| <i>Pseudohyperproteinemia:</i> Hemoconcentration caused by dehydration (in vivo), sample desiccation (in vitro) | Prolonged application of a tourniquet increases concentrations of all proteins in the blood sample. Sample obtained above an IV infusion site can show erroneously low values as a result of local hemodilution. ¹³ Erroneously increased protein concentrations can be caused by evaporation of serum samples in the laboratory. Inadequate mixing of thawed samples may cause values in error by 10-200% of true values. |
| S ↓ <i>Protein loss:</i> Protein-losing gastroenteropathies, acute burns, and nephrotic syndrome | Upright posture for several hours after rising increases concentrations of all macromolecular analytes. ¹⁴ Significantly over levels are found early in the day. Even 1 hr of ambulation after overnight recumbent posture results in a demonstrable increase. Serum total protein for bedridden patients is lower by ~0.3 g/dL [~3 g/L] than expected for the same age. |
| <i>Decreases caused by decreased synthesis of proteins:</i> Severe protein deficiency, chronic liver disease, malabsorption syndrome, malnutrition, and agammaglobulinemia | Serum total protein decreases in the third trimester of pregnancy. During overnight recumbency values decrease 1.0-1.3 g/dL [10-13 g/L]; they decrease still farther with prolonged bed rest. IV infusions substantial enough to cause hemodilution will decrease serum total protein levels. Venous stasis resulting from occlusion caused by disease processes or peripheral vascular collapse can elevate levels. |
| | Refractometric determination of total protein can be affected by hyperglycemia when glucose accounts for a large proportion of total blood solutes; total protein concentration appears to be greater than it actually is. Severe hyperlipidemia, hyperbilirubinemia, or hemolysis has the same effect. Results of the biuret method may be falsely elevated by lipemia, icterus, and hemolysis; reliable procedures incorporate corrections to minimize these effects. Refractometric and biuret methods give comparable results on clean, clear serum samples. |
| U ↑ Nephrotic syndrome, diabetic nephropathy, monoclonal gammopathies such as multiple myeloma and other myeloproliferative or lymphoproliferative disorders, abnormal renal tubular absorption (e.g., Fanconi syndrome, heavy metal poisoning, sarcoidosis, and sickle cell disease), urinary tract malignancies, and inflammatory, degenerative, and irritative conditions of the lower urinary tract. After exercise (levels vary with type of exercise, 22-340 mg/day). | False-negative results may occur with highly alkaline urine. Total urine protein by precipitation methods cannot be relied on to quantify urinary immunoglobulin light chains. Some samples will remain fully soluble after precipitation of all other species. Turbidimetric and dye-binding based methodologies may not have equal sensitivity or specificity for all proteins and may underestimate low-molecular-weight proteins and immunoglobulin light chains. ¹ |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↓ <i>Congenital deficiency:</i> Type I protein C deficiency with low activity and low antigen level; type II with low activity but normal antigen level.</p> <p><i>Acquired deficiency is observed in:</i> liver disorders; during warfarin therapy; vitamin K deficiency; consumptive coagulopathies; renal insufficiency; acute thrombosis; postoperative state; and plasma exchange.</p> | <p>Heterozygous protein C deficiency is associated with an increased risk of venous thrombosis. Homozygous protein C deficiency is rare, but it is associated with neonatal venous thrombosis, usually presenting as purpura fulminans neonatorum.</p> <p>Laboratory evaluation of protein C includes antigenic and functional assays. The antigenic assays include ELISA, electroimmunoassay, and radioimmunoassay. The functional assays are clot-based or chromogenic, the latter usually favored because of less interferences. In general, a chromogenic assay is recommended for initial testing.</p> <p>The diagnosis of protein C deficiency should only be established after acquired causes of protein C deficiency are excluded.</p> <p>Measurement of protein C levels is not advised during acute illness/acute thrombotic event due to consumption of protein C and in patients receiving oral anticoagulant because warfarin will decrease protein C levels. Repeat testing is recommended once patients are off oral anticoagulation (best done 30 days after cessation). Correlation with family studies is also recommended.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>S ↑ Nephrotic syndrome, subacute and chronic inflammatory disorders, and tumors</p> <p>S ↓ Hemolysis, pancreatitis</p> | <p>The α_2-fraction contains α_2-macroglobulin, haptoglobin, and apolipoprotein B. α_2-Macroglobulin is the component that increases markedly with nephrotic syndrome.</p> |
| <p>S ↑ Primary or secondary hyperlipoproteinemias (especially type II), monoclonal gammopathies</p> <p>S ↓ Hypo-β-lipoproteinemias, IgA deficiency</p> | <p>The β-fraction contains transferrin (increases with iron deficiency), hemopexin, complement factors, antithrombin III, and immunoglobulins. In fresh serum, the β-globulin region is often split. The smaller β_2-fraction mainly contains lipoproteins. With specimen degradation, the β_2-band becomes diminished and may no longer be visible, particularly with samples older than 3 days.⁴ Monoclonal proteins of the IgA type frequently migrate within the beta region or near the β-γ junction. Consequently, these may be missed if obscured by the β-bands.</p> |
| <p>S ↑ <i>Polyclonal gammopathies</i>: Chronic inflammatory conditions, chronic infections, autoimmune disease, and liver disease (may be associated with β-γ bridging)</p> <p><i>Oligoclonal gammopathies</i>: Response to infection, autoimmune disorders, circulating immune complexes, and previous immunosuppressive therapy</p> <p><i>Monoclonal gammopathies</i>: Plasma cell dyscrasias/lymphoproliferative disorders (e.g., multiple myeloma, Waldenstroms macroglobulinemia, amyloidosis, lymphoma, chronic lymphocytic leukemia), monoclonal gammopathy of undetermined significance</p> <p>S ↓ Immune deficiency or suppression, lymphoproliferative disorder</p> | <p>The γ-fraction contains immunoglobulins G, A, M, D, and E. Spikes suspected to be caused by M-proteins within the γ-, β-, or α-globulin regions require immunofixation electrophoresis for confirmation and characterization. Fibrinogen migrates within the γ region, near the β-γ junction. It may be present if a plasma sample (rather than serum) is used, the patient has received anticoagulant therapy or has a coagulopathy, or if the specimen was not allowed to clot sufficiently. C-reactive protein (CRP) also migrates within the γ-fraction and like fibrinogen, can appear as a small band if sufficiently increased. Both fibrinogen and CRP can be mistaken for the presence of an M-protein if immunofixation electrophoresis is not performed.</p> <p>Monoclonal cryoglobulins (most frequently IgM) may precipitate at room temperature, resulting in falsely low quantitation of the M-protein peak. When their presence is suspected, the specimen should be warmed to 37° C immediately before electrophoresis. Monoclonal immunoglobulins may polymerize (most often IgM, less often IgA), inhibiting optimal migration. Sample pretreatment with a reducing agent such as 2-mercaptoethanol may be required.⁴</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| CSF ↓ <i>Physiological</i> : In infants of 3-4 mo of age, congenital hypo- or agammaglobulinemia | High-resolution agarose electrophoresis of CSF is useful when assessing for the presence of oligoclonal bands. The CSF electrophoretic pattern should be compared with that of a simultaneously collected serum sample. The use of silver staining can be used to increase sensitivity. CSF oligoclonal bands in the γ region are found in the majority of patients with multiple sclerosis. They can also be present with other conditions involving the CNS such as neurosyphilis, subacute sclerosing panencephalitis, progressive rubella panencephalitis, and other infections, as well as metastatic and primary CNS malignancies. |

↓ *Hereditary deficiency*: Type I—activity and antigen (free and total) levels are decreased; type II—activity decreased and antigen (free and total) normal; type III—low activity, low free, normal total.

Acquired deficiency: Acute thrombotic events, DIC, surgery; liver disorders; oral anticoagulant treatment (repeat at least 30 days after cessation of warfarin therapy); L-asparaginase treatment; acute phase reactant (the in vivo increase of C_{4b}-binding protein [C4b-BP] may contribute to increased binding of protein S and result in decreased free and functional protein S levels).

Protein S is a vitamin K-dependent protein synthesized in the liver. It enhances the anticoagulant action of activated protein C as a cofactor. In normal human plasma, protein S exists in two forms: free (~40%) and bound to C4b-BP (~60%). Only the free form of protein S expresses biological activity, whereas the bound one is functionally inactive.

Protein S assays are technically challenging. Protein S can be tested by functional (activity) and immunologic (antigen) assays. Current ELISA tests can measure free and bound PS antigen. Measurement of free PS may be more useful than total PS. A functional test is generally recommended for initial screening.

Protein levels vary with age, sex, and hormonal status. It is preferable not to test for PS deficiency during an acute thrombotic event (although a normal PS level would essentially exclude PS deficiency).

| Prothrombin Time ¹⁻⁴ | Plasma (blue top-citrate). Stable for 24 hr at room temperature. | Reference values will vary with the type of thromboplastin. Each laboratory should determine its own reference range. In general: 11-16 sec Newborn: Prolonged, reaches adult levels by 6 mo Monitoring warfarin ⁴ : <i>INR</i> * generally 2.0-3.0 * $INR = [Patient\ PT / Normal\ mean\ PT]^{ISI\dagger}$ $\dagger ISI$ = International Sensitivity Index of thromboplastin. The manufacturer assigns an ISI for each thromboplastin reagent. | \uparrow V Acetaminophen (poisoning), acetohexamide, aminosalicic acid, anabolic steroids, anistreplase, asparaginase, aspirin (large-dose effect), carbenicillin, cephalosporins (particularly cefamandole, cefmetazole, cefoperazone, cefotetan, moxalactam), cholestyramine (rare), cholestipol (rare), cyclophosphamide, ethanol (large quantities, alcoholism), halothane, heparin (concentration-related effect, more likely with intermittent doses), hetastarch (transient), interferon α -2b, laxatives, methotrexate, niacin, oral anticoagulants, plicamycin, pyrazinamide, quinidine, quinine, thi azides, ticarcillin, tolazamide, and tolbutamide. The drugs listed above may produce an additive effect to oral anticoagulants. Other drugs that may interact with the oral anticoagulant to enhance its action include allopurinol, amiodarone, chloral hydrate (initial effect), |
|--|--|---|---|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| PR3 autoantibodies are detectable in >80% of patients with active WG and have a high positive predictive value for WG. ¹ | PR3 is a 29 kDa serine protease that exists as a protein triplet in human neutrophils. PR3 autoantibodies may be involved in the pathogenesis of WG. |

↑ Oral anticoagulant drugs (warfarin); liver disease; vitamin K deficiency; DIC; hereditary deficiency of factors VII, X, V, and II; afibrinogenemia, hypofibrinogenemia, and dysfibrinogenemia; a circulating anticoagulant affecting the PT system (rarely lupus anticoagulant).

The prothrombin time (PT) is the most widely performed coagulation assay. The PT evaluates the extrinsic and common coagulation pathways and may be prolonged with low plasma levels of factors II, V, VII, X, and fibrinogen. The sensitivity of the PT test to factor deficiencies varies among the reagent thromboplastins available from different manufacturers. The thromboplastin reagents may be from a human, rabbit, or bovine source.

The PT is the most commonly used test for monitoring oral anticoagulant therapy (warfarin). In addition to results reported in seconds, the International Normalized Ratio (INR) is calculated. The INR was introduced in 1983 to improve PT reporting and enhance standardization. An International Sensitivity Index (ISI) is assigned to each thromboplastin by the reagent manufacturer. The ISI is a measure of a reagent's responsiveness to low levels of Vitamin-K–dependent coagulation factors compared with the primary WHO International Reference Preparation.

Despite the improvement with INR reporting, significant variation in INR results between laboratories persists. These differences in INR reflect local variables (i.e., reagent and/or instrument system used in the local laboratory). A high-sensitivity, low ISI thromboplastin reagent (e.g., recombinant thromboplastins) is recommended to improve precision and accuracy of the INR, resulting in better anticoagulation control.³

International consensus with regard to optimal INR ranges for prophylaxis and treatment of venous and arterial thromboembolism has been recently established.⁴

| | | | INTERFERENCES AND IN VIVO EFFECTS |
| PT, aPTT Mixing Studies (Inhibitor Screen) ^{1,2} | Plasma (blue top tube-citrate). Stable for 1 hr at 4° C, 4 hr on ice, or for 28 days if frozen. | Three patterns seen: 1. PTT of mixture normal immediate and after 2-hr incubation (correction pattern): consistent with factor deficiency. No evidence of an inhibitor. 2. PTT of mixture prolonged at immediate and after 2-hr incubation: consistent with an inhibitor, most commonly a lupus anticoagulant. Of note, some specific inhibitors may not be time dependent (e.g., factors IX, XI, or XII) and will show a similar mixing study pattern to a lupus anticoagulant. 3. PTT of mixture is initially normal but prolonged at 2-hr incubation: consistent with a specific factor VIII inhibitor. A rare factor V inhibitor may have a similar pattern. Same considerations with a <i>PT</i> mixing study. Patients on warfarin will show a “correction pattern” consistent with factor deficiency(ies). | ↑ Heparin, hirudin, and argatroban |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>Mixing studies are typically performed when there is an unexplained prolonged aPTT or PT. If there is a factor deficiency (e.g., hemophilia), normal plasma (1:1 mixture) will correct an abnormally prolonged aPTT or PT. If there is a nonspecific inhibitor such as a lupus anticoagulant, normal plasma will generally not correct the aPTT.</p> | <p>Specific (e.g., factor VIII inhibitor) or nonspecific inhibitors (e.g., lupus anticoagulant) affecting the aPTT or PT may be immediately acting or time dependent. To detect both types of inhibitors, a mixing study is tested immediately after mixing and after incubation at 2 hr. A factor VIII inhibitor may only be detected after 2-hr incubation.</p> <p>The test is based on the evaluation of aPTT or PT in a 50:50 mixture of patient's plasma with normal plasma. Normal plasma and the patient's plasma are also tested immediately and at 2 hr as controls.</p> |
| <p>↓ B6 deficiency</p> | <p>4-Pyridoxic acid is the major metabolite of vitamin B₆, and its excretion may reflect recent dietary intake of vitamin B₆ rather than functional tissue status. Measurement of urine metabolites and xanthurenic acid (or cystathionine) after tryptophan (or methionine) oral loads can provide an indirect measure of functional vitamin B₆ deficiency.¹ These tests of urine metabolites are not widely used but can provide confirmation of vitamin B₆ deficiency. See <i>Vitamin B₆</i>.</p> |

|--|---|--|--|
| Red Cell (Erythrocyte) Mass (RCM)¹⁻⁴ | Sterile whole blood (heparin or EDTA) after 15-min rest. Label red cells and reinject. | <i>mL/kg³</i> M: 20.0-39.7 F: 17.2-32.3 | ↓ C Ascorbic acid and antibiotics impair the labeling process when chromium-51 is used. |
| ⁵¹ Chromium (⁵¹ Cr) | Take samples of whole blood (heparin or EDTA) 10 and 20 min after injection to measure radioactivity. | | ↓ V Obesity can cause spurious low values because RBC is related to lean body mass. ⁵ |
| ^{99m} Technetium (^{99m} Tc) | | | |
| ³² Phosphorus (³² P) | | | |
| ¹²⁵ Iodine (¹²⁵ I) | | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>There is no known pathologic cause of a decreased RDW.</p> <p>See Table II-15.</p> | <p>Some authors recommend using RDW in conjunction with the mean cell volume (MCV) for improved classification of anemias. For differential diagnosis, refer to Table II-15.</p> <p>See also <i>Mean Cell Volume (MCV)</i>.</p> |

↑ *Primary Polycythemia (Polycythemia vera)*

↑ *Secondary polycythemia caused by tissue hypoxia:* Pulmonary disease, right to left cardiac shunt, congenital cardiac abnormalities, methemoglobinemia, carboxyhemoglobinemia (especially smoking), high-affinity hemoglobinopathy, and high altitude

↑ *Secondary polycythemia caused by excess erythropoietin or steroid production:* Renal cell carcinoma, hepatoma, cerebellar hemangioma, large uterine leiomyomas, polycystic kidney disease, hydronephrosis, adrenal cortical hyperplasia, and newborn infants

An elevated red cell mass is seen in primary and secondary polycythemia but not in relative polycythemia as a result of decreased plasma volume.

↓ Anemia, acute and chronic hemorrhage, bed rest, old age, pheochromocytoma, chronic infection, radiation, starvation, chronic azotemia, and obesity (fat is relatively avascular).

Red cell volume (RCV) is the actual measured parameter from which RCM is calculated. ^{99m}Tc is considered to be slightly less accurate than ⁵¹Cr but has lower radioactivity. Red cell mass is calculated from red cell volume as follows:

$$\text{RCM, mL/kg} = \frac{\text{RCV (mL)}}{\text{patient weight (kg)}}$$

At hematocrit values between 20 and 55% [0.20 and 0.55], a linear relationship exists between Hct and RCV. If Hct >55% [0.55], RCV increases disproportionately to Hct; i.e., Hct underestimates RCV. When RCV is related to total body water or lean body mass (instead of body weight), there is no difference between the values of obese and lean persons and between those of males and females.

Recently published data suggest that the ¹²⁵I method is simpler and less expensive with equivalent results as compared with ⁵¹C.

| <p>↑ Any cause of glycosuria (see <i>Glucose</i>), normal late pregnancy and lactation (lactose), galactosemia (galactose), essential pentosuria (pentoses), muscular dystrophy (ribose), and infants on artificial diets</p> | <p>Lower limit of detection for the Clinitest procedure (5-drop method) is 250 mg/dL [13.9 mmol/L], as glucose. Comparison of results from copper reduction tests and glucose oxidase reagent strips differentiates glucose from other reducing substances.</p> <p>Urines with low specific gravity show enhanced positive results. X-ray contrast media (HYPAQUE Meglumine) cause reduced reactivity and possible false-negative results.⁵</p> <p>Clinitest tablets should be used when screening infants and young pediatric patients because glucose oxidase strips will not detect galactose and other sugars of potential importance.³ Healthy neonates (10-14 days old) may show positive reaction because of excretion of glucose, galactose, fructose, and lactose. Normal pregnant and postpartum women may show positive Clinitest results because of lactose in urine.²</p> <p>The 2-drop Clinitest method was devised to detect very high levels (5 g/dL; 278 mmol/L) of reducing sugars that might otherwise be missed (false negative) on the 5-drop method. Pass-through phenomenon refers to the color change from orange back to blue to blue-green, which occurs when very high concentrations of glucose are encountered. This phenomenon causes false-negative results unless the reaction is monitored constantly until it is complete.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ An elevated RLP-C concentration is associated with an increased risk of CHD.</p> <p>An elevated RLP-C/TG ratio is associated with type III hyperlipoproteinemia.</p> | <p>This test is obsolete and nonspecific for listed metals. Quantitative tests for specific metals are more accurate for diagnosis. 0.5 mL of potassium cyanide will dissolve a deposit caused by arsenic, selenium, tellurium, and/or sulfur; 1 mL of nitric acid, 2.25 mol/L, will selectively dissolve a deposit caused by bismuth. See specific metal for quantitative methods.</p> <p>Chylomicron and VLDL remnants are formed by the removal of triglycerides and phospholipids by lipolysis. The accumulation of these remnant particles is atherogenic.</p> <p>Measurement of RLP cholesterol is useful for CHD risk assessment and for the diagnosis of type III hyperlipoproteinemia.</p> |

| Reticulin Antibodies^{1,2} | Serum. Stable 1 wk at room temperature, 2 wk at 4° C, and 1 yr frozen. | Normal: Negative | Testing in children is not as useful because celiac disease antibodies may not have developed. May be negative in pa- tients taking gluten-free diets. 2.6% of patients will be negative because of selec- tive IgA deficiency. A |
|---|---|------------------|--|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ In hypertension related to renal artery stenosis or unilateral renal parenchymal disease</p> <p>A functionally significant stenotic lesion is inferred if the absolute renin activities are elevated and if the PRA on the stenotic side is increased >1.5 times that of the contralateral side. In some patients, this may be apparent only after furosemide administration.</p> | <p>This is a test for determining the functional significance of a stenotic renal arterial lesion; it is also useful for determining whether unilateral renal parenchymal disease may be responsible for hypertension.² It is used only rarely to evaluate the presence of a renin-secreting tumor.</p> <p>The patient should not receive drugs that inhibit renin (propranolol, methyldopa, guanethidine, or clonidine) for 1 wk before the test.</p> |

| | |
|--|---|
| <p>↑ Hereditary: Decreased or abnormal fibrinogen (hereditary afibrinogenemia, hypofibrinogenemia, or dysfibrinogenemia)</p> <p>Acquired: Liver disease, paraproteinemia (multiple myeloma, Waldenström's macroglobulinemia, primary systemic amyloidosis)</p> | <p>Reptilase is an enzyme derived from the venom of the snake, <i>Bothrops atrox</i>. The reptilase time is essentially similar to the thrombin time. The snake venom used as the reagent is, in contrast to the thrombin reagent used in the thrombin time, not inhibited by heparin.</p> <p>The reptilase test, together with the thrombin time, is generally performed together in evaluation of a qualitative fibrinogen disorder (dysfibrinogenemia); the reptilase time is generally more affected than the thrombin time by dysfibrinogenemia.</p> |
|--|---|

| | |
|---|---|
| <p>In celiac disease, the IgA assay is 60% sensitive and 60% specific. In dermatitis herpetiformis, the sensitivity is 25%.</p> <p>The IgG assay is positive in other diseases (Crohn's, bullous dermatosis) and normal subjects.</p> | <p>See <i>Tissue Transglutaminase Antibody</i>, <i>Endomyosial Antibody</i>, and <i>Gliadin Antibody</i>.</p> <p>Celiac disease is an immune disorder found in 1% of the NA population that is stimulated by gluten. It is characterized by typical GI symptoms and a variety of less common symptoms.</p> <p>Small bowel biopsy is needed for definitive diagnosis.</p> <p>More than 97% of people with celiac disease have DQ2 and/or DQ8 HLA haplotypes compared with 40% of the population.</p> |

| Rheumatoid Factor (RF) ¹⁻⁴ | Fresh serum. Store for 24 hr at 2-8° C. If test cannot be done within 24 hr, freeze serum at -20° C. Do not re-freeze. Do not use plasma. | Negative | Lipemia, cryoglobulins, incomplete heat inactivation of serum, and circulating immune complexes |
| <i>Agglutination of latex particles coated with human IgG</i> ⁴ | | | ↑ V Methyl dopa |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| Increased rT_3 with low T_3 (and sometimes low T_4) suggests sick euthyroid syndrome rather than true hypothyroidism. Sensitive TSH, however, is probably better for this differential diagnosis. (See <i>Thyroid-Stimulating Hormone Stimulation Test</i> .) | rT_3 is increased several fold in sick euthyroid syndrome. |
| AF \uparrow Diabetes mellitus (overlap with normal interval), very sick and anemic fetuses | The correlation of rT_3 concentrations in amniotic fluid with those in fetal serum suggests the possibility of monitoring fetal thyroid status. rT_3 concentrations decrease with increasing gestational age, correlating significantly with the L/S ratio. There is no correlation with subsequent Apgar scores. |
| Rheumatoid factor is found in rheumatoid arthritis, Sjögren's syndrome, scleroderma, dermatomyositis, Waldenström's disease, sarcoidosis, and SLE. Only ~75% of patients with rheumatoid arthritis have detectable RF of the IgM class. In rheumatoid arthritis, the highest titers are seen in severe, active, chronic disease with vasculitis and subcutaneous nodules. | Rheumatoid factor (RF) consists of autoantibodies that will react with autologous IgG and that are usually of the IgM class, although ~15% of patients with rheumatoid arthritis have IgG-class RF. ² Most methods detect only IgM-class RF. |
| Eighty to 90% of patients with Sjögren's syndrome will have high titers of RF. ² | Titers $\leq 1:80$ are questionable and can be seen in infectious mononucleosis, acute inflammation, and elderly persons. Standardization with reference serum is mandatory. The latex agglutination test is more sensitive [75% positive in rheumatoid arthritis (RA)] but less specific than the sheep cell test (75% true-positive in RA). Positive results should be confirmed. |

DIAGNOSTIC INFORMATION

REMARKS

Negative results have been observed in the presence of rheumatoid disease. SCAT is less sensitive than the latex procedure. The test is relatively specific when positive (90% true-positive in RA) but less sensitive than the latex test (50-60% positive in RA).

Thirty to 50 U/mL [30-50 kU/L] is considered weakly positive in the nephelometric reaction.

↓ Alcoholism, hypothyroidism, liver disease, anorexia, malabsorption (tropical sprue, celiac disease, malignancy, small bowel resection, GI and biliary obstruction, diarrhea, infectious enteritis, irritable bowel syndrome), phototherapy of infants with jaundice, oculourogenital syndrome, angular cheilitis, atrophic glossitis (magenta tongue), conjunctivitis, genital hyperpigmentation (resembling zinc deficiency), and seborrheic dermatitis around the nose, eyes, and ears

Vitamin B₂, in the form of riboflavin-5'-phosphate, serves as a component of prosthetic units (FAD and FMN) of the flavoproteins that function as hydrogen carriers in biologic oxidation-reduction processes.¹

Ariboflavinosis (dietary deficiency of riboflavin) occurs almost invariably in combination with other water-soluble vitamin deficiencies. Deficiency causes a syndrome characterized by sore throat, hyperemia and edema of the pharyngeal and oral mucous membranes, cheilitis, angular stomatitis, glossitis, corneal vascularization, dyssebacia with dermatitis, and normochromic, normocytic anemia.

Severe deficiency of vitamin B₂ can diminish conversion of vitamin B₆ to its active "coenzyme" form and curtail conversion of tryptophan to niacin.

During recent years, deficiencies of riboflavin and vitamin B₆ have been suggested as potentiating factors for chronic progressive nerve compression disorders, such as carpal tunnel syndrome.²

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| S100 β has been suggested as a marker for stroke. S100 β begins to increase within the first 8 hr after the onset of stroke and remains increased for 72 hr. ⁴ The concentration of S100 β correlates to the infarct volume and neurological outcomes. ⁵ S100 β is also increased in other neurological disorders associated with the breakdown of the blood-brain barrier ⁶ and seizures. ⁷ | S100 is a family of acidic calcium binding proteins. It has solubility in 100% ammonium sulfate. There are some 20 isoforms of S100, mostly found in free cytosolic pools. The $\alpha\alpha$ isoform is found in cardiac myocytes, $\alpha\beta$ in glial cells, and $\beta\beta$ in astrocytes and Schwann cells of the brain. ⁸ The S100 β is 21 kDa, which may facilitate appearance of this marker into blood from the cerebrospinal fluid. The biological half-life in blood is \sim 2 hr. |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| ASCAs occur in patients with inflammatory bowel diseases, especially Crohn's disease. ¹ Positive results for both IgA and IgG ASCA occur in ~40% of patients with Crohn's disease with a positive predictive value that approaches 90%. ASCAs occur less commonly in other inflammatory intestinal diseases, including ulcerative colitis and celiac disease. | Testing for ASCA is often performed along with the test for pANCA. Patients with ulcerative colitis often test positive for pANCA and do not usually have elevated levels of ASCA, ² whereas patients with Crohn's disease test negative for pANCA. These two patterns of results (ASCA positive, pANCA negative, and vice versa) have high predictive values for Crohn's disease and ulcerative colitis, respectively, but occur in <50% of patients with inflammatory bowel disease. The test for ASCA is not appropriate for screening patients with intestinal symptoms for inflammatory bowel disease. |

| | |
|--|--|
| ↑ Intraduodenal acidification (50-fold over fasting). Gastric acid hypersecretion (e.g., gastrinomas or Zollinger-Ellison syndrome), duodenal ulcers, starvation, diabetes mellitus, and chronic renal failure | Antacid medications or medications affecting intestinal motility should be discontinued 48 hr before testing. Wide variations in reference intervals have been reported, depending on the method of measurement. Plasma levels increase rapidly after acid stimulation, peaking at 3 min, and then decreasing to basal levels in 60 min. |
| ↓ Celiac disease (gluten-sensitive enteropathy), pernicious anemia, and achlorhydria | In patients with Zollinger-Ellison syndrome, secretin infusion causes an increase in serum gastrin (see <i>Gastrin Stimulation Test [after Secretin]</i>). |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>The type and number of formed elements may give valuable diagnostic information about the presence, type, and localization of pathological processes within the urinary tract (see below). Casts form only in the renal tubule and thus reflect disease within the renal parenchyma, generally high in the nephron.</p> | <p>Optimal preservation is achieved in acid, hypertonic urine. Refrigerate if examination is not performed within 2 hr. Approximately 50% of the cells are lost after 2-3 hr standing at room temperature. RBC (Erc) lysis occurs at a specific gravity <1.010.⁴ A combined cytocentrifugation and Papanicolaou staining method has been used to evaluate renal allograft recipients; a standard slide procedure (the KOVA system) is also available and is more reproducible than conventional bright-field microscopy.</p> |
| <p>↑ All renal diseases that cause glomerular proteinuria; also seen with fever, strenuous exercise, diuretic therapy, hypertension, acute pyelonephritis, and congestive heart failure</p> <p>The presence of particulate or cellular inclusions increases the likelihood of intrinsic renal disease. The presence of hyaline casts is a relatively sensitive indicator of intrinsic renal disease but is very nonspecific.</p> | <p>Increased acidity and electrolyte concentration enhance the precipitation of casts. Hyaline casts dissolve rapidly in alkaline urine; excessive excretion of hyaline and lightly granular casts can continue for decades in treated essential hypertension, gouty nephropathy, nonprogressive glomerulonephritis, and other inactive diseases.¹⁷ Casts reflect the shape and diameter of the lumina of origin.</p> |
| <p>The presence of RBC casts usually indicates glomerular pathology.</p> <p>↑↑ Acute poststreptococcal and rapidly progressive glomerulonephritis; present in other forms of glomerulonephritis, polyarteritis, subacute bacterial endocarditis, Goodpasture's syndrome, renal infarction, renal vein thrombosis, and malignant hypertension; very rarely in tubulointerstitial disease</p> | <p>RBC casts have greater diagnostic significance than any other variety. Their presence helps differentiate hematuria caused by glomerular disease from other sources of urinary tract bleeding.</p> |
| <p>The presence of WBC casts reflects tubulointerstitial disease, most notably pyelonephritis; these casts are also seen with lupus nephritis but are uncommon with glomerular disease and noninfectious interstitial nephritis.</p> | <p>WBC casts may be the only clue to pyelonephritis. When present they may greatly aid in the differentiation of pyelonephritis from cystitis.</p> |
| <p>Granular casts may be present in active glomerulonephritis, diabetic nephropathy, pyelonephritis, viral disease, lead intoxication, amyloidosis, malignant hypertension, acute allograft rejection (intermittent), strenuous exercise, fever, and pure carbohydrate diet. The presence of granular casts is indicative of pathology but is nonspecific.</p> | <p>There is no clinical difference between coarse and fine granular casts. Their presence in a resting, afebrile subject is indicative of renal disease. Bile-stained granular casts are excreted in large numbers in obstructive jaundice, often without any other evidence of renal disease.¹⁷</p> |
| <p>Waxy casts are observed most frequently in patients with chronic renal failure; they are also found in amyloidosis and occasionally in allograft rejection.</p> | <p>Broad, waxy casts ("renal failure casts") generally suggest severe, chronic renal disease.</p> |
| <p>These casts may be present in acute tubular necrosis, viral disease (e.g., CMV), heavy metal poisoning, ethylene glycol or salicylate intoxication, acute allograft rejection, or amyloidosis.</p> | <p>Epithelial casts are the rarest of casts. Their presence after the third postoperative day constitutes one of the most reliable indicators of acute allograft rejection.¹⁴</p> |

| TEST NAME AND METHOD | SPECIMEN REQUIREMENTS | REFERENCE INTERVAL, CONVENTIONAL [INTERNATIONAL RECOMMENDED UNITS] | CHEMICAL INTERFERENCES AND IN VIVO EFFECTS |
|----------------------------------|--------------------------|---|---|
| Sediment, Urinary—CONT | | | |
| Fatty casts | | Not seen | |
| Mixed casts | | Not seen | |
| Crystal casts | | Not seen | |
| Cells | | 0-2/hpf | ↑ V Allopurinol, amphotericin, anticoagulants, aspirin, colchicine, cyclophosphamide, gold, indomethacin, levodopa, methenamine, oxyphenbutazone, penicillins, phenols, phenylbutazone, radiographic agents, sulfonamides, and turpentine |
| Red blood cells (RBC, Ercs) | | | |
| White blood cells (WBC, Lkcs) | | M: 0-3/hpf F child: 0-5/hpf | ↑ V Allopurinol, ampicillin, aspirin, capreomycin, heroin (in addicts), ipodate, iron salts, kanamycin, L-dopa, and methicillin |
| Tubular epithelial cells | | Few; more frequent in newborn | ↑ V Acetaminophen, bismuth salts, caffeine, calcitonin, castor oil, cortisone, phenacetin, salicylates, and thallium |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Fatty casts are associated with nephrotic syndrome and major skeletal trauma.</p> | |
| <p>The presence of mixed casts suggests tubulointerstitial disease or any of the above, depending on composition.</p> | |
| <p>See <i>Crystals</i>, below.</p> | |
| <p>Erythrocytes are present in renal disease (e.g., glomerulonephritis), lupus nephritis, focal glomerulitis (Berger's disease [IgA nephropathy], Alport's syndrome, benign familial recurrent hematuria), calculus, tumor, infection, tuberculosis, infarction, renal vein thrombosis, trauma, hydronephrosis, polycystic kidney, analgesic nephropathy and occasionally acute tubular necrosis and malignant nephrosclerosis, urinary tract disease (including inflammation), infection, calculus, tumor, obstruction, prostatitis, and systemic febrile disease (including malaria, yellow fever, blackwater fever)</p> | <p>RBC (Ercs) may originate from any point along the genitourinary tract and may indicate hematological, neoplastic, or other genitourinary disease. Hence, their presence is relatively non-specific. The most common causes of isolated hematuria are urinary tract stones and neoplasms, tuberculosis, trauma, cystitis, and prostatitis, whereas the most common cause of recurrent hematuria of glomerular origin is Berger's disease (IgA nephropathy). RBCs, in conjunction with RBC casts, suggest an intrarenal source, whereas the absence of casts or proteinuria suggests a source distal to the kidney. Hematuria may be one of the earliest signs of inadequate anticoagulant control.</p> |
| <p>Various extrarenal diseases (e.g., appendicitis, salpingitis, diverticulitis); tumors of the colon, rectum, and pelvis; gout, scurvy, subacute bacterial endocarditis, polyarteritis nodosa, malignant hypertension, infectious mononucleosis, hemoglobinopathies, coagulation disorders, and heart failure</p> | |
| <p><i>Drugs and toxins:</i> See <i>Interferences</i>.</p> | |
| <p><i>Others:</i> Radiation, exercise, lordosis, smoking,⁴ and hypercatabolic states</p> | |
| <p>↑ Almost all renal disease and diseases of the genitourinary tract (especially tubulointerstitial nephritis, lupus nephritis, pyelonephritis, urinary tract infections), renal transplant rejection, fever, and exercise</p> | <p>Phosphaturia, not pyuria, is the most common cause of cloudy urine. Number and appearance of WBC (Lkcs) are influenced by urine pH, osmolality, temperature, associated proteinuria and bacteriuria, and the interval between voiding and examination. Repeated sterile cultures in the presence of 50 WBC/hpf may indicate tuberculosis or lupus nephritis, whereas gross pyuria may reflect rupture of a renal or urinary tract abscess. Concomitant presence of casts implicates renal origin.</p> |
| <p>Values >50 WBC (Lkcs)/hpf are strongly suggestive of acute infection.</p> | |
| <p><i>Acute tubular damage:</i> Pyelonephritis, necrotizing papillitis, acute tubular necrosis, various drugs and toxins (especially salicylate intoxication, heavy metal or ethylene glycol poisoning), malignant nephrosclerosis, and acute renal allograft rejection</p> | <p>It is often difficult to distinguish renal epithelial cells from other cells within the sediment; values >15 cells/hpf seen 3 days after transplantation provide strong evidence of impending allograft rejection.⁴ Tubular cells that have absorbed lipids (oval fat bodies) may result in fatty casts, suggestive of the nephrotic syndrome.</p> |

(see *Section IV, Ova and Parasite Examination*)

Yeast (Candida)

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| Transitional cell carcinoma may show clumps or sheets of transitional epithelial cells. | Normal desquamation may lead to the presence of a few transitional cells. Squamous cells have little diagnostic significance. |
| ↑ Urinary tract infections | <p>Significant infections are usually associated with counts $>10^5$ organisms/mL [$>10^8$ organisms/L] of a clean-catch mid-void specimen. A bacteriological loop represents ~ 10 mL. If bacteria are seen in a smear of a loopful, this is probably significant bacteriuria. The presence of many squamous epithelial cells and mixed vaginal-type flora indicates contamination and the need for a repeat specimen, regardless of the count. Low counts may be the result of dilution in a well-hydrated patient. Marked pyuria can mask bacteria in the sediment; obscuring crystals may be dissolved by warming the specimen. Bacteria are no longer present in the urine 24–48 hr after an appropriate antimicrobial treatment. Most urinary tract infections are ascending and involved gram-negative enteric organisms. Eighty percent of infections not associated with voiding defects involve <i>Escherichia coli</i>; 95% of all recurrent infections arise from an external rather than an internal port of entry. Only $\sim 50\%$ of patients with significant bacteriuria ($>10^5$ organisms/mL [$>10^8$ organisms/L]) have accompanying pyuria. Several types of chemical screening tests for bacteriuria exist. See <i>Bacteria Screen</i>. Screening procedures for positive urine cultures yield a sensitivity of 92% and specificity of 81% using the Bac T-Screen (Vitek Systems Inc., Hazelwood, MO). Addition of the leukocyte esterase dipstick improves the specificity of the combined tests to 99% but results in a sensitivity of only 73%.¹⁵</p> |
| See <i>Remarks</i> . | <p>Yeast may represent a harmless saprophyte or a significant pathogen, particularly in the immunocompromised or diabetic patient. Generally microscopic or gross pyuria accompanies <i>Candida</i> infection.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| See Remarks. | Demonstration of tumor cells provides an important mechanism for recognizing cancer of the kidney, ureters, or bladder. False-negative results are much more common than false-positive results. Multiple specimen examination improves accuracy. Automated staining with the Cyto-Tek (Miles, Inc., Diagnostic Division, Elkhart, IN) is available. The UROCYTE System (Dianon Systems, Inc., Stratford, CT) determines DNA aneuploidy and is effective in monitoring bladder cancer patients. |
| <i>Triple phosphate:</i> Increased amounts of fruit in diet | Most crystals have little clinical significance. Phosphates, urates, and oxalates are especially common in normal urine. |
| <i>Calcium oxalate:</i> Increased amounts of cabbage, asparagus, rhubarb in diet, ⁷ severe chronic renal disease, ethylene glycol and methoxyflurane toxicity, and small bowel resection | Knowledge of urine pH is a prerequisite to identification. Amorphous urates are seen in acid urine, whereas amorphous phosphates appear in alkaline urine. Cystine crystals are among the most important crystals found; renograffin crystals frequently appear after radiographic examinations of the urinary tract. |
| <i>Cystine:</i> Present in cystinuria, homocystinuria | High doses of ampicillin, sulfonamides, 6-mercaptopurine, or primidone may result in crystal formation. |
| <i>Leucine and tyrosine:</i> May be present in severe liver disease | |
| <i>Cholesterol:</i> May be seen in severe urinary tract infections, nephritis, rupture of lymphatic vessels into the renal pelvis | |
| <i>Uric acid:</i> Increased in 16% of gout patients, ¹³ malignant lymphoma, and leukemia | |

| | |
|---|--|
| After adequate vagotomy, sham feeding does not stimulate acid secretion. SAO/PAO ≤ 0.10 suggests complete vagotomy with 95% confidence. ^{3,4} | This test is rarely performed today because vagotomy has declined significantly. |
| If PAO is close to zero, use of SAO/PAO ratio may be misleading. ¹ Therefore in patients with a PAO < 5 mmol/hr, the results must be interpreted with caution. If BAO/PAO > 0.10 , SAO/PAO will be within the normal range even if SAO is not higher than BAO. Thus in a postoperative patient with a recurrent ulcer and a BAO $> 10\%$ of PAO, it may be unnecessary to carry out a sham feeding test. | Basal acid output (BAO) and sham feeding-stimulated acid output (SAO) are defined as the sum of four consecutive 15-min outputs during the basal and sham feeding hours, respectively. Peak acid output (PAO) represents the two highest consecutive 15-min outputs after pentagastrin; their sum is multiplied by 2 to express results in mmol/hr. ³ |
| | Sham feeding stimulates as much acid secretion as an IV insulin challenge of 0.1 U/kg. ⁵ |

U, Free ↑ Infantile sialic acid storage disease, Salla disease, and sialuria.

Sialic acid (SA) is a generic name for a group of compounds derived from the 9 carbon sugar neuraminic acid. SAs are generally found as terminal sugar residues on oligosaccharides of both glycoproteins and glycolipids. Their functions include stabilization of glycoprotein conformational states, protease resistance, cell-surface receptor components, antigenic determinants, cell-cell interaction, and developmental regulation. The most common sialic acid found on human plasma glycoproteins and glycolipids is 5-*n*-acetylneuraminic acid, frequently linked to galactose. *O*-acetylated derivatives are not normally found in the plasma of healthy human.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Test is positive in the presence of Hb S or other rare sickling hemoglobins, e.g., Hb C-Harlem. Disorders with Hb S include sickle cell anemia, sickle trait, and combinations of the Hb S gene with other disorders: α -thalassemia, β -thalassemia, α -chain structural hemoglobin variants, and β -chain structural hemoglobin variants. ³ | <p>The sickling test detects Hb S in concentrations of $>25\%$ [>0.25] Hb S. The test has largely been replaced by solubility tests.</p> <p>A positive sickling or solubility test does not distinguish reliably between sickle trait and sickle cell anemia, nor does it provide information about other coexisting hemoglobin abnormalities. Additional studies are required for diagnosis. (See <i>Hemoglobin Electrophoresis</i>.)</p> |
| | <p>The solubility test is unreliable in severe anemia, Hb <8 g/dL [<80 g/L], or in polycythemia unless adjustments are made in technique, such as using washed erythrocytes or using hemolysates with a standard hemoglobin concentration.¹</p> |
| Test is positive in the presence of Hb S and Hb C-Harlem, a rare sickling hemoglobin variant that has the identical valine for glutamic acid substitution. | <p>The immunoassay can detect even very small amounts of Hb S and should not be used to distinguish between sickle trait and any of the sickling disorders. (See <i>Hemoglobin Electrophoresis</i>.)</p> |
| Clinical findings of argyria are (irreversible) discolorations (gray to blue-black) of the skin, mucous membranes, and nails. Argyrosis refers to ocular silver deposition, with findings of limbic rings resembling Kayser-Fleischer rings. | <p>Silver salts are used as antiseptic and bacteriostatic agents. Ingestion or inhalation of silver or Ag salts can cause argyria or argyrosis.</p> <p>In normal individuals, silver slowly accumulates in body tissues with age but causes no apparent harm.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>S ↑ Conditions with water loss in excess of salt loss through skin (profuse sweating), lungs (prolonged hyperpnea), GI tract (severe vomiting or diarrhea of several etiologies), and kidneys (in polyuric states, e.g., diabetes insipidus, diabetic acidosis); increased renal sodium conservation in hyperaldosteronism, Cushing's syndrome or disease; inadequate water intake because of inadequate thirst mechanism (e.g., coma, hypothalamic disease); dehydration; and excessive saline therapy.</p> <p>S ↓ Low sodium intake; sodium losses (depletional hyponatremia) caused by vomiting, diarrhea, excessive sweating with adequate water and inadequate salt replacement, diuretics abuse (most common clinical cause), or salt-losing nephropathy (polycystic and medullary cystic renal disease, chronic pyelonephritis, renal tubular acidosis); osmotic diuresis; metabolic acidosis (with increased excretion of cations); primary and secondary adrenocortical insufficiency; congenital adrenal hyperplasia (CAH) with 21-hydroxylase deficiency (most common) and other forms of CAH with salt wastage, isolated hypoadosteronism, pseudohypoadosteronism (unresponsiveness of renal tubule to aldosterone); dilutional hyponatremia with edema, ascites in chronic cardiac failure, diabetes mellitus, hepatic cirrhosis, hepatic failure, nephrotic syndrome, interstitial nephritis, malnutrition, or fluid intoxication; hypothyroidism; hyperosmolality; SIADH, which may relate to carcinoma of lung, pancreas, CNS disease, lung infections; acute intermittent porphyria; psychogenic polydipsia; artifactual hyponatremia in extremely marked hypertriglyceridemia or hyperproteinemia; and hyperglycemia</p> | <p>Ratio of plasma Na to osmolality is 0.43-0.50. The ratio is decreased when there is an increase in osmotically active substances (e.g., salicylate poisoning, uremia, diabetes). Sodium decreases ~1.5-3.0 mmol/L for each 100-mg/dL increase of blood glucose. The combination of hyponatremia with urine osmolality consistently higher than plasma osmolality suggests the possibility of inappropriate ADH secretion. Na <120 mmol/L results in weakness; <110 mmol/L results in bulbar or pseudobulbar palsy; 90-105 mmol/L results in severe neurological signs and symptoms. Concentrations >155 mmol/L may produce cardiovascular and renal symptoms, especially if accompanied by plasma volume depletion. Values >160 mmol/L are potentially hazardous.</p> <p>Methods using ion-selective electrodes measure ion activity, not concentration. Corrections are generally calculated by the instrument.</p> <p>Changes in methodologies, mainly to ISEs, require a reevaluation of the reference interval. For sera from patients with hyperlipemia or severe hyperproteinemia, the solvent exclusion effect will affect the results differently, depending on the specific method used, e.g., direct or indirect potentiometry. Therefore the reference interval may be higher or lower than that given here.</p> <p>Direct ISE measurements do not give the volume displacement error in specimens with high lipid or protein content, as indirect ISE and flame measurements do.</p> |

Excessive ADH production

| F ↑ Diarrhea (may exceed 60 mmol/L) | Fecal sodium estimations are performed only in metabolic balance studies. |

↑ Somatostatin-producing tumor (somatostatinoma), medullary thyroid carcinoma, pheochromocytoma, duodenal ulcer, active ulcerative colitis, irritable bowel syndrome, alcoholic liver disease, and acromegaly (fasting somatostatin, mainly SS-14, levels).⁸

↓ After vagotomy

Somatostatin is a 14-amino acid peptide found in the hypothalamus, pancreas, gastric mucosa, and intestine. It is a potent inhibitor of pituitary, pancreatic, and GI hormones but possesses other nonendocrine functions as well. Somatostatin is rapidly degraded in blood and has a very short half-life (1-4 min). Some tumors are associated with elevated plasma somatostatin levels; others such as carcinoid tumors, small cell carcinomas of the lung, retinoblastomas, and endocrine tumors of the pancreas and gut have also been shown to contain varying numbers of somatostatin-positive cells.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| Positive in PNH | <p>portion of PNH cells may be low, and most of the PNH cells produced may have been destroyed in the circulation.</p> <p>Both tests are screening tests. The acidified serum test is considered the confirmatory test for PNH.</p> |
| <p><i>Positive:</i> In acute myeloid leukemia (AML, M1-M6), $\geq 3\%$ of blast cells (myeloblasts) are positive. Reaction is strongest in promyelocytic leukemia (M3) and is weak to negative in acute monocytic leukemia (M5).</p> <p><i>Negative:</i> Blast cells in acute lymphoid leukemia (ALL) and in acute megakaryocytic leukemia (M7).</p> <p>See also Table II-14.</p> | <p>Sudan black B (SBB) stain has been traditionally used to distinguish AML from ALL. The stain has affinity for sterols and phospholipids. Staining rather closely parallels the peroxidase reaction and may be slightly more sensitive, but rare SBB-positive cases of ALL have been reported. Myeloblasts that have no stainable granules with Wright's stain may be positive with Sudan black B (and peroxidase).</p> |
| <p>↑ Chronic constipation, purging</p> | <p>Sulfhemoglobin is an impure, green monochrome formed by oxidative sulfation of one or two of the four heme groups of hemoglobin.³ It cannot be reduced to Hb but may be oxidized further and will contribute to Heinz body formation in some instances. Generally it is very stable in blood and is lost from the circulation only with the breakdown of erythrocytes. It is incapable of carrying oxygen and shifts the P50 to the right. Sulfhemoglobinemia is characterized by cyanosis. Symptoms are not usually present.¹</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <i>Normal:</i> low vol.; high visc.; firm clot; ~100 WBC/mm ³ ; few PMN; no crystals; glucose ≈ serum glucose. | Mucin clot produced on addition of acetic acid. |
| <i>Noninflammatory:</i> ↑ vol.; ↑ visc.; firm clot; ↑ WBC. | Microbiology and microscopy can be diagnostic, but gross and chemical findings are generally nonspecific. |
| <i>Inflammatory:</i> ↑ vol.; ↓ visc.; cloudy; friable clot; ↑↑ WBC w/ ↑ PMN. | Uric acid is best measured in serum, which parallels synovial fluid levels. |
| <i>Septic:</i> ↑ vol.; ↑ visc.; cloudy; friable clot; ↑↑↑ WBC w/ ↑ PMN; ↓ glucose. | Elevated protein levels occur in inflammation, but this is insensitive and nonspecific. |
| <i>Crystal:</i> ↑ vol.; friable clot; cloudy; ↑↑ WBC w/ ↑ PMN; ↓ glucose. | Very low glucose levels can occur in septic arthritis, but there is considerable overlap with other inflammatory processes. |
| <i>Hemorrhagic:</i> ↑ vol.; red. ↑ RBC; hemosiderin; hematoidin crystals | |
| | |
| P ↑ Sulfite oxidase deficiency, sepsis ¹³ | Contamination with leukocytes and thrombocytes will falsely elevate plasma values. |
| P ↓ Manic depressive disorder, depressive neurosis, and after abdominal surgery (day 4) ¹⁴ | |

| DIAGNOSTIC INFORMATION | REMARKS |
|-------------------------------|---|
| ↑ Hirsutism, hyperandrogenism | <p>The assay measures the non-SHBG-bound testosterone (free plus albumin-bound testosterone).</p> <p>Testosterone circulates in three forms: non-protein-bound or free, a weakly bound or albumin bound, and tightly bound to SHBG. SHBG-bound testosterone is not biologically active. In females, 1-2% of testosterone is free and 25-65% is weakly bound to albumin. The remainder is tightly bound to SHBG.</p> <p>Bioavailable testosterone is independent of SHBG concentrations. In obesity, SHBG and total testosterone are low, but bioavailable testosterone is within the reference intervals. In hirsutism, SHBG levels may be low and total testosterone may not be elevated. Bioavailable testosterone is an apparent marker for androgen activity.</p> |

| | |
|--|---|
| ↑ Hirsutism, adrenal virilizing tumor, polycystic ovary syndrome, and androgen resistance | Free (non-protein-bound) testosterone is independent of changes in concentrations of the principal testosterone transport protein, sex hormone-binding globulin. In those situations in which SHBG is frequently increased (e.g., hyperthyroidism, hyperestrogenic states such as pregnancy or oral contraceptive use, and administration of antiepileptic drugs) or decreased (e.g., hypothyroidism, androgen excess, and obesity), measurements of free testosterone may be more appropriate than measurements of total testosterone. |
| ↓ Hypogonadism, P-450 _{C17} enzyme deficiency | Values for free testosterone performed by equilibrium tracer dialysis compare favorably with those performed by membrane ultrafiltration and gel filtration methods. Alternative assessments of free testosterone include bioavailable testosterone (an estimation of free and weakly bound testosterone); analog |
| An increase in concentration of sex hormone-binding globulin (SHBG) and a decrease in plasma-free testosterone are reported in old age in men. | |
| See <i>Testosterone, Total</i> ; <i>Testosterone, Bioavailable</i> ; and <i>Sex Hormone-Binding Globulin</i> . | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Idiopathic sexual precocity and adrenal hyperplasia in boys (values may be within adult range), some adrenocortical tumors, extragonadal tumors producing gonadotropin in men, trophoblastic disease during pregnancy, testicular feminization, idiopathic hirsutism, virilizing ovarian tumors, arrhenoblastoma, hilar cell tumor, and virilizing luteoma</p> <p>↓ Down syndrome, uremia, myotonic dystrophy, hepatic insufficiency, cryptorchidism, primary and secondary hypogonadism, and delayed puberty in boys</p> | <p>This test is a measure of total circulating testosterone, both protein-bound and free. In boys, a sharp increase in serum testosterone occurs during pubertal (Tanner) stages 3 and 4. Subsequently the testosterone level remains relatively constant. In adult men, serum testosterone levels peak in the early morning, decreasing 25% to the evening minimum; levels increase after exercise and decrease after immobilization and after glucose load; progressive decreases begin after age 50 yr.</p> <p>In women, values are lower than in men, showing a cyclic pattern of elevation for 1-2 days at midcycle. In virilizing conditions, values are usually >200 ng/dL [>6.94 nmol/L]; slight elevations are seen in idiopathic hirsutism and in a majority of patients with polycystic ovary syndrome.</p> <p>Secretion is episodic, with peak about 7:00 AM and minimum about 8:00 PM; multiple or pooled samples give more reliable information than a single sample.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| ↑ Congenital adrenal hyperplasia caused by 11 β -hydroxylase deficiency; pancreatitis, eclampsia, and other forms of severe stress | Measurement of THS is also useful in determining pituitary reserve with the metyrapone test. See <i>Metyrapone Stimulation Test</i> . |
| ↓ Addison's disease, hypopituitarism | After metyrapone administration, there is normally a 10-fold increase over baseline THS. |

Symptoms of poisoning include alopecia (unique sign), ataxia, choreiform movements, pulmonary edema, vomiting, abdominal pain, GI bleeding, diarrhea, restlessness, delirium, and eventually coma. Poisoning results in optic neuropathy, blindness, facial paralysis, paresthesias, peripheral neuropathy, respiratory paralysis and liver and renal damage.

Thallium salts (sulfate and acetate) are used in medications, cosmetics, and pesticides. Tl salts burn with a bright green flame. Trace amounts of ^{201}Tl are used in radiological procedures. Tl poisoning occurs from ingestion or from absorption through intact skin and mucous membranes. Average lethal dose is 10-15 mg Tl/kg.⁵ Tl accumulates in liver, kidney, bone, and muscle tissue. Elimination half-life after poisoning is <2 days.⁶

See Table II-6.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>S, B ↑ Leukemia, polycythemia vera, and Hodgkin's disease</p> <p>S, B ↓ Alcoholism with and without liver disease, deficient diet, excessive consumption of raw fish (which contains a microbial thiaminase) and tea (which contains an antithiamine factor), chronic febrile infections, prolonged diarrhea, diabetes, cancer, and chronic illness</p> <p><i>Thiamine-responsive inborn errors:</i> Megaloblastic anemia of unknown origin, impaired pyruvate carboxylase, impaired ketoacid dehydrogenase, and subacute necrotizing encephalopathy</p> <p><i>Wet beriberi:</i> Symptoms are (or include) high-output left ventricular heart failure, tachycardia, increased central venous pressure, sodium retention, and edema. In acute deficiency, there is severe dyspnea, increased thirst, cardiac failure, glove-stocking cyanosis, marked cardiomegaly, and hepatomegaly.</p> <p><i>Dry beriberi (Wernicke-Korsakoff syndrome):</i> Progression of symptoms includes symmetrical motor and sensory dysfunction, nystagmus, ophthalmoplegia, ataxia, confusion, coma, and death. Impaired memory and cognition may persist after treatment.</p> <p>Thiamine deficiency causes an increase in serum level of lactate, α-ketoglutarate, pyruvate, and glyoxylate.</p> | <p>Thiamine (vitamin B₁) is a coenzyme for transketolase and the E₁α subunit of the enzymes, pyruvate dehydrogenase, α-ketoglutarate dehydrogenase, and branched chain α-ketoacid dehydrogenase complexes.^{5,6} The average total thiamine pool in adults is ~30 mg, and an intake of 0.5 mg/1000 kcal/day is needed to maintain this pool.^{5,7} Thiamine deficiency most commonly occurs in elderly persons and in individuals with chronic gastrointestinal problems, on cancer treatment, or on long-term treatment with diuretics.^{5,7,8} Because of its short storage time in vivo, marginal thiamine deficiency can occur within 10 days and more severe deficiency within 21 days if dietary intake is inadequate.⁹ Severe thiamine deficiency results in cardiac failure (beriberi) or neurological manifestations (Wernicke's encephalopathy).⁵ Subclinical insufficiency may affect intellectual performance and general well-being without overt clinical symptoms.⁵ Because the symptoms associated with thiamine deficiency are nonspecific and could be observed in a variety of clinical settings, determination of a patient's thiamine status is frequently requested in diverse clinical situations.</p> <p>Thiamine diphosphate (TDP) is the physiologically active form of thiamine, and TDP is the predominant form present in erythrocytes. Several authors have suggested that thiamine status is best determined by measurement of TDP in whole blood or erythrocyte blood by high-performance liquid chromatography (HPLC).^{4,7,10} Blood TDP measurement may be a more sensitive indicator of thiamine status than the transketolase activation assay.^{1,11} Further studies are needed to confirm this.</p> <p>Free thiamine is the predominant form in plasma, which contains no appreciable amount of TDP. Thiamine has a relatively short half-life in plasma. The utility of measurement of plasma thiamine to assess thiamine nutritive status needs further study.</p> <p>Determination of urinary thiamine in a timed collection may be helpful in differentiating extremes of thiamine deficiency; however, excretion can be influenced by dietary intake, absorption, and other factors.¹²</p> <p>Toxicity to thiamine only occurs when it is given parenterally in doses several hundredfold in excess of requirements. See <i>Transketolase</i>.</p> |

DIAGNOSTIC INFORMATION

REMARKS

Thyroglobulin (Tg) is a tumor marker for monitoring the status of patients with well-differentiated (papillary or follicular) thyroid cancer. It is used for the determination of residual thyroid tissue or recurrent disease, not for the diagnosis of thyroid cancer. Sensitivity for detecting recurrence can be improved with TSH stimulation of Tg concentrations after either thyroxine withdrawal or recombinant TSH administration. In this setting, Tg may be used in conjunction with whole body ^{131}I scans. Validation of use of Tg as a tumor marker postoperatively can be confirmed by preoperative measurements where two thirds of patients have elevated Tg concentrations.^{2,3}

The majority of patients with elevated Tg concentrations have benign thyroid conditions because Tg is a nonspecific indicator of thyroid dysfunction. Concentrations can be elevated in Hashimoto's thyroiditis, Graves' disease, thyroid adenoma, and subacute thyroiditis. Serum Tg measurements may also aid in diagnosing thyrotoxicosis factitia, characterized by a low serum Tg, and investigating the etiology of congenital hypothyroidism in infants.^{1,4}

Tg is a 660-kDa dimeric glycoprotein synthesized in the follicular colloid of the thyroid gland and regulated by TSH. Tg is the precursor protein for thyroid hormone synthesis. Most normal euthyroid individuals have detectable serum Tg concentrations. Tg concentrations and therefore reference intervals can be affected by iodine intake influenced by geographic location.^{1,3}

Assays for Tg include both RIA and immunometric (IMA) formats, and several methods are available on automated platforms. Both assay formats can be affected by interference from Tg autoantibodies present in ~20% of thyroid cancer patients and 10% of normal subjects. IMA assays are more likely to be affected by Tg autoantibodies, causing an underestimation in Tg concentrations. Therefore the Tg autoantibody status of patients should be determined when measuring Tg.^{1,3,5}

↑ Hyperthyroidism, states with decreased TBG (e.g., androgen treatment, chronic liver disease), protein loss (renal, gastrointestinal) or genetically low TBG, and thyrotoxicosis factitia

↓ Hypothyroidism, states with increased TBG (e.g., estrogen treatment, pregnancy, acute hepatitis, genetically high TBG)

Concordant variance of T_4 and THBR tests suggests altered thyroid function; discordant variance suggests primary change in TBG in a euthyroid state (e.g., pregnancy). In pregnancy, the FT_4I ($\text{THBR} \times T_4$) should be within the reference interval. (See also *Free Thyroxine Index*.)

The THBR is derived from a version of the T_3 or T_4 uptake test. In the isotopic T uptake test, resin (or other solid-phase binding material) and radioactive T_3 or T_4 are added to a patient's serum, and the proportion of tracer bound by the solid matrix (the "uptake") is measured. In most nonisotopic assays, the binder is a T_4 antibody.

The result for the patient's serum is divided by that for a reference serum to give a ratio. The ratio is proportional to the free fraction of T_4 or T_3 in serum and is properly known as the THBR:

$$\text{THBR} = \frac{\% \text{ T uptake (patient serum)}}{\% \text{ T uptake (reference serum)}}$$

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>A THBR >1.15 indicates reduced availability of TBG binding sites for T_4, whereas a THBR <0.85 indicates an increased availability of TBG binding sites for T_4.</p> <p>In pregnancy, the THBR gradually decreases (as early as 3-6 wk after conception) until the end of the first trimester and then remains relatively constant. It returns to normal 12-13 wk postpartum, but in certain cases of habitual threatened abortion and in pregnancy complicated by hyperthyroidism decreases are not observed.</p> | <p>Although centered on a ratio of 1.0, reference values may differ with laboratory and method. THBR replaces the T_3 resin uptake test.</p> <p>The THBR test is useful in differentiating T_3 and T_4 changes in primary thyroidal disorders from changes in total T_3 and T_4 as a result of primary changes in TBG.</p> <p>THBR is not acceptable as an independent and isolated test because it correlates poorly with the concentration of T_4 in serum and with the clinical status of the patient, largely because of the variability of the concentration of TBG in health and disease. THBR is only useful when combined with total T_4 to calculate the FT_4 index. (See <i>Free Thyroxine Index</i>; <i>Thyroxine, Free</i>; and <i>Thyroxine-Binding Globulin</i>.)</p> |
| <p>Low titers have been detected in 5-10% of normal individuals with no symptoms of disease.</p> <p>An agglutination test positive at a 1:2500 dilution is equivalent to histological proof of Hashimoto's disease. There is no greater frequency of detection in multinodular goiter and thyroid adenomas or carcinomas than in normal subjects.</p> <p>Titers decrease progressively during pregnancy and increase transiently postpartum.</p> | <p>This test is more sensitive for Hashimoto's thyroiditis than the thyroglobulin antibodies assay but not better than the thyroid peroxidase antibody test for assessing thyroid antibodies. See <i>Thyroglobulin Antibodies and Anti-TPO</i>.</p> <p>Frequency of positive results in thyroid autoimmune disease is higher than in the thyroglobulin antibodies test, especially in people aged <20 yr but about the same for anti-TPO.</p> |
| <p>Positive: Hashimoto's thyroiditis (up to 8% give negative results), thyroid carcinoma (positive in $<10\%$ of cases), early hypothyroidism (positive in 99% of cases), pernicious anemia (in $>5\%$ of cases, low titers); also detectable in some patients with Graves' disease.</p> | <p>Positive titer in conjunction with the presence of thyroglobulin antibodies is highly indicative of Hashimoto's thyroiditis. Complement-fixing microsomal antibodies are often not found in proven cases of thyroiditis, suggesting a lack of sensitivity of the technique. Any positive test should be accepted as significant.</p> |

|--|----------------------------------|-------------------------------------|--------------|--------------------|-------------|

Immunometric assay⁴

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| | Sensitivity: 20 U/mL [20 kU/L]; abnormal values with this method may exceed 500,000 U/mL [500,000 kU/L]. It is claimed that the CPB method gives high results in 80-90% of patients with Hashimoto's thyroiditis and is elevated in all patients with Graves' disease. ¹³¹ I treatment of Graves' disease increases the levels ~15-fold. |
| Values >400 U/mL [>400 kU/L] have been observed in Graves' disease (77% of cases, median value being 8100 U/mL [8100 kU/L]). ⁶ | IRMA and ELISA ⁷ techniques are more sensitive and specific than hemagglutination assays for the detection of thyroid autoantibodies and are now the methods of choice for determining thyroid autoantibodies. In addition, measurement of antibodies to thyroid peroxidase (anti-TPO) has essentially replaced the measurement of antimicrosomal antibody titers for assessing thyroid autoantibodies in patients with thyroid disease. See also <i>Thyroid Peroxidase Antibodies</i> . |

↑ Autoimmune thyroid disease (Hashimoto's thyroiditis, idiopathic myxedema, Graves' disease)

Positive titers are found in >50% of patients with Graves' disease, >80% of patients with autoimmune thyroiditis, and ~40% of patients with insulin-dependent diabetes mellitus. Approximately 14% of pregnant women have a positive titer for anti-TPO.

