₀ is normal. Patients often have infections resulting from <i>N. meningitidis</i>, <i>H. influenzae</i>, <i>Proteus</i> sp., and <i>Pseudomonas</i> sp.</p> | <p>C4 has an internal thiolester group that becomes exposed when the molecule undergoes cleavage during complement activation. This cleavage allows formation of bonds with nearby nucleophile groups where C4A preferentially binds to amino groups and C4B preferentially binds to carboxyl groups. The wide range of titers reflects the variation of C4A and C4B haplotypes in the population. The distribution of titers among the population tends to be triphasic, with C4B having higher titers than C4A. C4A is a more efficient opsonin for immune complexes, which may be why deficiency of C4A is linked with SLE and other diseases in which immune complexes play a role. C4 function is sensitive to treatment by chaotropic agents, hydrazine, hydroxylamine, ionic detergents (SDS), and denaturants such as urea and guanidine HCl.</p> |
| <p>S ↑ <i>Acquired:</i> End-stage kidney disease with loss of filtration leads to increased factor D levels in plasma, in correlation with serum creatinine levels.¹⁷ SLE patients with renal disease, polycystic kidney disease, and rheumatoid arthritis with secondary amyloidosis.¹⁸</p> | <p>Factor D (FD) is an MW 25,000 serine esterase with specificity for factor B when the latter is bound to C3b or C3b-like C3. It is the only complement enzyme that circulates in its active state. It is essential for triggering the alternative pathway of activation and is the rate-limiting factor in this pathway. FD is identical to the enzyme adipisin, produced in adipocytes, and involved in lipid metabolism.³³ Its primary site of synthesis <i>in vivo</i> is not known, but it is produced in culture by monocytes and macrophages and by HepG2 cells.³⁴</p> |

In hypothalamic-pituitary dysfunction there is no response; in prepubertal state, anorexia nervosa, and postmenopausal females, there is no or inadequate response.

A normal response essentially rules out organic impairment of gonadotropin secretion (e.g., pituitary tumor) and may be of value in assuring patients with delayed puberty that sexual maturity will ensue. An abnormal response suggests an organic lesion.

In healthy individuals clomiphene blocks estrogen feedback mechanisms in the hypothalamus, thus leading to an increase in gonadotropin-releasing hormone and, consequently, circulating LH and FSH.⁵

Because of the pulsatile nature of pituitary gonadotropin secretion, obtain three separate blood samples 20 min apart for baseline and poststimulation specimens. Aliquots of the sera on each day may be pooled.

In prepubertal children and in early puberty, clomiphene suppresses rather than stimulates gonadotropin release; therefore this test has little usefulness in these situations. In females, risks include hyperstimulation of the ovaries, cystic ovarian changes, and multiple pregnancies. There are no significant risks in men.

Lack of a decrease in norepinephrine is suggestive of pheochromocytoma.

Clonidine inhibits neurogenic catecholamine release and will cause a decrease of plasma norepinephrine into the reference interval in hypertensive subjects without pheochromocytoma.

Intermittent catecholamine secretion by a pheochromocytoma may also give a false-negative response.

In patients without pheochromocytoma, the majority of plasma metanephrine is derived from norepinephrine released by sympathetic nerves and is therefore decreased in response to clonidine. The inclusion of plasma normetanephrine measurements has been shown to increase the sensitivity of the clonidine stimulation test, particularly when used in patients with only slight elevations of plasma metanephrines.⁴

| | Urine. Collect in acid- washed, metal-free container. | 1-2 mcg/L | $\times 16.97$ | [17-34 nmol/L] | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| ↓ Hereditary deficiency (rare hereditary combined deficiencies may be seen) | The PTT and the PT are the basis for these factor assays. Factors VIII, IX, XI, and XII are PTT based. Factors II, V, VII, and X are PT based. The test is based on the ability of patient plasma to correct the PTT or PT of specific factor-deficient plasma. Quantitative results are obtained from comparing with a standard curve made from dilutions of normal reference plasma and specific factor-deficient plasma. |
| Factor VIII deficiency: in addition to decreased levels in hemophilia, patients with von Willebrand disease may also have low FVIII. | Nonspecific and specific inhibitors can interfere with a factor assay; therefore multiple dilutions should be performed to dilute out the effect of the inhibitor. A common example is an acquired inhibitor to FVIII that interferes with the FIX assay, resulting in a falsely decreased FIX value. With additional dilutions the specific factor VIII inhibitor will be diluted out, and the factor IX assay will normalize. |
| <i>Acquired deficiency:</i> | |
| Specific inhibitors may arise to virtually any coagulation factor. Most common specific inhibitors are antibodies to FVIII and IX. | |
| Multiple factor deficiencies: liver disease (except factor VIII), DIC. | |
| Factors II, VII, IX, and X: vitamin K deficiency or warfarin. | |
| Of note, heparin, hirudin, and argatroban can act as “inhibitors” and interfere with specific factor assays. | Although the factor assays are typically clot-based (PTT or PT), chromogenic and immunologic assays do exist for some of the factors, including FVIII. Differences between the standard PTT-based FVIII assay compared with the chromogenic FVIII have been noticed in the monitoring of the B-domain–deleted recombinant factor VIII concentrate, with PTT assay levels ~50% of chromogenic activities. |
| Factor II: rare patients with lupus anticoagulant | |
| Factor X: acquired factor X deficiency may occur in patients with amyloidosis. | |

Toxic effects due to excess cobalt intake have been noted in renal patients receiving erythropoietic agents and in very heavy drinkers of beer with added cobalt. Toxic effects include thyroid gland hyperplasia, myxedema, cardiomyopathy (particularly in alcoholism), polycythemia, and nerve damage. Co deficiency has not been reported in humans. Cobalt exposure or inhalation of Co dust in industrial settings may produce allergic dermatitis, asthma, and pulmonary symptoms.

Co is an integral component of vitamin B₁₂. It is found in most foods and is readily absorbed from the gastrointestinal tract. Co concentrations may be increased in individuals with deteriorating orthopedic implants.^{5,6} Cobalt chloride is used in the treatment of some refractory anemias, including sickle cell anemia,⁷ but use has decreased since the introduction of erythropoietin as a therapeutic agent. Co is used in treating cancer of the oral cavity, pharynx, and larynx, rhabdomyosarcoma, carcinoma of the penis, and radiosensitive but widespread tumors. Samples collected to assess occupational exposure should be collected at the end of shift on the last day of the work week.

DIAGNOSTIC INFORMATION

REMARKS

gen peptides. Total DPD and PYD can be measured by HPLC following acid hydrolysis of urine. N-telopeptide (NTx) and C-telopeptide (CTx) immunoassays recognize the N-telopeptide cross-links and β -isomerized C-telopeptide cross-links, respectively.

NTx, CTx, and DPD are specific and sensitive markers of bone resorption and can be used to measure bone resorption in osteoporosis and other metabolic bone diseases. In osteoporosis, although they are potentially useful for predicting bone loss and fracture risk and for selecting patients for therapy, they have been most useful in monitoring the effectiveness of antiresorptive therapy. Even for monitoring the efficacy of treatment, their usefulness has been compromised by preanalytical and analytical variation.

Most bone markers exhibit a significant diurnal variation with peak in the early morning and a nadir in the afternoon, a result of the nocturnal peak in bone turnover. Consequently, specimens should be collected at a specific time of day to minimize the impact of diurnal variation when comparing specimens with previous results (monitoring) or with reference intervals. A second morning void is usually recommended for urinary markers. Because urinary markers are normalized by dividing by urinary creatinine, the variability between creatinine measurements, within-subject variability in creatinine, and its dependence on muscle mass all contribute to overall variability. Less within-subject variation is observed with the serum telopeptides.

Reference intervals depend on the reason for ordering the test. For osteoporosis, reference intervals should be based on healthy premenopausal women and healthy men <50 yr because of the aged-related increase in bone resorption, osteopenia, and osteoporosis. Depending on the bone marker, a reduction of 30-60% should be observed after 3-6 mo of antiresorptive therapy. NTx and CTx decrease faster and to a greater extent than DPD.

Pyridinium cross-links have largely replaced hydroxyproline as a marker of bone resorption.³³ (See *Hydroxyproline, Total*.)

| Complement, Total Hemolytic CH_{50} ^{1,2} <i>Quantitative functional assay</i> | Serum; CNS, pleural, or synovial fluid (pair with serum sample col- lected at the same time for comparison). Col- lect blood in plain red- top tube and allow to clot for 30 min. Do not let blood or body fluid stand at room tempera- ture or 37° C for >1 hr. Centrifuge sample and transfer cell-free and clot-free serum or fluid to clean tube. Store at −70° C (−20° C ac- ceptable for overnight only). Ship on dry ice. Avoid repeated freeze/thaw cycles. | Serum: CH_{50} U/mL 26-58 ³ 33-61 ⁴ Normal synovial, pleural, or CNS fluid complement ⁴ = 70% of serum complement after correction for protein: $\frac{\text{Fluid C}}{\text{Serum C}} \div \frac{\text{Fluid protein}}{\text{Serum protein}} \times 100$ Synovial fluid: $\geq 33\%$ of matching serum CH_{50} . ⁵ | CH_{50} kU/L [26-58] [33-61] | ↓ C EDTA, EGTA, ACD (Calcium chelators may decrease the CH_{50} due to dissociation of the C1qrs complex.) ↑ V Cyclophosphamide (in SLE patients), danazol |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>S ↓ <i>Congenital</i>: Inherited deficiency of complement component or control protein</p> | <p>The CH₅₀ measures total hemolytic activity of the classical pathway of complement (C1, C2, C4, C3, C5, C6, C7, C8, and C9). There is interlaboratory variability, similar to other bioassays, in the ranges reported. The quantitative functional hemolytic assay uses sheep erythrocytes (E) that have been coated with rabbit antisheep erythrocyte antibodies (A) to form sensitized erythrocytes (EA). After incubation, the unlysed EA are removed by centrifugation, and the percentage of cells lysed is determined from the amount of hemoglobin in the supernatants.</p> |
| <p>Fluid ↓ Decreases <70% of serum value, after correction for protein, are indicative of local consumption and are seen in synovial fluid from patients with seropositive rheumatoid arthritis or acute rheumatic fever and in pleural effusions from SLE patients.⁴</p> | <p>The CH₅₀ unit is defined as the reciprocal of the dilution of serum that will lyse 50% of the cells in 1 mL of the suspension.</p> |
| <p>S ↑ <i>Acquired</i>: Acute phase response</p> | <p>The CH₅₀ is useful for detecting complement deficiencies and for monitoring complement consumption in patients with immune complex diseases such as vasculitis or systemic lupus erythematosus. The CH₅₀ is less sensitive to changes due to complement activation than is measurement of complement split products that are produced only during activation. Complement function can be evaluated by assessing deposition of activation products on serum activation with immobilized complement-activating molecules (IgM for classical pathway, LPS for alternative pathway, or mannose for the lectin pathway).⁵ The CH₅₀ depends on the classical pathway (C1, C4, C2) for activity and shares the terminal components (C3, C5-C9) with the alternative pathway. If there is a complete deficiency of one of the components (C1q, C1r, C1s, C4, C2, C3, C5, C6, C7, or C8), then the CH₅₀ will be 0 U/mL. C9 deficiency causes the CH₅₀ to be low but usually not absent. If tested together with the AH₅₀ (Total Alternative Pathway Activity), the CH₅₀ can be used to narrow the search for the missing component:</p> |
| | <p>If both the CH₅₀ and the AH₅₀ = 0 U/mL (kU/L), then the defect is in one of the late components (test C3, C5, C6, C7, and C8).</p> |
| | <p>If the CH₅₀ is 0 U/mL (kU/L) and the AH₅₀ is normal, then the defect is in one of the classical pathway components (test C1q, C1r, C1s [or C1 function], C2, and C4).</p> |
| | <p>If the CH₅₀ is normal and the AH₅₀ = 0 U/mL (kU/L), then one of the alternative pathway components is deficient (test factors D and B and properdin).</p> |

DIAGNOSTIC INFORMATION

REMARKS

If the CH_{50} and/or AH_{50} are low but not absent or if more than one component is low, then the most likely reason is depletion of complement due to *in vivo* activation; however, the patient may be heterozygous for a complement deficiency. Test for complement split products for evidence of activation, for factor H or factor I in the case of suspected congenital deficiency, or follow the above suggestions to identify the pathway involved in heterozygous deficiency.

The rate-limiting components in the CH_{50} reaction are C2, C5, C3, and C4, and the main heat-labile components are C1q and C2.

Note: Absence of C9 causes the CH_{50} and AH_{50} to be low but not usually as low as 0 U/mL. Deficiencies of factors H or I result in uncontrolled complement activation, with significant decreases in C3 and the late components.

This test is semiquantitative and is used as a screen for hemolytic complement activity (See CH_{50}). A variation on this method measures alternative pathway activity by incorporating rabbit erythrocytes into the agarose gel. The CH_{100} test can be used as a rapid screen for complement deficiency or to monitor complement activity in patients with SLE or other immune complex disorders.

The AH_{50} requires all of the components of the alternative pathway and the terminal pathway (Factor D, Factor B, properdin, C3b, C3, C5, C6, C7, C8, and C9). The assay is most useful in helping to decide which complement component is missing in a complement-deficient patient, as described under CH_{50} , or in evaluating the performance of the alternative pathway as a whole.

S ↓ *Congenital*: Inherited deficiency of complement component or control protein

S ↓ *Acquired*: Complement consumption due to immune complex disease, infectious process, autoimmune process, malignancy, cryoglobulinemia, trauma, burns

S ↑ *Acquired*: Acute phase response.

The AH_{50} hemolytic assay uses rabbit or guinea pig erythrocytes (Erab, Egg) that have not been sensitized with antibodies and a buffer containing EGTA (to block the Ca^{+} -dependent classical pathway activity) plus Mg^{2+} (required by the alternative pathway). The percentage of cells lysed is determined from the amount of hemoglobin in the supernatants.

The AH_{50} unit is defined as the reciprocal of the dilution of serum that will lyse 50% of the cells in 1 mL of the suspension.

DIAGNOSTIC INFORMATION

REMARKS

5. Hedberg H: Studies on the depressed hemolytic complement activity of synovial fluid in adult rheumatoid arthritis, *Acta Rheum Scand* 9:165-193, 1963.
6. Delk AS: A rapid sensitive immunologic agglutination test for phosphatidylglycerol (PG), *Am Clin Prod Rev* 10:8-13, 1984.

S ↑ Age, infections and inflammation, pregnancy, leukemia, biliary cirrhosis, typhoid fever, Hodgkin's disease, pellagra, pulmonary tuberculosis, most anemias, thalassemia major and minor, rheumatic fever, acute myocardial infarction, brain infarction, ankylosing spondylitis, rheumatoid arthritis, hypothyroidism and hyperthyroidism, collagen diseases, SLE, complications of renal dialysis and neonatal transfusions; trauma and malignant neoplasms of the GI tract, lung, bone, breast, cervix, and hematopoietic system

S ↓ Wilson's disease (40-60 mcg/dL; 6.3-9.4 $\mu\text{mol/L}$), GI disease (sprue, small bowel, celiac), cystic fibrosis, nephrotic syndrome, Menkes' syndrome, ACTH or prednisone-induced remission of leukemia, some iron-deficiency anemias, burns, disproteinemia, protein malnutrition, chronic ischemic heart disease.

During estrogen therapy (and pregnancy), the synthesis of ceruloplasmin in the liver is greatly increased. As a result, plasma Cu is about twice the normal level. Plasma ceruloplasmin is also increased during administration of oral contraceptives or antiepileptics (carbamazepine, phenobarbital, and phenytoin).

Ercs ↑ Pulmonary tuberculosis (characteristic), lead toxicity

Ercs ↓ Protein malnutrition

U ↑ Wilson's disease (>100 mg/day, >1.57 mmol/day; may be lower in young presymptomatic siblings),¹² chronic active hepatitis, biliary cirrhosis, rheumatoid arthritis, proteinuria

U ↓ Protein malnutrition

90-95% of plasma Cu is in the copper oxidase enzyme ceruloplasmin. Plasma Cu and/or ceruloplasmin oxidase activity can be used as a measure of body copper status. Copper absorption may be impaired in patients with diffuse small bowel disease and in those with high intakes of the competing ions zinc and cadmium. Cu deficiency has been observed in infants (especially premature) on Cu-deficient milk diets, in patients receiving long-term TPN with solutions deficient in trace metals, and in patients receiving zinc therapy or copper chelators such as penicillamine. Symptoms of copper deficiency include neutropenia, anemia (iron-unresponsive), osteoporosis, various bone/joint abnormalities, decreased skin pigmentation, and possibly neurological and cardiac abnormalities. Genetically determined diseases of copper metabolism include Wilson's disease (hepatolenticular degeneration), a Cu accumulation disease, and the rare Menkes' steely-hair syndrome, an infant copper deficiency disease. Indian childhood cirrhosis may also reflect an inherited metabolic disease requiring high concentrations of environmental Cu.¹⁴

Cu is increased in CSF of persons with brain infarction and in synovial fluid of persons with rheumatoid arthritis. Symptoms of Cu salt poisoning include nausea, vomiting, headache, diarrhea, and abdominal pain. Liver injury, jaundice, and hemolytic shock may follow. Copper toxicity may occur, owing to ingestion of Cu-contaminated solutions, use of Cu IUDs, or exposure to Cu fungicides. Serum total Cu and ceruloplasmin are reduced in Wilson's disease, owing to decreased hepatic synthesis of ceruloplasmin, whereas serum ionized calcium, urinary Cu excretion, and liver Cu levels are increased.

Assay of urine is useful only in diagnosing or assessing treatment for Wilson's disease.

| <p>↑ %Coproporphyrin I⁵⁻⁷ Dubin-Johnson syndrome >80% Rotor syndrome 60-80%</p> | <p>Porphyrins are intermediate metabolites of the heme synthetic pathway, which occurs in the liver and bone marrow. The three clinically important types of porphyrins are uroporphyrins, protoporphyrins, and coproporphyrins. In biologic fluids, porphyrins can exist as different configurations of the same compound (isomers).</p> <p>Dubin-Johnson and Rotor syndromes are rare hereditary disorders with impaired intrahepatic bile excretion and hyperbilirubinemia (conjugated). Other than jaundice, affected individuals are typically asymptomatic.</p> <p>One characteristic of both Dubin-Johnson and Rotor syndrome is chronic hepatic retention of coproporphyrin III. This retention diminishes the urinary excretion of coproporphyrin III.^{4,8}</p> |
| <p>7. Frank M, Doss M, de Carvalho D: Diagnostic and pathogenetic implications of urinary coproporphyrin excretion in the Dubin-Johnson syndrome, <i>Hepatology</i> 37:147-151, 1980.</p> <p>8. Koskelo P, Mustajoki P: Altered coproporphyrin-isomer excretion in patients with the Dubin-Johnson syndrome, <i>Int J Biochem</i> 12:975-978, 1980.</p> | |
| <p>↑ Ovarian hyperfunction, estrogen therapy, pregnancy, chronic active hepatitis, during treatment with anticonvulsant drugs.⁴</p> <p>↓ Ovarian hypofunction, complicated pregnancies after the first trimester, fetal death, septic shock, CBG familial deficiency, inflammation, chronic liver diseases, hyperthyroidism, nephrosis, other protein-losing conditions.⁵</p> | <p>CBG, a glycoprotein primarily synthesized in the liver, binds and transports cortisol, corticosterone, progesterone, 17α-hydroxyprogesterone, and, to a much lesser degree, testosterone. However, dexamethasone does not bind to CBG. The protein is polymorphic with inheritance expressed as autosomal codominant.</p> <p>Concentration in blood is sensitive to exogenous estrogens in a dose-responsive manner. CBG concentrations in patients with endometrial cancer are claimed to be higher than in normal premenopausal women. There is no diurnal variation and no changes during the menstrual cycle.</p> <p>MW: 55,700 t_{1/2}: 5 days</p> |

| <p>8. Riad-Fohmy D, Read G, Walker R, et al: Steroids in saliva for assessing endocrine function, <i>Endocr Rev</i> 3:367, 1982.</p> <p>9. Orth D, Kovacs D, DeBold C: The adrenal cortex. In Wilson JH, Foster DW, editors: <i>Williams textbook of endocrinology</i>, ed 8, Philadelphia, 1992, WB Saunders.</p> | |
| <p>↑ Cushing's (pituitary) disease, adrenal adenoma, carcinoma</p> <p>↑↑ Ectopic ACTH syndrome</p> <p>↓ Addison's disease, congenital adrenal hyperplasia (adrenogenital syndromes), hypopituitarism (need for functional tests)</p> | <p>Most assays displace cortisol from binding proteins to measure total hormone (free and bound). Increased secretion is seen in hypoglycemia, stress, ether narcosis, pregnancy, obesity, depression, and hyperthyroidism. Decreased secretion can be seen in hypothyroidism, cirrhosis, and hepatitis. Blood cortisol levels, however, may be normal in these conditions due to altered clearance rates. Cortisol secretion does not change with age. In pregnancy there is a progressive rise (due to increased cortisol-binding globulin); in late pregnancy there is a 2.5-fold increase.</p> <p>There is a diurnal variation in secretion of cortisol; the level at 8:00 PM is normally 50% of the level at 8:00 AM. Random cortisol determinations are not very helpful. Loss of diurnal variation is often seen in Cushing's syndrome. The etiology of Cushing's syndrome may be established using various tests and protocols.</p> <p>(See <i>Dexamethasone Suppression Test, Standard</i>; and <i>Andrenocorticotrophic Hormone</i>.)</p> <p>For cases of hypocortisolism, adrenal reserve of cortisol may be demonstrated using ACTH stimulation tests.</p> <p>In primary adrenal insufficiency (Addison's disease), inadequate responses are seen following administration of cosyntropin (Cortrosyn). (See <i>Andrenocorticotrophic Hormone Stimulation Test, Rapid and Prolonged</i>). Hypopituitarism with ATH deficiency gives a delayed but normal response to prolonged exogenous ACHT stimulation but does not respond to a variety of other stimulation tests. (See <i>Andrenocorticotrophic Hormone Stimulation Test [after Insulin]</i> and <i>Metypapone Stimulation Test</i>.)</p> |
| <p>AF ↑ Cortisol/cortisone ratio in lung maturation (reliability of L/S ratio exceeds that of the cortisol/cortisone ratio)</p> <p>Decreases in AF have been reported in pregnancies with anencephalic fetuses.⁵</p> | <p>It has been reported that the competitive protein binding assay following chromatography yields concentrations of AF unconjugated cortisol that correlate poorly with maternal cortisol levels and highly with the duration of labor and the weight of the fetus.⁵ There is disagreement regarding the increase of corticoids during the last 10 wk of pregnancy. Those who found increasing levels of cortisol toward the end of pregnancy also found a good correlation between total cortisol and the L/S</p> |

Heterogeneity of serum CK activities have been de- scribed among racial groups. African-American men > Caucasian men > African-American women > Caucasian women; 97.5th percentiles were as follows: 520 U/L, 370 U/L, 290 U/L, and 145 U/L, respectively. ⁶ | S ↑ V Muscular exercise (significant elevations), aminocaproic acid, am- photericin B, bucindolol, captopril, carbenoxolone, carbromal, carteolol, chlorpromazine, clofi- brate, clonidine, colchicine, cyclopropane, diethyl ether, ethanol (al- coholics), gemfibrozil, halofenate, haloperidol, halothane, HMG CoA re- ductase inhibitors (e.g., lovastatin), isotretinoin, labetalol, lidocaine, lithium, D-penicillamine, perphenazine, pindolol, prochlorperazine, pro- pranolol, quinidine; halothane and succinyl- choline administered to- gether during anesthesia; poisoning with barbitu- rates, carbon monoxide, drugs of abuse (e.g., co- caine, lysergide, phency- clidine), ethchlorvynol, tricyclics; drugs given by IM injection. S ↑ C Hemolysis, serum Hb >39 mg/dL [>4.65 μmol/L] due to adenylate kinase. Some methods (e.g., SMAC) are very sensitive to adenylate kinase inter- ference. Bilirubin, lipemia, and heparin do not interfere. S ↓ Exposure of specimen to direct sunlight or to flu- orescent light; loss of CO ₂ . |

DIAGNOSTIC INFORMATION

REMARKS

S,B ↑ Trauma, surgery, myocardial infarction, and loss of blood supply to any muscle, myopathic disorders of any cause (e.g., rhabdomyolysis, polymyositis, dermatomyositis, myocarditis, alcoholism), muscular dystrophies of all types (especially Duchenne dystrophy in early stages), Reye's syndrome, poisoning with coma, malignant hyperpyrexia and prolonged hypothermia, hypothyroidism, infectious diseases (e.g., typhoid fever), arrhythmias (infrequently), direct-current countershock, congestive heart failure, tachycardia, pulmonary emboli, tetanus, generalized convulsions, extensive brain infarction (may mask concomitant MI), pregnancy, hypoxic shock, neoplasms of prostate, bladder, and GI tract, pulmonary edema, delirium tremens, acute psychotic reaction, head injury, infarction of GI tract.

Most increases relate to diseases of skeletal or heart muscle, rarely to diseases of smooth muscle. Oral contraceptives cause lower activities.

Lower than normal values probably have no meaning but reflect either small muscle mass, sedentary lifestyle, or both. MI may occur in frail, elderly persons with CK remaining below the upper reference limit (URL).⁸⁻¹⁶ Bed rest, even overnight, can lower CK activity by $\geq 20\%$.

Following MI, CK activity increases 4-8 hr after acute onset, activities peak at 12-36 hr, and usually return to normal activities in 3-4 days. Although total CK has been used as a diagnostic tool for MI detection, along with CK MB, it has predominantly been replaced with cardiac troponin I or T, due to the lack of myocardial tissue specificity. In developing countries, where cost is of primary concern, total CK still is a cost effective screening and diagnostic tool; however, clinical specificity is sacrificed (range, 70-80%).

The use of an optimized CK assay is encouraged because it possesses optimal reagent stability and maximally reactivates CK activity.

In the context of a cardiac (or coronary) care unit population, increased total CK has a sensitivity of $\sim 97\%$ and a specificity of 67% for the diagnosis of MI. Test performance varies with the selected decision threshold.¹⁷⁻²⁰

Creatine kinase (CK), Total—CONT

S ↓ C Very high or low Mg level; contamination with oxidizing agents (e.g., hypochlorite), heparin.

CK activity is found to the greatest extent in striated muscle (skeletal) and heart muscle. Therefore any type of injury to the muscle—skeletal or heart—will cause an elevation in serum CK, whether traumatic or pathologic.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Following AMI, the CK-MM₃ and the CK-MM₃/MM₁ ratio peak 18 and 10-12 hr, respectively, after chest pain. After reperfusion (spontaneously, or after treatments such as angioplasty or infusions with streptokinase or tissue plasminogen activator), peaks occur at 5-12 and 4-10 hr. Isoform profiles change before changes in total CK and CK-MB activities occur.⁶</p> | <p>Muscular exercise may cause significant elevations of CK-MM₃. Levels increase within 2 hr, peak at 6 hr, and then return to baseline values. Total CK does not increase significantly until 6 hr after exercise.</p> |
| <p>ROC-curve analysis shows that the CK-MM isoform ratio (CK-MM₃/CK-MM₁) has greater diagnostic efficiency than CK-MB activity between 3 and 9 hr after the onset of chest pain, whereas the reverse is true for the period between 10 and 18 hr.⁵ ROC-curve analysis also shows that the CK-MB and CK-MM isoform ratios have diagnostic efficiencies equivalent to the CK-2 mass assay in the 4-18 hr after onset of chest pain.⁷</p> | <p>The gene products are CK-MMc (or CK-MM₃) and CK-MB₂. In blood, the C-terminal lysine residues of the M-subunits are removed one at a time by the action of the plasma enzymes carboxypeptidase N (arginine carboxypeptidase, EC 3.4.17.3) or B (EC 3.4.17.2) to produce the more anodic CK-MM₂ and then the most anodic form, CK-MM₁.</p> |
| <p>Acute skeletal muscle injury produces an abnormal CK-2 isoform ratio during the first 12 hr following injury.⁸</p> | <p>In the case of CK-MB, there are two isoforms, CK-MB₂ and CK-MB₁, the latter being the more anodic form.</p> |
| <p>In polymyositis, the isoform profile can reliably distinguish between a clinically stable (or improving) condition and clinical deterioration.⁹</p> | <p>CK isoforms are not widely used in clinical practice today due to the use of myoglobin, CK-MB mass, and cardiac troponins.</p> |

| Electrophoresis, immunoinhibition ⁴ | | Roche Elecsys 2010 (s) | 0.1 | 2.9 | |
| | | Biosite Triage (p) | 1.0 | 4.3 | |

All results in mcg/L. Specimen types as indicated in the manufacturer's package inserts used for determination of 99th percentile reference ranges; s = serum, p = heparin plasma, b = both, n = not specified. Most commercial assays use the "Conan" anti-CK-MB antibody licensed from Washington University.⁶

All concentrations >99th limit are designated as irreversible myocardial injury. In the presence of the clinical setting of ischemia, an increased cTn >99th percentile indicative of acute myocardial infarction (MI).

CK-MB, as has been recognized for years for total CK, demonstrates a significant 1.5- to 3-fold higher 99th percentile reference limits for males versus females.

A standard reference material for CK-MB is available.⁷

DIAGNOSTIC INFORMATION

REMARKS

Although the measurement of CK-MB in serum or plasma has been replaced in many medical centers with cTnT or cTnI,⁸ it is still a useful laboratory test for the diagnosis of AMI, assessment of reinfarction, and detection of injury following PCI and recommended as an acceptable alternative to cardiac troponin. The classic time versus CK-MB level (activity or mass concentration) pattern observed following the onset of chest pain in AMI shows an initial increase takes 4-6 hr to increase above the upper reference limit. Peak levels occur at ~24 hr.⁹ Return to normal (baseline) takes 48-72 hr ($t_{1/2}$ of CK-MB is 10-12 hr). Factors that may affect the classic pattern include size of infarction, CK-MB composition in the myocardium, concomitant skeletal muscle injury, and reperfusion (spontaneous, following thrombolytics, or following angioplasty). The lack of tissue specificity and differentiation of increased CK-MB due to the heart or skeletal muscle becomes important because a normal percentage of CK-MB of total CK activity may be misleading if concomitant injury occurs in skeletal muscle coincident with an AMI. The fractional amount of CK-MB release from the heart would be obscured by the large release of total CK from skeletal muscle injury.

Clinical studies comparing CK-MB mass to activity assays have shown that CK-MB mass measurements provide earlier detection of abnormal CK-MB levels following AMI. Thus clinical sensitivity is improved without sacrificing specificity. Because >50% of patients with AMI present to emergency departments with a nondiagnostic ECG (NSTEMI), rapid and sensitive assays for the measurement of CK-MB will help clarify the diagnosis in those patients. As described by the ESC/ACC consensus document on the redefinition of AMI, sampling at a minimal 6-9 hr after presentation is suggested before ruling out AMI. The improved immunoassays are able to quantitate significant changes during the early hours after the onset of chest pain within the normal range for CK-2 to facilitate earlier AMI detection.

Clinical use of the percent relative index (%RI; $\%RI = [CK\text{-}MB\text{ mass}/total\text{ CK activity} \times 100]$) or %CK-MB ($\%CK\text{-}MB = [CK\text{-}MB\text{ activity}/total\text{ CK} \times 100]$) aids in the interpretation of CK-MB concentrations for the detection of AMI. Although not absolute, an increased %CK-MB or %RI points toward the heart as the source of CK-MB in serum. However, the %RI and %CK-MB should not be used for interpretation when the total CK activity remains within the reference interval because of the potential of falsely elevated values. It is also confounded if there is any concomitant skeletal muscle injury because the sensitivity for the detection of cardiac events is lost.¹⁰

Three cytosolic isoenzymes (CK-MM, CK-MB, CK-BB) and one mitochondrial isoenzyme (CK-Mt) of CK (~MW 80 kDa for all) have been identified and can be separated by electrophoresis. Three different genes have been identified that encode for and are specific for CK-M, CK-B, and mitochondrial CK subunits.¹¹ Although CK-MM is predominant in both heart and skeletal muscle, CK-MB has been shown to be more specific for the myocardium, which contains 10-20% of its total CK activity as CK-MB, compared with amounts varying from 2-5% in skeletal muscle.

Early studies involving animal hearts or specimens obtained at autopsy from human hearts suggested a uniform distribution of CK-MB ranging from 5-50% of the total CK activity. However, it has been shown that the proportion of CK-MB was 6-15% lower in the surrounding normal areas of tissue than in infarcted myocardium in humans. Further, in response to acute and chronic coronary artery occlusion in a dog model, myocardium showed twofold to threefold increases in CK-MB in both ischemic and nonischemic myocardium. When studied more completely in humans, CK-MB concentrations ranged from 15-24% of total CK in myocardial tissue obtained from patients with left ventricular hypertrophy (LVH) due to aortic stenosis, from patients with CAD without LVH, and from patients with CAD and LVH due to aortic stenosis. In contrast, patients with normal left ventricular tissue had a low percentage of CK-MB (<2%). These data suggest that changes in the CK isoenzyme distribution are dynamic and occur in hypertrophied and diseased human myocardium. Diseased cells also have less total CK per cell.

Normal skeletal muscle, depending on its location, contains very little CK-MB. Percentages as high as 5-7% have been reported, but <2% is much more common.¹² There are some differences related to slow versus fast twitch muscle and thus to race. Severe skeletal muscle injury following trauma or surgery can lead to absolute elevations of CK-MB above the upper reference limit of CK-MB in serum. However, the percent CK-MB in serum would be low (percentages advocated vary but when comparing activity to activity a percentage or <5% is often used and when one compares CK activity to CK-MB mass, a percentage of <2.5% is usually advocated). Increases in serum total CK and CK-MB in several patient groups often present a diagnostic challenge to the clinician. Persistent elevations of serum CK-MB resulting from chronic muscle disease occur in patients with muscular dystrophy, end stage renal disease, polymyositis, and in healthy subjects who undergo extreme exercise or physical activities.¹³ The increase in serum CK-MB in runners, for example, may be related to the adaptation by the skeletal muscle during regular training and after

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>acute exercise, resulting in increased CK-MB tissue concentrations.¹⁴ The mechanism responsible for increased CK-MB in skeletal muscle following chronic muscle disease or injury is thought to be due to the regeneration process of muscle, with reexpression of CK-B genes similar to those found in the heart; thus giving rise to increased CK-MB levels in skeletal muscle. Thus skeletal muscle can become like heart muscle in its CK isoenzyme composition, with up to 50% CK-MB in some patients with severe polymyositis.¹⁵</p> <p>Ion-exchange chromatography and electrophoresis have largely been replaced with immunoassays, although immunoinhibition techniques are still being used.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>U ↑ Primary hyperparathyroidism (about 85% of patients), humoral hypercalcemia of malignancy (~50% of patients), osteomalacia due to vitamin D deficiency, calcium malabsorption, calcium urolithiasis associated with hypercalciuria, type II pseudohypoparathyroidism, mania, familial Mediterranean fever</p> <p>U ↓ Hypoparathyroidism, type I pseudohypoparathyroidism, depression</p> | <p>portion is synthesized by the kidney and excreted by renal tubular cells. This latter portion of the total urinary cAMP is known as nephrogenous cAMP and is under direct influence of PTH. Plasma cAMP assays have limited clinical utility except in calculating the nephrogenous portion of the total urinary cAMP. Total urinary cAMP can be expressed as a rate per unit time or per gram creatinine. Because rates can vary with illness or sex, it is preferable to express total cAMP as a function of GFR using urine and serum creatinine levels:</p> $\text{cAMP}_u \times \left(\frac{\text{Cr}_s}{\text{Cr}_u} \right) = \text{cAMP}_u (\text{total})$ <p>$\text{cAMP}_u (\text{total}) = \text{nmol/dL glomerular filtrate}$ $\text{Cr}_s = \text{serum creatinine in mg/dL}$ $\text{Cr}_u = \text{urine creatinine in g/L}$ $\text{cAMP}_u = \text{urine cAMP in mmol/L}$</p> <p>Nephrogenous cAMP can be calculated by subtracting the amount of cyclic AMP filtered (plasma cAMP × creatinine clearance) from the total urinary cAMP.</p> <p>In routine clinical testing, urinary cAMP corrected for GFR is almost as good as nephrogenous cAMP for discriminating parathyroid secretory states. Because increased urinary cAMP excretion is associated with many cancers, this test should be used cautiously in a clinical diagnosis of hyperparathyroidism (see <i>Parathyroid Hormone</i>). The test, however, is very useful in evaluating states of PTH resistance and degrees of hypoparathyroidism.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Cystatin C can be used to diagnose impaired renal function; its concentration in serum or plasma is increased in patients with reduced glomerular filtration rate (GFR). The reciprocal of serum cystatin C concentration has been shown to be more strongly correlated with GFR (as determined by “gold standard” methods measuring the clearance of exogenous substances like inulin or ⁵¹Cr-EDTA) than the reciprocal of serum creatinine. Cystatin C increases more rapidly than creatinine in the early stages of GFR impairment.</p> | <p>Cystatin C is a low molecular weight (13 kD) cysteine protease inhibitor that is produced at a constant rate by all nucleated cells. It is freely filtered by the glomerulus and reabsorbed (but not secreted) by the renal tubules with no extrarenal excretion. Its concentration is not affected by diet, muscle mass, or acute inflammation, giving it an apparent advantage over serum creatinine and other proteins as a marker of renal function, particularly in pediatric patients, where near-adult levels are reached early in childhood. Cystatin C has been found to have improved clinical utility compared with serum creatinine in monitoring for early renal damage in patients receiving chemotherapy, patients with cirrhosis, rheumatoid arthritis, IgA nephropathy, and renal transplant patients.</p> |
| <p>Increased excretion in renal disorders. Good predictor of the severity of acute tubular necrosis.</p> | |

| <p>↑ Primary and secondary fibrinolysis; during thrombolytic therapy with tissue plasminogen activator; thrombosis, including deep vein thrombosis, pulmonary embolism, arterial thromboembolism, and DIC; vasoocclusive crises of sickle cell anemia; pregnancy (especially postpartum period); malignancy; surgery</p> | <p>Increased levels of D-dimer indicate a fibrin clot was formed and subsequently degraded by plasmin. Essentially, a D-dimer is present whenever the coagulation system has been activated, followed by fibrinolysis; therefore although a very sensitive test, it is not very specific.</p> <p>The D-dimer can be measured by a variety of methods, semi-quantitative and quantitative, manual and automated, latex agglutination versus ELISA. The use of automated quantitative methods such as an automated latex particle immunoassay or a enzyme-linked fluorescent assay on modern coagulation analyzers have increased significantly over the past few years.³</p> <p>These highly sensitive automated D-dimer tests reportedly may be used to exclude PE and DVT: a negative test essentially rules out thrombosis, but a positive test does not confirm the diagnosis, and further testing is recommended.⁵</p> |
| <p>↑ Genetic hemochromatosis (>10 mg Fe/day; >179 μmol Fe/day), other iron overload disorders</p> | <p>Test is an adjunctive test in detecting iron overload. Deferoxamine is a chelating agent with a high affinity for iron; it is used therapeutically in treating iron poisoning.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| ↑ Females with hirsutism, acne; congenital adrenal hyperplasia, adrenal cortex tumors (values higher in adrenal carcinomas than in adrenal adenomas), Cushing's disease, ectopic ACTH-producing tumors; polycystic ovary syndrome | <p>DHEA-S originates almost exclusively in the adrenals, although some may be derived from the testes; none is produced by the ovaries. DHEA-S is weakly androgenic but is metabolized in peripheral tissues to testosterone and dihydrotestosterone. Plasma levels of DHEA-S are >1000 times those of DHEA and 10 times those of cortisol. Unlike DHEA, DHEA-S does not exhibit a marked diurnal variation and has a low clearance rate. Unlike testosterone, DHEA-S does not circulate bound to sex hormone.</p> <p>Testing for DHEA-S instead of 17-KS in urine has been suggested for estimating adrenal androgen production. DHEA-S levels in men and women decline progressively with age.</p> <p>Levels are increased in cord blood during pregnancy and decrease precipitously on delivery. Levels in premature infants are generally much higher than in full-term infants. Pregnancy and oral contraceptives induce a moderate decrease. Virilizing ovarian tumors rarely produce DHEA-S.</p> <p>In addition to DHEA-S, other plasma markers of androgen excess are available. See <i>Testosterone, Total</i>; <i>Testosterone, Free</i>; <i>Dihydrotestosterone</i>; <i>Androstenedione</i>; and <i>3α-Androstanediol Glucuronide</i>.</p> |

| Dexamethasone Suppression Test, Standard ^{1,2} | For 6 days collect serum (8:00 AM and 8:00 PM) and 24-hr urine for baseline mea- surements (days 1 and 2) and during dexamethasone adminis- tration (days 3-6). | Serum cortisol, Suppression on day 4 to <50% of baseline × 0.01 [<0.50] or to <5 mcg/dL × 27.6 [138 nmol/L] | ↓ V Nonsuppression may occur with alcohol (chronic), barbiturates, carbamazepine, in- domethacin, meproba- mate, phenytoin, and ri- fampin. |
| Dose, adult, low dose: 0.5 mg dexa- methasone orally q 6 hr × 8 on days 3 and 4 | | Urine 17-KGS, Suppression on day 4 to <7 mg/day × 3.47 [$<24\ \mu\text{mol/day}$] | Enhanced suppression may occur with amphet- amine, benzodiazepines, and corticosteroids. |
| | | Urine 17-OHCS, Suppression on day 4 to <4.5 mg/day × 2.76 [$<12.4\ \mu\text{mol/day}$] | |
| | | Urine-free cortisol, Suppression on day 4 to <50% × 0.01 [0.50] | See also individual tests. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Cushing’s syndrome: >10 mcg/dL [>276 nmol/L]</p> <p>Half of patients with endogenous depression have suppression test values >5 mcg/dL [>138 nmol/L].³</p> | <p>1.1% of normals, 13% of obese, and 23% of hospitalized or chronically ill controls give false-positive results. Test is easy to perform on ambulatory patients and serves as a screening test for subjects suspected of having Cushing’s syndrome. Test may be abnormal if patient is stressed or pregnant. Because many conditions can invalidate the test, its use as a routine marker for endogenous depression may not be valid.⁴ Some patients with Cushing’s disease have false-negative results with this low dose of dexamethasone.</p> <p>A 24-hr urine free cortisol determination also serves as a useful screening test for Cushing’s syndrome. (See <i>Cortisol, Free</i>.)</p> |
| <p>Most patients with pituitary Cushing’s disease demonstrate suppression, whereas patients with adrenal adenoma, carcinoma, and ectopic ACTH-producing tumors do not.</p> | <p>False-negative test results with the low-dose overnight test can be assessed with a high (4 mg) or high-high (8-24 mg) dose of dexamethasone. With high-high dose testing, <10% of patients with pituitary Cushing’s disease fail to suppress.⁵ Simultaneous measurement of cortisol and dexamethasone in the 8:00 AM blood sample improves reliability of this test for Cushing’s syndrome.⁶</p> |
| <p>The low dose distinguishes normals from patients with Cushing’s syndrome, in whom incomplete or no suppression occurs.</p> | <p>A dose of 20 mg/kg/day should be used for children and obese subjects.</p> |

| High dose: 90% of patients with Cushing’s disease demonstrate suppression, whereas patients with adrenal adenoma, carcinoma, and ectopic ACTH-producing tumors do not. | |
| Exposure is most commonly by inhalation, although accidental and intentional ingestions have been reported. Chronic oral exposure may cause a microcytic anemia. Respiratory exposure may be associated with eye, nose, and skin irritation; headache; nausea; anemia; and hepatotoxicity. | <p><i>p</i>-Dichlorobenzene is used as a disinfectant, insecticide, and deodorant in restroom and animal facilities.</p> <p><i>Occupational exposure</i></p> <p>TLV = 75 ppm [450 mg/m³]</p> |
| ↓ Tetrahydrobiopterin-deficient hyperphenylalaninemia (cofactor variant of classic PKU) | Hyperphenylalaninemia can result from a deficiency of phenylalanine hydroxylase (classic PKU) or from defects associated with the enzyme cofactor tetrahydrobiopterin (BH ₄). BH ₄ defects can be caused by a deficiency of DHPR or by a defect in biopterin biosynthesis. BH ₄ defects account for 1-3% of patients with hyperphenylalaninemia. In addition to DHPR assays, cofactor variant screening also involves measurement of urine pteridines. |

See *Testosterone, Total*.

↓ 5α-Reductase deficiency, hypogonadism

↑ Hirsutism

DHT is largely derived from peripheral tissue conversion of testosterone catalyzed by a steroid 5α-reductase enzyme.

Serum levels of dihydrotestosterone decrease rapidly in males during the first week after birth; they then increase between 30 and 60 days to 12-85 ng/dL [0.41-2.92 nmol/L] and gradually decrease to 3 ng/dL [0.10 nmol/L] by 7 mo. In females, DHT decreases to prepubertal levels during the first month.

Serum concentrations of dihydrotestosterone are closely related to those of testosterone but are lower. There is a decrease in the ratio of dihydrotestosterone to testosterone throughout pregnancy.