TPO is the principal and possibly only autoantigenic component of thyroid microsomes. ELISA-based assays for anti-TPO antibodies provide greater sensitivity and specificity than hemagglutination assays for microsomal antibodies for detecting and monitoring autoimmune thyroid disorders.²

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>In nonimmune thyroid disease, the frequency of detectable anti-TPO antibodies is similar to that observed in normal individuals.</p> <p>Antibodies to thyroid peroxidase are found in 8-27% of the normal population.</p> | |
| <p>In Graves' disease, hyperfunctioning enlarged thyroid tissue usually delineates the entire gland; in toxic nodular goiter, only hyperfunctioning adenomas are visible on the scan; subacute thyroiditis fails to portray the thyroid gland when the inflammation is bilateral. The presence of a single "cold" nodule increases suspicion of malignancy. A "hot" nodule is considered benign in 99.8% of cases with ¹²³I scans and in 98% with ^{99m}Tc scans. (See <i>Technetium Scan Procedure</i>.)</p> <p>Indications for thyroid scan: Detection of ectopic thyroid tissue in thyroid agenesis; evaluation of extraglandular, functioning thyroid carcinoma after ablation of the normal gland; and evaluation of glands in patients with previous neck irradiation (of tonsils, thymus, and acne).</p> | <p>Cold nodules on ¹²³I (or ¹³¹I) scans are rarely hot on ^{99m}Tc scans. For children the thyroid scan has limited indications. Because technetium scans may be produced in a matter of minutes, they are generally preferred over ¹²³I for children, except for those rare instances that require definition of the kinetics of iodine metabolism, e.g., familial goiter resulting from enzyme defect. (See also <i>Perchlorate Discharge Test</i>.)</p> <p>A significantly larger dose of radioactive iodine is needed for a scan than for an uptake test. Unless specific information regarding distribution of function is desired, one should not request a radioactive iodine scan as part of a routine thyroid workup. ¹²³I is preferred over ¹³¹I for routine scanning because radiation exposure and half-life are less.</p> |

|---|---|--|--|
| Thyroid-Stimulating Hormone (TSH) Stimulation Test¹⁻³ | Day 1: Give 2-15 μCi ¹³¹ I. | Normal thyroid glands increase ¹³¹ I-uptake into the slightly hyperthyroid range, and the second ¹³¹ I-uptake should be higher than the first by 10-20%. Subjects with “low normal” uptake show increase to “high normal.” | <i>See Thyroid Uptake of Radioactive Iodine, ¹³¹I or ¹²³I.</i> |
| | Day 2: Measure 24-hr ¹³¹ I-uptake and give 10 U TSH, IM. | | |
| | Dose, adult: 10 U Thyrotropin (Thytropar), IM, daily for 1-3 days | Days 3-4: Give 10 U TSH on days 3 and 4. | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Hyperthyroidism with rapid release: 2 hr, >40% [>0.40]; 6 hr, >30% [>0.30]; and 24 hr, >55% [>0.55]. Compensatory hyperactivity without thyrotoxicosis (endemic goiter) caused by low iodide intake with slow release; gigantism and acromegaly (if basal metabolic rate is increased); after withdrawal of thyroid-suppressing drug; after excessive thyroxine loss in urine in some cases of nephrosis; and acute renal failure.</p> | <p>The only direct test of thyroid function uses a radioactive isotope of iodine. ^{123}I is preferred because of lower radiation dose. Reference interval varies with geographical location and is inversely related to the intake. The test is falsely low in individuals with expanded total iodine pool and falsely increased in patients with contracted iodine pool. Thirty to 70% of hyperthyroid patients with rapid iodine turnover in the thyroid give normal results (24-hr values); 6-hr values often demonstrate the thyroid's increased affinity for iodine.</p> |
| <p>↓ Hypothyroidism, hypopituitarism, chronic renal failure; in early phase of subacute thyroiditis at 24-hr activity decreased to 0-1% [0.0-0.01] unless the disease is still unilateral; thyrotoxicosis factitia; and iodine-induced hyperthyroidism.</p> | <p>False elevations may be seen in some euthyroid patients with Hashimoto's thyroiditis or congenital organification defects.</p> |
| <p>Identify hot and cold spots of iodine uptake directly to establish the diagnosis of thyroid adenoma or thyroid cancer.</p> | <p>Test is less reliable in hypothyroidism. In children, RAIU is limited to rare instances that require definition of the kinetics of iodine metabolism, e.g., familial goiter resulting from enzyme defect (see <i>Perchlorate Discharge Test</i>). See also <i>Technetium Uptake</i>.</p> |
| | <p>Test used less frequently than in the past because of improvements in indirect methods for assessing thyroid status and the widespread increase in dietary iodine intake in most countries.</p> |
| <p>Positive response in secondary hypothyroidism; no response in primary hypothyroidism or diminished thyroid reserve.</p> | <p>The 3-day test is preferred; nausea, vomiting, local painful reactions at the site of the injection, and hypersensitivity have been reported.</p> |
| <p>Other important uses of the test include determining whether nonfunctioning areas of the thyroid (as indicated by scanning methods) are actually capable of function; determining thyroid reserve in patients taking thyroid hormone replacement; and determining whether the thyroid is capable of function after ablation of thyroid adenomas.</p> | <p>The normal thyroid gland responds to exogenous TSH stimulation by increasing the rate of iodine accumulation. In primary hypothyroidism, the failing thyroid gland is maximally stimulated by endogenous TSH and does not respond to further stimulation. Availability of sensitive TSH assays and the TRH test has markedly reduced the use of this test in clinical practice.</p> |

| | | | | | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Primary hypothyroidism (3-100 times normal), Hashimoto's thyroiditis with clinical hypothyroidism and 33% of patients with Hashimoto's thyroiditis who are clinically euthyroid, ectopic TSH secretion (lung, breast tumors), subacute thyroiditis (recovery phase), nonthyroidal illness (recovery phase), and thyroid hormone resistance</p> <p>↓ Primary hyperthyroidism, secondary hypothyroidism (pituitary), tertiary hypothyroidism (hypothalamic), subclinical hyperthyroidism (e.g., toxic multinodular goiter, autonomous thyroid hormone secretion, exogenous thyroid hormone therapy, treated Graves' disease, ophthalmopathy of euthyroid Graves' disease), and euthyroid sick syndrome</p> <p>TSH measurements with sufficient sensitivity to distinguish low (suppressed) levels from normal have become the preferred first-line test for hyperthyroidism and hypothyroidism. The high-sensitivity test appears to be especially useful in distinguishing sick euthyroid patients; in differentiating mild, subclinical hyperthyroidism from overt Graves' disease; in monitoring thyroid cancer patients on thyroxine; and in monitoring the adequacy of thyroid hormone replacement in hypothyroid patients. If basal serum TSH levels are detectable by a sensitive assay, then no diagnostic benefit is gained by performing a TRH stimulation test.</p> | <p>TSH has diurnal rhythm, peaks at 2:00-4:00 AM, and has lowest level at 5:00-6:00 PM with ultradian variations (periods shorter than circadian). Moderately high TSH is often found in euthyroid patients during treatment for hyperthyroidism. In treated hyperthyroid patients, TSH may remain low for 4-6 wk after euthyroid state is achieved.</p> <p>TSH surges with birth, peaking at 30 min at 25-160 μU/mL [25-160 mU/L], declining back to cord blood levels by 3 days, and reaching adult values in the first week of life.</p> <p>Immunometric assays including chemiluminescence-based assay sensitivity: 0.01 μU/mL [0.01 mU/L]. Sensitive TSH test is considered by some to be the preferred screening test for evaluation of all thyrometabolic states. Reference ranges and diagnostic utility should be developed for each assay. Some endocrinologists have suggested that the upper reference limit for adults should be reduced to 2.5 mU/L.</p> <p>Reference ranges for newborn screening should be determined by each laboratory providing screening; significant numbers of samples must be screened to determine sensitivity and specificity for tests provided by that laboratory.</p> |

Autoantibodies to thyrotropin have been described in rare patients with hypopituitarism and spuriously high serum TSH.

Thyrotropin autoantibodies can interfere with immunoassay measurements of TSH; their presence should be considered whenever TSH results are incongruous with the clinical state. See *Thyroxine Autoantibodies*.

Values between 1.3 and 2.0 are seen in 10% of patients with thyroid diseases other than Graves' disease. Values >2.8 have been found only in patients with Graves' disease. High levels of TSI (thyroid-stimulating immunoglobulins) in pregnancy have some predictive value for neonatal thyrotoxicosis. High titers do not necessarily mean high risk to the fetus, but low titers indicate low risk. Test is also useful for predicting relapse or remission in hyperthyroid patients.⁷

Thyrotropin-receptor antibodies are generally used to (1) confirm clinical diagnosis of Graves' disease; (2) evaluate euthyroid patient with bilateral exophthalmos; and (3) determine prognosis of patients with Graves' disease treated with antithyroid agents.

Thyrotropin-receptor antibodies are a group of related heterogeneous IgG immunoglobulins that bind to thyroid cell membranes at or near the TSH-receptor site. Their effects on thyroid function are variable.

Two types of tests are usually used for the detection of thyrotropin-receptor antibodies. The first test (TBII) determines the capacity of patient serum or IgG to inhibit binding of ¹²⁵I-labeled TSH to TSH receptors from thyroid membrane preparations.

The second test, also called TSI or TSA_b (thyroid-stimulating antibodies), assesses the capacity of patient serum or IgG to stimulate adenylate cyclase or to enhance thyroid hormone or Tg secretion or iodine uptake in isolated thyroid epithelial cells. Routine use of this test has been improved by the use of cloned, functioning rat thyroid follicular cells (FRTL-5); human thyroid cells were used previously. The usefulness of the TSI test is limited because it detects stimulating antibodies only.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Assay detects TSH-receptor antibodies in >85% of patients with Graves' disease, treated or untreated.¹² Test is of some use in following the course of therapy, predicting remission or relapse, and predicting neonatal thyroid disease secondary to maternal disease.</p> | <p>The TBII (thyroid-binding inhibiting immunoglobulins) test detects all TSH-receptor antibodies (stimulating, neutral, and inhibiting antibodies) but gives no information regarding functions of the antibodies. TBII is more definitive than TSI for suspected acute toxic goiter, and the frequency of positive results in patients with active disease is ~90%.</p> |
| <p>↑ Graves' disease, autoimmune thyroiditis, and nonspecific goiter</p> <p>Further clinical correlation is needed, but presently test is most useful in identifying a possible cause for unexplained goiter (e.g., no TSI or TBII detected).</p> <p>In active thyrotoxicosis, TGI is detected only in the presence of thyroid enlargement. In simple goiters, TGI is present but has 10 times less potency.</p> | <p>Test is also called TGI (thyroid-growth immunoglobulins). TGI stimulates labeled thymidine uptake (DNA synthesis) causing follicle cell growth, independent of TSI. However, test has limited clinical usefulness.</p> |

| <i>Immunoassays (direct two-step and one-step)</i> ^{8,9} | | | 0.7-2.0 ¹² | | [9-26] | ↓ C Heparin (in analog assays) |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| Thyroxine autoantibodies are present in Hashimoto's thyroiditis and primary hypothyroidism (54%), Graves' disease (26%), nodular or diffuse goiter (9%), and thyroid cancer (1%); role in pathogenesis is unclear. ⁶ | <p>The presence of thyroxine autoantibodies is relatively rare but when present can interfere with RIA for total and free (direct-analog) thyroid hormone assays. This interference produces either low or high results, depending on the separation method.⁶ The calculated FT₄ index may also be abnormally high when T₄ autoantibodies are present.⁸ The presence of autoantibodies should be considered when T₄ test results are discordant with the clinical state. Autoantibodies to thyroid hormones are a rare cause of hypothyroidism. They usually do not interfere with thyroid function.</p> <p>FT₄ methods are still valid if the tracer does not come into contact with plasma proteins during the assay procedure.</p> |

| | |
|---|--|
| ↑ Hyperthyroidism; hypothyroidism treated with thyroxine | FT ₄ is 0.02-0.04% of total T ₄ . |
| ↓ Hypothyroidism; hypothyroidism treated with triiodothyronine; and late pregnancy | FT ₄ assays based on direct equilibrium dialysis (or ultrafiltration) are considered reference methods. These procedures separate free hormone from protein-bound hormone before direct measurement of the free fraction with a sensitive T ₄ immunoassay. All other methods for assessing FT ₄ concentrations are estimates: FT ₄ E is being used to denote FT ₄ estimate. FT ₄ derived from equilibrium tracer dialysis; direct, including two-step and one-step (analog), immunoassays; and the calculated FT ₄ index. |
| Fluctuations in FT ₄ level may occur in euthyroid patients during acute or chronic nonthyroidal illnesses. | |
| Used in conjunction with sensitive TSH result except in patients with known pituitary failure. | FT ₄ results obtained by dialysis or reference methods are independent of abnormal binding proteins. FT ₄ estimate methods give results comparable with reference methods in healthy subjects, hyperthyroid and hypothyroid patients, and patients with only mild binding protein abnormalities. FT ₄ estimate methods, particularly the FT ₄ index and one-step methods, are unreliable in euthyroid patients with dysalbuminemic hyperthy- |

|---|--|--|---|--------|---|--|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>2. Larsen PR, Davies TF, Schlumberger MJ, et al: The thyroid gland. In Larsen PR, Kronenberg HM, Melmed S, et al, editors: <i>Williams textbook of endocrinology</i>, ed 10, Philadelphia, 2003, WB Saunders.</p> | |
| <p>↑ Hyperthyroidism, familial dysalbuminemic hyperthyroxinemia, and congenital TBG excess</p> | <p>The thyroxine/TBG ratio correlates variably with FT_4I but is particularly useful in cases with mildly altered TBG concentrations. The ratio represents an approximation to free thyroxine (FT_4) concentration.</p> |
| <p>↓ Hypothyroidism (values overlap with euthyroid patient), third trimester of pregnancy, and congenital TBG deficiency</p> | <p>See also <i>Free Thyroxine Index</i> and <i>Thyroid Hormone-Binding Ratio</i>.</p> |
| <p>In primary increases of TBG, both T_4 and TBG will increase and the ratio will remain essentially unaltered. In primary decreases of TBG, both T_4 and TBG will decrease and the ratio will also remain unaltered. Higher than expected ratios have been observed with very low TBG levels and vice versa.⁶</p> | |
| <p>S ↑ Hyperthyroidism, states with increased TBG (e.g., pregnancy, oral contraceptives, genetically determined increases in TBG, acute intermittent porphyria, primary biliary cirrhosis), thyrotoxicosis factitia, some cases of acute thyroiditis, hepatitis (by 4 wk), obesity, acute psychiatric illnesses, and hyperemesis gravidarum</p> | <p>Sensitive TSH measurements are now used as the initial test of thyroid function (see <i>Thyrotropin</i>). T_4 testing is more commonly used to confirm abnormal TSH results when TSH levels are abnormally high or low.¹⁰</p> |
| <p>T_4 may also be elevated in euthyroid patients because of familial dysalbuminemic hyperthyroxinemia, increased T_4 binding by TBPA, or T_4 autoantibodies; T_3 will be normal in these cases.</p> | <p>By itself, the serum total T_4 does not provide adequate clinical information. A free thyroxine estimate, such as free T_4 by immunoassay or a calculated FT_4 index, should be reported with every total T_4 measurement (see also <i>FT_4 Free Thyroxine Index</i> and <i>Thyroid Hormone-Binding Ratio</i>).</p> |
| <p>S ↓ Hypothyroidism, states with decreased TBG (e.g., nephrotic syndrome, chronic liver disease, GI protein loss, genetically decreased TBG, malnutrition), panhypopituitarism, and strenuous exercise</p> | <p>T_4 levels are lower in cord blood from preterm than from full-term infants¹¹ and correlate positively with birthweight in term neonates.¹² T_4 values are higher in the neonate because of elevated TBG; FT_4 is near adult levels. Values increase abruptly in the first few hours after birth and decline gradually until the age of 5 yr. Males experience a gradual decline in T_4 as they mature sexually; females do not.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| S ↑ Infectious hepatitis, acute intermittent porphyria, genetically determined high TBG, ¹¹ hypothyroidism (some cases), and pregnancy | This glycoprotein is the principal carrier for T ₃ and T ₄ . The balance of these hormones is carried by transthyretin (prealbumin) and albumin. |
| S ↓ Major illness, surgical stress, protein malnutrition, malabsorption resulting from various causes, protein-losing enteropathy, nephrotic syndrome, active acromegaly, ovarian hypofunction, and genetically determined low TBG | <p>TBG declines with age in parallel with total and free T₄ and T₃. The latter changes are accompanied by an increase in rT₃ and rT₃ index, suggesting a decrease in peripheral conversion of T₄ and T₃ rather than a change in the secretory behavior of the thyroid gland itself. With the availability of better free thyroid hormone tests, the determination of TBG is rarely used to assess thyroid hormone binding status. The TBG test was used to differentiate total T₃ and T₄ changes in primary thyroidal disorders from changes in total T₃ and T₄ as a result of primary changes in TBG.</p> <p>Molecular variants of TBG with low avidity for T₃ and T₄ are not uncommon, especially in certain ethnic groups such as the Australian aborigines.¹²⁻¹⁴</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>Information is limited concerning the toxicity of tin in humans. Inorganic tin is not readily absorbed. The ingestion of soluble salts or large doses of metallic tin from nonlacquered or corroded cans may result in gastric irritation. Acute exposure to tin oxide results in mild irritation to eyes, skin, and mucous membranes. Chronic inhalation of tin dust in industrial settings causes stannosis, a benign form of pneumoconiosis.</p> | <p>Tin is used in the manufacture of alloys. Tin plating is used for food containers, and tin salts are used in calico printing. Organic tin compounds are found in polyvinyl plastics, chlorinated rubber paints, fungicides, insecticides, and antihelmintics.</p> |
| <p>Increased levels in DVT, after venous occlusion, stress, exercise, desmopressin (DDAVP) infusion; also in a rare hereditary disorder associated with bleeding.³</p> <p>Reduced levels have been documented as a familial defect associated with thrombotic manifestations.³</p> | <p>Tissue plasminogen activator (tPA) is a major component of the fibrinolytic system. Deficiency of tPA has been proposed to be associated with thromboembolic disease.</p> <p>In light of the fact that there is no conclusive evidence that tPA deficiency contributes to the risk of thrombosis, a 2002 consensus conference on thrombophilia stated that routine evaluation of tPA in patients with apparent thrombophilia is not recommended.²</p> <p>tPA can be measured by functional (activity) and/or immunologic (antigenic) assays. The presence of plasminogen activator inhibitors (PAI-1) and antiplasmin interferes with functional tPA assays but not with the determination of tPA antigen.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| In celiac disease, it is 90-98% sensitive and 94-97% specific. | See <i>Reticulin Antibody</i> , <i>Endomyosial Antibody</i> , and <i>Gliadin Antibody</i> . |
| It is 70% positive in dermatitis herpetiformis. | Celiac disease is an immune disorder found in 1% of the NA population that is stimulated by gluten. It is characterized by typical GI symptoms and a variety of less common symptoms. |
| | TTG is the antigen for endomyosial antibodies. |
| | Small bowel biopsy is needed for definitive diagnosis. |
| | More than 97% of people with celiac disease have DQ2 and/or DQ8 HLA haplotypes compared with 40% of the population. |

Toxic effects include headache, nausea, lassitude, impairment of coordination, and loss of memory. Chronic abuse causes permanent changes to brain structure, including loss of gray and white matter differentiation; and cerebral, cerebellar, and brainstem atrophy.

Toluene is a product of petroleum distillation and has many commercial uses, including aerosols, paints and paint thinners, lacquer, adhesives, and industrial solvents. Most toxic exposures are occupational or the result of abuse by inhalation. Eighty percent of absorbed toluene is metabolized to benzoic acid, which is excreted conjugated with glucuronide or glycine (hippuric acid). Urinary hippuric acid (normally 1.4 mg/L [7.81 $\mu\text{mol/L}$]) is increased with exposure to toluene. Twenty percent of toluene is eliminated in breath.⁶

Analyze fresh or store at 4° C for <72 hr. Stable frozen at -20° C for 6 mo or at -70° C indefinitely. Specimens without lipemia or hemolysis are preferred. | 37-171 pmol/L ¹¹ 600-1500 pmol/L ⁹ 400-930 pmol/L ¹⁰ | None found. |
|---|---|---|-------------|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>TPS is a useful indicator of progressive disease in most forms of epithelial-cell carcinoma. It can be used to monitor therapy and predict recurrence of disease in patients with breast, prostate, gynecological, gastrointestinal, lung, and bladder cancers. The marker indicates tumor activity and not tumor burden. Values may be increased in pregnancy and inflammatory disease.¹⁻³</p> | <p>TPA (tissue polypeptide antigen) is a cytokeratin marker measuring cytokeratins 8, 18, and 19. TPA is a more specific assay detecting a defined epitope on cytokeratin 18 using the M3 monoclonal antibody. TPS is reported to be an indicator of cell proliferation. It is produced during the S and G₂ phase of the cell cycle and is released immediately after mitosis. Impaired liver or kidney function, as well as infection and various inflammatory disorders, may cause increased values. These elevations are transient and can be identified by repeated assays.¹⁻³ TPS immunoassays are available from IDL Biotech AB (Bromma, Sweden) and on the IMMULITE platform (Diagnostic Products Corporation). This test does not have FDA approval for clinical use.</p> |
| <p>↑ TC-II: Myeloproliferative disorders (not in leukemoid reactions), monocyte-macrophage neoplasia, lymphoproliferative disorders, and autoimmune diseases.¹⁰</p> <p>↓ TC-II: Infants with severe megaloblastic anemia, TC II congenital deficiency, and TC II functional deficiency</p> <p>↓ HoloTC: Vitamin B₁₂ deficiency</p> | <p>Transcobalamin II (TC II) binds and transports vitamin B₁₂ in plasma. Other cobalamin binders are haptocorrin in plasma and intrinsic factor in the intestine. Intrinsic factor is needed for vitamin B₁₂ uptake in the intestine, and transcobalamin II ensures internalization of the vitamin into all cells of the body. Haptocorrin carries most of the vitamin B₁₂ in plasma, but its function is unknown.</p> <p>Holotranscobalamin (holoTC) represents the biologically active fraction of vitamin B₁₂ that can be delivered into DNA-synthesizing cells.⁴ It has therefore been suggested that holoTC may be a sensitive marker of vitamin B₁₂ deficiency.</p> <p>Laboratory support for the diagnosis and management of vitamin B deficiency is controversial and somewhat problematic.¹² Plasma vitamin B₁₂ concentration does not readily rule out vitamin B₁₂ deficiency.⁴ The use of methylmalonic acid (MMA) and homocysteine (HCY) measurement has been helpful, but the specificities of these tests has been debated because renal insufficiency may also cause elevation of MMA and HCY.⁴</p> <p>More work needs to be done to determine the best diagnostic strategy for assessment of vitamin B status.</p> |

↑ Estrogen (e.g., pregnancy, oral contraceptives), iron deficiency (elevated levels often precede the appearance of anemia by days to months)

Serum ferritin levels decrease with iron deficiency and with generalized malnutrition but remain normal in the presence of inflammation and iron deficiency. The combination of ferritin and transferrin levels is therefore useful in differentiating these disorders.^{6,7} See also *Ferritin*.

↓ Inherited atransferrinemia (rare)⁸; in any disorder associated with inflammation or necrosis; chronic inflammation or malignancy, especially of the lower intestinal tract (↓↓); generalized malnutrition; in the nephrotic syndrome; and in conditions with increased oncotic pressure (multiple myeloma, hepatocellular disease).¹ Serum transferrin levels decrease with evolving iron overload states, including multiple transfusion and hereditary hemochromatosis.

Indications for quantitation include screening for nutritional status and differential diagnosis of anemia. To control the effects of estrogens and acute phase responses, other acute phase proteins should be assayed at the same time. Iron deficiency and iron overload are best diagnosed using assays of serum levels of iron, transferrin, and ferritin in combination.⁸

Transferrin is the major plasma transport protein for iron. Only a small amount of transferrin is required for normal homeostasis. A level >0.15 g/L is associated with nearly normal erythrocyte production in patients with congenital atransferrinemia.⁷

The presence of moderate amounts of unsaturated transferrin may be important in control of infections and infestations by iron-requiring organisms.⁹ As a result, anemia in the face of severe infection or parasitic infestation should probably be treated by transfusion rather than supplementation with iron (if indeed treatment of the anemia is essential) until the infection is controlled.

Immunochemical assays of transferrin are more accurate than chemical assays of total iron-binding capacity.¹⁰ Assuming a molecular weight for transferrin of 89,000, 1 mg of transferrin binds 1.25 mcg of iron. Therefore a serum transferrin level of 300 mcg/dL [3.0 g/L] is equal to a total iron-binding capacity of 300×1.25 or 375 mcg/dL [3.75 g/L].

Transferrin in CSF appears in its desialated form, the Tau protein (β_2 -transferrin). This form can be identified electrophoretically by immunofixation with antitransferrin antibody. The clinical application for identification of the Tau protein is the investigation of rhinorrhea or otorrhea, where the presence of the Tau protein confirms the source being cerebrospinal leakage through a fracture or operative or traumatic site.^{11,12} Partly desialated transferrin is also found to be a marker of heavy alcohol ingestion.^{13,14}

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ With elevated erythroid proliferation or with iron deficiency such as thalassemias, hemolytic anemias, and polycythemias</p> <p>↓ Aplastic anemia, posttransplantational anemia, and chronic renal failure</p> | <p>Transferrin receptor (TfR) is a transferrin-specific membrane receptor, which mediates the uptake of iron into a cell. TfR binds diferric transferrin to form a complex; the transferrin-TfR complex is internalized; and the iron is released into the cytosol. Almost all cells, except mature red cells, have TfR on their surface, but are highly expressed on immature erythroids, placental tissue, liver, and actively dividing cells.</p> <p>TfR is a disulfide-linked dimer of two identical 95-kDa subunits. Each subunit consists of a 61-amino acid N-terminal cytoplasmic domain, a transmembrane region, and a large extracellular domain. The extracellular domain is subject to proteolytic cleavage and released into circulation primarily as a truncated 74-kDa monomer.</p> <p>The major serum TfR (sTfR) is the cleaved extracellular monomer that is complexed with transferrin. The sTfR levels are proportional to the estimated total body mass of cellular transferrin receptor and reflect the number of bone marrow-nucleated erythroids for patients with adequate iron stores. About 80% of sTfR is contained within erythroid marrow.</p> <p>In the absence of iron deficiency, the level of sTfR provides a quantitative measure of total erythropoiesis that is more sensitive and less invasive than bone marrow examination.</p> <p>The sTfR is a more reliable marker than ferritin to distinguish iron deficiency anemia from the anemia of chronic disease. Plasma transferrin levels are usually normal or elevated for patients with iron deficiency who have coexisting anemia of chronic diseases. However, sTfR levels are usually not elevated unless iron supply of the bone marrow is limited.</p> <p>The sTfR levels determined by different assay systems cannot be directly compared because reference intervals differ.</p> <p>MW: 190,000 (membranous dimer), 95,000 (membranous monomer), and 85,000 (soluble or serum monomer).</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| B ↑ Pernicious anemia. See also <i>Thiamine</i> . | Repeated freezing and thawing significantly decreases ETK activity. |
| B ↓ Diabetes mellitus, polyneuritis | |

If anemia is present, erythrocyte transketolase (ETK) activity should be expressed per unit of hemoglobin.

Ercs ↑ Thiamine deficiency ($\geq 25\%$); 15-24% indicates marginal deficiency, but this criterion is not wholly reliable when used as the sole index of thiamine status.⁸

$$\% \text{ TPP stimulation} = \frac{\text{ETK with TPP} - \text{ETK without TPP}}{\text{ETK without TPP}} \times 100$$

The TPP stimulation test indicates thiamine deficiency when addition of TPP to the reaction mixture enhances transketolase activity $>25\%$ over the unstimulated activity. Blood TDP measurement may be a more sensitive indicator of thiamine status than the transketolase activation assay.^{9,10}

See *Thiamine*.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Chronic renal failure,⁸ high concentrations of corticosteroids, and Hodgkin's disease</p> <p>↓ Inflammation, hepatic dysfunction, protein deficiency states, cancer, cystic fibrosis, and chronic illness</p> | <p>Transthyretin (prealbumin) is a homotetrameric unglycosylated protein that transports the thyroid hormones T₃ and T₄, as well as retinol (with retinol-binding protein). Because its hepatic synthesis is highly dependent on the availability of sufficient energy and protein stores, in addition to its comparatively short half-life, this protein has been used as a surrogate marker of nutritional status.³ Transthyretin is also a negative acute-phase reacting protein; consequently levels decrease rapidly in inflammatory states, despite adequate nutritional stores.⁹ Consequently it has been suggested that simultaneous measurement of an inflammatory marker such as CRP may be helpful in the assessment of changes in transthyretin levels.⁸</p> <p>Approximately 38 variants are currently known, and many are associated with dissociation of the tetrameric protein, formation of insoluble fibrils, and amyloid deposition (familial). All are the result of single amino acid substitutions caused by single point mutations.³ Amyloid disease caused by deposition of fibrils containing wild-type protein (senile systemic amyloidosis) also occurs. Onset of disease is typically at an earlier age with the familial forms. Nonsteroidal antiinflammatory medications can inhibit amyloid fibril formation.¹⁰</p> <p>MW: 54,980 t_{1/2}: 1-2 days</p> |

ing third and fourth generation TSH assays, *J Clin Endocrinol Metab* 76:494-498, 1993.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>Exaggerated response, $>35 \mu\text{U/mL}$ [$>35 \text{ mU/L}$], observed in primary hypothyroidism and with thyroid hormone resistance. Inadequate or no response found in hypothyroidism caused by pituitary deficiency (secondary) and in primary hyperthyroidism (except with TSH-producing tumors). In hypothyroidism secondary to hypothalamic disorders (tertiary), response of normal magnitude is seen, but peak may be delayed ($>60 \text{ min}$). These responses are not seen consistently, and differentiation of pituitary and hypothalamic hypothyroidism often requires other tests of thyroid and pituitary function.⁸ Patients with nonthyroidal illnesses have a normal response.</p> | <p>Test essentially amplifies basal TSH levels. With the advent of high-sensitivity TSH assays, test has become less useful.¹⁰</p> |
| <p>Hormonal responses to TRH are also useful in the diagnosis and treatment of hypothalamic-pituitary disorders (e.g., increased ACTH in Cushing's disease, increased GH in acromegaly, increased FSH and LH in gonadotropin-secreting pituitary adenomas).⁵</p> | <p>Test should always be performed in the morning because of nyctohumeral rhythmicity in TSH secretion.</p> |
| <p>In major depressive disorders, TSH blunting, $\leq 7.0 \mu\text{U/mL}$ [$\leq 7.0 \text{ mU/L}$], is seen in 25% of patients. Failure of the response to normalize after antidepressant or electroconvulsant therapy is associated with a higher rate of relapse. The test may help differentiate mania from schizophrenia.⁹</p> | <p>The magnitude of TSH release is proportional to the dose of TRH (up to a dose of 200-300 mcg of TRH) and the age and sex of the subject; responses decline with increasing age in men aged $>40 \text{ yr}$ but not in women. Response is increased in pregnancy. Side effects of IV TRH include mild nausea, flushing, dizziness, peculiar taste, an increase in arterial blood pressure, and an urge to urinate. These effects last only a few minutes and may be lessened by slow injection.</p> |
| | <p>Because dopamine and glucocorticoids suppress TSH production, use of these agents is contraindicated for this test.</p> |
| | <p>With the introduction of third-generation TSH assays, TRH stimulatory testing is now rarely needed (1) to differentiate mild (subclinical) hyperthyroidism from Graves' disease; (2) to distinguish sick hyperthyroidism from sick euthyroid patients; (3) to adjust T_4 replacement therapy in hypothyroid patients; and (4) to monitor T_4 suppressive therapy in patients with thyroid carcinoma.^{11,12}</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Familial hypertriglyceridemia, familial combined hyperlipidemia, familial dysbetalipoproteinemia, severe hypertriglyceridemia (type V, TG >1000 mg/dL), pancreatitis, familial lipoprotein lipase deficiency, apolipoprotein C-II deficiency, eruptive or planar xanthomas, and lipemia retinalis</p> | <p>Metaanalysis of recent epidemiological studies indicate that an elevated TG is an independent risk factor for CHD, especially in women. TG is also important in the diagnosis and treatment of certain hyperlipidemias, in the assessment of abdominal pain and pancreatitis, and in the estimation of LDL cholesterol with the Friedewald equation. In clinical practice, an elevated TG is often a component of metabolic syndrome.</p> |
| <p>The following primary disease states or conditions are associated with elevation of TG: obesity, impaired glucose tolerance, type 2 diabetes, hyperuricemia, viral hepatitis, alcoholism, biliary cirrhosis, extrahepatic biliary obstruction, nephrotic syndrome, chronic renal failure, Cushing's syndrome, pregnancy, infection, inflammation, certain glycogen storage diseases, and stress.</p> | <p>The National Education Program (NCEP) recommends that all adults aged >20 yr be screened with measurement of total cholesterol, HDL-C, and LDL-C and triglyceride concentrations. Fasting TG can vary by as much as 40% over ≥ 1 mo in some individuals. Because of biological and analytical variation, at least two serial samples may be necessary for clinical decision-making.</p> |
| <p>↓ Abetalipoproteinemia, hypobetalipoproteinemia. The following primary disease states can lead to secondary decrease of TG: malnutrition, malabsorption.</p> | <p>In the clinical laboratory, TG is almost always measured by enzymatic methods. Goals for TG measurement as defined by the Working Group on Lipoprotein Measurement of NCEP are a total error $\leq 15\%$, consistent with a bias $\pm 5\%$ and a total variability $\leq 5\%$ CV. Most laboratories do not correct for endogenous glycerol, which typically accounts for an ~ 10 mg/dL overestimation of TG, although free glycerol can be markedly elevated as a result of strenuous exercise, liver damage, diabetes, hemodialysis, parenteral nutrition, IV medications containing glycerol, and stress.</p> |

↑ Hyperthyroidism, T_3 toxicosis, peripheral resistance syndrome, and high altitude

↓ Hypothyroidism, third trimester of pregnancy

In nonthyroidal illness, a low FT_3 is a nonspecific finding.

See also *Triiodothyronine, Total*.

Neither FT_3 nor FT_4 has demonstrated a clear advantage over the other in analyzing thyrotoxicosis. FT_3 by tracer dialysis is an indirect estimate of the free hormone and is determined by multiplying the fraction of T_3 (measured by equilibrium tracer dialysis) by the total T_3 concentration (measured separately by immunoassay). Measuring FT_3 is mainly of value in diagnosing T_3 toxicosis, in determining the T_3 response to therapy, and in clarifying protein binding abnormalities. FT_3 can also be of use in the early progression of subclinical hyperthyroidism to overt thyrotoxicosis when FT_4 is normal and TSH is suppressed. In this setting, FT_3 is often the first to be increased.

FT_3 is ~0.2-0.5% of total T_3 .

Triiodothyronine autoantibodies produce erroneous results unless serum is pretreated with PEG.⁶

FT_3 can be measured by a two-step immunoassay method using chemiluminescence.³

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>↑ Hyperthyroidism, T₃ thyrotoxicosis, treated hyperthyroidism, early thyroid failure, iodine deficiency goiter, states with increased TBG, thyrotoxicosis factitia, and pregnancy</p> <p>↓ Hypothyroidism, states with decreased TBG, and acute and subacute nonthyroidal illnesses</p> <p>In early or mild primary hypothyroidism, T₄ is reduced more than T₃ (high T₃/T₄ ratio). In sick euthyroid syndrome, a reduced T₃ is often the first change observed.</p> | <p>At least 80% of circulating T₃ is derived from monodeiodination of T₄ in peripheral tissues. T₃ has 10- to 15-fold lower affinity for TBG than T₄ but has 15-fold higher affinity for thyroid receptor. T₃ is 4-5 times more potent in biological systems than T₄. Even though serum T₃ levels are 100-fold lower than T₄ concentrations, most T₃ immunoassays have negligible cross-reactivity with T₄. Because T₃ levels fluctuate rapidly in response to stress and other nonthyroidal factors, measurement of T₃ is not a good general test of thyroid status.⁸</p> <p>T₃ toxicosis is uncommon in the early stages of thyrotoxicosis. There is a state of “compensated hypothyroidism” (after surgery or treatment with radioactive iodine or antithyroid drugs) in which serum T₄ is high, T₃ is high or normal, and TSH is high.</p> <p>Serum T₃ values decrease with age even in healthy individuals.</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| No response or inadequate response is consistent with hyperthyroidism and subclinical Graves' disease. Normal suppression excludes the diagnosis of hyperthyroidism. Normal suppression is also seen in goiter (in iodine deficiency) and in congenital and acquired defects in hormone synthesis. | <p>Test assesses the integrity of a normal thyroid-pituitary feedback. Test is used to detect thyroid gland autonomy or the presence of an abnormal stimulator. This test is rarely used in clinical practice because a suppressed basal TSH level or an absent TSH response to TRH provides the same information (see <i>Thyrotropin</i> and <i>TRH Stimulation Test</i>).</p> <p>Test should be used with caution in elderly patients with heart disease, hypertension, or other vascular problems. T₃ may precipitate atrial fibrillation, angina, or heart failure. Test is infrequently used. In very young children or in patients with heart failure or general debility, a dose of 25-50 mcg T₃/day is recommended.</p> |
| <p>This test was designed to correct for variability in protein binding of thyroid hormone when used in conjunction with total thyroid hormone measurements.</p> <p>See <i>Thyroid Hormone-Binding Ratio</i>.</p> | <p>This test should be replaced with the thyroid hormone-binding ratio test in those few instances where direct free hormone measurements are not useful.</p> |

Stable -20 to -80° C for 6 mo to several years when freeze/thaw cycles are avoided. | All concentrations >99th limit are designated as ir- reversible myocardial injury. In the presence of the clinical setting of ischemia, an increased cTn >99th percentile indicative of acute myocardial infarction (MI). | | | | |
| | Limited information is available on serum and plasma tubes (glass and plastic) containing sep- arator gels. | | | | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑↑ Myocardial infarction, severe muscle damage caused by trauma, viral and bacterial infections, alcohol, cocaine, or ischemia. A myopathy may increase serum tropomyosin; neurogenic atrophy of skeletal muscle will not.</p> | <p>Serum tropomyosin increases 2-6 hr after infarction and can remain elevated for up to 12 days.¹</p> <p>Antibody generated against α-tropomyosin from cardiac muscle is contaminated with minor quantities of the β-form and may give false-positive results with the test. In addition, both α- and β-forms are found in skeletal muscle. Thus false-positive results may occur after muscle damage such as observed during very severe exercise.^{1,2}</p> |

To assist in differentiating patients with AMI from non-AMI, the ESC/ACC has redefined AMI, predicated on biomarkers, specifically cTnI or cTnT: (1) a maximal concentration of cTnI or cTnI >99% of a reference group, on at least one occasion during the first 24 hr after the event; (2) a maximal value of CK-MB mass >99% of a reference group on two successive samples or a maximal value >2× reference limit during the first hour after the event (although the consensus document states values for CK-MB should increase and decrease, either a increasing or decreasing pattern should be considered diagnostic; however, values that remain increased without change are rarely due to MI; and (3) in the absence of availability of a cTn or CK-MB assay, total creatine kinase (CK) >2× the upper reference limit.^{12,13}

Also, the ACC/AHA guidelines for management of unstable angina recommend monitoring cTn in ACS patients for differentiating unstable angina (defined as when cTn within the 99% limit) and non-ST-segment-elevation MI (NSTEMI, defined as when cTn > the 99th percentile limit). Blood should be obtained for testing at admission (0 hr), 6-9 hr, and 12-24 hr if the earlier specimens are normal and the clinical index of suspicion is high.¹⁴

For patients in need of an early diagnosis, that will parallel a rapid triage protocol, a rapidly appearing biomarker has been suggested along with serial cTn. Some studies suggest a role for multimarker testing, including myoglobin, for risk stratification in chest pain units and for exclusion of MI.¹⁵ The early release kinetics of cTn are similar to those of CK-MB after

Increased cTn is predictive of adverse outcomes in acute coronary syndrome (ACS). From 26 studies, odds ratios (ORs) for both short-term (30 days) and long-term (5 mo-3 yr) outcomes (endpoint death or nonfatal MI) in patients with and without ST-segment elevation and in UA patients for 6000 patients studied was 8.4.²⁰ Because cTnI offers powerful risk assessment, cTn monitoring should be included in practice guidelines, not only regarding diagnosis and management of ACS patients but also for risk stratification.

The timing of sampling is critical for cardiac marker because results from a single draw at presentation may conflict with findings based on serial draws 24 hr after presentation. Two samples are recommended for cTn on ACS patients who do not rule in for AMI; at presentation and ≥6-9 hr after.²¹ To allow for an increase in cTn above baseline in a patient presenting with a recent acute coronary lesion. However, a normal cardiac cTn does not remove all risk. cTn results should be reported within 30-60 min (from the time blood is drawn to results reported to the physician), either using POC testing or the central laboratory.

The contractile proteins of the myofibril include troponin C (Ca-binding), I (inhibitory), and T (tropomyosin-binding). Subunits exist in as isoforms, distributed between cardiac muscle and slow and fast twitch skeletal muscle. Only two major isoforms of troponin C are found in human heart and skeletal muscle, characteristic of slow and fast twitch muscle. The heart isoform is identical with the slow twitch skeletal muscle isoform. Isoforms of cTnT and cTnI are products of unique genes.

DIAGNOSTIC INFORMATION

REMARKS

AMI with increases above the upper reference limit seen at 2-6 hr. The initial increase is caused by the 3-6% cytoplasmic fraction of cTn (CK-MB is 100% cytoplasmic). Second, cTn can remain increased up to 4-14 days after AMI because of ongoing release from the 94-97% myofibril-bound fraction. Third, the very low to undetectable cTn in healthy patients allows lower cutoffs than CK-MB for myocardial injury. Finally, cardiac tissue specificity of cTn eliminates false clinical impression of AMI in patients with increased CK-MB concentrations following skeletal muscle injuries.

Troponin is localized primarily in the myofibrils (94-97%), with a smaller cytoplasmic fraction (3-6%). cTnT and cTnI have different amino acid.¹⁶

Human cTnI has an additional posttranslational 31-amino acid residue on the N-terminal end compared with skeletal muscle TnI, giving cardiac specificity and I isoform. cTnI is not expressed in normal, regenerating, or diseased human or animal skeletal muscle. Troponin T is also encoded for by a different gene than encodes for skeletal muscle isoforms. An 11-amino acid amino terminal residue gives this marker unique cardiac specificity. However, during human fetal development, in regenerating rat skeletal muscle, and in diseased human skeletal muscle, small amounts of cTnT are expressed as one of four identified isoforms in skeletal muscle. In humans, cTnT isoform expression has been demonstrated in skeletal muscle specimens obtained from patients with muscular dystrophy, polymyositis, dermatomyositis, and end-stage renal disease.¹⁷ cTnI is part of the T-I-C ternary complex as a structural and regulatory component of the myofibril. Following myocardial injury or because of genetic disposition, multiple forms are expressed in tissue and in blood including T-I-C, IC, free I, and multiple modifications of these, including oxidation, reduction, phosphorylation and dephosphorylation, and C- and N-terminal degradation. Detection of seven different cTnI forms in an injured human heart can appear depending on the antibodies used.¹⁸ Different antibodies can lead to a substantially different recognition patterns. Assays should use antibodies that recognize epitopes in the stable region of cTnI and demonstrate an equimolar response to the different cTnI forms in blood.¹⁹

See *Troponin-I, Cardiac* for a discussion of the clinical significance of cardiac troponin. In renal failure, increased cardiac troponin T and I are associated with an increased incidence of cardiac death at 2 yr. There is a considerably higher incidence of positive results for cTnT than cTnI at any cutoff (99th percentile, 10% CV, or receiver-operator characteristic curve cutoff).⁶

See *Troponin-I, Cardiac*.

Apple FS, Murakami MM, Pearce LA, et al: Predictive value of cardiac troponin I and T for subsequent death in end-stage renal disease, <i>Circulation</i> 106:2941-2945, 2002.</p> | |
| <p>Inadequate trypsin secretion can lead to malabsorption, flatus, and abdominal discomfort.</p> | <p>This test will probably be replaced by fecal elastase.</p> |
| <p>F ↓ Loss of >85% of pancreatic exocrine function; cystic fibrosis (feces and duodenal fluid)</p> | |
| <p>Absent in stool but present in duodenal aspirate in neonatal intestinal obstruction.⁴</p> | |
| <p>S ↑ Acute pancreatitis (particularly alcohol induced), chronic renal failure, liver disease, occasionally in peptic ulcer and gallstones, and in cystic fibrosis (cord blood)</p> | <p>Trypsin levels have diurnal variation, with higher values in the late evening.¹¹ Serum trypsin must be measured by mass (as a protein) rather than by its activity (as an enzyme) because the antiproteases in serum inhibit enzyme activity. Problems of standardization and different specificities of antisera to the various forms of trypsin (trypsinogen, trypsin bound to α_1-antitrypsin or to α_2-macroglobulin, and free trypsin) have been reported and account for major differences in assays with the two most common antisera (Sorin and Behringwerke). Measurement of trypsin in duodenal fluid after hormonal stimulation is very specialized, and results are too variable to define reference values.</p> |
| <p>S ↓ Chronic pancreatitis (especially if steatorrhea is present), pancreatic cancer (Some cases may have increased or normal values.)</p> | |
| <p>Both low and high values occur in β-thalassemia. High values occur in acute malnutrition, and low values occur in chronic malnutrition.</p> | |
| <p><i>Diabetes:</i> Both juvenile and maturity-onset show depressed levels.</p> | <p>Increases are highly sensitive. In pancreatitis it offers no diagnostic advantage over standard testing, and the specificity is low.²</p> |
| <p><i>Viral infections:</i> Serum levels are increased when silent invasion of pancreas has occurred.</p> | |
| <p>High values are found in neonates with cystic fibrosis, readily distinguishing these infants from normal; values decrease with disease progression. Test has been incorporated into neonatal screening programs in some centers with promising results.⁵⁻⁸ Test should be performed in the first month of life.</p> | <p>Not recommended for screening or diagnosis of CF.</p> |
| <p>A two-step testing protocol has been proposed.⁹ Using the CIS assay, 1-4-day-old infants with ≥ 140 mg/L are retested at 2-8 wk of age. If the value is ≥ 80 mg/L, a sweat test is performed. Another protocol retests, by direct gene analysis, all 4-5-day-old infants in the highest 1% of population.¹⁰</p> | |

↑ Hypoparathyroidism, pseudohypoparathyroidism

↓ Hyperparathyroidism (false-negative results may occur in 25% of cases)

$$\text{TRP}\% = 100 \times \left[1 - \left(\frac{P_u \times Cr_s}{Cr_u \times P_s} \right) \right]$$

P_u = urine phosphate in mg/dL
 P_s = serum phosphate in mg/dL
 Cr_u = urine creatinine in mg/dL
 Cr_s = serum creatinine in mg/dL

Any degree of renal insufficiency increases excretion of phosphate relative to creatinine and invalidates the test. Serial measurements on consecutive days are recommended.

Using calculated TRP and measured serum phosphate, the renal phosphate threshold concentration can also be estimated with a nomogram.³

TRP reflects the role of PTH in regulating renal clearance of phosphate. However, determination of TRP does not replace direct measurements of PTH itself (see *Parathyroid Hormone*).

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ <i>Diabetes insipidus</i>⁴</p> <p><i>Central:</i> Pituitary pathology</p> <p><i>Nephrogenic:</i> Acquired renal disease [especially pyelonephritis, analgesic nephropathy, multiple myeloma, amyloidosis, obstructive uropathy, sarcoidosis, hypercalcemic or hypokalemic nephropathy (including primary aldosteronism and hyperparathyroidism), Sjögren's syndrome, sickle cell anemia, renal transplantation, renal artery stenosis, postobstructive diuresis, diuretic phase of acute tubular necrosis, medullary cystic disease, and sodium wasting in tubular damage]</p> <p><i>Drug-induced:</i> See <i>Interferences</i></p> <p><i>Excessive fluid intake:</i> Psychogenic polydipsia, hypothalamic disease (postencephalitic, histiocytosis X), drug-induced polyuria (anticholinergic effect, especially thioridazine, chlorpromazine), and iatrogenic overhydration</p> <p><i>Osmotic diuresis:</i> Diabetes mellitus (glucosuria), high-protein diet or tube feedings, IV or hyperalimentation therapy (with Na⁺, amino acids, and/or glucose), excessive salt intake, urea or mannitol infusion, radiographic contrast media, chronic renal failure, adrenal insufficiency, and drugs (see <i>Interferences</i>)</p> <p><i>Others</i>⁶: Last trimester of pregnancy, protein malnutrition, hyperthyroidism, altitude,⁵ postmenstruation,⁵ psychogenic polydipsia, and hypothalamic disease</p> <p>↓ <i>Prerenal perfusion impairment:</i> Dehydration, blood loss, shock, congestive heart failure, cirrhosis, "third space" fluid losses (e.g., edema, peritonitis, bowel obstruction), nephritic syndrome, and acute arterial or renal vein obstruction</p> <p><i>Obstructive uropathy</i></p> <p><i>Renal parenchymal disease:</i> Acute tubular necrosis, glomerulonephritis, acute vasculitis (SLE, periarteritis nodosa, dermatomyositis, Wegener's granulomatosis, hypersensitivity angiitis), DIC (sepsis, transfusion reaction), urate, hypercalcemic or analgesic nephropathy, chronic renal failure, and drug- or toxin-induced (see <i>Interferences</i>)</p> <p><i>Postrenal obstruction</i>, e.g., missing or poorly functioning kidney, renal calculi, cysts, and obstruction of ureter by tumors or calculi</p> | <p>Under ordinary physiological conditions, the chief determinant of urine volume is water intake. Patients cannot always distinguish urinary frequency from polyuria. Polyuria must be substantiated by 24-hr urine collection.</p> <p>In oliguria, urinary output is between 50-400 mL/day. In anuria, the urinary output is 0-50 mL/day.</p> <p>Some common laboratory tests can be used to differentiate prerenal from renal or postrenal oliguria, although the methods listed are not infallible. Generally in prerenal oliguria, urinary Na⁺ is <20 mmol/L; urine/plasma (U/P) creatinine ratio is >40; U/P osmolality >1.2; and the fractional excretion of Na⁺ is <1. In renal or postrenal oliguria, the urinary Na⁺ is >40 mmol/L; U/P creatinine ratio is <20; U/P osmolality <1.2; and the fractional excretion of Na⁺ is >1. The fractional excretion of Na⁺ is most reliable.</p> |

|---|--|
| <p>↓ Congenital erythropoietic porphyria (CEP)</p> <p>Values for UROS <75 relative units are suggestive of a biochemical diagnosis of CEP. This test does not reliably distinguish between individuals with heterozygous UROS deficiency and normal subjects.</p> | <p>Congenital erythropoietic porphyria (CEP) is an extremely rare and severe porphyria with a typical onset during early infancy. In most cases, the disorder has been suggested during the first few days or weeks of life by pink, violet, or brown urinary staining of diapers. A few cases of adult-onset CEP have been reported. Dermatological signs include skin photosensitivity, scarring and blistering, red or pink-brown dental discoloration, and hypertrichosis. Growth and cognitive developmental delays are commonly observed in individuals with CEP. CEP is inherited as an autosomal recessive trait.</p> <p>Circulating red cells normally contain high levels of activity of UROS, and the diminished activity associated with CEP is readily demonstrable by incubation of red cells from an affected person.⁴</p> |
| <p>P ↑ Branched-chain ketoaciduria (maple syrup urine disease), ketosis, and hypervalinemia</p> <p>P ↓ Protein malnutrition (kwashiorkor), carcinoid syndrome, acute hunger, hyperinsulinism, after severe burn (day 4),¹⁵ Huntington's chorea, and hepatic encephalopathy</p> | <p>High levels of leucine, isoleucine, and alloisoleucine are also seen in maple syrup urine disease as a result of a defect in branched-chain ketoacid decarboxylase. In this autosomal recessive disorder of metabolism, there may be extreme acidosis, vomiting and CNS symptoms, mental retardation, respiratory failure, and death. In ketosis, leucine and isoleucine are elevated, but alloisoleucine is not present.</p> <p>See Table II-2B.</p> <p>Renal Fanconi syndromes may include other metabolic diseases, including hepatorenal tyrosinemia, galactosemia, and Lowe syndrome.</p> |
| <p>U ↑ Maple syrup urine disease, Hartnup disease, first trimester of pregnancy (levels decrease thereafter), hypervalinemia, burn patients,¹⁶ and generalized aminoaciduria-renal Fanconi syndromes</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Vanadium toxicity in humans is almost always associated with industrial processes. Major effects of vanadium toxicity include irritation to the mucous membranes of the eyes, nose, throat, and respiratory tract; bronchitis; GI distress; fatigue; cardiac palpitation; kidney damage; and other physiological disturbances of the CNS and cardiovascular system.¹ A clinical presentation of V toxicity may be green discoloration of the tongue.</p> | <p>Vanadium is used extensively in the steel industry and to a lesser degree in photography and in the manufacture of insecticides, dyes, inks, paints, and varnish. Vanadium is a component of some orthopedic prostheses. Vanadium particles have been observed in periprosthetic tissues, liver, and spleen.⁷</p> |
| <hr/> | |
| <hr/> | |
| <p>↑ In pheochromocytoma, paraganglioma, and neuroblastoma.</p> | <p>VMA is the major metabolite of the catecholamines and historically has been used to screen for pheochromocytoma. The current recommended test is now fractionated plasma-free metanephrines (See <i>Metanephrines, Fractionated</i>.)</p> <p>Urinary VMA is elevated in ≥90% of patients with neuroblastoma, but concentrations within the reference interval do not exclude the diagnosis. Increased concentrations are consistent with pheochromocytoma but are not diagnostic. Additional tests for neuroblastoma includes HVA (See <i>Homovanillic Acid</i>).</p> <p>In patients with neuroblastoma, a HVA/VMA ratio <1 or >2 had an unfavorable prognosis.¹⁴</p> |

| <p>↑ Pancreatic VIP-secreting tumors (VIPomas), neural crest tumors in children (e.g., ganglioneuroblastoma, ganglioneuroma, and neuroblastoma), pancreatic islet cell hyperplasia, liver disease, MEN syndrome type I, pheochromocytoma, medullary thyroid carcinoma, bronchogenic carcinoma, retroperitoneal histiocytoma, and congestive heart failure.⁶</p> | <p>VIP is a member of the secretin-glucagon family; highest concentrations are found in the gut and nervous system. Measurement of VIP concentrations is useful to screen for VIP-secreting tumors, to detect occult metastases, and to evaluate the success of surgical or drug therapies.</p> <p>Hypersecretion of VIP is believed to result in the Verner-Morrison syndrome (also called pancreatic cholera syndrome or WDHA [watery diarrhea with hypokalemia and achlorhydria] syndrome). However, VIP does not appear to be the sole mediator of the WDHA syndrome. Levels of VIP in CSF are ~10 times higher than in plasma. In Crohn's disease, there is a reported increase of 100% in the VIP content of the bowel.</p> |

Long term exposure to vinyl chloride is associated with hepatotoxicity and angiosarcoma.

Studies of workers who have developed "vinyl chloride disease," a syndrome consisting of Raynaud's phenomenon, acroosteolysis, joint and muscle pain, enhanced collagen deposition, stiffness of the hands, and scleroderma-like skin changes, indicate that this disease may have an immunologic basis.⁶

Vinyl chloride is an intermediate in the synthesis of polyvinyl chloride and has been used as an aerosol propellant. Industrial exposure is by inhalation. Blood concentrations are not helpful in monitoring exposure. A major urinary metabolite of vinyl chloride is thiodiglycolic acid.

Vinyl chloride in the breath of exposed workers declines slowly after removal from the source of exposure. Concentrations in the breath have been reported from 0.6 to 3.0 ppm [10-48 $\mu\text{mol/L}$].

Thiodiglycolic acid concentrations in urine of unexposed workers average 0.5-0.7 mg/L, whereas in workers exposed to 1-7 ppm [16-112 $\mu\text{mol/L}$] of vinyl chloride, thiodiglycolic acid concentration can range up to 4 mg/L.⁷

DIAGNOSTIC INFORMATION

REMARKS

Serum retinol, because of homeostatic control exerted by the liver, is not a good general indicator of body vitamin A stores. Values >20 mcg/dL [>0.70 $\mu\text{mol/L}$] represent adequate liver stores, whereas values <10 mcg/dL [<0.35 $\mu\text{mol/L}$] indicate severe deficiency and depletion of liver stores.

Children show an age-related increase in serum retinol, and the values are lower before puberty. Levels in adults increase slightly with age. Premenopausal females have slightly lower values than males; after menopause, values are similar.

the level of retinyl esters can be >1500 mcg/dL [>15 mg/L].¹⁰ Symptoms of toxicity appear to occur only when the amount of plasma vitamin A exceeds the capacity of RBP to bind to it. Normal molar ratios of A:RBP are ~ 0.8 -1.0.

Clinical manifestations of acute hypervitaminosis A include bulging fontanelles in infants, headache in adults, nausea, vomiting, and occasionally fever, vertigo, visual disorientation, and peeling of the skin. These symptoms are generally transient and do not result in permanent adverse effects. Chronic hypervitaminosis A is more common and is associated with anorexia, dry itchy skin, hair loss, increased intracranial pressure, hepatomegaly, and fatigue. Vitamin A toxicity is rarely associated with causing congenital abnormalities and death. Water-miscible preparations of vitamin A are more toxic than oil-based formulations. Toxicity is best assessed by measuring plasma retinyl ester levels rather than the concentration of vitamin A.

Diseases and conditions that impair the conversion of carotene to vitamin A or reduce the levels of RBP can contribute to the development of vitamin A deficiency. Symptoms of deficiency include bronchopulmonary dysplasia in prematures, night blindness, xerophthalmia, keratomalacia, Bitot spots, follicular hyperkeratosis, and photophobia. Ocular changes can be further documented by a dark adaptation test and electroretinography.

Further understanding of cellular retinol-metabolizing enzymes/proteins like lecithin-retinol acyltransferase and cellular retinol binding protein and their interaction with retinol and its metabolites will provide insights into better dietary management of vitamin A status.¹¹ See *Retinol-Binding Protein*.

Avoid repeated freezing and thawing. | ng/mL 5-50 Deficiency: <5 | $nmol/L$ [20-202] ⁶ [<20] | ↓ V Amiodarone, anticonvulsants (e.g., carbamazepine, phenobarbital, phenytoin, primidone), cycloserine, disulfiram, ethanol (alcoholics), hydralazine, isoniazid, levodopa, oral contraceptives (plasma levels only), penicillamine, pyrazinoic acid, and theophylline |
|--|---|-----------------------------------|--|---|

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↓ Malabsorption, cirrhosis, chronic cholestasis, hepatocellular disease, protein-calorie malnutrition, and zinc deficiency</p> <p>RDR values >20% indicate depleted liver vitamin A stores.</p> | <p>The oral dose test is subject to the limitations of other absorption tests. In the absence of malabsorption or when the RDR is done with an IV dose, results of the RDR correlate well with liver stores of vitamin A and with dark adaptation. Plasma levels of vitamin A are maintained at normal concentrations until hepatic stores are almost depleted (<20 mcg/g; <0.07 μmol/g).</p> |

Modified:
Circulating concentration of DRA is relatively low, allowing a single measurement at 4-6 hr after a given oral dose. DRA is being made available to researchers through the University of Wisconsin-Madison, Department of Nutritional Sciences.⁴ See *Vitamin A*.

| | |
|---|---|
| <p>↓ Chronic alcoholism, malnutrition, uremia, neonatal seizures, malabsorption, industrial exposure to hydrazine compounds, normal pregnancies, gestational diabetes, pellagra, lactation, renal dialysis, asthma, carpal tunnel syndrome, smoking, preeclamptic edema, and acute myocardial infarction.⁷</p> <p>↑ Hypophosphatasia⁸</p> | <p>Plasma contains several forms of vitamin B₆, but PLP is quantitatively and biologically the most important. Plasma PLP levels are high in infants but decrease with age. Deficiency usually occurs in association with other nutrient deficiencies. Vitamin B₆ deficiency is associated with symptoms of irritability, weakness, depression, dizziness, peripheral neuropathy, dermatitis, cheilosis, glossitis, and seizures. Deficiencies in pediatrics have been characterized by diarrhea, anemia, seizures, and failure to thrive. Both erythrocyte and plasma transaminase activities are diminished in conjunction with vitamin B₆</p> |

DIAGNOSTIC INFORMATION

REMARKS

3. Leklem JE: Vitamin B-6: a status report, *J Nutr* 120(11S):1503-1507, 1990.

S ↑ Chronic renal failure, severe congestive heart failure, diabetes, increased levels of transcobalamin, acute and chronic myelogenous leukemia, about one third of cases of chronic lymphatic leukemia, some cases of monocytic leukemia; leukocytosis, polycythemia vera, some carcinomas (especially with liver metastases), liver disease (acute and chronic hepatitis, cirrhosis, hepatic coma), drug-induced cholestasis, erythroleukemia, and protein malnutrition

S ↓ Untreated vitamin B₁₂ deficiency usually resulting in megaloblastic anemia. Causes: Lack of IF (PA, total or partial gastrectomy, atrophic gastritis, intrinsic factor antibody); malabsorption (e.g., regional ileitis, resected bowel, sprue, celiac disease, pancreatic insufficiency, small bowel bacterial overgrowth, achlorhydria); loss of ingested vitamin B₁₂ (fish tape-worm); dietary deficiency (vegetarians); congenital disorders (orotic aciduria, transcobalamin deficiency, Immerslund-Grösbeck syndrome); progressive decrease during pregnancy sometimes to below normal levels in the last trimester (normal serum B₁₂ in megaloblastic anemia of pregnancy)

B₁₂ values obtained by CPB radioassay can be invalidated if the patient has previously received radioisotopes.