DHT is the primary active metabolite of testosterone that is responsible for hair growth. Measurements of circulating DHT may not be useful in evaluating hirsutism because serum concentrations reflect intracellular concentrations poorly. However, DHT is metabolized to a 3α-androstanediol glucuronide (3α-diol). See *Testosterone, Free*; and *3α-Androstanediol Glucuronide*.

| Impairment of carbohydrate absorption may occur as a result of mucosal damage or dysfunction as in sprue, celiac disease, or acute gastroenteritis, or as a result of a deficiency of a single or all brush border oligosaccharidases. | <p>These tests are used to diagnose malabsorption due to specific or generalized disaccharidase deficiencies (lactose, fructose, sorbitol). The most common form is lactase deficiency. (See <i>Lactose Tolerance Test</i>.) To eliminate misinterpretations of serum test results, a glucose tolerance test and absorption tests of the component monosaccharides may be needed to rule out monosaccharide malabsorption. Diagnosis of disaccharidase deficiencies is confirmed by assay of the disaccharidase in a small-intestinal biopsy specimen.</p> <p>Breath testing is highly sensitive and specific.</p> |

| Hemolysis in blood that has been chilled and then warmed indicates the presence of bithermic cold hemolysins or Donath-Landsteiner antibodies (D-L Ab). D-L Ab are IgG immunoglobulins, typically with anti-P specificity, although other specificities such as anti-I or anti-HI may occur very rarely. PCH itself is rare. Originally described in congenital or late syphilis, PCH is usually acute, transient, and associated with viral infections but may be idiopathic. | Hemolysis is complement dependent, and a fresh source of complement may be needed to demonstrate the D-L Ab. The D-L Ab is a nonagglutinating IgG that binds complement in the cold and lyses erythrocytes at 37° C. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>S ↑ 90-100% of patients with neuroblastoma and 70-90% of individuals with small cell cancer of the lung (SCCL). In SCCL, elevations are related to extent of disease and are observed in only 50-60% of patients with limited disease. Enzyme activity shows excellent correlation to clinical status when used in monitoring. There is significantly lower survival in SCCL patients with markedly elevated values. Elevations may also be observed in septic shock, pneumonia, or neural trauma.</p> <p>NSE is also increased in patients with stroke.^{14,15} NSE concentrations are a predictor of the extent of neural damage and neurological deficits.</p> | <p>NSE is a specific serum marker for the family of neuroendocrine tumors of the APUD series (amine precursor uptake and decarboxylation). These include neuroblastoma and retinoblastoma, medullary carcinoma of the thyroid, pancreatic islet cell carcinoma, carcinoid, pheochromocytoma, and SCCL. The test is intended for research (investigational) use only and does not have FDA approval for general clinical application.</p> |

↑ Infections, inflammatory disease, tissue destruction, and other conditions leading to increased plasma fibrinogen or globulins (asymmetrical molecules) such as malignant neoplasms, paraproteinemia (e.g., macroglobulinemia, multiple myeloma); anemia, increasing with severity

↓ *Conditions in which the ESR does not increase with conditions listed above:* Polycythemia, sickle cell anemia, spherocytosis, hypofibrinogenemia

The ESR correlates well with the plasma fibrinogen level and depends on rouleaux formation of erythrocytes. Poikilocytosis therefore tends to inhibit sedimentation; conversely, increased flattening of erythrocytes, as in obstructive liver disease, tends to accelerate sedimentation. The sensitivity of the ESR in detecting plasma protein abnormalities is best in the absence of anemia; in anemia, the ZSR has an advantage. The Wintrobe method is more sensitive in the normal to slightly elevated range, whereas the Westergren is more sensitive in the elevated range.⁷ The micromethod may be useful in pediatric patients.

The ESR should not be used to screen asymptomatic patients for disease. When the ESR is increased, a careful history and physical examination will usually disclose the cause. The test is useful and is indicated for the diagnosis and monitoring of temporal arteritis and polymyalgia rheumatica. The ESR is included in the Jones Criteria for diagnosis of rheumatic fever. The ESR has little diagnostic value in rheumatoid arthritis but may be useful in monitoring disease activity when clinical findings are equivocal. Because the test is often normal in patients with neoplasms, infection, and connective tissue disease, the ESR cannot be used to exclude these diseases in patients with vague complaints.⁸

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Anemias (including aplastic anemia), secondary polycythemia (e.g., high-altitude hypoxia, chronic obstructive pulmonary disease, pulmonary fibrosis), erythropoietin-producing tumors (e.g., cerebellar hemangioblastomas, pheochromocytomas, renal tumors), pregnancy (striking change), polycystic kidney disease, kidney transplant rejection (early manifestation?), following moderate bleeding of a normal individual</p> <p>↓ Renal failure, primary polycythemia (Polycythemia vera)</p> | <p>Erythropoietin is a glycoprotein hormone that regulates erythropoiesis. Erythropoietin levels in anemia are primarily determined by the degree of anemia and not by any specific effect of the underlying illness on the production of erythropoietin.⁵ This test is useful in differentiating primary from secondary polycythemia and in detecting recurrence of erythropoietin-producing tumors. It has been suggested that morning values are higher than afternoon values because of the diurnal rhythm of secretion.</p> <p>Electrophoretic mobility methods have been recommended for detection of DNA-recombinant human erythropoietin when use is suspected by competitive athletes.⁶</p> |

See *Estriol, Free*; and *Estriol, Total*.

Estetrol (15 α -hydroxyestriol), contrary to earlier expectations, does not appear to be a better indicator than estriol (E₃) for detecting fetal distress during the third trimester.⁴ In contrast to E₃, negligible E₄ is contributed by the placenta. E₄ (as well as E₃) increases throughout gestation, with threefold to sevenfold increase between the 24th and 40th weeks.

|---|--|
| S ↑ Feminization in children, estrogen-producing tumors, gynecomastia, hepatic cirrhosis, hyperthyroidism | <p>Estradiol is the most active of endogenous estrogens. The test is of value, together with gonadotropins, in evaluating menstrual and fertility problems in adult females. Measurement is also useful in the evaluation of gynecomastia or feminization states due to estrogen-producing tumors, menstrual cycle irregularities, and sexual maturity in females and in monitoring of hMG (Pergonal) therapy.</p> |
| S ↓ Primary and secondary hypogonadism | <p>Direct (no extraction) assays for E_2 in serum or plasma may give inaccurate results, particularly in prepubertal children or subjects receiving oral estrogen replacement therapy.⁷ E_2 levels are markedly elevated at birth and decrease rapidly during the first week. In females, serum estradiol levels increase progressively throughout puberty. During the normal ovulatory cycle, estradiol is secreted in a biphasic pattern, with midcycle and luteal phase peaks. In males, estradiol levels increase during puberty as a result of peripheral testosterone conversion.⁸</p> |

↑ Sharp increase if delivery is imminent

↓ In about half of pregnancies in which the fetus has major malformations of CNS not involving anterior pituitary; congenital heart disease, Down syndrome

Free E_3 measurements are more specific than total E_3 for monitoring the output of the fetoplacental unit at the time of phlebotomy.

Values vary widely from patient to patient; serial determinations are recommended. AM concentrations are higher than PM; therefore specimens should be drawn at the same time of day to allow comparison of values. E_3 increases progressively during pregnancy. (See *Estriol, Total*.) The surge in unconjugated serum E_3 levels during the 35th-36th weeks has proved useful in estimating fetal age.

Subnormal levels or a decrease in serum concentration in two or more successive measurements suggests fetal distress. Unfortunately, the sensitivity and specificity of this test for predicting fetal distress are very poor; thus its use for this purpose has been largely abandoned. However, serum determinations of E_3 in combination with β -hCG and AFP (triple test) or with β -hCG, AFP, and inhibin A (quadruple test)⁸ are used for maternal screening for Down syndrome at 16-18 wk gestation. A great number of drugs interfere with the chemical determination of estriol; thus the RIA test is preferred for this and other analytical reasons.

Saliva is used as an alternative testing sample for free E_3 analysis.⁹⁻¹¹

Jung K, Diego J, Strobelt V, et al: Diagnostic significance of some urinary enzymes for detecting acute rejection crises in renal-transplant recipients: alanine aminopeptidase, alkaline phosphatase, γ-glutamyltransferase, N-acetyl-β-D-glucosaminidase, and lysozyme, <i>Clin Chem</i> 32:1807-1811, 1986.</p> | |

↓ High-risk pregnancies involving diabetes, postmaturity, preeclampsia, fetal growth retardation, Rh immunization, intrauterine fetal death, anemia, malnutrition, pyelonephritis, intestinal disease and hemoglobinopathies, hypoplasia of fetal adrenals, anencephalic fetus; decreased in pregnancy with fetus affected by virilizing form of congenital adrenal hyperplasia; decreased in placental sulfatase deficiency or 16 α -hydroxylase deficiency.

The predominant urinary estrogen during pregnancy is E₃. Serial measurement reflects the integrity of the fetoplacental complex. E₃ measurements are sometimes useful in following the high-risk pregnant patient. Declining values indicate fetal jeopardy, particularly if present over several days. A single determination cannot be interpreted in a meaningful fashion. Unfortunately, in some high-risk pregnancies, estriol values may not be reduced. In recent years E₃ measurements have been used less frequently in clinical practice in favor of ultrasound determinations and evaluations of maternal blood pressure, renal function, or carbohydrate metabolism. When serial measurements are performed, serum samples should be collected at the same time of day. Highest serum levels are seen at midday. See *Estrogens, Total*; and *Placental Lactogen*.

AF ↓ Anencephaly, erythroblastosis fetalis

At term E₃ represents >90% of the total amniotic fluid estrogens because it increases 5- to 10-fold in its mean values. Unconjugated E₃ is ~10% of total E₃ in amniotic fluid. The demonstration of a good correlation between E₃ levels in the amniotic fluid and in maternal urine would suggest no specific advantage of amniotic fluid over urinary E₃ determination. Decreases of amniotic E₃ closely parallel the severity of the hemolytic process in the fetus. It is claimed that amniotic fluid concentrations of E₃ of <100 ng/mL [<350 nmol/L] indicate that the fetus is in jeopardy. A highly significant correlation exists between amniotic fluid E₃ levels and the weight of the infant and placenta. Meconium in the amniotic fluid may give erroneously high E₃ levels. E₃ in a single amniotic fluid specimen is of limited value.

6. ARUP-Cleveland Clinic Laboratory: *Reference manual*, Cleveland, OH, 1991, ARUP-Cleveland Clinic Laboratory.

Test is used primarily for identifying patients with breast cancers likely to respond to either additive or ablative hormone therapies.

Patients positive for both ERP and progesterone receptor protein (PRP, see also *Progesterone Receptor Protein*) have a higher percentage (75-80%) response to hormonal therapy than do women positive for either ERP or PRP alone. Only 40-50% of ERP-positive, PRP-negative patients respond; 25-30% of ERP-negative, PRP-positive show a response. Response is observed in only 10% or fewer of patients who are negative for both ERP and PRP. The percentage of positive specimens is greater in postmenopausal women than in those who are premenopausal. Receptor status is also influenced by age.

Patients who are hormone-receptor positive have a better prognosis for both disease-free survival and overall survival than those who are receptor negative.

The definition of positive or negative may vary from one laboratory to the next. Results can vary due to tissue and antibody treatment and antibody specificity.^{3,5}

Estrogen receptors are a part of the nuclear steroid hormone receptor family and play a role in hormone directed transcriptional activation. There are two estrogen receptor isoforms: ER α (classic ER) and ER β , which have 96% homology and 58% homology for DNA and ligand-binding domains, respectively. Ligand-binding properties and biological activities are different for the two isoforms with ER α playing a more predominant role in breast cancer.^{1-3,5}

Estrogen receptors can be measured by quantitative ligand-binding assays (DCC) and immunoassays and semiquantitative/qualitative immunocytochemical assays. IHC measures receptors in the invasive carcinoma cells and not intraductal carcinoma or normal breast tissue in contrast to ligand-binding methods and are not influenced by the presence of estrogens, antiestrogens, or steroid-binding proteins.

Although clinical data and guidelines for the use of estrogen receptors were primarily developed using older techniques such as DCC, immunohistochemistry is considered equivalent or superior and is the preferred method in clinical practice.^{3,6,7}

The American Society for Clinical Oncology, among other groups, recommends measurement of estrogen and progesterone receptors in primary breast cancers.^{5,6}

| Ethyl glucuronide (EtG) ¹ | Serum | Undetectable (<0.1 mg/L) ^{3,4} | Unknown. |
| Chromatographic methods, ELISA | | | |

Urine, stable for 4 days
at room temperature.² Undetectable (<0.1 mg/L)⁵

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| U ↑ Hyperlysinemia, primary hepatoma, ethanolaminosis | Relatively high concentrations of free EA are present in human tissues, especially in the brain, lung, and liver. In urine a very high excretion occurs on the first day of life. |
| | Values in children (3 mo-10 yr) were measured using reversed-phase liquid chromatography. |
| ↑ Alcohol intake. | <p data-bbox="592 1315 1094 1472">Ethyl glucuronide (EtG) is a highly specific but minor metabolite of ethanol. It is generated by conjugation of ethanol with glucuronide in the liver. Shortly after intake of even small amounts of ethanol, EtG is detectable, peaks at 2-3.5 hr in blood and subsequently decreases exponentially. The half-life ranges from 2-3 hr. EtG is eliminated through urine excretion.</p> <p data-bbox="592 1506 1094 1605">EtG is nonvolatile, water-soluble, and stable. It can be detected up to 80 hr after the complete elimination of ethanol from the body. It is used as a sensitive and specific marker for detecting recent alcohol use and a marker for detecting lapse/relapse.</p> |

Dahl H, Stephanson N, Beck O, et al: Comparison of urinary excretion characteristics of ethanol and ethyl glucuronide, <i>J Anal Toxicol</i> 26:201-204, 2002.</p> | |
| <p>Lysis is marked and rapid in primary fibrinolysis but is only minimal or is not present in conditions associated with secondary fibrinolysis (e.g., liver disease, DIC).</p> <p>Increased fibrinolysis (shortened lysis time) may be associated with severe stress (exercise, surgery, cancer), α_2-antiplasmin deficiency,² or plasminogen activator inhibitor-1 deficiency.</p> <p>A falsely low lysis time may be seen in DIC due to low fibrinogen.</p> | <p>The Eugloblin clot lysis time (EGT) is a global test of the fibrinolytic system. When plasma is diluted and acidified, the precipitate formed contains plasminogen and its activators but is devoid of most of the plasmin inhibitors. When this precipitate is redissolved, the ability to lyse a fibrin clot is then assessed.</p> <p>EGT is a screening test for determining fibrinolysis in the absence of inhibitors. This test may also be used to monitor therapy with urokinase, streptokinase, and tissue plasminogen activator. If fibrinogen is low, no clot may form unless fibrinogen is added to the sample. If plasminogen has been depleted, test may be normal. Heparin therapy does not affect the results. Lysis time may be shortened in healthy persons after exercise. Prolonged venous occlusion by tourniquet may increase fibrinolytic activity. Traumatic venipuncture may cause an increase in fibrinolytic activity.</p> |
| <p>2. Aoki N, Saito H, Kamiya T, et al: Congenital deficiency of α_2 plasmin inhibitor associated with severe hemorrhagic tendency, <i>J Clin Invest</i> 63:877-884, 1979.</p> | |
| <p>Specific factor inhibitors may arise against any coagulation factor.</p> <p>Specific inhibitors to factors VIII and IX are by far the most common. A specific inhibitor may arise in patients with known hereditary factor deficiency or rarely in nonhemophiliac patients. These antibodies may arise spontaneously or in association with drugs or autoimmune disorders. Specific inhibitors to other factors are very rare. Specific factor inhibitors may be associated with severe clinical bleeding.</p> | <p>The presence of an inhibitor to factor VIII or factor IX is usually suspected with a prolonged APTT in the presence of a normal PT and a mixing study with a "no correction" pattern (immediate and/or at 2 hr incubation).</p> <p>The classic Bethesda quantitative inhibitor assay is typically described for factor VIII inhibitors. The Bethesda assay may be modified as follows: <i>porcine</i> factor VIII may be used to determine whether the factor VIII inhibitor cross-reacts with porcine factor VIII; the incubation time of 2 hr is not necessary to quantify a factor IX inhibitor; the normal plasma may be substituted by factor VIII concentrate (Oxford method).</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Positive: Hereditary factor XIII deficiency | Hereditary factor XIII deficiency is rare. Symptomatic patients usually have <1% activity. Factor XIII deficiency typically causes delayed bleeding and poor wound healing. In the neonate it can present as umbilical stump bleeding. |
| Rare acquired factor XIII inhibitors (some associated with isoniazid, penicillin, or phenytoin). | The factor XIII screen evaluates clot stability in 5 mol/L urea. This test will detect most symptomatic patients. Kits for confirmatory quantitative assays for factor XIII antigen are now available. |

| | |
|---|--|
| ↑ Fat malabsorption results from three disorder categories: pancreatic insufficiency (loss of lipase and inability to split triglycerides), hepatobiliary (bile deficiency and inadequate emulsification), and intestinal (rapid transit, inadequate absorptive surface, etc.); thus small-bowel diseases with fat malabsorption, viral hepatitis, diabetes mellitus, peptic ulcer disease, carcinoid syndrome, α-β-lipoproteinemia, cystic fibrosis, multiple sclerosis, gastroduodenal fistula, regional enteritis, extrahepatic biliary obstruction, psoriasis, progressive systemic sclerosis, dumping syndrome, pancreatic insufficiency or obstruction, Whipple's disease, malnutrition, celiac disease, tropical sprue, thyrotoxicosis, pernicious anemia, Addison's disease, liver cirrhosis, increased intestinal motility | <p>A dietary fat intake of 50-150 g/day of long-chain triglyceride should be maintained for at least 2 days before and during the collection period for the fecal fat determination. Patients should consume 30 mL corn or olive oil with each meal. Butter is composed of short chain FA and does not count.</p> <p>Procedures without hydrolysis measure only total fatty acids, which represent 60-80% of total fecal lipids. Variation among methods depends on which fatty acid is used as the standard.</p> <p>Various lipid tolerance tests (ingestion of lipid followed by serum measurements) are not useful.</p> $\text{Coefficient of fat absorption (\%)} = \frac{\text{Fat ingested} - \text{fat excreted}}{\times 100 \text{ Fat ingested}}$ |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| | <p>Patients with steatorrhea have, on average, 10 times as many fat droplets per standard volume of stool as healthy controls.</p> <p>Screening methods are 98% sensitive when performed with great care. Routine performance of this test generally does not provide results equivalent to those reported in the medical literature.</p> <p>The ability of assays to distinguish total, split, and neutral fats is overemphasized because bowel flora can hydrolyze triglyceride. Total fat, regardless of form, is the clinically important value.</p> |
| <p>Heart-type fatty acid binding protein is released into blood after irreversible myocardial damage and is an early marker of myocardial infarction. H-FABP is released with the same kinetics as myoglobin, i.e., first increased within 3-6 hr and returns to normal within 24 hr.² However, H-FABP is more specific to cardiac damage, as the ratio of heart to skeletal muscle for H-FABP is higher (~7) than for myoglobin (~0.6).³ Some have advocated the use of a myoglobin to H-FABP ratio.⁴</p> | <p>Fatty acid binding protein is a low molecular weight protein (14-15 kDa) found in the cytoplasm of most cells. There are at least nine isoenzymes, including heart (H), liver (L), and intestinal (I).⁴ Whereas the heart type is found in the highest concentration in the myocardium, H-FABP is also found in skeletal muscles, distal renal tubules, and the brain.</p> |

| | <p>See also <i>Phytanic Acid, Fatty Acids, Free and Omega-3 and Omega-6 Fatty Acids</i>.</p> <p>The test has limited clinical application. Used in nutritional and lipid research.</p> <p>Using the FA profile to adjust dietary intake in otherwise normal persons is not widely accepted.</p> |
| ↓ Acrodermatitis enteropathica | <p>This condition is seen with impaired absorption and metabolism of essential fatty acids.</p> <p>Potential decrease in severe fat malabsorption, alcoholism, infants not breast-fed, and TPN.</p> <p>Omega-3 and -6 fatty acids may be considered part of an FA profile.</p> |

↑ Anything that causes a release of lipolytic substances (e.g., ACTH, epinephrine, glucagons, growth hormone, norepinephrine, thyrotropin, thyroxin); thus starvation, fasting, stress, exercise, diabetes (out of control), late pregnancy (placental hormones), pheochromocytoma, thyrotoxicosis, von Gierke's disease, most metabolic disturbances.

Most fatty acids have an even number of C atoms and are present in anionic form. They are carried largely by albumin and to some extent by lipoproteins.

Even when plasma is refrigerated, FFA increases 12-25% in 24 hr. However, fatty acids in heptane extracts are stable for several days if refrigerated.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| ↑↑ Iron overload (e.g., hemochromatosis, certain liver diseases) | Ferritin originates in the reticuloendothelial system (RES). It consists of a protein shell, apoferritin (MW 445,000), containing varying amounts of iron in its core as ferric hydroxide-phosphate complexes. |
| ↑ Fasting or inanition, acute leukemia, inflammatory diseases (e.g., pulmonary infections, osteomyelitis, chronic urinary tract infections, rheumatoid arthritis, SLE, burns), certain acute and chronic hepatocellular diseases (e.g., alcoholic and inflammatory liver disease), acute myeloblastic and lymphoblastic leukemia, Hodgkin's disease, breast carcinoma. Increase in serum or plasma ferritin due to inflammatory conditions (acute phase response) can mask a diagnostically low result. | Serum ferritin contains 20-25% iron; its concentration is a good measure of iron stores in normal persons and in individuals with iron deficiency; 1 ng/mL [1 mcg/L] of serum ferritin is equivalent to 8 mg [143 μmol] of stored iron. |
| ↓ Iron deficiency. Ferritin levels <10 ng/mL [<10 mcg/L] usually indicate iron deficiency anemia. | Fe uptake by ferritin requires previous oxidation of Fe^{2+} to Fe^{3+} . The measurement of serum ferritin is a good indicator of available iron stores in uncomplicated iron-deficiency states, idiopathic hemochromatosis, and transfusion siderosis. In conditions of iron overload and in some chronic diseases, serum ferritin is an unreliable estimate of the storage iron. Median values and the variability of serum ferritin levels increase with age in adults. ³ |
| | Serum ferritin concentration is a very sensitive and early indicator of iron deficiency that is uncomplicated by other concurrent disease. However, in the case of iron overload, serum ferritin is less sensitive than serum iron concentration, TIBC, or percent transferrin saturation. |
| ↑ <i>Hereditary disorders</i> : Homozygous β -thalassemia (20-100% Hb F [0.200-1.000, mass fraction of Hb F]), heterozygous β -thalassemia (up to 5% [0.050] Hb F in some cases), hereditary persistence of Hb F (homozygotes 100% [1.000], heterozygotes 15-35% [0.150-0.350]), sickle cell anemia (1-30% [0.010-0.300]), trisomy D | 30% of Hb F inhibits the sickling reaction of Hb S. Hb F is resistant to alkali denaturation (as are Hb Bart's, J, Rainier, and Bethesda). This technique is most useful for screening and for cases in which the percentage of Hb F is low (<15% [<0.150, mass fraction]). It is unreliable, usually falsely low, at higher levels of Hb F. |
| <i>Acquired disorders</i> (up to 10% Hb F): Pernicious anemia, PNH, refractory normoblastic anemia, sideroblastic anemia, pure red cell aplasia, aplastic anemia, pregnancy, molar pregnancy, hyperthyroidism, juvenile chronic myeloid leukemia (Philadelphia chromosome negative, marked elevation of Hb F), acute leukemias, erythroleukemia, benign monoclonal gammopathies, cancer with marrow metastases, chronic renal disease. ¹¹ | Electrophoresis is useful for confirmation of the alkali denaturation test and is more reliable at higher levels of Hb F. |
| ↓ Hemolytic anemia in the newborn | Cation-exchange chromatography is the best method for quantitation of high levels of Hb F. However, depending on the $G_\gamma:A_\gamma$ ratio, the retention time of Hb F may shift slightly. The G_γ is eluted faster than the A_γ and is enriched in newborn hemoglobin. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Fetomaternal hemorrhage; infants who are small for gestational age or with chronic anoxia. In blacks, hereditary persistence of fetal hemoglobin (HPFH) has a uniform distribution of Hb F among erythrocytes. In other forms of HPFH and in thalassemia and acquired conditions, Hb F is unevenly distributed among erythrocytes.</p> | <p>The Kleihauer-Betke acid elution technique can be modified to optimize detection and quantitation of fetal cells on a maternal blood smear or to distinguish between various types of congenital and acquired increases in fetal hemoglobin. The laboratory must always be notified of the suspected diagnosis so that the appropriate screening can be performed. Accurate quantitation of fetal/maternal hemorrhage is necessary for dosing of Rh immune globulin. Visual observation of distribution of fetal hemoglobin in red cells is a simple and inexpensive method for subtyping HPFH.</p> <p>The immunofluorescent determination is a more sensitive and more reproducible test for F cells than is the acid elution method.</p> |

| | |
|---|--|
| <p>Using 260 mP as the cutoff, this test has a sensitivity of 94% and a specificity of 84%. Supplemental use of the L/S ratio is not beneficial.¹³</p> | <p>NBD-phosphatidylcholine binds to albumin and to surfactant phospholipids. The resulting fluorescence polarization is a function of the surfactant/albumin ratio.¹⁸</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Maternal serum levels $>2\times$ the median should be investigated by ultrasound examination to rule out incorrectly estimated gestational age, multiple gestation, fetal death, or obvious malformation (e.g., anencephaly). Increased AFP concentrations in maternal serum and amniotic fluid are associated with open neural tube defects (NTD, e.g., anencephaly, spina bifida), omphalocele, esophageal or duodenal atresia, Meckel's syndrome, fetal hepatic necrosis secondary to viral infection, and other conditions.⁸</p> <p>↓ Down syndrome (trisomy 21),^{9,10} fetal demise, molar pregnancy, spontaneous abortion, trisomy 18, overestimated gestational age</p> | <p>AFP is synthesized in the liver. Some fetal AFP enters the maternal circulation. The serum AFP in maternal blood reaches its maximum at the 30th wk of pregnancy, then decreases rapidly to $<2\%$ of the maximum at 34–36 wk of pregnancy.</p> <p>Owing to the very steep concentration gradient between fetal serum, amniotic fluid, and maternal serum, very slight contamination of either amniotic fluid or maternal serum with fetal serum will cause very high apparent values. Only 44 μL of fetal blood in 10 mL or amniotic fluid can double the AFP concentration at 16 wk gestation.¹¹</p> <p>Maternal serum AFP (MSAFP) values are expressed as multiples of the median (MoM) by dividing the patient's AFP value by the median AFP for a normal pregnancy of the same gestational age. These MoMs are then corrected for maternal weight according to the following formula¹⁰: Weight-adjusted MoM = $10^{[0.2658 (0.00188 \times \text{maternal weight, pounds})]}$</p> <p>Values for maternal insulin-requiring diabetic patients should be adjusted by dividing by 0.8; values for black patients should be adjusted by dividing by 1.1. If the patient is known to be carrying twins, divide the MoM by 2.13.</p> <p>Maternal serum AFP (MSAFP) values are expressed as multiples of the median (MoM) by dividing the patient's AFP value by the median AFP for a normal pregnancy of the same gestational age. These MoMs are then corrected for maternal weight according to the following formula¹⁰:</p> <p>Weight-adjusted MoM = $10^{[0.2658 (0.00188 \times \text{maternal weight, pounds})]}$</p> <p>Values for maternal insulin-requiring diabetic patients should be adjusted by dividing by 0.8; values for black patients should be adjusted by dividing by 1.1. If the patient is known to be carrying twins, divide the MoM by 2.13.</p> <p>Maternal serum AFP values should be reported to the clinician as absolute concentrations and as adjusted multiples of the median for the stated gestational age. For various conditions, estimates of <i>a priori</i> and <i>a posteriori</i> risks should be calculated and reported.¹ To improve the detection rate of Down syndrome, some screening programs use multiple serum markers (e.g., AFP, hCG, and estriol).¹²</p> |

| Fibronectin (FN, Cold-Insoluble Globulin, Cell Surface Protein, Opsonic α_2 -Surface Binding Protein) ^{1,2} | Plasma. Analyze fresh or store at 4° C for <72 hr. Stable frozen at −20° C for 6 mo, or at −70° C indefinitely. Specimens without lipemia or hemolysis are preferred. | 300 ± 100 mcg/mL × 1.0 [300 ± 100 mg/L] | None found. |
|---|---|---|-------------|

EID

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ Fibrinogen is a sensitive acute phase reactant. Increased levels are also seen in pregnancy, oral contraception, postmenopausal women, smoking, and exercise.</p> | <p>Fibrinogen is typically performed in the investigation for unexplained bleeding, prolonged PT/PTT, or as part of a DIC panel.</p> |
| <p>↓ Inherited deficiency, resulting in an abnormal (dysfibrinogenemia), reduced (hypofibrinogenemia) or absent fibrinogen (afibrinogenemia).</p> | <p>An elevated fibrinogen has also been used as a predictor of arterial thrombotic events.</p> |
| <p><i>Acquired</i> deficiency: liver disease, consumptive coagulopathies such as DIC, and hemodilution.</p> | <p>Fibrinogen is generally measured by a clot based functional (activity) assay. The clot based assays performed on modern automated coagulation analyzers typically use photooptical technology. The older manual instruments (fibrometer) were based on electromechanical methods. The <i>Clauss</i> assay,⁵ based on a high concentration of thrombin added to dilute patient plasma, is the most commonly used method.</p> |
| | <p>The less frequently used immunological (antigenic) assays (ELISAs, RID) measure protein concentration but not functional activity.</p> |

↑ FN in synovial fluid is present in higher concentration than in the paired serum. Doubt remains as to whether FN is or is not a positive acute phase reactant. In severe infection FN levels may decrease markedly.

↓ In circumstances where protein loss is manifest (e.g., in coagulopathies, trauma, and vascular collapse), splenomegaly. Decreases may indicate sequestration of FN in association with other serum proteins, immune complexes, and platelets.⁵

Fibronectins are large adhesive glycoproteins that are integral parts of cell surfaces, extracellular matrices, and also occur in intravascular and extravascular fluids. FN molecules in plasma and in other fluids differ by virtue of their carbohydrate composition.⁶ The proteins are synthesized by a variety of cells, including endothelium, macrophages, synoviocytes, and hepatocytes.

FN is a dimer whose chains are interconnected by disulfide bridges. It binds to collagen, gelatin, heparin, and a variety of lectins through specific binding sequences. It also binds variably to glass and plastics, a factor that complicates its analysis. In addition, FN binds to immune complexes, C1q, IgM rheumatoid factors, cryoprecipitates, and fibrin. It can also be found bound to precipitates of denatured proteins and to proteins precipitated with polyethylene glycol.⁵ Its intensely adhesive nature may be one of the specific roles of FN in ridding the body of such materials.

See listing under serum. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>S ↑ Blind loop syndrome, vegetarian diet, distal small bowel disease, PA, B₁₂ deficiency</p> | <p>Folate deficiency is the most common vitamin deficiency and is prevalent in alcoholic liver disease, pregnancy, and the elderly. Folate deficiency may result from poor intestinal absorption (absence of intestinal microorganisms, in celiac disease or sprue, or after surgical intestinal resection), nutritional deficiency, excessive demands (pregnancy, liver disease, or malignancy), and in response to certain drugs (methotrexate, anti-cervical therapy, especially during pregnancy).⁴</p> |
| <p>S ↓ Untreated folate deficiency (usually resulting in megaloblastic anemia), infantile hyperthyroidism, alcoholism, malnutrition, scurvy, deficiency of certain enzymes, liver disease, B₁₂ deficiency, dietary amino acid excess, Lesch-Nyhan syndrome, achlorhydria, chronic hemodialysis, adult celiac disease, tropical sprue, Crohn's disease, sometimes in ulcerative colitis, malabsorption, hemolytic anemias, carcinomas, myelofibrosis (decreased in >50% of patients), vitamin B6 deficiency anemia, disorders of glutathione metabolism, sideroblastic anemia, pregnancy, regional enteritis, Whipple's disease, amyloidosis, extensive intestinal resection, severe exfoliative dermatitis</p> | <p>The sequence of abnormalities that occur in the development of folate deficiency is as follows: low serum levels (3 wk), hypersegmentation of neutrophils (11 wk), increased urinary excretion of FIGLU (13 wk), low erythrocyte folate levels (17 wk), macroovalocytosis of erythrocytes (18 wk), megaloblastic bone marrow (19 wk), and megaloblastic anemia (19-20 wk). There is also a decrease in granulocytes and thrombocytes and an increase in plasma homocysteine.</p> |
| <p>Ercs ↓ Untreated folate deficiency, usually associated with megaloblastic anemia (<140 ng/mL; <317 nmol/L); decrease in Ercs is also seen in 60% of uncomplicated vitamin B₁₂ deficiency. See also above.</p> | <p>Erythrocyte levels are better indicators of tissue stores of folate than are serum levels, which are responsive to recent dietary intakes. Except during pregnancy, the presence of neutrophil hypersegmentation (≥ 1 six-lobed PMN/100 cells) is a useful indicator of folate deficiency and a reliable predictor of megaloblastic bone marrow. However, megaloblastosis can occur despite normal folate levels in serum and erythrocytes. Only 50% of pregnant women with megaloblastosis have low levels of folate in erythrocytes.</p> |
| | <p>Folate-responsive disorders include homocystinuria type II and formiminotransferase deficiency. Hyperhomocysteinemia, as a result of folate or vitamin B₁₂ deficiency, is an independent risk factor for occlusive vascular disease. The therapeutic dose for treating megaloblastic anemia is 100 mcg/day; toxicity does not occur even at doses of 15 mg/day. Patients with low erythrocyte folate levels or with megaloblastic anemia should be evaluated for vitamin B₁₂ deficiency.</p> |
| | <p>Folate deficiency during pregnancy has been associated with the increased occurrence of neural tube defects. In a retrospective study of pregnant women without folate supplementation, neural tube defects were 4× more likely to occur than in women with supplementation.¹⁰</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|--|
| | Testing for homocysteine and methylmalonic acid determinations may help distinguish between B ₁₂ and folate deficiency states. In folate deficiency, homocysteine levels are elevated and methylmalonic acid levels are normal. In vitamin B ₁₂ deficiency, both homocysteine levels and methylmalonic acid (MMA) levels are elevated. ⁹ It has been suggested that early assessment of vitamin B ₁₂ and folate status by measuring homocysteine and MMA may have advantages over measuring folate and B ₁₂ . ¹¹ |

| | |
|---|--|
| S,U ↑ Primary gonadal failure, ovarian or testicular agenesis, Klinefelter's syndrome, Reifenstein's syndrome, castration, alcoholism, menopause, orchitis, gonadotropin-secreting pituitary tumors | Peak levels at midcycle are lower and shorter than for LH. Because of the episodic, circadian, and cyclic nature of pituitary gonadotropin secretion, clinical evaluation may require determinations of FSH in pooled blood specimens, multiple serial blood specimens, or timed urine specimens. For example, obtain three separate blood samples at 15- to 30-min intervals and pool equal volumes of serum. |
| S,U ↓ Anterior pituitary hypofunction, hypothalamic disorders, pregnancy, anorexia nervosa, polycystic ovary disease, hemochromatosis, sickle cell anemia, severe illness, hyperprolactinemia | In males there is less variation, and no values similar to the midcycle surge in females are normally seen. In males, correlations between sperm count and FSH are relatively poor. In the first year of life, gonadotropin levels are relatively high, then decrease to very low levels after 1-2 yr, and finally increase throughout puberty until adult levels are attained. |
| In hypogonadism, FSH and LH levels lower than normal for the patient's age indicate hypothalamic or pituitary problems; higher levels indicate a primary gonadal defect. | |

Nichols Institute Reference Laboratories: <i>Test catalog</i>, San Juan Capistrano, CA, 1993, Nichols Institute Reference Laboratories. 9. Endocrine Sciences: <i>Pediatric laboratory services</i>, Tarzana, CA, 1992, Endocrine Sciences. | <p>The FT₄I correlates well with free thyroxine except in severe illness and dysalbuminemic hyperthyroxinemia and provides an estimate of the biologically active (free) T₄. It is calculated by multiplying total T₄ by THBR. (See <i>Thyroid Hormone Binding Ratio</i>.) The resulting value has a reference range close to the normal range for total T₄. Calculations of FT₄I using the percentage T₃ resin uptake are now considered obsolete.</p> <p>In most instances, FT₄I is more convenient and less expensive than FT₄ estimate tests but has a lower sensitivity and specificity for the diagnosis of hyperthyroidism and hypothyroidism than a FT₄ E test.</p> <p>FT₄I provides results that are comparable with reference methods for FT₄ (e.g., direct equilibrium dialysis; see <i>Thyroxine, Free</i>) in healthy subjects, hyperthyroid and hypothyroid patients, and patients with only mild abnormalities in TBG. However, the diagnostic accuracy of FT₄I can be variable in euthyroid patients with extreme abnormalities in TBG or TBPA concentrations (e.g., congenital TBG excess or deficiency).</p> |

| <p>↑ Galactosemia because of deficiency of α-D-galactose-1-phosphate-uridylyl-transferase (EC 2.7.7.12) or UDP-glucose-4-epimerase (EC 5.1.3.2).</p> | <p>These screening tests should be performed immediately to enable institution of diet treatment if results are positive.</p> <p>Assay based on washed red cells is preferable for confirming diagnosis of galactosemia and for subsequent monitoring of response to therapy.</p> |

Galactosemia associated with decreased UDP-G-1-P activity may be responsible for the development of hepatic and renal disease, cataracts, and other abnormalities.

The enzyme catalyzes the conversion of galactose-1-phosphate and UDP-glucose to glucose-1-phosphate and UDP-galactose. Galactosemia is an inborn error of metabolism characterized by the inability to convert galactose to glucose and clinically by cirrhosis and cataracts. Activity is expressed as the total amount (micromole) of galactose-1-phosphate converted by 1 mL of packed erythrocytes/hr.

Can be used to diagnose galactosemia in patients transfused with normal erythrocytes.

| Galactosemia Newborn Screening ¹⁻⁶ <i>Metabolite Assays (galactose)</i> <i>Inhibition assay</i> ⁷ | Whole blood on filter paper | Bacterial growth. Inhibition of growth indicates the presence of galactose. | False-positive result: antibiotics, increased valine |
| <i>Paigen assay</i> | Whole blood on filter paper; cord or capillary blood (heparin) from newborn | No bacterial growth. Inhibition of bacterial growth is directly proportional to galactose concentration. | False-negative result: antibiotics |
| Gal-1-P Uridyltransferase Assay (Beutler) <i>Qualitative, fluorimetric</i> ⁸ | Whole blood on filter paper | Bright fluorescence at 1 and 2 hr (assuming no other enzyme is deficient). | False-positive result at 2 hr: inactivation of transferase because of shipping conditions, transferase variants (e.g., Duarte). However, heterozygotes for galactosemia and homozygotes for the Duarte variant may exhibit less fluorescence at 1 hr. |

| DIAGNOSTIC INFORMATION | | REMARKS | |
|---|--|--|--|
| Deficiency of any one of three erythrocyte enzymes leads to galactosemia and galactosuria: galactose-1-P uridyltransferase (classic galactosemia), galactokinase, or UDP galactose-4-epimerase. | | Metabolite assays are sensitive to increased galactose (inhibition assay) or increased galactose or gal-1-P (Paigen) and thus detect any of the three types of galactosemia. Difficulties with the inhibition assay are encountered because of characteristics of the bacteria used in the assay. | |
| ↓ Transferase-deficient galactosemia | | Transferase assays are specific for transferase-deficient galactosemia. Because these assays use intrinsic erythrocyte enzymes, low G6PD or G-6-PGM activities may delay the appearance of fluorescence or dye decolorization. Only severe G6PD or G-6-PGM deficiencies will give false-positive results. The qualitative assay detects only the presence or absence of transferase deficiency and is subject to a high incidence of false-positive results. | |

| Bile: | Present in 25% of normals |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| | <p>Quantitative assays, in addition to diagnosing transferase deficiency, can identify heterozygous transferase-deficient carriers and homozygous transferase variants. In addition to these screening assays, presumptive diagnosis of galactosemia may be made by the presence of serum and urine non-glucose-reducing substance with identification by TLC. Blood for galactosemia screening should be obtained as early in life as possible, and no later than 3-4 days. Positive screening tests should be rapidly confirmed by the assay of the specific enzyme as soon as possible and begin appropriate dietary therapy if necessary.</p> |
| <p>↑ Delayed emptying of stomach (e.g., pyloric obstruction, carcinoma of stomach), increased gastric secretion (e.g., duodenal ulcer, Z-E syndrome), regurgitation of duodenal content</p> | <p>The analysis of gastric content (basal and after stimulation) was once an important diagnostic procedure. However, the widespread use of fiberoptic endoscopy has rendered the test obsolete except for research investigations. Knowledge of normal stomach content is useful for identifying abnormal stomach aspirates.²</p> <p>Antacids and H₂-receptor antagonists should be avoided 24-48 hr before testing. Tricyclic antidepressants, anticholinergics, and reserpine should be avoided 12-72 hr before testing.³</p> |
| <p>Bile is frequently present after partial gastrectomy or gastroenterostomy, after regurgitation, and with obstructing lesions of the small intestine distal to the ampulla of Vater.</p> | <p>Excess mucus is found in cases of gastritis and pyloric obstruction.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Blood may be positive in gastric carcinoma, gastric ulcer, or gastritis. Bleeding gums can also cause a positive test. | In the presence of free HCl, hematin is formed, with brown, coffee grounds-like appearance. |
| | Fresh blood is red and may be caused by trauma or fresh bleeding from lesions (e.g., ulcer, carcinoma). |
| ↑ Duodenal ulcer, some cases of gastric ulcer, Z-E syndrome. The test is negative in those with pernicious anemia. | Diagnosis of achlorhydria is confirmed only if no free HCl is found after maximum stimulation; false achlorhydria may occur if free HCl is secreted but subsequently neutralized (e.g., by food, regurgitated material). |
| In those with pernicious anemia, pH is >7.0. | Red color after addition of Toepfer's reagent indicates the presence of HCl and a pH <3.0. |
| | Chloride measurements are helpful to detect false achlorhydria. |
| Lactate and butyrate are positive if pH is neutral or alkaline for >6 hr (e.g., carcinoma, pyloric stenosis). | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Zollinger-Ellison (Z-E) syndrome (frequently caused by pancreatic gastrinoma), antral G-cell hyperplasia, pyloric obstruction, vagotomy without gastric resection, retained antrum, chronic atrophic gastritis, pernicious anemia, chronic renal failure, gastric carcinoma, gastric ulcer</p> <p>↓ Antrectomy with vagotomy, hypothyroidism</p> | <p>The principal forms of gastrin in blood are G-34 (big gastrin; $t_{1/2}$, 42 min), G-17 (little gastrin; $t_{1/2}$, 5 min), and G-14 (mini-gastrin; $t_{1/2}$, 5 min). Each of these polypeptides circulates in nonsulfated (I) or sulfated (II) forms.</p> <p>Gastrin values follow a circadian rhythm (lowest 3:00 to 7:00 AM, highest during the day) or fluctuate physiologically in relation to meals. Increasing gastrin levels in older subjects may indicate a decline in the production of acid rather than atrophic gastritis. Basal gastric acid output is inversely related to gastrin levels. Interpretation of elevated levels requires knowledge of gastric acid secretion.</p> <p>Most Z-E patients have fasting gastrin levels >500 pg/mL [> 225 pmol/L] and high basal gastric acid secretion, but up to 40% of Z-E patients may have gastrin values between 100-500 pg/mL [45-225 pmol/L]. About 20% of Z-E patients also have parathyroid and pituitary adenomas (MEN type I or Werner's syndrome). About 90% of Z-E patients with borderline fasting gastrin levels (i.e., 100-500 pg/mL [45-225 pmol/L]) will show an increase of >200 pg/mL [95 pmol/L] above the baseline in response to secretin stimulation; a calcium infusion test gives similar responses in patients with gastrinomas.</p> <p>See also <i>Gastrin Stimulation Test (after Secretin)</i> and <i>Gastrin Stimulation Test (after Calcium Infusion)</i>.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Gastrinoma (Z-E syndrome, gastrin >400 pg/mL; >400 ng/L)</p> <p>Slight ↑ Duodenal ulcer (gastrin <400 pg/mL; <400 ng/L)</p> <p>↓ Pernicious anemia, atrophic gastritis</p> | <p>Serum calcium is measured to ensure that adequate calcium has been given. In patients with Z-E syndrome, gastrin levels increase more than twofold above baseline during Ca infusion. In one study the highest gastrin concentrations reached during Ca infusion were as follows: 620-66,000 pg/mL [620-66,000 ng/L] for gastrinoma; 44-328 pg/mL [44-328 ng/L] for duodenal ulcer.</p> <p>Test is useful in patients without marked elevation in basal gastrin levels. Test is more time consuming than the secretin stimulation test and may cause unpleasant side effects. The test should be reserved for patients with a negative secretin test, gastric acid hypersecretion, and a strong clinical suspicion of the Zollinger-Ellison syndrome.⁴</p> |
| <p>↑ Gastrinoma (Zollinger-Ellison syndrome)</p> <p>↓ Duodenal ulcer, antral G-cell hyperplasia, achlorhydria</p> | <p>In 95% of patients with gastrinomas, gastrin levels increase paradoxically by 100-200 pg/mL [48-95 pmol/L] 5 min after secretin injection. In one study, the highest gastrin concentrations reached after secretin injections were 759-103,335 pg/mL [759-103,335 ng/L] for gastrinoma and 43-317 pg/mL [43-317 ng/L] for duodenal ulcer.⁶ (See <i>Gastrin and Gastrin Stimulation Test [after Calcium Infusion]</i>.) The gastrin stimulation test (after secretin) is the preferred provocative test for patients suspected of having Zollinger-Ellison syndrome. (See <i>Gastric Stimulation Test</i>.)</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Testing for gliadin antibodies is useful to monitor compliance with a gluten-free diet in patients with celiac disease. Gliadin antibodies occur in patients with celiac disease but are not as specific for this disease as Ttg antibodies.¹</p> | <p>A decrease in the level of gliadin antibodies (IgA and IgG) after institution of a gluten-free diet is indicative of a favorable response in patients with celiac disease.</p> |
| <p>GBM antibodies are found in the serum of most individuals with active Goodpasture's syndrome when measured with sensitive and specific ELISAs and are not present in healthy subjects. Compared with clinical diagnosis, ELISA has been shown to have a sensitivity of 87% and a specificity of 98%. A small percentage of patients with other renal diseases (systemic lupus erythematosus, mixed connective tissue disease, systemic vasculitis) may have borderline titers.</p> | <p>In anti-GBM antibody disease, circulating autoantibodies are directed against an antigen (primarily the globular domain of the type IV collagen chains) in the glomerular basement membrane, resulting in acute and rapidly progressive glomerulonephritis that is typically associated with crescent formation.⁶ The antibody type is usually IgG or IgA, but IgM has also occasionally been found. Goodpasture's syndrome is a rapidly progressive autoimmune disorder that consists of the clinical constellation of acute glomerulonephritis, pulmonary hemorrhage, and anti-GBM antibodies. The pulmonary damage is caused by cross-reactivity of the GBM antibodies with the alveolar basement membranes.</p> |
| <p>IFA is less sensitive and specific than ELISA, with ~75% sensitivity in patients with confirmed Goodpasture's syndrome. False-positive results can occur because of background fluorescence caused by nonspecific IgG in the human kidney used to prepare the fluorescent antibody.</p> | |

2. Levey AS, Bosch JP, Lewis JB, et al: A more accurate method to estimate glomerular filtration rate from serum creatinine: a new prediction equation, *Ann Intern Med* 130:461-470, 1999.