Vitamin B₁₂ deficiency frequently causes macrocytic anemia, glossitis, peripheral neuropathy, weakness, hyperreflexia, ataxia, loss of proprioception, poor coordination, and affective behavioral changes. These manifestations may occur in any combination; many patients have the neurologic defects without macrocytic anemia.⁷

Serum levels of vitamin B₁₂ are a better indicator of B₁₂ status than are erythrocyte levels. However, the lower limit indicating frank deficiency is not well defined. Serum levels can be low in the absence of either anemia or macrocytosis (e.g., patients with myeloma or aplastic anemia). Conversely, elevated transcobalamin II can result in normal or elevated serum vitamin B₁₂ levels despite deficient liver stores. Diagnosis of vitamin B₁₂ deficiency is supported by evidence of blood and bone marrow megaloblasts and evaluation of histamine-fast achlorhydria and achylia. However, subclinical or early detection of cobalamin deficiency may be missed, and other factors may induce a megaloblastic anemia.⁸ Newly developed test methods and new testing algorithms have been proposed for the assessment of vitamin B₁₂ deficiency.⁹ An algorithm using B₁₂, MMA, IF blocking antibody and serum gastrin analysis has been developed and is being utilized at the Mayo Clinic, which may allow more reliable assessment of vitamin B₁₂ status.^{7,10}

Another test that shows promise for the assessment of vitamin B₁₂ deficiency is holotranscobalamin (holoTC). HoloTC represents the biologically active fraction of vitamin B₁₂ that can be delivered into DNA synthesizing cells.¹¹ It has therefore been suggested that holoTC may be a sensitive marker of vitamin B₁₂ deficiency.

Inadequate intake is rarely the cause of deficiency but occurs most commonly when there is damage to the stomach, ileum, or pancreas or the enterohepatic circulation of vitamin B₁₂ is impaired. In some patients (e.g., gastrectomy), severe iron deficiency may also be present. Manifestations of vitamin B₁₂ deficiency usually require several years to develop. Few infants develop deficiency, but it is frequently found in elderly persons. The latter may exhibit only neurological symptoms. Vitamin B₁₂ deficiency may contribute to osteopenia of aging. Low serum vitamin B₁₂ levels often occur in folate deficiency, and

| DIAGNOSTIC INFORMATION | REMARKS |
|------------------------|---|
| | <p>B₁₂ deficiency can be masked by folate therapy. Deficiency of vitamin B₁₂, but not folate, results in increased methylmalonic acid in urine and serum (see <i>Methylmalonic Acid</i>). Usual therapy is to administer vitamin B₁₂ parenterally.</p> <p>Elevated levels of cobalamin can be a sign of serious or even life-threatening disease.¹² Hematologic disorders like chronic myelogenous leukemia, promyelocytic leukemia, and polycythemia vera may result in high serum vitamin B₁₂. The cobalamin elevation is likely caused by the increased concentrations of the cobalamin binding protein haptocorrin, which are associated with these conditions.¹² In addition, several liver disorders, including acute hepatitis, cirrhosis, and hepatocellular carcinoma, may result in high serum vitamin B₁₂ concentration. This may be the result of cobalamin release during hepatic cytolysis and/or decreased cobalamin clearance by the liver. Even though a toxicity to vitamin B₁₂ has not been reported, an isolated observation of an elevated serum vitamin B₁₂ may warrant further diagnostic workup to assess the presence of disease.¹²</p> <p>See also <i>Transcobalamin</i> and <i>Vitamin B₁₂ Adsorption Test</i>.</p> |

8. Tietz NW, editor: *Fundamentals of clinical chemistry*, ed 3, Philadelphia, 1987, WB Saunders.

9. Wyngaarden JB, Smith LH Jr, editors: *Cecil textbook of medicine*, ed 18, Philadelphia, 1988, WB Saunders.

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>U ↓ After resection of terminal ileum, extensive and severe ileal disease, bacterial overgrowth, PA (in urine, 0-2.5% of administered dose is excreted), after total gastrectomy, sometimes with pancreatic insufficiency, defective ileal mucosal cell receptors for B₁₂ (rare), gluten-sensitive enteropathy, anatomical abnormalities of the small gut, chronic pancreatitis, cystic fibrosis, giardiasis, radiotherapy, Crohn's disease, myxedema, liver disease, and presence of antibodies to intrinsic factor in gastric juice</p> | <p>The Schilling test is useful for confirming PA and determining whether vitamin B₁₂ deficiency is caused by malabsorption; it is unreliable in the presence of renal impairment. (If creatinine clearance is <60 mL/min, 48-hr urine collection is necessary to compensate for decreased renal function.) Reproducibility is not good in the presence of intestinal disease. The 1-mg flushing dose is an effective treatment in malabsorption. Therefore bone marrow examination for megaloblastic changes should be carried out before the Schilling test, and the reticulocyte response must be followed as usual for anemic patients. After a partial gastrectomy, a B₁₂ deficiency may not be detected by the Schilling test.</p> |
| <p>F ↑ PA (85-100%) and in conditions listed above</p> | <p>If PA is suspected, the Schilling test may be repeated after 5 days with an additional 60-mg active hog intrinsic factor (IF) given orally. A normal result indicates IF deficiency. Simultaneous administration of ⁵⁷Co-B₁₂ and ⁶⁰Co-B₁₂-IF (or ⁵⁷Co-B₁₂-IF and ⁵⁸Co-B₁₂) has been suggested as a routine method for differentiating B₁₂ deficiency because of lack of IF from other causes of malabsorption.⁴</p> |
| <p>P ↓ PA (0-0.6%, \bar{x}: 0.2%) and in conditions listed above</p> | <p>The Schilling test is being utilized less frequently in the assessment of pernicious anemia. New testing algorithms have been developed using B₁₂, MMA, IF blocking antibody, and serum gastrin analysis have been developed that may ultimately replace the Schilling test.¹⁰ However, there is still controversy with this strategy that must be borne out with further research.^{11,12} See also <i>Vitamin B₁₂ Intrinsic Factor</i>.</p> |
| <p>L ↓ PA (counts near zero) and in conditions listed above</p> | <p>External counting over liver is especially useful for outpatients. Results are valid in the presence of renal disease. Daily counting over the liver and abdomen has been suggested as a method for monitoring bowel function throughout the test. Liver counts should be 2.5-4 times higher than abdominal counts.</p> |
| <p>10. Klee GG: Cobalamin and folate evaluation: measurement of methylmalonic acid and homocysteine vs vitamin B(12) and folate, <i>Clin Chem</i> 46:1277-1283, 2000.</p> <p>11. DIAGNOSTIC INFORMATION

REMARKS

An unequivocal response to therapy is the definitive sign for establishing vitamin B₁₂ deficiency. The oral dose is used for diagnosing dietary deficiency of B₁₂.

The parenteral dose is used for determining B₁₂ deficiency in megaloblastic anemia. The patient should be monitored for several days before test to rule out spontaneous reticulocytosis.

See also *Vitamin B₁₂*.

P ↓ Scurvy, hemodialysis, anemia, pregnancy, smoking,¹ steatorrhea, alcoholism, malabsorption, hyperthyroidism, rheumatoid disease, cancer, chronic renal failure, and Crohn's disease

Vitamin C is essential for enzymatic amidation of neuropeptides, production of adrenal cortical steroid hormones, promotion of the conversion of tropocollagen to collagen, and of the metabolism of tyrosine and of folate. Vitamin C is involved in activation of detoxifying enzymes in liver, antioxidation, interception, and destruction of free radicals, preservation and restoration of antioxidant potential of vitamin E, and blockade of the formation of carcinogenic nitrosamines. In addition, it appears to function in a variety of other metabolic processes in which its role has not been fully characterized.

Oral vitamin C supplementation will increase plasma levels; large doses (gram quantities) can result in transient plasma values of >2.0 mg/dL [113 μmol/L]. The renal threshold for vitamin C is ~1.0 mg/dL [57 μmol/L] with urine being the major excretory route. During periods of inadequate ascorbate consumption, plasma levels decrease before leukocyte levels (the latter reflect general tissue storage).

Lkcs ↓ Scurvy, peptic ulcer, gastroduodenal disorders, and postoperative state

Results may be misleading when either leukocyte or platelet count is abnormal.

Many benefits have been ascribed to megadose therapy, but such claims remain unproved. Megadose intakes of vitamin C are believed to be nontoxic but may result in diarrhea. Induc-

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| <p>↑ Tumoral calcinosis, primary hyperparathyroidism, idiopathic hypercalciuria, sarcoidosis, tuberculosis, lymphoma (some patients), normal growing children, and pregnant and lactating females</p> | <p>Hydroxylation of 25(OH)D takes place in the kidney where 1-α hydroxylase, under the control of parathyroid hormone, hydroxylates 25(OH)D to yield 1,25(OH)₂D. 1,25(OH)₂D, the most active form of vitamin D. It enhances Ca absorption and mobilization, and its synthesis is influenced by the calcium and phosphorus content of the diet, PTH, and 1,25(OH)₂D. It is often useful to measure PTH in conjunction with 1,25(OH)₂D. 1,25(OH)₂D is a hormone and the direct antirachitic factor. Lack of 1,25(OH)₂D results in hypocalcemia, osteomalacia, and related disorders. Levels can increase to 200-300 pg/mL [480-720 pmol/L] during treatment of osteomalacia with physiological doses of vitamin D.</p> |
| <p>↓ Azotemic chronic renal failure, hypoparathyroidism, pseudohypoparathyroidism, vitamin D-dependent rickets, vitamin D-resistant rickets (familial hypophosphatemia), postmenopausal osteoporosis, tumor-induced osteomalacia, and adolescents with insulin-requiring diabetes mellitus</p> | <p>Measurement of 1,25(OH)₂D is not a good measure of overall vitamin D status but is useful in differentiating primary hyperparathyroidism from hypercalcemia of cancer, distinguishing between vitamin D-dependent and vitamin D-resistant rickets, monitoring the vitamin D status of patients with chronic renal failure, and assessing compliance of 1,25(OH)₂D therapy.</p> |
| <p>1,25-Dihydroxy vitamin D [1,25(OH)₂D] is not detectable in anephric patients.</p> | <p>Most methods for 1,25(OH)₂D combine column chromatography with a radioreceptor assay. Vitamin D receptor from thymus is preferred and recognizes D₂ and D₃ equivalently.</p> |

DIAGNOSTIC INFORMATION

REMARKS

Deficiency manifests as rickets in children and as osteomalacia in adults. Both are characterized by decreased plasma calcium and phosphorus and increased alkaline phosphatase; deficiency of 25(OH) calciferol is similar in presentation to hyperparathyroidism, which may develop secondarily along with decreased citrate levels. Biochemical workup of suspected cases of rickets and osteomalacia should include measurement of serum calcium, phosphorus, PTH, and 25-OH-VitD. When testing is not completely consistent with the suspected diagnosis, particularly if serum 25-OH-VitD levels are >10 ng/mL. Consideration should be given to an alternative cause for impaired mineralization. Possible differential diagnosis includes partly treated vitamin D deficiency, extremely poor calcium intake, vitamin D-resistant rickets, renal failure, renal tubular mineral loss with or without renal tubular acidosis, hypophosphatemic disorders (e.g., X-linked or autosomal dominant hypophosphatemic rickets), congenital hypoparathyroidism, activating calcium sensing receptor mutations, and osteopetrosis. Measurement of serum urea, creatinine, magnesium, and 1,25-OH-VitD is recommended as additional workup for these patients.¹⁰

Vitamin D toxicity (25(OH)D >150 ng/mL [>375 nmol/L]) is more common in infants and children than adults. Doses up to 2370 U/day have no detrimental effect on growth, but 4000 U/day is associated with mild idiopathic hypercalcemia. Large doses (50,000-100,000 U/day) can cause hypercalcemia, hyperphosphatemia, hypercalciuria, increased citrate levels, soft-tissue calcification, vomiting, constipation, anorexia, nausea, and growth and mental retardation. Toxicity can be treated with calcitonin and glucocorticoids. Hypoparathyroid patients receiving physiological doses of vitamin D can have 25(OH)D levels as high as 1250 ng/mL [3120 nmol/L].¹² 25(OH)D is the drug of choice for treating cholestatic liver disease and osteomalacia. See also *Vitamin D, 1,25-Dihydroxy*.

Population reference intervals for 25(OH)D vary widely depending on ethnic background, age, geographic location of the studied populations, and the sampling season.¹⁰

For routine clinical purposes, 25(OH)D assays should measure 25(OH)D₂ and 25(OH)D₃. Competitive binding assays measure both D₂ and D₃. Measurement of 25(OH)D by RIA is now possible because of the availability of antisera that cross-reacts with D₂ and D₃ on an equimolar basis. HPLC methods allow separate measurement of D₂ and D₃, but independent determination is complicated and does not appear to be clinically useful.

An Lc-MS/MS method has been developed that measures both 25(OH)D₂ and 25(OH)D₃. Reference intervals have been established.¹⁰

| DIAGNOSTIC INFORMATION | REMARKS |
|---|---|
| <p>↑ Hyperlipidemia (obstructive liver disease); α-T levels can be normal or elevated, despite deficient tissue levels.</p> | <p>Vitamin E contributes to the normal maintenance of biomembranes, the vascular system, and the nervous systems and provides antioxidant protection for vitamin A. The level of vitamin E in the plasma or serum after a 12-14-hr fast reflects the individual's reserve status.⁶</p> |
| <p>↓ Malabsorptive states (steatorrhea, biliary atresia, cirrhosis, cystic fibrosis, chronic pancreatitis, pancreatic carcinoma, gluten enteropathy, regional enteritis, and chronic cholestasis, intestinal lymphangiectasia), premature infants (hemolytic anemia, encephalomalacia, retrolental fibroplasia and bronchopulmonary dysplasia), and abetalipoproteinemia</p> | <p>Deficiency of vitamin E in children leads to reversible motor and sensory neuropathies; this problem has been suspected in adults also. Premature infants who require an oxygen-enriched atmosphere are at increased risk for bronchopulmonary dysplasia and retrolental fibroplasia; supplementation with vitamin E has been shown to lessen the severity of and may even prevent those problems.⁶</p> |
| <p>Deficiency may be associated with platelet hyperaggregation, ceroid deposition in smooth muscle, decreased erythrocyte survival, and increased susceptibility to hemolysis. Neurological degeneration can occur. When plasma vitamin E levels are low, an assessment of total lipids should be made. Normal ratios of α-tocopherol to total lipid are >0.6 mg α-T/g total lipid in children and >0.8 mg α-T/g total lipid in adults.</p> | <p>Vitamin E deficiency caused by inadequate dietary intake is not known to occur. Colorimetric and fluorometric assays measure total plasma tocopherols rather than α-tocopherol, which usually constitutes $\sim 90\%$ of the total vitamin E and is the most active form biologically. Appreciable amounts of γ-tocopherol can be present. Serum α-T levels correlate directly with total lipids and β-lipoprotein levels. Very low blood levels of vitamin E may be associated with abetalipoproteinemia, presumably as a result of a lack of the ability to form very low-density lipoproteins and chylomicrons in the intestinal absorptive cells of affected persons.</p> |
| | <p>Vitamin E deficiency caused by malabsorption can generally be treated with water-miscible α-tocopheryl acetate preparations, whereas patients with biliary atresia and abetalipoproteinemia may require parenteral (IM) supplementation. Megadoses of vitamin E (100-800 mg/day) may significantly impair the absorption of vitamins D and K. Therefore beginning vitamin E supplementation in patients who are receiving oral anticoagulation therapy can result in overanticoagulation and increased bleeding risk. Such levels of supplementation have not been documented to have any health benefits except perhaps to alleviate intermittent claudication. Combined results from trials suggest that vitamin E supplementation does not beneficially or adversely affect cardiovascular outcomes.⁷ Vitamin E toxicity has not been established clearly. Chronically excessive ingestion has been implicated as a cause of thrombophlebitis; however, the implied relationship lacks verification.</p> |
| | <p>Platelet tocopherol is suggested to be a better measure of vitamin E nutritional status than plasma tocopherol because it is more sensitive to vitamin E intake and is not dependent on circulating lipid levels.⁵</p> |

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| <p>↓ All cases of hereditary or acquired von Willebrand's disease</p> <p>However, in the rare type II von Willebrand's disease, the antigen may be normal, although the function is impaired.</p> <p>For types of von Willebrand's disease, see Table I-24.</p> | <p>The von Willebrand factor is a multimeric plasma protein with two important functions in hemostasis: (1) promoting platelet adhesion at the site of injury; and (2) transporting and stabilizing factor VIII in plasma.</p> <p>von Willebrand disease (vWD) is caused by hereditary quantitative or qualitative defects of the vWF. The diagnosis of vWD is challenging because of the many variables that may affect the results. Repeat testing is recommended for confirmation. Acquired vWD can occur but is rare.</p> <p>Screening tests for vWD (bleeding time, platelet count, PT, and PTT) are typically followed by the diagnostic tests, R:CoF (functional assay) and vWF:Ag (antigenic assay). Further tests to distinguish among the subtypes of vWD include a factor VIII assay, a factor VIII binding capacity, platelet aggregation studies (low-dose ristocetin), and multimer analysis (crossed immunoelectrophoresis).</p> <p>Newer tests that may be used in association with the established tests include the collagen-binding assay (ELISA) and the platelet function analyzer (PFA-100).</p> |

Decreased renal tubular function: Specific gravity is <1.020.

In severe renal tubular impairment: Specific gravity approaches 1.010.⁵

Impairment of renal concentration ability:

Minimal: 600-800 mOsm/kg

Moderate: 400-600 mOsm/kg

Severe: <400 mOsm/kg

These values are lower in hospitalized patients.

The ability to concentrate urine decreases with age.

In central diabetes insipidus (also called hypothalamic or neurogenic diabetes insipidus): There is no significant increase in urine osmolality or urine specific gravity after water deprivation but a >10% increase in urine osmolality after ADH administration; serum osmolality and serum sodium are seen to

Fluid restriction starts at midnight if psychogenic water drinking is suspected or if polyuria is absent. Observe high-risk patients for >3% weight loss and cardiovascular problems. This test is unreliable in the presence of any severe water and electrolyte imbalance, low-protein or low-salt diet, chronic liver disease, or pregnancy. Fluid deprivation is dangerous in renal failure and obligatory polyuria, poorly compensated renal damage, or extrarenal uremia.

In patients with associated adrenal insufficiency, corticoid administration may unmask subclinical diabetes insipidus by altering both the GFR and the osmotic threshold. The effect of glucocorticoids on the test results for normal subjects is not known.

Some investigators prefer to test renal concentration ability using vasopressin without fluid restriction.^{6,7}

| | | | |
|---|--|---|---|
| Water Loading Antidiuretic Hormone Suppression Test ^{1,2} | After overnight fast patient should empty bladder. Tap water, 20 mL/kg, should be administered orally within 15-30 min. Keep patient in recumbent position. Collect urine specimens at hourly intervals for 4 hr after water ingestion for measurements of urine volume, specific gravity, and osmolality. Collect hourly speci- | Excretion of >90% [>0.9, volume fraction] of water load within 4 hr | The following drugs may produce a urine-diluting effect and will exaggerate test results: demeclocycline, lithium carbonate, and methoxyflurane. |
| | | Urine osmolality decreases to <100 mOsm/kg*, and urine specific gravity decreases to 1.003. The maximum ratio of urine flow will exceed 2-3 mL/min. | |
| | | Serum osmolality should decrease by ≥5 mOsm/kg.* | The following drugs may produce a urine-concentrating effect and thus diminish the magnitude of the test results: chlorpropamide, clofibrate, cyclophosphamide, diuretics, and diazoxide. |
| | | Plasma ADH should be appropriate for the serum osmolality. (See reference interval under <i>Antidiuretic Hormone</i> .) | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---------|
| <p>increase after fluid restriction, but plasma ADH values will be inappropriately low for the degree of hyperosmolality.</p> <p><i>In nephrogenic diabetes insipidus:</i> There is no significant increase in urine osmolality after water deprivation or after ADH administration.</p> <p><i>In psychogenic polydipsia:</i> Normal urine osmolality is usually seen after water deprivation. If the ratio of urine to plasma osmolality is <1.5 at the end of the test, primary polydipsia is unlikely. Measuring ADH in response to hypertonic saline may be needed if diagnosis is unclear.</p> <p>Muscular exercise and starvation decrease urine osmolality. See <i>Osmolality</i>.</p> | |

| | |
|--|---|
| <p>In decreased renal function, <80% of fluid intake is excreted and specific gravity may not decrease to <1.010; inadequate response is observed in adrenocortical insufficiency. Impaired diuresis is also observed in malabsorption syndrome, edema, ascites, obesity, hypothyroidism, dehydration, congestive heart failure, cirrhosis, and chlorpropamide therapy.</p> <p>Syndromes with excessive ADH secretion (SIADH) give inadequate response: <90% of water load is excreted within 4 hr, and urine osmolality remains >100 mOsm/kg [>100 mmol osmotically active particles/kg]. Plasma ADH measured at 90 or 120 min after water loading confirms the diagnosis of SIADH.</p> <p>Muscular exercise or starvation decreases urine-concentrating ability.</p> | <p>If diuresis does not occur in patients with adrenal insufficiency, diuretic function can be restored by steroid administration (50 mg cortisone acetate orally).</p> <p>Risks: In patients with hypoosmolality or impaired ability to excrete a water load, seizures and fatal hyponatremia can occur.</p> |

| | | | | | |
|---|--------------------------------|--|---|--|---|
| Xylose Absorption Test (D-Xylose Absorption Test) ¹⁻⁵ | Whole blood (NaF/oxalate) | Child, 1 hr: Adult, 2 hr, 25-g dose: | mg/dL >30 × 0.0666 >25 | mmol/L [>2.0] [>1.7] | B ↓ V Aminosalicyclic acid, arsenicals, colchicine, digitalis, ethionamide, gold, indomethacin, isocarbox-azid, kanamycin, MAO inhibitors, metformin, |
| Dose, adult: D-Xylose, 25 g in 250 mL of H ₂ O, | Children: before dose and 1 hr | | | | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| <p>Symptoms of acute exposure are typical of hydrocarbons and include headache, lightheadedness, dizziness, confusion, nausea, impaired gait, and blurred vision; excessive exposure can lead to tremors, rapid respiration, paralysis, loss of consciousness, coma, and death.</p> <p>Chronic exposure is associated with the development of permanent neuropsychiatric abnormalities, sometimes diagnosed as “chronic toxic encephalopathy.”¹</p> | <p>Exposures are most often occupational or the result of solvent inhalation abuse.</p> <p>Xylene exists as three isomers—ortho, meta, and para—and all three isomers are used as solvents, often as a mixture. Xylenes are rapidly metabolized to the corresponding <i>o</i>-, <i>m</i>-, or <i>p</i>-toluic acid (72%); 5% is excreted unchanged in breath and 0.01% in urine.²</p> <p><i>Kinetic values</i> $t_{1/2}$: 20–30 hr</p> |
| <p>B ↓ Intestinal malabsorption (but normal in malabsorption caused by pancreatic insufficiency), bacterial overgrowth in the small intestine, vomiting, ascites, delayed gastric emptying, and Whipple’s disease</p> | <p>This test is used in the diagnosis of malabsorption states and evaluates carbohydrate absorption by the mucosa of the proximal small intestine. Validity of the test is increased if blood and urine measurements are performed simultaneously to rule out renal retention. In patients with renal deficiency, rely on the serum test only; in functionally anephric patients, the test is unreliable.⁶ Twenty-four hr before test, subjects should not eat</p> |

| | Liver ¹ | mg/kg dry wt. 32-70 | × 15.3 | μmol/kg dry wt. [490-1071] | |
| X-ray fluorescence spectrometry ³ | Bronchoalveolar lavage (BAL) fluid | ng/10 ³ macrophages 0.03-2.85 | × 15.3 | fmol/macrophage [0.46-43.60] | |
| ICP-MS | Serum. ⁶ Collect in pretested, metal-free container. | M: 75-291 mcg/dL F: 65-256 mcg/dL | × 0.153 | [11.48-44.52 μmol/L] [9.95-39.17 μmol/L] | |
| | Urine. ⁶ Collect in acid- washed, metal-free container. | 150-1200 mcg/L | | [22.95-183.60 nmol/L] | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| S ↑ Primary osteosarcoma of bone, coronary heart disease, arteriosclerosis, and anemia | Seventy-five to 88% of the total Zn in whole blood is in the erythrocytes. The serum concentration of Zn undergoes circadian variations that appear to peak around 9:00 AM and again around 6:00 PM. ⁷ Serum Zn levels decrease postprandially. |
| S ↓ Acrodermatitis enteropathica (Danbolt's disease), typhoid fever, pulmonary tuberculosis, metastatic carcinoma to liver, celiac sprue, and other GI diseases, thalassemia major, acute myocardial infarction, severe hepatocellular disease, acute infections, hypogonadal dwarfism, leukemias, lymphomas, PA, renal disease, and pregnancy; impaired smell, taste, and wound healing; various dermatological conditions, alopecia, and skin lesions; hypoalbuminemia, acute stress | Protein precipitation methods with AAS give higher results for serum or plasma than do direct dilution techniques. |
| Ercs ↓ Sick cell anemia (SCA) | Elevated serum zinc may occur in patients undergoing hemodialysis against a dialysate containing a large amount of zinc. Exposure to the fumes of zinc salts can irritate the skin and the respiratory and GI tracts. Oral poisoning (uncommon) is caused by drinking from galvanized cans and produces fever and gastrointestinal distress. Zinc is important for wound healing, immune function, and fetal development. Zinc deficiency retards growth and sexual development and produces dermatitis, reduced taste acuity, anemia, and enlargement of the liver and spleen. Clinical signs of acute zinc deficiency will not usually be found until values decrease to <65 mcg/dL [10 μmol/L]. Skin rash, abdominal pain, diarrhea, and loss of appetite and of the senses of taste and smell are likely when levels remain <33 mcg/dL [5 μmol/L]. Human zinc deficiency is often associated with diets low in animal-derived protein but high in cereals (phytates) that bind zinc. Iatrogenic causes of zinc deficiency include treatment with anabolic or metal-chelating drugs (corticosteroids, penicillamine) and synthetic diet therapies (TPN). |
| U ↑ Hyperparathyroidism, alcoholism, sickle cell anemia, hepatic cirrhosis, viral hepatitis, SCA, postsurgery, and TPN | Long-term zinc supplementation may induce Cu deficiency. |
| U ↓ Hypogonadal dwarfism | Reduced levels of zinc in hair have been shown to accompany body zinc deficiency, but hair zinc, because of exogenous contamination and other factors, is not a reliable measure. (Zinc is a component of some antidandruff shampoos.) |
| Hair ↓ Diabetes [126 ± 49 mcg/g (SD); 1.9 ± 0.75 μmol/g]; celiac disease, protein malnutrition | |

Studies indicate that Zn- α_2 may serve as a marker of differentiation in breast carcinomas, prostate carcinomas, and stratified epithelium.³⁻⁵

Zn- α_2 is a soluble protein that is found in many body fluids.⁴ Its primary function is not yet completely known.⁴ It has been found to have RNase activity and has substantial structural homology with major histocompatibility complex (MHC) class I antigens.^{4,6} Evidence suggests that it may increase lipid catabolism in cancer-related cachexia.⁷

MW: 41,000.

↑ Fe deficiency, chronic lead poisoning, β -thalassemia,¹⁰ sideroblastic anemia, anemia of chronic disease,¹¹ and the mild iron-deficient erythropoiesis seen with inflammation or accelerated erythropoiesis.

ZPP concentration by hematofluorometry was once widely used to screen for lead exposure in children; but ZPP is not reliable at Pb concentrations of <250 mcg/L [0.40 μ mol/L] and should no longer be used for this application. However, it may be cost effective for screening of iron status.

TABLE II-1

SUMMARY CHART OF BLOOD COMPONENTS

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|---|--|--------|--|
| Whole blood | RBCs (Hct ~40%), plasma, WBCs, platelets | 500 mL | Increase both red cell mass and plasma volume (WBCs and platelets not functional, plasma deficient in labile clotting factors V and VIII) |
| RBCs | RBCs (Hct ~75%), reduced plasma, WBCs, platelets | 250 mL | Increase red cell mass in symptomatic anemia (WBCs and platelets not functional) |
| RBCs, adenine-saline added | RBCs (Hct ~60%), reduced plasma, WBCs, and platelets; 100 mL of additive solution | 330 mL | Increase red cell mass in symptomatic anemia (WBCs and platelets not functional) |
| RBCs, WBCs reduced (prepared by filtration) | >85% original volume of RBCs, <5 x 10 ⁶ WBCs, few platelets, minimal plasma | 225 mL | Increase red cell mass, <5 x 10 ⁶ WBCs to decrease the likelihood of febrile reactions, immunization to leukocytes (HLA antigens) or CMV transmission |

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|--|---|--------|---|
| RBCs washed | RBCs (Hct ~75%), $<5 \times 10^8$ WBCs, no plasma | 180 mL | Increase red cell mass, reduce risk of allergic reactions to plasma proteins |
| RBCs frozen; RBCs deglyc- erolized | RBCs (Hct ~75%), 5×10^8 WBCs, no platelets, no plasma | 180 mL | Increase red cell mass, minimize febrile or allergic transfusion reactions, use for prolonged RBC blood storage |
| Granulocytes pheresis | Granulocytes ($>1.0 \times 10^{10}$ PMNs/unit), lymphocytes, platelets ($>2.0 \times 10^{11}$ /unit), some RBCs | 220 mL | Provide granulocytes for selected patients with sepsis and severe neutropenia (<500 PMNs/ μ L) |
| Platelets | Platelets (5.5×10^{10} /unit), RBCs, WBCs, plasma | 50 mL | Bleeding caused by thrombocytopenia or thrombocytopathy |

TABLE II-1

SUMMARY CHART OF BLOOD COMPONENTS—CONTINUED

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|---|---|--------|--|
| Platelets, pheresis | Platelets ($>3 \times 10^{11}$ /unit), $<5 \times 10^6$ WBCs per final dose of pooled platelets | 300 mL | Same as platelets, sometimes HLA matched |
| Platelets WBCs reduced | Platelets (as above), $<5 \times 10^6$ WBCs per final dose of pooled platelets | 300 mL | Same as platelets; $<5 \times 10^6$ WBCs to decrease the likelihood of febrile reactions, alloimmunization to WBCs (HLA antigens), or CMV transmission |
| FFP; donor retested plasma; thawed plasma | FFP, donor retested plasma, all coagulation factors, thawed plasma has reduced factors V and VIII | 220 mL | Treatment of some coagulation disorders |

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|---|--|---------------|---|
| Cryoprecipitated AHF | Fibrinogen, factors VIII and XIII, von Willebrand factor | 15 mL | Deficiency of fibrinogen, factor XIII, second choice in treatment of hemophilia A, von Willebrand disease, topical fibrin sealant |
| Factor VIII (concentrates; recombinant human factor VIII) | Factor VIII, trace amount of other plasma proteins (products vary in purity) | Usually 10 mL | Hemophilia A (factor VIII deficiency), von Willebrand disease (off-label use for selected products only) |
| Factor IX (concentrates; recombinant human factor IX) | Factor IX, trace amount of other plasma proteins (products vary in purity) | Usually 10 mL | Hemophilia B (factor IX deficiency) |

TABLE II-1

SUMMARY CHART OF BLOOD COMPONENTS—CONTINUED

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|-----------------------|---|-----------|--|
| Albumin/PPF | Albumin, some α -, β -globulins | 5% 25% | Volume expansion |
| Immune globulin | IgG antibodies, preparations for IV and/or IM use | Varies | Treatment of hypogammaglobulinemia or agammaglobulinemia, disease prophylaxis, autoimmune thrombocytopenia (IV only) |
| Rh immune globulin | IgG anti-D, preparations for IV and/or IM use | 1 mL | Prevention of hemolytic disease of the newborn caused by D antigen, treatment of autoimmune thrombocytopenia |

| COMPONENT/ PRODUCT | COMPOSITION | VOLUME | INDICATIONS |
|-----------------------------------|---|---------------------------------------|---|
| Antithrombin | Antithrombin, trace amount of other plasma proteins | 10 mL | Treatment of antithrombin deficiency |
| Activated protein C (recombinant) | Activated protein C | | Severe sepsis |
| Factor VIIa (recombinant) | Factor VIIa | 2.2 mL (1.2 mg)/8.5 mL (4.8 mg) | Bleeding episodes for hemophilia A or B with inhibitors, off-label use for uncontrolled bleeding in various clinical settings |

RBC, Red blood cell; Hct, hemotocrit; WBC, white blood cell; CMV, cytomegalovirus; PMN, polymorphonuclear leukocyte; FFP, fresh frozen plasma; IV, intravenous; IM, intramuscular.

TABLE II-2 PRIMARY AND SECONDARY AMINO ACID DISORDERS¹**A. PRIMARY OVERFLOW AMINOACIDURIAS (AUTOSOMAL RECESSIVE DISORDERS)**

| DISORDER | PREVALENCE | ABNORMAL ENZYME(S) (OR OTHER DEFECTS) | EXCESS IN BLOOD | EXCESSES IN URINE |
|-------------------------------|-----------------------------------|---|---|---|
| Hyperphenylalaninemia | | | | |
| Type I (Classic PKU) | 1:10,000 | Phenylalanine hydroxylase total deficiency | Phenylalanine | Phenylalanine and its metabolites (phenylpyruvate, phenyllactate, phenylacetate) when untreated |
| Type II (Variant PKU) | 1:14,000 | Phenylalanine hydroxylase partial deficiency | Phenylalanine | Variable |
| Type III (Transient neonatal) | 1:30,000 | Immature phenylalanine hydroxylase | Phenylalanine | Phenylalanine metabolites usually not found |
| Tetrahydrobiopterin defects | Rare | Dihydropteridine reductase deficiency GTP cyclohydrolase I deficiency, 6-pyruvoyl-tetrahydropterin synthase deficiency Pterin 4 α -carbinolamine dehydratase deficiency | Phenylalanine Absent CSF neurotransmitters | Variable |
| Hypertyrosinemia | | | | |
| Type I (Hepatorenal) | 1:100,000 (1:16,000 in Quebec) | Fumarylacetoacetate hydrolase deficiency | Tyrosine | Tyrosine and its metabolites (PHPPA, PHPLA, PHPAA); generalized aminoaciduria |
| Type II (Oculocutaneous) | Rare | Tyrosine aminotransferase deficiency | Tyrosine | Tyrosine and its metabolites |
| Type III | Rare | 4-hydroxyphenylpyruvic acid dioxygenase deficiency | Tyrosine | Tyrosine and its metabolites |

Continued

| DISORDER | PREVALENCE | ABNORMAL ENZYME(S) (OR OTHER DEFECTS) | EXCESS IN BLOOD | EXCESSES IN URINE |
|---|------------------------------------|---|---|--|
| Transient neonatal | Full term, 1:10; premature, 1:3 | Liver immaturity | Tyrosine; phenylalanine | Tyrosine and its metabolites |
| Alkaptonuria | 1:250,000 | Homogentisic acid oxidase deficiency | Homogentisic acid (slight) | Homogentisic acid |
| Homocystinuria | 1:200,000 | Cystathionine β -synthase deficiency | Homocysteine, methionine | Homocystine, methionine and its sulfoxide |
| | Total deficiency is rare | Methylenetetrahydrofolate reductase deficiency | Homocysteine, normal or low methionine | As in blood |
| | Rare | Cobalamin defects | Homocysteine, methyl- malonic acid | Homocystine, methylmalonic acid (organic acid) |
| Histidinemia | 1:12,000 | Histidase | Histidine | Imidazole pyruvic acid (organic acid) |
| Branched-chain ketoaciduria (maple syrup urine disease) | 1:200,000 | Branched-chain ketoacid decarboxylase | Leucine, isoleucine, alloisoleucine, valine, and corresponding 2-ketoacids | Amino acids as in blood |
| Nonketotic hyperglycinemia | 1:150,000 | Glycine cleavage enzyme | Glycine (CSF) | Glycine not always elevated |
| Propionic acidemia | 1:50,000 | Propionyl CoA carboxylase | Glycine, propionic acid | Glycine, propionate, 3-hydroxypropionate, and methylcitrate (organic acids) |
| Methylmalonic acidemia | 1:20,000 | Methylmalonyl CoA mutase | Glycine, methylmalonic acid | Glycine, methylmalonic acid (organic acid) |
| Cystathioninuria | 1:70,000 | γ -Cystathionase | Cystathionine | Cystathionine |
| Carnosinemia | 1:500,000 | Carnosinase | Carnosine | Carnosine, homocarnosine |

TABLE II-2 PRIMARY AND SECONDARY AMINO ACID DISORDERS—CONTINUED**A. PRIMARY OVERFLOW AMINOACIDURIAS (AUTOSOMAL RECESSIVE DISORDERS)—CONTINUED**

| DISORDER | PREVALENCE | ABNORMAL ENZYME(S) (OR OTHER DEFECTS) | EXCESS IN BLOOD | EXCESSES IN URINE |
|---|---------------------------------|--|---|--|
| Hyperprolinemia I and II | 1:300,000 | Type I: Proline oxidase Type II: D5-Pyrroline-5-carboxylic acid dehydrogenase | Proline | Proline, hydroxyproline, and glycine Pyrroline-5-carboxylic acid (organic acid) |
| UREA CYCLE DISORDERS | | | | |
| Citrullinemia | 1:100,000 | Argininosuccinate synthetase | Citrulline, ammonia | Citrulline, orotic acid (organic acid) |
| Argininosuccinic aciduria | 1:75,000 | Argininosuccinate lyase | Argininosuccinic acid, citrulline, and ammonia | Argininosuccinic acid and its anhydride, citrulline, and orotic acid |
| Argininemia | Rare | Arginase | Arginine, ammonia after meals | Normal or excess arginine |
| Hyperornithinemia with gyrate atrophy of choroids | Rare | Ornithine aminotransferase (OAT) | Ornithine, glutamine, and homocitrulline (HHH) ammonia after meals | Ornithine |
| Hyperornithinemia/hyperammonemia/homocitrullinemia (HHH) | Rare | Mitochondrial ornithine transporter (ORNT1) | Ammonia, glutamine | Ornithine, homocitrulline, and orotic acid (HHH) |
| Ornithine transcarbamylase deficiency X-linked | Most common urea cycle disorder | Ornithine transcarbamylase | Ammonia, glycine, and glutamine | Orotic acid, uridine, and uracil |
| Carbamoylphosphate synthetase defects | Rare | Carbamoylphosphate synthetase/ <i>N</i> -acetylglutamate synthase | Normal or excess arginine | Glutamine |

TABLE II-2 PRIMARY AND SECONDARY AMINO ACID DISORDERS—CONTINUED**B. PRIMARY RENAL AMINOACIDURIAS (AUTOSOMAL RECESSIVE DISORDERS)**

| DISORDER | PREVALENCE | EXCESS AMINO ACIDS IN URINE |
|---|------------|---|
| Cystinuria, classic | 1:13,000 | Lysine, ornithine, arginine, and cystine |
| Hypercystinuria | Rare | Cystine |
| Dibasic aminoaciduria and lysinuric protein intolerance | Rare | Lysine, ornithine, and arginine |
| Hartnup disease | 1:18,000 | All neutral amino acids |
| Iminoglycinuria | 1:12,000 | Glycine, proline, and hydroxyproline, free |
| Dicarboxylic aminoaciduria | Rare | Glutamic acid, aspartic acid |
| Methionine malabsorption | Rare | Methionine; also tyrosine, phenylalanine, and branched-chain amino acids, α -hydroxybutyric acid, and urinary odor |

1. Silverman LM, Christenson RH, Grant GH: Amino acids and proteins. In Tietz NW, editor: *Textbook of clinical chemistry*, Philadelphia, 1986, WB Saunders (modified).

TABLE II-2 PRIMARY AND SECONDARY AMINOACIDURIAS

| DISORDER | AMINO ACIDS INCREASED IN URINE |
|---|---|
| C. SECONDARY AMINOACIDURIAS DUE TO PRIMARY INHERITED DISORDERS | |
| Cystinosis | Generalized aminoaciduria |
| Fanconi syndrome | Generalized aminoaciduria |
| Hereditary fructose intolerance | Generalized aminoaciduria |
| Galactosemia | Generalized aminoaciduria |
| Glycogen storage disease type I (rarely) | Generalized aminoaciduria |
| Lowe's syndrome | Generalized aminoaciduria |
| Tyrosinemia type 1 | Generalized aminoaciduria |
| Wilson's disease | Generalized aminoaciduria |
| D. NONINHERITED, TRANSIENT, AND ACQUIRED DISORDERS | |
| Aminoaciduria of normal newborns | Generalized |
| Body irradiation | Generalized |
| Connective tissue disorders | Hydroxyproline |
| Heavy metal toxicity | Generalized |
| Hepatic dysfunction | Tyrosine, methionine, and phenylalanine |
| Homocitrullinemia (nutritional) | Homocitrulline |
| Hyperparathyroidism | Hydroxyproline |
| Hyperthyroidism | Hydroxyproline |
| Malnutrition/ketosis | Leucine, valine, and isoleucine alanine |
| Neurosecretory tumors | Cystathionine |
| Nephrotic syndrome | Generalized |
| Outdated tetracycline ingestion | Generalized |
| Pregnancy | Generalized |
| Renal transplantation reaction | Generalized |
| Salicylate toxicity | Generalized |
| Steroid therapy | Generalized |
| Thermal burn | Cystathionine |
| Vitamin B deficiency | Generalized |
| Vitamin C deficiency | Generalized |
| Vitamin D deficiency | Generalized |

TABLE II-3 INTERPRETATION OF ACYLCARNITINE PROFILES

| ACYLCARNITINE | DISORDER |
|---------------------------------|---|
| C0-free carnitine | ↑ Free to acylcarnitine ratio in CPT 1A deficiency |
| C2-Acetyl- | ↑ In ketosis |
| C3-Propionyl- | ↑ PA, MMA |
| C3-DCA | ↑ MCD |
| C4-Butyryl-/Isobutyryl- | ↑ SCAD, isobutyryl-CoA dehydrogenase deficiency |
| C4-OH (hydroxyl C4) | ↑ SCHAD, possibly elevated in ketosis |
| C4-DCA | ↑ MMA (succinyl-carnitine has same mass) |
| C5-Isovaleryl, 2-methylbutyryl- | ↑ IVA, 2-methylbutyryl-CoA dehydrogenase deficiency |
| C5-OH 3-hydroxyisovaleryl- | ↑ MCC |
| C5-DCA glutaryl- | ↑ GA I, GA II |
| C6-Hexanoyl- | ↑ MCAD, GA II |
| C6-DCA methylglutaric- | ↑ HMG-CoA lyase |
| C8-Octanoyl- | ↑ MCAD, GA II |
| C10-Decanoyl- | ↑ MCAD, GA II |
| C10:1-Decenoyl | ↑ MCAD, GA II |
| C14:0 | ↑ VLCAD, CACT, and GA II |
| C14:1 | ↑ VLCAD, CACT |
| C14:2 | ↑ VLCAD, CACT |
| C14-OH | ↑ LCHAD, TFP |
| C16:0 | ↑ CPT 2, VLCAD (minor), CACT, and GA II |
| C16:1 | ↑ CPT 2, VLCAD (minor), and CACT |
| C16:2 | ↑ CPT 2, VLCAD (minor), and CACT |
| C16-OH | ↑ LCHAD, TFP |
| C18-OH | ↑ LCHAD, TFP |
| C18:1-OH | ↑ LCHAD, TFP |
| C18:2-OH | ↑ LCHAD, TFP |

CPT1A, Carnitine palmitoyltransferase 1A (hepatic) deficiency; *PA*, propionic acidemia; *MMA*, methylmalonic acidemia; *MCD*, malonyl-CoA decarboxylase deficiency; *SCAD*, short-chain acyl-CoA dehydrogenase deficiency; *SCHAD*, short/medium-chain 3-hydroxyacyl-CoA dehydrogenase deficiency; *IVA*, isovaleric acidemia; *MCC*, 3-methylcrotonyl-CoA carboxylase deficiency; *GA I*, glutaric acidemia type 1; *GA II*, glutaric acidemia type 2 (multiple acyl-CoA dehydrogenation defects MADD); *MCAD*, medium-chain acyl-CoA dehydrogenase deficiency; *HMG*, 3-hydroxy-3-methylglutaryl-CoA; *VLCAD*, very-long-chain acyl-CoA dehydrogenase deficiency; *CACT*, carnitine:acylcarnitine translocase deficiency; *LCHAD*, long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency; *TFP*, mitochondrial trifunctional protein deficiency.

TABLE II-4 DRUGS CAUSING APLASTIC ANEMIA AND HEMOLYSIS

| DRUG | APLASTIC ANEMIA | HEMOLYSIS | |

TABLE II-5 HEPATOTOXIC DRUGS**DRUGS CAUSING CHOLESTASIS**

| | | |
|---------------------|---------------------------|----------------|
| Aminosalicilic acid | Erythromycin | Penicillamine |
| Amitriptyline | Estrogens | Penicillins |
| Anabolic steroids | Ethionamide | Phenothiazines |
| Androgens | Glyburide (glibenclamide) | Phenylbutazone |
| Azathioprine | Gold salts | Progestins |
| Benzodiazepines | Imipramine | Propoxyphene |
| Carbamazepine | Mercaptopurine | Sulfonamides |
| Carbarsone | Methimazole | Sulfones |
| Chlorothiazide | Mitoxantrone | Sulindac |
| Chlorpropamide | Nicotinic acid | Tamoxifen |
| Clavulanic acid | Nitrofurantoin | Tolbutamide |
| Dapsone | Oral contraceptives | |

DRUGS CAUSING HEPATOCELLULAR INJURY

| | | |
|------------------------------|------------------------------|--------------------------|
| Acetaminophen | Estrogens | Paramethadione |
| Allopurinol | Ethanol (excess) | Perhexiline |
| Aminosalicilic acid | Ethionamide | Phenazopyridine |
| Amiodarone | Etretinate | Phenindione |
| Amitriptyline | Fluconazole | Phenobarbital |
| Anabolic steroids | Halothane | Phenylbutazone |
| Androgens | HMG-CoA reductase inhibitors | Phenytoin |
| Asparaginase | Ibuprofen | Plicamycin (mithramycin) |
| Aspirin | Imipramine | Probenecid |
| Azathioprine | Indomethacin | Procainamide |
| Carbamazepine | Iron salts (overdose) | Propylthiouracil |
| Chenodiol | Isoniazid | Pyrazinamide |
| Chlorambucil | Ketoconazole | Quinidine |
| Chloramphenicol (occasional) | MAO inhibitors | Rifampin |
| Chlorpropamide | Mercaptopurine | Salicylates |
| Cimetidine | Methotrexate | Sulfasalazine |
| Cyclosporine | Methoxyflurane | Sulfonamides |
| Danazol | Methyl dopa | Tamoxifen |
| Dantrolene | Naproxen | Tetracyclines |
| Dapsone | Nicotinic acid | Trimethadione |
| Diclofenac | Nitrofurantoin | Valproic acid |
| Dicoumarol (rare) | Oral contraceptives | Vitamin A |
| Disulfiram | Papaverine | Warfarin (rare) |

TABLE II-6 NEPHROTOXIC SUBSTANCES**METALS**

Antimony
 Arsenic
 Bismuth
 Cadmium
 Copper
 Gold
 Iron
 Lead
 Lithium
 Mercurials
 Silver
 Thallium
 Uranium

ANALGESIC DRUGS

Acetaminophen (overdose)
 Aminopyrine
 Nonsteroidal anti-inflammatory drugs
 (e.g., ibuprofen, indomethacin, naproxen, fenoprofen)
 Phenacetin
 Phenylbutazone
 Salicylates

ANTIMICROBIAL AGENTS

Aminoglycosides (e.g., amikacin, gentamicin, kanamycin, neomycin, streptomycin, tobramycin)
 Amphotericin B
 Capreomycin
 Cephalosporins
 (primarily cephaloridine and cephalothin)
 Colistin
 Cotrimoxazole
 Foscarnet
 Penicillins (e.g., ampicillin, methicillin, oxacillin)
 Polymyxin B
 Rifampin
 Sulfonamides
 Tetracyclines
 Vancomycin

ANTINEOPLASTIC DRUGS

Carboplatin
 Cisplatin
 Cyclophosphamide
 Ifosfamide
 Methotrexate (high dose)
 Mitomycin
 Nitrosoureas (e.g., lomustine, semustine)
 Pllicamycin (mithramycin)
 Streptozocin

ORGANIC SOLVENTS

Benzene
 Carbon tetrachloride
 Ethylene glycol
 Tetrachloroethylene

OTHER DRUGS

Acetazolamide
 ε -Aminocaproic acid
 Aminosalicilyc acid
 Boric acid
 Captopril
 Cyclosporine
 Dextran (low molecular weight)
 Furosemide
 Mannitol
 Methoxyflurane
d-Penicillamine
 Pentamidine
 Phenindione
 Quinine
 Radiographic contrast media
 Thiazide diuretics
 Triamterene
 Zoxazolamine

TABLE II-7 HEPATITIS TESTING

| PURPOSE | MARKERS | ADDITIONAL TESTING INDICATED |
|---------------------------------|---|--|
| Diagnosis of acute hepatitis | IgM-anti-HA Hb _s Ag IgM-anti-HB _c Anti-HCV | |
| Diagnosis of chronic hepatitis | Hb _s Ag Anti-HCV | <p>If negative but still suspect HBV: Anti-HB_s, anti-HB_c, and HBV-DNA (optional)</p> <p>If positive: HB_eAg, anti-HB_e, anti-HD, and HDAg (optional)</p> <p>To assess therapy of HBV: HB_eAg, anti-HB_e, and HBV-DNA</p> <p>If negative but still suspect HCV: HCV-RNA</p> |
| Determine efficacy of B vaccine | Anti-HB _s | |
| Determine natural immunity HBV | Anti-HB _c | |

TABLE II-8 SPHINGOLIPIDOSES*†

| DISEASE | NUMBER OF SUBTYPES | SPECIMEN USED FOR ENZYME ASSAY | ENZYME DEFICIENCY | LIPID ACCUMULATED |
|--|--------------------|--|--|--|
| Gaucher's disease | 3 | Leukocytes, cultured skin fibroblasts | Cerebrosidase β -glucosidase (β -glucosidase, EC 3.2.1.21) | Glucosyl ceramide |
| Metachromatic leukodystrophy | 4 | Leukocytes, cultured skin fibroblasts, and serum | Arylsulfatase A (EC 3.1.6.1) | Sulfatide |
| Tay-Sachs disease (GM ₂ gangliosidosis) | 1 | Leukocytes, cultured skin fibroblasts, and serum | Hexosaminidase A (<i>N</i> -acetyl- β -D-glucosaminidase, EC 3.2.1.30) | Ganglioside, GM ₂ |
| Sandhoff disease (GM ₂ gangliosidosis) | 2 | Leukocytes, cultured skin fibroblasts, and serum | Hexosaminidase A and B (<i>N</i> -acetyl- β -D-glucosaminidase, EC 3.2.1.30), GM ₂ activator protein | Ganglioside, GM ₂ , and globoside |
| GM ₁ gangliosidosis | 2 | Leukocytes, cultured skin fibroblasts | Acid β -galactosidase (EC 3.2.1.23) | Ganglioside, GM ₁ |
| Fabry's disease | 1 | Leukocytes, cultured skin fibroblasts, and serum | α -Galactosidase A (EC 3.2.1.22) | Trihexosyl ceramide |
| Niemann-Pick disease types A and B | 2 | Leukocytes, cultured skin fibroblasts, and serum | Sphingomyelinase (sphingomyelin phosphodiesterase, EC 3.1.4.12) | Sphingomyelin |
| Krabbe's disease (globoid cell leukodystrophy) | 2 | Leukocytes, cultured skin fibroblasts, and serum | Cerebrosidase β -galactosidase (β -galactosidase, EC 3.2.1.23) | Galactosyl ceramide |
| Farber's disease | 7 | Leukocytes, cultured skin fibroblasts, serum, and amniocytes | Acid ceramidase (acylsphingosine deacylase, EC 3.5.1.23) | Ceramide |
| Fucosidosis | 2 | Leukocytes | α -Fucosidase (EC 3.2.1.51) | H-antigen glycolipid |
| Schindler disease | 3 | Leukocytes, cultured skin fibroblasts, and amniocytes | α - <i>N</i> -Acetyl-galactosaminidase | Glycopeptides |

*All listed sphingolipidoses are autosomal recessive except Fabry's disease, which is X-linked. Prenatal diagnosis of homozygotes and identification of heterozygous carriers are available for the listed disorders.

†At present, diagnosis of Farber's disease is confirmed by biopsy and histological examination of subcutaneous nodules rather than by determination of enzyme activity.

TABLE II-9

INFORMATIVE BIOCHEMICAL FINDINGS
IN PORPHYRIA

| TYPE OF PORPHYRIA | DEFICIENT ENZYME | ENZYME ASSAY AVAILABLE |
|---|--------------------------------|------------------------------|
| Porphyria cutanea tarda (PCT) | Uroporphyrinogen decarboxylase | Y |
| Hepatoerythropoietic porphyria (HEP) | Uroporphyrinogen decarboxylase | Y |
| Congenital erythropoietic porphyria (CEP) | Uroporphyrinogen cosynthase | Y |
| Erythropoietic protoporphyria (EPP) | Ferrochelatase | N |
| ALA dehydratase deficiency (ALAD) | ALA dehydratase | Y |
| Acute intermittent porphyria (AIP) | Porphobilinogen deaminase | Y |
| Hereditary coproporphyria (HCP) | Coproporphyrinogen oxidase | N |
| Variegate porphyria (VP) | Protoporphyrinogen oxidase | N |

*Sometimes.

BIOCHEMICAL FINDINGS

| URINE | FECES | ERYTHROCYTES | PLASMA |
|---|--|---|---|
| Uroporphyrin, heptacarboxylporphyrin | Isocoproporphyrin, heptacarboxylporphyrin III | | Uroporphyrin |
| Uroporphyrin, heptacarboxylporphyrin | Isocoproporphyrin, heptacarboxylporphyrin III | Zinc protoporphyrin | Uroporphyrin |
| Uroporphyrin, coproporphyrin | Uroporphyrin I, coproporphyrin I | Uroporphyrin, coproporphyrin, and zinc protoporphyrin | Uroporphyrin I, coproporphyrin I |
| | Protoporphyrin | Free protoporphyrin | Protoporphyrin* |
| ALA | | | |
| ALA, PBG, uroporphyrin, and coproporphyrin* | Uroporphyrin,* coproporphyrin* | | Increased porphyrins and precursors during acute episodes |
| Coproporphyrin, ALA, and PBG | Coproporphyrin ↑ Coproporphyrin III/coproporphyrin I ratio | | Coproporphyrin |
| Coproporphyrin, PBG, and ALA | Protoporphyrin > coproporphyrin ↑ Coproporphyrin III/coproporphyrin I ratio | | |

TABLE II-11 CDC CLASSIFICATION OF BLOOD LEAD LEVELS IN CHILDREN

| CLASS BLOOD LEAD* | | ACTION |
|-------------------|--------------|--|
| I | <10 mcg/dL | None (not lead poisoned) |
| IIA | 10-14 mcg/dL | Educational intervention, rescreen within 3 mo |
| IIB | 15-19 mcg/dL | Educational, possible social intervention, rescreen within 2 mo† |
| III | 20-44 mcg/dL | Provide case and clinical management, environmental investigation, and consider chelation therapy |
| IV | 45-69 mcg/dL | Initiate case and clinical management, environmental investigation, and lead hazard control within 48 hr; start chelation therapy |
| V | >69 mcg/dL | A medical emergency, hospitalize child, initiate case and clinical management, environmental management, and lead hazard control immediately |

*Owing to possible contamination during collection, elevated levels should be confirmed with a second specimen before action is instituted.

†If two venous BLLs collected 3 mo apart are ≥ 15 -19 mcg/dL, proceed with action for BLLs 20-44 mcg/dL.

**TABLE II-12 OSHA-RECOMMENDED ACTION LEVELS
FOR WORKERS EXPOSED TO CADMIUM¹**

| LABORATORY FINDINGS | MCG/L | MCG/G CREATININE* | ACTION |
|---------------------------------------|-------|-------------------|---|
| LEVEL A | | | |
| Cadmium, whole blood† | ≤5 | | Monitor annually, biennial medical examination, no action required |
| Cadmium, urine‡ | | ≤3 | |
| β ₂ -Microglobulin, urine§ | | ≤300 | |
| LEVEL B | | | |
| Cadmium, whole blood | >5 | ≤10 | Monitor semiannually, annual medical examination, discretionary removal from source of exposure |
| Cadmium, urine | >3 | ≤7 | |
| β ₂ -Microglobulin, urine | >300 | ≤750 | |
| LEVEL C | | | |
| Cadmium, whole blood | >15 | >10 | Monitor quarterly, semiannual medical examination, mandatory removal from source of exposure |
| Cadmium, urine | >15 | >7 | |
| β ₂ -Microglobulin, urine | >1500 | >750 | |

1. *Cadmium action levels beginning January 1999*, Federal Register 1999, Std CFR, Part 1910, 1027 Appendix A.

*Blood cadmium estimates current Cd exposure.

†Urine creatinine value.

‡Urine cadmium estimates Cd body burden.

§Urine β₂-microglobulin is an early marker of irreversible kidney damage and disease.

||The determination of discretionary or mandatory removal is made by the examining physician consistent with the medical surveillance specifications in the Federal Register, 42456-42463.

TABLE II-13 SERUM IRON, TIBC, AND TRANSFERRIN SATURATION*

| | SERUM IRON | TIBC | TRANSFERRIN SATURATION |
|---|---------------|------|---------------------------|
| Ingestion of medicinal iron[†] | ↑ | N | ↑ |
| Parenteral iron administration[‡] | ↑ | ↑ | Var |
| Iron deficiency states | | | |
| Chronic blood loss | ↓N | ↑N | ↓N |
| Acute blood loss | N↓ | N | N↓ |
| Post-subtotal gastrectomy | N↓ | ↑N | ↓N |
| Dietary deficiency (infants and children) | N↓ | ↑N | ↓N |
| Polycythemia vera | ↓N | ↑N | ↓N |
| Kwashiorkor | ↓ | ↓ | Var |
| Pregnancy (without Fe supplement) | ↓N | ↑N | ↓N |
| Iron overload states | | | |
| Acute iron poisoning | ↑ | N | ↑ |
| Chronic iron overload (hemosiderosis, hemochromatosis, thalassemia major, sideroblastic anemias, other chronic anemias after numerous transfusions) | ↑ | N↓ | ↑ |
| Chronic disorders | | | |
| Chronic infections | ↓N | ↓N | N↓ |
| Rheumatoid arthritis | ↓N | ↓N | N↓ |
| Malignancies | ↓N | ↓N | N↓ |
| Laennec's cirrhosis | ↓N | ↓N | N↓ |
| Acute disorders | | | |
| Acute infections | ↓ | N | ↓ |
| Myocardial infarction | ↓ | N | ↓ |
| Hepatitis or hepatic necrosis [§] | ↑ | ↑N | Var |
| Physiological variations | | | |
| Diurnal rhythm | | | |
| Morning | N | N | N |
| Evening | ↓ | N | ↓ |
| Menstruation | ↓ | N | ↓ |
| Premenstrual interval | ↑ | N | N |
| Contraceptives (except when bleeding) | ↑ | ↑ | N |
| Pregnancy (with Fe supplement) | ↑ | ↑ | N |
| Miscellaneous | | | |
| Pernicious anemia | | | |
| Untreated | ↑ | N↓ | ↑ |
| Early treatment (first week) | ↓ | N↓ | ↓N |
| Treated | N | N | N |
| Congenital atransferrinemia (<i>very rare</i>) | ↓ | ↓ | ↑ |
| Acquired atransferrinemia (from nephrotic syndrome) | ↓ | ↓ | ↑ |
| Hemolytic anemias | Var | Var | Var |

*For each entry in this table, the most characteristic change is indicated first.

[†]The ingestion of a single tablet or capsule of an iron-containing medicinal can increase the serum iron concentration by 300-500 mcg/dL, an effect that often masks iron deficiency. Peak serum iron concentration occurs a few hours after ingestion; the effect is most pronounced in iron-deficient subjects.

[‡]Increased serum iron concentration may be observed for weeks after an injection of iron dextran. The mechanism of this has not been determined; most likely it reflects iron dextran in plasma. The increase in TIBC characteristically observed with automated methods probably does not reflect increased transferrin but a methodological artifact (additional release of iron from iron dextran as a result of the procedure?) because the unsaturated iron-binding capacity is normal in this situation.

[§]Increased iron concentrations are the result of extreme hyperferritinemia consequent to hepatocellular injury. The increase in TIBC characteristically observed with automated methods probably does not reflect increased transferrin but a methodological artifact (additional iron release from ferritin as a result of the procedure?).

*Values are given as cell counts in thousands per microliter: 10^3 cells/ μ L (10^6 cells/L). These values are calculated by multiplying the percent (%) of each type of cell by the total leukocyte count. The ranges are derived from several sources with an emphasis on the most recent sources, which include automated counts. Mean values are given where range is not available. A racial difference exists in neutrophil counts. Healthy black males and Asian and black females have lower absolute neutrophil counts than do white persons. White women have higher segmented neutrophil counts than white men until age 45 yr and then the reverse holds.

TABLE II-18A LEUKOCYTE DIFFERENTIAL COUNT: DIAGNOSTIC INFORMATION AND INTERFERENCES

NEUTROPHILIC SERIES¹⁻³

| ↑ NEUTROPHILS (NEUTROPHILIA) | ↓ NEUTROPHILS (NEUTROPENIA) | INTERFERENCES |
|--|---|--|
| <p><i>Infections:</i> Bacterial, mycotic, spirochetal, some viral, rickettsial, parasitic</p> <p><i>Inflammatory disorders or tissue necrosis:</i> Rheumatic fever, rheumatoid arthritis, tissue damage (e.g., after surgery), ischemic necrosis (e.g., myocardial infarction), gout, drug sensitivity, smoking, colitis, pancreatitis, nephritis, myositis, thyroiditis, dermatitis, peritonitis, hepatic necrosis</p> <p><i>Endocrinologic or metabolic disorders:</i> Diabetes mellitus, uremia, eclampsia, hyperthyroidism, overproduction of ACTH</p> <p><i>Hematological disorders:</i> Myeloproliferative disorders (including chronic myeloid leukemia, polycythemia vera, myelofibrosis with myeloid metaplasia), some types of acute myeloid and lymphoid leukemias, postsplenectomy, hemolytic anemias, hemorrhage, chronic idiopathic leukocytosis, rebound or recovery from bone marrow aplasia or nutritional deficiency</p> <p><i>Physical and emotional stimuli:</i> Cold, heat, exercise, pain, burns, labor, pregnancy, trauma, nausea and vomiting, electric shock, anoxia, fear, anger, joy, severe depression</p> <p><i>Malignant neoplasms:</i> A variety of neoplasms, especially bronchogenic carcinoma</p> <p><i>Hereditary conditions:</i> Down syndrome</p> | <p><i>Infections:</i> Bacterial (typhoid, paratyphoid, brucellosis), viral (influenza, measles, rubella, infectious hepatitis, chickenpox, Colorado tick fever, dengue, yellow fever), rickettsial (typhus, rickettsial pox, Rocky Mountain spotted fever), protozoal (malaria, kala-azar), overwhelming infections of any type (especially in elderly or debilitated individuals)</p> <p><i>Hematological disorders:</i> Aplastic anemia, some acute leukemias and myelodysplastic syndromes, idiopathic neutropenia, hypersplenism, megaloblastic anemia, myelophthisic anemia (marrow replacement), paroxysmal nocturnal hemoglobinuria, some cases of T-cell large granular lymphocytic leukemia</p> <p><i>Miscellaneous:</i> Anaphylactoid shock, hypothyroidism, thyrotoxicosis, hypopituitarism, cirrhosis of the liver, cyclic neutropenia, congenital neutropenias, Chédiak-Higashi syndrome, autoimmune</p> | <p>↑ V Pharmacologic granulocyte colony stimulating factors (G-CSF, GM-CSF), epinephrine, etiochonanalone, endotoxin, insect venoms, glucocorticoids, smoking tobacco, vaccines, lithium</p> <p>↓ V Agents affecting occasional subjects because of individual sensitivity: <i>analgesics:</i> acetaminophen, aminopyrine, dipyrone, nonsteroidal antiinflammatory agents (e.g., ibuprofen, indomethacin, phenylbutazone, oxyphenbutazone); <i>anti-convulsants:</i> carbamazepine, ethosuximide, mephenytoin, phenytoin, trimethadione, valproic acid; <i>antihistamines:</i> methaphenilene, tripeleminamine, brompheniramine; <i>antimicrobial agents:</i> cephalosporins, chloramphenicol, clindamycin, cotrimoxazole, gentamicin, imipenem, isoniazid, metronidazole, nitrofurantoin, novobiocin, <i>p</i>-aminobenzoic acid, penicillins, streptomycin, sulfonamides, tetracyclines, trimethoprim, vancomycin; <i>antithyroid agents:</i> carbimazole, methimazole, propylthiouracil, thiouracil; <i>antiviral agents:</i> ganciclovir, zidovudine; <i>cardiovascular agents:</i> ajmaline, amiodarone, aprindine, captopril, enalapril, quinidine, rauwolfia, tocainide; <i>diuretics:</i> acetazolamide, chlorthalidone, ethacrynic acid, spironolactone, thiazides; <i>hypoglycemic agents:</i> carbutamide, chlorpropamide, tolbutamide; <i>psychotropic agents:</i> antidepressants (e.g., amitriptyline, desipramine, imipramine, mianserin), barbiturates, benzodiazepines, clozapine, meprobamate, phenothiazines (e.g., chlorpromazine, prochlorperazine, thioridazine); <i>other agents:</i> aminogluthethimide,</p> |

TABLE II-19 PLATELET COUNT: INTERFERENCES¹⁻⁴

↑ C Cytoplasmic fragments of leukemic cells in blood counted as platelets, dust in diluent fluid, concentration of EDTA anticoagulant too high (>>2 mg/mL)

↓ C Platelet satellitism (EDTA dependent), platelet agglutination (usually EDTA dependent), platelet clumping caused by activation and incipient clotting in sample, cold agglutinins, abciximab (antiplatelet glycoprotein antibody used in cardiac revascularization), old specimen (platelets swell and degenerate with prolonged exposure to EDTA)

↑ V Acyclovir, alglucerase, aztreonam, cefotetan, ceftazidime, daptomycin, enoxacin, epinephrine, erythropoietin (high dose), metoprolol, miconazole, ofloxacin, penicillamine, propranolol, rifampentine, ticlopidine, vincristine

↓ V The following agents, if given in sufficient dose, affect all subjects

Antineoplastic agents: Actinomycin D, alemtuzumab, asparaginase, azathioprine, busulfan, chlorambucil, cisplatin, cyclophosphamide, cytarabine, dacarbazine, daunorubicin, doxorubicin, epirubicin, etoposide, fludarabine, imatinib, lomustine, mechlorethamine, mercaptopurine, methotrexate, nitrosoureas, plin-camycin, procarbazine, thioguanine, vincristine (rare), vinblastine

↓ V The following agents affect only some subjects because of individual sensitivity

Analgesics: Acetaminophen, antipyrine, aspirin, codeine, meperidine, morphine, nonsteroidal antiinflammatory drugs (e.g., ibuprofen, indomethacin, naproxen), oxyphenbutazone, phenacetin, phenylbutazone, sodium salicylate

Antineoplastic agents: Efalizumab, gemcitabine, bortezomib, oxaliplatin, ibritumomab, α -interferon, levamisol, rituximab, tositumomab, tamoxifen

Anticoagulants: Unfractionated heparin, low molecular weight heparins and heparinoids

Anticonvulsants: Carbamazepine, divalproex, ethosuximide, mephenytoin, paramethadione, phenytoin, trimethadione, valproic acid

Antihistamines: Chlorpheniramine, diphenhydramine

Antimicrobial agents: *p*-Aminosalicylic acid, amphotericin B, azithromycin, cephalosporins, chloramphenicol, clindamycin, cotrimoxazole, erythromycin, gemfloxacin, isoniazid, linzolid, novobiocin, organic arsenicals, penicillin, pyrazinamide, rifampicin, stibophen (Faudin), streptomycin, sulfonamides, tetracyclines, vancomycin, voriconazole

Antithyroid agents: Methimazole, propylthiouracil, thiouracil

Cardiovascular agents: Abciximab, alprenolol, amiodarone, amrinone, captopril, digitoxin, mexiletine, nitroglycerin, oxprenolol, quinidine, reserpine, tocainide

Diuretics: Acetazolamide, bumetanide, diazoxide, furosemide, mercurial diuretics, thiazides, triamterene

Heavy metals: Bismuth, copper, gold compounds, silver

Hypoglycemic agents: Carbutamide, chlorpropamide, glibenclamide, insulin, tolbutamide

Psychotropic agents: Antidepressants (e.g., amitriptyline, desipramine), barbiturates, meprobamate, phenothiazines (e.g., chlorpromazine, trifluoperazine)

Other agents: Alcohol, allopurinol, azathioprin, chloroquine, cimetidine, colchicine, cyclosporin, dextroamphetamine, dinitrophenol, ergot, estrogens, ganciclovir, heparin, hydroxychloroquine, methyl dopa, mycophenolate mofetil, penicillamine, potassium iodide, prednisone, procaine, quinine, ranitidine, saquinavir, sirolimus, ticlopidine, valgancyclovir, vitamin K

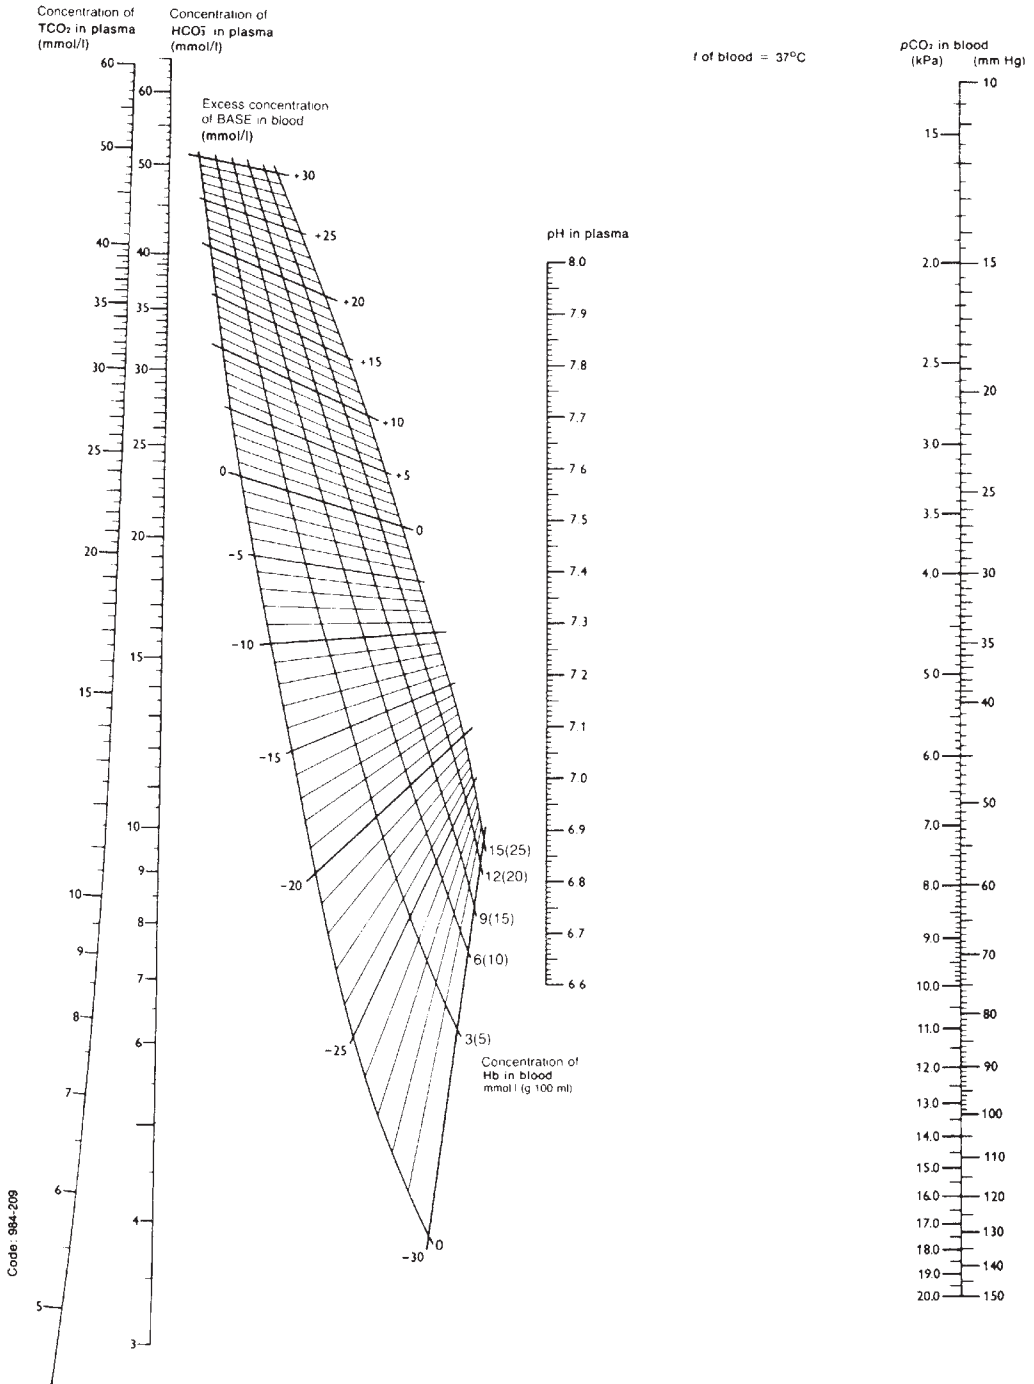

Figure II-1. The Siggard-Andersen alignment nomogram for the calculation of acid-base parameters. Modified from Radiometer A/S, Copenhagen, Denmark.

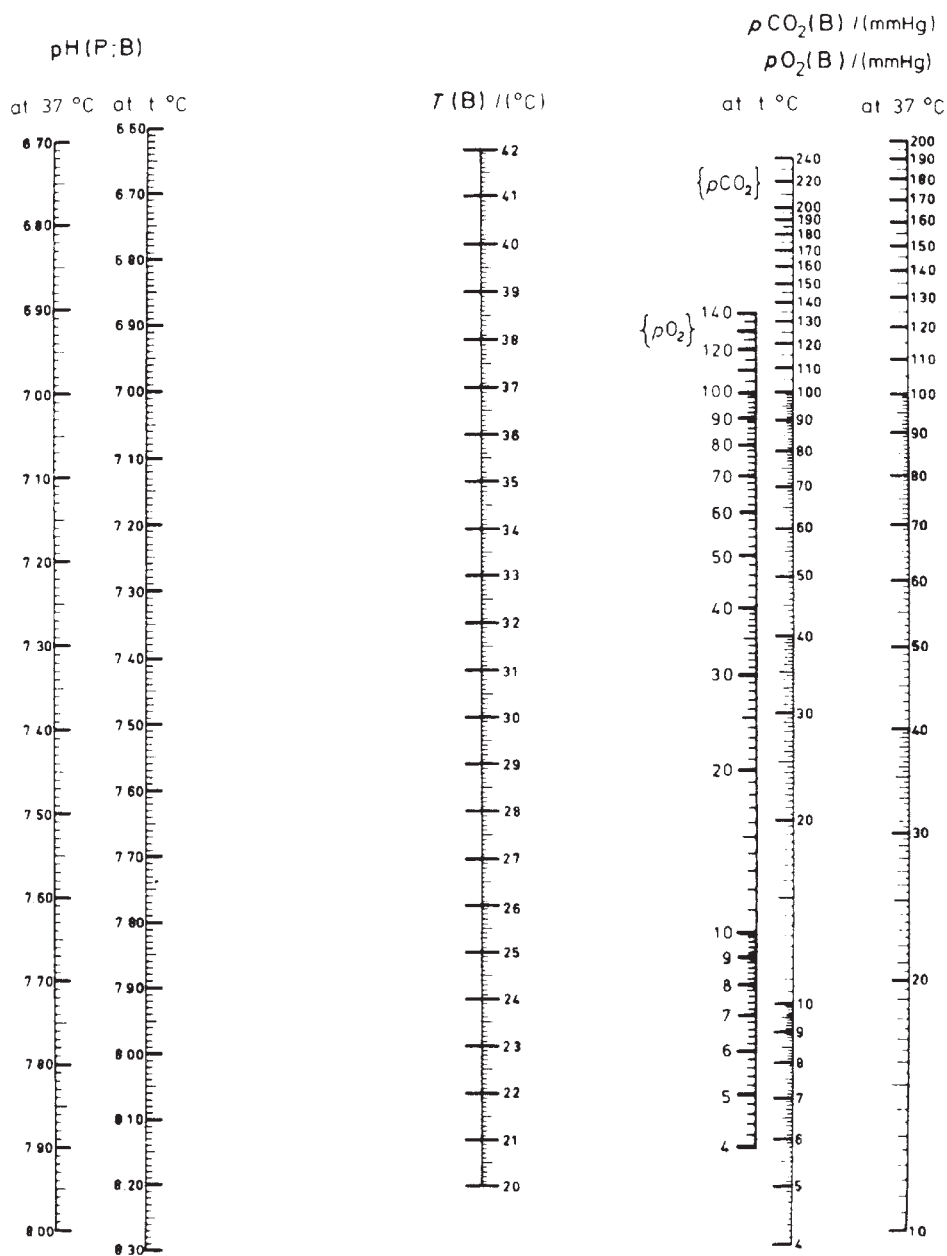

Figure II-2. Nomogram for the conversion of pH, $p\text{CO}_2$, and $p\text{O}_2$ values in a blood sample measured at 37°C to values corrected for the body temperature of the patient. The nomogram is based on the following formulas: $\Delta\text{pH(P)}/\Delta T = -0.015\text{ K}^{-1}$; $\Delta\log p\text{CO}_2/\Delta T = 0.021\text{ K}^{-1}$; $\Delta\log p\text{O}_2/\Delta T = 0.031\text{ K}^{-1}$.

Example: Measured $p\text{CO}_2 = 60\text{ mm Hg}$ at 37°C , temperature of patient = 31°C . Find 60 on the scale for $p\text{CO}_2$ at 37°C .

Find 31 on the temperature scale. Place line between the two points and read $p\text{CO}_2$ on the scale for $p\text{CO}_2$ at $t^\circ\text{C}$ (here 45 mm Hg). The procedure is similar for $p\text{O}_2$ and pH.

(Eds.): Oxford Textbook of Clinical Hepatology, Vol. 1. Oxford, Oxford University Press, 1991. Reproduced by permission of Oxford University Press.

SECTION III

MOLECULAR DIAGNOSTICS

PART A: MOLECULAR METHODS

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Fluorescence In Situ Hybridization (FISH) ¹ | Interphase FISH: Fixed tissue sections, exfoliated cells (smears or cytospin preparations). Samples must adhere to glass microscopic slides. Metaphase FISH: Chromosome spreads. | FISH localizes identified targets at the cellular or chromosome level. Traditional metaphase FISH is performed on chromosome spreads created from synchronizing cells in culture. Interphase FISH can be applied to routinely fixed histological and cytological specimens and to archived paraffin-embedded tissue samples. Test time: 2-7 days |

| | | |
|------------------------------------|---|---|
| Forensic/Criminal Identity Testing | Body fluids, tissue. Store all body fluids at 4° C and all tissue at ≤ -20° C until nucleic acids are isolated. Store isolated nucleic acids at ≤ -20° C. | DNA testing supersedes traditional genotyping because of increased discriminatory power, application to a variety of biologic sources, and DNA resistance to environmental factors. Most techniques assay for variable number tandem repeat (VNTR) loci. ^{1,4-8} |
| PCR, Southern blot, RFLP | | |
| Paternity Testing ¹ | Whole blood (ACD or EDTA), chorionic villi, and amniocytes. Store all body fluids at 4° C and cells at ≤ -20° C until nucleic acids are isolated. Store isolated nucleic acids at ≤ -20° C. | Multilocus probing provides unique individual identification and is more informative than single locus probing. A variety of probes have been used for both multilocus and single-locus probing. |
| Southern blot, PCR | | |
| Tissue Typing ¹⁻³ | | HLA class II genes (HLA-DR, -DQ, and -DP) are highly polymorphic, and subtyping is readily achieved. |

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|--|---|
| In Situ Hybridization (ISH)¹ | Fixed tissue sections, exfoliated cells (smears or cytospin preparations). Samples must adhere to glass microscopic slides. Chromogenic detection of target sequences. | Because ISH occurs localized at the cellular level, it allows direct correlation of molecular data with a pathological process. Another advantage is its applicability to routinely fixed histological and cytological specimens and to archived paraffin-embedded tissue samples. However, compared with other molecular techniques, ISH has low sensitivity. ISH is most useful for detecting targets such as viruses in infected cells, which are present in high copy numbers. Test time: 3-7 days |

| | | |
|---|---|---|
| In Vitro Amplification | Isolated nucleic acids (DNA or RNA). Crude cell lysates, serum, and whole blood may be used directly. Avoid anticoagulants. Nucleic acids should be stored frozen at $\leq -20^{\circ}\text{C}$. | Although traditional PCR was the first in vitro amplification technology to become widely used, many modifications to the PCR have been developed. The most common of these has become the real-time PCR or kinetic amplification technologies. Other in vitro amplification technologies have also been developed and have been applied to specific test types using specific instrumentation. |

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|--|
| Laser Capture Microdissection (LCM) ^{1,2} | Frozen or fixed tissue sections, cytology smears, or cytospin preparations. | LCM allows for the isolation of specific cell types from complex tissues or mixtures of cells. Once captured, the specimen can be used for isolation of nucleic acids or proteins. Test time: within 1 hr |

1. Fend F, Raffeld M: Laser capture microdissection in pathology, *J Clin Pathol* 53:666-672, 2000.

| | | |
|---|---|--|
| Line Probe Assays (LiPA) ^{1,2} | This detection method is typically preceded by a PCR-based amplification of target sequences. | LiPA has become a routine detection method of PCR products for use in genotyping. Currently the most common application of this technology is for cystic fibrosis genotyping and hepatitis C virus genotyping. The method is designed as a reverse hybridization whereby probes are immobilized to a membrane and denatured PCR products are applied. Test time: 1-4 hr |
|---|---|--|

2. Lewis MJ, Lewis EH, Amos JA, et al: Cystic fibrosis, *Am J Clin Pathol* 120:S3-S13, 2003.

| | | |
|---------------|---|---|
| Northern Blot | RNA isolated from tissue, cells, or RNA viruses | Test time: 5-7 days The Northern blot technique is preferentially utilized to determine gene expression levels by quantifying mRNA levels. Use extreme caution when isolating and examining RNA because RNAses are extremely stable and so resist many chemical treatments used in the extraction. |
|---------------|---|---|

| | | |
|--|---|--|
| Paternity Testing ¹ Southern blot, PCR | Whole blood (ACD or EDTA), chorionic villi, and amniocytes. Store all body fluids at 4° C and cells at ≤ -20° C until nucleic acids are isolated. Store isolated nucleic acids at ≤ -20° C. | Multilocus probing provides unique individual identification and is more informative than single-locus probing. A variety of probes have been used for both multilocus and single-locus probing. |
|--|---|--|

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|--|--|
| Polymerase Chain Reaction (PCR) | <p>Isolated nucleic acids (DNA or RNA). Crude cell lysates, serum, and whole blood may be used directly. Avoid anticoagulants. Nucleic acids should be stored frozen at $\leq -20^{\circ}\text{C}$.</p> <p>Heparin and heme are strong inhibitors of PCR; citrate and EDTA are acceptable anticoagulants.</p> | <p>Test time: 4-6 hr</p> <p>PCR allows amplification of specific sequences of DNA or RNA, thus making possible the identification and quantification of the sequences, for instance, as they occur in infectious agents or mRNA. PCR has the greatest sensitivity of current molecular techniques and is easily performed. Great caution is required to eliminate risk of contamination with extraneous DNA or RNA so that factitious amplification is avoided. Oligonucleotide (primer) synthesis is only possible if the DNA sequence is known and available.</p> |
| Restriction Fragment Length Polymorphism (RFLP)¹ | DNA isolated from tissue or cells | <p>RFLP analysis is easily performed and provides direct analysis of DNA for polymorphisms or mutations that alter restriction enzyme recognition sites. Mutations and polymorphisms arise from single base changes and also from deletions or insertions of DNA. This type of analysis is dependent on a known gene sequence, known alteration, and known restriction enzyme recognition site. RFLP analysis can also be used for genetic linkage studies to establish carrier (heterozygous) status in kindreds of individuals known to be afflicted with specific genetic disorders.</p> <p>Test time: 1-2 days</p> |
| Sequencing^{1,2} | DNA resulting from an in vitro amplification method or reverse-transcriptase polymerase chain reaction. | <p>DNA sequencing typically was used for the confirmation of genetic alterations identified by other molecular methods. The advent of highly automated capillary electrophoretic systems and the changes in sequencing chemistries have resulted in this technology becoming mainstream. Direct sequencing approaches can be found in applications to genetic diseases, oncology, and infectious diseases.</p> <p>Test time: 2-8 days</p> |

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|------------------------------|------------------------------------|---|
| Southern Blot ^{1,2} | DNA isolated from tissues or cells | <p>The Southern blot technique is used to detect the presence of DNA sequences in total isolated DNA. It requires digestion with specific restriction enzymes. Mutations such as deletions and insertions, as well as mutations that alter the recognition site for the restriction enzyme, can be detected. The technique also allows distinction of integrated from episomal DNA. It is used to establish presence of specific gene rearrangements within or between chromosomes as occurs in clones of malignant cells.</p> <p>Test time: 4-8 days</p> |

PART B: MOLECULAR TESTS

| DISORDER | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|--|
| Adenovirus, Enteric (EA)^{1,2} <i>PCR, Real-time PCR, RFLP, Southern blot</i> | Serum, stool, eye swab, and respiratory tract specimens. Store all body fluids at 4° C; store tissue at ≤−20° C. | The serotype determines the extent of disease. Pathology includes gastroenteritis, upper and lower respiratory infections, and conjunctivitis. The virus has oncogenic potential. Target: Hexon gene |
| <ol style="list-style-type: none"> McDonough M, Kew O, Hierholzer J: PCR detection of human adenoviruses. In Persing DH, Smith TF, Tenover FC, et al, editors: <i>Diagnostic molecular microbiology: principles and applications</i>, Washington, DC, 1993, ASM Press. pp. 389-393. Wilhelmi I, Roman E, Sanchez-Fauquier A: Viruses causing gastroenteritis, <i>Clin Microbiol Infect</i> 9:247-262, 2003. | | |
| Angelman Syndrome¹ <i>Chromosome 15q-q13 (γ-aminobutyric acid receptor subunit genes), ubiquitin-protein ligase E3A (UBE3A) gene</i> | Whole blood (ACD or EDTA), tissue. Store whole blood at room temperature or 4° C; store tissue frozen at ≤−20° C if nucleic acids cannot be immediately extracted. | Approximately 70% of patients show a deletion involving the maternally inherited chromosome 15q11-q13, whereas others show either chromosome 15 paternal uniparental disomy, mutations in the imprinting center, or intragenic mutations of the ubiquitin-protein ligase E3A (UBE3A) gene. |
| <ol style="list-style-type: none"> Guerrini R, Carrozzo R, Rinaldi R, et al: Angelman syndrome: etiology, clinical features, diagnosis, and management of symptoms, <i>Paediatr Drugs</i> 5:647-661, 2003. | | |
| α₁-Antitrypsin (α₁-AT, AAT) Deficiency^{1,2} <i>PCR, Real-time PCR, RFLP, Southern blot</i> | Whole blood (ACD or EDTA), tissue. Store whole blood at room temperature or 4° C; store tissue frozen at ≤−20° C if nucleic acids cannot be immediately extracted. | The Z mutation in the α ₁ -antitrypsin gene accounts for the vast majority of symptomatic disease. A primary screen for the disease can be performed with the quantitative AAT protein test in plasma or serum. |
| <ol style="list-style-type: none"> DeMeo DL, Silverman EK: Alpha1-antitrypsin deficiency. 2: Genetic aspects of alpha(1)-antitrypsin deficiency: phenotypes and genetic modifiers of emphysema risk, <i>Thorax</i> 59:259-264, 2004. | DISORDER | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|---|
| Astrocytoma ¹ <i>FISH, Comparative genomic hybridization, PCR, Southern blot</i> | Tissue (fresh, frozen, or paraffin-embedded) | The most common genetic abnormality in astrocytoma is a gain of chromosome 7 copy number. This may result in overexpression of platelet-derived growth factor A (PDGFA). Target: Chromosome 7 (aneuploidy) |

1. Shapiro JR: Genetic alterations associated with adult diffuse astrocytic tumors, *Am J Med Genet* 115:194-201, 2002.

| | | |
|---|--|--|
| Ataxia ^{1,2} <i>Southern blot, PCR, Sequencing</i> | Whole blood (ACD or EDTA), tissue. Store whole blood at room temperature or 4° C; store tissue frozen at ≤−20° C if nucleic acids cannot be immediately extracted. | The spinocerebellar ataxias (SCAs) are hereditary neurodegenerative disorders. The ataxias, characterized by mutations in the genes listed above, all exhibit an autosomal dominant mode of inheritance except Friedreich ataxia (autosomal recessive). Target: SCA1, SCA2, SCA3, SCA6, SCA7, SCA8, SCA12, SCA17, Friedreich ataxia, and dentatorubral-pallidoluysian atrophy (DRPLA) |

| Hemoglobinopathies (sickle cell anemia, α-thalassemia, β-thalassemia) ¹ <i>PCR, Southern blot, Sequencing</i> | Whole blood (ACD or EDTA), amniocytes, and chorionic villi. Store whole blood at 4° C; store cells at ≤−20° C if nucleic acids cannot be extracted immediately. | Hemoglobin electrophoresis is the screening method of choice; the advantage of the DNA test is discrimination of compound heterozygotes. In sickle cell anemia, variability of clinical manifestations and benefits of early therapeutic intervention are cause for molecular genetic evaluation. Molecular analyses detect abnormalities in the hemoglobin gene. Ninety-five percent of α-thalassemia cases are caused by defective α-globin synthesis and deletions of one or both α-globin genes. Diagnosis of α-thalassemia trait requires quantitative PCR to detect reduced numbers of α-globin genes. β-thalassemia is caused by defective production of β-globin chains. When one β-globin gene is nonfunctional, then mild hematological abnormalities occur. β-thalassemia major or Cooley’s anemia occurs when both β-globin genes are defective. |
|--|--|--|

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------|-----------------------------------|-------------------------------|
|-------------|-----------------------------------|-------------------------------|

Hemoglobinopathies (sickle cell anemia, α -thalassemia, β -thalassemia)—CONT

They are characterized by varying clinical severity and deletions or insertions within the β -globin gene.

Targets: hemoglobin, α -globin, β -globin

1. Clark BE, Thein SL: Molecular diagnosis of haemoglobin disorders, *Clin Lab Haematol* 26:159-176, 2004.

Hemophilia A and B¹

PCR, Real-time PCR,
RFLP, Southern blot

Whole blood (ACD or EDTA),
tissue. Store whole blood at
room temperature or 4° C.

Coagulation studies (factor VIII) can be used for carrier risk estimate; most mutations are family-specific. Hemophilia A is caused by defective factor VIII. Deletions, insertions, and point mutations have all been detected in the factor VIII gene. Hemophilia B is caused by abnormal factor IX. One third of cases result from a point mutation in the factor IX gene.

Target: Factor VIII, factor IX genes

1. Bolton-Maggs PH, Pasi KJ: Haemophilias A and B, *Lancet* 361:1801-1809, 2003.

Hepatitis B Virus (HBV)^{1,2}

PCR, ISH, Southern blot

Tissue, whole blood, urine.
Store all body fluids at 4° C
and all tissue at $\leq -20^{\circ}$ C.

Molecular diagnostic assays are not typically required to make a diagnosis of HBV infection in most instances. These assays are very useful in determining viral load or replicating virus.

Target: HBV surface and core antigen genes

1. Servoss JC, Friedman LS: Serologic and molecular diagnosis of hepatitis B virus, *Clin Liver Dis* 8:267-281, 2004.

| Neurofibromatosis (NF): von Recklinghausen's Disease (NF1) and Bilateral Acoustic NF (NF2)^{1,2} | Whole blood (ACD or EDTA), tumor tissue. Store whole blood at 4° C; store tissue at ≤−20° C if nucleic acids cannot be extracted immediately. | von Recklinghausen's NF is one of the most common genetic disorders of humans (1:3500). The NF1 gene is located at chromosomal region 17q11.2 and codes for the neurofibromin protein. Mutations in the merlin gene are responsible for NF2. This disorder is primarily characterized by bilateral vestibular schwannomas. |

SECTION IV

THERAPEUTIC DRUGS AND DRUGS OF ABUSE

INTRODUCTION

Measurement of drug concentrations in biological fluids for the detection of drug overdose and the development of therapeutic drug-dosing regimens are important parts of patient care. Laboratories engaged in the measurement of drug concentrations for therapeutic monitoring must take into account a range of practical and methodological issues. Analytical techniques, proper sample collection and storage, and knowledge of concurrent pathological and therapeutic conditions of the patient are particularly important. Effective monitoring is dependent on correct sample collection and time of last drug dose, appropriate laboratory analysis, and appropriate interpretation of data. It is our purpose to provide practical information in these areas.

An understanding of the capabilities and limitations of the analytical methods is important to ensure meaningful results. The ideal analytical procedure chosen should be accurate and precise, easy to perform, readily automated, and inexpensive. For the quantitation of drug concentrations, it is important to use procedures with adequate sensitivity and specificity with regard to endogenous compounds, other drugs, and accumulated metabolites. Analytical procedures lacking sensitivity and specificity have generally been excluded from the section, or when such procedures have been included, appropriate comments have been made under the *Interferences* or *Remarks* column. Because of rapid advances in drug analysis, identification of all potential analytical problems for the various drug methodologies is clearly beyond the scope of this section. It is essential that each assay be thoroughly evaluated for specificity, with particular emphasis on the drug's metabolites and other drugs frequently coadministered. Laboratory personnel should keep current with new drug entities and their potential interference with existing drug assays.

Reference ranges listed in this section are those generally accepted in the literature and are believed to be most consistent with the current state of the art. Discrepancies in the literature are common, and additional experience is required before well-established values will be available. Commonly given mean peak plasma concentrations are reported for drugs without documented ranges. It is important to realize that these values are for **reference only because age, other physiological conditions, disease states, concomitant medications, and dialysis procedures may alter drug disposition significantly**. The use of these reference ranges to interpret drug and chemical concentrations in postmortem specimens may not be appropriate because factors affecting drug and chemical concentrations in living patients are frequently altered after death.

| <p><i>Metabolism</i> Hepatic (CYP2E1, 1A2, 3A4, 2A6, 2D6)</p> <p><i>Excretion</i> Renal</p> <p><i>Disease</i> Hepatic: $t_{1/2} \uparrow$, $V_d \rightarrow$, $Cl_T \downarrow$ Hyperthyroidism: $t_{1/2} \downarrow$, $V_d \rightarrow$, $Cl_T \uparrow$ Obesity: $t_{1/2} \rightarrow$, $Cl_T \uparrow$</p> <p><i>Age</i> Neonates: $t_{1/2} \uparrow$</p> <p><i>Dialysis</i> Hemodialysis (+) Peritoneal (–)</p> | <p>Acetaminophen is commonly used for its antipyretic and analgesic effects. It is available in numerous forms, including extended-release formulas and in combination with other drugs such as codeine and diphenhydramine. Serum concentrations, used for toxicological evaluations, should be interpreted in conjunction with the time of ingestion. The potential for toxicity can be estimated using the Rumack-Matthew nomogram or by determining the half-life. Levels should be measured every 4–6 hr postingestion and treatment initiated if a level exceeds the lower limit defined on the nomogram or if the calculated $t_{1/2}$ is >4 hr.</p> <p>The metabolite <i>N</i>-acetyl-<i>p</i>-benzoquinone (NAPQI) is responsible for the hepatotoxicity described. Renal toxicity is related to NAPQI and other reactive glutathione metabolites such as aminophenol-S-conjugates. Toxic effects include renal tubular necrosis, hypoglycemia, and thrombocytopenia. Toxicity has been reported with therapeutic doses, especially if the drug is taken over a prolonged period or with ethanol. Dose-dependent elimination is observed when doses are >2 g [13.23 mmol]. Antidote: <i>N</i>-acetylcysteine</p> <p>See Tables II-5 and II-6.</p> |

|--|--|
| <p><i>Metabolism</i> Hepatic</p> <p><i>Excretion</i> Renal</p> | <p>Acetohexamide is a sulfonylurea oral hypoglycemic agent used in treating type 2 diabetes. The hypoglycemic activity occurs when the drug binds to ATP-sensitive receptors or the pancreatic islet cells and induces insulin secretion. Extrapankreatic actions contribute and include reduced hepatic glucose production and increased peripheral sensitivity to insulin. The prolonged hypoglycemic effects are related to the production of an active metabolite, hydroxyhexamide. Adverse effects include transient leukopenia, thrombocytopenia, hemolytic anemia, pancytopenia, gastrointestinal disturbances, headache, tinnitus, photosensitivity, allergic skin reactions, and intolerance to alcohol. More serious side effects include hypoglycemia (may progress to coma and death) and hepatic dysfunction.</p> |

Therapeutic and toxic concentrations are not well defined. *N*-Acetylprocainamide (NAPA), an active metabolite of the antiarrhythmic procainamide, is rapidly hydrolyzed in vitro to procainamide at a low pH. (See *Procainamide*.) NAPA concentrations should be evaluated in conjunction with procainamide concentrations. When the sum of NAPA and procainamide concentrations is >25 -30 mg/L, the risk of toxicity is increased.⁸

Interferences: Heparin (FPIA). Hemolysis and lipemia interfere with all methods except GC and HPLC.

This drug is a selective antiherpes viral agent available in topical, oral, and intravenous forms. Systemic absorption from the skin is limited. The bioavailability of acyclovir appears to decrease with increasing dosage. Mean peak acyclovir concentrations after multiple intravenous doses of 2.5, 5, 10, and 15 mg/kg [$\times 4.44 = 11.1, 22.2, 44.4$, and $66.6 \mu\text{mol/kg}$] every 8 hr were 5.2, 9.9, 20.7, and 23.6 mg/mL [$\times 4.44 = 23, 44, 92$, and $105 \mu\text{mol/L}$], respectively. Acyclovir appears to possess a wide therapeutic index.

Alprazolam, a triazolobenzodiazepine derivative, is used for treatment of anxiety disorder, panic disorder, and anxiety associated with depression. Symptoms of overdose include somnolence, confusion, coma, and diminished reflexes. Its major pathway of metabolism is oxidation (hydroxylation) to α -hydroxyalprazolam and 4-hydroxyalprazolam.

Amikacin is an aminoglycoside antibiotic. Therapeutic and toxic concentrations should be considered highly variable and individualized for the patient's condition. Penicillin and its derivatives inactivate amikacin in vivo and in vitro. Amikacin may be less sensitive than other aminoglycosides to this inactivation. A definitive cause-and-effect relationship between the trough concentration and the incidence of nephrotoxicity has not been established. Cl_T and $t_{1/2}$ are strongly correlated with glomerular filtration rate. Side effects include vestibular and auditory dysfunction (principally auditory), nephrotoxicity, and neuromuscular blockade.

Interferences: When a patient is also taking antibiotics (i.e., penicillins, cephalosporins, tetracyclines, clindamycin, chloramphenicol), the MB method may lack specificity. Penicillins and cephalosporins can be inactivated with a commercially available β -lactamase to minimize this interference.

See Table II-6.

Drug interactions: Indomethacin IV, amphotericin, loop diuretics, vancomycin, enflurane, and methoxyflurane can increase toxicity of amikacin. Administration of amikacin can increase the effect of neuromuscular-blocking agents and polypeptide antibiotics.⁶

Aminocaproic acid is used to treat excessive bleeding caused by hyperfibrinolysis. Its mechanism of action occurs primarily through the inhibition of plasminogen activators. Serum concentrations of 200-400 mcg/mL [1.52-3.05 mmol/L] correlate well with streptokinase clot lysis times of 36-48 hr.

Most significant adverse effects include thromboembolic complications, rhabdomyolysis, and metabolic acidosis. Other reactions include nasal stuffiness, abdominal discomfort, nausea, vomiting, diarrhea, hypotension, itching, and erythema. There have been reports of increased serum potassium concentrations and metabolic acidosis (with high anion gap) in patients with renal disease.

Metabolism

Excretion

Feces (primary)

Urine (secondary)

Dialysis

Hemodialysis (−)

This is a class III antiarrhythmic and an iodinated benzofuran derivative. Its therapeutic range is not well defined. A delay of as long as 28 days between the initiation of the amiodarone therapy and the antiarrhythmic effect is expected if no loading dose is administered. Side effects may not manifest until after >1 yr of therapy. Reported side effects include elevations of serum aminotransferases and alkaline phosphatase, jaundice, corneal microdeposits, facial pigmentation, thyroid dysfunction, and pulmonary toxicity. Because of its delayed onset of action, complex dosing schedule, and potential serious side effects, amiodarone is used only when other agents are ineffective or cannot be tolerated.

Drug interactions: Amiodarone is a major substrate of CYP2C8/9 and minor substrate of CYP1A2, CYP2C19, CYP2D6, and CYP3A4. It is a strong inhibitor of CYP1A2, moderate inhibitor of CYP2A6, CYP2C8/9, CYP2D6, and CYP3A4, and a weak inhibitor of CYP2B6 and CYP2C19.⁷ Because of the long half-life of amiodarone, drug interactions may take ≥ 1 week to develop. Amiodarone potentiates warfarin anticoagulation, probably through

Interferences: Some HPLC methods lack specificity for the parent compound and also measure desethylamiodarone (DEA), a major metabolite.

See Table II-5.

Amobarbital is an intermediate-acting barbiturate used in short-term treatment of insomnia, to reduce anxiety and provide sedation preoperatively. It produces the following effects as dosage is increased: hypnosis, sedation, coma, respiratory arrest, and death. Toxicity is intensified when the drug is combined with ethanol or other CNS depressants.

Drug interactions: Amobarbital is a CYP2A6 inducer and may decrease the levels of CYP2A6 substrates. MAO inhibitors and valproic acid may inhibit metabolism of barbiturates increasing the clinical effect or toxicity.

|--|---|
| <i>Metabolism</i> Hepatic, Active metabolites: 7-hydroxyamoxapine, 8-hydroxyamoxapine | Amoxapine is an antidepressant. Common side effects include anorexia, blurred vision, drowsiness, tachycardia, and weight gain. More serious adverse effects include arrhythmias, palpitations, hemotological dyscrasias, and jaundice. |
| <i>Excretion</i> Renal, fecal | |

| | |
|---|--|
| <i>Metabolism</i> Hepatic, CYP2D6 | Legal indications for the use of amphetamine include narcolepsy and adjunct treatment of attention deficit disorder with hyperactivity. Adderall contains d- and l-amphetamine salts in the ratio of 3:1. Chronic abuse of amphetamine may lead to emotional liability, loss of appetite, somnolence, and mental impairment. Symptoms of acute toxicity with amphetamine include pallor, flushing, palpitation, tachypnea, tremor, hypertension or hypotension, chest pain, heart block, cardiac arrhythmias, seizures, coma, and cardiovascular collapse. |
| <i>Excretion</i> Renal | Sympathomimetic amines may be distinguished from amphetamine and methamphetamine in urine by GC-MS. |
| Drug interactions: CYP2D6 inhibitors may increase levels/effects of amphetamine. Amphetamine is itself a weak CYP2D6 inhibitor. Acidification of the urine will enhance the renal excretion of amphetamine, whereas alkalization will reduce it. | For workplace drug testing, the widely accepted immunoassay cutoff concentration to separate positive and negative specimens is 1000 ng/mL [7400 nmol/L]; for GC-MS confirmation, 500 ng/mL [3700 nmol/L] (mandated by SAMHSA, formerly NIDA). At these cutoff concentrations, amphetamine may generally be detected in urine for 1-3 days following use. |
| | Alternative matrices used for nonfederally regulated workplace drug testing and being considered for regulated testing include hair, oral fluid, and sweat. |

|--|---|
| <i>Metabolism</i> Hepatic <i>Excretion</i> Expired air, renal | <p>Isoflurane, enflurane, halothane, sevoflurane, and desflurane are most commonly used. Cyclopropane and diethyl ether are seldom used because of their flammability. Chloroform and trichloroethylene are no longer used because of toxicities (cardiac arrhythmias, hepatotoxicity, and nephrotoxicity). The etiology of halothane-induced hepatitis is unknown but occurs more frequently in women >40 yr undergoing lengthy abdominal surgery. Enflurane can cause seizures, hepatic dysfunction, and nephrotoxicity (mild, reversible, decreased glomerular filtration rate). Methoxyflurane can cause hepatic dysfunction and nephrotoxicity.</p> |
| <i>Metabolism</i> Hepatic <i>Excretion</i> Renal | <p>Local anesthetics are used in a number of settings to control pain by blocking the action potentials of nerve conduction. The duration of the effect is dependent on the drug's pKa, lipid solubility and molecular size. Adverse effects include nausea, headache, muscular rigidity, bradycardia, arrhythmias, hypotension, and convulsions.</p> <p>Therapeutic and toxic ranges are not well defined for some of these agents.</p> |

|---|--|
| <p><i>Metabolism</i> Hepatic, Active metabolites: 7-hydroxyamoxapine, 8-hydroxyamoxapine</p> <p><i>Excretion</i> Renal, fecal</p> | <p>Amoxapine is an antidepressant. Common side effects include anorexia, blurred vision, drowsiness, tachycardia, and weight gain. More serious adverse effects include arrhythmias, palpitations, hemotological dyscrasias, and jaundice.</p> |
| <p><i>Metabolism</i> Hepatic, CYP2D6 Saturatable kinetics</p> <p><i>Excretion</i> Renal, fecal</p> <p>Drug interactions: Paroxetine is a potent inhibitor of CYP2D6 (the same CYP responsible for its metabolism) and possibly CYP3A4. Multiple drug interactions are possible.</p> | <p>Paroxetine belongs to the group of antidepressants that act by selectively inhibiting the reuptake of serotonin. Of this group, it is the most potent but least selective in its interaction with serotonin inhibition. It also exhibits an affinity for the muscarinic acetylcholine receptors similar to that of the tricyclic antidepressants. Paroxetine is also used to treat other psychiatric disorders such as obsessive-compulsive disorders, panic disorders, posttraumatic stress disorders, anxiety, and premenstrual dysphoric disorder. Common side effects include anorexia, gastrointestinal disturbances, insomnia, sweating, blurred vision, drowsiness, tachycardia, and weight gain. More serious adverse effects reported include suicide, hyponatremia, and seizures. Potentially lethal events include the development of serotonin syndrome and the syndrome of inappropriate antidiuretic hormone secretion.</p> |
| <p><i>Metabolism</i> Hepatic, Active (weakly) metabolite: desmethylertraline</p> <p>Drug interactions: Sertraline is known to inhibit CYP2D6 and CYP2C9 giving rise to possible drug interactions.</p> | <p>Sertraline is an antidepressant also used to treat other psychiatric disorders such as obsessive-compulsive disorder. The drug acts by selectively inhibiting the reuptake of serotonin. Common adverse effects reported include nausea, diarrhea, tremor, sweating, and sexual dysfunction. More serious adverse effects reported include suicidal ideologies, seizures, and hyponatremia. SSRIs should not be abruptly stopped but tapered. Increased transaminases have been observed during the first 9 wk of treatment. Trazodone, a serotonin reuptake inhibitor/antagonist, is used for treatment of major depressive episodes and has been used for treatment of chronic pain. Side effects include dizziness, syncope, drowsiness, lethargy, dry mouth, constipation, vomiting, blurred vision, skin rashes, and urinary hesitancy.</p> |
| <p><i>Metabolism</i> Hepatic, CYP3A4 (major); CYP2D6 (minor) Active metabolite: 1-<i>m</i>-chorophenylpiperazine (MCP)</p> <p><i>Dialysis</i> Hemodialysis (–)</p> <p>Drug interactions: Trazodone may increase the levels/effects of CYP2D6 substrates and may decrease the levels/effects of CYP2D6 prodrug substrates. Trazodone levels/effects may be decreased by CYP3A4 inducers and increased by CYP3A4 inhibitors.</p> | |

Metabolism

Hepatic, CYP2D6

Active metabolites: desmethylmaprotiline, maprotiline-*N*-oxide

Excretion

Renal (minimal)

Age

Elderly: $t_{1/2}$ ↓

Maprotiline is a tetracyclic antidepressant. Adverse effects include hypotension, tachycardia, gastrointestinal distress, and tremor. In overdose, more serious effects encountered include seizures, respiratory arrest and severe tachycardia, arrhythmias, and hypotension.

Drug interactions: Cisapride, monoamine oxidase inhibitors, in addition to those related to inhibition or induction of CYP2D6.

REMARKS AND INTERFERENCES

6. Frahnert C, Rao ML, Grasmader K: Analysis of eighteen antidepressants, four atypical antipsychotics and active metabolites in serum by liquid chromatography: a simple tool for therapeutic drug monitoring, *J Chromatogr B Analyt Technol Biomed Life Sci* 794:35-47, 2003.

Metabolism

Hepatic, CYP2D6 (major); CYP1A2, CYP2B6, CYP2C8/9, CYP2C19, and CYP3A4 (all minor)

Disease

Hyperlipoproteinemia: PB↑

Age

Elderly: $t_{1/2}$ ↑, V_d ↑, Cl_T →, PB→

Dialysis

Hemodialysis (−)

Peritoneal (−)

Amitriptyline is metabolized to two active metabolites (nortriptyline and 10-hydroxynortriptyline). The metabolism is highly variable among patients. Side effects include dry mouth, epigastric distress, constipation, palpitations, blurred vision, urinary retention, tachycardia, hypotension, and arrhythmias.

See Table II-5.

Drug interactions: CYP2D6 inhibitors may increase the levels/effects of amitriptyline. Amitriptyline is a weak inhibitor of the following enzyme systems: CYP1A2, CYP2C8/9, CYP2C19, CYP2D6, and CYP2E1.

Metabolism

Hepatic, CYP2D6, CYP2C19, and CYP1A2 (all major); CYP3A4 (minor)

Age

Elderly: $t_{1/2}$ ↑, C_{max} ↑

Dialysis

Hemodialysis (−)

Hemoperfusion (−)

Peritoneal (−)

Clomipramine is used for treatment of obsessive-compulsive disorder (OCD). It is metabolized to the active metabolite desmethylclomipramine and two other metabolites that may be active: 8-hydroxycloimipramine and 8-hydroxy-desmethylclomipramine. Side effects include dry mouth, blurred vision, urinary retention, constipation, hypotension, and arrhythmias. Adverse effects occurring more often with clomipramine than with other TCAs include sexual dysfunction, seizures, nausea, and vomiting.

Drug interactions: CYP1A2, CYP2C19, and CYP2D6 inducers may decrease the levels/effects of clomipramine, and inhibitors may increase its levels/effects.

Metabolism

Hepatic, CYP2D6 (major), and CYP1A2 (minor)

Dialysis

Hemodialysis (−)

Peritoneal (−)

Desipramine causes less sedation and anticholinergic effects than with amitriptyline or imipramine. It is metabolized to the active metabolite 2-hydroxydesipramine. Side effects include dry mouth, epigastric distress, constipation, tachycardia, palpitations, blurred vision, urinary retention, hypotension, arrhythmias, manic excitement, tremor, and sedation.

See also *Imipramine*.

Drug interactions: Desipramine is a moderate inhibitor of the following enzyme systems: CYP3A4, CYP2A6, CYP2B6, and CYP2D6

Metabolism

Hepatic, CYP2B6 (major), CYP1A2, CYP2A6, CYP2C8/9, CYP2D6, CYP2E1, and CYP3A4 (all minor)

Dialysis

Hemodialysis (–)
Peritoneal (–)

Bupropion is used in the treatment of major depressive disorder and, in the form of extended-release tablets (Zyban), as an adjunct in the cessation of smoking. It is metabolized to three active metabolites: hydroxybupropion, erythrohydrobupropion, and threo hydrobupropion. Side effects include nonspecific rashes, nausea, vomiting, headache, sleep disorders, agitation, abnormalities in mental status, and seizures. After an overdose, seizure is the most common neurologic effect, whereas cardiac abnormalities are rarely observed.

Drug interactions: Bupropion is a weak inhibitor of CYP2D6 enzyme system and may ↑ levels and risk of toxicity from antidepressants (SSRIs and tricyclic), some β-blockers, antiarrhythmics, and antipsychotics. Medications that affect CYP2B6 may interact with bupropion.

Metabolism

Hepatic, CYP2D6, and CYP1A2

Elimination

Renal (94% within 71 hr)

Drug interactions: Fluvoxamine is a strong inhibitor of CYP1A2 and CYP2C19 and a weak inhibitor of CYP2B6, CYP2C8/9, CYP2D6, and CYP3A4. CYP1A2 and CYP2D6 inhibitors may increase the levels/effects of fluvoxamine. Fluvoxamine may increase the levels/effects of CYP2C19 and CYP1A2 substrates. Fluvoxamine should not be given in combination with MAO inhibitors because of the possibility of a fatal serotonergic syndrome.

Fluvoxamine, a selective serotonin reuptake inhibitor (SSRI), is used for treatment of obsessive-compulsive disorder (OCD) in children ≥ 8 yr of age and adults and to relieve symptoms of depression. Fluvoxamine exhibits nonlinear, time-dependent kinetics; Cl decreases and $t_{1/2}$ increases with multiple doses > 50 mg/day. Side effects include somnolence, headache, agitation, insomnia, nausea, vomiting, dry mouth, constipation, anorexia, sexual dysfunction, and seizures. Fluvoxamine is metabolized to at least 9 metabolites, none of which are active.

These drugs are widely prescribed and available in OTC preparations. They are weakly basic tertiary amines with low serum concentrations. Metabolites and parent drugs are excreted primarily by the kidney. Side effects include drowsiness, which is intensified by ethanol or other CNS depressants. High doses (pediatric and adults) can cause hallucinations, excitement, ataxia, lack of coordination, athetosis, and convulsions. Fixed, dilated pupils with a flushed face and fever are common (atropine-like reaction). Overdose can produce coma and death.

Dialysis

Hemodialysis (+)

Bretylium is a class III antiarrhythmic used to manage serious and refractory ventricular arrhythmias. No correlation exists between plasma concentrations and bretylium's cardiac effects. The side effects are hypotension secondary to bretylium's adrenergic blocking action and gastrointestinal, nausea, and vomiting.

Drug interactions: Amphetamines abolish the hypotensive actions of bretylium. Tricyclic antidepressants may inhibit bretylium uptake by the myocardium. Increased toxicity when used with pressor catecholamines and digitalis. Risk of cardiotoxicity is increased with concurrent use of sparfloxacin, moxifloxacin, or gatifloxacin may increase toxicity because of the potential to prolong QT interval.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <p><i>Metabolism</i> Hepatic</p> <p><i>Excretion</i> Urine (primary) Feces (secondary)⁷</p> <p><i>Disease or condition</i> Hepatic: $t_{1/2} \uparrow$, $Cl_T \downarrow$ Pregnancy: $Cl_T \uparrow$</p> <p><i>Dialysis</i>⁸ Hemodialysis (+)⁹</p> <p>Drug interactions: Carbamazepine is a hepatic enzyme inducer and may enhance the elimination of ethosuximide, warfarin, and benzodiazepines that undergo hydroxylation. Cimetidine, diltiazem, erythromycin, isoniazid, propoxyphene, and verapamil may increase carbamazepine levels. Phenobarbital, primidone, and phenytoin have been shown to increase the metabolism of carbamazepine. The phenytoin-carbamazepine interaction is variable (i.e., phenytoin levels may increase, decrease, or stay the same, whereas carbamazepine levels usually decrease). Valproic acid may increase the $t_{1/2}$ and decrease protein binding of carbamazepine.¹⁰ Carbamazepine may decrease the effect of CYP1A2, CYP2BCYP2C8/9, CYP2C19, and CYP3A4 substrates. CYP3A4 inducers may decrease the effects of carbamazepine, whereas CYP3A4 inducers may increase the effects.⁶</p> | <p>Carbamazepine increases its own metabolism by enzyme induction. It is metabolized to an active metabolite (10,11-epoxide), which may accumulate in renal failure and may contribute to the therapeutic and toxic concentrations of carbamazepine. Although the significance of this metabolite is not well established, simultaneous monitoring of the parent drug and metabolite by HPLC methods may be occasionally indicated for a patient who may exhibit toxic symptoms in view of an apparently normal parent drug level³. The $t_{1/2}$ of the epoxide is ~17 hr.</p> <p>Concentration-related toxic effects include blurred vision, nystagmus, ataxia, dizziness, drowsiness, and diplopia. Side effects generally unrelated to concentration include urticarial rash, hepatic dysfunction, eosinophilia, and hematological depression.</p> <p>Carbamazepine has modest human teratogenic potential. It is not clear whether this is idiosyncratic or related to serum levels. Nonetheless, serum levels should be kept as low as possible, consistent with the desired therapeutic effect, in women at risk for pregnancy and throughout pregnancy.</p> <p>See Table II-5.</p> |

| <i>Metabolism</i> None <i>Excretion</i> Urine <i>Disease</i> Renal, Oliguria: $t_{1/2} \uparrow$ (15.7 hr) Oliguria and hepatic dysfunction: $t_{1/2} \uparrow$ (23.2 hr) <i>Age</i> Premature: $t_{1/2} \uparrow$ Neonate: $t_{1/2} \uparrow$ <i>Dialysis</i> Hemodialysis (+) ⁷ Peritoneal (+) ⁸ | Carbenicillin is a broad-spectrum penicillin antibiotic. Half-life and total body clearance values correlate strongly with creatinine clearance (CrCl). Hepatic dysfunction appears to be significant only in the presence of renal failure. Side effects include diarrhea, nausea, vomiting, ⁹ hypersensitivity, hepatotoxicity, electrolyte and acid-base disturbances, and hematological disorders, including bleeding diathesis, eosinophilia, and reversible granulocytopenia. Neurotoxicity has been observed at concentrations of 320 mcg/mL [845 μ mol/L] plasma and 37 mcg/mL [98 μ mol/L] spinal fluid. |

Drug interactions: Probenecid delays active renal tubular secretion and increases the $t_{1/2}$ of the drug. Tetracyclines may decrease effectiveness of carbenicillin. Carbenicillin may increase the effect of warfarin.⁹

Hemodialysis (+)

This is a third-generation cephalosporin that undergoes significant renal tubular secretion. Side effects include eosinophilia, granulocytopenia, and thrombocytopenia. Coombs test may be positive.

Interferences: The presence of the microbiologically active desacetyl metabolite may interfere with interpretation of microbiologic assays. (Overestimation of cefotaxime's $t_{1/2}$ can result with organisms partially susceptible to desacetyl-cefotaxime.)

Drug interactions: Probenecid decreases the renal clearance of cefotaxime by almost 50%. Concomitant administration of furosemide or aminoglycosides can lead to increased risk of nephrotoxicity.⁶

Ceftriaxone, a third-generation cephalosporin, does not undergo significant renal tubular secretion. Plasma protein binding is saturable; the peak plasma and tissue concentrations of free (unbound) drug increase disproportionately with increasing doses. Coombs test may be positive. Ceftriaxone is highly protein-bound and should be used with caution in hyperbilirubinemic neonates because of the displacement of bilirubin from serum albumin. Ceftriaxone is also associated with “biliary sludge” or pseudolithiasis.

Drug interactions: Probenecid may decrease clearance of ceftriaxone. Concomitant administration of furosemide or aminoglycosides with ceftriaxone may lead to increased risk of nephrotoxicity.⁵

Drug interactions: Probenecid may decrease clearance of cephalothin. Concomitant administration of aminoglycosides with cephalothin may lead to increased risk of nephrotoxicity.⁵

Cephalothin is a first-generation cephalosporin antibiotic. About 22-32% of cephalothin is metabolized to a desacetyl derivative that is 20% as active as cephalothin. In renal failure, the metabolite accumulates along with the parent compound. Toxicity of the metabolite is not fully understood. Side effects include hypersensitive reactions (fever, malaise, weakness, skin rash, and eosinophilia) and hypersensitive interstitial nephritis. Positive direct Coombs test, \uparrow AST, platelet aggregation, thrombocytopenia, granulocytopenia, hemolytic anemia, and diarrhea may accompany cephalothin administration.

Interferences: There are reports concerning cephalothin interference in creatinine determination with the Jaffé reaction.

| <p>Drug interactions: Probenecid may decrease clearance of cephradine. Concomitant administration of aminoglycosides with cephradine may lead to increased risk of nephrotoxicity.⁵</p> | |
| <p><i>Metabolism</i> Hepatic (primary), alcohol dehydrogenase <i>Age:</i> Neonates: $t_{1/2} \uparrow$ (TCE)</p> <p>Chloral hydrate was formerly widely prescribed as a sedative-hypnotic. It is a CNS depressant, and any effect is intensified with ethanol or other CNS-depressant drugs. Chloral hydrate is rapidly reduced to trichloroethanol (TCE) by alcohol dehydrogenase in the liver. TCE is then conjugated with glucuronic acid, and the product is excreted in the urine and bile. Variable amounts of chloral hydrate and TCE are oxidized to trichloroacetic acid. TCE is principally responsible for the CNS depressant effects. Adverse effects include drowsiness, gastrointestinal disturbances, hypotension, miosis, jaundice (overdose), coma, and death (principally because of respiratory depression). Metabolites of chloral hydrate may alter the protein binding of acidic drugs.</p> | |

| Metabolism Hepatic, CYP2D6 (major), and CYP1A2, CYP3A4 (minor) Age Child: $Cl_T \downarrow$ Elderly: $Cl_T \downarrow$ Dialysis Hemodialysis (–) Peritoneal (–) | Chlorpromazine is a phenothiazine commonly used for the symptomatic man- agement of psychotic disorders. It is also used for prevention and treatment of nausea and vomiting, relief of restlessness and apprehension before surgery, and for relief of intractable hiccups. Several metabolites are formed and signifi- cantly complicate the interpretation of serum concentrations. Side effects in- clude faintness, palpitations, nasal stuffiness, dry mouth, constipation, orthosta- tic hypotension, hyperthermia and hypothermia, extrapyramidal effects (parkinsonian syndrome), acute dystonic reactions, tardive dyskinesia, jaundice, leukocytosis, thrombocytopenia, leukopenia, and eosinophilia. Chlorpromazine is extensively metabolized, and 10-12 metabolites have been identified. |
| Drug interactions: CYP2D6 inhibitors may increase the levels/effects of chlorpromazine. Chlorpromazine may increase the levels/effects of CYP2D6 substrates and decrease the lev- els/effects of CYP2D6 prodrug substrates. Chlorpromazine is a strong inhibitor of CYP2D6 and a weak inhibitor of CYP2E1. | |

Chlorpromamide is an oral hypoglycemic agent. Like other sulfonylureas, the mechanism of action involves stimulation of the pancreatic islets to secrete insulin through the binding of the drug to the ATP-sensitive potassium channel receptors. Chlorpromamide has the longest $t_{1/2}$ and duration of activity of this group of drugs. Adverse effects include transient leukopenia, thrombocytopenia, hemolytic anemia, pancytopenia, eosinophilia, gastrointestinal disturbances, headache, tinnitus, photosensitivity, allergic skin reactions, and intolerance to alcohol. The most serious side effects include hypoglycemia (which may progress to coma and death) and hepatic dysfunction.

Chlorprothixene, an antipsychotic drug related to chlorpromazine, continues to be used in Europe to treat schizophrenia. The pharmacology of the drug is not well described despite its long use. Adverse effects include sedation, extrapyramidal effects, and hypotension. Hepatic dysfunction and eosinophilia, leukopenia, and thrombocytopenia have been reported.

Cimetidine is a histamine H_2 -receptor antagonist. Side effects include headache, dizziness, fatigue, muscle pains, constipation, diarrhea, skin rashes, confusion, slurred speech, delirium, hallucinations, gynecomastia, and coma. Most of these effects have been observed in renal failure and/or elderly patients. Rare cases of pancytopenia, granulocytopenia, and thrombocytopenia have been reported.

See Table II-5.

Drug interactions: Cimetidine has been implicated in numerous drug interactions occurring through three different mechanisms: (1) metabolic inhibition of compounds metabolized via CYP1A2, CYP2C19, CYP2D6, and CYP3A4, (2) alteration of gastric pH, and (3) inhibition of renal tubular transport of other basic compounds.

| Metabolism | Ciprofloxacin is a fluoroquinolone antibiotic. Therapeutic concentrations of ciprofloxacin are dependent on the MIC of the organism being treated. In vitro MIC susceptibility breakpoints are recommended as ≤ 1 mg/L [$\times 3.02 = \leq 3$ $\mu\text{mol/L}$] (susceptible), ≤ 2 mg/L [≤ 6 $\mu\text{mol/L}$] (moderately susceptible), and ≥ 4 mg/L [≥ 12 $\mu\text{mol/L}$] (resistant organisms). Metabolites of ciprofloxacin may have biological activity. A dose of 250 mg given orally leads to peak plasma concentrations of 0.94-1.53 mcg/mL [$\times 3.02 = 2.8$ -4.6 $\mu\text{mol/L}$], whereas a 500-mg dose given orally leads to peak plasma concentrations of 2.0-2.9 mcg/mL [6.0-8.8 $\mu\text{mol/L}$]. |

| Peritoneal (+) ⁸ | |

Drug interactions: Sucralfate, aluminum- and magnesium-containing antacids, and products containing iron or zinc decrease bioavailability. Probenecid decreases renal clearance of ciprofloxacin. Ciprofloxacin reduces the metabolism of xanthines (theophylline, caffeine) and may increase prothrombin time in patients receiving concurrent warfarin therapy. Ciprofloxacin is a strong inhibitor of CYP1A2 and a weak inhibitor of CYP3A4. It may increase the effects of CYP1A2 substrates like fluvoxamine.⁵

Clonidine is a potent antihypertensive agent, with α -adrenergic agonist activity. Dry mouth is associated with serum concentrations >1.0 ng/mL [4.4 nmol/L], and sedation with levels >1.5 ng/mL [6.6 nmol/L]. A linear relationship exists between serum concentration and change in mean arterial pressure. Side effects include dry mouth, sedation, impotence, orthostatic hypotension, bradycardia, convulsions, and coma. Hypertensive crisis has been seen with sudden withdrawal.

Drug interactions:

Antihypertensive effects of clonidine may be antagonized by mirtazapine. Tricyclic antidepressants may diminish the hypotensive effect of clonidine. β -Blockers may enhance the rebound hypertensive effect of clonidine if it is withdrawn abruptly.⁶

Metabolism

Hepatic, CYP2D6 (major), and CYP3A4 (minor)

Excretion

Renal

Codeine is a morphine derivative with potent analgesic properties. CNS depression and adverse reactions to the drug are similar to those of morphine. Codeine is partially metabolized to morphine and norcodeine. Concentrations of hydrocodone as high as 11% of parent drug have been detected, although hydrocodone is typically considered a minor metabolite.