DIAGNOSTIC INFORMATION

REMARKS

See *Glomerular Filtration Rate (measured)*.

MDRD equation^{2,3}:

$$\text{GFR (mL/min/1.73 m}^2\text{)} = 186 * \times (\text{P}_{\text{cr}})^{-1.154} \times (\text{Age})^{-0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American})$$

where:

GFR = glomerular filtration rate

P_{cr} = serum or plasma creatinine in mg/dL

Age = age in years

The National Kidney Disease Education Program (NKDEP)^{3,4} recommends the use of the MDRD equation to estimate or predict GFR from serum creatinine in adults with chronic kidney disease (CKD) and those at risk for CKD (diabetes, hypertension, and family history of kidney failure) and advocate routine reporting by laboratories of GFR estimates with serum creatinine.

The primary reasons for these recommendations are:

- GFR and creatinine clearance are poorly inferred from the serum creatinine alone because they are related inversely (nonlinearly) to serum creatinine and the effects of age, sex, and race on creatinine production complicate interpretation;
- Creatinine is more often measured than urinary albumin in practice;
- Measurement of kidney function (GFR or creatinine clearance) is essential once albuminuria is discovered;
- The MDRD equation is the most thoroughly validated equation and is superior to other methods of approximating GFR such as the Cockcroft-Gault equation and even 24-hr urine collections;
- Nephrologists routinely use an equation to estimate GFR because the laboratory reference limits for serum creatinine are crude; and
- The MDRD equation does not require weight as a variable and yields an estimated GFR normalized to 1.73 m² body surface area.

The MDRD equation is most accurate for GFRs ≤60 mL/min/1.73 m². It is recommended that values >60 mL/min/1.73 m² be reported as “greater than 60.”

*For laboratories who have creatinine concentrations calibrated to the NIST standard or traceable to isotope dilution mass spectrometry, use a coefficient of 175 instead of 186.

| <p>↑ High cardiac output, pregnancy, burns, carbon monoxide toxicity, high-protein diet, hypercatabolic states, anemia</p> <p>↓ <i>Decreased renal blood flow:</i> shock, hemorrhage, dehydration, congestive heart failure; intrinsic renal disease, glomerulonephritis, nephrotic syndrome, pyelonephritis, amyloidosis, acute tubular dysfunction, interstitial nephritis, papillary necrosis, postrenal obstruction to urinary flow; also decreased in malaria, multiple myeloma, adrenocortical hypofunction, cystinosis, hepatolenticular degeneration, vitamin D-resistant rickets, chronic obstructive lung disease, hepatic failure, eclampsia, and preeclampsia.</p> | <p>Inulin clearance is the best test for GFR, but no routine methods are available. Proteinuria and advanced renal failure make creatinine clearance an unreliable method for measuring GFR. When serum creatinine concentrations are elevated, tubular secretion results in overestimation of GFR by the creatinine clearance test. Urea clearance is a measure of total renal function and not a sensitive measure of GFR. It is greatly affected by urinary flow rate.⁵¹ Cr-EDTA shows excellent agreement with inulin clearance and requires no urine collection. Tests on edematous patients may require extra blood samples when GFR is measured by isotope tests.⁸ The ⁵¹Cr-EDTA method is suitable for measuring GFR of infants with obstructive uropathy.⁷</p> <p>GFR can also be reliably estimated from the serum creatinine, age, sex, and race using the MDRD equation. The National Kidney Disease Education Program recommends this approach for adults with kidney disease or at risk for kidney disease. (See <i>Glomerular Filtration Rate, Estimated</i>.)</p> |

Glucagon—CONT

Familial hyperglucagonemia (predominant elevation in proglucagon)

Others: acromegaly, cirrhosis, Cushing's syndrome, severe pancreatitis

↓ Cystic fibrosis, chronic pancreatitis, postpancreatectomy Glucagon deficiency may reflect a general loss of pancreatic tissue caused by inflammatory disease, neoplastic replacement of the pancreas, or its surgical removal.

DIAGNOSTIC INFORMATION

REMARKS

Severe stress, including infections, trauma, burns, surgery, acute hypoglycemia

Glucagon-like polypeptides of varying molecular weights are also found in stomach and intestinal tissues. Glucagon-like peptide-1 (7-36) is secreted into the circulation after a glucose load and is highly insulinotropic. Insulin-like effects of this peptide have also been reported.^{4,5}

Plasma pancreatic glucagon is heterogeneous and consists of four fractions: true pancreatic glucagon (MW 3500), proglucagon (MW 9000), small glucagon (MW 2000), and big plasma glucagon (MW 160,000). The latter may represent binding of the 3500-MW glucagon to plasma protein. This 3500-MW fraction is considered to be the biologically active hormone.

Measuring glucagon after ethanol extraction eliminates interference from big plasma glucagon (BPG).

Empirically, glucagon and glucagon-like polypeptides are classified based on their reactivity toward antibodies of known regional specificity. True pancreatic glucagons and other polypeptides that react with C-terminal antibodies are termed *immunoreactive glucagons*, or IRG; glucagon-like polypeptides that react only with N-terminal-specific antibodies are termed *glucagon-like immunoreactivity*, or GLI.⁸ Although it is probably an oversimplification, IRG is often associated with the pancreas and GLI with the gut. In healthy individuals, ~40-50% of circulating IRG is biologically active (3500-MW fraction). Most of the remainder consists of big glucagons.

In glucagons deficiency there is a failure of plasma glucagons to increase during arginine infusion. In contrast to normals, glucagon secretion in diabetic patients does not decrease after ingestion of a carbohydrate meal, whereas arginine infusion causes significantly greater increase of glucagon secretion. (See *Glucagon Stimulation Test [after Arginine]* and *Glucagon Suppression Test [after Glucose Load]*.) Abnormally elevated fasting levels of glucagons in patients with chronic renal failure return to normal after successful renal transplantation. Renal rejection has resulted in a dramatic increase in plasma glucagons several days before changed in blood creatinine levels. Fasting and moderate or severe exercise cause a glucagon release, and this may play an important part in neonatal hypoglycemia in these babies.

Hypoglycemic stimulation of glucagon release is lost in insulin-dependent diabetes.

In gastrectomized subjects, oral loads of glucose, galactose, and fructose all produce significant increases in plasma glucagons; glucose has the greatest effect, and fructose has the least. See *Glucagon Suppression Test (after Glucose Load)*.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| | The source of amniotic fluid glucagon (predominantly big glucagon) is unknown. |
| Exaggerated response in diabetes, chronic renal failure, and liver failure. | Arginine also stimulates insulin secretion. The failure of glucagons to increase after arginine stimulation is seen in glucagon deficiencies such as cystic fibrosis and chronic pancreatitis. This test is of rare clinical utility. |
| S ↑ <i>Primary:</i> Diabetes mellitus (adult and juvenile) | Glucose can be measured in whole blood, serum, or plasma, but plasma is recommended for diagnosis of diabetes mellitus. Furthermore, it is the WHO/ADA criteria and not reference ranges that are used for diagnosis of diabetes mellitus. |
| <i>Physiological:</i> Strenuous exercise, strong emotion, increased epinenphrine from injection, shock, burns; infection (?) | |
| <i>Endocrine disorders:</i> Pheochromocytoma, thyrotoxicosis, acromegaly, gigantism, Cushing's syndrome, glucagonoma, somatostatinoma | Concentration of glucose is higher in arterial than in venous samples. For fasting samples, a 6- to 8-hr fast is required. |
| <i>Pancreatic disease:</i> Acute and chronic pancreatitis; pancreatitis resulting from mumps, cystic fibrosis, hemochromatosis; neoplasms of pancreas | The enzymatic hexokinase method is the basis for the reference method for the determination of glucose in serum or plasma. |

|--|--|--|--|
| Glucose Tolerance Test, Intravenous (IV GTT) ¹⁻⁶ | Serum or plasma. Fasting, 3, 5, 10, 20, 30, 45, and 60 min after the end of infusion for glucose. For plasma insulin (if desired), collect blood at 2, 3, and 5 min. | Newborn: Normal glucose disappearance rate is less than that in older infants and adults. Plasma insulin response on first day is characterized by a small spike and large wave. | See <i>Glucose Tolerance Test, Oral</i> ; and <i>Insulin, Immunoreactive</i> . |
|--|--|--|--|

For 3 days before test, patient should maintain a diet containing at least 150 g of carbohydrate/day, followed by an overnight fast (> 10 hr).

Dose: 0.5 g glucose/kg given as 25 g/100 mL solution, IV, within 1-2 min

Adult: $K_t^* > 1.5\%/min$ [>0.015 , fraction/min]; K_t declines by $\sim 0.09\%/min/decade$ [$0.0009/min/decade$] over 50 yr. Shortly after infusion, glucose concentration of 250 mg/dL [13.9 mmol/L] may be seen. Fasting level is regained by 90 min, subfasting level by 2 hr, returning to fasting level by 3 hr. Some glycosuria is expected because of blood glucose concentrations above the renal threshold. Insulin reaches a peak during the first 5 min.⁷

| | K_t %/min (SEM) | K_t fraction/min (SEM) |

| 14-16 yr: | 1.7 ± 0.3 | [0.017 ± 0.003] |

* K_t , Mean rate of glucose disappearance.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Diabetes mellitus (>200 mg/dL; >11.10 mmol/L)</p> <p>See also <i>Glucose Tolerance Test, Oral</i>.</p> | <p>Individuals with values between 140 mg/dL [7.8 mmol/L] and 200 mg/dL [11.1 mmol/L] need to be studied further.</p> <p>General use of this test is not recommended because of many factors that influence the results. For differences in capillary and venous blood, see <i>Glucose Tolerance Test, Oral</i>.</p> |

$K_t < 1\%/min$ is considered suggestive of diabetes. Results of the IVGTT often fail to correlate with results of the oral glucose tolerance test. In liver disease the decrease from the peak values is delayed, and fasting levels are regained by 3-5 hr. In Addison's disease and hypopituitarism, the peak levels are normal, but severe hypoglycemia follows. In cases of G6PD deficiency, the oral test is normal, but IV test results are significantly higher. Hyperinsulinemia is characteristic of erythroblastosis and β -cell neoplasia or hyperplasia; the condition is also seen in infants of gestational diabetic patients and those who are small-for-date.

This test is not currently used to diagnose diabetes but is often used in clinical research studies to evaluate first phase insulin release. As the number of β cells decreases, there is a loss of insulin secretion. The Diabetes Prevention Trial type 1⁶ found that subjects often had an abnormal IVGTT before onset of diabetes. The most consistent abnormality of diabetic patients appears to be a blunting of the early insulin peak in the first few minutes after IV glucose injection.

Test may be performed to eliminate factors related to rate of glucose absorption from the GI tract. For example, some patients cannot tolerate an oral carbohydrate load; others may have had previous gastric surgery.

No difference is observed in mean rate of glucose disappearance (K_t) whether 0.5 or 1.0 g/kg glucose is given.⁷

Blood glucose levels decrease exponentially. The rate of glucose disappearance (K) can be calculated as follows:

$$\frac{70}{K} = t_{1/2}$$

where $t_{1/2}$ is the number of minutes required for the blood glucose to decrease to one half of the 10-min level, and K is the rate of disappearance of blood glucose, expressed as $\%/min$.⁴

The presence of insulin antibodies in the plasma may invalidate measurements of plasma insulin by conventional RIA. The preparation of the patient is similar to that described for the OGTT. (See *Glucose Tolerance Test, Oral*.)

*Diabetes mellitus (DM) in nonpregnant adult*⁶: The 120-min sample must be ≥ 200 mg/dL [≥ 11.1 mmol/L]; 120-min values of 140-199 mg/dL (7.8-11.1 mmol/L) are defined as impaired glucose tolerance (IGT). The test should be confirmed on another day.

Fasting plasma glucose of >126 mg/dL (7.0 mmol/L) after a fast of at least 8 hr on two occasions is diagnostic of diabetes mellitus. Fasting plasma glucose of 100-125 mg/dL (5.6-6.9 mmol/L) is defined as impaired fasting glucose (IFG)

A random plasma glucose of >200 mg/dL (11.1 mmol/L) with symptoms of diabetes is diagnostic. A confirmatory FPG test or OGTT should be completed on a different day if the clinical condition of the patient permits.

Two-step approach to screening for gestational diabetes mellitus. A glucose challenge test: 50 g oral glucose load is administered between 24th and 28th wk gestation without regard to time of day or time of meal. A 1-hr venous plasma glucose of ≥ 130 mg/dL (7.2 mmol/L) indicates need for a 100-g oral glucose tolerance test.

Patients with IFG and/or IGT are referred to as having “prediabetes” because of their high risk of developing the disease in the future. These patients are also at high risk for cardiovascular disease.

Risk assessment for gestational diabetes mellitus should be undertaken at the first prenatal visit. Women at high risk (obesity, personal history of GDM, glycosuria, strong FH of diabetes) should undergo testing as soon as possible. If negative, then retest at 24-28 wk. Women at average risk should be tested at 24-28 wk of gestation.

For proper interpretation of test results, careful selection and preparation of patient are required. In addition to receiving adequate food intake, the patient must not be stressed (e.g., must have had no recent surgery, infection, or illness), endocrine function should be evaluated (e.g., adrenal, thyroid, and growth hormone), and nonessential medications should be discontinued. An 8- to 14-hr fast is recommended; no coffee or smoking is allowed.

Test should be performed on ambulatory patients. Patient should not be exercising during test. Test should be initiated before 10:00 AM. When capillary blood is used for OGTT, levels may be 20-70 mg/dL [1.1-3.9 mmol/L] higher than those in venous blood.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Deficiency causes hemolytic anemia after ingestion of 8-aminoquinoline antimalarials, nalidixic acid, nitrofurantoin, phenacetin, large doses of vitamin C, and some sulfonamides and sulfones.¹² (See Table I-4.) Hemolytic episodes may also occur after exposure to fava beans in diabetic acidosis and in infections. Deficiency may be the cause of hemolytic disease of newborns in Asians and Mediterraneans.</p> | <p>Activity is higher in young Ercs.¹ Testing of reticulocyte-depleted blood may be necessary after recent hemolysis to detect deficiency. Deficiency is usually difficult to detect in female heterozygotes and immediately after hemolytic episodes in persons with G6PD A−.¹³ Heterozygotes for any G6PD-deficiency variants are often impossible to identify except by pedigree analysis.</p> |
| <p>Three G6PD variants are of high frequency and have clinical consequences in different ethnic groups. They are defined by electrophoretic and kinetic criteria as:</p> | <p>Mutation analysis is available to diagnose variation in G6PD.</p> |
| <p><i>G6PD A−</i>: Common in blacks (10% of males). Associated with moderately severe self-limited hemolysis after ingestion of 8-aminoquinolines, such as primaquine, and other drugs.</p> | <p>$\text{U/g Hb} \times 29 = \text{U}/10^{12} \text{ Ercs}$ $\text{U/g Hb} \times 0.34 = \text{U/mL Ercs}^*$</p> |
| <p><i>G6PD Mediterranean</i>: Common particularly in Iraqis, Kurds, Sephardic Jews, and Lebanese; less common in Greeks, Italians, Turks, North Africans, Spaniards, Portuguese, and Ashkenazic Jews; associated with severe and sometimes fatal hemolysis after exposure to fava beans; may also cause hemolytic disease of the newborn (HDN).</p> | <p>*See Note, <i>Acetylcholinesterase</i>.</p> |
| <p><i>G6PD Mahidol</i>: Common in Southeast Asians (22% of males). Associated with hemolysis after ingestion of 8-aminoquinolines, such as chloroquine; also associated with HDN.</p> | |
| <p>Some G6PD variants, such as G6PD A+, have no clinical importance. There are many other common clinically important variants caused by several different mutations.¹²</p> | |

↓↓ In Pompe's disease (glycogen storage disorder type II), acid form is low or absent. The neutral form (pH 6.0) is increased in a variety of unrelated disorders, but greatest increases occur in acutely ill patients with cystic fibrosis and necrotizing pancreatitis.³

α-Glucosidase activity measured at pH 4 increases with age of amniotic cell culture. If time of incubation is short and if the pH 4/pH 6 ratio is used without the thermal treatment, there is a potential for misdiagnosis of an affected fetus as normal.^{2,10}

Pompe's disease (type II glycogenosis)¹ is characterized by the accumulation of glycogen in all body tissues as a result of the deficiency of lysosomal acid α -glucosidase. This enzyme has a pH optimum of ~ 4 . An additional form of α -glucosidase not deficient in Pompe's disease shows an optimum of $\sim \text{pH } 6$ with overlap at pH 4. Specificity of the pH 4 form is achieved by heat denaturing the pH 6 form, which is more heat labile. Prenatal diagnosis of Pompe's disease is facilitated by the analysis of α -glucosidase in cells cultured from amniotic fluid. Absence of this enzyme has also been demonstrated in heart, skeletal muscle, liver, skin, fibroblasts, urine, and leukocytes of patients with Pompe's disease.

No activity detected in Pompe's disease.

GLD is abnormal in all categories of hepatic and biliary tract diseases.^{4,5} Others have shown that GLD activities do not differentiate between patients with and those without alcoholic hepatitis or hepatocyte necrosis.^{6,7}

GLD is a mitochondrial enzyme present in highest concentration in liver, where it is found particularly in the central areas of the liver lobule. It is also present in erythrocytes.

Serum GLD is markedly inhibited by guanosine triphosphate in Reye's syndrome so that serum activities are low. Dialysis removes the inhibitor; therefore the ratio of dialyzed to undialyzed activity markedly increases (up to 700-fold). Increase in this ratio is diagnostic for Reye's syndrome.^{8,9}

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| P ↑ Malignant neoplasm of pancreas, gout, glutamic acidemia, rheumatoid arthritis | Glutamic acid content of erythrocytes is much higher than that of plasma. |
| P ↓ Histidinemia, 4 days after abdominal surgery, ¹⁴ chronic renal failure | Improper storage of specimens may lead to decomposition of glutamine and formation of high concentrations of glutamic acid. See also Table II-2. |
| U ↑ Dicarboxylic aminoaciduria | Excretion in newborns is usually low. Aspartic acid is also significantly increased in dicarboxylic aminoaciduria. |
| CSF ↑ Bacterial meningitis, meningoradiculitis Garin-Bujadoux-Bannwarth, carcinomatous meningitis ¹⁵ | Values in children (3 mo-10 yr) were measured using reversed-phase liquid chromatography. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---------|
| Deficient in very rare congenital hemolytic anemia (autosomal recessive) | |

| | |
|---|---|
| ↑↑ Obstructive liver disease and posthepatic obstruction ⁶ | The test has been useful in detection of male (but not in female) early-risk drinkers ¹⁰ and is probably most applicable as part of an alcoholic-screening panel ¹¹ or as follow-up on patients with chronic alcoholism undergoing treatment. ¹² It is said to be a more sensitive indicator of liver disease in children than is alkaline phosphatase. ¹ |
| ↑ Liver disease (inflammation, cirrhosis, space-occupying lesions), obesity, infectious mononucleosis, renal transplant, hyperthyroidism, myotonic dystrophy, diabetes mellitus, pancreatitis, alcohol-induced liver disease | |
| ↓ Hypothyroidism | GGT may form complexes with apolipoproteins and immunoglobulin A. ¹³ |
| γ-Glutamyltransferase is useful as a marker for pancreatic cancer, prostatic cancer, and hepatoma because levels reflect remission and recurrence. ⁷ The enzyme is also used in ratio with HDL cholesterol (alcohol abuse), alkaline phosphatase (alcoholic liver disease), and aspartate aminotransferase (distinguishes neonatal hepatitis from biliary atresia). ^{8,9} | Enzyme activity is an index of exposure to enzyme-inducing drugs such as phenytoin and phenobarbital, as well as ethanol. GGT is related to body weight and body mass index but is most highly correlated to abdominal fat. ¹⁴ Activity decreases after meals but increases with prolonged fasting. |
| | The serum enzyme shows heterogeneity on electrophoresis, electrofocusing, and lectin-affinity chromatography. Isoforms are attributed to variation in carbohydrate content. ¹⁵ |
| | Claims have been made for the existence of cancer-specific forms, especially in hepatoma and colorectal carcinoma, but sensitivity is too low for the test to be useful. ^{16,17} |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Glycated hemoglobins are increased as a reflection of hyperglycemia during the lifespan of erythrocytes (120 days).</p> <p>Note: Different analytical methods may measure different glycated hemoglobins. Caution must be exercised in the interpretation of results.</p> | <p>This test, although not useful for the diagnosis of diabetes mellitus, has been shown to be useful in monitoring its long-term control. Glycated hemoglobin concentration appears to reflect the mean blood glucose concentration over the previous 4-8 wk. Note that improvement in glucose control occurring in the 4 wk before the drawing of the sample is not well reflected in the result because formation of glycated hemoglobin is irreversible. Agar gel EP and HPLC measure HbA_{1i}; isoelectric focusing, Hb A_{1c}.</p> <p>Labile forms may be removed by overnight incubation in saline at room temperature, by incubation for 5 hr at 37° C, or by incubation in a pH 5 buffer for 15 min at 37° C.¹</p> <p>See also <i>Fructosamine</i>.</p> <p>This method measures Hb A₁ and Hb A_{1c}. Like HPLC, it is particularly sensitive to variations in temperature and pH.</p> <p>This method is usually a cationic exchange procedure and measures Hb A_{1c} and Hb A_{1a+b}. The procedure is highly sensitive to variations in temperature and pH.</p> <p>This method measures A₁ and non-A₁-glycohemoglobins. Note also that units differ from those of other glycated hemoglobin procedures.</p> <p>Column or affinity chromatography measures total glycated hemoglobins. Results tend to be slightly higher than with other methods.</p> |

| Glycolic acid is increased in all nonuremic patients with primary hyperoxaluria type I (usually >100 mg/day; >1.31 mmol/day). In patients with hyperoxaluria type II (L-glyceric aciduria) the excretion of glycolic acid is within the reference range. | Glycolic acid is the principal toxic metabolite of ethylene glycol and should be monitored in addition to ethylene glycol concentrations after ethylene glycol poisoning. It accounts for >90% of the anion gap in ethylene glycol-poisoned patients. Initial glycolic acid concentrations ≥ 10 mmol/L predict acute renal failure. See also <i>Ethylene Glycol and Oxalate</i> . |

| | | Prepubertal child: | Absent or minimal response | |
| | | Puberty and adult: | 1.5- to 3-fold increase above baseline | |

DIAGNOSTIC INFORMATION

REMARKS

At least 35% of patients undergoing chrysotherapy develop some degree of Au toxicity. The most common manifestation of toxicity is dermatitis with eosinophilia. Other common side effects are pruritus and albuminuria. More adverse reactions ascribed to gold therapy are enterocolitis, intrahepatic cholestasis, skin hyperpigmentation, peripheral neuropathy, chrysiasis, and diffuse pulmonary infiltrates.

Other effects are leukopenia, hematuria, and thrombocytopenia. Aplastic anemia may be life threatening.⁵

Gold salts are used in the treatment of rheumatoid arthritis. Au appears to accumulate in different tissue compartments at varying rates, and there is evidence that long-term maintenance therapy is superior to larger doses for a shorter period. Au is detectable in serum 10 mo after cessation of treatment. Correlations between therapeutic doses, serum or urine concentration, and clinical effects are not well established. It has been suggested that only serum levels >300 mcg/dL [$15.2 \mu\text{mol/L}$] are effective in the treatment of rheumatoid arthritis.

Methotrexate may be superior to Au therapy for treatment of psoriatic arthritis.⁶

See Tables II-5 and II-6.

In a majority of patients with pituitary disease there is an absent or blunted response. In hypothalamic disease there is a normal or prepubertal response, but repeated stimulation may be necessary. In anorexia nervosa the peak response is reduced. In delayed puberty there is no response, or response is greater for FSH than for LH. In primary gonadal failure the response is exaggerated and prolonged. In children with true sexual precocity, GnRH-induced LH release is in the pubertal range. In children with precocious thelarche or adrenarche, LH responses are prepubertal.⁵

Because of considerable overlap of response in patients with hypothalamic or pituitary diseases, the test is more useful in assessing pituitary gonadotropin reserve than in localizing the site of dysfunction. In patients with pituitary tumors, response to GnRH may be normal, and absent responses can be seen in patients with hypothalamic disease. Release of LH (after GnRH) is dose dependent; in normal men 10 mg of GnRH gives significant increase, and further increase is observed with increase in dose to 150 mcg. The lowest dose evoking FSH release is 100 mcg of GnRH. Peak responses for both LH and FSH occur between 15 and 30 min. Because of the pulsatile secretion of gonadotropins, two baseline values for LH and FSH

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>are obtained before GnRH administration. Third-generation LH and FSH assays, with sensitivities of 0.01 mU/mL, are recommended for prepubertal GnRH testing.⁶</p> <p>LH increases 15-30 min after GnRH. Peak LH excretion is slight in prebuteral children (both sexes), increases during puberty, and increases still further in adulthood. However, there is no clear correlation between the stage of puberty and the magnitude of the response to the GnRH. Females usually show a significant variability during the menstrual cycle, with greater stimulation of LH during the luteal phase. Pituitary release of LH is biphasic in prepubertal subjects, suggesting either a second intragonadotrope LH pool that is more slowly mobilized or new LH synthesis during the prolonged infusion. FSH release is greatest in prepubertal females.</p> <p>Responses to GnRH may be used to monitor treatment of sexual precocity.</p> |

Useful in identifying and monitoring patients previously immunized by transfusions, pregnancies, or allografts.

Can be helpful in confirming the diagnosis in immune-mediated neutropenia, including neonatal alloimmune neutropenia (NAIN),⁴ and in transfusion-related acute lung injury (TRALI).⁵

In most granulocyte antibody assays fresh purified granulocytes from normal subjects are used as substrate, which make these tests challenging to perform and therefore limited to special laboratories.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Determination of the neutrophil antigen type in babies with NAIN and other patients with immune neutropenia confirms the specificity of the granulocyte antibody.</p> | <p>Serologic typing of granulocyte antigens has been largely replaced by DNA-based genotyping methods. All neutrophil antigen variants may not be detected by currently available PCR-SSP assays.</p> |
| <p>Parental genotyping is required to assess the risk of NAIN in subsequent pregnancies.</p> | <p>Genotyping methods allow the determination of neutrophil antigen type even in severely neutropenic patients.</p> |
| <p>When donor-derived granulocyte antibody is implicated in TRALI, neutrophil antigen typing of the recipient confirms antibody specificity.⁶</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>S ↑ Pituitary gigantism, acromegaly (to 400 ng/mL [400 mcg/L]), Laron dwarfism (defective GH receptor), ectopic GH secretion (neoplasms of stomach, lung), malnutrition, renal failure, cirrhosis, stress, exercise, prolonged fasting, uncontrolled diabetes mellitus, anorexia nervosa</p> | <p>Secretion of GH is episodic and pulsatile; transient levels up to 40 ng/mL [40 mcg/L] have been observed in healthy subjects. Highest values occur during periods of deepest sleep. In acromegaly and gigantism, rhythmicity is lost. Test is also useful for evaluating the efficacy of acromegaly treatment. In obesity, release of GH is reduced, and response of GH to insulin, arginine, sleep, or exercise may be impaired. Ability to secrete GH in response to a conventional challenge declines with age.⁹</p> |
| <p>S ↓ Pituitary dwarfism, hypopituitarism, adrenocortical hyperfunction</p> | <p>Random levels of GH provide little diagnostic information; GH secretion is best assessed during tests that stimulate or suppress release. Patients with acromegaly, for example, have subnormal GH responses to glucose load. (See <i>Growth Hormone Suppression Test [after Glucose]</i>.) Patients with GH-producing pituitary tumors often release GH in response to TRH or GnRH, and patients with suspected GH deficiencies have subnormal responses to stimulation tests. (See <i>Growth Hormone Suppression Test [after Arginine]</i>, <i>Growth Hormone Suppression Test [after Insulin]</i>, <i>Growth Hormone Suppression Test [after L-Dopa]</i>, <i>Growth Hormone Suppression Test [after Glucagon and Propranolol]</i>, and <i>Insulin Tolerance Test</i>.) Continuous or intermittent GH sampling over a 24-hr period, however, has been used to identify partial GH deficiency overlooked with stimulation tests; such procedures are laborious and expensive.</p> <p>The presence of GH variants in serum often leads to discrepancies among the results given by different immunoassay systems. To prevent misdiagnosis, reference values for GH and cutoff values for GH stimulation tests should be established separately for each method proposed for routine use.^{10,11}</p> |
| <p>AF ↓ Anencephalic fetus</p> | <p>The progressive increase of GH levels in amniotic fluid correlates well with both increased pituitary content and fetal serum concentration of GH and contrasts with the lack of change in maternal serum GH throughout gestation.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| ↑ Acromegaly caused by GHRH secretion by neoplasms (e.g., pancreatic islet tumors, bronchial or thymic carcinoid tumors, neuroendocrine tumors) | GHRH is produced by the hypothalamus and stimulates the release of GH from the pituitary. Hypersecretion of GHRH is a rare cause of acromegaly. Excessive production of GHRH may be caused by a hypothalamic tumor, or more commonly, by peripheral tumors. Chronic stimulation of the pituitary by GHRH causes pituitary hyperplasia, which cannot be distinguished from a GH-secreting pituitary tumor by imaging techniques. Circulating levels of GHRH are useful in differentiating between a pituitary tumor and ectopic GHRH hypersecretion. |

| | |
|--|---|
| Hypopituitarism, no response (all levels <5 ng/mL [<5 mcg/L]) | <p>Arginine HCl should be given with caution to patients with severe liver or renal disease and acidosis. If the fasting GH level is >5 ng/mL [>5 mcg/L], no increase may be seen. Release of GH is augmented in normal male subjects by pretreatment with diethylstilbestrol, 2.5 mg, twice a day for 2 days. The main advantage of this test is the absence of significant side effects. A subnormal response should be confirmed by performing another provocative test (e.g., stimulation with insulin, glucagon, clonidine, or L-dopa) because $\sim 20\%$ of healthy individuals may not respond to arginine.</p> <p>For initial testing of GH deficiency, a vigorous exercise test is considered by many investigators to be a simple, relatively risk-free stimulus for assessing GH reserve, particularly in children. However, much controversy surrounds the use of all GH stimulation tests, and a diagnosis of GH deficiency must be considered in the context of the clinical picture.</p> |

|---|--|--|-------------------------|------------------------------------|--|
| Growth Hormone Stimulation Test (after Insulin) ¹⁻⁴ | Serum, fasting. Draw at 30, 60, and 90 min through an indwelling needle. | After insulin: Glucose Decrease: <50% of baseline [<0.5 fraction] and <40 mg/dL × 0.0555 | | | Values are reduced by cyproheptadine, methysergide, and phen- tolamine; they are aug- mented by propranolol. See also <i>Growth Hormone</i> . |
| Dose, adult: Regu- lar insulin, 0.1-0.15 U/kg, IV. When hypopitu- itarism is strongly suspected, a dose of 0.05 U/kg should be used. Child: 0.05 U/kg | | Growth hormone Increase above baseline: Peak response: | ng/mL >5 >10 | × 1.0 [>5] [>10] | mcg/L [>5] [>10] |
| | | Cortisol Increase above baseline: Peak response: | mcg/dL >7 >20 | × 0.0276 [>0.19] [>0.55] | μmol/L [>0.19] [>0.55] |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <i>Hypopituitarism:</i> No response or inadequate response (all levels <5 ng/mL [<5 mcg/L]) | Test is contraindicated in heart disease, bronchial asthma, and diabetes mellitus. Glucagon is not a potent stimulus for GH release, and although propranolol augments the response, other stimulation tests are often preferred (e.g., with arginine, L-dopa, insulin, or clonidine). |

| | |
|--|---|
| No response or inadequate response is seen in hypothalamic or anterior pituitary dysfunction (e.g., growth hormone and ACTH deficiencies). | <p>Blood glucose level must fall below 40 mg/dL [2.2 mmol/L] and/or adrenergic signs must be observed. If such criteria are not met within 45 min to 1 hr after insulin, a repeat dose should be given. Risks are severe hypoglycemia with seizures, cardiac arrhythmias, and coma. A solution of 50% dextrose for IV administration should be available. Patients with resistance to insulin (e.g., those who have Cushing's syndrome, diabetes, obesity, or acromegaly) may require a higher dose of insulin (0.15-0.3 U/kg) for this test.</p> <p>For initial testing of growth hormone deficiency, a vigorous exercise test is considered by many investigators to be a simple, relatively risk-free stimulus for assessing GH reserve, particularly in children. For subsequent testing, a subnormal GH response to insulin-induced hypoglycemia should be confirmed by performing another provocative test (e.g., stimulation with glucagons, L-dopa, arginine, or clonidine) because ~20% of healthy individuals may not respond to insulin. Much controversy surrounds the use of all GH stimulation tests, and a diagnosis of GH deficiency must be considered in the context of the clinical picture.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Inflammation, infection, tissue injury, trauma, major depressive episodes, malignancies.³</p> | <p>Haptoglobin (Hp) is a positive acute phase reacting protein (APR), which covalently binds free hemoglobin. The subsequent haptoglobin-hemoglobin complexes are quickly cleared from circulation by the reticuloendothelial system, allowing recycling of iron. Consequently, rapid decreases in HP concentrations are a sensitive marker of hemolysis. In patients experiencing both hemolysis and an acute phase response, which can complicate interpretation of HP values, HP levels frequently decrease faster than the simultaneous acute phase increase. Assessment of other APRs within the specimen that are not affected by hemolysis should be helpful in these cases. HP is found in nearly all body fluids. Synthesis is not confined to the liver but also takes place in the adipose tissue and lung, where it serves in an antimicrobial and antioxidant capacity. By complexing with hemoglobin, the generation of lipid peroxide and hydroxyl radical promoted by hemoglobin in sites of inflammation are avoided.³ Evidence suggests that HP promotes angiogenesis and cholesterol crystallization.³</p> |
| <p>↓ Hepatic dysfunction, any cause of hemolysis, including autoimmune, mechanical (artificial heart valves, hypersplenism), transfusion reactions, hemoglobinopathies (sickle cell, hemoglobin C, thalassemias).³ Can also be decreased with ineffective erythropoiesis, disaggregation of internal hematomas,³ red cell membrane or metabolic defects (G6PD deficiency, hereditary spherocytosis, paroxysmal nocturnal hemoglobinuria).</p> | <p>Three main phenotypes of haptoglobin are known, Hp 1-1, 2-1, and 2-2. Hp 1-1 circulates as a monomer, and 2-1 and 2-2 are polymers. Ahaptoglobimemia is not typically associated with any clinical manifestations and is frequently noted in neonates and infants (up to the age of 3 mo).³</p> |
| | <p>Indications for quantitation include evaluation for suspected hemolysis, pregnancy-associated hypertension,² transfusion reactions (comparison of pretransfusion and posttransfusion results), assessing disease status. Interpretation of Hp values should be performed with regard to the overall clinical findings, given that many factors affect results. Subtyping has been useful for forensic and paternity testing purposes.³</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ In G6PD deficiency and other enzyme deficiencies of hexose monophosphate shunt, Heinz bodies and hemolysis may be caused by lower doses of the oxidant drugs listed under <i>Interferences</i> and by designated drugs in Table II-4.</p> <p>↑ Unstable hemoglobin disorders (congenital Heinz body anemia), after splenectomy, or when challenged with oxidant drugs.</p> <p>↑ Homozygous β-thalassemia</p> | <p>Heinz bodies are precipitated hemoglobin, either oxidatively denatured or inherently unstable. They are usually invisible on Wright's stained, air-dried films.</p> <p>Visualization requires phase microscopy or supravital staining. With methyl violet or crystal violet, Heinz bodies stain purple and the precipitated RNA in the reticulocytes does not stain. In reticulocyte preparations utilizing brilliant cresyl blue or new methylene blue, Heinz bodies stain pale blue, and the precipitated RNA in the reticulocytes stains purple. Heinz bodies tend to adhere to the erythrocyte membrane.</p> |

| | |
|--|---|
| <p>↑ Polycythemia, extreme physical exercise or excitement, hemococoncentration, high altitude</p> <p>↓ Anemia, recumbency</p> | <p>A calculated HCT is ~2% lower than a microhematocrit resulting from trapped plasma in a centrifuged column of erythrocytes. Healthy pregnant women usually have slightly lower hematocrit than do nonpregnant women. HCT is ~2% lower in deoxygenated than in fully oxygenated blood. Immediately after blood loss or transfusion, the HCT is not a reliable estimate of anemia.</p> <p>Hb, HCT, and erythrocytes (RBCs) are slightly lower between 5:00 PM and 7:00 AM and after meals (up to 10% lower); they are up to 5.7% lower if drawn from a recumbent patient. Falsely high results may occur because of prolonged venous stasis during venipuncture. A slight but significant decrease occurs in the lower reference limit of Hb, HCT, and erythrocytes (RBCs) in men aged 65-74 yr. There is no significant change in men or women over age 85 yr compared with ages 65-74 yr.¹⁰</p> |

|--|---|---|---|--|
| Hemoglobin (Hb) Electrophoresis¹⁻⁴ | Hemolysate prepared from whole blood (EDTA, citrate, or heparin). Use fresh or re- frigerated at 4° C. | <i>% Hemoglobin</i> Hb A: >95 Hb A ₂ : 1.5-3.7 Hb F: <2 | <i>Hb fraction</i> × 0.01 [>0.95] [0.015-0.037] [<0.02] | Blood transfusions may obscure or dilute abnor- mal Hb for 3-4 mo. |
| <i>Cellulose acetate or agarose gel EP, pH 8.4-8.6</i> | | For newborns and infants, see <i>Fetal Hemoglobin</i> . | | |
| <i>Citrate agar gel EP, pH 6.0-6.5</i> | | | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ <i>α-Thalassemia (α-thal) syndromes, Hb Bart's measured in cord blood:</i> 100% [1.00] in Hb Bart's hydrops fetalis syndrome (homozygous α⁰-thal, deletion of 4 α-genes); 19-27% [0.19-0.27] in Hb H disease (double heterozygosity for α⁰-thal and α⁺-thal, deletion of 3 α-genes); 3-6% [0.03-0.06] in α-thalassemia minor (homozygous α⁺-thal or heterozygous α⁰-thal, deletion of 2 α-genes); 1-3% [0.01-0.02] in the silent carrier state (heterozygous α⁺-thal, deletion of 1 α-gene).</p> | <p>The levels of Hb Bart's in cord blood as given correspond only approximately to proposed genotypes of α-thalassemia. It is not possible to predict the genotype from the level of Hb Bart's in cord blood.</p> |
| <p>There is considerable overlap in the levels of Hb Bart's in cord blood in the various α-thalassemia syndromes, especially in different populations.</p> | <p>Cellulose acetate at pH 8.6 is a screening procedure; at alkaline pH, Hb Bart's migrates anodally to Hb A, between Hb A and Hb H.</p> |
| | <p>This is the best method for demonstrating small amounts. At acid pH, Hb Bart's migrates cathodally (with Hb F) and Hb H migrates cathodally (with Hb A).</p> |
| | <p>This technique allows rapid quantitation of Hb Bart's on small sample size.</p> |
| <p>↑ Hb S, A>S: Sickle trait (Hb AS), sickle-α-thalassemia S, F, no A: Sickle cell anemia, sickle-β⁰-thalassemia, sickle- δβ⁰-thalassemia, sickle-HPFH S>A, F: Sickle-β⁺-thalassemia</p> | <p>Several hemoglobin variants migrate like S on cellulose acetate at pH 8.6 (D and G, most common), but of these only Hb S gives a positive sickling or solubility test. Iron deficiency or α-thalassemia may decrease the relative proportions of hemoglobins S, C, and A₂.</p> |
| <p>↑ Hb C, A>C: Hb C trait (Hb AC) C, F, no A: Hb C disease, Hb C-β⁰-thalassemia, Hb C- δβ⁰-thalassemia, Hb C-HPFH C>A: Hb C-β⁺-thalassemia</p> | <p>It is possible with paper electrophoresis to separate hemoglobins A, S, C, A₂, and others, but resolution is not sharp.</p> |
| <p>↑ Hb F (see <i>Fetal Hemoglobin</i>)</p> | <p>This is the traditional method of choice for screening for common variants, but small amounts of Hb A or Hb F are difficult to detect.</p> |
| <p>↑ Hb A₂ (see <i>Hemoglobin A₂</i>)</p> | <p>Citrate agar at acid pH separates Hb S from Hb D and G and separates Hb C from O-Arab and E; these groups have similar migrations at pH 8.4-8.6.</p> |
| <p>↑ Hb H (see <i>Hemoglobin H</i>)</p> | |

|--|---|-----------------------------|--|
| Hemoglobin H (Hb H, β_4) ¹ <i>Isopropanol precipitation^{2,3}</i> | Whole blood (ACD, EDTA, or heparin). Use fresh. | No precipitation at 40 min. | ↑ Hb F (>5%; >0.05, mass fraction) may cause false-positive results. |
|--|---|-----------------------------|--|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| | <p>Starch gel at pH 8.8-9 may be a better general method for resolution and reproducibility; it is especially useful for resolving minor fractions.</p> |
| | <p>This starch gel method separates Hb H and Hb Bart's from other hemoglobins.</p> |
| | <p>Globin-chain electrophoresis identifies variants not distinguishable by other electrophoretic techniques. It is particularly useful for identifying Hb D-Punjab, Hb G-Philadelphia, and Hb Hasharon.</p> |
| | <p>IEF is increasingly used in identifying mutant hemoglobins; it enables detection of variants that migrate with Hb A.</p> |
| | <p>HPLC possesses both the high resolution and sensitivity for detection of hemoglobin variants and has been increasingly used in the routine clinical laboratories.</p> |
| <p>↑ <i>Hb H disease</i>: Slight opacity appears at 10 min; precipitation occurs before 40 min.</p> | |
| <p>Blood older than 3 days may give false-positive result.</p> | |

| Hemoglobin (Hb), Plasma ¹⁻³ | Whole blood (heparin, ACD, EDTA). Use butterfly set with 18-gauge needle. Discard first 4 mL, and then collect blood for test. Store plasma at 4° C. | <3 mg/dL With meticulous technique, the value should be <1 mg/dL | × 0.155* × 0.155* | [<0.47 μmol/L] [<0.16 μmol/L] | ↑ Hemolysis during or after venipuncture; alglucerase ↑ V Drugs causing hemolysis in G6PD-deficient individuals or through an immune mechanism, e.g., analgesics, antimalarials, cinchona alkaloids, nitrofurans, sulfonamides, sulfones; specific agents are listed in Table I-4. ↓ V Anistreplase, α-interferon |
|---|--|---|--------------------------|--------------------------------------|---|

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ <i>Hb H disease</i>: 10-100% of erythrocytes develop pale blue inclusions by 1 hr (single, large inclusions are present after splenectomy).</p> <p>↑ <i>α-Thalassemia trait</i> (some cases): A very few erythrocytes may contain inclusions.</p> <p>↑ <i>Unstable hemoglobin disorders</i>: If spleen is intact, inclusions develop later than Hb H; after splenectomy, Heinz bodies (inclusions) are preformed.</p> | <p>This method utilizes the reticulocyte-rich fraction of erythrocytes, concentrating the Hb H-positive cells, which are found more easily in α-thalassemia minor. Reticulocyte precipitates of RNA are dark purple; Hb H precipitates are pale blue.</p> |
| <p><i>Hb H disease</i>: In adults, 2-40% of total hemoglobin is Hb H. The occurrence of Hb H may be an acquired disorder in some cases of erythroleukemia and other myeloproliferative diseases.⁷</p> | <p>Starch gel or starch block EP, pH 6.8-7.0, gives better separation of Hb H from Hb A than an alkaline pH.</p> |
| <p>↑↑ Intravascular hemolysis (e.g., PNH, PCH), major transfusion reaction, traumatic hemolytic anemia, falciparum malaria, cold hemagglutinins, violent exercise, burns, March hemoglobinuria.</p> <p>↑ Extravascular hemolysis, transfusion reaction; slight elevations in sickle cell anemia, β-thalassemia major, warm-type autoimmune hemolytic anemia.</p> | <p>Measurement of free Hb in plasma is of no practical value in the diagnosis of chronic hemolytic anemias. Hemolysis in the process of blood collection is an important variable that limits the value of an isolated estimation of plasma hemoglobin. Serial estimations may be of greatest use.⁴</p> |

| ↑ Polycythemia, after vigorous exercise or excitement, hemoconcentration (as in dehydration, burns, severe vomiting, intestinal obstruction) | The cyanmethemoglobin technique is the method of choice selected by the International Committee for Standardization in Hematology (ICSH). The method measures all hemoglobin derivatives except sulfhemoglobin by hemolyzing the specimen and adding a reducing agent. As such, this method does not distinguish between intracellular versus extracellular hemoglobin (hemolysis). |
| ↓ Anemia, recumbency; drugs that cause aplastic anemia or that cause hemolysis, either in G6PD deficiency or by an immune mechanism (specific agents listed in Table II-4) | Hb at birth is usually lower in premature infants than in term infants. The mean Hb in black persons is 0.4-1.0 g/dL [4-10 g/L] lower than in whites after the first decade of life. ⁹ Hb, Hct, and erythrocyte count are slightly lower between 5:00 PM and 7:00 AM and after meals (up to 10% lower); values are up to 5.7% lower in recumbency. Falsely high results may occur because of prolonged venous stasis during venipuncture. A slight but significant decrease occurs in the lower reference limit of Hb in men aged 65-74 yr. There is no significant change in men or women >age 85 yr as compared with ages 65-74 yr. ¹⁰ |

DIAGNOSTIC INFORMATION

REMARKS

The difference in percent denatured Hb between patient and control at 10 min is a semiquantitative estimate of the amount of unstable Hb.