Drug interactions: CYP2D6 inducers may decrease levels/effects of codeine, and CYP2D6 inhibitors may increase its levels/effects. Codeine is a weak inhibitor of CYP2D6.

For federally regulated workplace drug testing (SAMHSA), the immunoassay cutoff concentration to separate positive and negative specimens for opiates is 2000 ng/mL [7000 nmol/L] morphine equivalents; for GC-MS confirmation, 2000 ng/mL [7000 nmol/L] codeine.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| See <i>Nicotine</i> . | Cotinine, a metabolite of nicotine, is used as a specific indicator of nicotine exposure. Unlike carboxyhemoglobin and thiocyanate, cotinine is derived <i>only</i> from the metabolism of nicotine. Its concentration is not influenced by diet or environment, and it is stable in body fluids. Cotinine has an added advantage of a longer $t_{1/2}$ (7-40 hr) compared with the parent drug. |

| | |
|---|---|
| <i>Metabolism</i> Hepatic Kidney (small amount) Intestinal wall (small amount) | Cyclosporine is an immunosuppressant. It is highly bound to erythrocytes and plasma lipoproteins; the binding is temperature dependent in vitro and concentration dependent in vivo. Its main adverse reaction is dose-related nephrotoxicity. Other adverse effects include hirsutism, gingival hyperplasia, hepatotoxicity, hypertension, anaphylaxis, neurotoxicity, and lymphoproliferative disorders. Enterohepatic recycling has been reported for cyclosporine. |
| <i>Excretion</i> Bile (primary) Urine (secondary) | |
| <i>Disease</i> Hepatic: $Cl_T \downarrow$ | Interferences: HPLC is highly specific for parent drug and considered as the gold standard assay. Immunoassays are less specific, with metabolites cross-reacting to varying degrees with antisera. (Cross-reactivity with the major active metabolite, M17, is ~45% but may vary.) The polyclonal FPIA assay is relatively nonspecific and measures both parent drug and metabolites. The new monoclonal FPIA is more specific than the polyclonal assay. In terms of specificity, $EMIT < CEDIA < AxSYM^9$. Because CsA metabolite formation can be highly variable in individual patient samples, immunoassays can potentially show small to very large bias, when compared with HPLC, and may have an impact on CsA monitoring ¹ . More recently, simpler and rapid LC-MS-MS methods are available for specific monitoring of CsA parent drug. ^{2,10} |
| <i>Age</i> Child: $Cl_T \uparrow$ | |
| <i>Dialysis</i> Hemodialysis (–) Peritoneal (–) | |
| Drug interactions: Cyclosporine is a major substrate of CYP3A4. It moderately inhibits CYP3A4 and weakly inhibits CYP2C8/9. ⁸ | |

| <p>Androgens, cimetidine, danazol, diltiazem, erythromycin, estrogens, ketoconazole, and miconazole have been reported to increase cyclosporine plasma concentrations. Phenytoin, the rifampin-isoniazid combination, cotrimoxazole, and phenobarbital increase Cl_T. Long-term steroid therapy may increase Cl_T of cyclosporine. Aminoglycosides, amphotericin B, cotrimoxazole, melphalan, furosemide, and nonsteroidal antiinflammatory drugs may potentiate cyclosporine nephrotoxicity. Oral absorption of cyclosporine may be affected by elapsed time after surgery, dose administered, gastrointestinal dysfunction, external bile drainage, liver disease, and food.</p> | <p>See Tables II-5 and II-6.</p> |

|---|---|
| <i>Metabolism</i> Hepatic | Dantrolene is a peripherally acting skeletal muscle relaxant used to treat malignant hyperthermia, spasticity, and heat stroke. The drug is alkaline and chemically unstable (light-sensitive). Adverse effects include weakness, phlebitis, respiratory failure, drowsiness, and fatigue. Reports of hepatotoxicity after oral administration. Coma can be produced by overdose. Its metabolite, 5-hydroxy-dantrolene, is also active. |
| <i>Excretion</i> Renal, biliary | |
| | |
| | See Table II-5. |
| | |
| <i>Metabolism</i> Hepatic, CYP3A4, CYP2C19 (major), CYP1A2, CYP2B6, CYP2C8/9 (minor) Active metabolites: desmethyldiazepam, oxazepam. | Diazepam is a benzodiazepine used in the treatment of anxiety, status epilepticus, and acute alcohol withdrawal. The drug has a high lipid solubility and is extensively distributed to adipose tissue. Side effects include drowsiness, fatigue, lethargy, muscular incoordination and ataxia, behavioral disturbances, anorexia, and hyperphagia. |
| <i>Disease or condition</i> Hepatic: $t_{1/2} \uparrow$, 59.7-112 hr $V_d \uparrow$, 1.74 ± 0.21 L/kg $Cl_T \downarrow$, 0.20 mL/min/kg PB \downarrow Hypoalbuminemia: PB \downarrow , $Cl_T \uparrow$, $V_d \uparrow$ Pregnancy: PB \downarrow | Acute CNS toxicity may be treated by administering the benzodiazepine antagonist flumazenil. Half-life of desmethyldiazepam (major metabolite): 50-100 hr. |
| <i>Age</i> Premature newborn: $t_{1/2} \uparrow$, 75 hr; PB \downarrow Child: $t_{1/2} \downarrow$, 18 hr $V_d \uparrow$, 2.6 L/kg $Cl_T \uparrow$, 1.67 mL/min/kg Elderly: $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \rightarrow \downarrow$, PB \rightarrow | See also <i>Oxazepam</i> . |
| <i>Dialysis</i> Hemodialysis (—) | |
| Drug interactions: CYP3A4 and CYP2C19 inducers may decrease diazepam levels/effects, and CYP3A4 and CYP2C19 inhibitors may increase diazepam levels/effects. Diazepam is a weak inhibitor of CYP2C19 and CYP3A4. | |

Digitoxin is a cardiac glycoside used in the treatment of congestive heart failure and to control ventricular rate in patients with atrial fibrillation or flutter. The drug undergoes significant enterohepatic circulation. The effect of disease states on the kinetics of digitoxin is not well described. Side effects include anorexia, nausea, vomiting, abdominal discomfort and pain, blurred vision, cardiac anomalies (arrhythmias, A-V conduction defects, and, occasionally, impaired conduction in the atria), multifocal PVCs, ventricular tachycardia, A-V block, sinus bradycardia, SA block, atrial fibrillation, and accelerated A-V junctional rhythms. Eosinophilia and thrombocytopenia have been reported.

Interferences: Metabolites may interfere with some RIA procedures. Digitoxin cannot be measured accurately by immunoassay in patients being switched from digoxin. Digitalis-like immunoreactive substances may interfere with FPIA but not chemiluminescent IA assays.⁸

Drug interactions: Digitoxin is a major substrate of CYP3A4.⁷ Metabolism of digitoxin may be enhanced by phenylbutazone, phenobarbital, phenytoin, and rifampin (induction of hepatic microsomal enzymes). Plasma digitoxin is increased during coadministration with amiodarone, quinidine, verapamil, and diltiazem. Cholestyramine and colestipol (binding resins) have been shown to reduce the enterohepatic circulation of digitoxin (may decrease the drug's half-life). Antacids, cholestyramine, colestipol, kaolin-pectin, metoclopramide, neomycin, and sulfasalazine may decrease digitoxin absorption.

REMARKS AND INTERFERENCES

7. Lexi-Comp, Inc.: *Up-to-date online 12.2, Drug information*, Hudson, OH, 2004, Lexi-Comp, Inc.
8. Biddle DA, Datta P, Wells A, et al: Falsely elevated serum digitoxin concentrations due to cross-reactivity of water-extractable digitoxin-like immunoreactivity of Chinese medicine Chan SU: elimination of interference by use of a chemiluminescent assay, *Clin Chim Acta* 300:151-158, 2000.

Drug interactions: Digoxin is a minor substrate of CYP3A4.⁶ Drugs associated with decreased digoxin absorption include antacids, cholestyramine, colestipol, kaolin-pectin, metoclopramide, neomycin, and sulfasalazine. Quinidine decreases digoxin clearance and has been reported to double steady-state digoxin concentration. Other drugs reported to decrease digoxin clearance include verapamil, spironolactone, nifedipine, and amiodarone. Mexiletine, procainamide, disopyramide, ibuprofen, and quinine may increase plasma digoxin concentrations. Rifampin, phenytoin, and phenylbutazone may decrease plasma digoxin concentrations.

Digoxin is commonly used in the treatment of congestive heart failure and to decrease ventricular response in atrial flutter and fibrillation. A strong correlation exists between creatinine clearance and Cl_T . Side effects include anorexia, nausea, vomiting, abdominal discomfort and pain, blurred vision, and cardiac anomalies (arrhythmias, impaired A-V conduction, and, occasionally, impaired conduction in the atria). Severe toxicity may be treated by digoxin Fab antibody (Digibind) administration.

Biological activity of digoxin is linked to serum K^+ concentration. Digoxin overdose may cause hyperkalemia. In cases of suspected digoxin overdose, it is important to measure potassium in whole blood or serum.

Interferences: Spironolactone, canrenone, and other steroids may cause falsely low digoxin results by MEIA.⁷ Patients not on digoxin therapy, but with renal failure or combined renal and hepatic failure, as well as pregnant women, neonates, and infants, exhibit assayable levels of DLIS (digoxin-like immunoreactive substance). The degree of DLIS interference varies widely from patient to patient and from one immunoassay method to another.^{1,8,9} Fosinopril may cause a falsely low level with the Digi-Tab RIA kit. Digibind may falsely increase digoxin values by immunoassay, and monitoring by free digoxin assays may be useful post-Digibind administration.¹⁰

| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Renal (70-76%), fecal (20%), and pulmonary (20-30%)</p> | <p>For many years disulfiram was the primary treatment of alcoholism. Because of its adverse risks, other treatment options have been developed. The drug is rapidly metabolized and stored as the diethyldithiocarbamate in fat. Adverse effects include allergic dermatitis, urticaria, drowsiness, fatigue, restlessness, and hepatotoxicity. In combination with alcohol, mild reactions have been reported with blood alcohol concentrations as low as 5 mg/dL. Symptoms are typical when alcohol concentrations are >50 mg/dL, and the patient may become unconscious when alcohol concentrations are >125 mg/dL.</p> |
|--|---|

Drug interactions: Multiple drug interactions reported because of inhibition of CYP2E1.

See Table II-5.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|--|
| | Tests to support poisoned patients who present to the emergency department include a combination of qualitative screens in urine and quantitative measurements of selected drugs in serum. |
| <i>Metabolism</i> Hepatic <i>Excretion</i> Urine <i>Disease</i> Cirrhosis: Cl _T ↓, F↑ Renal: t _{1/2} ↓, V _d ↓, Cl _T ↓, PB↑ | Encainide is a class IC antiarrhythmic. Its two major metabolites, <i>O</i> -demethylencaïnide (ODE) and 3-methoxy- <i>O</i> -demethylencaïnide (MODE), possess antiarrhythmic activity and are largely excreted by the kidney. Seven to 9% of people are poor metabolizers incapable of rapidly forming ODE. These subjects accumulate very high concentrations of encainide in plasma and have prolonged t _{1/2} (8.7 hr). Antiarrhythmic efficacy appears to be predicted well by plasma ODE concentrations in most patients. Adverse effects include hypotension, bradycardia, seizures, chest pain, ventricular arrhythmias, and death. ⁸ |
| Drug interactions: Cimetidine may increase plasma concentrations of encainide and its active metabolites. Concurrent use of other antiarrhythmic drugs, adenosine, antipsychotics, foscarnet, and antibiotics like clindamycin and erythromycin can lead to an increased risk in cardiotoxicity. ⁷ | Interferences: Maximum cross-reactivity with NDE (the <i>N</i> -demethyl metabolite) is reported to be 18% with RIA. |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| | <p>Epoetin alfa is a recombinant form of human erythropoietin. This protein, normally produced primarily by the kidneys and to a lesser extent by the liver, serves to stimulate erythrocyte production. The drug is used to treat anemia resulting from cancer and HIV chemotherapy and chronic renal failure. Erythropoiesis occurs as rapidly as 7-10 days after initiation of therapy. The increase in hemoglobin and reticulocyte count is proportional to the dose and the duration of therapy. Common side effects include headache and arthralgias, whereas more serious events include hypertension, hyperfibrinogenemia, hyperkalemia, and hyperphosphatemia. The drug is also abused to enhance athletic performance.</p> |

| | |
|--|---|
| <p><i>Metabolism:</i></p> <p>Hepatic, alcohol dehydrogenase, microsomal ethanol oxidizing system, and peroxides-catalase</p> <p><i>Excretion:</i></p> <p>Renal, pulmonary</p> <p>↑ V_d after ingestion of alcohol, aspirin (1 g), and cimetidine.</p> | <p>Ethanol is a CNS depressant. Acute toxicity ranges from inebriation to seizures, coma, and death. Toxicity from chronic ingestion/exposure includes addiction, malnutrition, dementia, hepatic dysfunction, and pancreatitis. Ethanol consumption during pregnancy is associated with fetal alcohol syndrome.</p> <p>Medical-legal cases: Proper collection, handling, and storage of the blood alcohol specimen are essential. Blood is the specimen of choice. Concentration determined in a specimen other than whole blood cannot always be converted to blood alcohol concentration. Specimen storage: Blood specimen without sodium fluoride is stable (not opened) at 25° C up to 2 days, at 5° C up to 2 wk, and at −15° C up to 4 wk. With 1% sodium fluoride preservative, specimen is reliable at 25° C up to 2 wk, at 5° C up to 3 mo, and at −15° C up to 6 mo.</p> |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|---|
| <i>Metabolism</i> Hepatic | Ethosuximide is an antiepileptic agent. ⁹ Toxic effects are not highly correlated with serum concentration. Concentration-related side effects include nausea, vomiting, anorexia, headache, fatigue, lethargy, and dizziness. The drug may also cause aplastic anemia, leukopenia, and thrombocytopenia. Ethosuximide has been reported to cause a positive Coombs test and an increased antinuclear antibody titer. Serum AST can be elevated. |
| <i>Excretion</i> Feces (primary) | |

| <i>Dialysis</i> ⁸ Hemodialysis (+) | |
| Drug interactions: Ethosuximide is a major substrate of CYP3A4. CYP3A4 inducers like carbamazepine, phenobarbital, phenytoin, and rifamycins may decrease the levels/effects of ethosuximide by increasing its metabolism. CYP3A4 inhibitors like azole antifungals, ciprofloxacin, clarithromycin, diclofenac, doxycycline, erythromycin, imatinib, isoniazid, nefazodone, nicardipine, propofol, protease inhibitors, quinidine, and verapamil may increase the levels/effects of ethosuximide. ⁷ Valproic acid may increase or decrease plasma ethosuximide concentrations. | |

|---|---|
| <p><i>Metabolism</i></p> <p>Hepatic</p> <p>Alcohol Dehydrogenase (ADH) to the principal toxic metabolite, glycolic acid, and other acidic compounds, resulting in a metabolic acidosis.</p> | <p>Ethylene glycol, a component of antifreeze and other products, may be ingested accidentally or intentionally (by alcoholics). Adverse effects include signs of intoxication, abdominal pain, metabolic acidosis, CNS depression, tetany, and renal failure. Oxalate crystals are found in only 33-65% of known ethylene glycol cases. Any amount of ethylene glycol in plasma may be associated with toxicity. Monitoring of ethylene glycol-poisoned patients should include determination of ethylene glycol and glycolic acid levels. One treatment is the administration of ethanol to saturate the enzyme with a preferred substrate. In such cases, ethanol levels and glycol levels must be monitored.</p> <p>See also <i>Glycolic Acid</i> and Table II-6.</p> |

| <p><i>Metabolism</i> Hepatic, CYP3A4</p> <p><i>Excretion</i> Renal (minimal) Hemodialysis (–) Hemoperfusion (–)</p> <p>Drug interactions: CYP3A4 inhibitors may increase the levels/effects of fentanyl. Fentanyl is a weak inhibitor of CYP3A4. Not recommended to use fentanyl within 14 days of use of MAO inhibitors.</p> | <p>Fentanyl is a strong analgesic used preoperatively, during surgery, and postoperatively. It is also used intrabuccally in the management of breakthrough cancer pain in patients who are tolerant to opioid therapy. It is 50–100 times as potent as morphine and has a time to peak analgesia of 5 min compared with 15 min for morphine and meperidine. Side effects include hypotension, CNS depression, nausea, respiratory depression, bradycardia, and vomiting. Congeners of fentanyl used as analgesics are sufentanil (Sufenta), alfentanil (Alfenta), and remifentanil (Ultiva). Sufentanil's properties are similar to those of fentanyl. Alfentanil and remifentanil have a more rapid onset of action than fentanyl and sufentanil and are used for short, painful procedures that require intense analgesia and blunting of stress responses. α-Methylfentanyl (China White) is one of several illicit fentanyl derivatives.</p> |

**FACTORS INFLUENCING
DRUG DISPOSITION**
REMARKS AND INTERFERENCES

Drug interactions: Flecainide is a major substrate of CYP2D6 and minor substrate of CYP1A2. It inhibits CYP2D6 weakly.⁵ Cimetidine may decrease flecainide clearance, thereby increasing flecainide plasma concentrations. Amiodarone may also increase flecainide concentrations. Coadministration with digoxin may cause a 24% increase in digoxin levels. Coadministration with propranolol may result in slightly elevated plasma levels of both drugs. Acidification of the urine may increase flecainide elimination, whereas alkalization may decrease it.

Fluconazole is an antifungal drug used to treat candidiasis and cryptococcal meningitis. Resistance by some *Candida* species has developed with long-term use. The most common adverse effects involve the gastrointestinal tract (diarrhea, nausea, and pain). Thrombocytopenia, hyperlipidemia, and increased liver function tests are also reported.

Fluconazole is considered teratogenic.

See Table II-5.

Drug interactions: Fluconazole is known to inhibit CYP2C9 and CYP3A4, leading to numerous potential drug interactions.

Flumazenil, an imidazobenzodiazepine derivative, is an antagonist used to reverse benzodiazepine-induced sedation. It is administered IV as a 0.1 mg/mL solution (initial dose 0.2 mg/30 sec) with a maximum recommended cumulative dose of 5 mg total. It should not be used in patients with serious cyclic antidepressant poisoning. Flumazenil is rapidly metabolized to inactive metabolites, including *N*-desmethylflumazenil.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <i>Metabolism</i> Hepatic <i>Excretion</i> Renal | 5-Fluorouracil is a fluorinated pyrimidine antimetabolite used as an antineoplastic agent. The drug is used in the palliative management of breast, colon, stomach, and pancreatic cancers. It is also used to treat dermatological cancers, such as actinic keratoses and basal cell carcinomas. |
| Drug interactions: Prolonged prothrombin time and INR with coadministration of 5-FU and warfarin. Increased risk of hepatotoxicity with coadministration of 5-FU and levamisole. | The conversion of 5-FU to 5,6-dihydrofluorouracil, a possibly active metabolite, is governed by dihydropyrimidine dehydrogenase (DPD). Patients with a genetic deficiency of DPD may experience severe toxicity. Adverse and toxic effects include alopecia, photosensitivity, anorexia, diarrhea, bleeding, myelosuppression, thrombophlebitis, and myocardial ischemia. |

| <p><i>Metabolism</i></p> <p>Hepatic, CYP2D6, CYP3A4, CYP2C9, and CYP2C19</p> <p>Active metabolite: norfluoxetine</p> <p><i>Excretion</i></p> <p>Renal</p> <p><i>Dialysis</i></p> <p>Hemodialysis (–)</p> | <p>Fluoxetine belongs to the group of antidepressants that act by selectively inhibiting neuronal reuptake of serotonin. It is used to treat other psychiatric disorders, including obsessive-compulsive disorder, posttraumatic stress disorder, premenstrual dysphoric disorder, and anxiety disorders. The S- and R-enantiomers exhibit equivalent pharmacological activity. The enantiomers are metabolized to active S- and R-norfluoxetine, which have half-lives of 4–16 days.</p> |
| <p>Drug interactions: Fluoxetine is an inhibitor of CYP2D6, CYP3A4, CYP2C9, and CYP2C19. Numerous interactions are reported, including with desipramine, methadone, alprazolam, triazolam, carbamazepine, thiorophylline, clozapine, and warfarin. The metabolites contribute to the reported interactions.</p> | |

Metabolism

Hepatic, CYP3A4, weak inhibitor of
CYP2E1

Age

Elderly: $t_{1/2}$ ↑

Dialysis

Hemodialysis (—)

Flurazepam, a benzodiazepine, is used as a hypnotic agent in the short-term treatment of insomnia. Overdose symptoms include respiratory depression, unsteady gait, hypotension, and hypoactive reflexes. Steady-state plasma concentrations are usually attained in 7-10 days.

Drug interactions: Carbamazepine and other CYP3A4 inducers may increase hepatic metabolism. CYP3A4 inhibitors such as azole antifungals, antibiotics such as erythromycin, and so on, may inhibit hepatic metabolism of flurazepam.

| <p><i>Metabolism</i></p> <p>Hepatic, metabolized to succinic acid, which enters the TCA (Krebs) cycle</p> <p><i>Excretion</i></p> <p>Expired as carbon dioxide.</p> <p>Drug interactions: GHB should not be used with alcohol or other CNS depressants.</p> | <p>Gamma hydroxybutyrate (GHB), a naturally occurring metabolite of GABA, is thought to function as a neurotransmitter. Xyrem (sodium oxybate) is the first and only FDA-approved medication for cataplexy associated with narcolepsy. Its use is very restricted and regulated. Even at recommended doses, the use of Xyrem has been associated with confusion, depression, neuropsychiatric events, and respiratory depression. The most commonly observed adverse events associated with the use of sodium oxybate were headache, nausea, dizziness, pain, somnolence, pharyngitis, and infection.</p> <p>GHB and its precursors gamma butyrolactone (GBL) and 1,4-butanediol have emerged as recreational euphorants. GHB has been used as a “date rape” drug and has been designated as an illicit intoxicant in many states.</p> |

| | |
|---|---|
| <p><i>Metabolism</i></p> <p>None</p> <p><i>Excretion</i></p> <p>Urine</p> <p><i>Disease</i></p> <p>Renal: $t_{1/2} \uparrow$, $V_d \rightarrow$, $Cl_T \downarrow$</p> <p>Burns: $Cl_T \uparrow$</p> <p>Cystic fibrosis: $V_d \rightarrow$, $Cl_T \uparrow$</p> <p>Obesity: $V_d \uparrow$ (based on IBW)</p> <p>$Cl_T \uparrow$ (based on IBW)</p> <p><i>Age</i></p> <p>Newborn: $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \downarrow$</p> <p>Child: $t_{1/2} \downarrow$, $V_d \uparrow$, $Cl_T \uparrow$</p> <p>Elderly: $t_{1/2} \rightarrow$, $V_d \rightarrow$, $Cl_T \rightarrow$</p> <p><i>Dialysis</i></p> <p>Hemodialysis (+)</p> <p>Peritoneal (+)¹¹</p> | <p>Gentamicin is an aminoglycoside antibiotic. Therapeutic and toxic concentrations should be considered highly variable and individualized for the patient's condition. Penicillin and its derivatives inactivate gentamicin in vivo and in vitro. A definitive cause-and-effect relationship between trough concentration and the incidence of nephrotoxicity has not been established. Cl_T and $t_{1/2}$ are strongly correlated with glomerular filtration rate. Side effects include vestibular and auditory dysfunction (principally vestibular), nephrotoxicity, cholestasis, leukopenia, eosinophilia, and neuromuscular blockade. Gentamicin may cause decreased serum calcium, potassium, and magnesium concentrations.</p> <p>Interferences: When patient is also taking other antibiotics (penicillins, cephalosporins, tetracyclines, clindamycin, and chloramphenicol), the MB method may lack specificity. Penicillins and cephalosporins can be inactivated with a commercially available β-lactamase to minimize this interference. Heparin has been implicated in the formation of an inactive complex with gentamicin, thereby deactivating the antibiotic.</p> |

**FACTORS INFLUENCING
DRUG DISPOSITION**
REMARKS AND INTERFERENCES

Drug interactions: Concomitant use of gentamicin with neuromuscular blockers may lead to aminoglycoside-induced respiratory paralysis. Coadministration of cyclosporine or tacrolimus with gentamicin may lead to increased risk of nephrotoxicity. Concomitant usage of furosemide with gentamicin is associated with a risk of ototoxicity and nephrotoxicity.¹²

See Table II-6.

Peritoneal (–)
Hemoperfusion (+)

This drug is a highly lipid-soluble sedative, a hypnotic agent producing CNS depression. Because of its high abuse potential, the drug has been replaced by less addictive and more efficacious drugs. Absorption from the intestinal tract is erratic. Approximately 2% of a dose is excreted unchanged into the urine. This drug undergoes extensive enterohepatic recirculation. Additionally, glutethimide is a potent stimulator of the hepatic microsomal enzyme system. Side effects include excitement, blurring of vision, gastric irritation, headache, and skin rashes. Respiratory depression, circulatory collapse, and coma accompany acute overdosage. Osteomalacia has been reported after chronic use.

In some patients, toxicity may occur within the therapeutic range.

| <i>Metabolism</i> Hepatic, CYP2D6, CYP1A2, and CYP3A4 | Haloperidol is an antipsychotic drug used in the treatment of schizophrenia and also in reducing tics and vocal utterances of Tourette's syndrome. It is also used to control the choreiform movements of Huntington's disease. Adverse effects frequently seen include blurred vision, tardive dyskinesia, muscular rigidity, tachycardia, hypotension, and arrhythmias, sedation. Rare cases of hepatic dysfunction and leukopenia have been reported. |

| <i>Dialysis</i> Hemodialysis (–) Peritoneal (–) | |

| | |
|---|--|
| <i>Metabolism</i> Rapid deacetylation by blood and tissue esterases to 6-acetylmorphine (6-AM) and then morphine | Diacetylmorphine or heroin, the most widely abused opioid, is synthesized by the acetylation of morphine. It has two to three times the potency of morphine and has better penetration across the blood-brain barrier because of the 2-acetyl groups. In some countries, medical prescription of diacetylmorphine is being used or considered as a treatment option for heavily dependent addicts and for the management of chronic pain during terminal illness. It can be administered orally, by intramuscular, intravenous, or subcutaneous injection, intranasal insufflation, or smoking. The analgesic effects of heroin are principally caused by the effect of 6-AM and morphine. |
| <i>Elimination</i> Renal as morphine glucuronides | |

For federally regulated workplace drug testing (SAMHSA), the presence of morphine at immunoassay and GC-MS cutoff concentrations of 2000 ng/mL [7000 nmol/L] morphine equivalents plus 6-AM at a cutoff concentration > 10 ng/mL are considered unequivocal evidence of heroin use.

| <i>Metabolism</i> Hepatic | Hydromorphone is a strong analgesic used to treat moderate to severe pain. It also has antitussive activity. It is subject to abuse. CNS depression and adverse reactions are similar to those of morphine. |
| <i>Metabolism</i> Hepatic (N-acetyltransferase) <i>Excretion</i> Renal <i>Disease</i> Hepatic: $t_{1/2} \uparrow$ Hepatitis (acute viral): $t_{1/2} \uparrow$ Renal: $Cl_T \downarrow$, $t_{1/2} \uparrow$ (significant in slow acetylators) <i>Dialysis</i> Hemodialysis (+) Peritoneal (+) | Isoniazid, used to treat tuberculosis primarily, is metabolized by N-acetyltransferase in the liver. Genetic polymorphism is the cause of the high interindividual variation observed in the rate of metabolism of the drug. Rapid acetylators are not as responsive to the drug. Side effects in slow acetylators include SLE, drowsiness, nausea, polyneuropathy, and CNS toxicity caused by the intact drug. Severe hepatic toxicity is well described and may be more prominent in fast acetylators. The mechanism of toxicity may be related to metabolites. Serum ALT and AST are often increased. Cases of eosinophilia, anemia, and leukopenia have been reported. |
| Drug/food interactions: Food, particularly a fatty meal, can decrease C_{max} ~50%. | |

|---|---------------------------|

Phenobarbital, ethanol, and corticosteroids may increase the metabolism of isoniazid. *p*-Aminosalicylic acid, procainamide, and chlorpromazine have been reported to increase isoniazid's $t_{1/2}$. Multiple interactions are related to the inhibition of CYP2C9 by isoniazid.

See Table II-5.

| | |

| <i>Metabolism</i> Hepatic, alcohol dehydrogenase | Isopropanol is a common solvent readily available in 70% solution as rubbing alcohol. The compound is a CNS depressant about twice as potent as ethanol and producing similar effects. Routes of ingestion include oral, dermal, and inhalation. An acute lethal dose in an adult is ~240 mL. Isopropanol is slowly metabolized by alcohol dehydrogenase to acetone. Both are excreted to a small degree in breath and urine. Acetone may be detected in serum ~0.5 hr and in urine ~3 hr after ingestion. Acetone may remain elevated after isopropanol is undetectable. Hypoglycemia and increased osmolar gap are commonly found. |

| <i>Metabolism</i> Hepatic, conjugation with glucuronic acid | Levorphanol is used for relief of moderate to severe pain, parenterally for pre-operative sedation, and as an adjunct to nitrous oxide/oxygen anesthesia. It is excreted primarily as the glucuronide conjugate. CNS depression and adverse reactions are similar to those of morphine. |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|---|
| <p>Metabolism Hepatic, active metabolite: monoethylglycinexylidide (MEGX) and glycinexylidide (GX).</p> <p>Excretion Feces (primary) Urine (secondary)</p> <p>Disease Hepatic: $t_{1/2}\uparrow$, $V_d\uparrow$, $Cl_T\downarrow$ CHF: $V_d\downarrow$, $Cl_T\downarrow$ MI: $t_{1/2}\uparrow$, $Cl_T\downarrow$, $PB\uparrow$ Shock: $Cl_T\downarrow$ Uremia: $PB\uparrow$ Cardiopulmonary bypass surgery: $t_{1/2}\rightarrow$, $V_d\downarrow$, $Cl_T\downarrow$, $PB\uparrow$</p> <p>Age Neonate: $t_{1/2}\uparrow$, $V_d\uparrow$, $Cl_T\downarrow$, $PB\downarrow$ Elderly: $t_{1/2}\rightarrow$, $V_d\rightarrow$, $Cl_T\rightarrow$</p> <p>Dialysis Hemodialysis (—)</p> <p>Drug interactions: Enzyme inducers phenobarbital and phenytoin may increase the metabolism of lidocaine, whereas drugs that decrease cardiac output or hepatic blood flow (e.g., propranolol, anesthetics, and norepinephrine) probably decrease the drug's clearance. Cimetidine may decrease the hepatic clearance of lidocaine.</p> | <p>Lidocaine has both antiarrhythmic (class Ib) and local anesthetic activity. When used as an antiarrhythmic agent, the drug is administered intravenously. Lidocaine undergoes first-pass metabolism and is dependent on hepatic blood flow for its elimination. An increase in the $t_{1/2}$ with prolonged administration has been observed. Protein binding is concentration and pH dependent and is strongly correlated to α_1-acid glycoprotein concentration, a protein often elevated in response to inflammation or body stress.¹¹ Side effects include dissociation, paresthesias, drowsiness, agitation, impaired hearing, disorientation, muscle twitching, convulsions, hypotension, asystole, arrhythmias, and respiratory arrest. Both MEGX and GX are potential contributors to toxicity.</p> <p>Interferences: Lidocaine may be displaced from protein binding sites by plasticizers in collecting devices. Immunoassays fail to quantitate important metabolites monoethylglycinexylidide (MEGX) and glycinexylidide (GX). Some GLC methods lack specificity and sensitivity.</p> |

LSD is classified as a schedule I agent with high abuse potential, no known use in medical treatment, and lack of established safety even under medical supervision. LSD and other indoleamines act at multiple sites in the CNS. Mydriasis, tachycardia, tremor, weakness, paresthesias, and labile mood are produced. Euphoria may result with bizarre effects characterized by synesthesias. Adverse effects are primarily psychological in nature. There may be unpredictable recurrence of hallucination for weeks or months after the last dose. Hysterical behavior, hyperactivity, hyperthermia, and psychotic reactions may be delayed. Protein binding decreases to ~65% in overdose subjects.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|---|
| Metabolism Hepatic, CYP2D6 Active metabolites: desmethylmaprotiline, maprotiline- <i>N</i> -oxide Excretion Renal (minimal) Age Elderly: $t_{1/2} \downarrow$ Drug interactions: Cisapride, monoamine oxidase inhibitors, in addition to those related to inhibition or induction of CYP2D6. | Maprotiline is a tetracyclic antidepressant. Adverse effects include hypotension, tachycardia, gastrointestinal distress, and tremor. In overdose, more serious effects encountered include seizures, respiratory arrest, and severe tachycardia, arrhythmias, and hypotension. |

| | |
|--|--|
| Metabolism Hepatic Disease Hepatic: $t_{1/2} \uparrow$, 6 hr; $V_d \rightarrow$, $Cl_T \downarrow$, $F \uparrow$ Age Elderly: $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \rightarrow$, $PB \downarrow$ Drug interactions: Meperidine is contraindicated in patients who have received MAO inhibitors during the previous 14 days. Serotonin agonists may enhance adverse effects of meperidine leading to serotonin syndrome. | Meperidine is a strong analgesic used for relief of moderate to severe pain. It is metabolized to an active metabolite (normeperidine), which may accumulate in renal failure. Normeperidine has been shown to possess half the analgesic potency of meperidine but twice the seizure-inducing properties of its parent compound. Side effects include nausea, vomiting, tremors, muscular twitches, dilated pupils, hyperactive reflexes, and convulsions. Naloxone is a specific antagonist of meperidine. |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <i>Metabolism</i> Hepatic <i>Dialysis</i> Hemodialysis (+) Peritoneal (+) | Meprobamate is a sedative used for management of anxiety disorders. It is rapidly metabolized in the liver to inactive metabolites excreted in urine. Up to 19% is excreted unchanged. The drug induces some hepatic microsomal enzymes. Adverse effects include drowsiness, ataxia, confusion, hypotension, and weakness. |

| | |
|--|--|
| <i>Metabolism</i> Hepatic, CYP3A4 (major); CYP2D6 (minor); CYP1A2 (probable) <i>Dialysis</i> Hemodialysis (−) Peritoneal (−) | Methadone is an opiate analgesic, but its primary use is for detoxification and maintenance treatment of narcotic addiction. Adverse reactions include excessive sweating, bradycardia, nausea, vomiting, constipation, thrombocytopenia, and weakness. Toxic effects are similar to those of morphine; diminished pulmonary ventilation predominates. Treatment is similar to that for morphine toxicity, specifically the use of naloxone. |
|--|--|

Drug interactions: CYP3A4 inhibitors may increase the effects of methadone. Methadone is a moderate inhibitor of CYP2D6 and may increase the effects of CYP2D6 substrates. It is also a weak inhibitor of CYP3A4.

Metabolism

Hepatic, CYP2D6

Excretion

Renal, excreted as unchanged parent drug (up to 45%) and metabolites including amphetamine (~7%)

Drug interactions: CYP2D6 inhibitors may increase levels/effects of methamphetamine. Acidification of the urine will enhance the renal excretion of methamphetamine, whereas alkalinization will reduce it.

Amphetamine is a common drug of abuse. Methamphetamine (d isomer) is used for treatment of attention deficit disorder with hyperactivity and as a short-term adjunct for exogenous obesity. Symptoms of acute toxicity with methamphetamine include seizures, hyperactivity, hypertension, and coma.

For federally regulated workplace drug testing (SAMHSA), the widely accepted immunoassay cutoff concentration to separate positive and negative specimens for methamphetamine is 1000 ng/mL [7400 nmol/L] for amphetamine screening and 500 ng/mL [3700 nmol/L] for GC-MS confirmation. In addition, amphetamine (metabolite of methamphetamine) must be detected at a cutoff concentration of 200 ng/mL to report a specimen as positive for methamphetamine. At these cutoff concentrations, methamphetamine may generally be detected in urine for 1-3 days after use.

Alternative matrices used for nonfederally regulated workplace drug testing and being considered for regulated testing include hair, oral fluid, and sweat.

See *Phenethylamines and Amphetamine*.

Interferences: Nonprescription decongestants and diet aids containing ephedrine and phenylpropanolamine and prescription drugs including selegiline, benzphetamine, fenfluramine, mephentermine, phenmetrazine, and phentermine may cause positive IA results.

Excretion

Renal, pulmonary

Dialysis

Hemodialysis (+)

Peritoneal (~)

Methanol (wood alcohol) is a widely used solvent, a denaturing agent, an antifreeze constituent, and a fuel in internal combustion engines or cooking appliances. Absorption occurs by inhalation, skin contact, and ingestion. Trace amounts are occasionally found and may be the result of bacterial metabolism or food ingestion (fermented fruit). Some alcoholic beverages (e.g., wine, bourbons) may contain methanol. Serum concentrations of up to ~3 mg/dL have been reported after ingestion of these products.

Intoxication effects are milder than those associated with ethanol toxicity, but accumulation of formic acid leads to optic nerve damage, blindness, and severe acidosis. Methanol is metabolized by liver alcohol dehydrogenase to formaldehyde, which does not accumulate but is converted to formic acid. Ten to 20% of methanol is eliminated by lungs, 3% by the kidneys, and up to 60% is oxidized. Urine formic acid (normal, 17 mg/L [0.37 mmol/L]) should not exceed 100 mg/L [2.17 mmol/L] in exposed workers. A high anion gap and osmolar gap are typically found.

Ethanol competitively inhibits the metabolism of methanol and is administered as one form of treatment of methanol toxicity. 4-Methylpyrazole (fomepizole) also inhibits methanol metabolism and is used as an antidote.

| <i>Metabolism</i> | Methotrexate is a folate antimetabolite used to treat numerous malignancies including childhood acute lymphocytic leukemia, osteosarcoma, and non-Hodgkin's lymphoma, as well as cancers of the head, neck, breast, and lung. It is one of the few chemotherapeutic drugs to be given intrathecally. Methotrexate is also used to treat noncancerous diseases such as rheumatoid arthritis and psoriasis because of its immunosuppressive and antiinflammatory actions. Therapeutic concentrations depend on the treatment protocol. High-dose therapy is usually followed by leucovorin rescue depending on the concentration at 24, 48, and 72 hr. |

**FACTORS INFLUENCING
DRUG DISPOSITION**
REMARKS AND INTERFERENCES

Bioavailability is related to drug dose.

Drug interactions: Methotrexate is weakly acidic. Most reported drug interactions occur when the drug displaces another drug from protein binding (e.g., phenytoin, salicylates, tetracyclins, and chloramphenicol). Weakly acidic drugs such as probenecid and salicylates may reduce renal excretion of methotrexate.

Side effects include bone marrow depression, reversible nephrotoxicity, leukopenia, thrombocytopenia, anemia, stomatitis, mucositis, nausea, vomiting, diarrhea, maculopapular rash, fever, pneumothorax, and cholestasis. AST, ALT, and serum creatinine may be increased. Serum glutamyltransferase may be increased in psoriatic patients.

See Tables II-5 and II-6.

Metabolism
Hepatic

Drug interactions: Interactions with other AEDs are well documented. Carbamazepine, phenobarbital, phenytoin, and primidone may increase metabolism. Methsuximide decreases topiramate, valproic acid, and lamotrigine. Valproic acid may increase or decrease plasma ethosuximide concentrations.

Methsuximide is used to control petit mal seizures unresponsive to other antiepileptic drugs. It is extensively metabolized to an active metabolite, *N*-desmethylmethsuximide, which contributes to the therapeutic concentration. Side effects include nausea, vomiting, anorexia, drowsiness, lethargy, euphoria, dizziness, and headache. Severe depression, skin rash, fever, periorbital edema, leukopenia, aplastic anemia, nephropathy, and hepatotoxicity have been reported.

|--|--|
| Metabolism Hepatic Excretion Renal, intra-neuronal, and fecal Disease Renal: $t_{1/2} \uparrow$, $Cl_T \downarrow$ Age Neonate: $t_{1/2} \uparrow$ Dialysis Hemodialysis (+) Peritoneal (+) | Methyl-dopa is an antihypertensive that undergoes metabolism intraneurally through successive decarboxylation and <i>p</i> -hydroxylation reactions to form the pharmacologically active α -methyl-dopamine and α -methyl-norepinephrine. First-pass metabolism and enterohepatic recirculation have been suggested. Increased sensitivity to methyl-dopa in renal failure may be attributable to the accumulation of α -methyl-dopamine, the sulfate conjugate, as well as to methyl-dopa itself. Side effects include systemic lupus-like syndrome and hepatic disturbances (increased ALT and AST, jaundice). Direct Coombs test can be positive. Cases of hemolytic anemia, eosinophilia, and leukopenia have been reported. CNS side effects include sedation, vertigo, nightmares, and depression. See Table II-5. |

Metabolism

CYP2B6, CYP1A2, CYP2D6, and CYP3A4
Metabolites include MDA (8-9%). Nonlinear pharmacokinetics apparently are caused by autoinhibition of CYP2D6.

Excretion

Renal

MDMA, an illicit psychostimulant drug, is a potent releaser and/or reuptake inhibitor of serotonin, dopamine, and norepinephrine. It is structurally similar to methamphetamine and mescaline. The racemic mixture is consumed. Psychostimulant and empathic effects result from S(+) isomer, and hallucinogenic effects result from R(−) isomer. Common side effects include jaw clenching, dry mouth, palpitations, cold sensitivity, drowsiness, and tremor. Effects of severe overdose include hyperthermia, delirium, seizures, hypotension, tachydysrhythmias, coma, and renal failure.

Drug interactions: Antiretroviral drugs and MAO inhibitors are reported to cause life-threatening interactions.

Most immunoassays for amphetamines do not detect MDMA.

Dialysis

Hemodialysis (+)

Hemoperfusion (+)

Peritoneal (\pm)

Methyprylon is metabolized to a series of products, some of which are active. Only ~3% of unchanged drug is excreted in the urine. This sedative-hypnotic is a CNS depressant and produces drowsiness and ataxia. Acute overdose is generally characterized by coma, apnea, hypotension, shock, and pulmonary edema. The plasma $t_{1/2}$ is prolonged to ~50 hr in acute overdosage. The product is no longer used in the U.S.

Metoprolol exhibits dose-dependent bioavailability secondary to saturable first-pass metabolism. Alterations of dose in renal dysfunction are not warranted. Plasma concentrations that produce minimal β -blockade vary widely. There is no good correlation between serum concentrations and therapeutic effects. Thus determination of serum levels is of limited value in routine therapy.

Drug interactions: Metoprolol is a major substrate of CYP2D6 and minor substrate of CYP2C19. Metoprolol weakly inhibits CYP2D6. CYP2D6 inhibitors like chlorpromazine, fluoxetine, miconazole, paroxetine, pergolide, quinidine, quinine, and ritonavir may increase the effects of metoprolol. Barbiturates and other enzyme inducers may enhance metoprolol metabolism. Phenothiazines and cimetidine may increase plasma concen-

Mexiletine is a class Ib antiarrhythmic. Metabolites are not pharmacologically active. Adverse effects include hypotension, vomiting, tremor, toxic confusional states, and atrioventricular dissociation. Can be proarrhythmic. May cause acute hepatic injury. Use cautiously in patients with first-degree block, preexisting sinus node dysfunction, intraventricular conduction delays, significant hepatic dysfunction, hypotension, or severe CHF.

Drug interactions⁴: Mexiletine is a major substrate of CYP1A2 and CYP2D6. It inhibits CYP1A2 strongly. Phenytoin and rifampin or cigarette smoking can induce mexiletine metabolism, thereby decreasing its plasma concentrations and $t_{1/2}$. Cimetidine appears to slow absorption of mexiletine slightly. Metoprolamide may increase the rate of mexiletine absorption. Mexiletine may increase plasma digoxin concentration.

Midazolam is an ultra-short-acting imidazole used for preoperative sedation, anxiolysis, and anterograde amnesia. It is extensively metabolized in the liver and intestine with the principal metabolite being 1-hydroxymidazolam. Adverse reactions of midazolam include decreased respiration, hypotension, drowsiness, headache, nausea, and vomiting.

Drug interactions: CYP3A4 inducers (e.g., carbamazepine, rifampin, and phenytoin) may increase hepatic metabolism. CYP3A4 inhibitors (e.g., diltiazem, azole antifungals, and erythromycin) may inhibit hepatic metabolism.

| Mycophenolic Acid (CellCept) ¹⁻⁵ | Plasma, ⁷ serum (red top, no SST) | Therapeutic concentration ^{2,6,8-10} : | *Trough: 1.0-3.5 mcg/mL | PK ^{3,8,12,13} : | |
| | | | | t _{1/2} : | 16-18 hr |
| | | | | V _d : | 3.6-4.0 L/kg |
| <i>HPLC, EMIT, LC-MS-MS</i> | Stable at -20° C for 3 wk; 4° C for 96 hr | Toxic concentration: | Not available | Cl _T : | 140-193 mL/min |
| | | | | PB: | 97% |
| | | | | F: | 94% |

EMIT shows a positive bias compared with HPLC because the antibody detects acyl glucuronide, an active metabolite of MPA.⁶

Although therapeutic trough levels remain to be conclusively defined, MPA AUC data are more significantly correlated with toxicity/efficacy; a study showed 12-hr AUCs >40 mcg/mL/hr were correlated with efficacy and decreased episodes of rejection, whereas another study showed 12-hr AUC of 32.2-60.6 mcg/mL/hr was correlated to a rejection rate of <10%.¹¹

Drug interactions: Muromonab-CD3 may enhance the adverse/toxic effect of vaccines (live organisms). Echinacea may antagonize the immunosuppressive effect of muromonab-CD3 and decrease its effectiveness.⁶

OKT3 is a murine monoclonal antibody directed against the CD3 receptor on human T lymphocytes and is given in the treatment of allograft rejection in renal and other solid organ transplant patients. It is also used for the treatment of acute hepatic and pancreatic rejection episodes, as well as acute graft-versus-host disease after bone marrow transplantation resistant to conventional treatment.^{1,7}

Side effects of parenteral muromonab-CD3 include headaches, diarrhea, nausea, and vomiting.⁷ First-dose effect (cytokine release syndrome) may occur 1-3 hr after the first dose and may last for 12-16 hr. Symptoms include mild flulike symptoms to life-threatening anaphylactic shock. Reactions tend to decrease with repeated doses.⁶

Mycophenolic acid is an immunosuppressive agent used for prophylaxis of organ rejection in patients undergoing heart, kidney, and liver transplantation.¹² Its use in combination with cyclosporine and steroids has decreased incidences of acute rejection in renal transplant patients.²

The prodrug mycophenolate mofetil is completely hydrolyzed in the liver to the active metabolite, MPA; it is converted to its primary inactive glucuronide metabolite, MPAG, which is predominantly excreted renally.^{2,3}

Side effects include nausea, diarrhea, constipation, anemia, leukopenia, headache, weakness, urinary tract infection, liver function test abnormalities, infection related to immunosuppression, and skin rash. Hemorrhagic gastritis and pancreatitis have been reported in a few cases.¹²

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|---|
| increase because of competition for tubular secretion. Cholestyramine and antacids should not be administered together with mycophenolic acid because its absorption can be reduced. | Most PK data on MPA relate to use of MMF after renal transplantation in combination with CsA. Concomitant therapy with tacrolimus or sirolimus can affect MPA AUCs and trough levels differently; it remains to be established whether different drug therapies affect interpretations of trough or target AUC values. ⁶ |
| Food can cause C _{max} decreases by ~40%; should avoid Cat's Claw and Echinacea herbal supplementation, which have immunosuppressant activities. ⁸ | |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|---|
| <i>Metabolism</i> Hepatic <i>Excretion</i> Urine (primary) Hepatic (secondary) ⁸ <i>Disease</i> Renal: $t_{1/2} \uparrow$ <i>Dialysis</i> Hemodialysis (+) | Biliary secretion may account for up to 41% of elimination. Nadolol appears to be eliminated via the biliary system in anephric patients. Plasma concentrations that produce minimal β -blockade vary widely. There is no good correlation between serum concentrations and therapeutic effects. Thus determination of serum levels is of limited value in routine therapy. |
| Drug interactions: Phenothiazines may increase plasma concentrations, probably through their effect on hepatic metabolism. NSAIDs and salicylates may reduce the anti-hypertensive effects of nadolol. ¹⁰ | |

| | |
|--|--|
| <i>Metabolism</i> None <i>Excretion</i> Urine <i>Diseases</i> Renal: $t_{1/2} \uparrow$, $V_d \rightarrow$, $Cl_T \downarrow$ Cystic fibrosis: $t_{1/2} \downarrow$, $Cl_T \rightarrow$ <i>Age</i> Neonate: $t_{1/2} \uparrow$ <i>Dialysis</i> Hemodialysis (+) Peritoneal (+) | Netilmicin is an aminoglycoside antibiotic. Therapeutic and toxic concentrations are highly variable and therefore should be individualized for the patient's condition. Penicillin and its derivatives inactivate netilmicin in vivo and in vitro. Cl_T and $t_{1/2}$ are strongly correlated with glomerular filtration rate. Netilmicin appears to have less incidence of ototoxicity than other aminoglycosides. |
| | Interferences: When patient is also taking other antibiotics (penicillins, cephalosporins, tetracyclines, clindamycin, chloramphenicol), the MB method may lack specificity. Penicillins and cephalosporins can be inactivated with a commercially available β -lactamase to minimize this interference. |

**FACTORS INFLUENCING
DRUG DISPOSITION****REMARKS AND INTERFERENCES**

Drug interactions: Concomitant use of netilmicin with neuromuscular blockers may lead to aminoglycoside-induced respiratory paralysis. Coadministration of cyclosporine or tacrolimus with netilmicin may lead to increased risk of nephrotoxicity.¹¹

Metabolism

Hepatic, minor substrate of CYP1A2, CYP2A6, CYP2B6, CYP2C8/9, CYP2C19, CYP2D6, CYP2E1, and CYP3A4

Excretion

Renal

Nicotine is used as an aid in smoking cessation. It may be delivered by over-the-counter and prescription means, including chewing gum, lozenge, patch, intranasal spray, and oral inhaler. Early effects of nicotine overdose include nausea, vomiting, abdominal pain, cold sweat, confusion, and weakness. Late effects of toxicity include hypotension, breathing difficulty, seizures, and possible death.

Nicotine is metabolized to >20 metabolites, the principal ones being cotinine and nicotine-1'-N-oxide. The nicotine metabolite, cotinine, is a sensitive and specific biochemical marker of exposure (direct and passive) to cigarette smoke.

See also *Cotinine*.

Nifedipine is a calcium channel blocker with potent vasodilator activity. Its metabolism appears to exhibit oxidative polymorphism; thus there are two phenotypes (rapid and slow metabolizers) in the general population.

Nifedipine may be displaced from protein binding sites by plasticizers in collection devices. Rare cases of hepatic dysfunction have been reported.

Drug interactions: Nifedipine is a major substrate of CYP3A4 and minor substrate of CYP2D6. Nifedipine moderately inhibits CYP1A2. CYP3A4 inducers like carbamazepine, phenobarbital, phenytoin, and rifamycins may decrease the effects of nifedipine. CYP3A4 inhibitors like azole antifungals, ciprofloxacin, clarithromycin, and erythromycin may increase the effects of nifedipine.¹⁰ Cimetidine may increase nifedipine serum concentrations by inhibiting hepatic metabolism. Concomitant administration of nifedipine and digoxin occasionally results in up to 50% increase in serum digoxin concentrations.¹¹

The gas is eliminated very rapidly by pulmonary diffusion. There is no evidence of biotransformation.¹

This is a nonflammable, nearly odorless gas that is a good analgesic at safe concentrations. It is sometimes abused, and fatalities have occurred as a result of simple asphyxia.¹

Drug interactions: Nitrous oxide can increase the neuromuscular blocking effect of nondepolarizing muscle relaxants (e.g., pancuronium, gallamine, tubocurarine, vecuronium), leading to respiratory depression.³

Peritoneal (—)

Food decreases the rate but not the extent of absorption of diclofenac. Age does not appear to affect diclofenac disposition. Side effects include nausea, vomiting, dizziness, drowsiness, edema, rash, peptic ulceration, and gastrointestinal bleeding. The mean peak plasma concentrations of diclofenac after oral doses of 50 mg and 75 mg are 1.5 and 1.9 mg/L [$\times 3.14 = 4.7$ and $6.0 \mu\text{mol/L}$], respectively.

Drug interactions: Aluminum or magnesium hydroxide containing antacids may decrease the rate of absorption of diclofenac. Diclofenac may decrease the renal elimination of lithium, digoxin, and methotrexate, causing increases in serum concentrations. The drug may decrease the antihypertensive and diuretic effects of hydrochlorothiazide and furosemide and may increase renal toxicity of cyclosporine.

|--|--|
| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Renal, biliary, and fecal</p> <p><i>Age</i></p> <p>Premature newborns: $t_{1/2} \uparrow$</p> <p>Elderly: $t_{1/2} \uparrow$</p> <p><i>Dialysis</i></p> <p>Hemodialysis (–)</p> <p>Peritoneal (–)</p> | <p>A dose-response relationship has been demonstrated for the inhibition of prostaglandin synthesis, but in rheumatoid arthritis patients, no significant differences in mean steady-state plasma indomethacin concentrations were seen between responders and nonresponders. Indomethacin is almost completely absorbed after oral administration. It undergoes extensive enterohepatic recirculation, which may account for its variable elimination $t_{1/2}$. Adverse effects include peptic ulceration, leukopenia, agranulocytosis, thrombocytopenia, nausea, vomiting, dizziness, and tinnitus. Adverse effects increase with increasing plasma indomethacin concentrations.</p> |

Drug interactions: Magnesium- and aluminum-containing antacids may decrease the rate of absorption but not extent. Sodium bicarbonate increases the absorption rate of indomethacin. Probenecid increases plasma indomethacin concentrations. Indomethacin may increase plasma concentrations of digoxin, lithium, and methotrexate by decreasing renal excretion. Indomethacin may inhibit the diuretic effect of furosemide.

| | |
|---|---|
| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Renal</p> <p><i>Dialysis</i></p> <p>Hemodialysis (–)</p> <p>Peritoneal (–)</p> | <p>Administering probenecid along with ketoprofen may decrease the peak to trough variation seen with ketoprofen. Mean steady-state C_{\max} of ketoprofen after a 50-mg dose given four times a day are ~ 5.6 mcg/mL [$\times 3.93 = 22$ $\mu\text{mol/L}$]. Side effects include dyspepsia, peptic ulceration, gastrointestinal bleeding, headache, insomnia, anxiety, thrombocytopenia, anemia, agranulocytosis, rash, and edema. Rare cases of nephrotoxicity and hepatotoxicity have been reported.</p> |
|---|---|

Drug interactions: Salicylates may reduce ketoprofen's conjugative metabolism while increasing the drug's conversion to nonconjugated metabolites. Salicylates also displace ketoprofen from plasma protein binding sites. Probenecid may inhibit the conjugation of ketoprofen. In addition, probenecid inhibits the renal excretion of ketoprofen conjugates. Ketoprofen may increase plasma concentrations of digoxin, lithium, and methotrexate by decreasing their renal elimination.

Because of extensive metabolism, protein binding, and passive reabsorption in the distal renal tubule, only traces are excreted in urine.</p> <p>After a single dose, glucuronidation seems to be the dominant reaction, whereas oxidation reactions increase with multiple dosing (i.e., clearance increases with multiple dosing to 0.03 mL/min/kg). Adverse effects include peptic ulcer, hypersensitivity reactions, ulcerative stomatitis, hepatitis, nephritis, aplastic anemia, leukopenia, agranulocytosis, and thrombocytopenia. The $t_{1/2}$ is dose dependent. Spectrophotometry measures the drug and its metabolites; GLC measures the drug only. HPLC measures the drug but has poor response to the metabolite.</p> |
| <p>Drug interactions: Phenylbutazone enhances the anticoagulant effects of warfarin. The drug may also enhance the hypoglycemic effect of some sulfonylureas. In addition, the drug may decrease the concentrations of digoxin and digitoxin.</p> | |
| <p><i>Metabolism</i> Hepatic</p> <p><i>Excretion</i> Renal</p> <p><i>Dialysis</i> Hemodialysis (—) Peritoneal (—)</p> | <p>With a dose of 20 mg/day, the peak concentration at steady state is in the range of 4.5–8.0 mcg/mL [14–24 μmol/L]. There is no correlation between toxic effects and plasma piroxicam concentrations. Food decreases the rate of absorption and may decrease the extent. Piroxicam undergoes enterhepatic recirculation. The therapeutic threshold (6.7 mcg/mL [20 μmol/L]) is not well defined. Side effects include epigastric distress, nausea, constipation, stomatitis, diarrhea, flatulence, peptic ulceration, and gastrointestinal bleeding. Less frequent adverse effects include anemia, leukopenia, eosinophilia, thrombocytopenia, nephrotoxicity, and hepatotoxicity.</p> |
| <p>Drug interactions: Concomitant aspirin administration may decrease piroxicam concentrations. Piroxicam may increase plasma digoxin, lithium, and methotrexate concentrations.</p> | |

| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Renal (secondary)</p> <p><i>Disease or condition</i></p> <p>Hepatic: $Cl_T \downarrow \rightarrow$, $PB \downarrow$</p> <p>Renal: $Cl_T \uparrow$, $PB \downarrow$</p> <p>Pregnancy: $PB \uparrow$</p> <p>Hypoalbuminemia: $PB \downarrow$</p> <p><i>Age</i></p> <p>Newborn: $t_{1/2} \uparrow$, $Cl_T \downarrow$, $PB \downarrow$</p> <p>Drug interactions: Alkalinization of the urine (pH 8) will increase the renal clearance, whereas acidification will decrease it. Plasma concentrations of salicylic acid may be decreased by aluminum or magnesium hydroxides.</p> | <p>Salicylic acid is the major hydrolysis product of acetylsalicylic acid (ASA, aspirin) metabolism. Its kinetic parameters ($t_{1/2}$, V_d, Cl_T, PB) are dose or concentration dependent. As the concentration increases, the apparent $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \downarrow \rightarrow$, and $PB \downarrow$.</p> <p>See Tables II-5 and II-6.</p> <p>Salicyluric acid and salicylphenolic glucuronide undergo dose/concentration-dependent metabolism and follow Michaelis-Menten kinetics. The renal excretion of salicylic acid is dependent on urinary pH. Severe toxicity is characterized by CNS disturbances (EEG abnormalities), skin eruptions, and marked alterations in acid-base balance. A respiratory alkalosis is produced that may revert to metabolic acidosis, particularly in young children. High doses of the drug may increase liver enzymes and may cause acidosis. The estimated minimum lethal adult dose is 15 g. Cases of leukopenia and thrombocytopenia have been reported.</p> <p>Interferences: Colorimetric and fluorometric methods are subject to a number of interferences but are useful as emergency procedures. Diflunisal interferes with the FPIA and colorimetric methods. Other drugs and metabolites may interfere. Lipemic, icteric, or hemolyzed specimens may yield false-positive results with colorimetric methods.²¹</p> |
| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Dialysis</i></p> <p>Hemodialysis (—)</p> <p>Peritoneal (—)</p> <p>Drug interactions: Sulindac may increase plasma concentrations of digoxin, lithium, and methotrexate. Aspirin may decrease plasma concentrations of sulindac's active sulfide metabolite. Probenecid increases plasma concentrations of sulindac and its sulfone metabolite.</p> | <p>Sulindac is metabolized to its active metabolite sulindac sulfide, which has a longer $t_{1/2}$ than the parent drug. The active metabolite reaches its maximum plasma concentration in ~2 hr. A 200-mg dose of sulindac leads to a mean C_{max} of 4 mcg/mL [11 $\mu\text{mol/L}$], 3 mcg/mL [8 $\mu\text{mol/L}$], and 2 mcg/mL [6 $\mu\text{mol/L}$] for sulindac and its sulfide and sulfone metabolites, respectively. Oxidation to the sulfone metabolite is irreversible, whereas reduction to sulindac sulfide is reversible. Adverse effects include dyspepsia, gastrointestinal distress, flatulence, diarrhea, constipation, vomiting, gastritis, peptic ulceration, and gastrointestinal bleeding. Cases of leukopenia, thrombocytopenia, hemolytic anemia, nephrotoxicity, and hepatotoxicity have been reported.</p> |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|--|
| Metabolism Hepatic (small amount) Excretion Urine (primary) Feces (secondary) Disease or condition Renal dysfunction: $t_{1/2}\uparrow$, $Cl_T\downarrow$ Age Elderly: $t_{1/2}\uparrow$ Dialysis Hemodialysis (+) | Ofloxacin is a fluoroquinolone antibiotic. Therapeutic concentrations of ofloxacin are dependent on the MIC of the organism being treated. MIC values ≤ 4 mg/L [$\times 2.77 = \leq 11$ $\mu\text{mol/L}$] are considered susceptible to moderately susceptible. Doses of 200 mg, 400 mg, and 600 mg lead to plasma C_{max} of 1.6–2.2 mg/L [4.4–6.1 $\mu\text{mol/L}$], 3.2–4.3 mg/L [8.9–11.9 $\mu\text{mol/L}$], and 6.7–8.1 mg/L [18.5–22.4 $\mu\text{mol/L}$], respectively. Interferences: The presence of other antimicrobials may interfere with bioassays. |

Drug interactions: Ofloxacin is a strong inhibitor of CYP1A2. Ofloxacin may increase the effects of CYP1A2 substrates like theophylline and fluvoxamine.⁷ Sucralfate, aluminum- and magnesium-containing antacids, and products containing calcium, iron, or zinc may decrease the bioavailability of ofloxacin. Probenecid may decrease renal clearance of ofloxacin. Ofloxacin may increase the degree of warfarin-induced anticoagulation.

DRUG DISPOSITION****REMARKS AND INTERFERENCES**

Drug interactions: Probenecid may impair glucuronide conjugation.

9. Bennett WM, Aronoff GR, Golper TA, et al: *Drug prescribing in renal failure: dosing guidelines for adults*, ed 2, Philadelphia, 1991, American College of Physicians.

Metabolism

Hepatic, CYP2D6 (major)

Drug interactions: CNS depressants, MAO inhibitors, general anesthetics, and tricyclic antidepressants may potentiate the effect.