Isopropanol precipitation is a more sensitive test than heat denaturation (50° C, Tris buffer). Unstable hemoglobins begin precipitation at 5 min and become flocculent after 20 min. To exclude a false-negative test, incubation should be continued until precipitation of the control occurs.

See also *Heinz Body Preparation* and *Hemoglobin H*.

↓ During intense hemolytic processes

Hemopexin is a weak acute phase reactant with levels rarely increasing more than twofold over resting levels.

This polymorphic protein is synthesized by hepatocytes. Hemopexin binds heme/metheme with high affinity at a 1:1.11 (mg/g) ratio. The complex is cleared from the circulation by the liver, in contrast to the hemoglobin-haptoglobin complex that is cleared by the reticuloendothelial system. Hemopexin also binds porphyrins other than heme. The heme-hemopexin complex, once processed in the liver, releases hemopexin for return to the circulation, unlike haptoglobin, which is destroyed once complexed with hemoglobin. Serial analysis of hemopexin may be a better index of hemolysis than is haptoglobin analysis during processes where haptoglobin is consumed (e.g., after surgery in which extracorporeal blood oxygenation is employed, and decreasing hemopexin levels indicate continued erythrocyte destruction).

This test can be used to monitor heparin therapy. It is also useful for determining heparin overdose. It can establish precisely the level of heparin in plasma.

Although the aPTT is the most commonly used test for monitoring heparin therapy, the heparin anti-Xa assay is increasingly being used and in some laboratories has replaced the aPTT. Proposed advantages of the anti-X assay include obtaining therapeutic levels more rapidly, differentiating patients at risk of bleeding, and less influence from biologic variables that affect the aPTT.

LMWH and danaparoid generally do not prolong the aPTT; therefore the anti-Xa assay is also used for monitoring these anticoagulants when indicated.

The anti-X assay is a chromogenic assay that measures heparin concentration indirectly. Antithrombin and factor Xa are used as the assay reagents. Heparin in the patient's plasma binds with the added excess antithrombin and inhibits excess factor Xa. The quantity of residual factor Xa is measured using a chromogenic substrate, and the released colored compound is measured spectrophotometrically. The quantity of residual enzyme is inversely proportional to the amount of heparin present in plasma.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Heparin-induced thrombocytopenia.</p> <p>Note: The diagnosis should be made if there are clinical abnormalities present and HIT antibodies are detected. Negative testing for HIT antibodies using two assays (ideally one activation and one antigen assay) essentially rules out HIT.</p> | <p>HIT is a serious clinicopathologic syndrome (thrombocytopenia, thrombosis) associated with heparin therapy or even small amounts of heparin (e.g., heparin-coated lines). The HIT antibodies are directed at neoepitopes on platelet factor 4 (PF4), which appear on exposure to heparin. However, only a minority of patients who form HIT antibodies actually develop thrombocytopenia or thrombosis. Testing for HIT should be performed when clinically suspected.</p> <p>Two types of assays are used for a diagnosis of HIT. The functional (platelet activation) assays are based on the patient antibodies activating test platelets in the presence of heparin. These assays include the platelet aggregation method, the washed platelet activation assays (serotonin release assay and heparin-induced platelet agglutination), and flow cytometry. The washed platelet activation assays have greater diagnostic specificity but are technically demanding and usually done in reference laboratories.</p> <p>The antigenic assay (ELISA) is based on detection of antibody binding to PF4/heparin (usually IgG). However, they may detect nonpathogenic IgA and IgM antibodies. A particle gel immunoassay (ID-H/PF4 test) is also available.</p> <p>The antigen assays are more widely available. The ELISA assay is generally considered the most sensitive test. However, the activation assays have a greater diagnostic specificity than antigen assays.</p> |

Hepatitis A, formerly called *infectious hepatitis*, is a picornavirus usually transmitted through either oral or fecal contact (but rarely transmitted parenterally³) that can cause either asymptomatic infection or symptomatic clinical hepatitis. Both IgG and IgM antibodies occur early in the acute infection (see Fig. II-4) with IgG persisting for years. Diagnosis of acute HAV infection requires positivity for IgM-anti-HA (see Table II-7). After an acute infection, IgM-anti-HA usually disappears in 3-4 mo but may persist up to 10 mo. With increasing use of vaccination, most positive IgM anti-HA results are false positive; CPC recommends the test only be used in the setting of acute hepatitis.⁴ Patients with IgG-anti-HA are

A high percentage of the population has protective antibody to the hepatitis A virus (total anti-HA) acquired from clinically unapparent infections. This is why *standard immune globulin* has been effective as prophylaxis for hepatitis A exposures.

See Table II-7.

DIAGNOSTIC INFORMATION

REMARKS

The presence of HBV-DNA in serum confirms active hepatitis B infection and implies infectivity of serum. Current use of the assay is primarily for assessing responses of hepatitis B to therapy, such as interferon- α , lamivudine, or adefovir.³ HBV-DNA measurement is also important in persons infected by mutant strains of HBV that do not make antigen or normal surface antigen. HBV-DNA is also used before and after liver transplantation to detect low-level viral replication. HBV-DNA typically can be detected using very sensitive techniques even in those thought to have recovered from HBV infection and positive for anti-HBs and anti-HBc.⁴ Viral load fluctuates over time in most patients and may vary by as much as 10^2 - 10^4 in serial measurements.⁵

Hepatitis B (HBV)-DNA and -RNA can also be detected in tissues using molecular biological techniques, but these tests are not generally available. A variety of methods are used, separated into amplified and nonamplified methods. The detection limit for nonamplified methods is typically on the order of 10^4 U/mL, but most have detection limits $>10^5$ U/mL. Polymerase chain reaction (PCR) assays are generally the most sensitive amplified methods, but current branched DNA assays have detection limits of $\sim 10^3$ U/mL. Differences between assays may exceed one log.⁵

The World Health Organization has recognized an international standard for HBV-DNA quantification,⁶ and assays are commonly reported in International Units based on comparison with the standard. Correlation between copies/mL (or genome equivalents) and International Units are not the same for all assays, and the conversion factor can differ with viral load even with the same assay. On a theoretical basis, 1 pg of genomic HBV-DNA is equivalent to 2.85×10^5 copies of virus.

See also *Section II, Hepatitis B Virus*.

See Table II-7.

With naturally occurring hepatitis B infections, anti-HBs usually appear in the serum several weeks after disappearance of HBsAg (see Fig. II-5). The presence of anti-HBs generally means there is protection against hepatitis B infection. However, convalescent anti-HBs may fall below limits of detection. A qualitative anti-HBs test is usually adequate to assess natural immunity, but a quantitative finding of >10 U/L for postvaccine testing is the accepted concentration that confers protection.

Anti-HBs is now mainly used to assess efficacy of hepatitis B vaccine but remains an adjunct test along with anti-HBc for determining whether subjects have immunity because of a naturally acquired infection or whether chronic hepatitis B may exist in an HBsAg-negative patient.

DIAGNOSTIC INFORMATION

REMARKS

HBsAg is the surface lipoprotein coat of the hepatitis B virus. It was originally discovered by Blumberg² and was called *Australian antigen*. Antigenic differences in HBsAg characterize the eight genotypes (A-H) of the hepatitis B virus. These are composed of a common a determinant, an a, d, or y determinant, and either an r or w determinant.

Hepatitis B is a DNA virus of the *Hepadnaviridae* family that replicates via an RNA intermediate using reverse transcriptase. It can cause persistent infection leading to cirrhosis and hepatocellular carcinoma. It has a unique partially double-stranded, circular DNA that utilizes the same nucleotide sequences to code for different proteins by frame-shifting. The virus infects hepatocytes, which then produce complete viral particles and excess HBsAg. The hepatitis B virus is not cytopathic. Instead, the host immune reaction to foreign viral proteins lyses infected hepatocytes and causes hepatitis. Because of immature host immunity, infected neonates and young children are much more likely to become chronic carriers of hepatitis B than adults. (See Fig. II-5 for the serological responses and the various outcomes of hepatitis B infections.)

HBsAg comprises three proteins (SHBs, encoded by the S domain of the hepatitis B genome; MHBs, encoded by S + preS1; and LHBs, encoded by S + preS1 + preS2). Detection of HBsAg is usually the first detectable marker of hepatitis B infection and remains positive in persistent infections (see Fig. II-5). Therefore HBsAg should be tested in the clinical settings of both acute and chronic hepatitis.

HBsAg produced by recombinant DNA techniques in yeast is used as a highly effective vaccine. Original vaccines used purified HBsAg harvested from chronic hepatitis B carriers.

Quantitation of HBsAg is possible but not usually performed. With acute hepatitis B a 50% decrease in HBsAg serum concentrations after 1 mo indicates resolving infection, whereas an increase implies persistence.¹

Assays for HBsAg typically detect the common a determinant, as do antibodies induced by the hepatitis B vaccine. There are rare mutations in the a determinant that affect recognition by the antigen-binding region of anti-HBs. These variants may result in falsely negative HBsAg assays.¹ Such variants may also escape detection by antibody induced by the vaccine, producing infection in anti-HBs-positive individuals. Such mutations do not typically occur in genotype A, owing to differences in folding of the surface antigen that do not favor production of such mutants.^{3,4}

A number of reports have documented chronic hepatitis B infections without HBsAg detectable in serum, largely because of such variants.⁵ Although this is rare, the presence of the virus can be deduced by testing for anti-HBc, anti-HBs, and HBV-DNA (see Table II-7).

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>HB_eAg and anti-HB_e are ordered together and should only be studied in patients who are chronically HB_eAg positive. There is no rationale for ordering these studies in patients with acute hepatitis. The HB_e gene includes part of the HB_c gene along with a “core promoter” region and an upstream “precore” region that generates a signal peptide causing carboxy-terminal truncation of the core protein. The resulting HB_eAg is produced along with infectious viral particles but is not incorporated into virus. Its exact function is unknown, but some believe it may function to induce host immune tolerance, especially in congenital or neonatal infection. In general, active hepatitis B viral replication is associated with infective serum that is HB_eAg positive and anti-HB_e negative. On conversion to a nonreplicative state, anti-HB_e appears in the serum and HB_eAg disappears. Mutants in the precore region (particularly insertion of a stop codon by a G to A mutation at nucleotide 1896)² prevent expression of HB_eAg, but anti-HB_e and infectious viral particles are still produced. These precore mutants are responsible for the majority of infections in Asia, Africa, and Southern Europe but are less common in Northern Europe and North America^{2,3} because they do not occur in the endemic genotype A hepatitis B strain.⁴</p> | <p>Presence of HB_eAg implies that infective hepatitis B virus is present in serum. However, its absence on conversion to anti-HB_e does not rule out infectivity, especially in persons infected with genotypes other than A. HB_eAg-negative strains respond similarly to antiviral treatment.⁵ Measurement of HBV-DNA is now recommended, especially in persons with increased ALT but negative HB_eAg.</p> |
| <p>The main utility of testing for HB_eAg and anti-HB_e is to assess response of the hepatitis B infection to therapy.</p> | |

DIAGNOSTIC INFORMATION

REMARKS

The hepatitis C virus (HCV) is a single-stranded RNA virus of the *Flaviviridae* family that is now known to be responsible for >95% of the cases of “non-A, non-B” hepatitis (see Fig. II-6). The most common mode of acquisition of HCV is through injection drug use, but transfusion before effective blood donor testing was available (1992) and noninjection drug use are also common risk factors. Transmission by needlestick or transmission to a fetus by an infected mother occurs in ~3-5% of exposures. Sexual transmission is rare. Hepatitis C is the most common cause of chronic hepatitis, cirrhosis,³ and hepatocellular carcinoma and is the major cause of cryoglobulinemia.⁴ However, long-term follow-up evaluation (~18 yr) of patients with transfusion-acquired non-A, non-B hepatitis (most of whom presumably had hepatitis C infections) did not show an increase in overall mortality, although there was a slight increase in liver-related mortality.⁵

The hepatitis C genome was discovered using molecular techniques, although the virus had not been isolated.⁶ The second-generation EIA and RIBA tests use the c100-3, c200, c22, and c33c antigens, whereas third-generation EIA and CA tests utilize c22, c33, c100, and NS-5 antigens. Antibody becomes detectable an average of 9 weeks after exposure with third-generation assays and 12 weeks after exposure using second-generation assays; ~40-50% of those with acute HCV infection have negative anti-HCV at the time of diagnosis.⁷ Approximately half of those with acute HCV clear virus and some of these never develop anti-HCV. In the remainder, ~15-30% subsequently lose anti-HCV over 15-20 yr of follow-up evaluation.^{8,9} Most (90%) of those truly positive for anti-HCV are chronically infected.¹⁰ Presence of anti-HCV does not imply protective immunity.

Usually anti-HCV is obtained first to diagnose HCV (see Table II-7). RIBA is equivalent to Western blot in confirming true positive anti-HCV. Samples that are weakly positive (signal to cutoff value ratio <3.9 for ELISA, <8.0 for CA, or <10.0 for MEIA) are usually negative on RIBA,^{10,11} and CDC guidelines recommend confirmation with RIBA before reporting these as positive.¹² Samples that are strongly positive are almost never RIBA negative. HCV-RNA can also be obtained if there is high clinical suspicion of HCV despite a negative anti-HCV, especially in immunosuppressed individuals or in the setting of acute hepatitis. Anti-HCV and the RIBA often do not become positive during an acute infection; thus repeat testing several months later is required if HCV-RNA is negative.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>See <i>Hepatitis C Antibody</i> for information regarding the virus and its clinical course. HCV antigen appears at about the same time as HCV-RNA with acute infection and increases in parallel to it. There is a strong correlation between core antigen and HCV-RNA, with 1 pg/mL of core antigen approximately equivalent to 8000 U/mL of HCV-RNA. HCV antigen becomes undetectable with successful treatment but is not as sensitive at detecting residual virus as are HCV-RNA assays with detection limits <50 U/mL.</p> | <p>HCV core antigen has similar sensitivity in infection with all genotypes of HCV. Assays detect total HCV antigen and require dissociation of antigen from antibody before measurement.</p> <p>See Table II-7.</p> |

See *Hepatitis C Antibody* for information regarding the virus and its clinical course. Detection of HCV-RNA is used to confirm current infection and to monitor treatment with interferon- α (with or without ribavirin). The most widely used genomic area for detection by PCR seems to be a well conserved 5'-noncoding region, although newer assays also use the NS5b region.

Assays for HCV-RNA are typically divided into qualitative and quantitative forms. Qualitative assays have generally had lower detection limits, but real-time PCR and TMA quantitative assays are generally replacing qualitative assays. Quantitative assays (viral load) are needed pretreatment to assess response (<2 log decrease after 12-wk treatment indicates lack of response).⁴

RNA is very susceptible to degradation; thus improper specimen handling can cause false-negative results. Monitoring of treatment at time points beyond 12 wk requires use of assays with lower detection limits ≤ 50 U/mL.⁵ Assays are now generally reported in U/mL, with standardization using the WHO reference material.⁶ Although this improves reproducibility between methods, it does not eliminate differences.⁷

There are six genotypes of HCV, with <70% homology in nucleic acid sequence. Determination of genotype, either by line probe analysis or direct sequencing of either the 5'-noncoding or NS5b region, is critical pretreatment, as genotypes 2/3 respond to lower doses and shorter duration of treatment than do other genotypes.⁴

DIAGNOSTIC INFORMATION

REMARKS

Hepatitis Delta is a replication-defective RNA virus or virusoid that requires the surface coat of hepatitis B (HBsAg) to become an infectious virus. After transcription of the RNA into mRNA, the virus produces a protein, HDAg, which may interfere with translation of other mRNAs and produce cell damage. When hepatitis D infection occurs simultaneously with hepatitis B, the course of both infections tends to be more severe, but self-limited. However, in the case of acute hepatitis D superinfection of an established hepatitis B infection, there is much more hepatitis D replication, and a more severe clinical hepatitis occurs. In this situation, the hepatitis D infection usually becomes chronic, and HBV replication is suppressed. Anti-HD does not necessarily indicate active infection, but the presence of HDAg does.

The role of testing for either HDAg or anti-HD is currently controversial because the incidence of infection with HDV has declined markedly in the U.S. with use of HBV vaccine. Generally one tests for hepatitis D only in patients positive for HBsAg. It has been suggested, for prognostic reasons, that all patients with chronic hepatitis B be tested for anti-HD, especially if there is exacerbation of a stable hepatitis.

See also *Section II, Hepatitis Delta Virus*.

See Table II-7.

Her-2/neu gene amplification and overexpression of the *Her-2/neu* protein is found in 25-30% of primary breast cancers. The protein is expressed on normal epithelial cells and is overexpressed in other epithelial tumors, including lung, hepatocellular, pancreatic, colon, stomach, ovarian, cervical, and bladder cancers.¹⁻⁴

The *Her-2* (human epidermal growth factor receptor-2)/*neu* oncogene, located on the long arm of chromosome 17, encodes a 185 kDa transmembrane protein (p185) that is part of the epidermal growth factor receptor family (EGFR) and has tyrosine kinase activity. Binding of ligand, including EGR, EGF-like ligands, and neuregulins, to the receptor causes dimerizations, which initiates an intracellular signaling cascade leading to cell proliferation. The extracellular domain of the protein (p105) is a glycoprotein that is shed into the circulation.¹⁻⁴

Trastuzumab (Herceptin) is a humanized monoclonal antibody against the extracellular domain of *Her-2/neu* that acts by inhibiting the activated proliferation signal. High levels of *Her-2/neu* expression or amplification in tissue are recommended to identify patients with metastatic, recurrent, and/or treatment-refractory unresectable locally advanced breast cancer for trastuzumab treatment.⁵ *Her-2/neu* expression may also have negative prognostic value. Tumors scored as weakly positive (2+) using IHC (scale 0-3+) are typically sent for additional testing using FISH.¹⁻⁴

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---------|
|------------------------|---------|

Three predominant isoenzymes of lysosomal hexosaminidase have been identified in serum: hexosaminidase A (or acid form), hexosaminidase B (or basic form), and hexosaminidase S. Separation is readily accomplished by DEAE cellulose chromatography or isoelectric focusing. Alternatively, the isoenzymes may be distinguished as the thermolabile hexosaminidase A and thermostable components, hexosaminidases B and S. Distinction by thermostability consistently yields a lower absolute and lower relative hexosaminidase A than does column separation. The enzyme exists as the following dimers: S ($\alpha\alpha$), A ($\alpha\beta$), and B ($\beta\beta$). Newly developed specific substrates may distinguish the separate isoenzymes characteristic of Tay-Sachs and Sandhoff diseases.

For the diagnosis of Tay-Sachs disease, total hexosaminidase determinations are of no value. Tay-Sachs victims lack the A isoenzyme but may have increased B and/or S. Hexosaminidase is usually determined in serum. It has also been reported in platelets, peripheral blood leukocytes, urine, saliva, tears, and fibroblast cultures from skin.¹⁷ Amniotic fluid and fetal blood obtained at fetoscopy have been used for the antenatal diagnosis of Tay-Sachs disease (by demonstrating the absence of the heat-labile hexosaminidase A isoenzyme) and for Sandhoff disease, in which hexosaminidases A and B are absent.

DIAGNOSTIC INFORMATION

REMARKS

U ↑ Glomerulopathies, nephrotic syndrome, Goodpasture's disease, direct injury to renal cells, acute renal transplant rejection, immunosuppressive nephrotoxicity, thrombosis of donor renal artery or vein as a result of ischemia or nephrotoxicity, urinary tract infection; active phase of acute tubular necrosis, heavy metal poisoning, active glomerulonephritis, analgesic nephropathy, aminoglycoside toxicity, chronic pyelonephritis, renal injury resulting from hypotension or anoxia.

Diseases with secondary renal involvement: renal artery stenosis in hypertensives, rheumatoid arthritis, degenerative joint disease, diabetes mellitus, stroke, myocardial infarction, carotid thrombosis, chronic liver disease, after surgery, burns, cardiac bypass operation, hypertension, multiple myeloma, and chemotherapy.^{14,15}

NAG is the most widely assayed urinary enzyme used for the detection and diagnosis of renal disease.¹⁸ This is because of its stability in urine, its high molecular weight (130,000), which prevents glomerular filtration, and its very high activity in tubular lysosomes. An increase in urinary activity therefore indicates renal damage. Increased urinary NAG activity resulting from renal damage by antibiotics or chemotherapy appears earlier than elevations in serum creatinine or decreased creatinine clearance. However, analytically sensitive assays are necessary because of its low activity in health.

Urinary excretion of NAG provides an early warning of rejection episodes for renal transplants. The urine reference interval shows an almost linear increase in NAG activity from ages 10 yr to >70 yr, from 40-90 nmol/hr/mg creatinine [75.6-170 U/mol creatinine]. Children >40 nmol/hr/mg creatinine [>75.6 U/mol creatinine].⁶

Changes have also been observed in the urinary pattern of NAG isoenzymes in renal disease. When using ion-exchange chromatography several isoenzyme forms, B₁, I₁, I₂, and A^S, are detected between the main A and B hexosaminidases. For example, after renal transplantation, no change in the urinary isoenzyme profile is observed in the stable transplant, whereas reversible rejection shows a marked increase in the I₂ form with a decrease in the relative proportion of the A form; the profile normalizes when rejection is treated. When patients do not respond to treatment, both the B and I forms increase, whereas the A form decreases.¹⁸

This chromophore has a higher molar absorbance than 4-nitrophenol; therefore 15-fold urine dilution can be used, and the effect of endogenous inhibitors thus is eliminated.

↑ Familial hyperalphalipoproteinemia. Secondary increase because of primary biliary cirrhosis, chronic hepatitis, and alcoholism.

↓ Familial hypoalphalipoproteinemia, Tangier disease, or other apo A-I variants, fish-eye disease, familial lecithin-cholesterol acyltransferase (LCAT) deficiency, familial cholesteryl ester transfer protein (CETP) deficiency, familial apo A-I deficiency (with or without apo CIII/apo A-IV deficiency), and coronary heart disease.

The following can lead to secondary decrease in HDL-C: hypertriglyceridemia, Cushing's syndrome, type 2 diabetes, hepatocellular disorders, cholestasis, nephrotic syndrome, chronic renal failure, obesity, and malignancy.

HDL particles are antiatherogenic; they promote cellular cholesterol efflux and reverse cholesterol transport, and they also appear to have antiinflammatory, antioxidant, and anticoagulant properties.

Epidemiological studies demonstrate an inverse association between HDL-C concentration and coronary heart disease (CHD). The measurement of HDL-C is useful in identifying lipoprotein disorders and assessing CHD risk. The National Cholesterol Education Program (NCEP) recommends that all adults >20 yr be screened for CHD risk with measurement of fasting total cholesterol, HDL-C, LDL-C, and triglyceride concentrations. According to NCEP guidelines, HDL-C <40 mg/dL is a risk factor for CHD. HDL-C \geq 60 mg/dL is a "negative" risk factor; its presence subtracts one risk factor from the total count.

It is suggested that for every 5-mg/dL [0.13 mmol/L] decrease in HDL-C below the mean, the risk of CHD increases 25%.

Intraindividual variation in HDL-C is ~7% over 1-12 months. Because of biological and analytical variation, at least two serial samples may be necessary for clinical decision making.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↓ Hereditary HMWK deficiency. Functional levels of HMW-kininogen are also significantly decreased in acute myocardial infarction and in association with elevation of serum levels of prolactin.²</p> | <p>HMW-kininogen is a contact factor of the intrinsic pathway of the coagulation system. HMW-kininogen, together with kallikrein, enhances the activation of factor XII.</p> <p>Similar to deficiencies of factor XII and prekallikrein, HMW-kininogen deficiency may cause a prolonged PTT but no bleeding.</p> <p>A deficiency of HMW-kininogen can be initially suspected with a mixing study: a correction of aPTT would support a factor deficiency. If there is no history of bleeding, a factor XII assay will be commonly performed in most laboratories. If factor XII is normal, both prekallikrein and HMW kininogen assays should be ordered (these are usually send-out tests done in a few reference laboratories).</p> |
| <p>P ↑ Histidinemia, pregnancy, transient histidinemia of newborns, hemolysis</p> <p>P ↓ 1-16 days after abdominal surgery,¹⁷ rheumatoid arthritis</p> | <p>In pregnancy, plasma histidine increases ~50%. Histidinemia results from an inherited absence of histidase. This is regarded as a benign inborn error of amino acid metabolism.</p> <p>See also Table II-2.</p> |
| <p>U ↑ Histidinemia, Hartnup disease, pregnancy, generalized aminoaciduria</p> | <p>Increases in urinary levels may follow heavy meat ingestion.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| U ↑ Hyperornithinemia-hyperammonemia-homocitrullinuria (HHH) syndrome, hyperlysinemia, saccharopinuria ³ | Excretion decreases gradually with age; only traces are found in older children and adults. See also Table II-2C. |

| | |
|--|---|
| ↑ Homocystinuria (defects in cystathionine-β-synthase [CBS], methionine synthase [MS], MS reductase, or intracellular cobalamin metabolism). | Homocystinuria refers to an inborn error of metabolism associated with the excretion of large amounts of Hcy and greatly elevated plasma Hcy levels (typically >100 μmol/L). Although the most common defect is CBS deficiency, other enzymes and factors involved in the metabolism of homocysteine may be involved. |
| ↑ Homocystinuria, heterozygous CBS defect, MTHFR 677C→T homozygosity, vitamin B ₁₂ deficiency, folate deficiency, vitamin B ₆ deficiency, cigarette smoking, coffee consumption, renal failure, hypothyroidism, hyperproliferative disorders, diabetes, psychiatric disorders, impaired cognitive function in elderly persons, pregnancy complications (e.g., preeclampsia, low birth weight, premature delivery, recurrent pregnancy loss, placental abruption), and birth defects (e.g., neural tube defects). | Serum or plasma homocysteine is used as a functional test for vitamin B ₁₂ , folate, and/or vitamin B ₆ deficiency. Elevated Hcy is also an independent risk factor for cardiovascular disease. |
| ↓ Down syndrome, pregnancy, hyperthyroidism, and early diabetes. | Hcy measurement in conjunction with methionine load testing is generally considered a research tool and of limited clinical utility. Intraindividual variability is ~8% over a 1-yr period, although it can be as much as 25% in patients with hyperhomocysteinemia. Generally, a single measurement is considered adequate to determine Hcy status. |

Like cyanide, sulfide inhibits cytochrome oxidase and produces cellular anoxia. Death occurs rapidly at concentrations of 1000 ppm [29.3 mmol/L].

Sulfide is widely used in industry; hydrogen sulfide gas is produced by decomposing protein, e.g., sewer gas or marsh gas. Its odor is easily detected at a concentration of 0.03 ppm [0.9 μ mol/L], but at 150 ppm [4.4 mmol/L], the olfactory nerves are paralyzed.

Sulfide is partially oxidized in erythrocytes and liver to thiosulfate; a portion is excreted by lungs as hydrogen sulfide.

β -Hydroxybutyrate (BOHB) (the predominant ketone) is a better indicator of clinical state than acetoacetate in diabetic ketoacidosis (DKA). The BOHB/AcAc ratio is normally 3:1. This ratio will increase to 6:1 or 12:1 during ketoacidosis, particularly if there is associated decreased tissue perfusion, metabolic acidosis, and tissue catabolism. All of these will favor reductive metabolism and hence BOHB production. Acetoacetate may increase during therapy for DKA because BOHB is oxidatively metabolized to acetoacetate.⁵

↑ Alcoholic ketoacidosis, lactic acidosis (shock, renal failure), liver disease, infections, phenformin, and salicylate poisoning.

β -Hydroxybutyric acid is not detectable by common tests for ketone bodies (Acetest, Chemstrip, and Ketostix).

β -Hydroxybutyrate is an extremely reliable guide for monitoring the progress of insulin therapy in the treatment of diabetic ketoacidosis. During successful therapy, total ketones and β -hydroxybutyrate decrease, but acetoacetate increases.

β -Hydroxybutyrate measurements quantitate this decrease; Acetest, Ketostix, Chemstrip, and Multistix results show an initial increase reflecting the acetoacetate activity.

The hallmark of alcoholic ketoacidosis is ketoacidosis without marked hyperglycemia; β -hydroxybutyrate component is markedly increased, not acetoacetate. Therefore the reagent strip tests for ketoacidosis will appear normal in alcoholic ketoacidosis.⁶

No interferences from mesna, acetylcysteine, cysteine, dimer-caprol, captopril, or D-penicillamine, which cause false-positive results with urinary reagent strips.

Although valuable in specific circumstances, this test has largely been replaced by plasma and urine cortisol assays.

See *Cortisol, Total* and *Cortisol, Free*.

Although plasma 18-hydroxycorticosterone is increased in a majority of patients with aldosterone-producing adenomas, this test is of limited value for an individual patient.

Radiographic studies and adrenal vein aldosterone sampling are preferred for the differential diagnosis of primary aldosteronism.

| | |
|--|--|
| Excessive secretion of 18-OH DOC has been demonstrated in four forms of hypertension with suppressed PRA: in 17 α -hydroxylase deficiency, Cushing's syndrome, primary aldosteronism, and essential hypertension (a small number of patients). ⁵ | Secretion of 18-OH DOC appears to be primarily ACTH-dependent, but small increments in 18-OH DOC secretion may possibly be associated with activation of the zona glomerulosa by sodium depletion. |
| ↓ Ratio aldosterone/DOC + 18-DOC with malignant adrenocortical tumors. ⁶ | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Midgut carcinoid tumors (e.g., ileal carcinoids), foregut carcinoid tumors (e.g., pancreatic, duodenal, or biliary carcinoids), ovarian carcinoid tumors, celiac sprue, tropical sprue, Whipple's disease, oat cell carcinoma of the bronchus, and bronchial adenoma of carcinoid type</p> <p>↓ Depressive illness, small intestinal resection, mastocytosis, PKU, and Hartnup disease</p> | <p>Estimations of urinary 5-HIAA are generally more useful than measurements of the parent hormone (serotonin) for diagnosing carcinoid tumors. When dietary sources of 5-hydroxyindoles (e.g., walnuts, bananas, avocados, eggplants, pineapples, plums, and tomatoes) are excluded, urinary 5-HIAA excretion >25 mg/day [$>130 \mu\text{mol/day}$] is diagnostic of the carcinoid syndrome. Functioning metastatic carcinoid tumors may show striking 5-HIAA elevations, often exceeding 350 mg/day [$1820 \mu\text{mol/day}$]. In such cases, a qualitative screening test gives a positive result.</p> <p>When tumors are small and have not metastasized, a sensitive and specific quantitative test is needed. If normal or borderline results are seen in patients with clinical evidence of carcinoid syndrome, blood levels of serotonin or 5-hydroxytryptophan should be assessed. In some cases, 5-HIAA secretion may be intermittent, and repeat urine collections may be needed to document a clinical diagnosis. (See also <i>Substance P</i>.)</p> <p>Hindgut tumors (rectal carcinoids) rarely secrete 5-HIAA and are often not associated with the carcinoid syndrome. Foregut carcinoids frequently produce other hormones such as catecholamines, ACTH, insulin, and growth hormone. They are also associated with multiple endocrine neoplasia (MEN type I).</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ Congenital adrenal hyperplasia caused by 21-hydroxylase deficiency and 3β-hydroxysteroid dehydrogenase-isomerase deficiency, idiopathic hirsutism, and adrenal carcinomas</p> <p>↓ Adrenal insufficiency</p> | <p>17-OHP has a marked circadian variation in secretion (highest value in morning). The luteal phase elevation indicates corpus luteum activity. There is a significant increase 1 day before the LH peak, followed by a peak that coincides with that of the LH midcycle peak. This is followed by a short decrease and increase, which correlate with those of estradiol and progesterone. Highest values are found in patients with 21-hydroxylase deficiency. Increased basal and ACTH-stimulated serum 17-OHP concentrations are used to diagnose classic and non-classic forms of 21-hydroxylase deficiency and their carrier states.^{5,6} Test may be useful in monitoring patients with CAH who are receiving glucocorticoid treatment. Cross-reacting substances present in neonatal and infant serum specimens may interfere in direct (nonextraction) assays.⁷</p> |
| <p>↑ Congenital adrenal hyperplasia caused by 21-hydroxylase (P-450_{C21}) deficiency (values 4000-22,000 ng/dL [121-666 nmol/L]); 11β-hydroxylase (P-450_{C11}) deficiency associated with modest elevations; and some cases of adrenal or ovarian neoplasms</p> <p>↓ Male pseudohermaphrodites [17β-hydroxylase (P-450_{C17}) deficiency]; Addison's disease</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ Acromegaly, hyperthyroidism, hyperparathyroidism, Paget’s disease, rickets and osteomalacia, extensive fractures, bony metastases, osteoporosis, sarcoidosis, severe burns, acute osteomyelitis, congenital hypophosphatasia, fibrous dysplasia, growth spurts, and in elderly persons</p> <p>↓ Hypopituitarism, hypothyroidism, hypoparathyroidism, malnutrition, and muscular dystrophy (chronic)</p> | <p>Hydroxyproline, produced by the posttranslational hydroxylation of proline, constitutes ~13% of the collagen molecule. Urinary total hydroxyproline excretion reflects total collagen turnover. Approximately half of total body collagen is in bone with the remainder in skin, muscle, and other tissues. Hydroxyproline is also found in serum proteins, notably C1q, a component of complement. During collagen degradation, ~10% of hydroxyproline is excreted in urine, mainly as small peptides. Urinary hydroxyproline is increased by ingestion of meat, fish, and other foods or products containing gelatin or collagen. There is a diurnal rhythm of excretion of hydroxyproline with highest excretion at night.</p> <p>Total hydroxyproline is measured after acid hydrolysis. Although total hydroxyproline was used as a marker of bone resorption, hydroxyproline is also produced during collagen synthesis (collagen propeptides). Collagen telopeptides and cross-links (see <i>Collagen Telopeptides and Pyridinium Cross-links</i>) are more sensitive and specific markers of bone resorption. Consequently, hydroxyproline is no longer routinely used to measure bone resorption.</p> |

| | |
|---|---|
| <p>U ↑ Alcohol intake or serotonin-rich food (such as bananas). 5-HTOL/5-HIAA ratio increases after alcohol intake but not bananas.⁶</p> | <p>Serotonin is metabolized to 5-hydroxytryptophol-3-acetic acid (5-HIAA) and 5-hydroxytryptophol (5-HTOL), both of which are normal constituents of urine. Under normal physiological conditions, 5-HIAA is the major metabolite. Alcohol dose-dependently shifts serotonin metabolism toward 5-HTOL and leads to the increase of urinary 5-HTOL and 5-HTOL/5-HIAA ratio. The 5-HTOL/5-HIAA ratio is usually monitored to compensate for urine dilution and dietary intake of serotonin.</p> |

DIAGNOSTIC INFORMATION

REMARKS

The CNS synthesis rate of IgG by B cells infiltrating areas of active demyelination is a useful parameter for monitoring disease activity in multiple sclerosis.²

See also *IgG Index*.

Synthesis rate (mg/day) =

$$\left[\left(\text{IgG}_{\text{CSF}} - \frac{\text{IgG}_\text{S}}{369} \right) - \left(\text{Alb}_{\text{CSF}} - \frac{\text{Alb}_\text{S}}{230} \right) \left(\frac{\text{IgG}_\text{S}}{\text{Alb}_\text{S}} \right) \times (0.43) \right] \times 5$$

where:

IgG_{CSF} = concentration of IgG in cerebrospinal fluid in mg/dL

IgG_S = concentration of IgG in serum in mg/dL

Alb_{CSF} = concentration of albumin in cerebrospinal fluid in mg/dL

Alb_S = concentration of albumin in serum in mg/dL

369 = ratio of serum/CSF IgG concentrations in normal subjects

230 = ratio of serum/CSF albumin concentrations in normal subjects

0.43 = MW albumin/MW IgG

5 = average volume (in dL) of CSF normally formed in 24 hr

Alternative formulas may perform better.³

S ↑ Polyclonal: Increased serum IgA concentrations are found in chronic inflammatory disorders, infectious processes, and in association with tumors. These include rheumatoid arthritis, inflammatory bowel disease, ankylosing spondylitis,¹⁷ mixed connective tissue disease,¹⁸ and chronic liver conditions of both infectious and noninfectious etiology. Elevated levels have been reported in patients with malignancies of diverse organ sites and in patients with Wiskott-Aldrich syndrome.

Monoclonal: Multiple myeloma, solitary plasmacytoma, alpha-heavy chain disease, monoclonal gammopathy of undetermined significance (MGUS), lymphoma, and chronic lymphocytic leukemia.

S ↓ Selective IgA deficiency is one of the most frequently encountered primary immunodeficiencies. Although clinical manifestations are absent in many cases, it can be associated with infectious, autoimmune, and allergic complications,¹⁷ gastric carcinoma, and lymphoma.²⁰

IgA is present in both monomeric and dimeric forms and is the predominant immunoglobulin type found in secretions. It activates complement by the alternative pathway. Two subclasses have been identified (IgA_1 , IgA_2). Secretory IgA, which provides mucosal protection, consists of a dimer, a joining J-chain, and a secretory component obtained from epithelial cells. The secretory component may provide some resistance to enzymatic cleavage.

IgA cannot cross the placenta. Although it can be produced by infants, their serum values are typically low.^{24,25} Demonstration of increased concentrations in cord blood has been used as evidence of maternal blood contamination when performing serological assessment for possible intrauterine infection. Secretory IgA of maternal origin in colostrum and milk provides breast-fed infants with protection against infection within the intestinal tract.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Decreased or undetectable levels of IgA may be a component of other immunodeficiency states such as hyper-IgM, common variable immunodeficiency,²¹ and ataxia telangiectasia,²² or secondary to conditions such as thermal burns or suppression of uninvolved polyclonal immunoglobulins when a non-IgA M-protein is present.</p> | <p>IgA is the second most frequent type of monoclonal immunoglobulin (M-protein) identified in multiple myeloma (10-15%).²⁶ In standard serum protein electrophoretic studies, IgA M-proteins commonly migrate within the beta region or near the beta-gamma junction; consequently, their presence can be obscured by the beta bands. Quantitated IgA concentrations can also be normal or low despite the presence of an IgA M-protein. Serum immunofixation studies should be performed if an IgA monoclonal immunoglobulin is suspected. Polymerization commonly occurs with these M-proteins, resulting in multiple bands in electrophoretic studies. Complex formation with other serum proteins and enzymes are not infrequent and may complicate isoenzyme identification because of changes in migration characteristics.²⁷</p> |
| <p>U↑ IgA nephropathy (Berger's disease), severe nephrotic syndrome, surgical neobladder²³</p> | <p>Isolated IgA deficiency is reportedly the most frequently identified primary immunodeficiency (estimated at 1:400 to 1:3000 blood donors).²⁸ Some of these individuals will have anti-IgA antibodies and can experience an anaphylactic reaction if transfused with IgA-containing blood products. Anaphylactic transfusion reactions related to IgA deficiency, however, are relatively uncommon. Antibodies can be directed against the alpha chain or a specific subclass. Quantitated total IgA values can be within the normal interval despite a subclass deficiency with antsubclass antibodies.</p> |
| <p>Sal .↑ Can be increased rheumatoid arthritis, Sjögren's syndrome, or other autoimmune conditions.</p> | <p>Immunochemical methods do not differentiate monoclonal from polyclonal immunoglobulin concentrations. Serum electrophoresis and immunofixation should be performed for quantitation of M-proteins. For optimum avoidance of antigen excess, serum dilutions resulting in IgA concentrations of 50-100 mg/dL (500-1000 mg/L) have been recommended.</p> |
| | <p>Indications for quantitation include assessment for possible immunodeficiency, investigation of an anaphylactic transfusion reaction, diagnosis and serial monitoring of patients with monoclonal gammopathies, and evaluation for ataxia telangiectasia.</p> |

S ↑ *Polyclonal*: Smoking,⁶ infections, including AIDS,³ acute viral hepatitis,⁷ chronic obstructive pulmonary disease,⁸ hyperIgD and periodic fever syndrome,⁸ after allogeneic bone marrow transplant (children).^{9,10}

Monoclonal: IgD multiple myeloma, monoclonal gammopathy of undetermined significance

S ↓ Hereditary or acquired deficiency syndromes.

IgD exists in both a secreted and a membrane-bound form. It is sensitive to proteolytic cleavage and has a relatively short half-life of 2.8 days in the serum.² Membrane-bound IgD is found on the surface of mature B-cells and appears to have an immunoregulatory function. Antibody activity against a variety of antigens has been identified.³ Autoantibodies of the IgD type can be found in some patients with autoimmune diseases.¹¹

IgD multiple myeloma (mm) is estimated to represent ~2% of all myelomas.¹² The majority is of the λ light chain type, and a Bence Jones proteinuria, typically heavy, is present in >90% of cases.^{12,13} An increased incidence of amyloidosis, renal insufficiency, and shorter overall survival has been reported with the IgD type as compared with other types of mm.¹²

S ↑ *Polyclonal*: Chronic or recurrent infections. Autoimmune disorders including rheumatoid arthritis, sarcoidosis, Sjögren's syndrome, systemic lupus erythematosus, autoimmune pancreatitis, autoimmune hepatitis, and idiopathic portal hypertension. Some intrauterine contraceptive devices.¹⁴

Monoclonal: Multiple myeloma, solitary plasmacytoma, gamma-heavy chain disease, monoclonal gammopathy of undetermined significance (MGUS), lymphoma, and chronic lymphocytic leukemia.

S ↓ Primary immunodeficiency states including severe combined immunodeficiency, X-linked agammaglobulinemia, common variable immunodeficiency, hyper-IgM syndrome, and Nijmegen breakage syndrome.¹⁵ Conditions secondarily affecting serum immunoglobulin levels, such as protein-losing enteropathies, the nephrotic syndrome, thermal burns, myotonic dystrophy, treatment with immunosuppressant drug regimens, or suppression of uninvolved polyclonal immunoglobulins when a non-IgG M-protein is present. Quantitated total IgG values can be increased or within the normal range, or a generalized hypergammaglobulinemia can be present despite an IgG subclass deficiency.¹⁶ The clinical presentation of a subclass deficiency is variable, ranging from asymptomatic to recurrent infections and other signs of immunodeficiency.

Concentrations are variable with HIV infection. They are often elevated, however, a hypogammaglobulinemia can be present, or there may be deficiencies of one or more IgG subclasses.

Representing 70-80% of the total serum immunoglobulins in the normal adult, immunoglobulin G (IgG) is the major circulating immunoglobulin. It exists in four subclasses (IgG₁, IgG₂, IgG₃, IgG₄), with IgG₁ predominating at ~65% of total IgG. During the secondary immune response, IgG is the major antibody type produced.¹ Deficient individuals typically experience recurrent pyogenic infections.

IgG is the most frequent type of heavy chain identified in multiple myeloma, representing 50% of whole immunoglobulin M-proteins.¹⁹ Similar to the normal distribution of immunoglobulins, the majority of these (~70%) are IgG₁.²⁰ Monoclonal IgG proteins, usually at levels of ≥4000 mg/dL [40 g/L], can be associated with the hyperviscosity syndrome consisting of variable cardiovascular, neurologic, and bleeding complications.²¹

IgG of maternal origin provides passive immunity to the neonate. It is the only class of immunoglobulin transported across the placenta, and this appears to be Fc receptor mediated. Although initially very low, maternally derived IgG increases during the second and third trimesters in the fetus, eventually surpassing maternal levels by term in most cases.² IgG₁ is transported preferentially, with IgG₂ shown to have the lowest capacity for placental transfer.³ After birth, IgG of maternal origin progressively decreases as the infant's immune system matures, with total IgG levels lowest at ~3 months of age.¹⁷ Small-for-gestational age and premature infants are at increased risk of immunodeficiency because of lower initial IgG levels.^{2,17} IgG₂ and IgG₄ levels have been reported to mature relatively slower; consequently, evaluation of decreased values may be difficult in patients <2 yr of age.^{16,22}

DIAGNOSTIC INFORMATION

REMARKS

Immunochemical methods do not differentiate monoclonal from polyclonal immunoglobulin concentrations. Serum electrophoresis and immunofixation should be performed for quantitation of M-proteins. For optimum avoidance of antigen excess, serum dilutions resulting in IgG concentrations of 100-200 mg/dL [1000-2000 mg/L] have been recommended.

Indications for quantitation include assessment for possible immunodeficiency and the diagnosis and serial monitoring of patients with monoclonal gammopathies. IgG subclasses evaluation may be helpful if other causes of immunodeficiency cannot be identified.

MW: 150,000 (monomer)

$t_{1/2}$: 24 days.

CSF \uparrow Increased intrathecal synthesis is found in most cases of multiple sclerosis. It can also be found in other inflammatory conditions involving the CNS such as Guillain-Barre syndrome, infections, and subacute sclerosing panencephalitis, and less frequently in various disorders such as CNS neoplasms and cerebrovascular diseases.^{17,18}

Increased CSF IgG values can be caused by intrathecal synthesis or alternately may reflect the presence of blood-derived immunoglobulins resulting from elevated plasma levels or an increased permeability of the blood-brain barrier (BBB). Evaluation of the BBB and investigation of suspected intrathecal IgG synthesis involve assessment of the CSF/serum albumin ratio, CSF/serum IgG ratio, and IgG index or IgG synthesis rate. CSF protein electrophoretic studies showing bands of restricted heterogeneity (oligoclonal) in the gamma region that are not present in serum electrophoretic studies are evidence of immunoglobulin production within the CNS.¹⁸

DIAGNOSTIC INFORMATION

REMARKS

S ↑ *Polyclonal*: A selective increase in IgM concentration can represent a response to infection. Increases in antigen-specific IgM commonly occur on exposure to a diverse variety of viral (including HAV, HBV, CMV, EBV, and other viruses) bacterial or parasitic agents. Chronic inflammatory conditions such as rheumatoid arthritis and primary biliary cirrhosis can also be associated with increased serum IgM values. “Classical” rheumatoid factors (RF) are IgM autoantibodies against IgG¹⁵; however, RF can be other immunoglobulin types. Serum IgM concentrations can be elevated secondary to the nephrotic syndrome or with the inherited hyper-IgM syndrome.

S ↑ *Monoclonal*: Waldenström’s macroglobulinemia, lymphoma, chronic lymphocytic leukemia, μ -heavy chain disease (rare), multiple myeloma (also very rare), Schnitzler’s syndrome,¹⁶ cold IgM antibody agglutinin, monoclonal gammopathy of undetermined significance (MGUS).

S ↓ Selective IgM deficiency is uncommon and can be associated with autoimmune disorders.¹⁷ Recurrent infection is a typical manifestation. Decreased levels are more frequently seen in conjunction with general immunodeficiency states such as occurs with monoclonal gammopathies, splenectomy,¹⁸ enteric protein loss or some other causes of protein deficiency, thermal burns, or treatment with immunosuppressive drug regimens.

CSF ↑ Levels >3.0 mg/dL [>30 mg/L] suggest bacterial rather than viral meningitis.¹⁹

During B-cell development, IgM is the first immunoglobulin type produced and becomes a component of the B-cell surface receptor. It is also the initial antibody type secreted during the primary humoral response to antigen. The majority of “natural antibodies” that bind antigens not previously exposed to the individual are IgM in nature. On antigenic exposure, the typical antibody response sequence consists of an increase in antigen-specific IgM, isotype switching, and then subsequent increases in antigen-specific immunoglobulins of other classes.³ IgM levels peak, then frequently decline, but can remain elevated.

Because of its pentameric structure (five subunits with a joining J-chain, 10 sites available for antigen binding), IgM is an effective activator of complement.³ Most cold-reactive autoantibodies are IgM. Low molecular weight monomeric and oligomeric forms can be found in patients with lymphoproliferative, infectious, and autoimmune disorders.⁴ Small amounts of these forms may be detected in normal sera using sensitive methods.²⁰

IgM can be produced by the fetus and cannot cross the placenta. Consequently, serological assessment of antigen-specific IgM in fetal cord blood or in serum during the immediate postnatal period is used in the diagnosis of congenital infection. A substantial fraction of total IgM in neonates can be in the low molecular weight form.²¹

Monoclonal IgM proteins, usually at levels of ≥ 3000 mg/dL [30 g/L], can be associated with the hyperviscosity syndrome, consisting of variable cardiovascular, neurologic, and bleeding complications.²² Immunochemical methods do not differentiate monoclonal from polyclonal immunoglobulin concentrations. Serum electrophoresis and immunofixation should be performed for quantitation of M-proteins. For optimum avoidance of antigen excess, serum dilutions resulting in IgM concentrations of 50–100 mg/dL [500–1000 mg/L] have been recommended.

Indications for quantitation include the diagnosis of infection, assessment for possible immunodeficiency, and the diagnosis and serial monitoring patients with monoclonal gammopathies.

There is a decrease in total T-lymphocytes (CD_3^+), normal or increased B-lymphocytes (CD_{19}^+), and normal or increased natural killer cells ($CD_3^-CD_{56}^+$) in congenital severe combined immunodeficiency.

T-helper cells (CD_4^+) are depleted in HIV/AIDS, and CD_4^+ lymphocyte levels are used as a marker of prognosis and response to therapy.

An increase in total T-lymphocytes (CD_3^+) or cytotoxic lymphocytes (CD_8^+) is associated with acute renal allograft rejection, with severe viral infection (especially cytomegalovirus and Epstein-Barr virus), and with large granular lymphocytic leukemia. A decrease in total T-cells (CD_3^+) is associated with the effectiveness of therapy with antilymphocyte globulin (ALG) or anti-T-cell monoclonal antibody (OKT_3).

Current published reference intervals should be used with caution. Interlaboratory variations can result from differences in antibodies and equipment utilized, as well as whether the absolute numbers are calculated using a dual-platform method (total leukocyte count measured by separate automated counter multiplied by cell fraction measured by flow cytometry) versus a single-platform method (absolute count measured and calculated by single-flow cytometry method).

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>S ↑ Normal pregnancy, ovarian (granulosa cell) cancers, preeclamptic toxemia, Down syndrome pregnancy.</p> <p>S ↓ Ovarian aging.</p> | <p>Inhibins, like activins, belong with the transforming growth factor-β family, sharing structural homology through the β subunit. Inhibins are heterodimers and hence have two forms: α-βA (inhibin A) and α-βB (inhibin B).</p> <p>The synthesis and secretion of dimeric inhibins seem confined to the ovary (granulosa cells), testis (Sertoli cells), and placenta. Physiologically, inhibins inhibit the release of FSH from the anterior pituitary, serving as a negative feedback regulator for FSH.</p> <p>Circulating inhibins bind to α2-macroglobulin with a low affinity, which does not seem to interfere with the current ELISA assay.</p> <p>The current clinical applications are mainly limited to the second trimester screening for Down syndrome by inhibin A and the detection and monitoring of ovary granulosa cell tumors.</p> |

↑ Impaired renal function, diabetes.^{6,7}

Myoinositol is found in many foods.⁸ It has been shown to have a chemopreventative effect against tumorigenesis.^{2,9}

Studies indicate that it may also be important for fetal development, and serum values are higher in the fetus and the neonate compared with adult concentrations.¹⁰ Inositol supplementation can improve outcomes in premature infants with respiratory distress syndrome.³

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Skin and lungs are most likely routes of exposure. Toxicity in mammals is low. Topical exposure may cause local irritation. Headache, nausea, and paresthesia have been reported after human exposure to pyrethroids. Massive exposure may cause convulsions and death from respiratory and circulatory failure.</p> | <p>Pyrethrins and pyrethroids are rapidly metabolized, so blood concentrations of these compounds are not helpful. Urinary metabolites have been measured in occupationally exposed individuals, but monitoring is not common because of the low toxicity of these compounds in humans compared with other insecticidal agents.</p> |

| Insulin Antibodies (Anti-Insulin Ab) ¹⁻⁵ <i>Radiobinding assay</i> | Serum, separated from cells and frozen. Do not use plasma. | $<3\%$ binding of labeled human, beef, or pork in- sulin by patient's serum. ¹ | None found. |
|--|--|--|-------------|

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Concentrations of <45 mg glucose/dL [<2.5 mmol glucose/L] with a simultaneous serum insulin value (RIA) >6 μU/mL [>41.7 pmol/L] (>3 μU/mL on ICMA insulin assay) is diagnostic of insulinoma. C-peptide levels of ≥ 200 pmol/L and proinsulin levels of ≥ 5 pmol/L are consistent with hyperinsulinemia molar ratio of C-peptide and insulin is 0.2. An elevated insulin level with very low or undetectable C-peptide suggests factitious insulin use.</p> | <p>This is a very sensitive test for insulinoma; $>90\%$ of insulinoma patients will show hypoglycemia ≤ 48 hr of fasting. Test is indicated if patient has significant symptoms of fasting hypoglycemia and has fasting serum glucose <60 mg/dL [<3.3 mmol/L]. The fast is terminated when the patient develops significant symptoms of hypoglycemia and/or has plasma glucose value <45 mg/dL [<2.5 mmol/L]. There is no advantage to prolonging the fast beyond 72 hr. Patients with insulinoma have suppressed levels of plasma beta hydroxybutyrate (<2.7 nmol), whereas levels are higher in normals. At the end of the 72-hr fast, if plasma glucose is ≤ 60 mg/dL, 1 mg of glucagons IV is administered, and plasma glucose is measured after 10, 20, and 30 min. Patients with insulinoma have an increment of ≥ 25 mg/dL increase in glucose over the terminal fasting plasma glucose. Normal individuals have lower increments.</p> |

↑ Immune insulin resistance, pre-type I diabetes (before insulin treatment), polyendocrine autoimmune syndromes

Insulin antibodies are produced in nearly all diabetic patients treated with exogenous (bovine or porcine) insulin and in surreptitiously administered insulin.

Binding of $>10\%$ indicates significant insulin antibody levels and affinity.

The most common type of anti-insulin Ab is IgG, but IgA, IgM, IgD, and IgE have been reported. Most of these insulin antibodies have low affinity and do not cause clinical problems. However, their presence will interfere with and complicate most insulin immunoassays. In this case, measurements of C-peptide may be indicated because C-peptide is not found in commercial insulin preparations. Occasionally high-affinity insulin antibodies may bind to exogenous insulin and interfere with its action. The widespread use of human insulin, plus improvements in the purity of animal insulins, has led to significant reductions in the production of interfering antibodies.

A sensitized radiobinding assay and a direct ELISA solid-phase assay have been designed to detect insulin autoantibodies in prediabetic (type I) patients and others with autoimmune disorders.⁶

Insulin resistance can also be caused by antibodies to the insulin receptor.⁷ These antibodies have varying effects on circulating blood glucose, ranging from hypoglycemia to hyperglycemia. Antibodies to insulin receptors have been found in

The presence of islet cell antibodies indicates ongoing β -cell destruction. The test is helpful in the early diagnosis of type 1a diabetes mellitus and in the identification of patients at high risk for type 1a diabetes.

To date, insulin is the only β -cell-specific autoantigen.¹ However, IAA by itself is a weak predictor of type 1 diabetes.² The combination of IAA and ICA improves risk prediction for type 1 diabetes.³

Children at onset of type 1 diabetes are more commonly IAA positive than adults.^{4,5} Up to 80% of new-onset type 1 diabetic patients before the age of 5 yr have IAA compared with only ~30% for adults.⁶ IAAs appear to be inversely correlated with age for both new-onset type 1 diabetic patients and their high-risk nondiabetic relatives.⁷

IAA measured by ELISA should be avoided because IAA detected by ELISA does not correlate with autoimmune diabetes.^{8,9}

IAA should be determined before insulin therapy because insulin antibodies (IA) will develop 5-7 days after insulin introduction; the concentrations induced by exogenous insulin are often ≥ 10 -fold than those by IAA.

|---|--|
| <p>↑ Insulin overdose, insulin resistance syndromes, and endogenous hyperinsulinemia</p> <p>↓ Inadequately treated type I diabetes mellitus</p> | <p>Free (bioactive) insulin is measured after PEG precipitation of insulin antibodies and their bound insulin. Total insulin (free insulin plus antibody-bound inactive insulin) can be measured using the same immunoassay if the sample is acidified to dissociate insulin from endogenous insulin antibodies before treatment with PEG. If insulin antibodies are not present, the free and total insulin assays are equivalent.</p> <p>Circulating insulin antibodies develop after diabetic patients are treated with exogenous insulin preparations. Insulin antibodies not only interfere with insulin assays but also they reduce the amount of active insulin present in circulation by binding exogenous insulin. Free insulin assays therefore have proved valuable in monitoring insulin therapy. In insulin-dependent diabetic patients, free insulin levels are usually $\leq 10\%$ of total insulin, and values up to $100\ \mu\text{U/mL}$ [$694\ \text{pmol/L}$] can be found.</p> |

| | |
|---|---|
| <p>↑ Insulinoma (pancreatic islet cell tumor), non-insulin-dependent (type II) diabetes mellitus, liver disease, acromegaly, Cushing's syndrome, dystrophia myotonica, familial fructose and galactose intolerance, obesity (may be twice normal), surreptitious use of insulin or oral hypoglycemic agents</p> <p>↓ Insulin-dependent (type I) diabetes mellitus ($<20\ \mu\text{U/mL}$ [$<139\ \text{pmol/L}$]), hypopituitarism. An insulin-glucose ratio >0.3 [$>38 \times 10^{-9}$] is presumptive evidence of insulinoma.</p> | <p>From a clinical standpoint, measurement of insulin has little value except in the diagnosis of fasting hypoglycemia. Accordingly, fasting hypoglycemia associated with inappropriately high serum insulin concentrations strongly suggests an islet cell tumor (insulinoma). (See <i>Insulin and Glucose Response to 72-hr Fasting</i>.) To distinguish insulinoma from factitious hypoglycemia resulting from insulin administration, serum C-peptide values are recommended. (See <i>C-Peptide</i>.)</p> <p>Insulin assays are not included in diagnostic criteria for DM, and insulin values may range from low (IDDM) to high (NIDDM); however, insulin measurements during an OGTT may help in the diagnosis of early prehyperglycemic DM.¹¹ It is claimed that insulin levels obtained after a 75-g oral glucose load may be useful in predicting degenerative complications of DM (e.g., retinopathy) or in predicting the benefits of insulin therapy.¹² (For an alternative strategy, see <i>C-Peptide Stimulation Test</i>.)</p> |

DIAGNOSTIC INFORMATION

REMARKS

Values are consistently higher in plasma than in serum; thus serum is preferred. Compared with fasting values in nonobese nondiabetic individuals, insulin levels are higher in obese nondiabetic persons and lower in trained athletes. Although proinsulin cross-reacts in most competitive insulin assays, it does not contribute appreciably to insulin values except in certain situations (e.g., insulinomas). Proinsulin does not cross-react in two-site immunometric assays for intact insulin.^{10,13} In most insulin assays, bovine and porcine insulin are indistinguishable from human insulin. Insulin antibodies develop in patients treated with bovine or porcine insulin and in some patients treated with human insulin. (See *Insulin Antibodies*.) These antibodies may interfere with immunoassays for insulin, even for months or years after discontinuation. In rare cases, these antibodies may interfere with the action of the administered insulin. To monitor insulin therapy, some investigators suggest measuring insulin after PEG precipitation of the insulin antibodies (see *Insulin, Free*) or measuring “total” insulin after acidification (to separate bound insulin) and PEG precipitation of insulin antibodies. The widespread use of human insulin, plus improvements in the purity of porcine and bovine insulin, has led to significant reduction in the production of interfering antibodies.

In pregnancy, there is a relative insulin resistance. A progressive decrease of plasma glucose, immunoreactive insulin, and C-peptide during sleeping hours from the second to third trimester of pregnancy has been claimed.¹⁴

The elevation of insulin in amniotic fluid $>8 \mu\text{U/mL}$ [56 pmol/L] during the 34–38th weeks of gestation prevents the normal increase of the L/S ratio. The complete absence of insulin during the last trimester is associated with intrauterine death.

It has been suggested that amniotic fluid insulin is of fetal origin. In poorly controlled diabetic patients, amniotic fluid, umbilical cord, and newborn urinary levels of insulin are markedly increased (up to 27 times the normal level) and could perhaps be used to predict neonatal hypoglycemia and macrosomy.

S ↑ Acromegaly

S ↓ Dwarfism, hypopituitarism, hypothyroidism, malnutrition (after refeeding, high levels of GH decrease and low levels of IGF-I increase), anorexia, emotional deprivation syndrome, Laron dwarfism (in the presence of elevated GH), cirrhosis of the liver, and other hepatocellular diseases

The primary source of circulating IGF-I is from liver, although many tissues synthesize IGF-I. Only ~1% of circulating IGF-I is present as free, uncomplexed molecules⁸; the remainder are bound to IGF-specific binding proteins (IGFBPs). Six of the IGFBPs have been identified.¹⁴ IGFBP-3 is the most abundant IGF binding protein, which forms a ternary complex with IGF-I and another protein, the acid labile subunit (ALS). The IGFBP-3 is tightly regulated by growth hormone.¹⁵

Blood concentrations of IGF-I are constant during the day and after eating. In acromegaly, the test may serve as an indicator of the severity of the disease; serial determinations may be used to monitor the efficacy of treatment. In dwarfism IGF-I may be used to determine the response to GH therapy. Concentrations of IGF-I increase during the first year of life, reaching the highest values in preadolescent or early adolescent years. Thereafter normal values tend to decline progressively until age 50 yr. In pregnancy values are progressively higher. Children with low levels of IGF-I may need provocative testing to establish a diagnosis of GH deficiency, especially if a child is well-nourished and no cause of growth failure is apparent.

The test is also useful in diagnosing patients with active acromegaly who have relatively low basal levels of GH and patients suspected of acromegaly who show suppression of GH to normal after glucose administration. This test also appears to be more sensitive than prealbumin, retinol-binding protein, or transferrin in evaluating the effectiveness of nutritional repletion.

Circulating IGF-I increases insulin sensitivity. Reduced levels of IGF-I are associated with insulin resistance or a risk for subsequent development of impaired glucose or type 2 diabetes.¹⁶

IGF-I is also associated with several types of tumors.¹⁷⁻¹⁹ Plasma IGF has been proposed to be a predictor of prostate cancer.²⁰

↑ Hypoglycemia associated with non-islet cell tumors, hepatoma, and Wilms' tumor

Like IGF-I, the plasma is the main source of plasma IGF-II released into the circulation.

↓ Growth hormone deficiency

IGF-I (somatomedin C) and IGF-II are structurally related to proinsulin. In its actions, IGF-I is more insulin-like than IGF-II.

Unlike IGF-I, IGF-II does not usually increase in acromegaly but does increase in tumor-related hypoglycemia. Eighty-two percent of growth hormone-deficient children have low levels of IGF-I, and 52% have low levels of IGF-II; 96% have decreased levels of either IGF-I or IGF-II, or both.⁶

IGF-II may be associated with atherosclerosis.⁷

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>IA-2 is a predictor to the future progression to overt type 1 diabetes.</p> <p>Combination of IA-2 and GADA improves the sensitivity for predicting type 1 diabetes.</p> | <p>The IA-2 autoantigen is a member of the protein tyrosine phosphatase family of receptor-like and cytoplasmic signal-transducing enzymes that catalyze dephosphorylation of phosphotyrosines. It has a signal peptide, an extracellular domain, a transmembrane domain, and a cytoplasmic domain. ICA512 includes the transmembrane domain and the cytoplasmic domain of IA-2.</p> <p>More than 60% of new-onset cases of type 1 diabetes are IA-2A positive compared with 2-3% of the general population.² The autoantibodies are also detected in individuals at increased risk of developing the disease.³</p> <p>A combination of IA-2 antibodies and GADA autoantibodies has a higher sensitivity as a predictive marker for type 1 diabetes than ICA alone.³</p> |
| <p>↓ S Concentrations are decreased with cirrhosis, malignancies, and some inflammatory conditions.³⁻⁵</p> <p>U Increased urinary concentrations of EDC1, a fragment of α1TI, can be found in patients with malignancies.^{4,6}</p> | <p>The α1TI family consists of several serine protease inhibitors that are similar structurally.⁷ Activity of human α1TI is against trypsin, chymotrypsin, cathepsin G, and leukocyte elastase.⁸</p> <p>Proteolytic cleavage of α1TI releases its light chain (bikunin), which is excreted into the urine.⁹ Bikunin has been shown to be an inhibitor of calcium oxalate crystal formation.¹⁰</p> <p>MW: 220,000.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ In 50% of patients with PA, false-positive results are rare.</p> | <p>Pernicious anemia (PA) results from failure of the gastric mucosa to form IF and is invariably associated with severe gastric mucosal atrophy.</p> <p>Much evidence supports the hypothesis that PA is an autoimmune disease. Sera of patients with PA commonly exhibit antibodies to gastric parietal cells and to IF. Detection of the IF antibodies is of diagnostic value because they are rarely encountered in other disorders (3-6% in persons with hyperthyroidism or insulin-dependent diabetes). Parietal cell antibodies are so commonly found in sera of persons who do not have (and do not develop) PA that tests for gastric parietal cell antibodies are not usually of diagnostic value.^{6,7}</p> <p>See also <i>Vitamin B₁₂ Intrinsic Factor</i> and <i>Vitamin B₁₂ Absorption Test</i>.</p> |

See *Glomerular Filtration Rate*.

Measurement of inulin clearance on a patient at rest may not reflect true “active” GFR. Edematous patients or those in renal failure may require several tests to attain a meaningful result. Inulin clearance is the most accurate measure of GFR, but methods for quantitating inulin are limited. Adequate hydration of the patient is essential. Children <2 yr and adults past middle age have reduced clearance rates.

The test traditionally has been the reference method for measuring GFR. However, it has not been used widely because it requires continuous infusion, is time-consuming, and has low precision. Isotope tests are now done with increasing frequency. See *Glomerular Filtration Rate*.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ <i>Storage iron</i>: Hemochromatosis, hemolytic anemias, anemias resulting from decreased erythropoiesis (e.g., aplastic anemia), anemias with ineffective erythropoiesis (e.g., megaloblastic anemias, sideroblastic anemias), anemias of chronic disorders.</p> | <p>The Prussian blue reaction stains iron in aggregated ferritin and hemosiderin blue but does not stain iron in heme. Storage iron, as ferritin and hemosiderin, is stained in macrophages of the bone marrow (and other reticuloendothelial organs). Normoblasts containing stainable iron granules are known as sideroblasts; erythrocytes containing them are siderocytes. Generally, the ratio of the serum iron concentration to total iron-binding capacity closely parallels the proportion of marrow normoblasts that are sideroblasts (in normal individuals, 1/3). Some sideroblastic granules in pathological conditions also appear as basophilic granules with Romanowsky stains; these are known as Pappenheimer bodies.</p> |
| <p>↑ <i>Sideroblasts</i>: Hemochromatosis, hemolytic anemias, anemias resulting from decreased erythropoiesis (e.g., aplastic anemia), anemias with ineffective erythropoiesis (e.g., megaloblastic anemias). In sideroblastic anemias, a large proportion of the normoblasts are ring sideroblasts.</p> | <p>See <i>Ferritin and Iron-Binding Capacity, Total</i>.</p> |
| <p>↑ <i>Siderocytes (blood)</i>: After splenectomy or in asplenia.</p> | |
| <p>↓ <i>Storage iron</i>: Iron deficiency anemia, usually resulting from chronic blood loss (except in infancy, adolescence, and pregnancy).</p> | <p>Hemosiderin is not detected in alkaline urine.²</p> |
| <p>↓ <i>Sideroblasts</i>: Iron deficiency anemias, anemia of chronic disorders.</p> | |
| <p>U ↑ Stainable iron is present in epithelial cells (or as granules from degenerated epithelial cells) in urinary sediment in hemochromatosis or in intravascular hemolysis, especially PNH, PCH, transfusion reactions (after several days), and fragmentation hemolysis (resulting from microangiopathy or heart valve). (See also <i>Hemosiderin</i>.)</p> | |
| <p>↑ Hypochromic anemias, acute hepatitis, and late pregnancy</p> | <p>TIBC correlates with serum transferrin, but the relationship is not linear over a wide range of transferrin values and is disrupted in diseases affecting transferrin-binding capacity or other iron-binding proteins. Large analytical and within-subject biological variations have been observed for TIBC levels.</p> |
| <p>↓ Anemia (non-iron deficient), chronic infections, hemochromatosis, cirrhosis, neoplastic and renal disease, and thalassemia</p> | <p>See also <i>Transferrin</i>.</p> |
| <p>See also Table II-13.</p> | |

8. Sinha MK, Gaze DC, Tippins JR, et al: Ischemia modified albumin is a sensitive marker of myocardial ischemia after percutaneous coronary intervention, *Circulation* 107:2403-2405, 2003.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>The test is cleared by the FDA according to the following statement: “in patients with chest pain or equivalent symptoms suggestive of cardiac origin, with non-diagnostic ECG and normal troponin, a negative IMA can be used as an aid to rule out ACS in low risk patients.”⁴⁻⁶ The test is not FDA cleared as a biomarker for ischemia.</p> | <p>Serum albumin in patients with myocardial ischemia produces a lower metal binding capacity for cobalt than albumin in non-ischemic normal controls. This has been demonstrated in a coronary angioplasty model whereby myocardial ischemia without irreversible necrosis is induced by the inflation of the balloon.^{7,8} The ACB test is a quantitative assay that measures ischemia modified albumin (IMA) in human serum. In principle, in serum of patients with ischemia, cobalt added to serum does not bind to the N-terminus of IMA, leaving more free cobalt to react with dithiothreitol and form a darker color. The absorbance is read at 500 nm. The total assay imprecision is <9% at the medical decision cutoff, a lower limit of detection at 14 U/mL, and linearity to 200 U/mL.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Test is usually performed as a component of ABO typing. In this situation, it is often referred to as “back-typing.” Expected antibodies may be absent or decreased in concentration in immune deficiency (infancy, hypogammaglobulinemia, infection, neoplasia, immunosuppressive therapy, and old age).</p> <p>Isoagglutinin titers may be helpful in following engraftment kinetics after hematopoietic stem cell transplantation.</p> | <p>Titer increases after exposure to antigens. Elevated titers may be observed after transfusion, pregnancy, vaccination,⁸ and <i>Toxocara</i> infection.⁹</p> <p>Weak subgroups of antigens may be associated with the presence of antibodies to antigens of the ABO system, e.g. anti-A₁ and anti-B in A₂ and B_{o1} individuals, respectively.</p> <p>Isoagglutinins include IgM and IgG classes of immunoglobulins.</p> |

| | |
|---|---|
| <p>S ↑ Viral, toxic, and chronic hepatitis; carcinoma metastatic to liver, hepatic hypoxia resulting from hemodynamic causes, bacterially infected hepatic lesions, cirrhosis, obstructive jaundice, infectious mononucleosis, acute inflammation of biliary tract, neonatal biliary duct atresia, kwashiorkor, preeclamptic toxemia, severe pulmonary infarct, myeloid leukemia, megaloblastic anemia, and hyperthyroidism</p> <p>Serum values are normal in uncomplicated myocardial infarction and normal pregnancy.</p> | <p>Increase in ICD activity is a sensitive indicator of parenchymal liver disease. Measured activity in serum is the result of the cytoplasmic NADP-dependent enzyme from liver. In hyperthyroidism, ICD is increased out of proportion to ALT (compared with the greater increases in ALT in other forms of hepatic injury), perhaps because of ICD’s centrilobular distribution.⁵ Although the myocardium is rich in ICD activity, no elevation of serum ICD activity is found after a myocardial infarction; the released mitochondrial ICD activity is heat labile and is rapidly cleared.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>LD activity is found in most cells in the body. The highest activities are found in the heart, liver, muscle, kidney, lung, and red blood cells. Thus serum LD activity is increased in a variety of clinical pathologies.</p> | <p>The pyruvate-to-lactate reaction is preferred on theoretical grounds because the equilibrium constant (2.7×10^{11}) is so large.⁷ The rates for any given amount of enzyme are 2-3 times faster for the pyruvate-to-lactate reaction; hence, smaller samples and shorter observation periods can be used.</p> |
| <p>Historically, LD has been monitored regarding tumor activity involving anemias and lung cancer, liver disease, renal disease, and after MI. The use of LD for MI detection has been replaced with cardiac troponins.</p> | <p>Disadvantages of the pyruvate-to-lactate reaction include its earlier loss of linearity as compared with the lactate-to-pyruvate reaction and the greater substrate inhibition of the enzyme.</p> |
| <p>↑↑↑ Megaloblastic and pernicious anemia, extensive carcinomatosis, viral hepatitis, shock, hypoxia, and extreme hyperthermia</p> | |
| <p>↑↑ Cirrhosis, obstructive jaundice, renal diseases of many types, skeletomuscular diseases, neoplastic diseases, and congestive heart failure</p> | |
| <p>↑ Any cellular injury that results in loss of cytoplasm, myocardial or pulmonary infarction, leukemias, hemolytic anemias, hepatitis (nonviral), sickle cell disease, lymphoma, renal infarction, and acute pancreatitis.</p> | |
| <p>↓ Genetic deficiency of H or M subunits</p> | |
| <p>↑ Intracerebral meningeal deposits of carcinoma, leukemia, or lymphosarcoma; meningitis, subarachnoid hemorrhage, and cerebrovascular accident</p> | |
| <p>Deficiency produces no known clinical effects.</p> | <p>Values are slightly higher in young erythrocytes.⁸</p> |

B, P \uparrow *Type I lactic acidosis* (increased lactic acid, no significant acidosis, normal L/P ratio): muscular exercise, hyperventilation, glucagon, glycogen storage disease, severe anemia, insulin infusions, and Reye's syndrome

Type IIA, hypoxia related (increased L/P ratio): any condition with inadequate oxygen delivery to tissues, acute hemorrhage, severe acute congestive heart failure or other causes of circulatory collapse, cyanotic heart disease or other causes of acute hypoxia, and extracorporeal circulation

Type IIB, idiopathic (increased L/P ratio): mild uremia, infections (especially pyelonephritis), cirrhosis, third trimester of pregnancy, severe vascular disease, leukemias, anemias, chronic alcoholism, subacute bacterial endocarditis, poliomyelitis, and diabetes (~50%)

Use of tourniquet or clenching of hands increases lactate. Lactate increases rapidly in improperly preserved samples and during exercise and hyperventilation. In McArdle's disease, sample drawn 1 min after initiation of exercise will show no increase in lactate. Lactic acidosis is suspected when the anion gap is >18 mmol/L in the absence of other causes, such as renal failure, salicylate ingestion, methanol poisoning, ethanol abuse, and significant ketonemia.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| CSF ↑ Reduced cerebral blood flow or oxygenation, increased intracranial pressure, trauma, seizures, intracranial hemorrhage, brain abscess, multiple sclerosis, primary or metastatic CNS carcinoma, hypocapnia, and bacterial and tuberculous meningitis (see <i>Remarks</i>) | Recent reports indicate that the measurement of CSF lactate may be a useful screening test for CNS disease and an aid in distinguishing bacterial from viral meningitis. In essentially all bacterial and fungal meningitides, the value will exceed 35 mg/dL [3.9 mmol/L], whereas in viral meningitis the concentration is invariably <35 mg/dL [<3.9 mmol/L]. Measurement is of doubtful clinical value because culture of the organism gives the final answer. Increased levels of lactate in CSF following head injury suggest a poor prognosis. ^{10,11} |

GF ↑ Carcinoma of stomach, pyloric obstruction

| | |
|---|---|
| LD isoenzyme patterns cannot be interpreted without knowledge of the clinical history. | Chemical inhibition methods using urea or lactate give unreliable results. Heat inactivation procedures in which LD-5 is destroyed are also of very limited use because all isoenzymes show some heat instability, and excellent temperature control is required to get reproducible results. Immunoinhibition methods detect changes in LD-1 only. ³ Minicolumn methods can separate LD-1 and LD-2 but include LD-3 to LD-5 in the first fraction. ⁹ Some minicolumn methods, however, may only separate LD-1. ¹⁰ |
| ↑ LD-1 and/or LD-2 (LD-1/LD-2) “flip” can be present in patients after acute myocardial infarction; in pernicious, hemolytic, acute sickle cell or megaloblastic anemia; in acute renal cortical necrosis; or in cases of in vivo or in vitro hemolysis of any cause. The optimum decision threshold for the LD-1/LD-2 ratio is, by ROC-curve analysis, 0.92-0.94. ^{7,8} | An additional LD isoenzyme, called LD-6, has been described cathodal to LD-5; it may be released from liver. It is seen only when prognosis is poor. LD-6 has provisionally been identified as alcohol dehydrogenase. |
| ↑ LD-1, particularly in germ cell tumors (e.g., teratoma, seminoma of testis, dysgerminoma of ovary); injury to skeletal muscle. | LD binding to IgA or IgG can produce a variety of additional or decreased LD zones or distorted LD patterns. |
| ↑ LD-5, in injury to skeletal muscle, any inflammatory or degenerative diseases of skeletal muscle, many types of liver injury (cirrhosis, all types of hepatitis, and passive congestion of the liver), and cancer (insensitive and nonspecific finding) | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>The “isomorphic pattern,” i.e., a normal-appearing pattern in the presence of an abnormal total LD in serum, is observed in many patients with cardiac, liver, skeletomuscular, neoplastic, and other disorders, including multisystem diseases.</p> | <p>Hemolysis may invalidate test, depending on the endogenous LD-1/LD-2 ratio of erythrocytes¹¹; this ratio is likely to be elevated when reticulocytosis is markedly increased.¹² The ratio depends on method of separation; cellulose acetate more often gives a ratio >1, agarose a ratio <1.¹³</p> |
| <p>Increases in the midzone fractions, i.e., LD-2, LD-3, and LD-4, are seen when there is massive platelet destruction (e.g., pulmonary embolism, after extensive blood transfusion) and in lymphatic system involvement such as infectious mononucleosis, lymphomas, and lymphocytic leukemias; injury to skeletal muscle.</p> | <p>Chemical inhibition methods using either 1,6-hexanediol or sodium perchlorate are effective.^{4,5}</p> <p>The use of LD isoenzymes for detection of late-presenting MIs has been replaced with cardiac troponin monitoring.¹⁴</p> |

| | | | |
|---|---|--|--|
| Lamellar Body Count (LBC) ¹ | Amniotic fluid, ≤500 μL. Sample should be mixed on a rocker for 2 min or with 20 gentle inversions of the collection tube. Do not centrifuge speci- mens. Samples collected from “free-flowing” vaginal pools are accept- able, but vaginal pool specimens containing obvious mucus should not be used. ² | ≥50,000/μL: Mature ² >15,000/μL – <50,000/μL: Transitional ≤15,000/μL: Immature Reference ranges can vary based on type of instru- ment used for counting and whether samples are centrifuged (centrifugation is not recommended). Institutions performing LBC should determine ref- erence values by performing clinical outcome stud- ies and by comparing their method with a method used in an outcome study with paired amniotic fluid specimens. ³ | Samples with hematocrit >1% will produce a biphasic change in LBC, initially increasing counts because of platelets, then decreasing counts as clot- ting occurs. ^{1,4} Moderate meconium increases LBC by ~5000/μL. ^{1,2} |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Impairment of carbohydrate absorption is caused by a deficiency of small bowel mucosal lactase. (See also <i>Disaccharide Absorption Tests</i> .) | Serum glucose must be quantitated using a method specific for glucose. To eliminate misinterpretation of test results, a glucose tolerance test and a galactose tolerance test may need to be performed to rule out monosaccharide malabsorption. |
| >20 ppm increase over baseline is diagnostic of lactose intolerance. | 99% sensitive, 90% specific |
| Positive in some cases of bacterial overgrowth of the small intestine. | A late increase in H ₂ may occur if lactose reaches the large bowel. |
| The LBC has a slightly better specificity than the L/S ratio. ⁵ As with other FLM tests, LBC is a strong predictor of maturity but a weak predictor of immaturity. ⁶ | Lamellar bodies constitute the storage form of surfactant released into amniotic fluid by fetal breathing movements. Because of their size (0.2-2 μ m), lamellar bodies can be enumerated using the platelet channel of an electronic cell counter. This is the basis for the LBC test. ¹ |
| | Advantages of LBC include a rapid result time (<20 min), low cost to perform, wide availability of instrumentation, and high intraassay precision. ^{7,8} |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Industrial exposure, ingestion of Pb-containing paint, ceramic glazes, and so on.</p> <p>Pb poisoning may result in anorexia, abdominal pain, vomiting, irritability, apathy, Pb encephalopathy, anemia, and peripheral neuropathy. Increased exposure to Pb results in an increased risk of hypertension⁹ and accelerates progression of chronic renal disease.¹⁰ Behavioral delays in puberty and neurological effects have been documented in subclinical lead poisoning of children.^{11,12} High-risk children include those aged 3-12 yr who live in or visit old, dilapidated housing.</p> <p>See also Table II-11 for classification of blood levels in children and OSHA action levels.^{13,14}</p> | <p>Lead levels in blood may fluctuate in part because of specimen contamination during collection. If blood or random urine is analyzed, several specimens may be needed to rule out lead poisoning. The use of contamination-free specimens is extremely important. Urinary δ-aminolevulinic acid and coproporphyrin III and free erythrocyte protoporphyrin increase in Pb poisoning. Diagnostic sensitivity of ALA and protoporphyrin assays at threshold of 10 mcg/dL is poor.¹⁵ Blood lead measurement is considered the best indicator of lead poisoning and is recommended by the CDC.</p> <p>Pb poisoning can be confirmed with a mobilization test. See also <i>δ-Aminolevulinic Acid</i>, <i>Lead Mobilization Test</i>, and <i>Protoporphyrins</i>.</p> <p>See also Tables II-6, II-9, and II-11.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--------------------------------------|--|
| ↑ Lead intoxication (index value >1) | Test for Pb burden not poisoning should be reserved for asymptomatic patients. |

| | |
|--|---|
| ↑ Hypertriglyceridemia. | LCAT activity represents the endogenous cholesterol esterification rate, which depends not only on the amount of functionally active enzyme present but also on the enzyme substrates, cofactors, and other constituents in the plasma. Use of an artificial substrate (lecithin-cholesterol liposomes containing apo A-I) allows more accurate measurement of the active enzyme in plasma. |
| ↓ Familial LCAT deficiency, fish-eye disease, and hepatocellular disorders. | Except in rare cases, LCAT mass is highly correlated with enzyme activity. Calculation of the cholesterol esterification rate (CER) is useful for differential diagnosis of fish-eye disease (LCAT activity is very low or absent, but CER is low normal). |
| Patients with LCAT deficiency may develop renal disease, anemia, and corneal opacities, but premature CHD is rare. | The fractional esterification rate (FER) in HDL is proportional to the amount of small HDL particles in the circulation. |

**Leukocyte
Esterases**

Naphthol AS-D
chloroacetate,
pH 7.0-7.6¹⁻⁶

Blood or bone marrow films. If films are kept dry and in the dark, they are stable for 4 wk unfixed. Films are stable several months if fixed in buffered formalin/acetone. Histological sections from tissue fixed in buffered formalin are stable indefinitely. Decalcified acid-fixed tissues are unacceptable.

Positive: Neutrophilic series (strongest reaction in more mature cells), mast cells. Normal myeloblasts are negative, but leukemic myeloblasts may be positive.

Negative: Eosinophils, lymphocytes, plasma cells, normoblasts, megakaryocytes, and monocytes.

None found.

α -Naphthyl acetate,
pH 6.0-6.3²⁻⁵

Blood or bone marrow films. If films are kept dry and in the dark, they are stable 1 wk unfixed. Histological sections cannot be used.

Positive: Monocytes (diffuse), macrophages, megakaryocytes, and platelets; variable in promyelocytes and in neutrophilic myelocytes; focal in plasma cells and some lymphocytes.

Negative: Myeloblasts, eosinophils, basophils, lymphocytes, and normoblasts.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p><i>Positive:</i> Blast cells of most cases of acute myeloid leukemia (AML)</p> <p><i>Negative:</i> Blast cells of acute lymphoid leukemia (ALL) and some AMLs (M5, M7)</p> | <p>Reaction parallels the reaction of Sudan black B and myeloperoxidase but is more consistently negative in monocytes. Sudan black B and peroxidase are more sensitive and reliable in neutrophilic series. This technique is useful in the subclassification of acute nonlymphocytic leukemia (ANLL).</p> <p>See also Table II-14.</p> |
| <p><i>Positive:</i> >20% of nonerythroid cells of M4 marrow, >80% of nonerythroid cells of M5 marrow, erythroid cells of M6 marrow, erythroid cells in megaloblastic anemia, leukemic cells in some cases of M3 and M7, and monocytes and monoblasts in myelodysplastic syndromes</p> <p><i>Negative:</i> Blast cells of M1, M2, M3, and most cases of ALL (focal cytoplasmic positivity in some cases of ALL)</p> | <p>Activity in monocytes, megakaryocytes, platelets, and plasma cells is inhibited by NaF, but it is not inhibited in lymphocytes and neutrophils. This method is useful in the subclassification of ANLL.</p> |

|---|--|---|-------------|
| Leukocyte Peroxidase (Myeloperoxidase) ¹⁻³ | Freshly made films from blood or marrow. Process within 1 day or store in the dark no longer than 2 wk at room temperature. | Positive: Neutrophilic and eosinophilic granulocytes and precursors, monocytes (weaker, smaller granules), leukemic myeloblasts, and basophils (some methods) | None found. |
| <i>Diaminobenzidine oxidation</i> ^{1,4} | EDTA samples are satisfactory if films are made within 2 hr of collection. | Negative: Early myeloblasts, lymphocytes, lymphoblasts, plasma cells, megakaryocytes, platelets, normoblasts, and basophils (most methods) | |
| <i>p-Phenylene-diamine dihydrochloride</i> ⁵ | | | |
| <i>Flow cytometry (fluorescent-labeled myeloperoxidase antibody)</i> ^{3,6} | Flow cytometry can be performed on EDTA or heparin anticoagulated blood or bone marrow stored at room temperature <24 hr or refrigerated <48 hr. | | |
| <i>Immunohistochemistry</i> ³ | Immunohistochemical methods are available for frozen or paraffin-embedded tissue. | | |

1. Beutler E, Lichtman MA, Coller B, editors: *Williams hematology*, ed 6, New York, 2000, McGraw-Hill.
2. Brunning RD, McKenna RW: *Tumors of the bone marrow*, Washington, DC, 1994, Armed Forces Institute of Pathology.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p><i>Positive:</i> >20% of nonerythroid cells of M4 marrow, >80% of nonerythroid cells of M5 marrow, monocytes and monoblasts in myelodysplastic syndromes, and hairy cell leukemia (characteristic pattern)</p> <p><i>Negative:</i> Blast cells of M1, M2, M3, M7, and ALL</p> | <p>This reaction is less sensitive but more specific for monocytes than the α-naphthyl acetate method. Activity in monocytes is inhibited by NaF. A characteristic pattern of positivity (cytoplasmic granules and paranuclear crescents) is exhibited in a high proportion of cases of hairy cell leukemia.</p> |
| <p><i>Positive:</i> In acute myeloid leukemia (AML; M1 through M6), $\geq 3\%$ of blast cells (myeloblasts) are positive. Reaction is strongest in promyelocytic leukemia (M3); it is weak to negative in acute monocytic leukemia (M5).</p> <p><i>Negative:</i> Blast cells in acute lymphoid leukemia (ALL), M5 (usually), and M7. In hereditary myeloperoxidase deficiency, all neutrophils and monocytes are deficient, but eosinophils are positive.</p> <p>See Table II-14.</p> | <p>Presence or absence of intracellular myeloperoxidase is used to distinguish AML from ALL. Myeloblasts that have no granules stainable with Wright's stain may be positive by cytochemical or immunostaining methods for peroxidase. Auer rods are positive. Peroxidase is demonstrable in the ultrastructure of platelets and in the nuclear envelope of megakaryocytes. A positive reaction may be used to define the megakaryoblasts of M7.</p> <p>Peroxidase in mature neutrophils may be deficient in some mature neutrophils of myelodysplastic syndromes, in AML, and in severe infections.</p> <p>Immunocytochemical methods are more sensitive for the detection of myeloperoxidase in the blasts of minimally differentiated acute myeloid leukemia (M0).^{3,6}</p> <p>Plasma levels of myeloperoxidase have been proposed to be an early predictor of myocardial infarction.</p> |

DIAGNOSTIC INFORMATION

REMARKS

6. Kaleem Z, Crawford E, Pathan MH, et al.: Flow cytometric analysis of acute leukemias, *Arch Pathol Lab Med* 127:42-48, 2003.

↑ *S Polyclonal*: Immunoglobulin free light chains undergo primarily renal catabolism, and renal dysfunction is associated with increased serum values.⁷

↑ *S Monoclonal*: Serum concentrations are also frequently increased with disorders associated with a monoclonal gammopathy.

↑ *U Polyclonal*: Increased urinary concentrations of polyclonal free light chains can be found with impaired renal protein reabsorption (tubular proteinuria) or with conditions involving B-lymphocyte activation such as systemic lupus erythematosus⁸ and chronic infectious processes.⁹ Despite their polyclonal nature, multiple, evenly spaced bands can be seen with urine immunofixation studies using concentrated urine samples.¹⁰ This pattern can complicate the identification of/ or be mistaken for the presence of a Bence Jones protein.¹

↑ *U Monoclonal*: Monoclonal free light chains are characteristically found with malignant B-cell-derived disorders such as multiple myeloma, plasmacytomas, Waldenström's macroglobulinemia, and amyloidosis. They are also found with the benign monoclonal gammopathy of undetermined significance and in association with a wide variety of connective tissue, endocrine, hematologic, inflammatory, neurologic, and neoplastic conditions.²

Whole immunoglobulin molecules consist of two identical light chains joined to two identical heavy chains. Although there are five classes of heavy chains (μ , γ , α , δ , ϵ), there are only two types of light chains (κ , λ). Antigen recognition involves the variable regions of both the heavy and light chains.

Because they are produced in excess of immunoglobulin heavy chains, small quantities of free light chains are normally found in both serum and urine.⁷ These exist as monomers, fragments, and polymers. Urine concentrations are also affected by adequacy of renal function.