Oxycodone, a synthetic phenanthrene-derivative opiate agonist, is used orally for the management of moderate to moderately severe pain. Sustained-release oxycodone (Oxycontin) is often abused by crushing the tablet to release the oxycodone and negate the sustained-release properties. CNS depressant and adverse reactions are similar to those of morphine. Naloxone is a specific antidote. Most immunoassays for opiates do not detect oxycodone.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <i>Metabolism</i> Hepatic | Pancuronium is used as a nondepolarizing neuromuscular blocking agent as an alternative to d-tubocurarine. The drug is metabolized to less active products, which are typically measured along with the parent drug. |
| <i>Excretion</i> Renal, biliary | |
| <i>Disease</i> Uremia: $t_{1/2}\uparrow$, $Cl_T\downarrow$ | |
| Cirrhosis: $V_d\uparrow$, $t_{1/2}\uparrow$, $Cl_T\downarrow$ | |
| <i>Age</i> Elderly: $t_{1/2}\uparrow$, $Cl_T\downarrow$ | |

| | |
|-------------------------------|---|
| <i>Metabolism</i> Hepatic | Paraldehyde may be occasionally used to treat delirium tremens and seizures. |
| <i>Excretion</i> Pulmonary | Adverse effects include disagreeable taste, irritation to the throat and stomach, cyanosis, cough, hypotension, respiratory depression, acidosis, hepatitis, nephrosis, pulmonary hemorrhage and edema, and dilation of the right ventricle. About 25% is excreted via the pulmonary route, leading to a characteristic smell to the breath. Some GC methods measure the paraldehyde metabolite, acetaldehyde. |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <p><i>Metabolism</i></p> <p>Hepatic, CYP2D6</p> <p>Saturatable kinetics</p> <p><i>Excretion</i></p> <p>Renal, fecal</p> | <p>Paroxetine belongs to the group of antidepressants that act by selectively inhibiting the reuptake of serotonin. Of this group, it is the most potent but least selective in its interaction with serotonin inhibition. It also exhibits an affinity for the muscarinic acetylcholine receptors similar to that of the tricyclic antidepressants. Paroxetine is also used to treat other psychiatric disorders such as obsessive compulsive disorders, panic disorders, posttraumatic stress disorders, anxiety, and premenstrual dysphoric disorder. Common side effects include anorexia, gastrointestinal disturbances, insomnia, sweating, blurred vision, drowsiness, tachycardia, and weight gain. More serious adverse effects reported include suicide, hyponatremia, and seizures. Potentially lethal events include the development of serotonin syndrome and the syndrome of inappropriate antidiuretic hormone secretion.</p> |

Drug interactions: Paroxetine is a potent inhibitor of CYP2D6 (the same CYP responsible for its metabolism) and possibly CYP3A4. Multiple drug interactions are possible.

| | |
|--|--|
| <p><i>Metabolism</i>⁵</p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Urine</p> <p><i>Disease or condition</i></p> <p>Renal dysfunction: $t_{1/2} \uparrow$</p> | <p>Pentamidine is primarily used in the treatment of infections caused by <i>Pneumocystis carinii</i>. A 3-mg/kg dose led to a mean C_{\max} of 249 ± 80 ng/mL [$\times 2.94 = 732 \pm 235$ nmol/L].⁸ Although <5% of pentamidine is renally excreted, the $t_{1/2}$ is prolonged in dialysis patients (i.e., terminal half-life measured after the last dose of a multiple dosing regimen: 12.5 ± 2.4 days).⁸ Heating pentamidine samples to 56°C for 1 hr (for HIV deactivation) does not appear to affect pentamidine concentrations. Adverse effects are rare with inhaled pentamidine therapy; chest pain, congestion, cough, dyspnea, wheezing, pharyngitis, skin rash, and extrapulmonary pneumocytosis have been reported. Adverse effects reported with parenteral administration include hyperglycemia, hypoglycemia, leukopenia or neutropenia, elevated liver function tests, nephrotoxicity, thrombocytopenia, anemia, pancreatitis, and hypotension. Rapid intravenous infusion may lead to a precipitous decrease in blood pressure.</p> |
| <p>Drug interactions: Pentamidine is a major substrate of CYP2C19 and weakly inhibits CYP2C8/9, CYP2C19, CYP2D6, and CYP3A4. CYP2C19 inducers like carbamazepine, phenytoin, and rifampin may decrease the effects of pentamidine. CYP2C19 inhibitors like fluconazole, fluvoxamine, gemfibrozil, isoniazid, and omeprazole may increase the effects of pentamidine.⁶ Concomitant usage of cisapride or droperidol with pentamidine may lead to an increased risk in cardiotoxicity.⁷</p> | |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|---|
| <p><i>Metabolism</i></p> <p>Hepatic, CYP3A4</p> <p>Drug interactions: CYP3A4 inhibitors may increase the levels/effects of PCP. PCP is a weak inhibitor of CYP3A4. Acidification of the urine (pH <5) significantly accelerates renal excretion.</p> | <p>Phencyclidine (PCP) is a highly lipophilic basic amine and appears to affect all neurotransmitter systems. Side and toxic effects include staggering gait, slurred speech, nystagmus, increased sensitivity to stimuli, mood elevation, agitation, increased blood pressure, hallucinations, paranoia, violent behavior, status asthmaticus, and coma. For workplace and drug abuse testing, the widely accepted immunoassay and GC-MS confirmation cutoff concentration to separate positive and negative specimens for phencyclidine (PCP) is 25 ng/mL [103 nmol/L]. At these cutoff concentrations, PCP may generally be detected in urine for 1-2 wk after use.</p> <p>Alternative matrices used for nonfederally regulated workplace drug testing and being considered for regulated testing include hair, oral fluid, and sweat.</p> |

| Acidic urine increases the rate of urinary excretion of phenethylamines. | <p>These drugs are CNS stimulants, anorexigenic agents (fenfluramine, phenmetrazine), antidepressants (methylphenidate, tranylcypromine), decongestants (ephedrine, phenylpropanolamine), and hallucinogenics (<i>p</i>-methoxyamphetamine, methylenedioxamphetamine). Many are widely abused. They are metabolized to a variety of derivatives that are largely inactive and primarily excreted by the kidney. Adverse effects include insomnia, agitation, nervousness, hyperthermia, hyperventilation, hypertension, and convulsions.</p> <p>The cross-reactivity of amphetamine immunoassays varies. A positive result may be obtained with those of broader cross-reactivity when some phenethylamines such as ephedrine, pseudoephedrine, phenylpropanolamine, or phen- termine are present in sufficient concentration. See also <i>Amphetamine</i>.</p> |

| Metabolism Hepatic Excretion Urine Bile/feces | Phensuximide is used in the treatment of seizure disorders. Limited pharmacokinetic and pharmacologic data are available. Side effects include nausea, vomiting, anorexia, headache, fatigue, lethargy, and dizziness. The drug is rapidly absorbed and converted to the <i>N</i> -desmethyl metabolite, an active species. |
| Drug interactions: Carbamazepine, phenobarbital, phenytoin, and primidone may increase phensuximide metabolism. Valproic acid may increase or decrease plasma concentrations. | |

| | |
|--|---|
| Metabolism: Hepatic Excretion: Urine Disease or condition Hepatic: $t_{1/2} \uparrow$, $Cl_T \downarrow$, PB \downarrow Renal: $t_{1/2} \downarrow$; $V_d \uparrow$, 1.0 L/kg; PB \downarrow , 70% Pregnancy: $Cl_T \uparrow$, PB \downarrow Burn: PB \downarrow Age Premature: $t_{1/2} \uparrow$, $Cl_T \downarrow$ Newborn: $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \downarrow$, PB \downarrow Child: $t_{1/2} \downarrow$, $V_d \uparrow$, $Cl_T \uparrow$ Elderly: $Cl_T \downarrow$ Dialysis Hemodialysis (–) Peritoneal (–) | Phenytoin is commonly used in the treatment of seizure disorders. It is also used unlabeled/investigational as an antiarrhythmic agent (class Ib) for ventricular arrhythmias. The metabolism and, consequently, $t_{1/2}$ of phenytoin are dose/concentration dependent, making it difficult to titrate dosages based on serum or plasma concentration. Dosage increases should therefore be made gradually. Wide interproduct variability in the bioavailability of the drug has been demonstrated. ⁷ Side effects include behavioral changes, GI symptoms, gingival hyperplasia, osteomalacia, megaloblastic anemia, hepatic disturbances, and hirsutism. Rare cases of thrombocytopenia, leukopenia, and eosinophilia have been reported. Additionally, when IV is given at an excessive rate (>50 mg/min; >198 $\mu\text{mol/min}$), cardiovascular collapse or CNS depression has been reported. Total phenytoin plasma concentrations >35 mcg/mL [>139 $\mu\text{mol/L}$] have been shown to precipitate seizure activity. Free drug may be monitored using ultracentrifugation to separate free drug from bound drug. Phenytoin binding is temperature dependent, and the therapeutic range for free drug is 1–2 mg/L at 37° C at a total level of 10–20 mg/L. The free drug level is the pharmacologically active fraction, and various factors like hypoalbuminemia, uremia, illness, pregnancy, and coadministration of other drugs can unpredictably affect the free fraction in these states. Thus free drug level may be indicated in these complex clinical cases. ⁸ |
| Drug interactions: Phenytoin is a major substrate of CYP2C8/9 and CYP2C19 and a minor substrate of CYP3A4. It induces CYP2B6, CYP2C8/9, CYP2C19, and CYP3A4 strongly. ⁶ Metabolism is inhibited by isoniazid, chloramphenicol, dicumarol, warfarin, disulfiram, and amiodarone. | Phenytoin is a known human teratogen. Serum levels should be kept as low as possible, consistent with the desired therapeutic effect, in women at risk for pregnancy and throughout pregnancy. |

Thioridazine and imipramine may increase plasma phenytoin concentrations. More rapid metabolism is induced by carbamazepine, clemastine, and cimetidine.

**FACTORS INFLUENCING
DRUG DISPOSITION**
REMARKS AND INTERFERENCES

azepam, phenobarbital, rifampin, and alcohol. Salicylates, phenylbutazone, and sulfonylureas compete with phenytoin for serum protein binding sites. The end result is decreased total serum concentration of phenytoin with no change in free phenytoin concentration or pharmacologic effect. Sodium valproate displaces phenytoin from protein binding sites and inhibits its metabolism. Antacids and sucralfate may decrease phenytoin bioavailability.

Interferences: The principal metabolite of phenytoin, 5-(*p*-hydroxyphenyl)-5-phenylhydantoin, may cross-react with phenytoin in the RIA and EIA methods. Cross-reactivity may be of significance only in the presence of renal failure.

Specimens should not be collected in serum separator tubes because phenytoin may be extracted by the separator gel.

This β -blocker possesses intrinsic sympathomimetic activity (ISA). Plasma concentrations that produce minimal β -blockade vary widely. Therapeutic concentrations are expressed in terms of plasma concentrations that produce β -blockade. However, there is no good correlation between plasma concentrations and therapeutic effects. Thus determination of serum levels is of limited value in routine therapy. Slight but persistent increases in liver enzymes, without injury, have been reported.

Drug interactions: Pindolol is a major substrate of CYP2D6. CYP2D6 inhibitors like chlorpromazine, fluoxetine, miconazole, quinidine, quinine, and ritonavir may increase the effects of pindolol.⁷ Phenothiazines and cimetidine may increase plasma concentrations, probably through an effect on hepatic metabolism.

Drug interactions: Sedative effects and/or respiratory depression may be additive with CNS depressants.

Prazepam is a prodrug for desmethyldiazepam and undergoes almost complete first-pass dealkylation by the liver to form desmethyldiazepam. Side effects include confusion, ataxia, excitement, agitation, transient hypotension, vertigo, drug fever, GI upset, leukopenia, and liver disease. Abuse of prazepam may be monitored by urine drug testing with a benzodiazepine-class assay; confirmation of positive specimens is performed by GC-MS determination of the metabolite oxazepam. Procainamide is a class IA antiarrhythmic agent. The drug undergoes metabolism by hepatic *N*-acetyltransferase. This metabolic reaction is distributed bimodally (i.e., as rapid and slow metabolizers). *N*-acetylprocainamide (NAPA), procainamide's major metabolite, possesses significant pharmacologic activity and should also be monitored. Side effects include anorexia, nausea, vomiting, diarrhea, giddiness, psychosis, hallucinations, mental depression, and cardiac anomalies. Hypersensitivity reactions include fever, hepatic disturbances, agranulocytosis, and SLE-like syndrome. Slow acetylators are at a greater risk of developing procainamide-induced SLE.

Procainamide concentrations should be evaluated in conjunction with NAPA concentrations. When the sum of procainamide and NAPA concentrations is >25-30 mcg/mL, the risk of toxicity is increased.

See also *N-Acetylprocainamide* (active metabolite).

| Metabolism Plasma hydrolysis | Procaine is rapidly hydrolyzed in plasma by cholinesterase. Sodium arsenite or echothiopate added to drawn blood minimizes in vitro hydrolysis. Although procaine is rarely administered except as a spinal, topical, or nerve-blocking agent, monitoring the drug or metabolite assesses the degree of peripheral absorption. Adverse effects include hypertension, tachycardia, mydriasis, and convulsions. Colorimetric methods are nonspecific. |
| Excretion Urine | |
| Drug interactions: Concurrent use of succinylcholine with procaine can lead to prolonged neuromuscular blockade. Procaine is a PABA derivative, and it can antagonize sulfonamide's antibacterial effects. ⁵ | |

Hemodialysis (—)

Propranolol may be displaced from protein binding sites by plasticizers in collection devices. Propranolol undergoes significant first-pass metabolism. 4-Hydroxypropranolol, its principal metabolite, is reported to have equal β -blocking activity. It is found in animals only after oral administration. Chronic oral dosing results in a saturation of this pathway, causing decreased Cl_T and increased F. Protein binding is strongly correlated to α_1 -acid glycoprotein (protein often elevated in response to inflammation or body stress).⁹ Side effects include nausea, vomiting, mild diarrhea, constipation, hallucinations, nightmares, insomnia, lassitude, dizziness, depression, heart failure, increased airway resistance, and, rarely, hepatic disturbances with liver enzyme increases. There is no good correlation between plasma concentrations and therapeutic effects.

The fluorometric method is associated with high and variable backgrounds.

Drug interactions: Propranolol is a major substrate of CYP1A2 and CYP2D6 and a minor substrate of CYP2C19 and CYP3A4. It inhibits CYP1A2 and CYP2D6 weakly.⁷ Aluminum hydroxide gel appears to decrease GI absorption. Barbiturates and other enzyme inducers may enhance propranolol metabolism. Phenothiazines and cimetidine may increase plasma concentrations, probably through an effect on hepatic metabolism.⁸

Drug interactions: Quinidine is a major substrate of CYP3A4 and a minor substrate of CYP2C8/9 and CYP2E1. It strongly inhibits CYP2D6 and CYP3A4 and weakly inhibits CYP2C8/9.¹¹ Enzyme inducers (rifampin, phenobarbital, and phenytoin) may enhance the metabolism of quinidine. Quinidine levels may also be decreased by disopyramide and nifedipine. Plasma quinidine levels may be increased during coadministration with amiodarone, cimetidine, verapamil, and thiazides. Renal quinidine clearance can be enhanced by acidifying the urine. Antacids (sodium bicarbonate, acetazolamide) tend to increase renal reabsorption and elevate plasma or serum concentration.

Quinidine is a class IA antiarrhythmic agent. The drug is metabolized to 3-hydroxyquinidine, 2'-oxoquinidinone, and O-desmethylquinidine. These metabolites may contribute to quinidine's antiarrhythmic and toxic effects. Earlier studies should be interpreted with caution because of lack of assay specificity. The optimal therapeutic concentration of quinidine is method dependent because of interference by metabolites and by dihydroquinidine. The optimal therapeutic concentration by double-extraction fluorometric procedures and by EIA is 2-5 mcg/mL [6.2-15.4 $\mu\text{mol/L}$]; by liquid chromatography it is 1.5-4.5 mcg/mL [4.6-13.9 $\mu\text{mol/L}$]. Side effects include nausea, vomiting, diarrhea, tinnitus, loss of hearing, blurring of vision, headache, diplopia, photophobia, hypotension, tachycardia, ventricular fibrillation, hemolytic anemia, leukopenia, thrombocytopenia, hepatic dysfunction, and cardiac anomalies.

Quinidine may be displaced from protein binding sites by plasticizers in collecting devices. Increased protein binding of quinidine to α_1 -acid glycoprotein after myocardial infarction or other stressful events may increase total quinidine concentrations.¹² However, free quinidine concentrations may remain unaltered, and dosage adjustment may not be warranted.

Interferences: EIA and FPIA assays do not differentiate quinidine from dihydroquinidine (a naturally occurring analog of quinidine found in all drug products). Metabolites of quinidine may cross-react and cause false increases in quinidine concentration. (This may be important in renal failure patients, who have lower clearance of quinidine and metabolites.) The fluorometric technique without extraction and separation is nonspecific and should not be used. Quinine and other drugs that fluoresce may interfere.¹³

Specimens should not be collected in serum separator tubes because quinidine may be extracted by the separator gel.

Excretion

Feces (primary)

Saliva (secondary)

Urine (secondary)

Quinine is metabolized by oxidation to more polar metabolites. Blood concentrations up to 11 mcg/mL [33.9 μ mol/L] are found in heroin fatalities. An old treatment for malaria, this drug is encountered now as a diluent in heroin and as a flavoring agent in beverages. Adverse effects include tinnitus, headache, nausea, visual disturbances, decreased body temperature, coma, and death as a result of respiratory arrest.⁷ Cases of hemolysis and thrombocytopenia may occur.

Drug interactions: Quinine is a minor substrate of CYP1A2, CYP2C19, and CYP3A4. It strongly inhibits CYP2D6, moderately inhibits CYP2C8/9, and weakly inhibits CYP3A4.⁶ Plasma quinine concentrations may be decreased by rifampin. Aluminum-containing antacids may decrease or delay absorption of quinine.

Interferences: TLC can separate quinine and quinidine.⁸ In most other assays, quinidine is not differentiated.

See Table II-6.

| <i>Metabolism</i> Hepatic <i>Excretion</i> Renal, fecal <i>Disease</i> Renal: $t_{1/2} \uparrow$, $Cl_T \downarrow$ Cirrhosis: $t_{1/2} \uparrow$, $F \uparrow$ <i>Age</i> Elderly: $t_{1/2} \uparrow$, $Cl_T \downarrow$ <i>Dialysis</i> Hemodialysis (+) Peritoneal (+) | Ranitidine is a histamine H_2 -receptor antagonist that is administered orally or parenterally. Reported adverse effects include severe headaches, mental confusion, visual disturbances, hepatotoxicity, and hepatitis. Rare cases of leukopenia and aplastic anemia have been reported. A slight increase in liver enzymes and serum creatinine may be found. Wide interpatient variability exists in the relationship between plasma concentration and degree of acid suppression. |

Drug interactions: Inhibitor of CYP2D6.

Ranitidine increases the bioavailability of midazolam. Ranitidine appears to compete with the renal tubular secretion of procainamide (decreasing the renal clearance of procainamide).

Metabolism

Hepatic, CYP2D6, and *N*-dealkylation
Active metabolite: 9-hydroxyrisperidone

Drug interactions: Numerous drug interactions are reported.

Risperidone, a benzisoxazole derivative, is an antipsychotic used to treat bipolar disorders and schizophrenia. The drug has high affinity for serotonin and dopamine D2 receptors, as well as α_1 - and α_2 -adrenoreceptors. Common adverse effects include agitation, extrapyramidal symptoms, somnolence, rhinitis, dizziness, anxiety, and constipation. More serious adverse effects reported include neuroleptic malignant syndrome, seizures, stroke, syncope, and transient ischemic attacks.

Salicylamide is an analgesic-antipyretic compound; however, because of its questionable effectiveness the drug is seldom used (even in over-the-counter preparations). It is not metabolized to salicylate but to inactive metabolites that are rapidly excreted. See *Nonsteroidal Antiinflammatory Drugs, Salicylic Acid*.

| Cyclosporine clearance may be reduced if taken concurrently with sirolimus. ⁶ Concomitant therapy with other immunosuppressives, especially CsA, will lead to higher sirolimus trough levels. ⁹ | |

| | |
|--|--|
| | <p>Strychnine is an alkaloid found in the seeds of <i>Strychnos nuxvomica</i>. By blocking the inhibition of postsynaptic neuronal impulses, it stimulates the CNS. For this reason, it was historically used as a tonic and, more recently, to treat impotence, nonketotic hyperglycemia, and sleep apnea. It is no longer used in medicine. Currently, its primary use is as a pesticide. Additionally, it has been found as an adulterant of street drugs such as cocaine, heroin, and amphetamines, and of alternative (herbal) medications. Ingestion of 60-100 mg may result in death (adult). Tachycardia, hypertension, tachypnea, convulsions, and hyperthermia may be seen. The patient usually remains alert during the convulsions. Twenty percent of strychnine is excreted in urine unchanged. Little metabolic information is available. Strychnine may be found in urine, blood, gastric fluid, and organs, but the levels do not correlate well with clinical toxicity.</p> |

|--|---|--|
| <i>Metabolism</i> Hepatic | Tacrolimus is a macrolide compound with potent immunosuppressant properties. It is used for prophylaxis of organ rejection in adult patients undergoing liver or kidney transplantation and in pediatric patients undergoing liver transplantation. It has also been used to prevent rejection in heart, small bowel, and allogeneic bone marrow transplant patients and to treat autoimmune diseases. Tacrolimus is extensively metabolized in the liver to 10 possible metabolites, and some of the major metabolites are active. ¹⁰ | |
| <i>Excretion</i> Feces (primary) Urine (secondary) | | |
| <i>Dialysis</i> Hemodialysis (–) Peritoneal dialysis (–) | | |
| Drug interactions: Tacrolimus is a major substrate and weak inhibitor of CYP3A4. Concomitant use with cyclosporine or ganciclovir can lead to increased risk of nephrotoxicity. Antacid or sucralfate administration should be separated by at least 2 hr. ⁹ | | |
| Immunoassays typically cross-react with tacrolimus metabolites as compared with LC-MS-MS method that can identify the parent compound. Thus patients with hepatic impairment may show unacceptable bias when drug is determined by immunoassay. ¹² | | |
| Side effects include tremor, headache, diarrhea, hypertension, nausea, and renal dysfunction. ¹⁰ | | |

| | |
|---|---|
| <i>Metabolism</i> | Teicoplanin is an investigational glycopeptide antibiotic. An initial 6 mg/kg dose generally led to a C_{\max} of 60 mg/L and a C_{\min} of 4 mg/L. ⁶ Mean steady-state concentrations for C_{\max} and C_{\min} after 6 mg/kg/day are 75 mg/L and 14 mg/L, respectively. ⁶ Trough concentrations should be kept >5 mg/L for most gram-positive infections and not <10 mg/L for severe infections. Teicoplanin is a mixture of six components designated A2-1, A2-2, A2-3, A2-4, A2-5, and A3-1. It is highly soluble in water at pH >7, but it is poorly soluble in organic solvents. Only the HPLC method is able to discern the components of teicoplanin. |

|--|---|
| <p><i>Metabolism</i></p> <p>Hepatic, CYP1A2, and CYP2E1</p> <p><i>Disease</i></p> <p>Cirrhosis: $t_{1/2}\uparrow$, $Cl_T\downarrow$, PB\downarrow</p> <p>CHF: $Cl_T\downarrow$</p> <p>Pulmonary edema: $t_{1/2}\uparrow$, $Cl_T\downarrow$</p> <p>Cor pulmonale: $t_{1/2}\uparrow$, $Cl_T\downarrow$</p> <p>Obesity: $t_{1/2}\uparrow$, $Cl_T\downarrow$ (based on IBW)</p> <p>Smoking: $Cl_T\uparrow$</p> <p><i>Age</i></p> <p>Premature: $t_{1/2}\uparrow$, $V_d\uparrow$, $Cl_T\downarrow$</p> <p>Neonate: $t_{1/2}\uparrow$, $Cl_T\downarrow$, PB\downarrow</p> <p>Elderly: PB\downarrow</p> <p><i>Dialysis</i></p> <p>Hemodialysis (+)</p> <p>Hemoperfusion (+)</p> <p>Peritoneal (–)</p> | <p>Theophylline is a methylxanthine that acts to relax bronchial smooth muscles. It is used in the treatment of chronic asthma and bronchospasm associated with chronic obstructive pulmonary disease. The metabolism of theophylline to 3-methylxanthine (its primary metabolite) follows Michaelis-Menton kinetics.</p> <p>Adverse and toxic effects are usually concentration related and include nausea, vomiting, tachycardia, arrhythmias, and seizures. In the premature neonate, ~50% of theophylline is excreted unchanged in the urine, and the remaining 50% undergoes metabolism to caffeine and 1,3-dimethyluric acid. In older children and adults, caffeine is a minor metabolite.</p> <p>See also <i>Caffeine</i> (related compound).</p> |

Drug interactions: Numerous drug interactions are reported because of induction or inhibition of metabolic pathways. There is evidence that theophylline blocks adenosine receptors, thereby decreasing the sedative effects of the benzodiazepines. Theophylline decreases the clearance of cetirizine.

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|--|
| <i>Metabolism</i> | Thiopental is administered as an intravenous, ultrashort-acting anesthetic agent. When used to induce coma, cardiac and pulmonary support are required. |
| Hepatic | Thiopental is highly lipid soluble and distributes extensively to adipose tissue. |
| <i>Excretion</i> | Pentobarbital is a metabolite and may be detected at low concentrations. The principal toxic effect involves CNS depression. At high concentrations, e.g., 60 mcg/mL [248 μ mol/L], the elimination kinetics become nonlinear, and a $t_{1/2}$ of 60 hr may be seen. Rare cases of hepatic dysfunction have been reported. |

| Neonates: $t_{1/2} \uparrow$ | |
| Children: PB \downarrow | |

| | |
|-------------------|---|
| <i>Metabolism</i> | Thioridazine is a neuroleptic agent used to treat psychosis, schizophrenia, and some anxiety disorders. The drug is extensively metabolized in the liver and gastric mucosa. At least two pharmacologically active metabolites are known, with mesoridazine having greater activity than the parent compound. Kinetic values are not well defined. Side effects may include orthostatic hypotension, CNS effects (particularly extrapyramidal effects), pigmentation, and cardiac effects. Cases of anemia, leukopenia, and thrombocytopenia, as well as rare cases of hepatic dysfunction, have been reported. |

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|--|
| <i>Metabolism</i> Hepatic <i>Excretion</i> Biliary | Thiothixene is a potent antipsychotic drug used to treat schizophrenia and other psychotic disorders. Adverse effects include sedation, extrapyramidal effects, tachycardia, and hypotension. The exact mechanism of action of thiothixene is unknown. |

| | |
|--|---|
| <i>Metabolism</i> Hepatic (minimal amount) <i>Excretion</i> Urine (primary) Bile/feces (secondary) <i>Disease</i> Renal Oliguria: $t_{1/2} \uparrow$, 15.7 hr; $Cl_T \downarrow$ Oliguria and hepatic dysfunction: $t_{1/2} \uparrow$, 23.2 hr <i>Dialysis</i> Hemodialysis (+) ⁶ Peritoneal (+) ⁷ | Values for half-life and total body clearance of ticarcillin correlate strongly with creatinine clearance. Hepatic dysfunction appears to be significant only in the presence of renal failure. Side effects include hypersensitivity, hepatotoxicity, electrolyte and acid-base disturbances, hematological disorders (including diathesis and reversible granulocytopenia), and neurotoxicity (observed with plasma concentrations ≥ 320 mcg/mL [$\times 2.60 = \geq 832$ μ mol/L] and with CSF concentrations ≥ 37 mcg/mL [≥ 96 μ mol/L]). Ticarcillin has a lighter sodium load than carbenicillin. It generally possesses at least 2-4 times more activity against <i>Pseudomonas</i> than carbenicillin. |
|--|---|

Drug interactions: Probenecid delays active renal tubular secretion and increases the drug's half-life. Concomitant administration of ticarcillin and an aminoglycoside can lead to loss of aminoglycoside efficacy.⁶

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|---|---|
| <i>Metabolism</i> Hepatic <i>Excretion</i> Bile/feces (primary) Urine (secondary) <i>Dialysis</i> Hemodialysis (—) | Plasma concentrations that produce minimal β -blockade vary widely. Therapeutic concentrations are expressed in terms of plasma concentrations producing β -blockade. However, there is no good correlation between serum concentrations and therapeutic effects. Thus determination of plasma levels is of limited value in routine therapy. |
| <p>Drug interactions: Timolol is a major substrate of CYP2D6 and weakly inhibits it. CYP2D6 inhibitors like chlorpromazine, fluoxetine, miconazole, quinidine, quinine, and ritonavir may increase the effects of timolol.⁸ Phenothiazines and cimetidine may increase plasma concentrations, probably because of their effect on hepatic metabolism.</p> | |

| | |
|---|--|
| <i>Metabolism</i> None <i>Excretion</i> Urine (primary) Bile/feces (secondary) <i>Disease</i> Renal: $t_{1/2} \uparrow$, $Cl_T \downarrow$ Burns: $Cl_T \uparrow$ Cystic fibrosis: $Cl_T \uparrow$ Obesity: $V_d \uparrow$ (based on IBW), $Cl_T \uparrow$ (based on IBW) | Tobramycin is an aminoglycoside antibiotic. Therapeutic and toxic concentrations should be considered highly variable, differing with each patient's condition. Penicillin and its derivatives inactivate tobramycin in vivo and in vitro. A definitive cause-and-effect relationship between the trough concentration and the incidence of nephrotoxicity has not been established. Cl_T and $t_{1/2}$ are strongly correlated with the glomerular filtration rate. Side effects include vestibular and auditory dysfunction, nephrotoxicity, and neuromuscular blockade. Very rare cases of anemia, leukopenia, and thrombocytopenia have been reported. |

|---|---------------------------|
|---|---------------------------|

Drug interactions: Concurrent use of cimetidine or rifampin can result in a decreased to-cainide effectiveness. Administering lidocaine to a patient receiving tocinide can result in serious CNS toxicity.⁹

| | |
|--|--|
| <i>Metabolism</i> Hepatic, CYP2C9 | Tolbutamide is the shortest acting and least potent of the sulfonylureas used to treat type II diabetes. The drug is useful in treating diabetic patients with renal disease because it is extensively metabolized to inactive metabolites. Adverse effects include transient leukopenia, thrombocytopenia, hemolytic anemia, pancytopenia, gastrointestinal disturbances, headache, tinnitus, photosensitivity, allergic skin reactions, and intolerance to alcohol. Most serious effects include hypoglycemia (may progress to coma and death) and hepatic dysfunction. See Table II-5. |

Dialysis⁹

Hemodialysis (+)¹⁰

Peritoneal (+)¹¹

Valproic acid is commonly used in the treatment of seizure disorders. Studies in epileptic patients suggest a $t_{1/2} \downarrow$, $V_d \uparrow$, and $Cl_T \uparrow$ compared with healthy control populations. Side effects are of low incidence but may include anorexia, nausea, vomiting, CNS depression, leukopenia, thrombocytopenia, and hepatotoxicity. Protein binding is concentration dependent and will decrease with increasing concentration. Free drug concentrations may be monitored using ultrafiltration to separate free from bound drug. Therapeutic free valproic acid serum concentrations are 2.5-11 mcg/mL [17-76 $\mu\text{mol/L}$]. Patients on poly-medicines or homeopathic medicines and those who are hypoalbuminemic may have elevated free drug level.^{13,14}

Valproic acid is a known human teratogen that produces a 10-fold increase in the incidence of neural tube defects. Its use in women at risk for pregnancy must be weighed against its benefits. Fetuses exposed during organogenesis should be studied for evidence of neural tube defects.

See Table II-5.

Drug interactions: Valproic acid is a minor substrate of CYP2A6, CYP2B6, CYP2C8/9, CYP2C19, and CYP2E1. It weakly inhibits CYP2C8/9, CYP2C19, CYP2D6, and CYP3A4. It weakly induces CYP2A6.¹² Enzyme inducers (i.e., phenobarbital, phenytoin, and carbamazepine) have been shown to increase the metabolism of valproic acid. Mefloquine may decrease valproic acid plasma concentrations.

Vancomycin is primarily used in the treatment of infections caused by β -lactam-resistant, aerobic gram-positive bacteria. Therapeutic and toxic concentrations are not well established. Vancomycin declines in a triexponential manner with distribution not completed until ~ 6 hr. Therefore specimens drawn before 6 hr may not be representative of the drug's concentration in the target organ. Half-life and total body clearance are strongly correlated with creatinine clearance. Primary side effects include ototoxicity, nephrotoxicity, leukopenia, eosinophilia, thrombocytopenia, and hypersensitivity reactions. Liver enzymes may be increased.

Appropriate dosing and monitoring may be challenging in patients with end-stage renal disease (ESRD). Various polyclonal immunoassays may give falsely higher results because of cross-reactivity with vancomycin pseudometabolite, termed vancomycin crystalline degradation product (CDP), which accumulates in renal failure patients.¹⁻³ Immunoassays using monoclonal antibodies (EMIT or FPIA Vancomycin II), are less sensitive to CDP cross-reactivity.³

Drug interactions: Coadministration of vancomycin and an aminoglycoside can lead to increased risk of nephrotoxicity. Concomitant use of vancomycin with metformin can lead to increased plasma concentration of metformin. There may be an increased risk of bleeding when vancomycin is used in patients taking warfarin.⁸

| FACTORS INFLUENCING DRUG DISPOSITION | REMARKS AND INTERFERENCES |
|--|---|
| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Urine (primary)</p> <p>Bile/feces (secondary)</p> <p><i>Disease</i></p> <p>Cirrhosis: $t_{1/2} \uparrow$, $V_d \uparrow$, $Cl_T \downarrow$</p> <p><i>Age</i></p> <p>Elderly: $Cl_T \downarrow$</p> <p>Drug interactions: Verapamil is a major substrate of CYP3A4 and a minor substrate of CYP1A2, CYP2B6, CYP2C8/9, CYP2C18, and CYP2E1.⁷ Verapamil causes a significant increase in plasma digoxin concentrations and also appears to inhibit the metabolism of quinidine. Concomitant administration of verapamil and β-blockers may result in severe cardiovascular depression. Rifampin may decrease the bioavailability of verapamil.</p> | <p>Verapamil, a calcium channel blocker, is a racemic compound. The dextrorotary and levorotary isomers show pronounced differences in disposition and first-pass metabolism. Two- to three-fold greater plasma verapamil concentrations are required after oral dosing, as compared with IV dosing, to elicit the same increase in A-V conduction time. This is caused by presystemic stereoselective elimination of the pharmacologically more active levorotary isomer.</p> <p>Nonlinear accumulation is observed after multiple oral dosing. Norverapamil, the <i>N</i>-demethylated metabolite, possesses some vasodilatory activity. Verapamil is bound to albumin (60%), but α_1-acid glycoprotein accounts for ~70% of protein-binding variability. Side effects include rare hepatic dysfunction and eosinophilia. Constipation is the common side effect. Toxic effects include nausea, weakness, bradycardia, hypotension, and A-V block.</p> <p>Interferences: After oral administration, fluorescent methods are unsatisfactory for quantitation of verapamil plasma concentrations because of the appearance of fluorescent metabolites.</p> |
| <p><i>Metabolism</i></p> <p>Hepatic, CYP2C9, and isomers are metabolized through different pathways.</p> <p><i>Disease</i></p> <p>Renal failure: $V_d \uparrow$, $Cl_T \uparrow$, PB \downarrow</p> <p>Cancer: PB \downarrow</p> <p>Drug interactions: Multiple drug interactions occur because of competition for albumin binding sites, polymorphisms of CYP2C9, and induction or inhibition of metabolic pathways.</p> | <p>Warfarin, an anticoagulant, is administered as a racemic mixture. The S-enantiomer is two to five times more active than the R-enantiomer. The pharmacologic effect (indicated by the prothrombin time) is more useful for the purpose of drug monitoring than is serum concentration. Plasma protein binding is a major determinant of warfarin elimination and an important cause of interindividual variations in drug clearance. An increase in the free fraction of warfarin in plasma will result in increased drug clearance. Factors that enhance hypoprothrombinemia include inadequate diet, disease of the small bowel, disease associated with vitamin K deficiency, hepatic disease, chronic alcoholism, fever, hyperthyroidism, and aging. Factors decreasing pharmacologic response to warfarin include pregnancy, hypothyroidism, and hereditary resistance. Side effects include hemorrhage, anorexia, nausea, vomiting, and various cutaneous lesions (purpura, urticaria, and alopecia). Reversible increases in liver enzymes</p> |

| <p><i>Metabolism</i></p> <p>Hepatic</p> <p><i>Excretion</i></p> <p>Bile/feces (primary)</p> <p>Urine (secondary)</p> <p><i>Disease or condition</i></p> <p>Cirrhosis: $t_{1/2} \uparrow$, $Cl_T \downarrow$, $C_{max} \uparrow$</p> <p>Uremia: $t_{1/2} \uparrow$, $Cl_T \downarrow$, $C_{max} \uparrow$</p> <p>Drug interactions: Zidovudine is a minor substrate of CYP2A6, CYP2C8/9, CYP2C19, and CYP3A4.¹² Probenecid increases plasma zidovudine (AZT) concentrations. Morphine may inhibit hepatic glucuronidation. Clarithromycin may decrease peak plasma concentrations and area under the curve.</p> | <p>The therapeutic range of zidovudine, a synthetic dideoxynucleoside antiviral agent, is not well established. Serum containing HIV may be treated to kill the virus before AZT concentrations are measured. Heating HIV-infected serum to 58–60° C for 1 hr will reduce virus reverse transcriptase activity below detectable levels with no effect on AZT.¹³ Spills on work surfaces may be disinfected with bleach or 70% ethanol.¹³ No extraction of samples is required for RIA. Measurement of intracellular forms of AZT may be important in the near future. Only HPLC allows for concurrent measurement of AZT-glucuronide (GAZT).</p> <p>Patients started on antiretroviral AZT therapy are typically monitored for CD4 counts and HIV viral loads. The HIV viral load should be measured at 4 wk after initial therapy, again at 8–12 wk, and approximately every 6–8 wk until the viral load is undetectable on standard assays (<50 copies/mL). At that point, the viral load can be measured every 3 mo.¹²</p> <p>Interferences: The antibodies used in RIA and FPIA show limited cross-reactivity with GAZT. DPV requires a fasting specimen because lipemia interferes. Because AZT has activity against Enterobacteriaceae and may interfere with antimicrobial susceptibility testing, metronidazole may interfere with the peak of β-hydroxyethyl-theophylline used as an internal standard in HPLC.</p> |

TABLE IV-1 DRUG SCREENS RECOMMENDED TO SUPPORT POISONED PATIENTS PRESENTING TO EMERGENCY DEPARTMENT (NACB LABORATORY MEDICINE PRACTICE GUIDELINES)¹

STAT (TURNAROUND TIME <1 HR) QUALITATIVE URINE TOXICOLOGY ASSAYS

Cocaine
 Opiates
 Barbiturates
 Amphetamines (based on regional prevalence of abuse)
 Propoxyphene (based on regional prevalence of abuse)
 PCP (based on regional prevalence of abuse)
 Tricyclic antidepressants (TCAs) (in conjunction with ECG)

STAT (TURNAROUND TIME <1 HR) QUANTITATIVE SERUM TOXICOLOGY ASSAYS

Acetaminophen (paracetamol)
 Lithium
 Salicylate
 Cooximetry for oxygen saturation, carboxyhemoglobin, and methemoglobin
 Theophylline
 Valproic acid
 Carbamazepine
 Digoxin
 Phenobarbital (if urine barbiturates positive)
 Iron
 Transferrin (or UIBC assay if transferrin not available)
 Ethyl alcohol
 Methyl alcohol (realistic turnaround time: 2-4 hr; not needed in countries where these agents not available)
 Ethylene glycol (realistic turnaround time: 2-4 hr; not needed in countries where these agents not available)

TABLE IV-2 **WORKPLACE DRUG SCREENS**

FEDERALLY REGULATED (SAMHSA, FORMERLY NIDA)

| DRUGS (CLASS) | SCREENING CUTOFF, NG/ML | CONFIRMATION CUTOFF, NG/ML |
|--------------------|----------------------------|--|
| Amphetamines | 1000 | Amphetamine 500 Methamphetamine 500 (plus amp ≥200) |
| Cannabinoids | 50 | THC metabolite 15 |
| Cocaine metabolite | 300 | Benzoylcegonine 150 |
| Opiates | 2000 | Codeine 2000 Morphine 2000 6-acetyl morphine (6-AM) 10 |
| PCP | 25 | 25 |

SPECIMEN VALIDITY TESTING

Creatinine, specific gravity (when creatinine <20 mg/dL), pH, nitrites, oxidizing agents

NONFEDERALLY REGULATED

Testing typically includes the drugs listed above (“NIDA 5”) plus combinations of drugs listed below. Cutoffs may be at lower levels, and samples analyzed may include alternative matrices such as hair, oral fluid, or sweat instead of urine.

- Barbiturates
- Benzodiazepines
- Ethyl alcohol
- Methadone
- Methaqualone
- Propoxyphene

SECTION V

CLINICAL MICROBIOLOGY

A: MICROBIOLOGY TESTS

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Acid-Fast Stain for Mycobacteria (Ziehl-Neelsen, Fluorochrome Stain, AFB Stain, TB Stain) ¹⁻⁴ (See <i>Mycobacteria Culture</i> .) | Specimen used for culture. | <p>Smears should preferably be prepared from concentrated specimens, screened using a fluorochrome stain, and results reported with quantitation within 24 hr of specimen receipt. Organisms appear yellow to orange using a fluorochrome stain. Specimens and colonies may also be stained using either a Cold Kinyoun or Ziehl-Neelsen stain. Acid-fast organisms appear as red-staining bacilli. Observation of only one or two acid-fast bacilli per specimen should warrant specimen recollection. Smears should only be used as an adjunct to culture.</p> <p>Smears for AFB may not correlate with corresponding cultures and/or molecular tests. For example, some mycobacteria other than tuberculosis do not stain well, if at all, with a fluorochrome stain, yet they will grow in culture. In contrast, some organisms may be detected on the smear that are not recovered in culture, either because of too harsh decontamination procedure, the patient may be receiving antituberculous medications, or the culture conditions may not be appropriate for the species of mycobacterium present. Therefore AFB smears can be used as a quality control measure.</p> <p>The presence of acid-fast bacilli may be caused by pathogenic or saprophytic acid-fast bacilli. In urine, for example, the saprophyte <i>Mycobacterium smegmatis</i> may appear in the acid-fast preparation.</p> <p>An AFB stain may be used to monitor patients on therapy for purposes of infection control.</p> |
| Acid-Fast Stain (Modified) for <i>Nocardia</i> spp. ¹ | Same specimen used for <i>Nocardia</i> culture. | <p><i>Nocardia</i> spp. are partially acid-fast, requiring a shorter or less harsh decolorization process than that of the <i>Mycobacterium</i> spp. The acid-fast characteristic is variable; thus a negative result may not rule out <i>Nocardia</i>. The stain is most helpful in distinguishing <i>Nocardia</i> spp. from <i>Actinomyces</i> spp.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|---|---|
| <i>Actinomyces</i> spp. ¹ Culture | Exudate from draining sinuses; pleural fluid; and tissues such as lung. See <i>Anaerobic Culture</i> for specific requirements for anaerobic cultures. Notify the laboratory if actinomycosis is suspected. | <p>Actinomycosis is a suppurative disease characterized by the formation of draining sinuses and the presence of granules ("sulfur" granules) composed of aggregates of filamentous, branching, gram-positive bacteria in the exudate. The granules are ~5 mm in diameter, firm in consistency, and usually white or yellow in color. Infections generally involve areas in the respiratory tract because the organisms involved are part of the normal oral flora. An association has also been made between infections and the use of IUDs.</p> <p>Suppurative exudates and pleural fluid should be examined for the presence of granules, as should the gauze dressings applied to draining sinus tracts. Other organisms, however, such as <i>Staphylococcus aureus</i> and agents of fungal mycetoma, can also produce granules. Specimens may require up to 14 days of incubation in culture for isolation of <i>Actinomyces</i> spp., and thus the laboratory should be made aware of the organisms that are suspected to provide for this extended anaerobic incubation. <i>Actinomyces</i> spp. are part of the normal flora of the oral cavity; therefore the isolation of the organism without a corresponding clinical picture of actinomycosis should be evaluated carefully. A Gram stain of the exudate, with or without granules, is helpful in making a presumptive identification of the <i>Actinomyces</i> spp. <i>Nocardia</i> can also produce granules, but <i>Nocardia</i> spp. may be ruled out by performing a partial acid-fast stain. A direct fluorescent antibody stain for <i>Actinomyces</i> spp. is available at certain large referral laboratories for use in selected specimens.</p> |

| Adenovirus, Direct Test for Antigen ^{1,2} <i>EM, IFA, LA, EIA, DNA probe, DNA amplification</i> | Respiratory secretions, urine, tissue, and stool. Rectal swabs are not acceptable. If not processed immediately, freeze at -70° C. | <p>EM and IEM have been used to detect adenovirus in a variety of specimens, including respiratory secretions, urine, stool and tissue. Adenovirus types 40 and 41 associated with infantile gastroenteritis were first identified by this method.</p> <p>IFA are widely used for direct detection of adenovirus and other pathogens in respiratory specimens.</p> <p>EIA and LA have been shown to be very useful for detection of enteric adenovirus antigens in stool specimens. Similarly, DNA probe assays have been successful for detection of enteric adenoviruses.</p> <p>Several PCR-based assays that amplify hexon gene for detection of all adenoviruses are available in some reference laboratories.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

| | | |
|---|--|--|
| Adenovirus Serological Test ^{1,2} <i>CF, EIA, HI, NT</i> | Serum, acute and convalescent. See <i>General Information</i> . | <p>Adenoviruses are endemic throughout the year among all age groups but are most common among children. They are responsible for many clinical syndromes including lower and upper respiratory tract infections (primarily school-aged children but accounting for ~2-5% of all ages); >50% of the cases of acute respiratory disease in military recruits; a pertussis-like syndrome; pharyngoconjunctival fever, epidemic keratoconjunctivitis, acute hemorrhagic conjunctivitis, cystitis, infantile gastroenteritis, meningitis, and diseases of the immunocompromised patient (diarrhea, pneumonia, and upper respiratory tract infections).</p> <p>There are 51 known serotypes of adenovirus. Serotypes 1-8, 11, 21, 31, 35, 37, 40, and 41 are responsible for the majority of clinical diseases. Serotypes 31, 40, and 41 are specifically associated with infantile gastroenteritis.</p> <p>Serological diagnosis of adenovirus includes the genus-specific CF and EIA assays and the type-specific HI and NT assays. In most cases, the genus-specific assays are sufficient. EIA is more sensitive, standardized, and automated than CF and hence the more widely used assay. HI and NT are usually available only in larger reference laboratories.</p> <p>IgM assays may be more appropriate for the diagnosis of acute disease, but these are not commercially available. Serological procedures alone may not be used to establish the diagnosis without concomitant viral isolation or associated epidemiologic factors. Infants and children may especially present with falsely negative serological tests. Antigen detection, specifically for serotypes 40 and 41, is available for cases of infantile gastroenteritis and may enhance sensitivity and specificity.</p> |

| Agar Screening Tests ¹⁻⁴ <i>High-level aminoglycoside resistance (HLR) Enterococci (See Disk Diffusion.)</i> | <i>Enterococcus</i> isolate. | BHI broth containing 500 mg/mL of gentamicin or 1000 µg/mL of streptomycin is inoculated with a 0.5 McFarland suspension of <i>Enterococcus</i> spp. that has been prepared by direct colony or broth inoculation according to CLSI (NCCLS) guidelines. As an alternative, BHI agar containing 500 mg/mL of gentamicin or 2000 µg/mL of streptomycin is spot inoculated with 10 µL of a 0.5 McFarland suspension of <i>Enterococcus</i> spp. Any growth in the BHI broth or >1 colony or a haze of growth on agar after 24 hr of incubation indicates resistance, i.e., the agent will |
|---|------------------------------|--|

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--------------------------------------|---|
| Agar Screening Tests—CONT | | |
| | | <p>not be synergistic with cell-wall active agents. Enterococci that are resistant to gentamicin should be considered resistant to tobramycin and amikacin. Streptomycin must be tested separately because resistance is mediated by a different mechanism.</p> <p>Aminoglycosides have poor activity against enterococci and cannot be used as monotherapy. However, an aminoglycoside plus a cell wall-active agent such as a penicillin or vancomycin act synergistically to enhance bacterial killing and may be used together in treating systemic enterococcal infections such as endocarditis. Acquired aminoglycoside resistance in enterococci accounts for high-level aminoglycoside resistance (HLR) and generally corresponds to MICs above concentrations normally tested, e.g., $\geq 1000 \mu\text{g/mL}$ for streptomycin and $\geq 500 \mu\text{g/mL}$ for gentamicin.</p> |
| Vancomycin-resistant <i>Enterococci</i> (VRE) Screen (See Minimum Inhibitory Concentration; Etest.) | <i>Enterococcus</i> isolate. | <p>One to 10 μL of a 0.5 McFarland enterococcal suspension is spot inoculated onto brain heart infusion (BHI) agar containing 6 $\mu\text{g/mL}$ of vancomycin to screen for VRE. Isolates that grow on the screening plate should be confirmed by MIC using CLSI guidelines.</p> <p>Presence of VRE does not indicate infection because this organism may colonize the intestine. Positive results should be telephoned immediately to infection control to ensure that the patient is placed on appropriate precautions. Patients infected or colonized with high-level (Van A phenotype) and moderate- to high-level vancomycin (Van B phenotype) resistant <i>Enterococci</i> spp. should be placed on Contact Precautions in contrast to those with an isolate expressing intrinsic low-level resistance caused by vanC gene.</p> <p>Three negative specimens collected on separate days are generally required to remove previously positive patients from Contact Precautions. For surveillance purposes, specimens submitted for <i>Clostridium difficile</i> testing may be used to screen for VRE.</p> |
| Oxacillin/ Methicillin-resistant <i>Staphylococcus aureus</i> (ORSA/MRSA) Screen | <i>S. aureus</i> isolate. | <p>Mueller Hinton Agar (MHA) with NaCl and 6 $\mu\text{g/mL}$ of oxacillin is spot inoculated with a 1-μL loop of 0.5 McFarland prepared by direct colony inoculation or from broth. Growth of >1 colony indicates oxacillin/methicillin resistance. The isolate should be considered resistant to all B-lactam agents.</p> <p>Positive results should be telephoned immediately to infection control. Patients colonized or infected with ORSA should be placed on Contact Precautions. Three negative specimens collected on separate days are generally required to remove a patient from isolation. For surveillance purposes, specimens should be collected from the anterior nares and the site of infection as appropriate.</p> |

| <i>Vancomycin-resistant S. aureus</i> Screen | | BHI agar containing 6 µg/mL of vancomycin is spot inoculated as above with a 0.5 McFarland suspension prepared by direct colony inoculation or from broth. Growth of >1 colony indicates high-level vancomycin resistance. Results should be telephoned immediately to infection control to ensure appropriate precautions are followed, and to other individuals as appropriate. Identification and at least two other AST methods should be used to confirm the results, and isolates should be sent to a reference laboratory for confirmation. This procedure may not detect VISA using the new CLSI breakpoint of 4-8 mcg/mL. |

| Amebiasis Serological Test ^{1,2} | Serum, acute and convalescent, 1-3 wk apart. | Test is used to support the diagnosis of amebiasis caused by <i>Entamoeba histolytica</i> . Eighty-five percent of patients with proven intestinal amebiasis will have a detectable antibody response, whereas 99% of those with extraintestinal disease will demonstrate antibodies. Persons with <i>E. dispar</i> (morphologically indistinguishable from <i>E. histolytica</i>) do not produce detectable antibodies. Titers may persist for up to 10 years after cure of invasive amebiasis. A fourfold increase in titer is the most indicative result. False-positive results in amebic liver disease rarely occur when the titers are ≥1:256. With acute presentation of <7 days, however, antibody tests may be negative; repeat examination in 7 days should be positive in amebic liver disease. ³ |
| <i>IHA, EIA, IFA</i> | | |
| <i>EIA for antigen</i> ² | Stool. See <i>Cultures, General Instructions</i> , above. | Test demonstrates antigen of <i>E. histolytica</i> in the stool, if present. Sensitivity has been reported between 87-100% and specificity at 97-99%. |

| Amebic Meningoencephalitis Primary Test (PAM; <i>Naegleria</i> , <i>Acanthamoeba</i> , Free-Living Pathogenic Ameba) ^{1,2} <i>Direct examination, culture</i> | CSF. See <i>CSF Culture, Routine</i> . Tissue, e.g., brain, lung, and corneal biopsy. See <i>Miscellaneous Sites Culture, Routine</i> . Do not refrigerate or freeze specimens. Notify the laboratory before collection so that specific media can be prepared if culture is requested. | <p><i>Naegleria</i> spp. can cause a fulminant and often fatal meningoencephalitis in children and young adults, called primary amebic meningoencephalitis (PAM). CSF examination may have a normal or slightly decreased glucose and increased protein similar to bacterial meningitis. Gram stains will be negative. The portal of entry is through the nasal passages after exposure to the organisms in fresh water (lakes or swimming pools).</p> <p><i>Acanthamoeba</i> spp. cause subacute or chronic meningoencephalitis with focal granulomatous lesions in the brain referred to as granulomatous amebic encephalitis (GAE). The route of invasion into the CNS is believed to be hematogenous from a primary focus in the respiratory tract or skin. No exposure to water sources is necessary preceding the infection, and most patients have reported previous trauma or underlying diseases, such as alcoholism, diabetes, Hodgkin's disease, pregnancy, or steroid use. In addition, keratitis and corneal ulcerations have been produced by species of <i>Acanthamoeba</i> after use of soft or hard contact lenses (primarily daily-wear or extended-wear soft lenses).</p> <p>For either etiology, direct examination of the CSF or involved tissue is part of the diagnostic workup. CSF should be placed on a slide, not in a counting chamber, because amebas resemble leukocytes. Stains such as Giemsa or Trichrome for <i>Naegleria</i>, and GMS, calcofluor white, or PAS for <i>acanthamoeba</i> should be utilized because Gram staining is not useful. Cultures for both of these amebas may be done on nonnutrient agar to which a suspension of <i>Escherichia coli</i> or <i>Enterobacter aerogenes</i> has been overlaid. These cultures are examined daily for 7 days.</p> <p>All personnel working with specimens that might contain these amebas should wear surgical masks and gloves, and processing should be carried out in a biological safety cabinet to ensure safety. Serological tests are not widely available.</p> |

|----------------------------------|---|---|
| Anaerobic Culture ¹⁻⁸ | Body fluid aspirate, e.g., pleural, synovial, peritoneal, and pericardial (See <i>Body Fluid Culture, Routine</i>); surgical tissue or biopsy sample, sulfur granules (See <i>Miscellaneous Site Culture, Routine</i>). | <p>Transport all specimens for anaerobes in an anaerobic transport vial or container as soon as possible for processing, e.g., ≤10 min to ≤30 min for <1.0 mL to 1.0 mL of aspirated fluid, respectively. Tissue may be placed in a sterile container, which is then placed in a sealable plastic bag with an anaerobic atmosphere. Large specimen volumes and large pieces of tissue may be placed in a sterile container and hand-delivered to the laboratory for immediate processing. Ensure that the sample is collected from the active site of infection. Do not refrigerate specimens.</p> <p>The microbiology laboratory should provide guidelines for the collection of acceptable specimens for anaerobic culture. Unacceptable specimens from sites that normally contain anaerobic flora should be rejected, e.g., throat, rectal, cervicovaginal swabs, sputum, and feces, because they may give misleading results.</p> <p>Clinical clues to the presence of an anaerobic infection include putrid-smelling discharge; infections adjacent to a mucosal surface; presence of gas or infection in necrotic avascular tissue; Gram stain revealing mixed, pleomorphic bacterial flora; negative aerobic culture with positive Gram stain; infection following the use of aminoglycosides; septic thrombophlebitis; and a clinical setting suggestive of an anaerobic infection, e.g., septic abortion or after gastrointestinal surgery.</p> <p>A Gram stain and culture for aerobes should be performed whenever an anaerobic culture is requested. Specimens collected on swabs are inferior and should only be used in rare instances when a very small quantity of specimen is obtained. At least two swabs, one for a Gram stain and the other to inoculate media, should be submitted in an anaerobic transport container. Processing of swab specimens should be limited to a Gram stain and solid media. Abbreviated identification schemes may be used to report results, e.g., “anaerobic gram-negative bacilli.” A disclaimer should be recorded on reports generated from swab specimens that state the preferred specimens for optimal recovery of anaerobes are fluid and tissue.</p> |

| Antideoxyribonuclease B Serological Test (ADN-B Titer, Anti-DNase Titer, Antibody Titer for Group A Beta-Hemolytic Streptococci) ^{1,2} | Serum | More reliable than the antistreptolysin O (ASO) in identifying patients with pyoderma or post-impetigo nephritis caused by group A streptococcus (GAS). Used to identify GAS infection in patients who lack documentation of recent infection but present with nonsuppurative sequelae of <i>Streptococcus pyogenes</i> infection, e.g., acute rheumatic fever, Sydenham's chorea, and acute glomerulonephritis. Serum antibody titers do not peak until 4-6 wk after onset and, in contrast to antistreptolysin O (ASO), remain elevated for several months. Therefore this test may be used to support a diagnosis of Sydenham's chorea because of the associated latency of 3-12 mo between infection and onset of disease. Measurement of ASO and DNase B antibodies reduces the percentage of false-negative results. Values of 1:60, 1:170, and 1:85 are considered normal for preschool children, school-aged children, and adults, respectively. |

|---|--------------------------------------|---|
| Antistreptolysin O Titer (ASO Titer, Antibody Titer for Group A B-Hemolytic Streptococci) ¹ | Serum | <p>The most common acute group A <i>Streptococcus pyogenes</i> (GAS) suppurative illnesses are pharyngitis and pyoderma, and the most common nonsuppurative complications are acute rheumatic fever, Sydenham's chorea, and acute glomerulonephritis. Rheumatic fever may occur after pharyngitis but not after pyoderma, whereas glomerulonephritis may follow either pharyngitis or pyoderma. Although culture provides a definite laboratory diagnosis during a suppurative GAS illness, serologic tests are useful in providing evidence of antecedent streptococcal infections.</p> <p>Increased ASO titers are found in ~85% of patients with rheumatic fever or pharyngitis. The test is less reliable compared with the anti-DNase B test in patients with post-pyoderma nephritis. Titers increase as early as 1 wk after infection, peak in 3-5 wk, and return to baseline in 6-12 mo. A value of ~166 Todd units (TU) is considered normal; however, each laboratory should establish the upper limit of normal applicable to the region. An increase in titer of at least two dilution increments over a 1- to 2-wk period is of greater clinical value than results obtained from one random sample.</p> |

| Bartonella Culture ¹⁻⁵ | Blood collected in EDTA or Isolator tube (Wampole); lymph node, liver, spleen, and skin tissue. | <p>The most common cause of cat scratch disease (CSD) is <i>Bartonella henselae</i>. Humans become infected after the bite or scratch of a cat, a natural reservoir of <i>B. henselae</i>, or as a result of autoinoculation when scratch-infected flea blood or feces enters into their skin. Approximately 80% of cases are in individuals aged <21 yr. Patients most commonly present with tender, regional lymphadenopathy. Most immunocompetent patients experience a self-limiting infection. In 14% of patients with CSD, complications will develop, including Parinaud's ocular syndrome, hepatosplenic abscesses, encephalopathy, endocarditis, myocarditis, and occasionally osteomyelitis. In immunodeficient patients, <i>B. henselae</i> and <i>B. quintana</i> may cause a vascular proliferative disease known as bacillary angiomatosis, peliosis hepatis, or bacteremia.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Bartonella—CONT

Routine bacterial cultures are not suitable for recovery of *Bartonella* spp. because the majority of isolates require >7 days of incubation. Culture is indicated in the following settings: atypical cat scratch disease; fever of unknown origin with a cat exposure history; fever or lymphadenitis in an immunocompromised patient; and bacillary angiomatosis and peliosis. Culture is not recommended for most cases of cat scratch disease. Specimens should be collected before the initiation of antimicrobial therapy.

Blood cultures from patients with endocarditis are rarely positive; however, *Bartonella* may be recovered from patients with other bacteremic conditions. *B. henselae* is susceptible to concentrations of sodium polyanethol sulfonate (SPS) found in commercial blood culture media. Therefore the use of lytic blood culture systems, such as the Isolator system, is preferred for optimal recovery.

Culture may require up to 30 days.

Histological examination, PCR, and/or serology are generally more productive. A fourfold or greater increase in IgG-specific antibody titer between a serum specimen collected early in the course of infection and a second specimen collected in 7-8 wk is becoming a mainstay of diagnosis for CSD and CNS infection.

See *Bartonella* serological test.

|---|--|---|
| <p>Blood Culture¹⁻²⁶</p> <p>(See <i>Brucella Culture</i>.)</p> <p>Routine</p> | <p>Recommended volume of blood is based on age/body weight. Children aged <1 yr (<9 lb) = 1.0 mL; 1-6 yr 1 mL for each year divided between two blood cultures; children (30-80 lb) = 10-20 mL divided between two blood cultures; adults and older children (>80 lb) = at least 30-40 mL divided between two blood cultures. The minimum collection is two draws totaling 20-30 mL of blood. Bottles should not be overfilled because excess leukocytes may cause automated systems to flag bottles as positive.</p> | <p>Blood volume is the most important factor in optimizing the recovery of pathogens. With the exception of neonates, two or three separate venipunctures are required to document sepsis and to distinguish a significant positive from contamination. If bacterial endocarditis is present, most patients will have a continuous bacteremia and all blood cultures will be positive. For other sources of bacteremia, there may be intermittent shedding of organisms into the blood, requiring three or more blood cultures.</p> <p>There are no standards to support collection of blood at specific intervals, e.g., 30 min apart. Two blood cultures should be collected consecutively from separate venipuncture sites from patients requiring immediate delivery of antimicrobial therapy.</p> <p>Blood cultures should be collected just before the next dose in patients receiving antimicrobial agents.</p> <p>To decrease blood culture contamination, specimens should preferably be drawn from a peripheral site rather than from an indwelling catheter port. Meticulous collection of blood using either tincture of iodine or chlorhexidine skin disinfectant should be used according to manufacturer's directions. The septum of the blood culture bottles should also be disinfected. If poor access requires that blood be drawn through a catheter port, the second blood culture should be collected by venipuncture. The catheter hub connection should be scrubbed with two separate</p> |

Blood Culture—CONT

70% alcohol pledgets and allowed to air dry. Once the tubing or cap of the catheter is disconnected, a syringe is used to collect 3 mL of discard blood in adults and 0.2 mL in children. Blood is then collected for culture through the hub using a new syringe.

Each automated blood culture system uses different media formulations. Media with resins or dematiaceous earth may be used to enhance recovery of organisms, particularly from patients who have already received antimicrobials. Sodium polyanethol sulfonate (0.025-0.05% SPS) is generally incorporated into media as an anticoagulant, antiphagocytic agent, and antimicrobial neutralizing agent. However, SPS may inhibit recovery of *Neisseria* spp., *Peptostreptococcus*, and *Gardnerella vaginalis*. Depending on the patient population, each blood collection is generally inoculated into an aerobic, anaerobic, and/or fungal blood culture bottle. The aerobic bottle should be inoculated first. Anaerobic bottles should be included when collecting blood from febrile neutropenic patients and patients with diabetes or wound infections. Alternatives to automated blood culture systems include manual broth cultures, biphasic media with agar and broth in one bottle, and lysis-centrifugation for colony quantitation. When using the later system, both pediatric and adult collection tubes are available for blood processing before inoculation onto solid media.

Blood cultures should not be refrigerated, even if there is a delay in sending the inoculated bottles to the laboratory. Preferably, incubation and monitoring of blood cultures should begin within 4 hr of specimen collection. Although credentialing agencies may require routine monitoring of blood cultures for 5 days, some laboratories have performed documented verification studies supporting reduction in monitoring to 3 or 4 days. Positive blood cultures are Gram stained and called to the ordering physician or patient-care nurse as soon as possible, and subcultured based on the morphotypes seen on the Gram stain. All blood subcultures should be performed in a biosafety cabinet. Terminal subcultures are not required when using an automated system.