Reagent strips and standard urine protein precipitation or dye-binding methods are not adequate for the detection of Bence Jones proteins. Protein electrophoresis of concentrated urine combined with immunofixation is currently recommended. Some monoclonal light chains, however, have "hidden determinates" and despite the use of polyclonal reagent antisera cannot be typed by immunofixation. In such cases, other techniques, such as immunoselection, have been used.¹¹

|--|---|
| <p>Ascitic fluid may have very high lipase activity in pancreatitis. Pleural transudates may contain lipase activity; the lipase rarely comes from a lung tumor.</p> | <p>Methods with substrates such as tributyrin, triacetin, methyl butyrate, β-naphthyl laurate, β-naphthyl palmitate, or β-nitrophenyl stearate should not be used because these compounds are true substrates for esterases, not lipase. Good clinical correlation with pancreatitis has been shown for methods employing emulsified vegetable oils (e.g., olive oil, corn oil) because lipase acts only at the interface of an oil-in-water emulsion.²</p> <p>Two or more lipase isoforms may be present in serum.¹</p> |
| | <p>The Vitros method utilizes an unconventional substrate of questionable specificity for pancreatic lipase.¹</p> |

↓ Hypertriglyceridemia (hyperchylomicronemia and increased VLDL), low HDL cholesterol. Associated with recurrent abdominal pain, pancreatitis, hepatosplenomegaly, eruptive xanthomas, and lipemia retinalis, obesity, diabetes, hypothyroidism, chronic renal failure, pancreatitis, alcoholism, and nephrotic syndrome.

LPL is synthesized in many tissues, but it is predominantly active in adipose tissue, skeletal muscle, and cardiac muscle. It is transferred to capillary endothelium where it hydrolyzes triglycerides from triglyceride-rich lipoproteins. Although LPL is frequently measured in adipose and muscle tissue, a simpler method involves measurement in plasma after an IV injection of heparin to release LPL and hepatic triglyceride lipase (HTGL) from the vascular endothelial surface into the blood. Unlike LPL, HTGL is resistant to protamine and salt and does not require apo C-II as a cofactor. Use of a specific inhibitor or antibody to LPL or HTGL allows the selective measurement of one of the two enzymes in postheparin plasma.

LPL mass can also be measured directly in plasma by ELISA. LPL mass is highly correlated with LPL activity in postheparin plasma. LPL measurement in postheparin plasma is assumed to reflect the LPL available at the endothelial surface.

LPL activity before and after heparin injection do not correlate, suggesting a lack of equilibrium between bound and circulating LPL levels.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| An elevated Lp-PLA ₂ concentration is associated with an increased risk of CHD. | Lp-PLA ₂ (also known as platelet-activating factor acetylhydrolase) is a member of the phospholipase A ₂ enzyme family, primarily secreted by macrophages. Lp-PLA ₂ attaches to circulating LDL particles where it apparently contributes to atherogenesis by attacking oxidized LDL, generating lysophosphatidylcholine and oxidized fatty acids, which subsequently trigger the expression of adhesion molecules and inflammatory cytokines. |

| | |
|--|--|
| LKM1 antibodies are a serologic marker for autoimmune hepatitis type 2. Type 2 AIH patients tend to be young, female, and have a severe disease that responds well to treatment with immunosuppressive drugs. ¹ | LKM1 antibodies react with cytochrome monooxygenase P450 2D6. LKM1 antibodies that react with different epitopes than in patients with AIH type 2 occur in some patients with chronic hepatitis C infection (1). |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Familial hypercholesterolemia, familial combined hyperlipidemia, familial dysbetalipoproteinemia (type III), familial defective apo B-100, polygenic (sporadic) hypercholesterolemia, and coronary heart disease. Secondary elevation caused by hypothyroidism, nephrotic syndrome, obstructive liver disease, hepatocellular disorders, pregnancy, diabetes, chronic renal failure, and Cushing's syndrome.</p> <p>↓ Hypobetalipoproteinemias, abetalipoproteinemia. Secondary decrease caused by hyperthyroidism, severe hepatocellular dysfunction, infection, inflammation, and malignancy.</p> | <p>There is a direct relationship between LDL-C and the incidence of coronary heart disease (CHD). Intervention to decrease LDL-C will decrease CHD risk.</p> <p>The National Cholesterol Education Program (NCEP) recommends that all adults aged >20 yr be screened for CHD risk with measurement of total cholesterol, LDL-C, HDL-C, and triglyceride concentrations. Treatment decisions and therapeutic goals are also largely based on LDL-C concentrations.</p> <p>Recent epidemiological studies have confirmed the efficacy of aggressive cholesterol-lowering therapy in high-risk patients. In high-risk individuals, the recommended LDL-C goal is <100 mg/dL, but when risk is very high, an optional goal is <70 mg/dL or a 30-40% reduction in LDL-C levels.</p> <p>In clinical laboratories LDL-C is most often determined using the "Friedewald formula" using measured values for total cholesterol (TC), HDL-C, and triglyceride (TG):</p> |

$$\text{LDL-C} = (\text{TC}) - (\text{HDL-C}) - (\text{VLDL-C})$$

where:

$$\text{VLDL-C (mg/dL)} = \frac{\text{TG (mg/dL)}}{5}$$

or:

$$\text{VLDL-C (mmol/L)} = \frac{\text{TG (mmol/L)}}{1.181}$$

This calculation is not valid for specimens having TG >400 mg/dL [>4.52 mmol/L], for patients with type III hyperlipoproteinemia or chylomicronemia, or nonfasting specimens. Alternative equations for LDL-C estimation based on apo B measurement are not subject to these same assumptions but are less well validated.

Intraindividual variability in LDL-C measurement averages 9.5%. Because of analytical and biological variability, at least two serial samples may be necessary for clinical decision making.

The goal for LDL-C determination, as defined by the Working Group on Lipoprotein Measurement of NCEP, is a total error ≤12%, consistent with a precision ≤4% CV and a bias ±4%.

LDL phenotype A is a component of the cluster of risk factors that comprise the metabolic syndrome and is associated with an increased risk of CHD.

Small, dense LDL particles are more atherogenic than larger particles. Prospective epidemiological studies have shown that smaller LDL particles are associated with an increased risk of coronary heart disease but suggest that LDL size is not independent of other risk factors.

Sensitivity is ~95% with 65% specificity. The predictive value of an L/S ratio ≥ 2.5 (mature) is 97-98% at relatively advanced gestational ages (28-34 wk) but falls off sharply with decrease in gestational age and as the incidence of respiratory distress syndrome (RDS) increases. There is disagreement as to whether poorly controlled diabetes affects test results.⁵

Precision for the L/S ratio is poor, especially between laboratories.¹⁰

The L/S ratio of blood varies between 1.5 and 2.0. Thus values from blood-contaminated amniotic fluid specimens are pulled into that range. A very high L/S ratio, even in the presence of significant blood contamination, can be used to predict lung maturity. Similarly, blood-contaminated specimens with very low ratios can safely be used to predict immaturity. Borderline ratios cannot be interpreted.¹

If a rapid FLM test is available, referral of L/S ratio requests to another laboratory is acceptable practice.¹¹

L/S ratio can be combined with analysis for phosphatidylglycerol (PG) and phosphatidylinositol to produce a "lung profile," which has been reported to enhance the ability to detect RDS.¹²⁻¹⁴ (See also *Phosphatidylglycerol*.)

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| Antiphospholipid antibody syndrome | <p>The antiphospholipid antibodies include the lupus anticoagulant, anticardiolipin antibodies (IgG, IgM, IgA), anti-<i>B₂</i>-glycoprotein I, and antiphosphatidylserine antibodies. These antibodies may be associated with thrombosis, autoimmune disorders (SLE), infections, and drugs, and may be further detected in otherwise healthy individuals.</p> |
| <p>LA may be identified in a variety of clinical conditions, including autoimmune disorders, rare cases of drug exposure, infection, and in otherwise healthy persons.</p> | <p>The lupus anticoagulant is generally considered a “nonspecific” autoantibody that recognizes various combinations of phospholipids and/or phospholipid-binding proteins, and which clinically may result in hypercoagulability (antiphospholipid syndrome).</p> |
| | <p>Current criteria for demonstration of a lupus anticoagulant require (1) prolongation of a phospholipid-dependent clot-based assay (e.g., screening APTT or dRVVT); (2) failure to correct the prolonged assay with a mixing study; (3) confirmation of the lupus anticoagulant by correction of the prolonged assay with excess phospholipids; and (4) rule-out of specific inhibitor.</p> |
| | <p>Screening should be performed on assays with low phospholipid concentrations (e.g., dilute PT, dilute PTT, and dilute dRVVT). Ideally, these tests evaluate different portions of the coagulation cascade: dilute PTT for the intrinsic pathway, dilute dRVVT for the common pathway, and dilute PT (also known as tissue thromboplastin inhibition test) for the extrinsic pathway.</p> |
| | <p>The anticardiolipin antibodies and anti-<i>B₂</i>-glycoprotein I and antiphosphatidylserine antibodies are detected by immunoassays (see separate section).</p> |
| | <p>Multiple tests (clot-based, ELISA) should be performed because patients may be negative with one test and positive with another. Transient antiphospholipid antibodies may be associated with infections and drugs, particularly in the pediatric population.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↑ Primary gonadal dysfunction, polycystic ovary syndrome (if LH is increased and FSH is normal or decreased, the LH/FSH ratio is abnormally high in ~60% of cases), postmenopause, and pituitary adenoma (rare).</p> <p>↓ Pituitary or hypothalamic impairment, isolated gonadotropic deficiency associated with anosmia or hyposmia (Kallmann's syndrome), anorexia nervosa, isolated LH deficiency ("fertile eunuch"), severe stress, malnutrition, and severe illness. Delayed onset of the pubertal synthesis and release of LH and FSH characterizes the syndrome of constitutional delay in growth and sexual development.</p> | <p>Physiological variations in gonadotropin secretion include episodic secretion, diurnal variation, and cyclic secretion. Throughout puberty circulating gonadotropin levels are higher during sleep than during waking time. Episodic fluctuations in LH secretion are greater than for FSH. This means that multiple or pooled samples give more reliable information than a single blood sample.</p> <p>Intact LH may cross-react with hCG in some radioimmunoassays such that LH estimations are invalid in pregnant or postpartum subjects and in individuals with hCG-secreting tumors. (LH and hCG show extensive similarities in the b-subunit with large regions of homology.) In some RIAs TSH also cross-reacts with LH to a small extent such that high levels of TSH in untreated hypothyroid patients can result in falsely elevated LH. The introduction of two-site immunometric assays has essentially overcome hCG and TSH interferences in LH assays.</p> <p>Owing to variation in purity of standards, many assays express concentrations in terms of international units of either the World Health Organization's 1st International Reference Preparation (WHO 1st IRP) of LH or the 2nd International Reference Preparation of human menopausal gonadotropin (IRP-2-hMG). Recently, highly purified pituitary reference material has been used for assay standardization of LH assays (WHO 2nd International Standard 80/552).</p> |
| <p>Test is used to determine the preovulatory LH surge; test also provides an integrated picture of LH secretion throughout the day.^{11,12}</p> | <p>Timed collections over a 3-hr period correlate with both 24-hr specimens and serum samples.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| P ↑↑ Saccharopinuria | Arginine is also elevated in hyperlysinemia that is associated with hyperammonemia. |
| P ↑ Hyperlysinemia, hyperornithinemia, and glutaric academia type 2 | See also Table II-2B. |
| P ↓ Carcinoid syndrome, 1-2 days after abdominal surgery Lysinuric protein intolerance | |
| U ↑↑ Saccharopinuria, dibasic aminoaciduria, lysinuric protein intolerance (LPI) ¹⁵ | Urinary excretion depends on age. Within the first half-year of life, a high excretion of lysine and cystine is frequently present (physiological cystinylsinuria). Slight cystinylsinuria may also occur in the second half of the first year and in toddlers. In addition to lysine, high levels of cystine, arginine, and ornithine are also seen in the cystinurias. In dibasic aminoaciduria, arginine and ornithine are also excreted in high amounts, but cystine excretion is normal. |
| U ↑ Cystinurias, hyperlysinemia, first trimester of pregnancy (levels decrease thereafter), and burn patients ¹⁶ | |
| CSF ↑ Hyperlysinemia, bacterial meningitis, meningoradiculitis, Garin-Bujadoux-Bannwarth, and carcinomatous meningitis ¹⁷ | Values in children (3 mo-10 yr) were measured using reversed-phase liquid chromatography. |

|--|--|
| Deficiency in rare congenital hemolytic anemia (autosomal dominant) reported in a single family. | |
| S,U ↑↑↑ Acute monocytic or myelomonocytic leukemia | <p>The highly basic, carbohydrate-free, low-molecular-weight protein is synthesized by macrophages, neutrophils, and monocytes and is a normal constituent of plasma. It catalyzes the hydrolysis of bacterial cell walls by disrupting <i>N</i>-acetylglucosamine linkages. External secretions contain very high levels of lysozyme, which acts as a first line of defense against bacterial pathogens. At birth, levels are equivalent to those of adults. However, they decrease during the first months of life and gradually assume adult levels in much the same manner as do other plasma proteins. Electrophoretically the protein migrates at the cathodal limit of the slowest immunoglobulins and even beyond. Appearance of a discrete band can often be misleading and may suggest the presence of a small monoclonal immunoglobulin.</p> <p>Serum and urine lysozyme may be useful as indicators of monocyte proliferation and, to a lesser extent, of neutrophil proliferation.⁵ An elevated lysozyme concentration of >3 times normal is one of the criteria that can be used for the diagnosis of both acute monocytic leukemia (M5) and acute myelomonocytic leukemia (M4) in the modified French-American-British (FAB) classification of acute leukemia.^{6,7}</p> <p>MW: 14,000.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| There are three distinct types of macroamylasemia. ¹ | Infusion of hydroxyethyl starch has produced macroamylasemia. ⁹ Macroamylase is considered an immune complex with circulating antibodies. |
| <i>Type I:</i> Classic macroamylasemia characterized by high total serum amylase activity, large proportions in serum of enzymatically active macroamylase complex, and low amylase/creatinine clearance ratio (see <i>Amylase/Creatinine Clearance Ratio</i>). | Macroamylase of types I and II causes elevated serum amylase without increased urine amylase. |
| <i>Type II:</i> Hyperamylasemia but lower proportion of macroamylase so that amylase/creatinine clearance ratio may not be diminished. | On electrophoresis, macroamylase appears as a diffuse isoenzyme complex when stained for amylase activity. |
| <i>Type III:</i> Normal activities of serum and urine amylase. | Total amylase level may fluctuate widely over time when macroamylase is present. ¹⁰ |
| Macroamylasemia is usually a benign condition with few signs or symptoms, but it must be differentiated from other conditions that cause hyperamylasemia (see <i>Amylase</i>). | Macroamylases react differently with different substrates. ¹¹ |
| Has been reported in association with macrolipase. ⁵ | |
| Macroamylasemia is more common in patients with celiac disease (16%). The rate is lower (7%) in treated celiac disease patients. ⁶ | |
| Screening for macroamylasemia may use amylase/creatinine clearance ratio, polyethylene glycol precipitation followed by P-type isoamylase assay on the supernatant, ⁷ or gel-filtration chromatography. However, a single report ⁸ documents a high amylase/creatinine clearance ratio occurring in a case of macroamylasemia caused by a renal cell carcinoma secreting an S-type isoamylase. The authors suggest that an amylase/creatinine clearance ratio may not always be a suitable screening test. | |

| <p>S ↑ Dehydration, renal insufficiency (acute and chronic), uncontrolled diabetes mellitus (rare), adrenocortical insufficiency, Addison's disease, tissue trauma, hypothyroidism, lupus erythematosus, and multiple myeloma. See also <i>Remarks</i>.</p> | <p>Serum Mg levels may remain normal even when total body stores of Mg are depleted up to 20%. Phytate, fatty acids, and an excess of phosphate impair Mg absorption. Hypomagnesemia may impair secretion and the end-organ action of PTH. Symptoms of deficiency usually do not occur until serum levels are <1.0 mEq/L [<0.50 mmol/L]. Symptoms of severe depletion are weakness, irritability, tetany, EKG changes, delirium, and convulsions. An upright position causes an increase in Mg of ~4%. Inappropriate dosage of therapeutic agents (magnesium sulfate) or antacids causes hypermagnesemia. Hypermagnesemia potentiates the cardiac effect of hyperkalemia.</p> |
| <p>S ↓ Disorders associated with inadequate intake and/or impaired absorption of Mg (e.g., malabsorption syndrome, kwashiorkor, and diet low in proteins and calories); acute pancreatitis, hypoparathyroidism, chronic alcoholism, delirium tremens, disorders associated with increased Mg requirement and inadequate replacement of prolonged or severe loss of body fluids, chronic glomerulonephritis, disorders associated with impaired renal conservation of Mg such as hypercalcemia of any cause (e.g., hyperparathyroidism), hyperaldosteronism, diabetic acidosis, excessive lactation, inappropriate secretion of ADH; pregnancy (second and third trimester); some cases of hypomagnesemia are idiopathic.</p> | <p>Effects of severe hypermagnesemia, 5.0-10.0 mEq/L [2.50-5.00 mmol/L]: Retards cardiac conduction system.</p> <p>10-13.0 mEq/L [5.00-6.50 mmol/L]: Deep-tendon reflexes are lost.</p> |
| <p>Tetany may occur at Mg concentrations of 0.3-1.0 mEq/L [0.15-0.50 mmol/L] at normal pH and normal calcium concentrations.</p> | <p>15.0 mEq/L [7.50 mmol/L]: Respiratory paralysis occurs; general anesthesia may occur.</p> |
| | <p>>25 mEq/L [>12.50 mmol/L]: Cardiac arrest occurs in diastole.</p> |
| | <p>At least 65-70% of Mg is in an ionized state; ~35% of serum Mg is protein bound.</p> |
| | <p>Serum concentrations are frequently paralleled in CSF and erythrocytes. Interference from mercurial diuretics can be removed by treating the sample with H₂S.</p> |
| | <p>Accuracy of the colorimetric method is within 10%.</p> |
| <p>U ↑ Alcohol, diuretics, Bartter's syndrome, corticosteroids, and cisplatin therapy</p> | <p>Urinary excretion of Mg is diet dependent. See <i>Magnesium Load Test</i>.</p> |

| <p>↑ Myocardial infarct, hemolytic diseases, megaloblastic anemias, sickle cell anemia, acute hepatic disease, generalized metastatic carcinoma, diseases of skeletal muscle, and trauma</p> <p>Determinations of MDH and mitochondrial MDH are suggested to be more diagnostically sensitive indicators of severe hepatic disease than AST and mitochondrial AST,³ particularly in hepatocellular carcinoma and in ischemic liver disease.</p> | <p>Controversy exists as to the stability of MDH activity. In general, MDH levels of activity follow those of lactate dehydrogenase (LDH). Because of the wide tissue distribution, serum determination of MDH lacks a high degree of diagnostic specificity. MDH exists as cytosolic and mitochondrial forms. The latter form is rarely present in serum unless organ damage is especially severe. The mitochondrial form can be determined by the ratio of activity using NAD versus thionicotinamide adenine dinucleotide (thio-NAD) as cofactor.³</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| For research purposes, matrix metalloproteinases have been examined in a variety of clinical conditions, including arthritis, ² acute coronary disease, ³ stroke, ⁴ and cancer. ^{5,6} | Matrix metalloproteinases (MMP-9) are a family of zinc and calcium-dependent endopeptidases that break down the extracellular matrix. MMP-9 is an 82-kDa enzyme with high specific activity for denatured collagens. It is produced by neutrophils, monocytes, macrophages, fibroblasts, osteoclasts, and endothelial and epithelial cells. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Overexposure, excessive therapeutic intake</p> <p>Acute poisoning is usually from oral ingestion of inorganic Hg, which has a corrosive effect on the GI tract and causes renal tubular damage. Chronic poisoning is from inhalation or ingestion of small amounts; it results in gingivitis, stomatitis, erethism, tremors, nephrotic syndrome, colitis, anemia, and acrodynia (in children). Organic Hg intoxication results in fatigue, headache, loss of memory, apathy, emotional instability, paresthesia, ataxia, deafness, dysarthria, progressive visual deterioration, and dysphagia, and may lead to coma and death. Transdermal absorption of very small quantities of dimethylmercury can be fatal.¹¹</p> | <p>Hg compounds are found in some medications, fungicides, dental amalgam, and in industrial processes. Elevated blood Hg levels and symptomatic Hg poisoning have been reported in dental workers. More than 90% of whole blood Hg is associated with erythrocytes. Whole blood or erythrocytes are recommended specimens for measuring methyl mercury poisoning. Toenail Hg may be associated with increased risk for myocardial infarction.¹²</p> <p>See Table II-6.</p> <p>Urine is the recommended specimen for measuring inorganic Hg. Bacteria may convert mercury compounds into a volatile Hg form.</p> <p>Investigations have shown that hair may represent a longitudinal record of Hg exposure.⁹</p> |

↑ Intravascular hemolysis, e.g., paroxysmal nocturnal hemoglobinuria (PNH), paroxysmal cold hemoglobinuria (PCH), hemolytic disease of the newborn (HDN), hemolytic transfusion reaction, traumatic hemolytic anemia, and falciparum malaria; acute hemorrhagic pancreatitis.

Methemalbumin (hematin bound to serum albumin) is formed in plasma when haptoglobin is depleted after intravascular hemolysis; oxidized heme is bound to hemopexin or to albumin (methemalbumin). In hemorrhagic pancreatitis, however, haptoglobin is present, suggesting that the methemalbumin is not the result of intravascular hemolysis but caused by the entrance of already oxidized heme (hematin) into the circulation.

↑ *Acquired: See Interferences.*

↑ *Hereditary:*

Deficiency of NADH-MetHb reductase (cytochrome b5 reductase).

Structural hemoglobin variants, designated hemoglobin M (Hb M).

In methemoglobin, the heme iron has been oxidized to the ferric state, and it is incapable of combining with and transporting oxygen. MetHb levels of 1-2 g/dL [155-310 $\mu\text{mol/L}$] result in visible cyanosis. Administration of methylene blue facilitates the reduction of MetHb to Hb in the enzyme deficiency and ameliorates the cyanosis. Methylene blue has no effect in reducing Hb M variants or in relieving the cyanosis that they cause. Heinz bodies may be associated with some forms of toxic methemoglobinemia.

|--|---|---|---|------|--|---|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| See <i>11-Deoxycortisol</i> (Compound S). | See individual steroids. This test should not be performed if primary adrenal insufficiency is likely. A normal response to exogenous ACTH should be demonstrated before initiating this test. (See <i>Adrenocorticotrophic Hormone Stimulation Test, Rapid.</i>) |
| <i>No or impaired response:</i> Hypopituitarism, Cushing’s syndrome caused by adrenal tumors or ectopic ACTH-secreting tumors. ^{2,5} | |
| <i>Exaggerated response:</i> Pituitary Cushing’s disease | To ensure accuracy of 24-hr urine collections and of metyrapone administration, and to monitor possible adverse effects, the standard test should be done on hospitalized patients. |

Test is useful to distinguish normal persons from patients with secondary adrenal insufficiency. Single-dose test may be done on outpatients.

↑ Conditions associated with increased cell turnover or immune activation, including inflammatory conditions, autoimmune diseases, infections, chronic renal failure, graft rejection,^{4,10,11} graft versus-host disease (acute and chronic),¹² lymphoproliferative, myeloproliferative, and myelodysplastic disorders.¹³

β₂-Microglobulin (β₂M) is a low-molecular-weight protein that is the light chain of the class I MHC antigens. Because it is present on all nucleated cells and is almost totally reabsorbed and catabolized by the proximal tubules,¹⁵ it serves as a marker of immune activation and proximal tubular function. It is found in nearly all body fluids.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Anti- β_2 M antibodies have been identified in patients with SLE, ¹³ ankylosing spondylitis, ¹³ and chronic hepatitis. ¹⁴ | Because of its accumulation with renal dysfunction and its ability to become glycosylated, form fibrils, and deposit in tissues, β_2 M is a cause of dialysis-associated amyloidosis. ¹⁶ |
| CSF \uparrow Central nervous system involvement with lymphoproliferative malignancy. | Serum β_2 M values are elevated in many hematological malignancies. An association has been found between serum β_2 M concentrations and tumor burden in some lymphoproliferative disorders, particularly multiple myeloma, making it a valuable prognostic marker in these conditions. ⁵ |
| | β_2 M is not stable in urine with a pH <7.0 and is markedly affected at pH <6.0. Consequently, it is recommended that urine specimens are alkalinized at the time of voiding because a random urine with acid pH may not provide an accurate result. ¹⁷ |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Positive results for AMA are detectable in >90% of patients with primary biliary cirrhosis (PBC¹). AMA is also highly specific for PBC. The titer or levels of AMA do not indicate disease activity or prognosis in patients with PBC.¹</p> | <p>The mitochondrial antigens recognized by AMA have been designated M1-M9. AMA from patients with PBC recognize the M2 antigen complex, which comprises enzymes of the 2-oxoacid dehydrogenase complex, including pyruvate dehydrogenase (PDH-E2) and 2-oxoglutarate dehydrogenase.² Positive AMA results are found occasionally in patients with CREST syndrome and other autoimmune diseases.</p> |
| <p>One case of molybdenum deficiency reported in a patient on long-term TPN showed decreases in serum and urine uric acid and sulfate, as well as increases in urine sulfite, oxypurine, xanthine, and hypoxanthine.</p> <p>Molybdenum toxicity mimics copper deficiency. Treatment with copper reverses symptoms.⁷</p> | <p>Molybdenum is a component of a few metalloenzymes, including xanthine, aldehyde, and sulfite oxidases. It is readily absorbed from the intestine and is excreted chiefly in urine. The normal pattern of urinary sulfur excretion is altered in Mo deficiency. Toxicity has not been established in humans. Molybdenum-poisoned mammals show inhibition of ceruloplasmin and cytochrome (copper oxidase) enzymes, as well as decreased activities of glutaminase, cholinesterase, and sulfite oxidase. Individuals who are copper deficient may be at greater risk for Mo toxicity.⁷ A high activity of xanthine oxidase caused by elevated Mo levels may result in high serum uric acid levels and a predisposition to gout.</p> |

| Myoglobin ¹⁻⁸ | Serum and plasma collected with or without separating gels (see individual manufacturer's package inserts for acceptable anticoagulants) are acceptable specimens for immunoassays. Specimens are stable at 2-8° C for 1 wk and at -20° C for 3 mo. ¹ Samples containing precipitates should be centrifuged before assaying. | Beckman Access Heparin plasma and serum F: 14.3-65.8 M: 17.4-105.7 EDTA plasma F: 11.1-57.5 M: 15.2-91.2 Bayer Centaur Ortho ECI All: <101 F: <61.5 M: <121 Biosite Triage <107 | <i>mcg/L</i> | Assays are generally unaffected by icterus (bilirubin, <65 mg/dL), hemolysis (Hb, <1.5 g/dL, lipemia (intralipid, <2200 mg/dL), and rheumatoid factors (<1500 U/L). High concentrations of HAMAs or heterophile antibodies may cause interferences. |
| <i>Immunoassay</i> ^{1,2} <i>Point-of-care immunoassays assays also available</i> ³ | | | | |
| Reference intervals for serum myoglobin vary according to age, race, and sex. On the average, serum concentrations increase with age, men have higher concentrations than women, and blacks have higher concentrations than whites. For consistency with cardiac troponin and CK-MB, the 99th percentile of a reference population should be used as the reference cutoff. The normal range also varies by assay. An effort of standardizing myoglobin has been initiated. ⁵ | | | | |

DIAGNOSTIC INFORMATION

REMARKS

Testing for myocardial antibodies is useful in patients suspected of having a post-cardiotomy or post-myocardial infarction inflammatory syndrome or inflammatory cardiomyopathy.¹ Positive results occur in 30-70% of such cases.

Circulating myocardial antibodies become positive 2-3 wk after myocardial injury because of infarction or surgery.

Myoglobin is known for its excellent clinical sensitivity early after AMI; however, it has not become a widely used test in clinical or laboratory practice.⁶⁻⁸ The majority of clinical and laboratory testing guidelines suggest a possible role for myoglobin for early myocardial detection and early monitoring. However, in general practice, the lack of tissue specificity has been its major obstacle for growth in clinical practice. The major advantage offered by myoglobin as a serum marker for early, myocardial injury is that it is released earlier from damaged cells than CK-MB and cardiac troponin, allowing for earlier detection of MI. Myoglobin is a very sensitive marker (90-100%) for AMI. Serum concentrations of myoglobin increase above the reference interval as early as 1 hr after MI, with peak sensitivity in the range of 2-12 hr, suggesting that serum myoglobin reflects the early course of myocardial necrosis. Myoglobin is rapidly cleared and thus has a substantially reduced clinical sensitivity after 12 hr. If myoglobin is to have a role in detecting AMI, it must be within the first 0-4 hr, the time period in which CK-MB and possibly cardiac troponin are still within its reference interval. The measurement of serum myoglobin has not been extensively utilized in clinical laboratories for the routine analysis in AMI because it has poor clinical specificity (60-95%), which is caused by the large quantities of myoglobin found in skeletal muscle. The best use of early serum myoglobin measurements after admission to emergency departments is as a negative predictor of AMI. If myoglobin concentrations remain unchanged and within the reference interval on multiple, early samplings within 2-6 hr after the onset of chest pain, there is almost 100% certainty (99% negative predictive value) that muscle (either cardiac or skeletal) injury has not occurred recently.

Myoglobin is an oxygen-binding protein of cardiac and skeletal muscle with a molecular mass of 17,800 Da. The protein's low molecular weight and cytoplasmic location probably account for its early appearance in the circulation after muscle (heart or skeletal) injury. There is no difference in the myoglobin protein localization in the heart versus skeletal muscle. Increases in serum myoglobin occur after trauma to either skeletal or cardiac muscle, as in crush injuries or MI. Serum myoglobin methods are unable to distinguish the tissue of origin because the proteins are identical. Even minor injury to skeletal muscle may result in elevated concentrations of serum myoglobin, which may lead to the misinterpretation for myocardial injury. Because myoglobin is cleared by the kidney, changes in GFR will cause increases. It has a very short half-life of 10 min in blood.

| <p>Neuromuscular, Autonomic, and Central Synaptic Autoimmunity: includes myasthenia gravis (MG), Lambert-Eaton syndrome (LES), acquired disorders of continuous muscle fiber activity (e.g., neuromyotonia), autoimmune autonomic neuropathies and miscellaneous autoimmune encephalomyeloneuropathies. All of these disorders can occur spontaneously or in a paraneoplastic context (usually with small-cell lung carcinoma or thymoma). The profile of muscle and neuronal autoantibodies revealed by comprehensive serological evaluation helps to formulate the neurological diagnosis and may predict the presence of a neoplasm. Serological evaluation is recommended for (1) confirming the autoimmune basis of a defect in neuromuscular, autonomic, and central nervous system transmission, (2) distinguishing LES from autoimmune forms of MG, (3) increasing the index of suspicion for thymoma or primary lung carcinoma, and (4) providing a quantitative autoantibody baseline for future comparisons in monitoring a patient's clinical course and response to immunomodulatory treatment or cancer therapy. The following tests are most pertinent:</p> | | | |
| <p>Muscle Acetylcholine Receptor (AChR) Binding Ab¹⁻³</p> <p>Radioimmunoassay; serum is added to detergent-solubilized skeletal muscle AChR complexed with ¹²⁵I-labeled α-bungarotoxin.</p> | <p>Serum.</p> <p>Refrigerate if not shipped same day. Serum stable up to 2 weeks.</p> | <p>≤0.02 nmol/L</p> | <p>A mixture of adult and fetal-type human muscle AChR antigens provides optimal sensitivity. Ab may disappear with immunosuppressant therapy; the neurological diagnosis is further confounded if steroid myopathy develops. Unexplainable positive muscle AChR or striational Ab values occur in 40% of patients with autoimmune liver disorders, ~10% of patients with lung cancer, and in patients with graft-versus-host disease and recipients of D-penicillamine.</p> |
| <p>Muscle AChR-Modulating Ab¹⁻³</p> <p>¹²⁵I-α-bungarotoxin detects AChR remaining on living muscle membranes.</p> | <p>Serum.</p> <p>Refrigerate if not shipped same day. Serum stable up to 2 weeks.</p> | <p>0-20% (reported as % loss of AChR)</p> | <p>Curare-like drugs used during general anesthesia can yield transient false-positive AChR-modulating Ab results. Multifactorial false-positive results also occur because this is a bioassay.</p> |
| <p>Muscle AChR-Blocking Ab¹⁻³</p> <p>Radioimmunoassay; ¹²⁵I-α-bungarotoxin is added to detergent-solubilized muscle AChR after serum.</p> | <p>Serum.</p> <p>Refrigerate if not shipped same day. Serum stable up to 2 weeks.</p> | <p>0-25% (reported as % AChR blockade)</p> | <p>Curare-like drugs used during general anesthesia can yield transient false-positive AChR-blocking Ab results.</p> |

DIAGNOSTIC INFORMATION

REMARKS

Muscle AChR-binding Ab is found in 90% of adult patients with acquired myasthenia gravis (MG) who have generalized weakness, 80% with weakness restricted to extraocular muscles, and in 100% of nonimmunosuppressed MG patients who have thymoma.¹ The seroprevalence of muscle AChR Abs is lower in children with MG. Severity cannot be predicted by Ab titer, but Ab levels are generally high with severe weakness. Ab specific for an alternative muscle autoantigen, MuSK, accounts for approximately one third of “seronegative” patients with acquired MG. These patients have predominantly oculobulbar symptoms.⁶ Muscle AChR binding or modulating Ab is detected in 10% of patients with Lambert-Eaton syndrome (LES) or autoimmune autonomic neuropathy, but calcium channel Abs are not found in patients with MG, nor with thymoma.¹⁻³

The patient’s autoAb profile is more informative than the result of any single test for supporting a diagnosis of MG or LES and for predicting the likelihood of thymoma or lung carcinoma.¹ Muscle AChR Abs are characteristic but not diagnostic of MG. AChR and striational Abs may be undetectable for 6-12 mo after MG symptom onset. Only ~5% of nonimmunosuppressed adult patients with generalized MG remain seronegative for muscle AChR and striational Abs beyond 12 mo.¹⁻³ All muscle AChR Abs can occur with neoplasia without evidence of a neuromuscular transmission defect.^{4,7}

AChR-modulating Ab is usually found with generalized MG. AChR-modulating Ab activity tends to parallel weakness. A positive striational Ab result is most predictive of thymoma, or other neoplasm, when the AChR-modulating Ab value $\geq 90\%$ AChR loss.¹⁻³

AChR-blocking Ab is the least sensitive of muscle AChR Ab assays for diagnosis of MG and is never positive when the AChR-modulating Ab assay result is negative. Only 55% of adult patients with acquired MG are seropositive. High values of AChR-blocking Ab are generally accompanied by severe clinical signs of MG.

Testing for muscle AChR-blocking Ab is not indicated unless the AChR-modulating Ab result is positive. The result provides a baseline value for future comparison in the course of remission, exacerbation, or immunosuppressant therapy. All muscle AChR Abs may be positive in LES, but calcium channel Abs are not found in MG, except in the context of lung cancer (N-type).¹⁻³

| TEST NAME AND METHOD | SPECIMEN REQUIREMENTS | REFERENCE INTERVAL, CONVENTIONAL [INTERNATIONAL RECOMMENDED UNITS] | CHEMICAL INTERFERENCES AND IN VIVO EFFECTS |
|--|--|---|---|
| Striational (Striated Muscle) Ab^{1,6,7} Indirect immunofluorescence; substrate of cryosectioned rodent muscle, or glycerinated myofibrils, pelleted by Cytospin. ELISA using KCL extracted rodent sarcomeric proteins. | Serum. Refrigerate if not shipped same day. Serum stable up to 2 weeks. Ship whole blood immediately. Negative at 1:60. | <1:60 | Immunosuppressant and chemotoxic therapies may reduce the antibody level below detection limit. |
| Muscle-Specific Tyrosine Kinase (MuSK) Ab⁴ Radioimmunoassay; antigen is ¹²⁵ I-recombinant extracellular domain of MuSK. | Serum. Refrigerate if not shipped same day. Serum stable up to 2 weeks. Ship whole blood immediately. | Lab-dependent | Immunosuppressant therapies may reduce the Ab level below the detection limit. |
| Calcium Channel Binding Ab, P/Q-Type^{1-3,5,8-10} Radioimmunoassay; antigen is detergent-solubilized brain VGCC complexed with ¹²⁵ I-labeled ω-conotoxin-MVIIC. | Serum | ≤20 pmol/L | High-dose intravenous IgG therapy may cause false-negative or lowering of values. Plasma specimens and monoclonal (myeloma M proteins) or polyclonal hypergammaglobulinemia can yield false-positive results. |
| Calcium Channel Binding Ab, N-Type^{1-3,5,8-10} Radioimmunoassay; antigen is detergent-solubilized brain VGCC complexed with ¹²⁵ I-labeled ω-conotoxin-GVIA. | Serum | ≤20 pmol/L | High-dose intravenous IgG therapy may cause false-negative or lowering of values. N-type calcium channel binding Ab may become undetectable soon after commencing corticosteroid treatment. |

DIAGNOSTIC INFORMATION

REMARKS

Striational Ab seropositivity aids the diagnosis of thymoma, especially in patients with MG onset younger than age 45 yr, or with an AChR modulating Ab value $\geq 90\%$ AChR loss.¹ This profile's predictive value for thymoma is greatest when accompanied by CRMP-5-IgG, GAD65 Ab, neuronal potassium channel Ab or ganglionic AChR Ab.⁴ Seronegativity does not exclude a thymoma (24% are negative). Striational Ab seropositivity is useful as a confirmatory test for MG in older patients, especially when tests for muscle AChR Abs are negative. Serial measurements are useful in monitoring the efficacy of immunosuppressant treatment in patients with MG, and after treating thymoma. Striational Abs may be detected in patients with LES, small cell carcinoma of the lung, breast carcinoma, treated with D-penicillamine, autoimmune liver disorders, and bone marrow transplant recipients with graft-versus-host disease.⁵

MuSK Ab is detected in ~30% of patients with generalized MG who lack detectable AChR Abs.⁶ A majority have a phenotype of bulbar MG, and are prone to respiratory failure. Thymectomy is not beneficial in treatment. Plasmapheresis and immunosuppressant therapies are effective, and acetylcholinesterase inhibitors sometimes help. No paraneoplastic case has been identified.

P/Q-type calcium channel Ab is detected in >90% of non-immunosuppressed patients who have LES (usually >100 pmol/L), and in 20% of patients who have encephalomyeloneuropathies related to carcinoma of lung, breast, or ovary.^{1,7,10} Seropositivity also implicates autoimmunity as a pathogenic mechanism in patients with complex neurologic presentations, particularly in those with a history of cancer, or risk factors for cancer. Seropositivity can occur with limbic encephalitis, cerebellar ataxia, peripheral neuropathy or autonomic neuropathy.

N-type calcium channel binding Ab is more frequent in LES patients who have lung cancer (75%) than in those with other types of cancer or no cancer (36%). This Ab is also found in patients with paraneoplastic encephalomyeloneuropathies complicating lung, ovarian or breast carcinoma, and in some adults and children with acquired cerebellar ataxia or autonomic neuropathy, including gastrointestinal dysmotilities without evidence of a tumor. Neuroblastoma is sometimes found in seropositive children.¹⁰

AutoAbs that bind to the contractile elements of striated muscle (titin, actin, alpha-actinin, myosin, or ryanodine receptor) are found in 30% of adult patients with MG and in 80% of those with thymoma. Striational Abs are detected in 21% of patients who have thymoma without clinical evidence of MG, 25% of rheumatoid arthritis (RA) patients treated with D-penicillamine, 4% of untreated RA patients, and 5% of patients with LES and/or small-cell lung carcinoma. The seroprevalence in healthy subjects is <1%. An increasing titer after removal of thymoma may indicate thymoma recurrence or a second neoplasm.⁷

MuSK is a muscle endplate tyrosine kinase receptor for the neurotrophic factor agrin, secreted by motor neurons. It is essential for establishing and maintaining high-density clusters of AChR in the postsynaptic membrane. MuSK Ab rarely coexists with muscle AChR or striational Ab.

P/Q-type calcium channels regulate neurotransmitter release at motor nerve terminals and are involved in central neurotransmission. AutoAbs directed against extracellular epitopes of P/Q-type calcium channels are implicated as the effectors of LES and possibly some cerebellar ataxias.¹⁻³ P/Q-type Ca^{2+} channel Ab commonly coexists with neuronal nuclear and cytoplasmic paraneoplastic autoAbs, except in patients whose LES is not accompanied by other paraneoplastic autoimmune neurologic disorders.⁷

N-type Ca^{2+} channel Ab commonly coexists with neuronal nuclear and cytoplasmic paraneoplastic autoAbs, except in patients whose LES is not accompanied by other paraneoplastic autoimmune neurologic disorders.^{1,7}

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>VGKC Ab is a marker of acquired neuromuscular hyperexcitability disorders (e.g. Isaacs disease, which is characterized electromyographically by high-frequency neuromyotonic discharges).^{11,12} VGKC Ab also is found (usually at higher levels), in patients with limbic encephalitis. Patients with this inflammatory disorder of mesial temporal lobes present with subacute seizures, memory impairment, and personality change. It is reversible in early stages by a 5-day course of high dose i.v. methylprednisolone. Maintenance immunosuppression is recommended to prevent relapse.¹³⁻¹⁵</p> | <p>Ganglionic AChR Ab complements VGKC Ab as a marker of autoimmune neuromuscular hyperexcitability and limbic encephalitis. Both autoAbs accompany small cell carcinoma and thymoma and can coexist with other autoantibody markers of these neoplasms.⁷</p> <p>Patients with subacute limbic encephalitis require thorough and repeated evaluation for neoplasia regardless of their Ab status.</p> |

Seropositivity distinguishes idiopathic and paraneoplastic autonomic neuropathy from other acquired forms of dysautonomia.^{16,17} Seronegativity does not exclude the diagnosis of autoimmune autonomic neuropathy. Ganglionic AChR Ab is detected in 50% of patients with autoimmune autonomic neuropathy (AAN). Serum Ab levels correlate with the severity of autonomic dysfunction and fall or disappear with clinical improvement. Patients with isolated gastrointestinal dysmotility, postural tachycardia and “pure autonomic failure” are sometimes seropositive. Ganglionic AChR Ab, usually in relatively low titer, complements VGKC Ab as a marker of autoimmune neuromuscular hyperexcitability disorders. Detection of ganglionic AChR Ab warrants aggressive search for a lung carcinoma or thymoma.

Ganglionic AChR Ab, isolated from serum of AAN patients or ganglionic AChR-immunized rabbits, causes subacute dysautonomia when injected into mice.^{18,19}

| <p>↑ Polycythemia vera (highest values), leukemoid reactions, Down syndrome,³ myeloproliferative disorders, stress, pregnancy, after administration of ACTH, acute lymphoblastic leukemia, Hodgkin's disease, agnogenic myeloid metaplasia, aplastic anemia, and bacterial infection.</p> <p>↓ Chronic myelogenous leukemia, sideroblastic anemia, idiopathic thrombocytopenic purpura (ITP), paroxysmal nocturnal hemoglobinuria (PNH), collagen diseases, AML, acute monocytic leukemia, cirrhosis, congestive heart failure with passive congestion of the liver, diabetes mellitus, gout, pernicious anemia (increases after treatment), hereditary hypophosphatasia, and sarcoidosis.</p> | <p>The terms <i>neutrophil alkaline phosphatase</i> and <i>leukocyte alkaline phosphatase</i> (LAP) are interchangeable. LAP is principally of value in distinguishing chronic myeloid leukemia (CML) from leukemoid reactions and other myeloproliferative disorders. In remission of CML, the LAP may return to normal, and in the aggressive phase of CML, or blast crisis, the LAP may be elevated.</p> |

| | |
|---|---|
| <p>ANCA occur in patients with vasculitis, both systemic and localized. The cANCA pattern of staining occurs in ~85% of patients with active Wegener's granulomatosis (WG) (renal and pulmonary involvement), and the pANCA staining pattern occurs in patients with microscopic polyangiitis and pauci immune necrotizing glomerulonephritis.^{1,2} A negative test for cANCA does not rule out WG, but false-positive results are rare. Positive results for pANCA may occur in patients with lupus erythematosus (LE) or Goodpasture's syndrome. In patients with documented WG, increasing titers of cANCA suggest relapse of disease and decreasing titers suggest successful treatment.</p> | <p>cANCA produce diffuse cytoplasmic staining of neutrophils and monocytes and are caused by antibodies to proteinase 3, a 29-kDa serine protease. pANCA produce perinuclear staining of ethanol-fixed neutrophils and are often specific for neutrophil enzymes, including myeloperoxidase (MPO). Testing for antibodies to PR3 and MPO by EIA is recommended to confirm the presence of autoantibodies in patients with positive cANCA or pANCA, respectively.³ The pANCA staining pattern can also be seen in patients with nonvasculitic diseases, including ulcerative colitis. This reactivity is not because of anti-MPO antibodies but represents reactivity with various other neutrophil autoantigens.</p> |

DIAGNOSTIC INFORMATION

REMARKS

↓ Pellagra, alcoholism, carcinoid syndrome, anorexia nervosa, ulcerative colitis, and Hartnup disease.

The diagnosis of Pellagra should be focused on three points “the 3Ds” (diarrhea, dermatitis, and dementia). Other findings may include anemia, hypoproteinemia, increased serum calcium, abnormal liver function tests, and increased serum porphyrins.⁷ Advanced dermatitis includes the appearance of Casal’s necklace. Mental changes include fatigue, insomnia, and apathy. These are followed by encephalopathy along with confusion, hallucination, loss of memory, and eventually frank organic psychoses.