Intense training and annual competency testing of phlebotomy staff are helpful to ensure the appropriate safety precautions are followed, including the use of safety needles, disposal of needles in labeled sharps containers, use of personal protective equipment, handwashing after phlebotomy, reducing blood culture contamination rate to $\leq 3\%$, and increasing the true-positive rate to 6-12%. Each laboratory that processes blood cultures should develop a quality assessment program that tracks the contamination rate for the hospital (and possibly for each unit and phlebotomist) and the true-positive rate.

|---|--|--|
| Blood Culture for Fungus ¹⁻³ | <p>Blood, 5 mL per 40-mL blood culture bottle (with SPS) or 10 mL per Wampole Isolator tube.</p> <p>See <i>Blood Culture, Routine</i>.</p> | <p>The presence of fungi in blood may be an indication of invasive or disseminated fungal disease. An increase in fungemia is found in patients receiving immunosuppressive agents or hyperalimentation and in patients with malignancies or implanted intravascular devices.</p> <p>Continuous monitoring blood culture systems with media to enhance fungal recovery, biphasic blood culture systems and lysis centrifugation systems (Isolator) are available. The ratio of blood to culture medium in bottles should be 1:5-1:10. A higher concentration of blood may reduce the chance of isolating the organism; therefore blood culture bottles should not be overfilled.</p> <p>All of the above methods provide adequate detection of bloodstream infections caused by yeasts. The lysis centrifugation system is the most sensitive for the recovery of filamentous fungi, especially <i>Histoplasma capsulatum</i> and other dimorphic fungi.</p> <p>A single negative culture does not rule out the diagnosis of fungemia. Recovery of fungi increases with volume of blood cultured. Because fungal sepsis may be intermittent, at least two samples should be separately collected and cultured. Cultures are usually held up to 4 wk, and isolation may require >2 wk.</p> |

| Body Fluid Culture, Routine ¹⁻³ and for Fungus | <p>Amniotic, cul-de-sac, synovial, pericardial, peritoneal, and pleural.</p> | <p>As much fluid as possible should be collected for culture by percutaneous aspiration using a safety needle and syringe. Culture of more than one large volume specimen processed both aerobically and anaerobically tends to increase the possibility of obtaining a laboratory diagnosis. Synovial and peritoneal fluid should be inoculated directly into aerobic and anaerobic blood culture bottles, as opposed to using the lysis-centrifugation method. Some fluid should be retained for Gram stain preparation. Small volume fluid may be submitted in an anaerobic transport vial, sterile screw-capped container, sterile blood collection tube, preferably without an anticoagulant, or in a Leur Lok-capped syringe that is hand-delivered to the laboratory for immediate processing.</p> <p>Drainage fluids in place >2 days, specimens collected on swabs, and routine cultures for acid-fast bacilli (AFB) and fungi are discouraged. Do not refrigerate specimens.</p> |
| Fungus ^{4,5} | <p>Body fluids, e.g., synovial, pleural, pericardial.</p> | <p>Swab specimens are not recommended. Submit as much fluid as possible for culturing fungi. Collection of fluids with heparin may prevent clotting. Alternatively the lysis centrifugation (Isolator) system may be used.</p> |

|--|--|--|
| <i>Bordetella pertussis</i> (Whooping Cough) ¹⁻⁶ | Nasopharyngeal specimens, e.g., nasal aspirates or washings, collected within 4 wk of onset. | Direct examination of nasopharyngeal specimens by DFA can be of value, especially in seriously ill children, because the results are rapidly available. The technique should be used in conjunction with appropriate cultures, owing to frequent false-negative results. Likewise, cross-reactions with other organisms, including <i>Legionella</i> spp., may give false-positive results. Serological studies to demonstrate antibodies are generally not helpful in diagnosing pertussis. |
| Molecular methods, e.g., PCR, are now considered the test of choice because of the higher sensitivity and more rapid turnaround time to results compared with culture. In June 1996, the | Vacuum-assisted nasopharyngeal aspirates, bulb- or syringe-collected nasopharyngeal washings, or transtracheal aspirates provide a higher yield on culture than swabs. If nasopharyngeal swabs are collected for culture, calcium alginate or Dacron tip swabs on a fine flexible wire should be used. Use | The diagnosis of whooping cough is frequently made on clinical grounds alone. Although knowledge of contact is helpful, the appearance of a paroxysmal cough and the typical “whoop” after a brief upper respiratory tract syndrome are strongly suggestive. In infants aged <6 mo, however, the typical whoop may be absent, whereas in adults, they generally only demonstrate catarrhal symptoms, a mild bronchitis, or both. Adults may serve as the reservoir for <i>B. pertussis</i> . |

| <i>Bordetella pertussis</i>—CONT | | |
| Council for State and Territorial Epidemiologists revised laboratory criteria to include positive PCR assays for <i>B. pertussis</i> as the official laboratory confirmation of pertussis. If PCR is not available, culture and direct fluorescent antibody (DFA) tests may be used. | <p>flocked pernasal swabs if nasopharyngeal swab specimens are collected for PCR assays. With the patient's head immobilized, gently insert a swab through one nostril to the posterior nasopharynx, rotate, and leave in place 15-30 sec. A second swab should be collected in the same manner for a DFA test for pertussis. Kits including the appropriate swabs, appropriate transport medium, slides for DFA, and instructions for specimen collection have been found to be helpful to ensure that specimens are collected in a manner that will maximize the sensitivity of culture and DFA.</p> <p>Specimens should be transported to the laboratory without delay. If ≤ 2 hr, use 0.5-1% casein hydrolysate (casamino acid) solution; if < 24 hr, use Amies medium with charcoal; and if > 24 hr but ≤ 3 days, use Regan-Lowe transport medium. Specimens should be plated as soon as possible on Regan-Lowe charcoal agar and incubated at 35°C without 5% CO_2 for 5-12 days. Colonies consistent with <i>B. pertussis</i> are confirmed using DFA.</p> | |

|---|--------------------------------|---|
| <i>Borrelia burgdorferi</i> Serological Test^{1,2} | | <p><i>Borrelia burgdorferi</i> is the etiologic agent of Lyme disease, an inflammatory disorder transmitted to humans by the tick <i>Ixodes scapularis</i>. The vector is prevalent in the northeastern and western U.S. IFA or EIA tests can be performed to detect IgM and IgG antibodies. False-negative results may occur early in disease. Serum cross-reactivity occurs with other spirochetal diseases, e.g., syphilis and relapsing fever and in patients with infectious mononucleosis and bacterial endocarditis.</p> <p>A two-step protocol is currently recommended for the testing of patients with suspected Lyme disease. Serum specimens should first be evaluated with a sensitive EIA or IFA. Specimens positive or equivocal by this test should be further evaluated using Western blot.</p> <p>Western immunoblotting is most frequently used as a supplemental test for equivocal and positive EIA or IFA results. It is not a quantitative test and should only be used to test specimens containing a significant amount of antibody. Ten proteins are currently recognized as useful in Lyme disease serodiagnosis. Positive blots are interpreted as follows:</p> <p>IgM: 2 of 3 of the following bands—21/25, 39, and 41</p> <p>IgG: 5 of the following 10 bands—18, 21/25, 28, 30, 39, 41, 45, 58, 66, and 93</p> |

|---|---|--|
| <i>Brucella</i>¹⁻⁶ (See <i>Blood Cultures</i> .) | Blood or bone marrow: acute and convalescent serum specimens. | <i>Brucella</i> is a fastidious, slow-growing, gram-negative coccobacillus. Individuals at risk include unvaccinated animal workers who contract the organism directly or by aerosol from infected tissue and those who ingest unpasteurized dairy products contaminated with brucellae. This organism is also categorized as a biothreat level B agent having a moderate chance of transmission and morbidity, but a low rate of mortality. Biphasic broth culture bottles are inoculated, inverted twice daily for the first 2 days and then daily for 21 days. If an automated blood culture system is used, bottles should be monitored for 7-10 days. They may require a terminal subculture with incubation in 5-10% CO ₂ for at least 72 hr. Suspected positive cultures should be handled in a biosafety cabinet because of the danger to laboratory workers handling these cultures. Antimicrobial susceptibility tests are unreliable and should not be performed because they erroneously show susceptibility to some agents. As an adjunct to culture, serologic testing such as a Wright's tube agglutination test may be performed. A titer $\geq 1:160$ is considered significant. |
| <ol style="list-style-type: none"> 1. |--|--|---|
| <i>Brucella</i> spp. Serological Test (Agglutinins for Brucellosis) ¹ | Serum, drawn the first week of illness and 3-6 wk later. | <i>Brucella</i> antibodies are detected during the second week in acute cases and peak in 3-6 wk. An increasing titer is considered positive. A single titer of $\geq 1:160$ is suggestive of infection if there is a compatible history. Rarely are antibodies absent in patients with bacteriologically proven disease. Higher titers of IgG than IgM suggest late disease, localized infection, relapse, or chronic infection. The febrile agglutinin test for <i>Brucella</i> is no longer recommended. Detection of <i>Brucella</i> antibodies in CSF indicates central nervous system infection, although results must be interpreted carefully to rule out CSF contamination by blood. Because of cross-reacting antibodies, <i>B. abortus</i> antigen will also detect infection with <i>B. suis</i> and <i>B. melitensis</i> but not with <i>B. canis</i> . |

Candidiasis Serological Tests¹⁻³

Antibody test Serum at onset of disease and
2-3 wk later (if required).

ID, LA, CIE

This assay is used to support the diagnosis of systemic (invasive) candidiasis in the immunocompetent host. Immunosuppressed patients may fail to produce antibody; therefore a negative test does not rule out the presence of disease.

The diagnosis of invasive candidiasis is often very difficult to make in the laboratory. LA, ID, and CIE are available to detect antibodies. The production of ≥ 1 ID precipitin band constitutes a positive test. LA and CIE titers $\geq 1:8$ are presumptive evidence of systemic candidiasis. LA titers of 1:4 and a positive ID test are regarded as evidence of early stages of candidiasis or of colonization with *Candida* spp. A fourfold increase in titer between acute and convalescent sera is presumptive evidence of infection. A fourfold decrease may indicate successful chemotherapy or elimination of the *Candida* colonization. In the immunocompetent host, sensitivity of these antibody tests may reach 80%.

Positive tests may occur as a result of colonization with *Candida* spp. Severe cases of vaginitis or mucocutaneous candidiasis can also produce falsely positive results.

Antigen test Serum

EIA

The assay is used to detect mannan, a candidal antigen, in the sera of patients with invasive candidiasis. This test should be more specific than determination of the presence of candidal antibodies.

Concentrations of >2 ng of serum mannan by EIA is suggestive of invasive candidiasis. Sensitivity in cancer patients is 65-70%, with a specificity of 100%. Mannanemia appears to be transient and is rapidly cleared from the body; therefore it has been recommended that weekly or twice-weekly assays be performed along with routine blood cultures for *Candida* spp. to best detect the presence of the disease in susceptible patients.

|----------------------------------|---------------------|---|
| Catheter Cultures ¹⁻⁶ | Catheter tip, blood | <p>Several methods are available to provide quantitative or semiquantitative colony counts.</p> <p>(1) The semiquantitative roll technique is commonly used to distinguish infection (≥ 15 colonies) from contamination. (2) Quantitative catheter flush and sonication cultures are based on a criterion of ≥ 100 colonies as a reflection of infection. Quantitation with sonication appears to be more sensitive than the semiquantitative method because it detects lumen colonization. A peripheral blood culture should be submitted along with the catheter.</p> <p>Note: Because catheter tip cultures without a concomitant blood culture have a low specificity, full identification and susceptibility testing is not indicated unless specifically requested.</p> <p>(3) To avoid removal of the catheter, two blood specimens (one peripheral and one through the catheter) can be submitted together to compare time to positive signal by an automated blood culture instrument. The infection is considered catheter related if the culture through the catheter is positive with the same organism at least 2 hr before the peripherally collected blood culture.</p> <p>(4) Blood can be collected peripherally and through the catheter and placed in Isolator tubes (Wampole). Catheter sepsis is likely if the blood collected through the catheter has a 5- to 10-fold higher colony count.</p> |

|---|---|---|
| Chlamydia Group Antibody Serological Test [Genus-Specific Test for Psittacosis or Lymphogranuloma Venereum (LGV)] ^{1,3} | Acute and convalescent sera drawn 2–4 wk apart. | A fourfold increase in titer between acute and convalescent sera is necessary for confirmation. A single titer $\geq 1:64$ is considered indicative of psittacosis or LGV. Titers in LGV may not increase in paired sera because most patients are tested after the acute phase of illness. For a diagnosis of psittacosis, previous contact with sick birds or employment in a poultry business or pet shop should be documented. The antigen is not species specific; thus a high titer can support the diagnosis of psittacosis or LGV. Titers $\leq 1:16$ may be found in the general population, depending on geographic location. There is no cross-reactivity of CF antibodies with those of syphilis, yaws, gonorrhea, or leprosy. The CF test is not useful in diagnosing trachoma, adult inclusion conjunctivitis, genital tract infections, or neonatal infections. |

Chlamydophila (Chlamydia) pneumoniae Culture—CONT

purpose transport medium specific for *Chlamydia*, virus, and mycoplasma. Antibiotics should be included in transport medium to reduce bacterial contamination.

1. Murray PR, Baron EJ, Jorgensen JH, et al, editors: *Manual of clinical microbiology*, ed 8, Washington, DC, 2003, ASM Press.

2. Mandell GL, Bennett JE, Dolin R, editors: *Principles and practice of infectious diseases*, ed 5, New York, 2000, Churchill Livingstone.

| | | |
|---|---|---|
| <i>Chlamydophila (Chlamydia) pneumoniae</i> Serological Test ^{1,2} MIF, CF | Acute and convalescent sera drawn 2-4 wk apart. | MIF is more sensitive than CF and has the added advantage of being able to discriminate between chlamydial species. <i>C. pneumoniae</i> differs morphologically and genetically from both <i>C. trachomatis</i> and <i>C. psittaci</i> . It has been associated with pneumonia in young adults, older adults, and individuals with chronic diseases that require hospitalization. The prevalence of antibodies in the adult population is >50%, but antibodies are uncommon in young children. It may be difficult to demonstrate increasing MIF titers because seroconversion may take >4 wk. In primary infection, an IgM titer >1:32 supports the diagnosis. |

| | | |
|--|---|--|
| <i>Chlamydophila (Chlamydia) psittaci</i> Culture ^{1,2} | Respiratory secretions: Lung tissue; transtracheal aspirates, bronchial washings/brushings, and sputum. See <i>Sputum Culture, Routine</i> . Blood. Transport to laboratory immediately in special transport medium such as 2SP or multi-purpose transport medium specific for <i>Chlamydia</i> , virus, and mycoplasma. Antibiotics | <i>Chlamydophila (Chlamydia) psittaci</i> pneumonia is associated with exposure to infected birds. It may be an occupational hazard of pet shop workers, pigeon handlers, or poultry workers. Organism recovery is optimal when specimens are collected during the first 2 wk of illness; however, isolation should only be attempted by laboratories experienced with this organism and with adequate containment facilities. Because isolation of <i>C. psittaci</i> is particularly hazardous to laboratory workers operating under standard conditions, serologic diagnosis is preferred. |

|--------------------------|--------------------------------------|-------------------------------|

Chlamydophila (Chlamydia) psittaci Culture—CONT

should be included in transport medium to reduce bacterial contamination.

1. Murray PR, Baron EJ, Jorgensen JH, et al, editors: *Manual of clinical microbiology*, ed 8, Washington, DC, 2003, ASM Press.
2. Mandell GL, Bennett JE, Dolin R, editors: *Principles and practice of infectious diseases*, ed 5, New York, 2000, Churchill Livingstone.

Chlamydia trachomatis

Serological Test¹⁻⁴

Acute and convalescent sera drawn 2-4 wk apart; single acute serum from infant with pneumonia.

A fourfold increase in titer between acute and convalescent sera is necessary for diagnosis, although very high ($\geq 1:2000$) titers occur in patients with LGV. High IgM titers ($\geq 1:256$) occur in *C. trachomatis* pneumonia in infants.

MIF

MIF is more sensitive than the genus-specific CF test and is specific for *C. trachomatis*; however, a fourfold increase in antibodies is difficult to demonstrate because of the chronic and persistent nature of some infections. Antibodies also may persist from previous infection, and the background prevalence of antibodies will vary among geographic areas.

Chromoblastomycosis Examination and Culture¹⁻³

Aspirates, biopsy material, scrapings, and tissue. Tissue should be placed between sterile gauze, and sterile nonbacteriostatic saline should be added to retain moisture. Send to laboratory immediately. Swab specimens are not effective for specimen collection and should be avoided.

Chromoblastomycosis, or chromomycosis, is a localized chronic mycosis of the skin and subcutaneous tissue leading to the development of warty nodules, tumor-like masses and raised, rough cauliflower-like lesions, primarily on the lower extremities. It is widespread in tropical and subtropical areas among barefooted agricultural workers, although occasionally it is found in temperate climates. The most common agents of chromoblastomycosis include *Exophiala jeanselmei*, *Fonsecaea pedrosoi*, *Fonsecaea compacta*, *Rhinocladiella aquaspersa*, *Phialophora verrucosa*, and *Cladosporium carrionii*.

**Chlamydia trachomatis* Identification can be found in the Appendix on p. 1761.

Chromoblastomycosis Examination and Culture—CONT

Diagnosis can be made by direct microscopic examination of the specimen and visualization of brown “sclerotic bodies.” The presence of sclerotic bodies is diagnostic of chromoblastomycosis. Darkly pigmented hyphae may also be seen near the surface of the lesions. Definitive identification of the organism causing disease requires culture. If cultures are performed, the organisms may require up to 4 wk for growth. Culture is not, however, required for diagnosis.

| <i>Clostridium difficile</i> ¹ Toxin assay | Stool, fresh | <p>Transport immediately to laboratory in leak-proof container without preservative. Refrigerate if delay in transport is anticipated. If referred to another laboratory, send on dry ice because the toxins are unstable.</p> <p><i>Clostridium difficile</i>-associated diarrhea (CDAD) occurs after antimicrobial therapy. The organism produces two toxins, toxin A (enterotoxin, causing extensive tissue damage) and toxin B (cytotoxin, causing cytopathic effect in cell culture). A more virulent strain of <i>C. difficile</i> has been identified that is associated with increased toxin production and may not respond to antimicrobial therapy.</p> <p><i>C. difficile</i> can be isolated in culture but does not necessarily reflect a toxigenic strain. For that reason and the fact that there is a delay in turnaround time to results, cultures are generally reserved for research-orientated laboratories. The reference method for the laboratory diagnosis of CDAD has been a cytotoxin cell culture assay for toxin B. Because cell culture results are generally not available for 24–48 hr, several rapid methods have been developed. These tests are available to detect toxin A only, toxin A and B, and toxin A plus a nontoxin protein called glutamate dehydrogenase associated with the organism.</p> <p>Individuals with three unformed stools per day or abdominal pain and a history of antimicrobial therapy within the previous 30-day period should be tested to confirm the diagnosis of CDAD or pseudomembranous colitis caused by <i>C. difficile</i>. CDAD rather than a parasitic or enteric pathogen should be considered in patients with diarrhea ≥ 3 days of hospitalization.</p> |

Coccidioidomycosis Serological Test
(Serological Test for *Coccidioides immitis*)¹⁻³

CF, ID, tube precipitin (TP), LA

Serologic tests for coccidioidomycosis should be considered in patients with symptoms of pulmonary or meningeal involvement who have lived or traveled in an endemic area. The TP test provides early evidence of acute coccidioidomycosis. TP antibodies appear early, within 1–3 wk after a primary infection, but disappear by 6 mo. The CF test is diagnostic and prognostic; antibody titers increase in proportion to disease severity and decrease in response to therapy. CF antibodies appear later than TP but remain throughout the course of the disease. Any CF titer should be considered presumptive evidence of infection. Titers $\leq 1:4$ usually indicate early, residual, or meningeal disease. CF titers $> 1:16$ should raise concern about disseminated infection. LA and ID tests yield results similar to the TP and CF test, respectively.

The TP test is best for diagnosis of early, primary disease and for diagnosis in endemic areas. CF is best for diagnosis of disseminated disease or to follow treatment effectiveness. The combination of CF and TP has a sensitivity of $>90\%$ for primary symptomatic disease.

| Cold Agglutinins (CA) Serological Test ¹⁻³ | Serum | Detection of cold agglutinins was one of the first serologic assays for detection of <i>Mycoplasma pneumoniae</i> infection. Only 30-50% of patients with <i>M. pneumoniae</i> infection will develop cold agglutinins. Therefore a negative test does not rule out infection. In addition a positive result may be associated with other infectious or collagen vascular diseases. Cold agglutinin testing is no longer recommended for the diagnosis of <i>M. pneumoniae</i> infections because of the availability of more sensitive and specific mycoplasma-specific antibody tests. |

| Cryptococcus neoformans Serological Tests ¹⁻⁴ | Serum | Serologic tests for <i>C. neoformans</i> should be considered in patients with symptoms of pulmonary or meningeal infection. TA and IFA antibody tests are reactive in ~50% of patients with active cases of extra-meningeal cryptococcosis. The IFA test has a specificity of 77% and the TA ~89%, both lower than the cryptococcal antigen test. Although the IFA has a lower specificity, it is useful for detection of cryptococcosis when the cryptococcal antigen test is negative. The TA test is useful in the early stages of CNS disease. TA titers of ≥1:2 are suggestive of infection. Titers may decrease as the antigen concentration increases. With effective chemotherapy, antibodies should reappear and may persist for long periods after therapy has ended. Negative serological assays do not rule out the diagnosis of cryptococcosis. |
| Antibody Test | | |
| TA, IFA | | |
| Antigen Test | Serum, CSF | Serologic tests for <i>C. neoformans</i> should be considered in patients with symptoms of pulmonary or meningeal infection. Detection of cryptococcal polysaccharide capsular antigen is the only serologic procedure that is clinically useful on a routine basis and detects both active meningeal and nonmeningeal infection. Detection of cryptococcal antigen is more sensitive than the India ink preparation and more specific than detection of cryptococcal antibodies. |
| LA, EIA | | |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Cryptococcus neoformans Serological Tests—CONT

The LA test has both diagnostic and prognostic value. A positive reaction in an untreated patient is suggestive of cryptococcal disease. LA titers $\geq 1:8$ are suggestive of active disease. The antigen titer is usually proportional to the extent of disease, increasing titers reflecting progressive infection and poorer prognosis. Declining titers generally indicate a favorable prognosis. False-positive reactions are uncommon but may occur in patients with disseminated *Trichosporon beigellii* and *Capnocytophaga canimorsus* infection and rheumatoid arthritis (test includes neutralization of rheumatoid factor). False-negative serum results are rare but may occur in cases of single, usually pulmonary, lesions in which sufficient antigen is not produced for detection.

The EIA test is capable of detecting lower antigen concentrations than the LA test. The reported sensitivity of the EIA is 93% and 100% in serum and CSF, respectively.

***Cryptosporidium* spp. Stool Examination^{1,2}**
Acid-fast stain;
fluorochrome or
Ziehl-Neelsen stain

Stool

See *Ova and Parasite Examination*.

Cryptosporidium spp. infect the brush border of intestinal epithelial cells but in immunocompromised patients may also infect cells of other areas, including the respiratory tract, biliary tree, liver, pancreas, or the stomach lining. Immunocompetent individuals develop a profuse, watery diarrhea that is self-limited (10-15 days), whereas immunocompromised hosts develop a more severe, long-lasting diarrhea that can last months to years. Infection with these organisms is associated with travel, exposure to farm animals, attending a day care center, or living in a medical institution.

The organisms are very small (4-5 μ m) and are best detected using the routine stool formalin-ethyl acetate concentration technique and acid-fast staining, or by simply centrifuging the specimen and using the newer immunoassay kits. Antigen detection assays are also commercially available. Permanent trichrome stains do not adequately stain *Cryptosporidium* spp. Several specimens may need to be examined to diagnose cryptosporidiosis.

|--|---|--|
| Cytomegalovirus, Direct Test for Antigen ^{1,2} <i>EM, FA, Antigene- mia test, PCR, bDNA, Hybrid Capture Assay</i> | Same as specimens for CMV culture. See <i>Cytomegalovirus Culture</i> . | <p>The direct examination of specimen using EM has shown to be laborious and unproductive. Fluorescent conjugated monoclonal antibodies can be used in FA of lung tissue or bronchoalveolar lavage (BAL) fluid for diagnosis of CMV pneumonia. However, in most cases FA is less sensitive than culture or shell vial.</p> <p>CMV antigenemia test is based on the use of monoclonal antibodies to detect CMV antigens directly in leukocytes of the patient's blood. The antibody reacts with CMV structural protein pp65 and product of UL 83. Horseradish peroxidase-labeled antimouse antibodies are added, followed by a substrate solution. The cells are examined under light microscope for dark brown nuclear staining. The test is fairly rapid, quantitative, and can detect CMV infection 5 days before development of the disease.</p> <p>Both quantitative and qualitative PCR assays that are based on traditional PCR or real-time PCR assays are available in most reference laboratories. PCR is shown to detect CMV 17 days in advance of disease development. Quantitative PCR assay provides better interpretation and monitors disease prognosis. bDNA signal amplification test, which is based on hybridization of branched DNA probes to CMV gb gene, also provides a reliable way to monitor disease progression in a CMV-infected individual.</p> |

| Cytomegalovirus (CMV) Culture ¹⁻³ | Urine, saliva, throat swab, BAL, blood (buffy coat), and tissue Clinical samples for viral isolation should be processed as soon as possible. Specimen may be stored at 4° C for 1-4 days. If prolonged storage is required, freeze at -70° C in the presence of cryopreservative such as sorbitol. Urine and other fluids should be added to equivalent volume of antibiotic-containing solution. | Human CMV is rarely pathogenic in healthy adults but can be associated with severe disease in immunocompromised individuals. CMV is also the most common cause of congenital infection. The disease may be congenital or acquired during the first year of life. Viruria during the first 3 wk of life usually indicates congenital CMV infection; viruria after 4 wk is usually an indication of postpartum or intrapartum infection. Urine or saliva may be used to diagnose congenital or perinatal infection with CMV. In adults, urine and buffy coat are used to detect CMV in blood as possible predictor of disseminated CMV disease. Detection of CMV in leukocytes is often a better indicator of symptomatic infection than is shedding of virus in urine or throat. Recovery of CMV in urine from adults may reflect asymptomatic viral replication or may indicate an active infection. In healthy adults, the asymptomatic excretion rate is <1%. During late pregnancy, excretion of virus from urine or uterine or cervical specimens is 2-13%. CMV infection is very common in organ transplant patients. It is recommended that weekly blood and urine be monitored for CMV infection. |

|--|--|--|
| Cytomegalovirus (CMV) Serological Test^{1,2} <i>EIA, IFA, LA, CF, N, IHA</i> | Serum, acute and convalescent. See <i>General Information</i> . | <p>CMV is a ubiquitous virus causing primary, acute, and reactivation infections. Active infections include mononucleosis, hepatitis, and pneumonitis in the immunocompetent host and more life-threatening diseases in the immunocompromised individual. Active infections occurring during pregnancy can be transmitted to the fetus or infant, and the result can be asymptomatic infection, mild infection, or severe CNS damage. Isolation of the virus may indicate active infection or chronic viral shedding.</p> <p>Serological testing can be helpful in conjunction with the culture results and the clinical symptoms. However, serology alone is not conclusive because CMV antibody prevalence in a population aged >30 yr may range between 40% and 100%.</p> <p>EIA, IFA, or ACIF (anticomplement immunofluorescence) are the most widely used for detecting CMV antibody. ACIF is as sensitive and specific as EIA and IFA, but the methodology is more cumbersome. Passive latex agglutination (LA) is a fairly simple and rapid mean to screen for CMV antibodies.</p> <p>Determination of IgM levels may be more appropriate for the diagnosis of primary infection and can be performed by EIA, IHA, or IFA. False-positive results may occur in the presence of rheumatoid factor, heterophil antibodies, and varicella. A negative test does not necessarily indicate absence of infection because the assays are not 100% sensitive. Newborn serum with large quantities of maternal IgG antibodies and only small amounts of infant IgM may yield a false-negative result (for IgM anti-CMV) because IgG can compete in the assay. Sera can be adsorbed with protein A to remove IgG, but unless there is sufficient IgM present, it too may be adsorbed. CF, IHA, and NT test are other tests that may be used to measure CMV antibody.</p> |
| Dengue Virus¹ <i>ELISA</i> | Serum, acute and convalescent. See <i>General Information</i> . | <p>Dengue virus is a mosquito-borne flavivirus and the most prevalent arbovirus in tropical and subtropical regions of the world. It causes dengue fever (DF) and its more serious forms, dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS). The World Health Organization estimates that there may be 50 million to 100 million cases of dengue virus infections worldwide every year, which result in 250,000-500,000 cases of DHF and 24,000 deaths. There are four distinct serotypes, serotypes 1-4. Infection induces a life-long protective immunity to the homologous serotype but confers only partial and transient protection against subsequent infections by the other three serotypes. In fact, it has generally been accepted that secondary infection with different serotype of dengue virus serotypes is a major risk factor for DHF-DSS because of antibody-dependent enhancement.</p> |

|-------------------------|--------------------------------------|-------------------------------|

Dengue Virus—CONT

At present, the three basic methods used by most laboratories for the diagnosis of dengue virus infection are viral isolation, detection of the genomic sequence by a nucleic acid amplification assay, or detection of dengue virus-specific antibodies. Two patterns of serological response can be observed: primary and secondary antibody responses, depending on the immunological status of the infected individuals. A primary antibody response is seen in individuals who are not immune to flaviviruses. A secondary antibody response is seen in individuals who have had a previous flavivirus infection. For acute- and convalescent-phase sera, serological detection of antibodies based on capture IgM and IgG ELISA is the standard for the detection and differentiation of primary and secondary dengue virus infections.

|---|--|--|
| Echinococcosis Serological Test ¹⁻³ | Serum. Collect in separation tube and freeze if not assayed immediately. | The immune response often depends on the location and viability of the cysts. IB serology is 80-100% sensitive and 88-96% specific for liver disease but is less sensitive for lung and other organ involvement (25-56%). IHA and EIA assays have a sensitivity of ~60-90%. It is recommended that all positive EIA or IHA assays be confirmed by IB. Because serologic cross-reactions have been noted in low titers in patients with other cestode infections, the IB can be useful to help rule out false-positive results. Imaging remains more sensitive than serology, and a characteristic scan together with negative serology results should still suggest a diagnosis of echinococcus. |

Encephalitis Virus Serological Test—CONT

Antibodies to one virus may be heterologous to those of other encephalitis viruses. Definitive diagnosis involves isolation or amplification of the viral nucleic acid causing the infection.

Antibody-capture ELISA for IgM (MAC-ELISA) is the test of choice for detecting antibody in cases of acute infection. Double-sandwich ELISA IgG or IF is recommended for serosurvey. HI and CF are used to supplement these tests, and the neutralization test is used for definitive and confirmatory determination of infecting agent.

2. Rose NR, Hamilton RG, Detrick B, editors: *Manual of clinical laboratory immunology*, ed 6, Washington, DC, 2002, American Society for Microbiology.

Enterovirus
Group Serological
Test (Enterovirus
Group Titers)^{1,2}

Serum, acute and convalescent.
See *General Information*.

The enterovirus group includes many serotypes of coxsackie, polio, echovirus, and enterovirus 69-71. They are found in the alimentary tract and produce varied clinical symptomatology.

CF, NT

Group-specific antigens are not available; thus serotype-specific assays are performed when considering the diagnosis. Hence, serological assays are not generally used but may be used in outbreak situations for epidemiological purposes.

A fourfold increase in titer by means of CF or NT usually indicates active infection. The presence of a single high IgM titer may also indicate active infection. NT titers persist for years; CF antibodies are short-lived (3-4 mo).

Isolation or amplification of the viral nucleic acid from blood, CSF, oropharynx, or feces is the usual mode for confirmation of the diagnosis.

2. Rose NR, Hamilton RG, Detrick B, editors: *Manual of clinical laboratory immunology*, ed 6, Washington, DC, 2002, American Society for Microbiology.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|---|
| Epstein-Barr Virus (Manual, Clin Micro, and Immuno, CDLI 7:451, 2000) Serological Test (EBV Titer) ¹⁻³ | Serum, acute and convalescent. See <i>General Information</i> . | EBV is a ubiquitous virus that infects B lymphocytes and establishes latent infections. EBV syndromes include mononucleosis and tumors such as Burkitt's lymphoma, nasopharyngeal carcinoma, and B-cell lymphoma. EBV may develop into encephalitis in adult AIDS patients and into interstitial pneumonitis in children with AIDS. Ninety to 95% of infectious mononucleosis (IM) is associated with EBV; the remaining cases are associated with CMV, <i>Toxoplasma gondii</i> and HIV, adenovirus, or rubella. These latter are generally heterophile antibody negative. |

IFA, EIA, CF, IHA

Serological assays are utilized for the following purposes: to determine susceptibility to, immunity to, or primary infection with EBV; to aid in determining the significance of heterophile antibody-negative mononucleosis syndrome; to show the possible association of EBV with other syndromes; and to conduct epidemiological studies.

Heterophile IgM antibodies peak in 2-3 wk and are detectable for several months. Currently, there are several commercially manufactured ELISA, immune adherence hemagglutination, and latex agglutination assays with similar sensitivity and specificity available in the U.S. They are generally more sensitive than traditional Paul-Bunnell for the diagnosis of IM but offer no advantage over the conventional slide test. The slide test is 90% sensitive in adults and <50% in children <4 yr. In individuals who fail to develop heterophile antibodies but who have the clinical and hematological criteria for IM, EBV titers by means of IFA, EIA, or IHA may be of value.

The EBV antibodies that are detected by means of serological assays are:

Antibody to the EBV nuclear antigen (EBNA). EBNA antibody appears weeks to months after onset of illness and lasts for life except in the immunocompromised individual.

Viral capsid antigen (VCA) antibodies. IgM and IgG appear during the acute stage; IgM decreases within 1-3 mo; IgG may persist at low levels for life. High titers of IgG-VCA are noted in Burkitt's lymphoma and nasopharyngeal carcinoma and in immunosuppressed patients. In addition, individuals with nasopharyngeal carcinoma demonstrate high IgA-VCA titers. *Early antigen (EA) antibodies.* Most patients with IM have a transient antibody response to early antigen. IgG-EA lasts several months to several years after infection with EBV.

Positive titers for IgG-VCA, IgM-VCA, and IgG-EA are diagnostic for acute IM. If there has been a past EBV infection, IgM-VCA will be negative, but IgG-VCA and antibody to EBNA will be present. IgG-EA will be negative or in low numbers if there has been a past EBV infection.

| Equine Encephalitis Serological Tests | Serum, acute and convalescent. See <i>General Information</i> . | EEE virus is a member of the group A arboviruses, the alphaviruses. The vector of transmission is the mosquito. Common animal hosts include birds, ducks, fowl, and horses. This virus has caused epidemics in the eastern U.S. from New Hampshire to Texas. The mortality rate is one of the highest of the viral encephalitides in the U.S. (65-75%). CAUTION: This organism has caused serious infection in laboratory workers involved in its isolation. |
| Eastern Equine Encephalitis Titer (EEE Titer)^{1,2} | | |
| IFA, CF | | SLE virus is a member of the group B arboviruses, the flaviviruses. The vector of transmission is the mosquito. The common animal host is the bird. Cases of SLE have occurred in the western, central, and southern U.S. Approximately 10-15% of patients with SLE do not develop CF antibodies. |
| St. Louis Equine Encephalitis Titer (EEE Titer)^{1,2} | | |
| IFA | | VEE virus is a member of the group A arboviruses, the alphaviruses. The vector of transmission is the mosquito. Common animal hosts are the horse and rodent. |
| Venezuelan Equine Encephalitis Titer (VEE Titer)² | | VEE has occurred in South and Central America, but the virus has also been isolated in Florida and Texas. |
| ELISA | | |
| Western Equine Encephalitis Titer (WEE Titer)² | | WEE virus is a member of the group A arboviruses, the alphaviruses. The vector of transmission is the mosquito. Common animal hosts include birds, snakes, horses, and squirrels. Cases of WEE have been diagnosed all over the U.S. west of the Mississippi. It is endemic in the Central Valley of California. |

| Fascioliasis/Fasciolopsiasis Serological Test ^{1,2} <i>EIA, IB</i> | Serum. Collect in separation tube and freeze if not assayed immediately. | <p>The test is used to support the diagnosis of <i>Fasciola hepatica</i> or <i>Fasciolopsis buski</i> infection, in conjunction with demonstration of eggs passed in the stool. The sensitivity of the FAST-EIA is reported to be 95%, whereas that of the IB is 100%. The test is best applied in the early stages of the disease or in chronic fascioliasis, when a paucity of eggs may be present. Antibodies usually appear 2-4 wk after infection. Levels decrease shortly after chemotherapy (within 6-12 mo), and their decline can be used to monitor chemotherapy. Titers of 1:128 by EIA are considered significant.</p> <p>Positive EIA assays can be followed up with more specific IB assays to rule out false-positive results, such as may occur in schistosomiasis.</p> <p><i>See General Comment.</i></p> |

| Filariasis Serological Test ¹⁻³ <i>EIA</i> | Serum. Collect in separation tube and freeze if not assayed immediately. | Filariasis is rarely seen in the U.S. except in visitors, immigrants, or U.S. citizens who visit endemic areas. It is caused by <i>Wuchereria</i> spp. or <i>Brugia</i> spp. Serologic tests may be of some use but do not determine between recent and past infections, nor do they discriminate between species of parasites. In addition, antibody tests have little value in endemic areas but may be helpful if a positive result is seen in someone who has traveled to an endemic area. A negative serological test may suggest no infection. <i>See General Comment.</i> |

|--|---|--|
| Genital Culture ¹⁻¹¹ | Amniotic fluid, transvaginal aspirate of endometrium, Bartholin gland, Skene's gland, or lymph node aspirate, endocervical, vaginal, vulval, urethral swab from epididymis, testicles, prostate fluid, and culdocentesis Swab of urethral exudate (males), urethral scrapings with swab or loop, cervical swabs, vaginal/rectal swabs to rule out group B <i>Streptococcus</i> , scrapings of skin lesions; ≥1 mL fluid, e.g., amniotic, bartholin, prostate in anaerobic transport system. Transport to the laboratory immediately in transport system or sterile tube. Do not refrigerate. | Indigenous organisms are age related in females. For prepubescent females, diphtheroids and coagulase-negative <i>Staphylococcus</i> predominate; in female adults, lactobacilli predominate; and in postmenopausal women, fewer lactobacilli and a greater number of <i>Enterobacteriaceae</i> are generally detected. Male urethra contains relatively few skin flora. Specific organism requests rather than a routine genital culture are advised because genital pathogens, e.g., <i>Neisseria gonorrhoeae</i> , group B <i>Streptococcus agalactiae</i> , <i>Haemophilus ducreyi</i> , <i>Staphylococcus aureus</i> , group A <i>Streptococcus pyogenes</i> , yeast, and genital mycoplasma, generally have specific growth requirements. Vulvovaginitis and bacterial vaginosis (BV) can generally be diagnosed by Gram stain or wet mount for clue cells, i.e., epithelial cells coated with bacteria, or a DNA probe assay for the identification of yeast, <i>Trichomonas</i> , and <i>Gardnerella vaginalis</i> as a marker of BV. |
|--|---|--|

| | | |
|---|--------------------|--|
| <i>Neisseria gonorrhoeae</i> (GC) Culture ^{5,6,8,12-14} | Cervical, urethral | There is excellent correlation between presumptive diagnosis of uncomplicated gonorrhea in the male, based on Gram-stained smear of urethral exudate, and confirmation by culture. In the female, the Gram-stained smear may not be as reliable, and culturing is required. Visualize the cervix with a speculum without lubricant. Remove mucus with a large swab and discard. Inoculate transport medium with noncotton swab collected from the endocervical canal, and deliver promptly to |
|---|--------------------|--|

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Genital Culture—CONT

the laboratory. Urethral specimens are collected after removing exudate from the urethral orifice. In males, insert urethrogenital swab ~1 in. into the urethral lumen, rotate swab, leave in place for several seconds, and inoculate transport medium. Specimens should never be refrigerated and should be plated within 2 hr of collection for optimal recovery.

Gram stain of specimens from the urethra is 95% sensitive and 100% specific for the diagnosis of gonococcal urethritis in males when intracellular gram-negative diplococci are detected. In females, endocervical smears are 65% sensitive compared with culture; therefore specimens must also be cultured.

A selective transport medium, e.g., JEMBEC plate, has been shown to increase positivity by as much as 10% over other methods of transport. Three to 10% of the gonococci are susceptible to vancomycin in selective media used for isolation of *N. gonorrhoeae*. Whenever possible, both a nonselective and a selective medium such as modified Thayer-Martin medium incubated in CO₂ should be inoculated.

Although culture traditionally has been the gold standard for identifying gonococcal infection and is still required for presumed rape cases, several molecular-based tests are currently available with excellent sensitivity and specificity. The advantage of these tests is that one specimen can be collected for both *N. gonorrhoeae* and *Chlamydia trachomatis* detection. Verification of polymerase chain reaction for *N. gonorrhoeae* and *C. trachomatis* from transport fluid used to prepare ThinPrep pap smears is also available.

| | | |
|---|------------------------|--|
| Group B Strep Culture ^{3,11,14} | Vaginal + rectal swabs | Specimens collected between 35-37 wk gestation to identify infants at risk for infection and guide antimicrobial prophylaxis are placed in Lim broth or other selective media for 18-24 hr amplification and subcultured onto sheep blood agar for identification. Molecular amplification assays are an excellent sensitive alternative to culture. |
|---|------------------------|--|

| | | |
|---|------------------------|---|
| <i>Haemophilus ducreyi</i> ⁴ | Vaginal + rectal swabs | <p>Thoroughly cleanse ulcer base with gauze pad saturated with normal saline. Two methods of collection are recommended.</p> <p>(1) Irrigate and agitate the genital ulcer base with nonbacteriostatic saline and aspirate. Mix well and use as inoculum. (2) Use a cotton swab moistened with saline to obtain material, prepare Gram stain, inoculate chocolate agar enriched with 1% IsoVitaleX and vancomycin, 5 mg/L, and incubate at 33° C. Cultures may require up to 4 days for isolation of <i>H. ducreyi</i>.</p> |
|---|------------------------|---|

The specimen should be transported to the laboratory immediately. Do not refrigerate. On Gram stain, organisms appear in a “school of fish” arrangement.

Gomori Methenamine Silver (GMS) Stain^{1,2}

Appropriate specimen is the same as that for culture of the corresponding site.

Stain is considered by many to be the most useful for direct microscopic examination of clinical specimens to identify fungal elements. GMS stains the fungal cell wall and is commonly used for the histopathological examination of deparaffinized tissue for fungi. Certain bacteria, including *Nocardia* spp., as well as *Pneumocystis jiroveci* (*carinii*) can also be observed with this stain.

2. Larone DH: *Medically important fungi: a guide to identification*, ed 4, Washington, DC, 2002, ASM Press.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|--|
| Gram Stain ^{1-5,7} | Clinical specimens (excluding blood, stool, sputum from cystic fibrosis patients, catheter tips, and throat and nasal swabs), colonies on solid media, and growth in broth or blood. Cultures <24 hr from noninhibitory media and fresh specimens yield the best results. Broth for assessment of morphology and organism arrangement, e.g., streptococci. Broth cultures are preferred. | <p>Select purulent or blood-tinged portion of specimens. If fluid or tissue cannot be obtained, collect two swabs, one for culture and one for Gram stain. Gently roll swab across the surface of a clean slide to maintain cell integrity and bacterial arrangement. For broth cultures and colonies on solid media, transfer 1-2 drops to a slide or emulsify a portion of a colony in 1 drop of sterile saline, respectively.</p> <p>Slides should be prepared so that newspaper print is visible through the smear. For anaerobes, a modified Kopeloff's Gram stain may be used instead of the traditional modified Hucker Gram stain. Carbol fuchsin or basic fuchsin counterstain is used instead of safranin for detecting weakly staining gram-negative organisms such as <i>Campylobacter</i> spp., <i>Legionella</i> spp., and <i>Brucella</i> spp.</p> <p>Gram stains are used for (1) presumptive identification of microorganisms, (2) cellular response, and (3) as a quality control measure to ensure recovery of all organisms present in a patient specimen. Poor quality smears resulting from use of unclean slides, too thick of a smear preparation, problems related to fixation, overdecolorization, excessive rinsing, or stain precipitate can lead to inaccurate interpretations. Decolorizers include 95% ethanol, acetone-alcohol, acetone alone, and methanol. The latter tends to maintain the integrity of cell morphology, produces a cleaner background, and prevents liquid specimens from washing off of the slides. Smears may be restained by removing immersion oil with xylene substitute and decolorizing.</p> <p>Cytocentrifuged slide preparations should ideally be used to concentrate organisms in noncloudy or viscous body fluids and to prepare a monolayer of organisms. This procedure increases Gram stain sensitivity and reduces examination time compared with conventional centrifugation of specimens. Smears should be examined for representative areas of inflammatory white blood cells (WBCs) and squamous epithelial cells (SECs). Using an oil immersion lens, examine 20-40 representative fields to identify the shape and Gram reaction of each morphotype present along with their quantitation. When possible, presumptively identify the organism, e.g., gram-negative bacilli consistent with <i>Haemophilus</i>.</p> |
| Sputum Screen ^{2,4-6} (See <i>Sputum Culture, Routine</i> .) | | Select portions of a specimen that are blood-tinged or purulent. For extremely viscous specimens, dilute with 1 drop of sterile saline before preparing slide. To ensure that the specimen quality is appropriate for culture, examine 20-40 representative areas under low power field (LPF), and apply one of the rejection criteria based on the number of SECs and WBCs. Likewise, endotracheal aspirates may be rejected using the criteria of ≥10 SECs/LPF or no organisms observed. |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|--|
| Gram Stain—CONT | | |
| Urine Screen | | The presence of a single morphotype of bacteria in unspun urine is consistent with a colony count of ≥ 105 CFU/mL and is indicative of infection, particularly in the presence of WBCs. Any number of organisms/mL is considered significant in suprapubic-collected urine specimens. |
| Vaginal Discharge from Posterior Fornix | | Use for women of child-bearing age and postmenopausal women on estrogen replacement therapy. Determine the relative number of lactobacilli compared with gram-negative curved rods and gram-variable coccobacilli using the Kopeloff's Gram stain modification and the presence of vaginal SECs coated with bacteria (clue cells) to aid in the diagnosis of bacterial vaginosis. |
| CSF (See CSF Culture, Routine.) | | To avoid potential contamination during specimen collection from a lumbar puncture, the second or third tube of CSF should be submitted for Gram stain and culture. Specimens should be processed immediately on receipt and not refrigerated. The number of organisms/mL may be below the detectable level when examining smears prepared from conventionally centrifuged specimens. To increase the sensitivity of the Gram stain ≥ 100 -fold, a cytocentrifuged specimen should be prepared. Results should be immediately called to the ordering physician. |
| Acridine Orange Stain^{2,3,7} | Gram stain-negative blood cultures, broth, and direct smears. | <p>Acridine orange (AO) is a fluorochromatic dye that stains nucleic acid and can be used to differentiate bacteria and fungi that stain bright orange from cellular material that stains yellow green using a fluorescent microscope.</p> <p>This stain is useful in discerning the presence of organisms in a Gram-stained specimen with WBCs but no organisms seen, when growth occurs on solid media, e.g., <i>Mycoplasma</i>, but does not Gram stain, and in blood cultures that are flagged positive by an automated system, but no organisms are seen. Gram stains can be performed over AO staining and vice versa, after removing the immersion oil.</p> |

|-----------------------------------|-----------------------------|--|
| <i>Helicobacter pylori</i> | Serum for IgA, IgG, or CagA | Gastric colonization by <i>Helicobacter pylori</i> is implicated in the development of gastritis, duodenal and gastric ulcer disease, and possibly gastric cancer. Tests for <i>H. pylori</i> IgG should be used to rule out disease in adults because IgG levels may be detected in a significant percentage of adults without clinical disease. Equivocal results may be resolved by performing a CagA IgG antibody test. There appears to be a correlation between the severity of peptic ulcer disease and antibody to the cytotoxin-associated gene A (CagA) protein. In some patients without detectable IgG levels, IgA levels may be helpful in identifying a <i>H. pylori</i> infection. <i>H. pylori</i> infections may be successfully treated with antimicrobial agents with subsequent decrease in IgG and IgA antibody levels. Testing for IgM is not helpful. |

***Helicobacter pylori* Antibodies—CONT**

Note that *H. pylori* antigen detected in stool by EIA is a highly sensitive, specific, and noninvasive test to identify active infection in symptomatic adult patients, not just exposure as determined by serological tests. The antigen test also can be used to monitor response during and after therapy. Eradication is confirmed by a negative antigen test.

1. Murray PR, Baron EJ, Jorgensen JH, et al: *Manual of clinical microbiology*, ed 8, Washington, DC, 2003, ASM Press.

***Helicobacter pylori* Culture and Rapid Urease Test (RUT)**¹⁻⁴

Gastric biopsy, duodenal biopsy

Transport specimens for culture within 3 hr in nonbacteriostatic saline on ice or in 1 mL of modified Cary-Blair transport medium. For a rapid urease test (RUT), place several biopsy pieces into a tube of urea test medium, incubate at 35° C, and examine at 30 min, 4 hr, and 24 hr. A color change in the medium constitutes a positive test.

Invasive procedures

Helicobacter pylori is the primary organism causing gastritis. It is associated with an increased risk for development of peptic ulcer disease, gastric adenocarcinoma, and gastric non-Hodgkin's B-cell lymphoma.

To diagnose *H. pylori* infection, both invasive tests using biopsy specimens, i.e., culture, rapid urease test, and histological examination, and noninvasive tests, i.e., serology, urea breath tests, and a stool EIA antigen test, can be used. Although isolation of the organism is possible if it is appropriately cultured, histological demonstration of the organism and/or a RUT is usually sufficient to make a diagnosis.

***H. pylori* Antigen Test**¹⁻³

Stool

For initial diagnosis and monitoring of patients on therapy, a stool EIA antigen test has proven reliable.

Noninvasive procedure (See Helicobacter pylori Antibodies.)

| Herpesviruses 1 and 2 Serological Tests (Herpes Simplex Titers, HSV-1 and -2 Titers, Herpes Simplex Serological Tests) ^{1,2} <i>EIA, IIF, ELISA, Immunoblot</i> | CSF, serum, acute and convalescent. See <i>General Information</i> . | <p>HSV is a ubiquitous virus that can present in humans with variable clinical symptoms ranging from mild pharyngitis to severe disease and death. Major syndromes include gingivostomatitis, keratitis, conjunctivitis, vesicular skin eruptions, aseptic meningitis, encephalitis, genital ulcer disease, and neonatal herpes disease.</p> <p>Serological tests are not used to make the diagnosis of herpesvirus disease but may be confirmatory if clinical signs are present and cultures are positive. Serological tests may also be used epidemiologically.</p> <p>Antibodies for HSV-1 and -2 reach peak titers ~4-6 wk after infection and, although they decline with time, usually persist at low levels. Reinfection in a person with preexisting antibodies does not cause a dramatic change in the titer. Serological confirmation of recurrence or infection with a second virus type is not easily performed.</p> <p>There is cross-reactivity between HSV-1 and HSV-2; thus distinguishing between them serologically may be difficult. There may also be cross-reactivity between HSV and VZV antibodies, but the increase in antibody titer to the infecting virus frequently exceeds the increase in heterologous antibody. HerpeSelect ELISA and HerpeImmunoblot test from Focus Technologies (Cypress, CA) are two assays that are FDA approved for detection of HSV-1 or HSV-2.</p> <p>Antibodies may be present in the CSF of patients with CNS infection. Level of CSF antibodies >6% of level of serum antibodies suggests CNS infection. Some level of antibody may be present in the normal population, and thus paired samples should be tested to demonstrate an increase in titer.</p> |
| Herpes Simplex, Direct Test for Antigen¹ | Genital specimens. See <i>Virus Culture</i> . | <p>Direct microscopic examination for HSV antigen in specimens is possible by examining for the presence of multinucleated giant cells; however, all herpes viruses, e.g., CMV and VZV, will induce similar morphologies.</p> <p>FA is more specific and has a sensitivity of 10% for a crusted lesion and 87% for specimen from genital ulcers. Immunoperoxidase test allows demonstration of viral antigen within the infected cells and similar to FA requires skilled reading to recognize the staining patterns. Several commercially produced EIA kits with varying degree of sensitivity (35-100%) are available in the market. They are rapid and may be automated.</p> |

| Histoplasmosis Tests ¹⁻³ | Serum, acute and convalescent collected 2-3 wk apart; CSF. | The standard method for the diagnosis of histoplasmosis remains cultural isolation and identification of the organism. However, culture often requires 2-4 wk. Antibody detection offers a more rapid alternative. CF tests are valuable in the diagnosis of acute, chronic, disseminated, and meningeal histoplasmosis. The antibodies appear within 4 wk after exposure. Sensitivity of the CF may be >90%, depending on the antigen used. |
| Antibody test | | |
| CF, ID, LA | | |

CF titers of $\geq 1:8$ are considered presumptive of infection; single titers $\geq 1:32$ or increasing titers are usually indicative of active infection. The higher the titer, the greater the probability of the disease; however, recent skin testing may cause positive titers in up to 20% of persons tested. The CF test is usually positive with CSF from patients with chronic meningitis.

Cross-reactions may be seen in patients with leishmaniasis, blastomycosis, coccidioidomycosis, and other fungal infections, but these titers are usually lower than those caused by histoplasmosis. Failure to demonstrate CF antibodies does not rule out the diagnosis.

ID is useful as a screening procedure or as an adjunct to CF. ID demonstrates 1 or 2 bands. A positive "H" band indicates active infection but is rarely found alone. The presence of an "M" band indicates acute or chronic infection or previous skin testing. The presence of both M and H bands is highly suggestive of active histoplasmosis.

The LA test is useful for early presumptive detection of acute histoplasmosis. Titers $\geq 1:16$ are usually considered strong evidence for active or recent infection. Skin testing before the test may elevate the titer significantly. Positive LA tests should be confirmed with a CF or ID test. False-positive results have occurred, particularly with low LA titers.

Antibodies may be undetectable in patients with HIV infection.

|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Histoplasmosis Tests—CONT

| | | |
|---------------------|--------------|---|
| Antigen test | Urine, serum | Detection of <i>Histoplasma</i> antigenemia or antigenuria is recommended for the detection of disseminated histoplasmosis and may be useful in the early acute stage of pulmonary histoplasmosis before the appearance of CF and ID antibodies. The test can also be used to monitor therapy or to follow relapses in immunocompromised patients. Sensitivity is ~90% in disseminated histoplasmosis. Urine is a superior specimen to serum. |
| EIA | | Decreases in antigen concentration indicate response to therapy, whereas increases indicate relapse or treatment failure. False-positive results occurred with blastomycosis and coccidioidal meningitis with the previously used RIA. The EIA has increased specificity. |

|---|--|---|
| HIV Resistance Testing¹ | Whole blood (citrate or EDTA). Spin to separate plasma and refrigerate at 4° C for up to 4 days. For prolonged storage, freeze at -70° C and transport on dry ice. | HIV resistance testing is an important tool in optimizing the efficacy of the combination therapy to treat HIV infection. The identification of resistance mutations allows the care providers to select antiviral agents with maximum therapeutic benefit and minimum toxic side effects. |
| <i>LiPA, Sequencing, PhenoSense, Antivirogram</i> | | Phenotypic resistance testing is available from at least two commercial laboratories: ViroLogic, Inc. (San Francisco, CA) and Virco (Mechelen, Belgium). These tests rely on PCR amplification of viral protease and RT gene sequences in lieu of viral isolation. The ViroLogic test (PhenoSense) relies on cloning and expression of the amplified viral RNA in an HIV-1 vector that lacks these regions and contains luciferase reporter gene in place of the viral envelope gene. The replication of the recombinant virus in the presence of antiviral agent is monitored by the amount of expressed luciferase. The Virco-developed phenotypic test (Antivirogram) also relies on amplified viral protease and RT genes. However, a mixture of PCR products and protease and RT-deleted HIV-1 proviral clone is transfected into CD4 ⁺ cell reporter cell lines. The cells produce recombinant virus containing the patient's viral PR-RT sequence. Susceptibility of resulting chimeric virus is tested in the reporter cell using real-time monitoring of HIV replication by high-resolution optics. |

| HIV Resistance Testing—CONT | | |
| <i>Genotypic resistance assays</i> | | The genotypic resistance assay detects specific mutations in the viral genome that are associated with resistance to various antiretroviral agents. There are several manufacturer- and in-house-developed genotypic assays available in the U.S. The initial step in all of these assays is PCR amplification of viral protease and a 250-400 codon segment of HIV RT gene. This is followed by either direct sequencing or by hybridization-based detection of the amplified products (LiPA assay) to assess the presence of mutations associated with antiviral resistance. |

| Human Herpes 6, 7, and 8¹ | Serum | Human herpes 6, 7, and 8 are the newest members of the human herpes virus family. Infection with these viruses is generally mild or subclinical in immunocompetent individuals, but clinically important and often severe disease does occur in immunocompromised persons. A variety of serologic assays has been developed to detect antibody to HHV-6, HHV-7, and HHV-8. They include NT, immunoblot, IFA, and ELISA. The overall performances of these assays for detecting antibody to these viruses are fairly similar, with a small sensitivity advantage for the ELISA and a specificity advantage for the immunoblot. |
| NT, IFA, ELISA, Immunoblot | | |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|--|--|
| Human Immunodeficiency Virus (HIV) Amplification Methods^{1,2} <i>Viral load, HIV proviral</i> <i>DNA</i> | Whole blood (citrate or EDTA). Refrigerate at 4° C for up to 4 days. | Monitoring HIV-1 RNA level (viral load) in sera of infected patients is used to assess HIV disease progression and patient response to antiviral therapy. Currently, there are three FDA-approved commercially developed assays to monitor HIV viral load. Two assays are based on target amplification (Roche Amplicor HIV Monitor v1.5 RT-PCR Assay and bioMerieux NucliSens HIV-1 RNA QT NASBA Assay), and one is based on signal amplification (Bayer Quantiplex HIV RNA v3.0 bDNA Assay). Comparative studies have shown fairly good correlation among the three assays. Amplicor and bDNA are generally more sensitive than NucleSens. Plasma is the specimen of choice. |

The bDNA is a signal amplification test that relies on a sandwich nucleic acid hybridization procedure. Initially the HIV genomic RNA is released from the virions and captured on a microwell by a set of specific synthetic oligonucleotide target probes. A second set of target probes hybridizes the viral RNA to the preamplifier probes. The preamplifier probes hybridize to the branched DNA (bDNA) amplifiers. Multiple copies of an alkaline phosphatase-labeled probe are then hybridized to the immobilized complex to amplify the signal. Detection is achieved by incubating the complex with a chemiluminescent substrate and measuring the light emission generated by the bound alkaline phosphatase. Light emission is directly proportional to the amount of HIV RNA present in each sample. The apparent dynamic range of this assay is ~75-500,000 viral particles/mL.

NASBA is based on coamplification of HIV-1 sample RNA together with internal calibrators. The quantity of amplified RNA is measured by means of electrochemiluminescence (ECL). Three synthetic RNAs of known concentrations (high, medium, and low) are added to the lysis buffer containing the HIV RNA. The extracted nucleic acid that includes the calibrators is then subjected to amplification. The HIV RNA and the calibrators serve as targets for the primer that hybridize to the gag region of HIV and contain the T7-RNA polymerase recognition site. Avian myeloblastosis virus reverse transcriptase (AMV-RT) extends the primer and generates a DNA/RNA complex. After the extension, enzyme RNase H degrades the RNA template and a second primer hybridizes to the cDNA. Synthesis of the second DNA strand is attained through extension of this primer by AMV-RT. Finally, the enzyme T7-RNA polymerase binds to the T7 promoter site and synthesizes multiple copies of the target RNAs. With the RNA synthesis, the system enters the isothermal cyclic phase, resulting in the accumulation of wild-type and calibrator RNA amplification products. To detect the amplification products, aliquots of the amplified sample are added to four hybridization solutions with specific probe for one of the amplification products. The respective amplification products are hybridized with a bead-oligonucleotide and a ruthenium-

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Human Immunodeficiency Virus (HIV) Amplification Methods—CONT

labeled probe. The magnetic beads carrying the hybridized amplification product/probe complex are captured on the surface of an electrode by means of a magnet. Voltage applied to this electrode triggers the ECL reaction. The light emitted by the hybridized ruthenium-labeled probes is proportional to the amount of amplification product. The next generation of this assay will rely on the use of molecular beacons probe technology for real-time detection of the amplification products.

The Amplicor HIV Monitor v1.5 RT-PCR Assay is an automated amplification and detection assay performed on Roche COBAS Amplicor. In this assay the plasma RNA is extracted with a lysis reagent containing guanidine thiocyanate and quantitation standard (QS) RNA. The QS that is introduced into each sample permits quantitation of HIV RNA by comparison of resulting optical densities after amplification and detection. A 142-base pair sequence in the gag gene of HIV and QS (primers SK145 and SKCC1B) is amplified and detected in a single reaction tube by reverse transcription (RT) and polymerase chain reaction (PCR). The reported dynamic range of this assay is 400-750,000 viral particles/mL. HIV monitor Ultrasensitive is a modified version of this assay that requires initial ultracentrifugation of the sample for 1 hr before RNA extraction and has a dynamic range of 50-50,000 viral particles/mL. The next generation of PCR-based techniques for monitoring HIV viral load will rely on real-time PCR that utilizes Taqman technologies.

HIV infection usually is documented by detection of HIV-specific antibodies in serum. Serologic assays do not readily identify HIV infection in neonates because of the passively acquired maternal antibodies or in individuals with “indeterminate” antibody profiles. The proviral DNA detect kit allows the detection of rare DNA sequences (1-5 copies) of HIV-1 proviral DNA in infected cells. This PCR-based kit can detect proviral DNA by amplification of a specific sequence in the highly conserved gag region of the HIV genome. The DNA PCR may also help to document HIV infection when routine diagnostic assays are not adequate. In recent years several new assays based on real-time PCR have been reported with similar sensitivities.

|--|--|---|
| Human Immunodeficiency Virus (HIV) Culture ^{1,2} <i>VCA, RT</i> | Peripheral blood mononuclear cells (PBMCs), plasma, CSF, tissue, and other body fluids. Collect blood in citrated tubes; process within 24 hr. Tissues: Transport in viral transport media (see <i>Virus Culture</i>); process immediately or freeze at −80° C for further processing. Body fluids: Collect and transport as for virus culture and refrigerate, if needed, before processing. | HIV culture isolation relies on cocultivation of PBMC of HIV-infected patient with PBMC from uninfected blood donors that has been stimulated to replicate with mitogen [usually phytohemagglutinin (PHA) and interleukin-2 (IL-2)]. Culture supernatants are assessed for HIV p24 antigen or reverse transcriptase activities at 3- to 4-day intervals for up to 4 wk. Positive culture is usually seen within 1-2 wk. The sensitivity of HIV culture (65-100%) depends on HIV viral load, CD4 count, and presence of inhibitors and susceptibility of donor PBMCs. The rate of virus isolation is higher among untreated patients with advanced disease. Because HIV culture is very laborious, expensive, and requires long incubation time, HIV culture is rarely used for diagnostic purposes. HIV culture, however, is a valuable tool to assess phenotypic resistance to antiretroviral drugs. |

|---|--|--|
| Human Immunodeficiency Virus-1 (HIV-1) Serological Test ^{1,2} <i>EIA</i> | Serum, plasma. See <i>General Information</i> . | A number of assays are commercially developed to detect antibody to the HIV-1. EIA is the most common assay for detection of the antibody in adults and children aged >15 mo. The assays can be used to screen blood or blood products, to make the clinical diagnosis of HIV infection, and for epidemiologic purposes. The tests measure antibody presence but cannot be used to predict whether an infected individual has AIDS or will go on to develop AIDS. AIDS is a clinical syndrome and can only be diagnosed clinically. |
| <i>Western blot</i> | Serum, plasma. Store at 2-8° C for up to 2 wk, −20° C if longer. | The Western blot (WB) is used to confirm EIA reactivity of sera to HIV-1 virus. A positive WB is defined as the presence of two of the following bands: p24, gp41, and either gp120 or gp160. Ten to 20% of patients who are reactive by EIA are indeterminate by WB; in a high-risk population, serial tests by WB may be needed to reach a diagnostic conclusion. Twenty to 30% of patients negative by EIA (as well as PCR) may react in the WB and are probably not HIV positive. The positive predictive value of a WB alone, especially in a low seroprevalence population, is only 29%. The predictive value of the combination of EIA plus WB is ~99.5%. There are some EIA- and WB-negative sera that are found to be positive for HIV by PCR, by antigen-detection assays, or by culture, but these are rare. Infants aged <15 mo may carry maternal antibodies and be falsely positive on EIA and WB. |

| Human Immunodeficiency Virus-1 (HIV-1) Serological Test—CONT | | |
| IFA | Serum, plasma. See <i>General Information</i> . | IFA is performed in some laboratories for screening and/or as a substitute for WB. IFA generally turns positive earlier in the course of infection than ELISA. IFA has also been used to discriminate between HIV-1 and HIV-2. A positive result requires >1+ fluorescence at a 1:20 dilution of the specimen compared with an equivalently treated negative control sample. However, the assay is subjective and requires highly skilled and experienced personnel to interpret the results; it is most useful for resolving indeterminate reactions with WB technique. |

2. Murray PR, Baron EJ, Jorgensen JH, et al, editors: *Manual of clinical microbiology*, ed 8, Washington, DC, 2003, American Society for Microbiology.