Pellagra is the clinical syndrome resulting from severe niacin deficiency. Niacin functions primarily as the coenzyme forms NAD and NADP. Erythrocyte NAD is often reduced in niacin deficiency. Niacin is biosynthesized from the amino acid tryptophan so that 60 mg of dietary tryptophan = 1 mg of niacin intake = 1 niacin equivalent (NE). U.S. RDA (1989) = 6.6 NE per 1000 kcal. Excess niacin is methylated in the liver and excreted, principally as N1-methylnicotinamide and N1-methyl-2-pyridone-5-carboxamide (2-pyridone). Excretion of the two methylated metabolites provides the most reliable measure of niacin intake and body status. (In children, levels of urine niacin metabolites are dependent on age.) Diagnosis of niacin deficiency is often based on patient history and physical examination. When clinic information points to niacin deficiency, niacin replacement is started and diagnosis is made in part based on patient’s response.⁸ Neither blood nor urinary niacin levels are of value in assessing niacin nutritional status.

There is usually a concurrent deficiency of other B vitamins in pellagra. Niacin deficiency may be associated with anemia or, in the young, with a failure to grow.

A protein-rich diet can be used to treat niacin deficiency. Food sources of niacin include meat, poultry, fish, eggs, nuts, whole grain cereals, and legumes.^{8,9}

Nicotinic acid given as a drug (1.0-3.0 g/day) improves lipoprotein abnormalities, reducing LDL cholesterol, triglyceride, and Lp(a), while increasing HDL. Immediate release, extended release, and long-acting formulations are available, and side effects vary depending on the formulation. Immediate release niacin is associated with flushing of the skin (face and hands), gastrointestinal symptoms, and elevations in blood glucose, whereas with long-acting time release niacin there is reduced flushing but increased risk of hepatotoxic effects. Rarer additional symptoms include hyperuricemia and gout, cardiac arrhythmias, hypotension, and acanthosis nigricans.¹⁰

| ↑ Industrial exposure, nickel carbonyl intoxication, acute myocardial infarction (early decrease followed by a sharp increase), acute stroke, extensive thermal burns, and dialysis patients. Disulfiram therapy. ¹⁰ | Serum and urine levels are useful indices of chronic environmental exposure and exposure from the manufacture of ink, magnets, spark plugs, paints, stainless steel (including welding), enamels, ceramics, batteries, glass, and alloys. |
| Inhalation of nickel compounds leads to malignancies of lungs and nasal sinuses. | One percent of soluble nickel in food is absorbed versus 25% in water after a 12-hr fast. ¹¹ |
| ↓ Hepatic and renal diseases | Chronic toxic effects are hypersensitivity (dermatitis) and carcinogenesis (respiratory). Nickel allergy affects 10-15% of the population and can develop from occupational exposure or exposure to nickel-containing jewelry or implanted prostheses and results in local or generalized dermatitis. Refinery dust and nickel subsulfide are classified as human carcinogens. |

These substances convert hemoglobin to methemoglobin and cause a decrease in the availability of oxygen to tissues. Prompt measurement of methemoglobin is a useful clinical test for nitrite toxicity. Toxicity is caused by uncontrolled vasodilation and/or methemoglobinemia.

Inorganic and organic nitrites are used therapeutically. When used therapeutically, all nitrite is completely metabolized. Sodium nitrite is used as an antidote for cyanide poisoning³ and as a curing agent for processed meats. The nitrite ion disappears rapidly from plasma, but urinary concentrations can be used to assess exposure.

↑ Patients with bacterial tuberculosis; some viral, some parasitic, and some fungal infections; and lymphomas

Normal in some viral and bacterial infections.

↓ Chronic granulomatous disease (CGD), some other neutrophil enzymatic defects, some types of complement deficiency, and agammaglobulinemia

↓ CGD carriers, 45-90% [0.45-0.90] positive cells

↓↓ CGD-positive cells

When stimulated to phagocytosis, neutrophils generate superoxides that reduce the nitroblue tetrazolium from a soluble, yellow compound to a blue precipitate. The spontaneous NBT test is not reliable in the differential diagnosis of bacterial infection and has no established use in clinical practice.

An alternative to the NBT slide test is the neutrophil oxidative burst assay (DHR), which is performed by flow cytometry.

The stimulated NBT test is useful in screening for CGD, in which there is a defect in the ability of neutrophils to generate superoxide in response to phagocytosis. It is particularly useful in detecting the carrier state in families with one of the X-linked subtypes of CGD. Carriers show a mixture of NBT-positive and NBT-negative cells. Screening of fetal blood by the NBT slide test is problematic because of maternal blood contamination.

|---|--|---|--------------------------------|--|
| NT-pro B-Type Natriuretic Peptide (NT-proBNP) | Serum, EDTA plasma collected. | <i>Cutoff concentration for HF:</i> <75 yr ≥ 75 yr | mcg/L^* 125 450 | Assays may differ in their susceptibility to analytical interferences. Interferences from rheumatoid factors or heterophilic antibodies may lead to false test results. |
| <i>Immunoassay^{1,2}</i> | Samples stable for 24 hr at room temperature, 72 hr at 2-8° C, and >3 days at -20° C. ^{3,4} | *Cannot convert to pmol/L because the assay measures NT-proBNP and proBNP. | | |
| <i>Roche Dade Behring, Ortho Clinical Diagnostics, Inverness Medical (POCT)</i> | | There are several practical issues regarding the use of serum/plasma/whole blood monitoring of NT-proBNP. First, reference intervals vary, depending on which assay is used and the nature of the reference population tested. Second, a number of clinical factors affect the NT-proBNP concentrations, most importantly age, gender, and renal function. Significant differences are observed between men and women (higher) and with increasing concentrations with age by decades. Third, the relative importance of those factors in relation to the degree of left ventricular dysfunction remains to be debated. | | |
| | | | | Formulation of immunoassay kits remains very important in minimizing interference from heterophilic antibodies, and in some situations only addition of the non-immune serum from the animal species that was used to raise the antibodies is effective. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| S,B ↑ High-protein diet, late pregnancy; prerenal azotemia, intrinsic renal disease, and urinary tract obstruction. | Blood or serum NPN is rarely measured because it offers no more information than urea nitrogen. |
| S,B ↓ Severe hepatic insufficiency, hepatic necrosis. | |
| See also <i>Urea Nitrogen</i> . | |
| U ↑ Metabolic stress, postoperative stress sepsis. ⁴ | Urine NPN (total urinary nitrogen, TUN) is ~85% urea, 3% ammonia, 5% creatinine, and 1% uric acid. These figures vary in individual patients depending on clinical circumstances, especially in those receiving enteral and parenteral nutritional support. ⁵ For this reason, total urinary nitrogen is a more reliable indicator of nitrogen balance than urinary urea nitrogen in some patients. |
| ↑ Severe diarrhea, steatorrhea, pancreatic disease, and gastrocolic fistula. | Output of fecal nitrogen is dependent on dietary intake; a standard diet (Schmidt or Nothman) is recommended. |

The biochemistry and physiology specifically of NT-proBNP have been described.⁶ In head-to-head comparisons, the clinical utility of NT-proBNP is similar to that of BNP.^{7,8} However, results of NT-proBNP cannot be converted to equivalent BNP results.⁹ See also *B-type Natriuretic Peptide*.

See *B-type Natriuretic Peptide*. NT-proBNP has been shown to be useful for diagnosis of heart failure in patients presenting with dyspnea,¹⁰ staging, and risk stratification of patients with HF¹¹ and acute coronary artery disease.¹²

There is uncertainty whether proBNP is split in the myocyte or later in the plasma as corin, a circulating protease, cleaves proBNP into the N-terminal and the active BNP moiety. Circulating proBNP has been documented.¹⁵ However, the major circulating forms are the resulting NT-proBNP, function unknown, and C-terminal BNP (physiologically active hormone). BNP is cleared via degradation by NEP (neutral endopeptidases), by receptor-mediated clearance, and perhaps a bit via the kidneys, which also can secrete BNP. The NT-proBNP is not cleared via receptor-mediated mechanisms, leading some to suggest that it will be more sensitive to changes in renal function.⁹

DIAGNOSTIC INFORMATION

REMARKS

↑ Bladder cancer (transitional cell carcinoma). Assay has a sensitivity of 70.6% and a specificity of 78.0% for recurrence of disease and a sensitivity of 62.5% and a specificity of 78% for detection of disease in symptomatic or high-risk individuals. Elevations observed in healthy individuals after extreme exercise, interstitial cystitis, urinary tract infections, renal cancer, patients treated with chemotherapy for any malignancy, and total cystectomy patients. Tissue damage from cystoscopy or urethral catheterization may cause elevated values within 5 days of the procedure.

Nuclear matrix proteins (NMPs) make up the internal structural framework of the nucleus and function in DNA replication, RNA synthesis, hormone binding, and regulation and coordination of gene expression. The NMP22 assay measures the nuclear matrix protein NuMA, nuclear mitotic apparatus protein, which is found in all cells. NuMA is overexpressed in bladder cancer and released into the urine during cell death and with breakdown in the bladder wall as a result of bladder cancer.^{1,2}

A quantitative EIA for NMP22 (Matritech, Inc., Newton, MA) in urine is indicated for the management of patients with transitional cell carcinoma (TCC) of the bladder, after surgical treatment to identify patients with occult or rapidly recurring TCC using an assay cutoff of >10 U/mL. The test is further indicated as an aid in the diagnosis of TCC of the bladder in patients with symptoms or risk factors in conjunction with standard diagnostic procedures with an assay cutoff of ≥ 7.5 U/mL. A qualitative, immunochromatographic, point-of-care NMP22 test (NMP22 BladderChek Test) is available as an aid in monitoring patients with a history of bladder cancer.

↑ Hepatobiliary disease with intrahepatic or extrahepatic biliary obstruction, hepatic carcinoma, early biliary cirrhosis, pregnancy (third trimester), preeclampsia,⁹ graft-versus-host (GVH) disease, and inflammatory arthritis.¹⁰

5'-Nucleotidase levels parallel those of alkaline phosphatase in cholestatic hepatobiliary diseases but are not significantly increased in bone disease.^{3,11} 5'-NT is a better test for secondary tumors and lymphomas of liver than is alkaline phosphatase.¹² Values are high in infants, decrease in adolescents, and increase again in elderly persons.^{6,13}

↑ Peptic ulcers, gastritis (especially associated with alcohol, aspirin, or indomethacin), variceal bleeding, GI malignancies (especially of colon), diverticular disease, GI polyps, ischemic bowel disease, Mallory-Weiss tears, inflammatory lesions (e.g., ulcerative colitis, Crohn's disease, shigellosis, amebiasis, typhoid fever), trauma, bleeding diatheses (e.g., primary blood dyscrasias, Osler-Weber-Rendu disease, scurvy, pseudoxanthoma elasticum), vasculitis (e.g., polyarteritis nodosa, Henoch's purpura, Schönlein's purpura), amyloidosis, Turner's syndrome, uremia, intussusception, hiatal hernia, radiation, neurofibromatosis, Kaposi's sarcoma, and hematemesis.

Isotope tests are more specific than peroxidase tests but are impractical for large-scale screening¹ and should be used only for measuring trace amounts. Combination with other techniques can lead to location of the bleeding source.

Sensitivity: >5 mL blood/day

Fluorometric assay for porphyrins and heme. Vegetable peroxidases do not interfere; however, red meat and aspirin should be avoided before testing. Limited used because of laboratory-based analysis and high false-positive rate.³ Available through reference laboratories as HemoQuant.

Immunochemical tests use antibodies to human intact hemoglobin and globin. Tests are unaffected by diet, animal hemoglobin, and medications. High sensitivity for colonic blood (0.3 mL). It is suited for screening for occult blood in the lower intestinal tract, but it is insensitive to upper GI bleeding. Tests require laboratory development and have limited acceptance and availability in the U.S.^{3,5,6}

In peroxidase tests, peroxidase/pseudoperoxidase activity in the sample, such as from heme, turns guaiac-impregnated slides blue with the addition of hydrogen peroxide in the developer solution. Hemoccult II Sensa, a more specific version of Hemoccult II, has sensitivity of 80% and a specificity of 94%. The reliability of the Hemoccult test is increased and the number of false-negative results obtained is reduced by performing the test on three separate days to account for intermittent neoplasia bleeding tests with the patient on a diet free from exogenous peroxidase activity (e.g., dietary Hb in red meat and fish, turnips, and horseradish) and vitamin C from supplements and citrus products (250 mg/day) 3 days before and during testing. Nonsteroidal antiinflammatory medications should also be avoided 7 days before and during testing. Rehydration of the test card is not recommended before developing. Small amounts of bright red blood on the stool surface are often because of hemorrhoids, anal fissures and fistulas, proctitis, or rectal polyps.^{3,5,6} The American Cancer Society recommends

This test is used to detect low-molecular-weight toxins such as ethanol, methanol, isopropanol, ethylene glycol, and acetone.

Millimole discriminant is the difference between calculated and measured osmolality. Osmolality can be calculated as follows:

$$(\text{Na, mmol/L} \times 2) + \frac{\text{Urea N, mg/dL}}{2.8} + \frac{\text{glucose, mg/dL}}{18}$$

The osmolal gap may also be elevated with hyperlipidemia or hyperproteinemia. In these cases, the serum water content is significantly reduced. (See *Osmolality*.)

↓ In polyuria of diabetes insipidus: 0.2-0.7, even after fluid restriction; ratio also decreased in patients with renal tubular deficiency.

In diabetes insipidus, ratio may be >1.0 with marked dehydration (serum osmolality >320 mOsm/kg; in the SI, >320 mmol osmotically active particles/kg).

In polyuria of neurogenic origin, the ratio may be normal without fluid restriction and will increase after fluid restriction. After diuretics or in severe renal insufficiency, ratio is ~1.0; in water intoxication, it is ~0.5.

DIAGNOSTIC INFORMATION

REMARKS

Normal in secondary hemolytic anemia, PNH, and G6PD deficiency

↑ *Hereditary spherocytosis*: An increase in incubated osmotic fragility compared with that of control blood is characteristic of HS and is greater than that in other hemolytic anemias, including autoimmune hemolytic anemia with spherocytes. OF values may be increased in hereditary elliptocytosis and in severe pyruvate kinase deficiency. In mild HS, the unincubated OF may be normal, with only the incubated OF showing abnormalities.

↓ *Hypochromic microcytic anemias*: Thalassemia, liver disease, and iron deficiency anemia

Incubation of the blood sample for 24 hr at 37° C (incubated osmotic fragility) may unmask abnormal OF in cases of mild HS that have normal or slightly increased OF by standard testing. Normal erythrocytes (and Ercs in most other disorders) swell during incubation causing them to become more spherical and hence demonstrate increased OF. Ercs in hereditary spherocytosis show a greater increase in OF than do normal cells or Ercs in other disorders, including autoimmune hemolysis with spherocytes.²

↑ High-turnover osteoporosis, Paget's disease, primary hyperparathyroidism, renal osteodystrophy, hyperthyroidism, osteomalacia, metastatic bone disease, acromegaly, recent fractures, bone growth, exercise, lactation, menopause, and age

↓ Pregnancy, growth hormone deficiency, hypothyroidism, hypoparathyroidism, liver disease, and alcoholism

Osteocalcin (OC) is produced by the osteoblast and is a marker of bone formation. It is the major noncollagenous protein in bone comprising ~1% of total protein. This 49 amino acid protein contains three glutamyl residues that are converted to γ -carboxyglutamyl (Gla) by a posttranslation, vitamin K-dependent enzymatic carboxylation. OC is cleared by the kidney and has a $t_{1/2}$, in vivo, of ~5 min. There is a marked diurnal variation in bone resorption/formation and serum OC levels, with a nocturnal peak, decreasing by as much as 50% to the morning nadir.

For monitoring therapy, serial specimens should be collected at the same time of the day. Serum bone alkaline phosphatase shows less within-subject variability (see *Alkaline Phosphatase, Bone*). The response of OC to antiresorptive therapies is delayed compared with resorption markers (see *Collagen Telopeptides and Pyridinium Crosslinks*) reading a plateau at 6 to 12 months.

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>Many competitive and noncompetitive immunoassays have been developed for OC, including RIAs, EIAs, IRMAs, ELISAs, and ICMAs. As illustrated by the methods listed here, OC levels are method-specific and vary widely between methods. In vitro, intact OC is rapidly degraded to a large amino(N)-terminal fragment containing the N-terminal and mid-region amino acids, probably 1-43. Serum OC levels are more stable when measured with methods recognizing both intact OC and N-terminal fragments. Consequently, these methods are more reproducible and widely used than intact OC methods.</p> <p>In normal individuals, serum OC levels are highest in children, higher in males than females, and increase with age in adults. The highest levels occur during periods of rapid bone growth. OC levels may not accurately reflect bone formation in several situations, including (1) patients treated with 1,25-dihydroxyvitamin D or abnormalities of this hormone because it regulates OC, (2) patients with impaired renal function, and (3) during bed rest.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Systemic poisoning is characterized by corrosive effects, renal damage, and a marked decrease in calcium levels with resulting shock, collapse, and convulsions. Primary hyperoxaluria is a genetic disorder resulting in increased serum and urine levels. Up to 99% of administered oxalic acid is excreted in urine within 36 hr.</p> <hr/> <p>U ↑ Primary hyperoxaluria (100-600 mg/day; 1110-6670 μmol/day), diabetes mellitus, cirrhosis, pyridoxine deficiency, sarcoidosis, steatorrhea caused by pancreatic insufficiency, celiac disease, bacterial overgrowth, ileal resection, jejunoileal shunt, biliary tract disease, bowel disease with excessive absorption, and small bowel disease</p> <hr/> <p>U ↓ Renal failure</p> | <p>Normally oxalate is derived from dietary oxalic acid (~10%) and the metabolism of ascorbic acid (35-50%) and glycine (40%). Oxalic acid and its salts are used in cleaning and bleaching agents.</p> <p>Urine samples from individuals taking megadoses of ascorbic acid when analyzed by ion chromatography may have increased levels of oxalate. The oxidation of ascorbic acid to oxalate in vitro can be avoided by using a diluent containing boric acid, 0.3 mol/L, instead of water.</p> <p>There is an increased incidence of urolithiasis in workers heavily exposed to oxalic acid.</p> <p>See also <i>Glycolic Acid</i> and <i>Glyceric Acid</i>.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---------|
| <p><i>Right to left shunt:</i> Intrapulmonary venoarterial shunting, congenital heart disease</p> <p>More than one of these mechanisms may operate simultaneously.</p> <p>Values <40 mm Hg [<5.32 kPa] indicate severe hypoxemia; values <20 mm Hg [<2.66 kPa] are frequently associated with death.</p> | |

| | |
|---|---|
| <p>Measurement of oxygen saturation may be clinically useful in cyanosis and erythrocytosis. It may differentiate between diminished oxygenation of blood, as in pulmonary diseases, and admixture of venous blood, as in an arteriovenous shunt.</p> <p>Estimation of oxygen saturation of samples obtained at various sites during cardiac catheterization is helpful when used in conjunction with intracardiac pressure measurements in the detection of intracardiac abnormalities.</p> <p>Oxygen desaturation may occur after sedation for peritoneoscopy with resultant hypoxemia, hypercarbia, and acidosis.⁴</p> <p>In Rh incompatibility caused by blocking antibodies, the oxygen-carrying capacity of Ercs is 10-15% less than normal.</p> | <p>The oxygen saturation is calculated as follows:</p> $SO_2 = \left(\frac{O_2 \text{ Hb}}{O_2 \text{ Hb} + \text{HHb}} \right) \times 100\%$ <p>The availability of oxygen to tissues is dependent not only on the SO₂ but also on the affinity of O₂ to Hb.</p> <p>See <i>Oxygen, P₅₀, and 2,3-Diphosphoglycerate in Erythrocytes</i>.</p> <p>Pulse oximetry is most accurate between 80 and 100% O₂ saturation. Below 80% saturation accuracy decreases, but measurements reflect trend. Pulse oximetry may give inaccurate results in severe anemia, hypovolemia, hypotension, hypothermia, and arrhythmias, as well as in the presence of carboxy-, met-, and fetal hemoglobin and angiographic dyes.³ Pulse oximetry cannot distinguish between PO₂ values of 100 or >100 mm Hg (13.3 kPa).</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| ↓ Stress and psychic factors (e.g., fright) | In females, oxytocin induces uterine contractions and stimulates the lactating mammary gland. Physiological effects are unknown in males. The origin of oxytocin in amniotic fluid is unknown. |

P component is not an acute phase reacting protein.³ Serum values increase with increasing age and may be higher in males compared with age-matched females.⁴

α_1 M is a member of the pentraxin family of proteins and is identical to C1t and amyloid P component.^{6,7} No polymorphisms or deficiency states have been identified.³ It can activate complement using the classical pathway and can opsonize microorganisms and other particles for phagocytosis by white blood cells.^{3,8} As the precursor of the P component of tissue amyloid deposits, evidence suggests that serum amyloid P component may stabilize amyloid β -peptide fibrils.⁹ It also binds to chromatin and appears to have a protective role against the development of autoimmunity.^{3,10}

|---|--|---|---|
| PABA (p-Aminobenzoic Acid) Test (NBT-PABA, Bentiromide Test) ^{1,2} <i>Colorimetric</i> Test Meal: Stan- dard lunch meal with 666 mg of bentiromide in 300 mL of water | Serum, before test meal and 90 min thereafter | mg/L >2 × 7.3 | mmol/L [>22] |
| <i>HPLC</i> ^{3,4} Dose: NBT-PABA, 1 g | Plasma (heparin), 3 hr after test meal. Sepa- rate plasma immedi- ately, and store at −20° C. | 48 ± 9.5 mmol/L (SD) ³ | ↑ C Procainamide-type local anesthetics ³ |
| <i>CHYMEX</i> ⁵ <i>Colorimetric</i> Dose, adult: 500 mg of benti- romide (contains 170 mg of PABA). Follow immedi- ately with 250 mL of water. Give an- other 250 mL of water 2 hr post- dose, then 500 mL of water between 2 and 6 hr post- dose. ⁶ Child: 14 mg ben- tiromide/kg body weight | Urine. After overnight fast, patient should uri- nate before taking the drug. Collect all urine up to 6 hr after drug dose. Refrigerate speci- men to retard microbial growth. ⁵ | ≥50% excretion of PABA (See <i>Diagnostic Information.</i>) | ↑ C Acetaminophen, ben- zocaine, chloramphenicol, furosemide, lidocaine, multivitamins, pancreatic enzymes, phenacetin, pro- cainamide, procaine, some sun-absorbing skin lo- tions, sulfonamides, and thiazide diuretics may cause false-negative re- sults. Apples, cranberries, plums, and prunes may in- terfere with urinary ary- lamine determinations by increasing the percent of PABA recovered. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| | The serum test has a greater specificity (88%), sensitivity (94%), and efficiency (91%) than the excretion ratio of PABA/14C-PABA. ² Test is less sensitive in detecting slight or moderate forms of exocrine pancreatic insufficiency. ¹ |
| ↓ Chronic pancreatitis (<5 μmol/L), cystic fibrosis, and steatorrhea | HPLC is more specific than colorimetric assays. ³ |
| Under conditions of normal pancreatic, gastric, gut, and kidney function, >50% of PABA contained in CHYMEX (Savage Laboratories, Melville, NY) appears in the urine within 6 hr after administration of this agent. | In testing diabetic patients, suitable adjustments in insulin may be needed to accommodate the fasting patient. In adults, oral pancreatic enzyme supplements should be discontinued 5 days before the administration of bentiromide. The time interval is reduced to 1 day in children with cystic fibrosis. ⁵ Some patients with documented pancreatic insufficiency may have normal results. ⁵ |
| The smaller the recovery of urinary arylamine, the greater the likelihood that there is diminished exocrine pancreatic function. ⁵ | |
| U ↓ Malabsorption, impaired renal function (creatinine >1.5 mg/dL; 133 μmol/L), severe hepatic dysfunction, and gastric stasis. ⁵ | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>Pantothenate deficiency is associated with nutritional erythromelalgia (burning foot syndrome), abdominal distress, burning cramps, paresthesia of hands and feet, and impaired wound healing. Because uncomplicated pantothenate deficiency is rare, symptoms described above that have been attributed to pantothenic acid deficiency may have resulted for multi-B vitamin deficiency. People fed synthetic diets free of pantothenate developed postural hypotension, rapid heart rate on exertion, epigastric distress, numbness and tingling of hands and feet, and hyperactive deep tendon reflexes, and the eosinopenic response to adrenocorticotrophic hormone was impaired.^{7,8}</p> | <p>Pantothenic acid is ubiquitous in nature, being present in most foods, and as such, uncomplicated pantothenic acid deficiency is unlikely to occur except in experimental situations.⁷</p> <p>Most (80%) pantothenic acid is converted to coenzyme A; it is also converted to acyl carrier protein. Pantothenate deficiency does not occur naturally; it can be caused either by antagonists or by a diet that is low in pantothenic acid. Toxicity is unknown; ingestion of 10-20 g of calcium pantothenate is associated with occasional diarrhea. Chronic alcoholics have increased excretion of pantothenic acid. Patients with circulatory, cardiovascular, and peptic ulcer diseases have reduced circulating pantothenic acid. Reduced levels and low urinary excretion of pantothenate have been reported in patients with chronic malnutrition and acute rheumatism.⁹</p> <p>Stable isotope dilution methods based on gas chromatography-mass spectrometry¹⁰ and liquid chromatography-mass spectrometry¹¹ have been developed for measurement of pantothenic acid in pharmaceuticals and foods.</p> |

| Paraneoplastic Autoantibody Evaluation is useful for (1) Investigating a subacute multifocal neurological disorder without obvious cause, especially in a patient with past or family history of cancer or smoking history, (2) directing a focused search for cancer, (3) investigating neurological symptoms that appear in the course or wake of cancer therapy and are not explainable by metastasis, (4) differentiating autoimmune neuropathies from neurotoxic effects of chemotherapy, (5) monitoring the immune response of seropositive patients in the course of cancer therapy, and (6) detecting early evidence of cancer recurrence in previously seropositive patients (Fig. II-7). | | | |
| Anti-Neuronal Nuclear Antibody (Ab), Type 1 (ANNA-1); anti-Hu¹⁻³ | Draw blood in a plain, red-top tube(s) or serum gel tube(s). Spin down and send 3.0 mL of serum refrigerated. | Negative at 1:120 Negative | Immunosuppressant and chemotoxic therapies may reduce the antibody level below detection limit. Applies to all antibodies in this section. |
| Indirect immuno-fluorescence; composite mouse tissue substrate. IgG binds to nucleus and cytoplasm of all neurons (CNS and PNS). | | | |
| Western blot; native CNS protein (35, 37, 38, and 40 kD bands) or recombinant antigen | | | |
| Anti-Neuronal Nuclear Ab, Type 2 (ANNA-2); anti-Ri^{3,4} | Draw blood in a plain, red-top tube(s) or serum gel tube(s). Spin down and send 3.0 mL of serum refrigerated. | Negative at 1:120 Negative | |
| Indirect immuno-fluorescence; composite mouse tissue substrate. IgG binding restricted to CNS neurons. | | | |
| Western blot; native CNS protein (50, 52, and 70 kD) or recombinant antigen | | | |

DIAGNOSTIC INFORMATION

REMARKS

Neurologic accompaniments of ANNA-1 are subacute in onset and usually multifocal¹; 66% of cases are female. Most frequent are neuropathies (pure sensory, mixed sensorimotor, predominantly autonomic, and rarely motor), limbic encephalitis, subacute cerebellar degeneration, myelopathy, or radiculopathy. Intestinal dysmotility (commonly gastroparesis or pseudoobstruction) occurs in 30% of ANNA-1-positive patients; gut dysautonomia is sometimes the sole paraneoplastic presentation.² Small cell lung carcinoma or extrapulmonary small cell carcinoma is almost always present but usually limited in spread and difficult to find. Rarely, thymoma is present. In most cases ANNA-1 detection precedes cancer diagnosis, new or recurrent.¹ Children presenting with intestinal dysmotility, cerebellar ataxia, brainstem encephalitis, or encephalomyeloneuropathy are sometimes positive for ANNA-1, with and without evidence of cancer (neuroblastoma).

Most ANNA-1-positive patients have a history of tobacco use, social/occupational exposure to carcinogen, or family history of lung cancer. PET scanning and magnetic resonance imaging of the chest may reveal malignant adenopathy when CT is negative. SCLC is confirmed in 83% of ANNA-1-positive patients with adequate follow-up evaluation. In 15% of these patients, the search for cancer reveals an unrelated but more obvious primary malignancy; surveillance for small cell carcinoma must continue. Thorough evaluation of serum and CSF is advised when a paraneoplastic disorder is suspected. The individual patient's profile of autoAbs predicts the underlying cancer but does not necessarily predict a specific neurological syndrome. One or more other paraneoplastic autoantibodies coexist with ANNA-1 in 43% of seropositive patients, all predicting small cell carcinoma or, rarely, thymoma.³

Neurologic accompaniments of ANNA-2 are subacute in onset and usually multifocal; 70% of cases are female. Neurologic signs, in decreasing frequency: brainstem syndrome (majority opsoclonus/myoclonus; also cranial neuropathy), cerebellar syndrome, myelopathy, neuropathy (sensorimotor > polyradiculopathy > cauda equina syndrome), movement disorder, encephalopathy, Lambert-Eaton myasthenic syndrome, seizures, laryngospasm, and trismus. A positive result has 80% predictive value for small cell lung carcinoma or breast adenocarcinoma.⁴

ANNA-2 is less common than ANNA-1 (1:20),³ but in 35% of seropositive patients, one or more autoAbs coexist with ANNA-2 (e.g., ANNA-1, ion channel, etc.).⁴ Thorough evaluation of serum and CSF is advised when a paraneoplastic disorder is suspected. The individual patient's profile of autoAbs predicts the underlying cancer (lung or breast carcinoma) but not necessarily a specific neurological syndrome.

DIAGNOSTIC INFORMATION

REMARKS

Neurologic accompaniments of ANNA-3 are subacute and usually multifocal; 64% of cases are female. Neurological presentations include sensory and sensorimotor neuropathies, cerebellar ataxia, myelopathy, brainstem, and limbic encephalopathy.⁵ A positive result has 90% predictive value for an aerodigestive carcinoma, usually small cell lung carcinoma that is new or recurrent and confined to the chest.⁵ A coexisting unrelated cancer is found in 15% of seropositive patients.

ANNA-3 is a very rare autoAb.^{3,5} Forty percent of seropositive patients have a coexisting paraneoplastic autoAb, all predicting small cell carcinoma.³

Ma2 Ab has been reported with subacute paraneoplastic limbic and brainstem encephalitis associated with testicular cancer.⁶ Seropositive female patients have been reported with several other neoplasms. The frequency of Ma2 detection has not been reported.

Scrotal ultrasound is advised for men who present with unexplained subacute rhomboencephalitis. A minority of Ma2-positive patients exhibit narcolepsy (with low CSF hypocretin), presumably reflecting autoimmune hypothalamitis.²⁴

PCA-1 Ab is found in serum and CSF of patients with paraneoplastic cerebellar ataxia associated with gynecologic or breast carcinoma. PCA-1 Ab is rare in male patients (1%; associated with intraabdominal adenocarcinoma). In 10% of PCA-1-positive patients, the presentation is sensorimotor, motor, or autonomic neuropathy, thus far all with gynecologic cancer.^{3,7} Cancer, new or recurrent, is identified in 91% of PCA-1-positive patients, usually after the neurologic presentation.³ The associated cancers are typically limited in metastatic spread, may not be detected by imaging procedures,⁸ and

PCA-1 Ab is not found in healthy subjects. It is rare in patients with gynecologic cancer without neurologic dysfunction (<2%) and not found with primary lung cancer. PCA-1 is readily distinguished from PCA-Tr (a marker of Hodgkin's lymphoma) and PCA-2 (a marker of small cell lung carcinoma) by immunostaining criteria. PCA-1 is remarkable for its lack of coexisting neuronal nuclear or cytoplasmic paraneoplastic autoAbs.³

| Collapsin Response-Mediator Protein (CRMP)-5 IgG; anti-CV2 ^{3,15,16} | Draw blood in a plain, red-top tube(s) or serum gel tube(s). Spin down and send 3.0 mL of serum refrigerated. | Negative at 1:120 Negative |
| Indirect immunofluorescence; composite mouse tissue substrate. IgG binds in a similar distribution to amphiphysin, but the pattern is fuzzy and bleached out. | | |
| Western blot using native CNS protein (62 kD) or recombinant antigen | | |

DIAGNOSTIC INFORMATION

REMARKS

Only a minority of amphiphysin Ab-positive women (~40%) and men (~10%) present with encephalomyelitis with rigidity (stiff-man phenomena). Very few patients fulfill neurologic criteria for diagnosis of stiff-man (Moersch-Woltmann) syndrome.¹² Neurologic presentations are usually multifocal and include, in decreasing frequency, peripheral neuropathy, encephalopathy, myelopathy, encephalomyelitis with rigidity, cerebellar syndrome, Lambert-Eaton syndrome, myoclonus, focal pain, optic neuritis, and pruritis.

Amphiphysin IgG is associated with small cell lung carcinoma (SCLC) more commonly than breast carcinoma. Melanoma is sometimes found.¹²⁻¹⁴

One or more coexisting paraneoplastic autoAbs are found in 38% of amphiphysin-IgG-positive patients. The autoAb profile predicts small cell carcinoma or breast carcinoma.³ Many of the neurologic manifestations are attributable to targeting of autoantigens identified by coexisting autoAb markers (e.g., ANNA-1 in sensory neuronopathies, K⁺ channel Ab in limbic encephalitis and neuromyotonia, P/Q-type Ca²⁺ channel Ab in Lambert-Eaton syndrome, and CRMP-5-IgG in optic neuritis and radicular pain).^{3,11}

Neurologic accompaniments of CRMP-5-IgG are subacute and multifocal and may mimic vascular disease or multiple sclerosis. Basal ganglionitis (particularly chorea), cranial neuropathies (particularly loss of vision and smell/taste), myelopathy, and radiculoplexopathy are considered “syndromic” because of their remarkably high frequency with CRMP-5-IgG. Most common are limbic manifestations, peripheral neuropathy, autonomic neuropathy, cerebellar ataxia, and neuromuscular junction disorders.

Small cell lung carcinoma (usually limited) is found in 80% of patients, and thymoma in 7%; rarely is thyroid carcinoma found.^{15,16} When accompanied by muscle AChR binding Ab, a high level of AChR-modulating Ab, and striational Abs, a thymoma is usually identified.

CRMP-5-IgG is as common as ANNA-1. Approximately 30% of CRMP-5-IgG-positive patients have a coexisting antineuronal nuclear or neuronal cytoplasmic autoAb, and 30% have a coexisting ion channel or striational Ab.³ Thromboembolic phenomena and systemic symptoms and signs suggestive of vasculitis are documented in ~10% of patients before lung cancer is found. Neurologic symptoms usually precede cancer diagnosis.

DIAGNOSTIC INFORMATION

REMARKS

Cancer-associated retinopathy is characterized by painless and progressive vision loss.¹⁷⁻¹⁹ Electroretinography demonstrates loss of rod and cone function. Small cell lung carcinoma is the associated neoplasm. CRMP-5-IgG is a far more common marker of paraneoplastic autoimmune vision loss related to small cell lung carcinoma. Its ophthalmologic presentation is a combination of optic neuritis and retinitis.²³

The “CAR” autoantigen, recoverin, is a retinal photoreceptor calcium-binding protein that regulates rhodopsin phosphorylation and is involved in light and dark adaptation. Case reports have linked paraneoplastic retinopathy to endometrial, cervical, ovarian, and breast carcinomas and melanoma.^{17,18}

GAD65 Ab is an important serological marker of predisposition to type 1 (insulin-dependent) diabetes. Its detection distinguishes type 1 from type 2 diabetes, but seronegativity does not exclude a diagnosis of type 1 diabetes. Eighty percent of type 1 diabetic patients are seropositive. GAD65 Ab also serves as a marker of predisposition to autoimmune diseases that frequently coexist with type 1 diabetes, e.g., Graves' disease, Hashimoto's thyroiditis, pernicious anemia, premature ovarian failure, Addison's disease (idiopathic adrenocortical failure), and vitiligo.²¹

GAD65 Ab prevalence is heightened in all autoimmune neurologic disorders (e.g., myasthenia gravis, Lambert-Eaton syndrome, neuromyotonia). Serum levels are highest in classic stiff-man syndrome (93% positive) and in acquired cerebellar ataxia, sporadic epilepsy, and nonparaneoplastic encephalomyelopathies. GAD65 Ab is the most recently recognized marker of thymoma-related neurological autoimmunity.²²

GAD is a neuronal enzyme involved in the synthesis of the neurotransmitter γ -aminobutyric acid (GABA) and is a major pancreatic islet cell and neuronal autoantigen. The serum level of GAD65 Ab in patients who have type 1 diabetes without a polyendocrine or autoimmune neurologic syndrome is generally <20 nmol/L and in those with polyendocrine disorders is generally ≥ 20 nmol/L. A second islet cell Ab (IA-2) is more predictive for development of type 1 diabetes, but the IA-2 Ab assay is less sensitive than the GAD65 Ab assay. Assays for gastric parietal cell Ab, thyroglobulin Ab, and thyroid peroxidase Ab complement GAD65 and IA-2 Abs in the serological evaluation of type 1 diabetes susceptibility.

About 8% of healthy subjects have low positive values. These are not “false-positives.” Values ≥ 0.03 nmol/L are consistent with susceptibility to autoimmune (type 1) diabetes and related endocrine disorders (thyroiditis and pernicious anemia).

Toxic effects of topical exposure include skin eruptions and epistaxis on contact. Ingestion leads to epigastric pain, vomiting, dysuria, and jaundice. The major target organ is the lung, where oxidative damage to the alveolar epithelium leads to fibrosis.⁶

Paraquat is a quaternary nitrogen herbicide used for broadleaf weed control. Toxicity in humans is associated with the generation of superoxide anion, which generates additional reactive oxygen species.⁶ Paraquat is not significantly biotransformed in humans. Elimination is mainly by the kidneys.

The chromophore formed in the colorimetric method is unstable.

Nearly all paraquat adsorbed on treated marijuana plants is pyrolyzed to dipyrpyridyl as the leaves burn. Paraquat treatment of leaves is not likely to increase the adverse effects of natural marijuana smoke on the lungs.⁷

DIAGNOSTIC INFORMATION

REMARKS

↑ Primary hyperparathyroidism; secondary hyperparathyroidism [e.g., chronic renal disease (up to 10 times the upper limit), pseudohypoparathyroidism, hereditary vitamin D dependency types I and II, vitamin D deficiency], Z-E syndrome, fluorosis, spinal cord trauma, pseudogout, familial medullary thyroid carcinoma, and MEN types I, IIa, IIb

↓ Autoimmune hypoparathyroidism; in surgical hypoparathyroidism associated with thyroidectomy (condition probably transient if PTH is detectable by RIA), sarcoidosis (even in the presence of renal failure), nonparathyroid hypercalcemia in the absence of renal failure, hyperthyroidism, hypomagnesemia, transient neonatal hypocalcemia, and DiGeorge syndrome

In normal individuals, intact “whole” PTH (amino acids 1-84) has a circulating half-life of ~5 min. Inactive carboxyl-terminal and midmolecule fragments (e.g., amino acids 53-84, 44-68, 35-64) make up ~90% of total circulating PTH. These fragments are cleared exclusively by the kidney and have half-lives of ~1-2 hr. A circulating amino-terminal fragment (amino acids 1-34) has an estimated half-life of 1-2 min; it is present in very small concentrations in blood. Only the intact PTH 1-84 and N-terminal PTH 1-34 possess biological activity. In addition to renal excretion, intact and N-terminal PTH is also removed from plasma by other mechanisms. Patients with chronic renal failure will have very high C-terminal/midmolecule PTH values even if parathyroid disease is absent.

PTH is detectable in infancy and increases in the early postnatal period. Circadian rhythm is observed with highest values at 2:00-4:00 PM, declining to baseline at 8:00 AM. Values in plasma are reported to be 5-10% lower than in serum. In humans, lowering of the plasma Ca by 1.5 mg/dL [0.38 mmol/L] may increase plasma PTH as much as 400%.

The C-terminal/midmolecule test measures the whole (intact) PTH molecule and carboxyl-terminal and midmolecule fragments.¹² The assay does not detect N-terminal fragments. In both normal and hyperparathyroid individuals, C-terminal and midmolecule fragments predominate. The test is ~85% sensitive and 95% specific for detecting hyperparathyroidism. For each assay system, PTH results must be used in conjunction with serum calcium data for meaningful clinical interpretation. Figure II-3 illustrates such data.

The N-terminal test measures both intact PTH molecule and amino-terminal fragments; it does not measure C-terminal and midmolecule fragments. The test is used mainly for evaluating patients with renal failure and patients with normal or equivocal results of other PTH assays. The bioassay is reported to be 75% sensitive for detection of primary hyperparathyroidism.

Most first-generation intact molecule assays are prone to falsely elevated results because of the presence of large PTH fragments in blood.^{8,9} These larger fragments of PTH include the N-terminal truncated (7-84) and the amino-PTH. The amino-PTH is formed from posttranslational modification of the PTH that makes it functionally inactive. The N-terminal truncated PTH is reported to act as a PTH antagonist with no biological activity. The clinical significance of the amino-PTH has not been determined. The second- and third-generation intact PTH assays are less prone to interference from these large PTH frag-

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>ments, and the enhanced assays measure only the biologically intact PTH molecule.⁹ Patients with chronic renal failure and renal bone disease are prone to present with higher levels of these large fragments. Clear distinction of primary hyperparathyroidism from hypercalcemia of malignancy is claimed. A good correlation with bone status in secondary hyperparathyroidism is reported. Most intact assays can also differentiate normal subjects from patients with hypoparathyroidism.¹³</p> |

↑ Humoral hypercalcemia of malignancy, lymphomas, squamous cell cancer, and breast cancer

Measurement of PTH-RP is useful clinically in differentiating primary hyperparathyroidism from hypercalcemia related to malignancy. The test is also useful as a marker in the management of patients with tumor-associated hypercalcemia.

Production of PTH-RP by the fetoplacental unit can cause transient increase during pregnancy, especially in the third trimester.⁷

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Chronic respiratory exposure can cause inflammation of the upper respiratory tract. Dermal exposure can cause dermatitis. There are limited data on oral exposure in humans, but animal studies indicate that pentachlorophenol affects liver, kidney, CNS, endocrine, and immune function.</p> <p>Pentachlorophenol toxicity is due, in part, to the uncoupling of oxidative phosphorylation.</p> | <p>Pentachlorophenol is used as a wood preservative in utility poles, railroad ties, and wharf pilings, and human exposure to this chemical usually is in the industrial setting. Plasma contains 99% of pentachlorophenol in whole blood. PCP is oxidized to tetrachlorohydroquinone, which is an inhibitor of glucuronidase.</p> <p>Conjugates must be hydrolyzed by hot acidic solutions before urine extraction.⁶</p> <p>The elimination half-life may be up to 20 days in chronically exposed persons.⁷</p> <p><i>Kinetic values</i></p> <p>$t_{1/2}$: 3-5 days⁶</p> <p>V_d: 0.35 L/kg</p> <p>PB: 99%</p> |
| <p>U ↑↑ Essential pentosuria</p> <p>U ↑ Fever, allergy, and cirrhosis</p> <p>U ↑ <i>Arabinose and xylose</i>: Alimentary pentosuria (<100 mg/day; <666 μmol/day)</p> <p>U ↑ <i>Xylulose</i>: Essential pentosuria (1.0-4.0 g/day; 7-27 μmol/day), cirrhosis</p> <p>U ↑ <i>Ribose</i>: Muscular dystrophy (<30 mg/day; <100 μmol/day)</p> | <p>Pentoses are reducing sugars. Their presence can be confirmed with Tollen's or Bial's test. Identification is obtained by TLC.</p> |

| Perchlorate Discharge (Flush) Test ^{1,2} Dose: 5 μCi ¹³¹ I orally | Perform standard uptake test at 1 hr; then give oral dose of 500 mg of liquid KClO ₄ and repeat ¹³¹ I-uptake 1 hr later. | Discharge should not exceed 10% [× 0.01 = >0.10-0.15, fraction discharge] of 1-hr uptake; i.e., 85-90% [0.85-0.90, fraction discharge] of the ¹³¹ I should be incorporated organically and not discharged by the perchlorate. | See <i>Thyroid Uptake of Radioactive Iodine, ¹³¹I or ¹²³I</i> . |
|---|--|--|---|

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Gastric and duodenal ulcers, Z-E syndrome, and acute and chronic superficial gastritis⁶</p> <p>↓ Gastrectomy, gastritis, gastric neoplasia, gastric resection, Addison's disease, and myxedema⁷</p> <p>Decreases with eradication of <i>H. pylori</i>⁸</p> | <p>Only PG II is found in the gastric antrum and proximal duodenum, Brunner's glands, and pyloric glands. Both PG I and PG II are found in serum, but PG II is not found in urine. Whereas an increased PG II level is a risk factor for gastric ulcer, a high level of PG I is a major risk factor for duodenal ulcer. In contrast to the low or undetectable levels of PG I seen in pernicious anemia, PG II levels in PA are normal. However, cheaper and more specific tests than the pepsinogens are available for identifying PA and Z-E syndrome, and endoscopy is preferred for diagnosing ulcers.</p> <p>Pepsinogen levels exhibit a diurnal pattern.⁷</p> <p>See <i>Pepsinogen I</i>.</p> |
| Ratio < 3.0 in gastric CA and chronic gastritis. ⁸ | |

| | |
|---|--|
| <p>This test is used to expose organification defects in patients who are euthyroid or hypothyroid and have an elevated radioactive iodine uptake test. Excessive discharge (loss) of accumulated radioactive iodine by perchlorate is seen in patients with inherited defects of organification of iodine and in those with Hashimoto's thyroiditis.</p> | <p>In the normal thyroid, iodide is trapped by an active transport mechanism and bound to thyroglobulin (Tg). Perchlorate selectively inhibits iodide trapping and releases (discharges) unbound iodide. The normal gland organifies most ¹³¹I, and only 10-15% of the accumulated radioactive iodine is lost after administration of perchlorate.</p> <p>The most common cause of an organification defect is Hashimoto's thyroiditis.</p> |

| pH (37° C)¹⁻³ <i>Potentiometry¹</i> | Whole blood, arterial (heparinized syringe); place on ice and send to the laboratory immediately. Do not ask patient to clench fist. To avoid dilutional errors and pH changes, do not use excess liquid heparin. | Cord blood ⁹ Arterial: 7.28 ± 0.05 (SD) Venous: 7.35 ± 0.05 Newborn Premature, 48 hr: 7.35-7.50 Full term Birth: 7.11-7.36 5-10 min: 7.09-7.30 30 min: 7.21-7.38 1 hr: 7.26-7.49 1 day: 7.29-7.45 | ↑ V Acetates, antacids, aspirin (initially respiratory alkalosis), carbenicillin, carbenoxolone, citrates, diuretics (e.g., bumetanide, ethacrynic acid, furosemide, thiazides), glutamic acid, glycyrrhiza (licorice), lactate, laxatives (chronic use), mafenide (respira- |
|---|---|--|--|

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p><i>Positive:</i> Lymphoblasts of ~67% of cases of acute lymphoid leukemia (ALL, FAB L1 and L2), coarse granules or blocks of PAS-positive material, acute monocytic leukemia (FAB M5, discrete granules in blasts of some cases), erythroblasts of some cases of erythroleukemia (FAB M6) and some cases of myelodysplastic syndrome, lymphocytes of Sezary syndrome, hairy cells of hairy cell leukemia, lymphocytes of glycogenosis type II (Pompe's disease), and Dutcher bodies in plasmacytoid lymphoma</p> <p><i>Less positive:</i> Erythroblasts of some cases of iron deficiency and thalassemia, lymphocytes of some cases of chronic lymphocytic leukemia (CLL), Hodgkin's disease, non-Hodgkin's lymphoma, and infectious mononucleosis</p> <p><i>Negative:</i> Lymphoblasts of ALL (FAB L3 or Burkitt lymphoma), megaloblasts of nutritional megaloblastic anemia (although a minority opinion holds that megaloblasts of pernicious anemia are positive)</p> | <p>PAS stains intracellular glycogen, polysaccharides, mucoproteins, and glycoproteins. Except for pigment in macrophages largely derived from cell debris, the PAS-positive material in blood and marrow cells is predominantly glycogen. Glycogen does not stain with PAS after treating the slides with amylase. The PAS reaction cannot be used to distinguish between ALL and acute myeloid leukemia (AML) or between benign and malignant lymphocytic disorders.</p> |
| <p>B, P ↑ <i>Metabolic alkalosis</i> (plasma bicarbonate excess)</p> <p><i>Excessive alkali administration</i> (see <i>Interferences</i>) <i>Loss of gastric HCl or gastric aspiration</i></p> <p><i>Potassium depletion:</i> Gastrointestinal loss (e.g., chronic diarrhea), lack of potassium intake (e.g., anorexia nervosa, IV fluids without potassium supplements for treatment of vomiting or postoperatively), diuresis (see <i>Interferences</i>), excess of adrenal steroids (e.g., primary aldosteronism, Cushing's disease) or administration of steroids, large amounts of licorice, glycogen</p> | <p>pH compatible with life is 6.80-7.80. The arteriovenous pH difference is 0.01-0.03 but is greater in patients with congestive heart failure and in shock. Arterialized capillary blood has been recommended as a suitable substitute for arterial blood. However, in decreased cardiac output when the systolic pressure is <95 mm Hg [<12.64 kPa] or when there is vasoconstriction, capillary blood yields unreliable data. Special care must be taken not to expose the sample to air. The pH of freshly drawn blood decreases on standing at a rate of 0.04 to 0.08 pH unit/hr at 37° C, by ~0.03 pH unit/hr at 25° C, but by only 0.008 pH unit/hr at 4° C. Changes are greater in leukemia.</p> |

Hema-Combistix, Combistix, Multistix, Bili-Labstix, Labstix⁴; BMC Chemstrips)^{1,5-7}</i> | Urine, fresh random. ³ | Newborn: | 5-7 | ↑ V Acetazolamide, aldosterone, amiloride, amphotericin B, carbenoxolone, epinephrine, mafenide, niacinamide, phenacetin, potassium citrate, and sodium bicarbonate |
| | Perform test immediately; otherwise, store | Thereafter: | 4.5-8 | |
| | filled container and refrigerate. Mix well after storage; do not | Average: | 5-6 | |
| | centrifuge. | | | ↓ V Acid phosphate, ammonium chloride, ascorbic acid, corticotropin, diazoxide, methenamine |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| deposition, chronic alkalosis, and potassium-losing nephropathy | If the analysis is to be performed on plasma, the blood must be warmed to 37° C before separation of red cells from plasma by centrifugation, or else falsely high pH values are obtained. pH values decrease with increase in body temperature and vice versa. Corrections must be made. See nomogram, Fig. II-2. The bicarbonate concentration can be calculated from the PCO ₂ and pH (see Fig. II-1). |
| <i>Respiratory alkalosis</i> (decreased dissolved CO ₂): Hysteria; stimulation of the respiratory center by increased intracranial pressure or brainstem lesions with normal lung function; stimulation of the respiratory center by hypoxia with normal overall alveolar diffusion of CO ₂ , fever, salicylate poisoning (early); and excessive artificial ventilation | |
| B, P ↓ <i>Metabolic</i> (bicarbonate deficit) <i>Increased formation of acids</i> : Ketosis (e.g., diabetes mellitus, starvation, hyperthyroidism, high-fat and low-carbohydrate diet, after trauma), cellular hypoxia including lactic acidosis | |
| <i>Decreased excretion of H⁺</i> : Renal failure (prerenal, renal, postrenal), renal tubular acidosis, Faconi's syndrome, acquired (drugs, hypercalcemia), inherited (cystinosis, Wilson's disease), ureterocolic anastomosis, Addison's disease | |
| <i>Increased acid intake</i> (e.g., ion-exchange resins, salicylates, ammonium chloride) | |
| <i>Increased loss of alkaline body fluids</i> : Intestine (e.g., diarrhea, fistulas, aspiration of contents), biliary (biliary and pancreatic fluids), renal (carbonic anhydrase inhibitors), and secondary to other metabolic disorders (excess potassium) | |
| <i>Respiratory acidosis</i> : Acute, caused by decreased alveolar ventilation (emphysema, pneumonia, pulmonary edema, bronchoconstriction, plugs, drugs depressing the respiratory center); congestive heart failure; chronic (with bicarbonate increase) obstructive or restrictive pulmonary disease | |
| U ↑ Diet high in fruits and vegetables, especially citrus fruits; metabolic alkalosis without potassium depletion, prolonged vomiting or gastric suction, respiratory alkalosis, urinary tract infection with urea-splitting organisms (e.g., <i>Proteus</i> or <i>Pseudomonas</i>), after meals (alkaline tide), renal tubular acidosis, ¹² Fanconi's and Milkman's syndrome (increased loss of HCO ₃ ⁻), and alkali therapy ⁸ | On standing, pH tends to increase because of formation of ammonia by microorganisms. Urine containing glucose may have decreasing pH as microorganisms metabolize the glucose. Therefore "standing" renders the sample unacceptable for pH measurement. pH of 9 is associated with improperly preserved samples. ⁷ |
| U ↓ Diet high in meat protein or cranberries, metabolic acidosis (e.g., diabetic), metabolic alkalosis resulting from potassium depletion, respiratory acidosis, starvation diets, and severe diarrhea | Bacterial infections can alter the pH in either direction, depending on the end products of bacterial metabolism. Persistently acid urine may indicate a predisposition to uric acid calculi. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Toxic effects include headache, dizziness, hyperpnea, weakness, and pulmonary, hepatic, or renal effects.</p> <p><i>o</i>-Cresol and <i>m</i>-cresol are normally not present in urine. Any detectable amount indicates exposure.</p> | <p>These substances are corrosive and are widely used in cleaning solutions as disinfectants. Absorption may occur by inhalation or by skin contact.</p> <p>Colorimetric methods are nonspecific.</p> <p><i>Kinetic values</i> TLV: 5 ppm (19 mg/m³)</p> |
| <p>P ↑ Hyperphenylalaninemias, sepsis, severe burns,¹⁶ transient tyrosinemia of the newborn, transient hyperphenylalaninemia of the newborn, phlebotomus fever, viral hepatitis, and hepatic encephalopathy. Immature liver particularly in premature newborn</p> | <p>Cord blood cannot be used for analysis. Two days of protein feeding are recommended before specimens are obtained. False-negative results are seen if protein intake is inadequate. False-positive results are seen in premature infants as a result of liver immaturity. Antibiotics will interfere in the assay, and results cannot be interpreted. All positive results must be confirmed with a quantitative chemical test or chromatography.</p> <p>In normal newborns, a diurnal variation of Phe is seen; highest levels occur at 7:00 PM and lowest levels occur at 7:00 AM.</p> <p>Hyperphenylalaninemia can result from a deficiency of phenylalanine hydroxylase (classic PKU) or from defects associated with the enzyme cofactor tetrahydrobiopterin (BH₄). BH₄ defects can be caused by a deficiency of dihydropteridine reductase (DHPR) or by a defect in biopterin biosynthesis. BH₄ defects account for 1-3% of patients with hyperphenylalaninemia.</p> <p>Specimens for measuring DHPR in blood and pteridines in urine are obtained if elevated phenylalanine levels are found. See <i>Dihydropteridine Reductase</i>.</p> <p>See also Table II-2A.</p> |
| <p>U ↑ Hyperphenylalaninemias, Hartnup disease, first trimester of pregnancy (levels decrease thereafter), oasthouse disease, cystinosis, and hepatolenticular degeneration</p> | |

| Phosphatidylglycerol (PG) <i>ID-TLC</i> ¹ (Commercially available with L/S ratio as Fetal Tek 200 from Helena, Beaumont, TX; see <i>L/S ratio</i> .) | Amniotic fluid, 3-4 mL minimum. (See <i>L/S ratio</i> for additional information.) | Absent: Fetal lung immaturity Present: Fetal lung maturity | ↑ C Excessive meconium contamination (>3%) can mimic the presence of PG by some methods. ^{5,6} Vaginal pool specimens may contain PG-producing flora. ⁷⁻¹⁰ |
| <i>Slide agglutination (Amnio-Stat-FLM)</i> ^{2,3} | Amniotic fluid, 0.025 mL. Excessive centrifugation may sediment PG and lead to falsely lowered results. ⁴ (See <i>L/S ratio</i> for additional information.) | <i>mg/L</i> High-positive: >2.0 ³ Low-positive: >0.5 Negative: <0.5 | None found. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| ↑ Ethanol intake | <p>Phosphatidylethanol (PE) is an aberrant phospholipid formed within cell membrane only in the presence of ethanol. The formation of PE is catalyzed by phospholipase D, which normally catalyzes the hydrolysis of phospholipids to phosphatidic acid.</p> <p>The rate of degradation of PE is slower than that of formation, with a half-life of ~4 days. Because of the high specificity and prolonged elimination, PE has been suggested as a long-term marker of alcohol intake.</p> |
| <p>High values of PG are reliable indicators of lung maturity even in samples with an immature L/S ratio. The absence of PG or presence of low levels cannot dependably predict the presence or absence of RDS.¹ By densitometry the cutoff point for maturity is PG = 2-3% of total phospholipid.¹¹ Because TLC methods for PG differ in sensitivity, laboratories should use this quantitative measure to guide qualitative assessment of PG.^{12,13}</p> | <p>PG and phosphatidylinositol (PI) serve to stabilize surfactant, although PG-deficient surfactant can have normal properties. The concentration of PG increases significantly after ~34 wk gestational age.¹</p> |
| <p>Diabetes, regardless of glucose control, delays PG production. Many diabetic patients will deliver term infants with mature surfactant status before PG is detected.^{14,15}</p> | <p>Measurement of PG is an especially valuable marker of fetal lung maturity when amniotic fluid samples are contaminated with moderate amounts of blood or <3% meconium. These substances will not cause interference in the majority of methods for detection of PG but will interfere in most other tests for fetal lung maturity.¹⁹</p> <p>This test is often combined with the L/S ratio and phosphatidylinositol (PI) to produce a “lung profile.”^{7,11,20} (See also <i>L/S Ratio</i>.)</p> |
| <p>A high-positive result (PG >2 mg/L) is reported to correlate 100% with the absence of RDS.¹⁶ A low-positive result (PG >0.5 mg/L) also has a high correlation with fetal lung maturity.¹⁷ The predictive value of this test for maturity is 98-100%, but the test is a very poor predictor for immaturity (40%).¹⁸</p> | <p>The test uses an antibody to PG. Advantages include rapid turnaround time, no interference from blood, meconium, and bilirubin, and the small volume of sample required.</p> |

DIAGNOSTIC INFORMATION

REMARKS

The measurement of total PL takes advantage of the fact that all PL contain a lipid-bound phosphate group. The most common enzymatic method uses phospholipase D to hydrolyze PC to free choline. The method is specific for PC, which accounts for ~95% of the total PL in plasma. This method does not require lipid extraction and is easily automated.

S ↑ Osteolytic metastatic bone tumors, myelogenous leukemia, sarcoidosis, milk-alkali syndrome, vitamin D intoxication, healing fractures, renal failure, hypoparathyroidism, pseudohypoparathyroidism, diabetes mellitus with ketosis, malignant hyperpyrexia following anesthesia, acromegaly, portal cirrhosis, pulmonary embolism, lactic acidosis, and respiratory acidosis

S ↓ Osteomalacia, steatorrhea, renal tubular acidosis, growth hormone deficiency, acute alcoholism, gram-negative bacterial septicemia, hypokalemia, familial hypophosphatemic rickets, vitamin D deficiency, severe malnutrition, malabsorption, severe diarrhea, vomiting, nasogastric suction, primary hyperparathyroidism, PTH-producing tumors, familial hypocalciuric hypercalcemia, severe hypercalcemia of any cause, acute gout, salicylate poisoning, respiratory infections, treatment of diabetes mellitus (hyperinsulinemia), respiratory alkalosis, osteoblastic metastases of cancer, renal tubular defects (e.g., Fanconi's syndrome), and diuretic phase of severe burns

Serum phosphorus concentrations have a circadian rhythm (highest level in late morning, lowest in evening) and are subject to rapid change secondary to environmental factors such as diet (carbohydrate), phosphate-binding antacids, and fluctuations in growth hormone, insulin, and renal function. There is a seasonal variation with maximum levels in May and June (lowest levels in winter). During first decade of menopause values increase ~0.2 mg/dL [~ 0.06 mmol/L]. Bed rest causes increase up to 0.5 mg/dL [0.16 mmol/L]. Ingestion of food may cause a transient decrease in blood levels. Low values are also seen during menstruation.

Serum or plasma should be separated from erythrocytes soon after the specimen is collected; otherwise, the phosphatase and inorganic phosphates present in the red cells will interfere and give falsely high values.

Hypophosphatemia is found in about half of the cases of primary hyperparathyroidism. The measurement of TRP (tubular reabsorption of phosphate) has been suggested as an adjunct test for diagnosis of 1° hyperparathyroidism.⁸ (See *Tubular Reabsorption of Phosphate*.)

DIAGNOSTIC INFORMATION

REMARKS

Plasminogen can be measured with a functional assay or antigenic (immunologic) assay. The functional (activity) is typically a chromogenic assay. A qualitative deficiency will not be detected with an antigenic assay.

↑ Acute phase reactant, myocardial infarction, deep vein thrombosis, sepsis, malignancy, hyperlipoproteinemia, hypertriglyceridemia, and pregnancy (in third trimester)

↓ Rare bleeding disorder resulting from hyperfibrinolysis secondary to PAI-1 deficiency

Plasminogen activator inhibitor-1 (PAI-1) is a glycoprotein in the normal fibrinolytic system. It is a potent inhibitor of tissue-plasminogen activator (t-PA) and urokinase plasminogen activator (u-PA). A deficiency or excess of PAI-1 has been associated with either bleeding or thrombosis, respectively. The predictive value of a high PAI-1 is uncertain, and there are insufficient data to recommend PAI-1 in evaluating thrombophilia.

PAI-1 is a rarely performed test for investigation of the fibrinolytic system. PAI-1 *activity* is measured by a functional chromogenic test. The PAI-1 *antigen* is measured by ELISA. Because PAI-1 may be free or t-PA bound, reference ranges have been difficult to establish.

An abnormal platelet aggregation study may be associated with hereditary and acquired disorders of platelet adhesion, activation, and aggregation. Interpretation of an abnormal profile should be done with caution since several factors (e.g., aspirin, garlic) may interfere with this test.

Glanzmann's thrombasthenia: Lack of glycoprotein IIb/IIIa; absent aggregation with ADP, collagen, epinephrine, and thrombin; normal agglutination with ristocetin

Platelet aggregation studies evaluate qualitative (functional) platelet disorders. These may include hereditary or acquired disorders of platelet adhesion, activation/release, or aggregation and are generally associated with variable degrees of bleeding. This study is usually performed after screening tests for bleeding disorders (PT, PTT, platelet count, vWD workup) are normal.

DIAGNOSTIC INFORMATION

REMARKS

Bernard-Soulier syndrome: Lack of glycoprotein Ib; normal aggregation with ADP, collagen, and epinephrine; lack of agglutination with ristocetin. Unlike von Willebrand's disease, agglutination with ristocetin is not corrected on addition of normal plasma.

Storage pool deficiency (Chédiak-Higashi syndrome, glycogen storage disease type I, gray platelet syndrome, Hemansky-Pudlak syndrome, TAR syndrome, Wiskott-Aldrich syndrome): Platelet aggregation may be abnormal with variable-decreased epinephrine and ADP (frequently because of absence or decrease in secondary ADP release).

Cyclooxygenase deficiency: Abnormal platelet aggregation caused by the inability to activate prostaglandin pathway; aspirin-like defect.

von Willebrand's disease: Normal aggregation with ADP, collagen, and epinephrine; absent or reduced agglutination with ristocetin (except in type IIB where abnormal agglutination with a low concentration of ristocetin occurs).

Acquired disorders of platelets also affect the platelet aggregation studies: uremia, paraproteinemia, and DIC, collagen-vascular disorders (Marfan's syndrome, osteogenesis imperfecta), and myeloproliferative disorders (essential thrombocythemia, polycythemia vera, CML).

Functional platelet disorders can be differentiated by the use of several aggregating agents, typically epinephrine, ADP, arachidonic acid, collagen, and ristocetin. Because aggregation is dependent on platelet count, the platelet count should be $>100,000$.

Drugs, typically aspirin, nonsteroidal antiinflammatory drugs, and platelet-inhibiting medications, are the most common cause of an abnormal platelet aggregation study: the patient should refrain from taking aspirin within 7-10 days of the test.

Interpretation of a platelet aggregation study is difficult and should always be interpreted in the context of the patient's clinical history. Otherwise normal individuals may have "abnormal" profiles (e.g., some individual's platelets do not aggregate with epinephrine).

Electron microscopy may be necessary for assessment of granular content. Newer methods for assessment of platelet function are also available, including the PFA-100, an automated whole blood platelet function analyzer, and flow cytometry.

Autoantibodies measured as IgG occur in $>90\%$ of patients with chronic ITP.

Note: Patients with nonimmune thrombocytopenias may have false-positive results.

Platelet antibodies may be alloimmune or autoimmune. Clinically significant platelet alloantibodies include those associated with neonatal immune thrombocytopenia, posttransfusion purpura, and platelet refractoriness caused by HLA antibodies. Idiopathic thrombocytopenic purpura (ITP) is associated with autoimmune platelet antibodies.

Alloantibodies are most commonly directed at the human platelet antigen referred to as HPA-1a (also known as PI^{A1}). In contrast, ITP autoantibodies typically target platelet glycoproteins IIb/IIIa (CD41) or less commonly Ib/IX (CD42).

Several methods with variable sensitivity and specificity are available, and no method detects all antibodies. Routine use of

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| | <p>these platelet antibody assays is generally not recommended; in selected cases (i.e., refractory ITP) these studies may be of value.</p> |
| | <p>A direct assay for the measurement of platelet-bound antibodies is more informative than detection of unbound plasma antibody. A combination of a sensitive binding assay such as a platelet immunofluorescence test (PIFT) along with an antigen capture immunoassay is recommended. The PIFT can be measured by fluorescence microscopy or flow cytometry and will detect platelet-associated immunoglobulins (commonly IgG in autoimmune thrombocytopenia). An antigen capture immunoassay (monoclonal antibody immobilization of platelet antigens) may differentiate between platelet-specific antibodies (anti-HPA) and HLA antibodies or detect platelet-specific glycoproteins. ELISA kits are also available that will detect specific antibodies against platelet glycoproteins or HLA class I antigens.</p> |
| | <p>Molecular genotyping by PCR analysis is also available for identifying polymorphism of platelet glycoproteins.</p> |
| <p>↑ von Willebrand disease (except type 2N); other hereditary or acquired platelet function disorders</p> | <p>The PFA-100 test system allows for a rapid and simple assessment of platelet function in primary hemostasis.</p> <p>The system comprises disposable test cartridges and an analyzer. An aliquot of whole blood is aspirated into a capillary system under high shear stress, simulating a damaged blood vessel wall. The system measures the ability of platelets to occlude an aperture in a biologically active membrane treated with collagen and ADP or collagen and epinephrine.</p> <p>The PFA-100 is a more sensitive test than the bleeding time for the screening of patients with vWD.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| Determination of human platelet antigen genotype offers a reliable alternative to serologic phenotyping. The test is most widely used in the evaluation of neonatal alloimmune thrombocytopenia. Other indications are posttransfusion purpura and platelet refractoriness caused by antibodies directed against platelet-specific antigens. | Platelet genotyping has largely replaced determination of platelet antigens by serological methods. Advantages of genotyping methods are that they can be readily performed in situations where serotyping cannot be used or is of limited utility, such as in typing for HPAs for which reliable serotyping reagents are rare, in thrombocytopenic states, in the presence of HLA class I antibodies, and in prenatal testing. |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>Toxic exposure may cause fatigue, joint pain, dizziness, and skin eruptions. Serum concentrations >0.001 mg/L are associated with a 14% incidence of increased ALT (SGPT). Increased urinary porphyrin excretion has also been correlated with elevated serum PBBs.</p> <p>Four epidemiologic studies have been conducted on workers at facilities where flame-retardant polymers were extruded. The workers were potentially exposed to brominated flame retardants, including PBDEs. These studies found no adverse effects attributable to exposure to these chemicals.⁴</p> | <p>PBBs are highly lipophilic. Excretion is slow (0.1% in urine and 6.6% in feces over 42 days). PBBs and PBDEs are fire retardants. Widespread contamination occurred in Michigan in 1975.</p> |
| <p>Toxic exposure causes local skin irritation leading to chloracne and neurological manifestations, including headache, nervousness, fatigue, and dizziness. Elevation in AST (SGOT) has been reported. PCBs accumulate in fish.</p> | <p>PCBs are highly lipophilic. The rate of elimination is a function of the metabolic rate, which in turn depends on the extent of chlorination. Highly chlorinated derivatives are extremely long lived. PCBs were formerly widely used in industry as coolant and insulator fluids, but their manufacture in the U.S. was halted in 1977. Electrical devices manufactured before 1977 may contain PCBs, and the compounds are a common environmental contaminant because of historically heavy industrial usage.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ During crisis in acute hepatic porphyrias (acute intermittent, variegate, and hereditary coproporphyria), may be slightly elevated in porphyria cutanea tarda.</p> <p>See Table II-9.</p> | <p>Uroporphobilinogen (PBG) excretion in urine increases in acute porphyric attacks, and the measurement of PBG is particularly important in diagnosing the acute porphyrias (acute intermittent porphyria, hereditary coproporphyria, and variegate porphyria) during the acute stage. Markedly increased urine PBG is diagnostic for acute porphyria.⁶ A qualitative test on random urine during the attack is the most common test used for diagnosis. However, the qualitative test should be confirmed with the quantitative test, performed on 24 hr urine, and by measuring porphyrins. If the diagnosis of acute porphyria remains a possibility, the quantitative test should be performed even in face of a negative qualitative test.</p> <p>Porphobilinogen quantitation by LC-MS/MS is both sensitive and specific. Mild PBG elevations can be detected between acute events in AIP. Mild PBG elevations (3.0-15 mg/24 hr) can be observed in affected yet asymptomatic (never had symptoms) postpubertal family members of patients with diagnosed AIP. This test has become very useful in family studies, identifying asymptomatic individuals who can be counseled to avoid substances/conditions known to precipitate acute episodes.</p> |

(Table II-10). |
| | Feces, pea-sized solid sample. ^{5,6} Protect from light. | Negative or trace | |
| | Plasma (heparin). ⁷ Sep- arate from cells; avoid hemolysis. | No emission peak at 626 nm, with excitation at 405 nm. | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↓ Acute intermittent porphyria (AIP)</p> <p>See also Table II-9.</p> | <p>AIP is an autosomal dominant acute hepatic porphyria that results from 50% decrease in activity of the PBG-D enzyme. Approximately 5% of patients with AIP will have normal PBG-D activity. The PBG deaminase assay can be used to confirm the diagnosis of AIP based on biochemical findings and to differentiate AIP from other acute porphyrias (variegate and hereditary coproporphyria). There is genetic heterogeneity in AIP mutations, but most appear to lead to decreased erythrocyte PBG deaminase activity and similar clinical presentations. The assay can be used to identify family members with genetic defect and latent symptoms (for genetic counseling and avoidance of precipitating drugs); however, young erythrocytes (accelerated hematopoiesis) have higher enzyme activity that could mask the diagnosis.</p> <p>There are ~170 different mutations in the PBGD gene. Molecular testing may be performed on families in which a diagnosis of AIP has been confirmed.</p> |

The porphyrias are uncommon disorders of the heme biosynthesis. However, because the clinical features of the porphyrias are wide and variable, they are included in the differential diagnosis of many diseases. Therefore acute care hospital laboratories should have available simple and reliable methods to exclude the porphyrias and to identify individuals who need more specialized methods for investigation of porphyria.¹ Please also refer to the sections on porphobilinogen and aminolevulinic acid testing. See Table II-9.

Use of qualitative porphyrin tests for urine and feces is not recommended because of their inaccuracies and the simplicity of quantitative fluorometric screening tests (see below).^{5,8}

Screening plasma specimens fluorimetrically for protoporphyrin-protein complexes can be helpful in differentiating variegate porphyria (VP) from other porphyrias.² The complex of variegate porphyria, excited at 405 nm, has an emission peak at 626 nm. Plasma fluorescence seen in porphyria cutanea tarda (PCT), acute intermittent porphyria (AIP), and hereditary coproporphyria (HCP), excited at 398 nm, has an emission peak at 619 nm; plasma fluorescence in protoporphyrin, excited at 409 nm, has a peak at 634 nm.

DIAGNOSTIC INFORMATION

REMARKS

See Table II-9.

“First-line” screening tests for porphyrins are generally quantitative, but they do not identify individual porphyrin species or isomers. There are numerous published methods, and some of the most commonly used ones are referenced. All are rapid and convenient. However, because there is never a need to determine porphyrins urgently, as there is for porphobilinogen in the acute porphyrias (see *Porphobilinogen*), an argument can be made that fractionation and quantitation of individual porphyrin species with HPLC methods is the best way to “screen” for disorders in porphyrin metabolism (see below).

For whole blood, the determination of total porphyrin includes both Zn-protoporphyrin (Zn-PP) and nonchelated or “free” protoporphyrin within the erythrocytes. If the total is elevated, then the gentler ethanol extraction method¹⁷ differentiates Zn-PP from protoporphyrin IX. This will allow diagnosis of protoporphyria (no increase in Zn-PP). HPLC fractionation of protoporphyrins from washed Ercs can also be performed⁴ to quantitate free and zinc protoporphyrin.

See Table II-9.

The interpretation of porphyrin elevations in urine and stool is complex. Patients with symptoms suggestive of the clinical porphyrias should be referred to an expert to avoid misdiagnosis, which is very common. Generally the porphyrias show marked elevations of particular heme precursors in particular fluids or tissues; the pattern and character of these elevations can aid in reaching a correct diagnosis. Minor elevations in urinary or stool porphyrins are usually nonspecific findings but often cause physicians who are not expert to label their difficult patients with a diagnosis of one of the rare porphyrias. Although reference intervals are cited, the degree of porphyrin elevation varies considerably.

Quantitative analysis of fecal porphyrins may be particularly helpful if porphyrin isomers are separated and separately quantitated.³ Fecal porphyrin analysis in this manner can distinguish between the acute porphyrias, with values being normal to mildly elevated in AIP, whereas HCP has elevated coproporphyrins with and increased coproporphyrin III to coproporphyrin I ratio (ratio 10-20:1 with normal ratio <1.2:1), and VP with increased coproporphyrins and protoporphyrins (protoporphyrin exceeding coproporphyrin) and an elevated coproporphyrin III:1 ratio (ratio 5-10:1).

DIAGNOSTIC INFORMATION

REMARKS

S, P ↑ *Increased supply of potassium:* Rapid K infusion, failure to stop K therapy when depletion has been corrected

Redistribution of potassium in the body [gain of K by extracellular fluid (ECF) from cells]: Massive hemolysis, severe tissue damage, severe acute starvation (as in anorexia nervosa), hyperkinetic activity (as in status epilepticus), malignant hyperpyrexia after anesthesia, hyperkalemic periodic paralysis (attacks occur especially 30-40 min after exercise), acidosis, and dehydration

Reduced renal excretion of potassium: Any cause of acute renal failure with oliguria or anuria and acidosis, end stage of chronic renal failure with oliguria (GFR <3-5 mL/min), Addison's disease, hypofunction of renin-angiotensin-aldosterone system, pseudohypoaldosteronism, other states with sodium depletion, after severe exercise (especially in individuals taking β -blockers), in shock, in presence of severe hemolysis, and in tissue ischemia

S, P ↓ *Reduced potassium intake:* Chronic starvation, dilution of extracellular K during prolonged administration of potassium-poor fluids when no additional K salts or potassium-containing foods are being taken by mouth (e.g., postoperative states)

Loss of potassium from the body

In intestinal secretions: Prolonged vomiting, diarrhea, loss because of intestinal fistulas, villous adenoma of the intestine

In urine: Renal tubular acidosis, renal tubular failure, Fanconi's syndrome, primary and secondary aldosteronism, Cushing's syndrome, Bartter's syndrome, osmotic diuresis (e.g., of hyperglycemia), alkalosis, in diabetic ketosis during gluconeogenesis; during administration of ACTH, cortisone, or testosterone

In sweat: Cystic fibrosis

S, P ↓ *Redistribution in the body (loss into cells):* Glucose and insulin therapy, familial periodic paralysis, loss of K from ECF by more than one route (into cells and urine in alkalosis and

Spuriously elevated serum K levels may be obtained in the following circumstances: Exercise of arm with occlusive cuff in place (may result in an increase of plasma K levels of 10-20%); hemolysis of blood sample or delayed separation of plasma from erythrocytes (hemolysis of 0.5% of the erythrocytes can increase serum K^+ level by 0.5 mmol/L); release of K from platelets during clotting if serum is used; chronic lymphatic leukemia with very high leukocyte counts if the blood sample is left at room temperature, thrombocytosis ($>1000 \times 10^9/L$), and leukemia.

There is a diurnal variation in serum K level (minimum at ~10:00 PM, maximum at 8:00 AM). Normal adults when deprived of a normal K intake continue to excrete 20-30 mmol of K/day for 4 days before the excretion rate decreases. Administration of NaCl to potassium-depleted patients will cause a further loss of K in the urine. In metabolic alkalosis with good renal function, plasma K concentrations are usually decreased; in metabolic alkalosis with poor renal function there is K deficiency, but the plasma K level is normal or elevated.

Clinical symptoms of hypokalemia (tiredness, weakness, hyporeflexia, and finally ventricular fibrillation) may occur at <2.0 mmol/L, especially if the decrease in K concentration is sudden. Hyperkalemia results in muscular irritability. ECG shows peaked T waves, and concentrations >7.0 mmol/L may be dangerous.

A calculation of the trans-tubular potassium gradient (TTKG) is useful for diagnosing the cause of hyperkalemia¹⁷:

$$TTKG = \frac{\text{urine}_K}{\text{plasma}_K} \div \frac{\text{urine}_{\text{osm}}}{\text{plasma}_{\text{osm}}}$$

The TTKG in a normal person on a normal diet is 8-9. With a high potassium intake, more potassium is excreted and the TTKG is >10 . During low potassium intake and hypokalemia, the TTKG should normally be reduced to <3 . A TTKG <7 during hyperkalemia may indicate a mineralocorticoid deficiency, especially if accompanied by hyponatremia and hyponatriuria.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ This protein is the major pregnancy-associated serum protein. Levels increase 20- to 100-fold during a normal gestation and are detectably increased within a few weeks of conception. Levels of 100 mg/dL [1 g/L] are not uncommon in late pregnancy. Serum levels also increase in both men and women during administration of estrogen. Increases have also been reported in patients with a variety of neoplastic and immunological disorders; however, because alterations in normal estrogen metabolism also may occur as a result of malignancy or therapy, the meaning of these increases is uncertain.</p> | <p>This large globulin is synthesized in the liver; it is also found to be synthesized in certain nonhepatoma neoplastic cell lines in vitro and in hepatitis B virus infections.⁵ Tissue localization has identified the protein in the syncytiotrophoblast and on the surface of B lymphocytes and monocytes. The function of PZP is uncertain, but there is good evidence that its function is to clear proteinases from the circulation by the formation of complexes. PZP may also be an acute phase reactant. The protein exhibits considerable homology with α_2-macroglobulin.</p> <p>MW: 360,000.</p> |
| <p>↓ A level of PZP below the expected value for the end of the first and the second trimester is often associated with a fetus at risk.</p> | |

DIAGNOSTIC INFORMATION

REMARKS

The pattern of the decrease of AF progesterone toward the end of pregnancy is contrary to its continued increase in maternal and fetal serum. Nonimmunologic techniques give much higher values.

Test is used primarily for identifying patients with breast cancers likely to respond to either additive or ablative hormone therapies.

Patients positive for PRP and estrogen receptor protein (ERP, see also *Estrogen Receptor Protein*) have a higher percentage (75-80%) response to hormonal therapy than do women positive for either ERP or PRP alone. Only 40-50% of ERP-positive, PRP-negative patients respond; 25-30% of ERP-negative, PRP-positive show a response. Response is observed in only $\leq 10\%$ of patients who are negative for both ERP and PRP. The percentage of positive specimens is greater in postmenopausal women than in those who are premenopausal. Receptor status is also influenced by age.

Patients who are hormone-receptor positive have a better prognosis for disease-free survival and overall survival than those who are receptor negative. The definition of positive or negative may vary from one laboratory to the next. Results can vary because of tissue and antibody treatment and antibody specificity.^{3,5}

Estrogen receptors are a part of the nuclear steroid hormone receptor family and play a role in hormone-directed transcriptional activation. Similar to estrogen receptors, progesterone receptors also consist of two separate receptors; however, in contrast to the estrogen receptors, the progesterone isoforms are transcribed from the same gene.^{1-3,5}

Estrogen and progesterone receptors can be measured by quantitative ligand binding assays (DCC) and immunoassays and semiquantitative/qualitative immunocytochemical assays.

IHC measures receptors in the invasive carcinoma cells and not intraductal carcinoma or normal breast tissue in contrast to ligand binding methods and are not influenced by the presence of estrogens, antiestrogens, or steroid-binding proteins.

Although clinical data and guidelines for the use of estrogen and progesterone receptors were primarily developed using older techniques such as DCC, immunohistochemistry is considered equivalent or superior and is the preferred method in clinical practice.^{3,6,7}

The American Society for Clinical Oncology, among other groups, recommends measurement of estrogen and progesterone receptors in primary breast cancers.^{5,6}

↑ Familial hyperproinsulinemia, pancreatic β -cell tumors (insulinomas), islet β -cell secretory defects, chronic renal failure, hyperthyroidism, cirrhosis, severe hypoglycemic hyperinsulinemia, and independent risk factors for death and morbidity of coronary heart disease in nondiabetic persons.⁹

Elevation of the proinsulin:insulin ratio has been used as an indirect marker of β -cell function.^{10,11} The elevation of the ratio correlates with a decreased acute illness response to glucose in type 2 diabetic patients.¹⁰ The increased ratio is also predictive of the development of type 2 diabetes.¹²⁻¹⁴

Proinsulin ($t_{1/2}$, 17 min) is cleared from plasma much more slowly than insulin ($t_{1/2}$, 5 min). In the fasting state, proinsulin-like immunoreactivity in peripheral blood accounts for ~10-20% of the total immunoreactive insulin on a molar basis.⁷ In the pancreatic islet cells, the amount of proinsulin is <5% that of insulin.

Proinsulin immunoassays using proinsulin-specific polyclonal and monoclonal antibodies and biosynthetic human standards are available. Cross-reactivities of these antibodies with insulin or C-peptide are claimed to be low (<1%). However, substantial cross-reactivities with proinsulin conversion intermediates occur in many assays, and caution should be used in interpreting results.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>There is no response in hypothalamic disease and in some patients with PRL-secreting tumors.</p> | <p>This test is used to assess pituitary PRL reserve. In healthy individuals, chlorpromazine increases PRL secretion by competitive inhibition of dopamine receptors in the hypothalamus and pituitary.⁴ Risks include hypotension, dizziness, and idiosyncratic drug reaction. Alternative agents with similar action include metoclopramide, sulpiride, and apomorphine.</p> |
| <p><i>Hyperprolactinemia related to pituitary tumor:</i> 90% of patients with prolactinoma have less than twofold increase above baseline; a blunted response is usually seen regardless of the cause of hyperprolactinemia. Subjects with hypopituitarism will have a low baseline and a blunted increase after TRH. Patients with hypothalamic disease usually have a delayed hyperresponse.</p> | <p>Responses vary with age, sex, and PRL base level. In postpubertal females, a maximum response is seen during the luteal phase of the menstrual cycle and postpartum. Renal failure and thyrotoxicosis may suppress prolactin response to TRH; hypothyroidism and hepatic failure may exaggerate the response. Basal prolactin levels increase during sleep or with stress.⁷</p> <p>A reduced or absent PRL response to TRH stimulation is consistent with, but not diagnostic of, a prolactinoma. The presence of a PRL response to TRH does not exclude a prolactinoma, nor does an exaggerated PRL response signify a hypothalamic origin of the hyperprolactinemia.⁸</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---------------------------------------|--|
| PRL-secreting tumors may not respond. | Failure to respond to L-dopa suggests autonomous function of the pituitary prolactin cells. Test may not differentiate PRL-secreting tumors from functional hyperprolactinemia. Normal suppression has been observed in many patients with documented PRL-secreting tumors, i.e., false-negative results are common. |

DIAGNOSTIC INFORMATION

REMARKS

used. Ultrasensitive PSA assays have been developed with limits of detection of ≤ 0.01 ng/mL. PSA doubling time can be used to predict risk of and time to recurrence.^{3,7}

The acceptable PSA concentration is less clear after radiation therapy, where values may not reach undetectable concentrations. With a nadir < 0.5 ng/mL, relapse is not likely with 5 yr of treatment. Biochemical recurrence has been defined by the American Society for Therapeutic Radiation and Oncology (ASTRO) as three consecutive increases in PSA above the nadir.^{2,3,7}

α_2 -macroglobulin (A2M). PSA assays measure free and complexed forms of PSA, exclusive of PSA-A2M. The differing proportions of free PSA in specimens from patients with cancer and benign prostatic diseases have been exploited to increase the specificity of PSA for cancer detection in the 4–10 ng/mL total PSA diagnostic gray zone.^{1–4}

PSA values increase with age, and there is intraindividual variation from day to day. Lack of consensus exists among physician groups in the use of PSA for population-based screening for prostate cancer.⁸

PSA has been recommended by the American Cancer Society for use in conjunction with a DRE for the early detection of prostate cancer starting at age 50 yr for men with at least a 10-yr life expectancy. Men at high risk, such as those of African descent or with a family history of the disease (first-degree relative[s] diagnosed < 65 yr) may begin testing at an earlier age.⁹ The test is of greatest value as a marker of therapeutic response after definitive treatments including surgery (radical prostatectomy), radiation, and hormonal (antiandrogen) therapy.^{2,3}

It is recommended that the same assay method be used for longitudinal monitoring.

DIAGNOSTIC INFORMATION

REMARKS

↑ Prostatic cancer, benign prostatic hyperplasia (BPH), and prostatitis.

The majority of studies, including a recent multicenter clinical trial,⁴ have shown similar sensitivity for cancer detection for cPSA compared with total PSA with increased specificity in the clinically relevant PSA range of 2-20 ng/mL.^{1,2} Increased specificity for cPSA has been particularly observed for total PSA concentrations <4 ng/mL.⁵ There is not agreement, however, comparing the diagnostic performance of cPSA with %free PSA.

cPSA correlated with total PSA in the longitudinal monitoring of prostate cancer patients⁶ and was equivalent to PSA in predicting organ-confined disease and favorable pathologic features. However, neither cPSA nor total PSA individually was a reliable predictor of final pathologic stage.⁷

PSA is present in serum in a free, unbound form (~<30%) and bound to protease inhibitors (~>70%), primarily α_1 -antichymotrypsin (ACT) and α_2 -macroglobulin (A2M). Total PSA assays measure free and complexed forms of PSA, exclusive of PSA-A2M. Proportions of free and complexed forms of PSA differ among men with prostate cancer and normal men or men with benign prostatic diseases. Men with prostate cancer have higher percentages of circulating complexed forms of PSA compared with men without cancer.

An assay for complexed PSA (cPSA) has been developed by Bayer HealthCare (Tarrytown, NY) that measures only serum PSA-ACT and other minor PSA complexes because free PSA is blocked with a free PSA-specific antibody and rendered non-reactive in the assay.³ Assays are available on automated platforms and in a microtiter plate ELISA format. The FDA-indicated uses for the cPSA assay include detection of prostate cancer (in men ≥ 50 yr in conjunction with DRE) and monitoring of disease and treatment in prostate cancer patients. A cPSA concentration of 3.2 ng/mL is equivalent to a PSA cutoff of 4.0 ng/mL, the standard cutoff for biopsy consideration. The proposed lower PSA threshold of 2.5 ng/mL corresponds to a cPSA concentration of 2.2 ng/mL.^{1,4}

Percent free PSA results can be interpreted using a single cutoff or a continuum of values to determine the relative risk of prostate cancer in individual men. In biopsies from men with a total PSA between 4 and 10 ng/mL and a DRE nonsuspicious for cancer, sensitivity for cancer detection was 95% using a %free PSA cutoff of $\leq 25\%$. Using this same cutoff ($>25\%$), 20% of men who underwent biopsy with benign disease could be spared from biopsy.³ Percent free PSA may also be beneficial in men with a total PSA between 4 and 10 ng/mL with a previous negative biopsy.¹

PSA is a glycoprotein and has a physiological function as a serine protease as part of the kallikrein family and as such is also termed hk3. PSA is present in serum in a free, unbound form (~<30%) and bound to protease inhibitors (~>70%), primarily α_1 -antichymotrypsin (ACT) and α_2 -macroglobulin (A2M). Total PSA assays measure free and complexed forms of PSA, exclusive of PSA-A2M.^{1,2}

DIAGNOSTIC INFORMATION

REMARKS

One approach to improve the specificity of PSA for prostate cancer detection to distinguish cancer from benign prostatic diseases, particularly in the 4-10 ng/mL total PSA diagnostic gray zone, is the measurement of free PSA. Free PSA is not used alone but is most useful expressed in a ratio with total PSA ($\% \text{free PSA} = \text{free PSA} / \text{total PSA} \times 100$). Patients with benign conditions have a higher proportion of free PSA compared with men with prostate cancer.

Total and free PSA measurements should be made from the same specimen in parallel using assays from the same manufacturer.

S ↑ Prostatic cancer (especially, but not always, with metastases),⁶ Gaucher's disease and Niemann-Pick disease, for 1-2 days after prostatic surgery or biopsy, after prostatic manipulation or catheterization, benign prostatic hypertrophy (BPH), prostatitis, and prostate infarct^{1,7}

Elevations in 80% of individuals with metastatic prostate cancer are related to the stage. PAP is not elevated in early stage prostate disease.⁶ Currently, PAP has little role in the early detection and management of prostate cancer, having been replaced by the more sensitive PSA test. PAP may have utility in limited cases. A high preoperative PAP in a patient with clinically localized prostate cancer suggests pathologically advanced stage disease, and this patient may not be a good candidate for surgical cure. PAP may also be used to monitor disease in very rare cases where a tumor does not produce PSA.⁸

Immunochemical methods are specific for prostatic acid phosphatase and more sensitive, although their use does not offer any advantages.⁸

Acid phosphatase is a lysosomal enzyme. The prostatic enzyme is found in lysosomes of the prostate epithelium and is a glycoprotein with an MW of 100,000. The biological $t_{1/2}$ is 1.1-2.6 hr.

The greatest activity per gram of tissue of total acid phosphatase and PAP is found in the prostate gland. Lesser activities of nonprostate-specific acid phosphatase are found in liver, spleen, erythrocytes, platelets, and bone marrow (with negligible quantities of PAP). Total serum acid phosphatase in males consists of approximately one half prostatic and the rest from liver and disintegrating platelets and erythrocytes. In females, the serum activity is presumably from liver, erythrocytes, and platelets.