Human Immunodeficiency Virus-2 Serological Assay¹⁻³

Serum; plasma. See *General Information*.

EIA, WB, IFA

HIV-2 is a retrovirus, closely related to the simian AIDS virus (SIV). The areas of the highest prevalence are the West African nations and Portugal. There have been a small number of reported cases in the U.S. since 1987. Similar modes of transmission are probable; in the U.S., most cases have had heterosexual contact with a West African-infected individual.

HIV-2 cross-reacts with HIV-1 in serological tests; the sensitivity of EIA for HIV-2 is ~60-90%. A negative EIA test for HIV-1 does not exclude HIV-2. A positive EIA for HIV-1 with a negative or indeterminate WB suggests possible HIV-2 infection.

Specific EIA and WB tests for HIV-2 are available. Similarly, an IFA test is available for screening and confirming HIV-2 infections. It has been shown to be as sensitive as EIA for screening and superior to WB for discriminating between HIV-1 and HIV-2 infections.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Human T-Cell Lymphotropic Virus-I/II (HTLV- I/II) Serological Assay¹ <i>EIA, WB, Line immunoassay, IFA</i> | Serum, plasma. See <i>General Information</i> . | <p>HTLV-I and HTLV-II are Oncovirinae subfamily. HTLV-I has been associated with adult T-cell leukemia (ATL) and myelopathy/tropical spastic paraparesis (HAM/TSP). HTLV-II has been associated with a neurological disease resembling HAM/TSP. The transmission of these viruses appears to be similar to that of HIV-1 (in utero, via breast-feeding, parentally, through intercourse). Two FDA-approved HTLV-I/II EIAs with reported sensitivity of 99.76-100% and specificity of 99.63-99.98% are used for blood donor screening and clinical diagnosis of these infections.</p> <p>WB, line immunoassay, and IFA are supplemental serologic tests that can differentiate between antibody to HTLV-I and HTLV-II.</p> |

| Infectious Mononucleosis (IM) Serological Tests¹⁻³ <i>Slide test, Latex agglutination, ELISA</i> | Serum, plasma. See <i>General Information</i> . | <p>In patients with primary EBV infection, demonstration of Paul-Bunnell heterophile antibody is diagnostic. The original Paul-Bunnell test has been largely replaced by rapid tests. They utilize either rapid qualitative agglutination or ELISA tests. They detect 80-85% of IM patients. A negative test should imply the absence of significant IM-specific heterophile antibodies. Heterophile antibodies appear in 60% of patients with IM within the first and second weeks and in 80-90% by the first month. In most cases, titers decline in 3-6 mo.</p> <p>The false-positive rate for the Paul-Bunnell antibodies is ~3%, mostly from individuals with a low but persistent level of antibody after their primary illness. In addition, false-positive tests may be associated with hepatitis A or B, leukemia, lymphoma, and pancreatic carcinoma.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Infectious Mononucleosis (IM) Serological Tests—CONT

The false-negative rate is 10-15% and is more frequently seen in children than adults. It is estimated that 10% of the patients with EBV-related IM never develop PB antibodies. This number increases to 50% in children aged <4 yr.

|--|--|--|
| Influenza A and B Serological Tests (Influenza A and B Titer) ^{1,2} | Serum, acute and convalescent. Acute phase: up to 7 days after infection. Convalescent: 14-60 days later. | Most individuals experience their first influenza infection before school age and may have more than one infection during each decade of life. The presence of antibodies may not indicate recent infection. HI titers are most sensitive for influenza A, and CF titers are most sensitive for influenza B. NT and EIA tests are the most widely used assays in serodiagnosis and epidemiologic studies of influenza. |
|--|--|--|

HI, CF, NT, EIA

A fourfold increase in titer between the acute and convalescent sera collected at least 10 days apart is considered diagnostic. Although serologic methods are accurate, they rarely provide guidance for patient management and/or timely prophylaxis of contacts. Serology, however, remains an important tool for surveillance and epidemiologic studies.

**Leishmaniasis
Serological Test¹⁻⁴**

EIA, CF, IFA, DA

Serum. Collect in separation tube and freeze if not assayed immediately.

Serological testing for visceral leishmaniasis (kala-azar) normally shows high titers and may aid in the clinical diagnosis for immunocompetent people. Patients with mucosal disease will frequently have demonstrable antibodies, whereas only some patients with cutaneous leishmaniasis will only have low titers of antibodies present.

Antibody tests are usually sensitive (>90%), but lack sensitivity because false-positive results can occur with Chagas' (*Trypanosoma cruzi*) and other trypanosomal diseases, malaria, leprosy, schistosomiasis, and toxoplasmosis.

Antigen tests with good sensitivity and excellent specificity have been described in the literature, but they are not readily available.

See *General Comment*.

**Leptospira sp.
Identification¹⁻⁴**

Clinical manifestations of leptospirosis range from mild illness to icteric disease with kidney and liver involvement.

Blood Culture¹⁻³

1-3 drops of fresh or SPS anti-coagulated blood in each of 3-4 tubes of Fletcher's semisolid medium (5 mL) or Ellinghausen, McCullough, Johnson, Harris medium (10 mL). Heparin, sodium oxalate, or citrate is adequate as an anticoagulant if needed.

Blood cultures are the most reliable means for recovering the organism during the first week of illness, but are rarely successful thereafter. Infection should be suspected in patients with a history of contact with leptospires in the previous 3 wk. Common animal hosts include rats, mice, skunks, opossums, foxes, dogs, cattle, and raccoons. The usual mode of infection is via the skin from contact with an infected animal or its waste products or by means of contaminated food or water. Sporadic cases are seen in sewer workers, farmers, fish cleaners, animal handlers, and construction workers.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|---|--|
| <i>Leptospira</i> sp. Identification—CONT | | |
| | | Culture usually requires several weeks for isolation, but may be held for up to 13 wk before being considered negative for <i>Leptospira</i> . Before drawing the specimen, call the laboratory to ensure that the medium is available. Serum should always be collected for antibody studies. |
| <i>Urine Culture</i> ¹⁻² | Urine. See <i>Urine Culture, Routine, Midvoid</i> . | <p>Leptospire usually occur in the urine after the first week of illness when they are no longer present in the blood. Shedding in the urine may persist for 2-3 mo.</p> <p>Leptospira are susceptible to acid urine and should be processed immediately after collection by neutralization of pH. The number of leptospire in the urine is usually low, and therefore repeat urine cultures should be attempted. Serum should always be collected for antibody studies.</p> |
| <i>Darkfield Examination</i> ^{1,3} | Blood, CSF, or urine transported to the laboratory immediately | <p>Blood and CSF should be submitted during the first week of illness; after this time, urine is preferable.</p> <p>Direct darkfield examination is relatively insensitive and should not be the only diagnostic procedure performed for leptospire. Diagnosis by microscopic exam should be confirmed by culture or serological methods.</p> <p>Leptospire are difficult to demonstrate by darkfield examination. A negative darkfield result does not rule out the presence of organisms since at least 10,000 leptospire/mL are required for visualization. In darkfield examinations of blood, caution should be taken not to confuse filamentous structures derived from erythrocytes (“pseudospirochetes”) with <i>Leptospira</i> spp.</p> |
| <i>Serological Test</i> ¹⁻⁴ <i>MAT, IHA, IgM dipstick</i> | Serum drawn at onset of disease and at least 1 wk (preferably 2-3 wk) later | <p>Test is used to support the diagnosis of leptospirosis; it is especially helpful when cultures or darkfield examinations are negative. Antibodies can be detected (MAT, IHA) in the first week of illness and reach a maximum within 4 wk of illness. MAT titers up to 1:25,000 have been found.</p> <p>A history of contact during the previous 3 wk with an environment in which leptospire have been present may be important. MAT and IHA titers of ≥1:100 are indicative of acute or recent infection; however, a fourfold increase in titer between acute and convalescent sera is diagnostic. The IgM dipstick assay is designed as a screening test; acute and convalescent samples should be tested. Weakly reactive results should be confirmed by MAT.</p> |

**Lymphocytic
Choriomeningitis
(LCM) Virus
Serological Test**^{1,2}

Serum, acute and convalescent;
CSF. See *General Information*.

LCM is a member of Arenaviridae, which includes Lassa fever virus. Humans are infected by contact with infected mice or hamsters. The frequency of infection is greatest among young adults; highest incidence occurs in winter and spring. Outbreaks have been reported in families with new pet hamsters and among persons exposed to infected hamsters in animal care units.

IFA, NT, CF

The laboratory diagnosis of LCM can be accomplished by viral culture (blood, CSF) or serology. The accepted serological test today is the IFA to determine IgM. Antibodies last <3 mo. Detection of IgM in the CSF is definitive for LCM.

The appearance of antibodies by IFA usually coincides with the disappearance of viremia. IFA positivity appears first; single titers may be presumptive evidence of the disease. Titers may remain high for years. With IFA there is cross-reactivity among other arenaviruses. NT titers are more specific; they appear after 6-8 wk, rise slowly, and remain for years. CF titers peak at 3-5 wk and are gone early after the disease subsides.

| Mycobacteria ¹⁻⁵ <i>Culture</i> | Decontaminated, concentrated specimens. | Note that smears should optimally be prepared from concentrated specimens and read within 24 hr of receipt (see AFB smears). |
| | | Both liquid and solid selective and nonselective egg-based (supports growth of most mycobacteria) or agar-based (more rapid detection caused by easier visibility of colonies) are recommended. |
| Blood, bone marrow, CSF | Blood with specific request for AFB. Collect 10 mL (or 1.5 mL for pediatrics) of blood into an Isolator lysis centrifugation tube (Wampole) or broth designed for AFB isolation using an automated or manual monitoring system. CSF ≥ 3.0 mL, tube #2 or #3 Other body fluids (e.g., pleural, synovial, and pericardial) | Mycobacteremia is most commonly caused by <i>M. avium-intracellulare</i> (MAC), particularly in HIV-infected individuals. Positive CSF cultures are uncommon because of a low number of bacteria present and a low volume of CSF submitted. Generally active tuberculosis infection often exists elsewhere in patients with tuberculous meningitis. Deliver as much fluid as possible; swabs are not adequate. |
| <i>Extrapulmonary</i> | Tissue, wounds | Other species of mycobacteria may be responsible for extrapulmonary disease (e.g., <i>M. fortuitum</i> and <i>M. chelonae</i> have been associated with endocarditis, <i>M. scrofulaceum</i> with cervical adenitis, <i>M. ulcerans</i> with chronic granulomatous ulcerations of the skin and underlying tissue [Buruli ulcer], and <i>M. marinum</i> with skin lesions). Based on specimen source and clinical presentation, cultures should be processed for <i>Mycobacteria</i> other than tuberculosis (MOTT) acid-fast bacilli (e.g., <i>M. marinum</i> or <i>M. haemophilum</i>). |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Mycobacteria—CONT

| | | |
|-----------|--|---|
| | | Smears may be most helpful in cases of disease caused by <i>M. leprae</i> , since in vitro culturing is not possible. Sputum, induced sputum, gastric lavage. |
| Pulmonary | Bronchial/tracheal aspirates | Sputum may be induced by inhalation of a hypertonic salt aerosol. Gastric lavage may be the only way of obtaining adequate material from infants and from children and adults unable to cooperate with sputum induction. If gastric lavage processing will be delayed for 2 hr, add sodium carbonate powder or another alkaline buffer salt. Culture reports should include results of concentrated AFB smears. |
| Urine | First morning, clean-voided urine specimens are preferred. Do not collect 24-hr specimens. | Renal tuberculosis results from hematogenous spread of the tubercle bacilli. Urinary tract tuberculosis should be suspected whenever there is pyuria without bacteriuria or unexplained hematuria or proteinuria. Diagnosis is dependent upon isolation of <i>M. tuberculosis</i> from the urine. Maximum yield is obtained by sending three specimens for culture. Smears of the urine for the presence of acid-fast bacilli may not be helpful owing to the paucity of organisms and may be misleading if, for example, saprophytic <i>M. smegmatis</i> is present. |

**Mycoplasma
Serological Test**

Serum drawn at onset of disease and 3 wk later.

(*Mycoplasma pneumoniae* IgG and IgM antibody)¹⁻³

CF, EIA, IFA,
Particle
Agglutination

Serological confirmation of recent infection is based upon the demonstration of a fourfold rise in IgG titer between acute and convalescent sera or the presence of detectable IgM antibody. A single CF titer of $\geq 1:32$ serves as presumptive evidence of recent infection. IgM antibody may persist for several months. In addition adults experiencing reinfection may produce a largely IgG response. This confirms the necessity for collection of acute and convalescent phase serum samples.

The CF test may have a false-positive rate $\geq 10\%$ because of cross-reactions with streptococcus antigens and common glycolipid antigens produced in acute inflammatory conditions. For this reason the CF test has been largely replaced with other methodologies.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|--------------------------------------|---|
| Nasal Culture for Surveillance ^{1,2} (See <i>Agar Screening Tests</i> , <i>ORSA/MRSA Screen</i> .) | Anterior nares swab specimen. | Used to detect <i>S. aureus</i> colonization. Rapid identification of resistant strains of <i>S. aureus</i> , particularly oxacillin/methicillin-resistant <i>S. aureus</i> (ORSA/MRSA), is important from an infection control perspective. Positive patients should be placed on Contact Precautions. To establish a common source outbreak, a molecular test, such as pulsed-field gel electrophoresis (PFGE), may be used to determine clone (e.g., USA 300) and compare molecular fingerprints of isolates recovered during an outbreak. Likewise, a multiplex polymerase chain reaction (PCR) assay may be used to distinguish community-associated from hospital-associated strains of <i>S. aureus</i> (e.g., SCC mec types I-V). |
| | Nasopharyngeal swab specimen. | |
| | | Infrequently used to detect <i>Neisseria meningitidis</i> or <i>Streptococcus pneumoniae</i> colonization. |

|---|--|---|
| <i>Nocardia</i> spp. ¹⁻³ (See <i>Modified AFB Stain</i> .) | Sputum, transtracheal aspirates, bronchial washings, surgical specimens (including lung and brain biopsy material), exudate, body fluids (CSF, urine, and blood), scrapings from ulcers, and granules sent on sterile gauze for microscopic examination and culture. | Nocardiosis, most commonly found in immunosuppressed or transplant patients, may present as a suppurative or cavitary pneumonia resembling tuberculosis, lymphocutaneous abscesses, cellulitis, or as a mycetoma with granule formation. The organism has a marked tropism for the CNS with dissemination from a primary pulmonary infection. |
| Culture | | The etiologic agents are primarily <i>N. asteroides</i> , <i>N. brasiliensis</i> , or <i>N. caviae</i> , and all are found as saprophytes in the soil. Humans may contract the organism via inhalation or traumatic implantation. The organisms are probably not part of the normal flora, although they are occasionally isolated from sputum, for example, without clinical evidence of disease. <i>Nocardia</i> spp. are aerobic bacteria that require 2-5 days or more for isolation. Direct Gram stains of specimens including granules, demonstrate delicate, beaded, branching, filamentous gram-positive organisms. <i>Nocardia</i> spp. are acid-fast using a modified Kinyoun acid-fast stain, a characteristic that helps to differentiate it from <i>Actinomyces</i> spp. |

|---|--|--|
| Norwalk-like Viruses Direct Examination ¹⁻³ <i>IEM, RIA, EIA, RT-PCR</i> | See <i>Rotavirus Direct Examination</i> . | <p>Outbreaks of gastroenteritis caused by Norwalk-like viruses including the classical Norwalk virus has occurred worldwide. The source of outbreak is often contaminated water or food. The epidemics of gastroenteritis usually occur in closed communities, such as schools, nursing homes, and recreational camps and cruise ships. It is a common pathogen of older children and adults. There is a wide range of symptomatology. Some patients have a mild case of vomiting or diarrhea; others have severe attacks. Cramps, headache, malaise, myalgias, low-grade fever, and nausea are common findings. The disease lasts 24-48 hr. Viral shedding is observed from onset to about 72 hr.</p> <p>Traditionally, direct examination has been the method of choice since the virus has not been directly cultured in cell culture. The direct examination may be performed by means of immune electron microscopy (IEM) or recombinant EIA. Today RT-PCR assays with excellent sensitivity and specificity are available in some reference and research laboratories</p> <p>See also <i>Norwalk Virus Serological Test</i>.</p> |
| Norwalk Virus Serological Test ^{1,2} <i>ELISA</i> | Serum, acute and convalescent. See <i>General Information</i> . | <p>Norwalk-like viruses, which include classical Norwalk virus, are members of Caliciviridae. They are nonenveloped single-stranded RNA viruses. The prevalence of the antibody among adults may reach as high as 98%. In developed countries the antibody is not commonly acquired until the first or second decade of life. In contrast in developing countries, antibody to NV may be present by the age of 2-5 yr. Norwalk virus has been associated with epidemics of gastrointestinal illness occurring in families, schools, and cruise ships. Because Norwalk virus does not grow in routine cell cultures or animals, all the current ELISA assays used to detect antibody response to NV are based on recombinant viral protein, such as rVLPs. The rELISA is highly sensitive in detecting similar NV, but because of significant variability among the genotypes, the assay may not detect antibody to strains with less than 80% homology.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Ova and Parasite Examination (routine) ¹⁻³ | Fresh sputum (or induced), bronchial alveolar lavage fluid, aspirates, or biopsy material. Keep all specimens at RT. | One negative result does not rule out the possibility of a parasitic infection. See <i>General Instructions, Parasite Culture</i> . |
| | Fresh random stool, preserved stool, sigmoidoscopy material, and duodenal contents. Transport to lab (immediately if unpreserved) in a leak-proof container. Generally, up to three specimens taken on separate days over a 10-day period is recommended. Specimens should be free of urine, water, and soil. Patients should not have taken mineral oil; bismuth; nonabsorbable antidiarrheal medications; antimalarials; some antibiotics, such as the tetracyclines; or have undergone barium studies of the intestinal tract for 1 wk before examination. | Sputum and other respiratory specimens may be used for the detection of <i>Strongyloides stercoralis</i> , <i>Cryptosporidium</i> spp., <i>Echinococcus</i> spp., and <i>Paragonimus</i> spp. Fecal specimens can be used for the detection of many parasites, including protozoans, such as <i>Entamoeba histolytica</i> and <i>Giardia lamblia</i> ; helminths, such as <i>Strongyloides stercoralis</i> , <i>Ascaris lumbricoides</i> , and hookworms; tapeworms; and trematodes, such as <i>Schistosoma</i> spp. For each stool examination, three components should be considered: A direct wet mount should be performed if the stool specimen is received fresh (within ½ hr of collection), and an examination of the stool concentrate should routinely be performed and an examination of a direct permanent stained preparation. The latter is essential for the recovery and identification of protozoans. If fresh specimens cannot be examined within 1 hr of collection, the stool material should be preserved. More than one stool should be examined before ruling out a parasite infection. |
| | Urine specimens. Collect a single unpreserved specimen, a 24-hr unpreserved specimen, or an early morning or midday specimen for 2-3 consecutive days. | Urine specimens can be used to detect <i>Trichomonas vaginalis</i> , eggs of <i>Schistosoma haematobium</i> , microsporidia, and microfilaria. |

Paracoccidioidomycosis Serological Test—CONT

found in patients with pulmonary lesions or multifocal disease. CF titers are prognostic and decline in response to therapy. Relapses are accompanied by high titers, and high, fluctuating titers suggest a poor prognosis. Titers may be negative when small, isolated lesions are the only physical findings and in young children. Cross-reactions may occur in patients with histoplasmosis or blastomycosis.

The ID test is excellent for the diagnosis of acute unifocal pulmonary, progressive pulmonary, and multifocal disease. Concurrent use of the CF and ID tests is recommended for establishing the diagnosis and can increase the sensitivity to more than 95%.

|--|---|--|
| Parainfluenza Viruses 1, 2, and 3 Serological Tests (Parainfluenza Virus 1, 2, 3 Titer) ¹⁻³ | Serum, acute and convalescent. See <i>General Information</i> . | Traditional serological diagnosis of parainfluenza virus is based on demonstration of a fourfold increase in titer between the acute and convalescent sera. Demonstration of IgM antibody in acute sera may provide timely diagnosis. However, the serological test is secondary to antigen detection and culture of the virus. Most individuals experience many parainfluenza infections throughout their lives; they will probably have antibodies to at least one serotype. In addition, there may be cross-reactivity among the parainfluenza and mumps viruses. Serological tests are primarily used to make a retrospective diagnosis or to obtain seroepidemiological data. EIA has replaced the traditional HI and CF and IF tests in most laboratories. NT although specific is too cumbersome and not very cost effective. |

|---|--|--|
| Q Fever Serological Test (<i>Coxiella burnetii</i> Titer)^{1,2} <i>IFA, MIF</i> | Serum drawn at onset of disease and 2-3 wk later | This test is used to aid in the diagnosis of Q fever pneumonia or its complications (e.g., endocarditis or hepatitis). Humans acquire the organism, <i>Coxiella burnetii</i> , a rickettsia, by inhaling aerosolized particles containing the organism, usually from contact with cattle or sheep. Tick bites (ixodid ticks) may also be a mode of transmission. |
|---|--|--|

Phase I and phase II antibodies are produced in response to the organism; phase II antibodies appearing first and phase I antibodies weeks to months later. Antibodies are usually detectable 2-4 wk after the onset of infection. The diagnosis of acute Q fever is confirmed by a fourfold rise in titer between acute and convalescent sera or the presence of an IgM titer to *C. burnetii*. In chronic Q fever, a single sample is diagnostic when high antibody titers are detected against phase I antigens. Recent vaccinations will cause a rise equal to that seen in infection.

Since antibodies for Q fever do not cross-react with other rickettsial antibodies, a rise in titer is considered diagnostic for recent infection in the absence of prior vaccination.

|---|---|
| Rapid Influenza Antigen Test^{1,2} | Nasopharyngeal aspirate, NP wash, NP swab, throat swab, BAL |
|---|---|

EIA antigen detection, RT-PCR

The availability of antiviral drugs to treat influenza is associated with increased demand for rapid detection and diagnosis of influenza virus infections. They are also thought to be useful in hospitals and nursing homes to detect nosocomial outbreaks. The rapid influenza tests currently available in the U.S. detect either viral NP or NA antigens and will generate laboratory results within 30 min. A positive result may be obtained with as few as 20 influenza infected cells. Based on the timing and type of the collected specimen the reported sensitivity of rapid influenza tests range from 40%-100% and specificity from 52%-100%. BAL, NP washes/aspirates and NP swabs are the most productive. Throat swab is least productive and is not recommended.

In recent years, a rapid real time RT-PCR assay that amplifies unique sequences within viral RNA is shown to have sensitivity greater than that of traditional viral culture. With this assay a laboratory diagnosis may be made within 4 hr.

|--|---------------------------------|
| Respiratory Syncytial Virus (RSV) Antigen¹⁻² | Nasal wash, nasopharyngeal swab |
|--|---------------------------------|

EIA, DFA, RT-PCR

RSV is an important cause of lower respiratory tract infections during the first 6 mo of life. Reinfection may occur in older children and adults in the form of a mild upper respiratory tract infection. Occasionally, RSV can cause severe respiratory infection in aged adults confined to nursing homes.

DFA is a highly reliable test for detecting RSV in exfoliated nasopharyngeal epithelial cells with sensitivity ranging from 80%-97%. A good specimen should have more than 100 cells on the slide. The titer of the virus is higher in wash than in swab specimens.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Respiratory Syncytial Virus (RSV) Antigen—CONT

EIA are generally less sensitive than DFA, but technically very simple with an assay time of 15-20 min.

RT-PCR is available in some reference and research laboratories. However, RT-PCR generally does not provide much advantage over DFA.

1. Lennette EH, Smith TF, editors: *Laboratory diagnosis of viral infection*, ed 3, New York, 1999, Marcel Dekker.
2. Murray PR, Baron EJ, Jorgensen JH, et al, editors: *Manual of clinical microbiology*, ed 8, Washington, DC, 2003, American Society for Microbiology.

**Respiratory
Syncytial Virus
(RSV) Serological
Test^{1,2}**

Serum, acute and convalescent.
See *General Information*.

NT, IF, EIA, Immunoblot assay

RSV is the most common viral agent causing lower respiratory tract infection in infancy. By the first year of life, 50% of all infants experience a primary RSV infection; by 2 yr, nearly all have contracted RSV disease. Young infants do not always respond serologically; the reaction may be very slow, and significant changes may be missed if convalescent serum is drawn too early. In addition, neonates may possess titers caused by passive transfer of maternal antibody. For older children and adults, the presence of antibodies may indicate previous infection, but antibody titers will also rise with occurrence of recent infections.

Neutralization antibody is the only antibody test that correlates with protection against reinfection with RSV. IF and EIA are much more rapid and are nearly as accurate as NT for detecting increase in antibody titer. Immunoblot assays are used in research laboratories. In any event the absence of a significant rise in antibody titer does not rule out infection. The preferred method of diagnosing RSV is the use of viral culture and/or direct examination of specimen by immunofluorescence procedures.

**Respiratory Tract,
Lower Culture for
Fungus¹⁻³**

Sputum, bronchial/tracheal aspirates. See *Respiratory Tract, Lower Culture, Routine*

Sputum is the most frequently submitted specimen for the diagnosis of systemic mycoses. Since contamination by airborne spores and normal mouth flora is common, the results of this procedure must be interpreted cautiously.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Respiratory Tract, Lower Culture for Fungus—CONT

The isolation of a fungus, e.g., *Aspergillus fumigatus*, from bronchial or tracheal aspirates may be difficult to interpret, owing to the ubiquitous nature of the spores of these organisms. Isolation may indicate colonization rather than infection. The same may be true for isolation of *Candida* spp., especially in hospitalized patients. The method of choice for diagnosis of *Candida* pneumonia is demonstration of tissue invasion by histopathologic examination.

| Respiratory Tract, Lower ¹⁻¹⁷ | Sputum (expectorated or induced), bronchial washings or bronchoalveolar lavage (BAL), protected bronchial brushing (PBB), pleural fluid, trans-bronchial biopsy, transtracheal aspirate (TTA). | Transport specimen to lab immediately in a sterile container or Leukin's trap and refrigerate until processed. Fastidious organisms may not be recovered if there is a delay of >2 hr in specimen processing. The laboratory should be notified if fastidious organisms are suspected. Select the most purulent or blood-tinged portion of the specimen for culture and Gram stain. |
| Culture, Routine | <p>The following methods of specimen collection are used to obtain specimens for routine, mycobacteria, and fungal cultures as appropriate. Induced sputum and BAL are particularly useful for detecting <i>Pneumocystis jiroveci</i>. Anaerobic cultures are generally reserved for TTA, pleural fluid, and biopsy specimens. For optimal results, specimens must be processed within 2 hr of collection (preferred) or refrigerated for <24 hr.</p> <p>Expectorated sputum: The patient should be instructed to rinse mouth with water, discard, and cough deeply into a sterile container to obtain lower respiratory tract secretions. The</p> | <p>Quantitative cultures of PBB and BAL specimens may be helpful in distinguishing pathogens from contaminants; the isolation of $\geq 10^4$ CFU/mL of BAL likely represents pneumonia, whereas by PBB, $\geq 10^3$ CFU/mL is consistent with bacterial pneumonia. Quantitative cultures can be performed using either a calibrated pipette or loop method, are useful in the diagnosis of ventilator-associated pneumonia, pneumonia in immunocompromised and cystic fibrosis patients, acute episodes in chronic obstructive pulmonary disease, and even in community-acquired pneumonia. Repeat cultures submitted within 48 hr should be rejected.</p> |

|--------------------------------------|---|-------------------------------|
| Respiratory Tract, Lower—CONT | | |
| | specimen should be processed for Gram stain and culture. | |
| | Induced sputum: The patient should rinse mouth with water and discard. Patients should inhale ~25 mL of 3%-10% hypertonic sterile saline using a nebulizer. The specimen is collected in a sterile container for immediate transport to the laboratory. | |
| | BAL: Patients aspirate ~20 mL saline in a suction device, and the lavage fluid is collected into a sterile container. This procedure is repeated five times, and the total collection (40-70 mL) is transported immediately to the laboratory for Gram stain (cytocentrifuged preferred), other special stains, and quantitative aerobic culture. | |
| | Single or protected double-lumen brush catheter: Following premedication with atropine and topical anesthesia, a catheter is introduced through a bronchoscope. The brush is advanced to obtain secretions that are used to prepare slides for Gram and other stains and then placed in 1 mL of sterile non-bacteriostatic saline for quantitative aerobic culture. | |
| | TTA: Rarely performed. Patients are placed in a supine position with neck hyperextended. A needle with attached catheter is placed through the cricoid membrane to obtain a transtracheal aspirate that bypasses normal respiratory flora. | |

| Legionella Culture ^{5,14,16} | | <p><i>Legionella</i> spp. survive for extended periods of time in the refrigerator. Specimens should not be rejected using Gram stain criteria for routine sputa since most patients with Legionnaires' disease produce sputum that contains few WBCs. Legionellae do not stain with Gram stain reagents. Specimens should be plated on buffered media (e.g., buffered charcoal yeast extract agar [BCYE-a], without increased CO₂ at 35° C for 7 days and adequate humidity). Direct immunofluorescent antibody (IFA) testing of respiratory specimens, although rapid, lacks sensitivity and should always be performed along with a culture.</p> <p>Serology at best will only provide a retrospective lab diagnosis since it generally takes more than 3 wk to mount a detectable antibody response.</p> |
| Legionella Urine Antigen ¹⁶ | Urine | <p>Urine antigen testing is a helpful adjunct to Legionella cultures since it provides a rapid turnaround for results. Although the specificity is excellent, the sensitivity ranges between 70%-90% since it detects primarily <i>L. pneumophila</i> serogroup 1 infections.</p> |

| Rhinosporidiosis Examination ¹⁻³ | Mucocutaneous tissue. Send to the laboratory in a sterile container. Swab specimens are unacceptable. | <p>Rhinosporidiosis is a chronic granulomatous, usually painless, localized infection of the mucous membrane. The lesion increases in size over months to years to form a friable pedunculated mass. Lesions typically appear in the nose, upper airway, or conjunctiva. Children and young adults are most commonly affected, but the disease can occur at any age. Generally the incidence is higher in males than in females. The patient's history will usually indicate exposure to streams or pools. The presence of a pink-to-purple friable lesion in which sporangia may be macroscopically visible in the polyps is indicative of the disease.</p> <p>Direct examination of the lesion for the presence of sporangia, indicative of the agent <i>Rhinosporidium seeberi</i>, is the only means of diagnosis. Cultures have thus far been unsuccessful. If the lesion is processed for histopathology, the diagnosis can be made by hematoxylin-eosin (H&E) staining.</p> |

| Rotavirus Direct Examination ¹⁻³ <i>EM, LA, EIA, RT-PCR</i> | Stool specimen. Deliver to lab immediately in closed container. If not examined immediately, store specimen at -70° C. If shipped to another laboratory, send on dry ice. | <p>Rotavirus is known to cause sporadic and epidemic cases of gastroenteritis in infants and young children, in particular during the winter months. Approximately one half of the infants and young children hospitalized with diarrhea are found to be infected with a rotavirus. The diarrhea lasts 5-8 days and is frequently accompanied by vomiting and fever. The virus is maximally present in the first 3 days of illness and generally shedding of virus is greatly diminished by the eighth day. Adult contacts may have a mild-to-asymptomatic infection; however, epidemics of gastroenteritis among adults have been described.</p> <p>For many years the direct examination of stool by EM was the only method to diagnose rotavirus infections and was considered the gold standard. Today several commercial EIA, LA, and dot blot kits are available. The sensitivity and specificity of EIA are about 95% (results may vary according to type of kit used). LA is not considered as sensitive as EIA, but they are rapid and highly specific assays. Unlike EM that detects all groups of rotavirus (A, B, C), EIA and LA only detect group A rotavirus.</p> |

| Rotavirus Serological Test ^{1,2} | Serum, acute and convalescent. See <i>General Information</i> . | Rotavirus is a major cause of infectious gastroenteritis in infants and young children with a peak incidence during the winter months. |
| <i>EIA, RIA</i> | | <p>In developing countries rotavirus accounts for 10% to 20% of gastroenteritis-associated death. Virtually all the children in both developed and developing counties are infected with rotavirus by 2 to 3 yr of age. There are three rotavirus groups (A, B, and C) that cause disease in humans. Rotavirus Group A accounts for majority of the outbreaks.</p> <p>Estimated incubation period is 24–48 hr. Serum antibodies are rapidly acquired between the ages of 6 and 24 mo. Approximately 90% of the population have various levels of preexisting rotavirus-specific serum antibody. A fourfold rise in titer of antibodies is needed for diagnosis.</p> <p>Direct examination of stool specimens is the primary mode of diagnosis since the isolation of rotavirus in routine cell culture is a relatively slow and laborious process.</p> <p>RIA and EIA have proved most sensitive for the detection of seroconversion. These tests are not readily available in most clinical laboratories.</p> |

|---|--|---|
| Rubella Virus Serological Test (German Measles Titer) ¹⁻³ <i>HI, EIA, CF, PHA, LA</i> | Serum, acute and convalescent. See <i>General Information</i> . | <p>Rubella is transmitted directly by contact or by droplets from the nasopharynx of infected individuals. The peak incidence is in late winter or early spring. Communicability of the virus is generally felt to have occurred a few days before rash development or 5-7 days after rash has developed. Most cases today occur in the U.S. in young unvaccinated and undervaccinated adults. Infants with congenital rubella may shed virus from nasopharynx or urine for up to 1 yr.</p> <p>Serological tests are used to determine the immune status of the individual, to diagnose postnatal rubella, and occasionally to support the diagnosis of rubella. IgM antibody disappears within 4-5 wk; IgG antibody remains for life.</p> <p>Demonstration of a fourfold rise in titer between acute and convalescent sera may be indicative of a recent infection. Single titers, even >1:256, cannot be interpreted as evidence of recent infection; they are more likely to indicate immune status.</p> <p>For diagnosis EIA is the preferred method, although HAI, CF, or FIAX are also acceptable. LA is useful as a stat assay. PHA is good only for determination of the immune status of a patient, not for diagnosis. In addition, any of the other assays are appropriate for evaluation of immune status. For any reactivity of the assay above a standard cutoff value is considered indicative of immunity.</p> <p>For the diagnosis of congenital rubella in an infant less than 6 mo old, HAI, EIA, or specific IgM assays are necessary. Between 6 and 12 mo old any of the following assays are acceptable: HAI, EIA, LA, or CF.</p> |

Rubeola Virus Serological Test—CONT

titer by HAI is >50 (NT >20), the diagnosis is enhanced. IgM antibody invariably appears and thus cannot be used as a marker for persistent infection.

Cross-reactions, as shown by increasing measles titers, have been demonstrated with other diseases, such as chronic active hepatitis, systemic lupus erythematosus, and infectious mononucleosis.

Patients with multiple sclerosis have had increased CSF titers (not false positives); however, increased titers against other enveloped viruses have also been observed.

| Stool Culture for Enteric Pathogens ¹⁻⁸ | Stool, rectal swabs | <p>General Comments. Freshly passed stool delivered to lab immediately in container with tightly fitting lid. Do not refrigerate specimen. If a delay of >30 min in processing is anticipated, transfer stool to transport vial containing Modified Cary-Blair medium with reduced agar content according to manufacturer's direction. Overfilling vial will lead to unsatisfactory preservation of enteric pathogens. Rectal swabs are collected by passing a swab tip approximately 1 inch beyond the anal sphincter, rotating to obtain a good sample, and placing the swab(s) in appropriate transport medium. Duodenal, colostomy, or ileostomy contents may be submitted in either a leakproof container or transport vial.</p> <p>Two stools collected from different days may be necessary to diagnose bacterial gastroenteritis. Specimens should be collected during the acute stage of disease. When specimens are submitted in a transport container with preservative or on swabs, the request should include information regarding specimen appearance (e.g., bloody, liquid, formed, solid, or mucoid). Bloody stools are generally associated with illness caused by either <i>Campylobacter</i> or strains of enterohemorrhagic <i>E. coli</i>.</p> <p>As part of the lab's rejection policy, stools should be rejected if: (1) stool is in transport >2 hr, but not in transport medium; (2) in transport medium longer than 24 hr at 25° C or 3 days at 4° C; (3) stool is hard or contains barium; (4) transport medium is yellow, indicating a low pH, which may kill <i>Shigella</i> spp.; (5) transport container is overfilled with stool; (6) specimen collected from patient hospitalized >3 days unless</p> |

|-------------------------|--------------------------------------|-------------------------------|
|-------------------------|--------------------------------------|-------------------------------|

Stool Culture for Enteric Pathogens—CONT

they are immunocompromised or are part of an institutional cluster epidemic; (7) swabs are dry or (8) more than three stools are submitted within a 3-wk period or more than one specimen is submitted within 1 day.

This procedure is used as a screen for the common enteric pathogens (e.g., *Salmonella* spp., *Shigella* spp., and *Campylobacter* spp.). Specify if other pathogens (e.g., *Vibrio* spp., *Yersinia* spp., enterohemorrhagic strains of *E. coli* [EHEC], including 0157:H7 that produce verotoxin, or *Clostridium difficile*) are suspected. Detection of large quantities of *Pseudomonas aeruginosa*, *S. aureus*, *Bacillus cereus*, yeast, or DF-3 should be reported without susceptibility testing. Antimicrobial susceptibility test (AST) should be performed on all enteric pathogens except: (1) EHEC since therapy can induce bacterial lysis, toxin release, and development of hemolytic uremic syndrome (HUS) and (2) *Salmonella* spp. since therapy may prolong the carrier state. The only instances when ASTs of *Salmonella* should be performed are when *Salmonella* serovar *typhi* is isolated, when the isolate is identified in urine or normally sterile closed body site fluid (i.e., extraintestinal site), in children less than 6 mo of age, or upon request.

Both differential and selective stool culture media should be inoculated to increase the chance of recovering the pathogen causing gastroenteritis. Because of the inhibitory properties of selective media, it should be inoculated heavily with a stool specimen. To increase recovery of small numbers of *Salmonella* or *Shigella*, enrichment broth may be inoculated and incubated for 6-24 hr before subculturing, depending on the broth selected. The method to minimize the number of plates of solid media used per specimen with little compromise in turnaround time to detection is to initially inoculate a MacConkey plate and GN broth. This broth is then subcultured in 6 hr onto selective media (e.g., XLD and Hektoen agar).

To recover campylobacter, avoid phosphate buffered glycerol transport media. Inoculate medium containing cefoperazone incubated at 42° C in a microaerobic environment. A wet mount of a fresh stool received within 30 min of collection may be useful to rapidly identify motile, darting curved rods moving in a zigzag fashion across the microscopic field. The use of a filtration technique that allows passage of motile campylobacters through pores of a filter for selective separation of campylobacters from nonmotile organisms and enrichment broth cultures may be helpful in recovering campylobacter after the acute stage of disease.

For hospitalized patients, positive results for enteric pathogens should be conveyed immediately to the infection control professional to place these patients on Contact Precautions. For cases suspected of life-threatening illness (e.g., *Salmonella* serovar *typhi* or *paratyphi* C, *V. cholerae*, or EHEC), the ordering physician should be notified immediately.

| Stool Culture for Enteric Pathogens—CONT | | |
| <i>Escherichia coli</i> 0157:H7 Culture (Verotoxin-producing <i>E. coli</i> or VTEC) ³ | | VTEC, also known as Shiga toxin-producing or enterohemorrhagic <i>E. coli</i> (EHEC), produces a toxin that is implicated in causing hemorrhagic colitis (HC) and is associated with hemolytic uremic syndrome (HUS), particularly in pediatric patients. Outbreaks have occurred with consumption of improperly cooked meat (e.g., hamburger). The most common toxin-producing strain is <i>E. coli</i> 0157:H7, although other <i>E. coli</i> serotypes can also produce toxin and have been related to disease. At a minimum, all bloody stools should be screened for <i>E. coli</i> 0157 using cefixime tellurite sorbitol MacConkey (MAC) agar (CT-SMAC). Sorbitol-negative colorless colonies are then tested by latex agglutination, and positive results generally can be confirmed with H7 flagellar antiserum and toxin testing at a public health lab. Preferably stool is inoculated into MAC broth for 24 hr at 35° C–37° C and tested using an EHEC EIA to detect verotoxin from <i>E. coli</i> 0157 and from other strains. |
| <i>Vibrio</i> <i>parahaemolyticus</i> ³ | | <i>V. parahaemolyticus</i> is a marine bacterium that may produce an explosive, watery diarrhea with abdominal cramps and nausea 15–24 hr after ingestion of contaminated seafood. The symptoms may last several hours to 10 days, but usually subside without treatment in 3 days. |
| <i>Vibrio cholerae</i> ³ | | <p>Crab, lobster, shrimp, and seafood cocktail have been implicated in outbreaks in the U.S. The bacterium is transmitted when these foods are improperly refrigerated, insufficiently cooked, or cross-contaminated.</p> <p>Specimens should be collected within the first 24 hr of illness before the administration of antimicrobial agents. <i>V. cholerae</i> is very sensitive to desiccation; thus specimens must not be allowed to dry out.</p> <p>Rectal swabs may be adequate in the acute stage, but are less satisfactory than stool specimens. If there will be a delay in specimen processing, transport specimens in Cary-Blair transport medium or alkaline peptone water. Do not use glycerol-buffered saline for transport; glycerol may be toxic to <i>Vibrio</i> spp.</p> <p>The most common form of the disease is an acute gastroenteritis with abdominal pain, with or without bloody diarrhea, and fever. Specimens are best taken during the acute stage of the illness.</p> <p>A stool positive for <i>V. cholerae</i> is typically rice watery in appearance with a fishy odor. The clinical symptom of very severe cases is massive loss of fluid and electrolytes. For every severe case, there are 25–100 mild-to-asymptomatic infections. During the 1980s, both epidemic and environmental strains of <i>V. cholerae</i> were isolated in the U.S. In 1991 cases of cholera were identified in the U.S. subsequent to an outbreak in South America.</p> |
| <i>Yersinia</i> <i>enterocolitica</i> ³ | | Selective CIN medium or MacConkey agar incubated at room temperature or a cold enrichment procedure at 4° C with subculturing for 3–4 wk may be needed for isolation of the organism. Most outbreaks have occurred in northern Europe and Canada; however, there have been sporadic cases in the U.S. |

|---|--------------------------------------|---|
| Stool Culture for Enteric Pathogens—CONT | | |
| <i>Clostridium difficile</i> Culture ¹ (See <i>Toxin Identification for Bacteriological Diseases, Clostridium difficile</i>) | Nonpreserved stool | Isolation of <i>C. difficile</i> from stool in suspected cases of antibiotic-associated diarrhea (AAD) or pseudomembranous colitis (PMC) may support the diagnosis, but demonstration of the specific toxin involved is necessary for confirmation. <i>C. difficile</i> has been recovered from stool of patients with diarrhea who have received antimicrobial therapy without a clinical diagnosis of PMC. In healthy adults, the rate of isolation of <i>C. difficile</i> is 4%; in infants and young children, rates may be significantly higher. Carrier rates may also be high in seriously ill hospitalized patients. |

Superficial Wound Culture for Fungus¹⁻³ Pus, exudates, and drainage. See *Superficial Wound Culture, Routine*.

The skin over pustular lesions should be disinfected and exudates aspirated using a sterile needle and syringe. Aspirates should be placed in a sterile container for transport to the laboratory. Biopsy of the lesion may be required if the aspirate fails to yield fungi. Swab specimens are not recommended.

If present, granules may signify an actinomycotic infection or may indicate a eumycotic mycetoma associated with *Pseudallescheria boydii*, *Acremonium* spp., *Madurella* spp., or a variety of other fungi.

Superficial Wound Culture, Routine¹⁻⁸ Aspirate (preferred) of material from wound, abscess, cellulitis

An aspirate ≥ 1 mL from a previously undrained abscess, if properly collected and transported, will be of greatest value. Swabs of deep wounds or abscesses are of limited value. Transport to lab as soon as possible in an anaerobic system or, in a transport system if a swab is used.

Repeated cultures of open, draining wounds or of large areas of devitalized tissue frequently yield many microorganisms of questionable significance. Histopathological examination of biopsy material may be a necessary adjunct to culture, in particular when a chronic, localized infection occurs.

Syphilis
(*Treponema pallidum*) Tests

| | | |
|---|--|--|
| Direct Examination (Darkfield Examination, DFA-TP) ^{1,2} | Darkfield examination: genital lesions. DFA-TP: oral, genital, and rectal lesions; amniotic fluid; placenta; umbilicus; skin lesions. | To obtain scrapings superficial debris should be cleaned before collection. Gently abrade the base of the cleansed chancre with saline-moistened gauze to obtain serous fluid. Specimens for darkfield microscopy should be collected on a glass slide, covered with a coverslip, and transported to the laboratory immediately. Specimens for DFA-TP should be collected on a glass slide and allowed to air-dry. Direct examination is useful for the diagnosis of primary, secondary, and early congenital syphilis. Serological tests are often not positive for 14-21 days after infection, and the direct detection of spirochetes may be the only way to establish an early diagnosis. Darkfield examinations should be performed within 30 min of specimen collection to ensure the presence of motile spirochetes. In addition dark-field examination is of no value for oral lesions due to the presence of nonpathogenic spirochetes in the normal oral flora. DFA-TP of tissue and body fluid is especially valuable in the diagnosis of congenital syphilis. |
| Treponemal Specific Tests | Serum. Reactive specimens must be reported to the state health department. | A negative direct examination of scrapings is not adequate to rule out infection with <i>Treponema pallidum</i> . Treponema lesions frequently exude infectious material; therefore care should be taken when handling these specimens. |
| Fluorescent Treponemal Antibody Absorption (FTA-ABS) ^{1,2} | | The test should be used only to confirm reactive nontreponemal (RPR, VDRL) serological tests for syphilis. Only when late syphilis is suspected should an FTA-ABS be performed when the nontreponemal test is nonreactive. |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|--|
| Syphilis—CONT | | |
| | | <p>The sensitivity of the FTA-ABS is as follows:</p> <p>Primary syphilis 84% (range: 70%-100%)</p> <p>Secondary syphilis 100</p> <p>Latent syphilis 100</p> <p>Late syphilis 96</p> <p>False-positive results may occur in cases of collagen vascular disease.</p> <p>The test is not to be used as a screen for syphilis and is not recommended for CSF specimens.</p> |
| <i>Treponema pallidum</i> Passive Particle Agglutination (TP-PA) ^{1,2} | Serum. Reactive specimens must be reported to the state health department. | <p>The test should be used only to confirm reactive nontreponemal (RPR, VDRL) serological tests for syphilis. Only when late syphilis is suspected should a TP-PA be performed when the nontreponemal test is nonreactive.</p> <p>The sensitivity of the TP-PA is as follows:</p> <p>Primary syphilis 86% (range: 86%-100%)</p> <p>Secondary syphilis 100</p> <p>Latent syphilis 100</p> <p>False-positive results have occurred in patients with connective tissue disease, leprosy, and infectious mononucleosis.</p> <p>The TP-PA, like the FTA-ABS test, is not to be used as a screen for syphilis and is not recommended for CSF specimens.</p> |
| Nontreponemal Tests | Serum. | <p>The RPR test is used as a screening test for primary and secondary syphilis. Sensitivity of the test varies in primary syphilis, but by 2 mo test sensitivity is 100%. Reactive RPR tests should be confirmed with an FTA-ABS or TP-PA. In addition reactive specimens should be titered to monitor therapy or establish reinfection. The titer should decline following successful therapy. A fourfold increase in titer usually indicates treatment failure or reinfection.</p> <p>Biological false-positive results may occur in cases of collagen diseases, such as rheumatoid arthritis and lupus erythematosus; in infections, such as infectious mononucleosis, leprosy, and malaria; in pregnancy; and in addition.</p> |
| Rapid Plasma Reagin (RPR) Screening Test ^{1,2} | | |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Syphilis—CONT | | |
| VDRL (Venereal Disease Research Laboratory) Test ^{1,2} | Serum, CSF (Grossly bloody specimens are unacceptable.) | <p>The serum VDRL test is used as a screening test for primary and secondary syphilis. Sensitivity of the test varies in primary syphilis, but by 2 mo test sensitivity is 100%. Reactive serum VDRL tests should be confirmed with an FTA-ABS or TP-PA. In addition reactive specimens should be titered to monitor therapy or establish reinfection. The titer should decline following successful therapy. A fourfold increase in titer usually indicates treatment failure or reinfection.</p> <p>Biological false-positive results may occur as with the RPR. (See <i>Rapid Plasma Reagin Screening Test</i>, serum, above.)</p> <p>The CSF VDRL test is used for the diagnosis of neurosyphilis. The test has a specificity of 99.8%, but a sensitivity of 50%. Therefore a negative test result does not rule out the presence of neurosyphilis. Reactive specimens should be titered to monitor therapy or establish reinfection. The titer should decline following successful therapy. Reactive CSF VDRL tests are not confirmed with a treponemal-specific test.</p> |
| <div><div>1. Murray PR, Baron EJ, Jorgensen JH, et al, editors: <i>Manual of clinical microbiology</i>, ed 8, Washington, DC, 2003, ASM Press.</div><div>2. Rose NR, Hamilton RG, Detrick B, editors: <i>Manual of clinical immunology</i>, ed 6, Washington, DC, 2002, ASM Press.</div></div> | | |
| Throat Culture ¹ <i>Routine</i> | Throat swab | <p>With the exception of deep pharyngeal cultures collected from patients with cystic fibrosis, throat specimens should not be routinely cultured. Only cultures to diagnose specific pathogens (e.g., group A <i>Streptococcus pyogenes</i>, <i>Corynebacterium diphtheriae</i>, <i>Neisseria gonorrhoeae</i>, <i>Arcanobacterium haemolyticum</i>) should be processed.</p> |
| Group A Streptococcus (GAS) Screen ^{2,3} <i>Rapid</i> <i>EIA, Probe, PCR</i> | Swab of oropharynx, tonsillar exudate | <p>Select a rapid group A strep (GAS) antigen test that has high sensitivity since even low numbers of organisms may reflect infection. Because of the difficulty in obtaining good specimens from young children, the American Academy of Pediatrics recommends that negative rapid antigen tests be confirmed by culture for beta-hemolytic GAS. In contrast negative GAS antigen screening tests on specimens collected from adults do not require a reflex culture if the sensitivity of the antigen test exceeds 80%.</p> <p>Colony quantitation should not be included on the report to distinguish colonization from infection. This distinction should be made on clinical grounds.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|---|
| Throat Culture—CONT | | |
| <i>Corynebacterium diphtheriae</i> ¹ | Nasopharyngeal swab from inflamed areas and beneath pseudomembrane, if present | <p>It is a requirement of the College of American Pathologists (CAP) that laboratories have a mechanism to culture <i>C. diphtheriae</i> in-house or to refer specimens when requested.</p> <p>The microbiology laboratory should be contacted before specimen collection to ensure appropriate processing of the specimen on special media. Specimens should be collected on cotton-tipped or polyester-tipped swabs. If delay in inoculation of media is anticipated beyond 24 hr, silica gel-containing transport containers should be used to maintain viability. If cutaneous diphtheria is suspected, throat, nasopharyngeal, and skin swabs or aspirates should be collected for culture.</p> <p>Specimens should be processed in a biosafety cabinet and inoculated media (e.g., blood agar, cystine tellurite blood agar) should be incubated aerobically without CO₂. Direct smears are not reliable for diagnosis since metachromatic granules are seen in other bacteria as well.</p> <p>If biochemical results are consistent with <i>C. diphtheriae</i>, a presumptive report may be issued without quantitation and the isolate forwarded to a public health laboratory for diphtheria confirmation based on a positive toxin test result. A less severe form of diphtheria with pharyngitis, endocarditis, septic arthritis, or other systemic manifestations may occur when the patient is infected with a nontoxigenic strain.</p> |
| <i>Neisseria gonorrhoeae</i> ¹ (See <i>Genital Culture</i> .) | Throat swab from tonsillar regions and posterior pharynx | <p>Plate at bedside or transport swabs to lab immediately following specimen collection.</p> <p>Oropharyngeal infection is generally asymptomatic and occurs preponderantly in homosexual males. A few patients, however, may have acute pharyngitis and tonsillitis.</p> <p>A Gram stain of the specimen is noncontributory. A culture of anorectal genital sites should also be requested. Inoculate specimens onto modified Thayer-Martin medium. Isolates must be confirmed biochemically since <i>N. meningitidis</i> may be present without symptoms.</p> |

Toxoplasmosis Serological Test
(Toxoplasmosis Titer)¹⁻⁴

Serum. Collect in separation tube and freeze if not assayed immediately.

Individuals with detectable antibodies to *Toxoplasma gondii* are in high numbers in most populations around the world making serodiagnosis troublesome. EIA and IFA are the preferred methods of testing in the U.S.

EIA, IFA

Elevation in IgG specific titers may suggest recent infection, although high titers can be present for a number of years after primary infection. Although this rarely occurs in practice, the demonstration of a conversion from a negative to a positive result or a fourfold rise in IgG titer over a period of several weeks will confirm a diagnosis. When IgG antibodies are present, a positive IgM result is suggestive of acute infection within the last 12 mo. However, one must keep in mind that although IgM titers normally return to undetectable levels within 6-9 mo, it can be detected for as long as 18 mo postinfection.

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|--|
| Urine Culture, Routine ¹⁻¹⁷ | <p>First morning midstream and clean voided</p> <p>Female: Clean meatus with green soap and gauze pads by spreading the labia and washing from front to back. Four pads should be used, one stroke per pad. Rinse the outer genitalia and area around the meatus with sterile water. Patients should urinate into commode and without interrupting the flow of urine collect the middle portion of the void.</p> <p>Males: Clean the urethral meatus with soap and rinse with sterile water.</p> | <p>Process specimen aerobically within 2 hr. If a delay in processing is anticipated, refrigerate the specimen or preferably place the urine in a transport device to preserve the colony count. <i>Anaerobic cultures and culture of urine in broth are inappropriate.</i></p> <p>One morphotype with a colony count of 10^5/mL from a properly collected urine specimen that has been incubating in the bladder for at least 5 hr is considered significant. Lower colony counts may be significant in young females with urethritis. There are several good references for quantitative interpretation of urine specimens.¹³⁻¹⁶</p> |
| | <i>Catheterized</i> | <ol style="list-style-type: none"> 1. Clamp drainage tubing for 10 min below the level of urine sample port. 2. Cleanse the urine sample port with an alcohol pledget. 3. Insert needle into urine sample port. 4. Withdraw 4 mL of urine. 5. Place specimen in sterile container. 6. Unclamp tubing. <p>Deliver urine to lab within 2 hr, refrigerate, or place in transport device for delivery to the laboratory.</p> |
| <i>Urine Screen</i> | | <p>A urine screening procedure may be used to rapidly detect bacteriuria/pyuria with a sensitivity of $\geq 10^5$. Lower counts may be considered significant and require culture confirmation. There are several methods for urine screens including Gram stain, dipsticks to detect leukocyte esterase that reflect white blood cells caused by pyuria, nitrate reduction; blood, and bacteria; and photometric, bioluminescence, and colorimetric filtration procedures. If approved by the medical staff, urine specimens may be screened and reflexed for culture in the event that a positive threshold is met.</p> |
| <i>Suprapubic</i> | Aspirated urine | <p>Puncture bladder through lower abdominal wall using a sterile needle and syringe. Deliver to lab immediately for processing.</p> <p>Suprapubic aspirates are indicated for patients with equivocal colony counts, clinical evidence of urinary tract infection, and for neonates and young children. The presence of all organisms are identified, with the exception of obvious skin contaminants. Urine collected in this manner is the only acceptable urine specimen for anaerobic culture.</p> <p><i>Culture of Foley catheter tips is inappropriate.</i></p> |

Vaginal Culture for Fungus¹

Swab of vagina, vulva, or labia placed into a transport system and delivered to the laboratory immediately.

Vaginal candidiasis is usually diagnosed based on clinical symptoms and direct microscopic examination of vaginal secretions. Since *Candida* spp. are part of the normal vaginal flora in up to 20% of healthy females, the recovery of *Candida* spp. is of little value. Cultures are useful in monitoring therapy in refractory disease.

See General Comments.

|--|--|---|
| Varicella-Zoster, Direct Test⁶ <i>Tzanck prep, EM, IFA, PCR</i> | Skin scrapings from base of fresh lesions. Vesicular fluid is collected in capillary pipette or aspirated with tuberculin syringe. | <p>Varicella is a highly communicable disease. Incubation period ranges from 10-23 days (average of 14 days). A history of previous varicella infection indicates immunity.</p> <p>Tzanck preparation is used for the direct examination of herpes virus in skin scrapings but cannot distinguish VZV from HSV.</p> <p>EM can also be used as well but not for distinguishing between VZV and HSV.</p> <p>IFA uses a monoclonal antibody and is specific for VZV. Specimens with too few epithelial cells should be considered unsatisfactory for examination.</p> <p>Real time and traditional PCR tests are highly reliable for detection of VZV from variety of sources, but the main use of PCR is to distinguish between WT and vaccine strains. PCR products from a WT virus contains <i>Pst</i>I restriction site. Vaccine strains do not contain <i>Pst</i>I restriction site. PCR is often used to investigate cases of possible transmission of vaccine and WT VZV to susceptible contacts.</p> |

| | | |
|---|---|--|
| Varicella-Zoster Virus Serological Test (Herpes Zoster Virus, Chickenpox) ¹⁻³ <i>EIA, NT, FAMA, CF</i> | Serum, acute and convalescent. <i>See General Information.</i> | <p>VZV is a highly contagious virus that causes two distinct clinical illnesses. A generalized vesicular rash characterizes primary infection, chickenpox. VZV may also reactivate decades after primary infection to cause a dermatomally distributed rash also known as shingles.</p> <p>The EIA test is the preferred assay for diagnosis and determination of immune status. The antibody can be detected within 48 hr after onset of rash. Passively acquired antibody can be detected up to 8 wk following VZ immune globulin administration.</p> <p>The CF test cannot be used to determine immune status of exposed patients, especially adults, since titers fall within 12 mo. Neutralization tests are useful, and the antibodies persist for life; however, the tests are not readily available. The fluorescent antibody to membrane antigen (FAMA) is a specific and sensitive test to determine immune status and to measure IgG, IgM, and IgA. The major disadvantage of FAMA is that live virus-infected cells are required</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|--|
| Virus Culture ¹⁻² | <p>Adequate specimen is mandatory. Aspirates, scrapings, and tissue are superior to swab specimens. If swabs are used, they should be cotton or Dacron, not calcium alginate.</p> <p>See Table IV-2 for appropriate specimens for viral isolation in selected clinical syndromes.</p> | <p>The ability to propagate viral particles in cultivated mammalian cells has been the backbone of clinical virology laboratories. Over the years several, primary, diploid, and continuous cell lines have been established to grow most viral agents. Based on suspected pathogen and the source of the specimen, one or more of these cell lines are used to detect the infecting viral agent. Despite these efforts a large number of viral agents either do not grow in vitro or requires several weeks to generate CPE. For many years direct examination of the specimen by electron microscopy (EM) had complemented the traditional viral culture. In recent years, however, highly sensitive and rapid EIA, IFA, and similar assays have virtually replaced EM in the diagnostic laboratories. More recently the introduction of molecular-based techniques, such as direct probe, traditional PCR, real time PCR, bDNA, and NASBA, into the clinical laboratories have transformed and provided a theoretical mean for the laboratories to detect virtually any viral agent. Using these techniques it is now possible to detect, monitor, and predict antiviral resistance and therapeutic outcomes for most viral infections.</p> |
| <i>Shell vial culture</i> | <p>Specimens should be processed as quickly as possible. For short-term transit or storage (>24 hr) of most viral suspensions, the specimen should be held at 4° C rather than frozen. If longer delays are expected, freeze at -60° C; when ready to process, thaw the sample slowly, raising the temperature about 2-5° C/min.</p> | <p>Shell vial assay is based on inoculating the specimen onto a shell vial, which contains a coverslip that has a monolayer of susceptible cells. Vials are centrifuged, media added, and incubated 16-24 to 48 hr. Following the incubation, the medium is aspirated, and the monolayer is removed and stained to detect viral antigen by FA.</p> <p>Shell vial was originally developed to detect CMV. The new generation of shell vial that is using hybrid cell lines, such as R-Mix (mink lung and A549), which detects all the respiratory viruses; E-Mix (A549 and Buffalo green monkey kidney), which detects enterovirus; H and V-Mix (MRC-5 and African green monkey kidney), which detects CMV, VZV, and HSV. In fact shell vial has begun to replace the traditional viral culture in some laboratories. Shell vial provides the advantage of amplifying low-level virus particles in a specimen by enhanced infection of monolayer and the use of monoclonal antibodies to detect viral antigens instead of viral CPE. Shell vial has greatly reduced the turnaround time for viral detection with sensitivity in most cases equivalent to culture.</p> |
| <i>The Enzyme-Linked Virus Inducible System (ELVIS®)</i> | <p>Cultures should only be sent during the first week of illness. The yield of a virus rapidly decreases >4 days after onset of illness.</p> | <p>ELVIS is a recently developed shell vial assay that uses genetically engineered cell lines for detecting HSV infection. The assay is based on an HSV-specific gene promoter sequence linked to the reporter gene galactosidase. When the cell monolayers are infected with HSV-1 or HSV-2, proteins produced by HSV-1 and HSV-2 shortly after infection of the cell by the virus turn on the HSV promoter sequence of the cells. The protein product from the transcribed LacZ message is β-galactosidase (β-gal), an enzyme cloned from <i>E. coli</i>, which accumulates inside the affected cell and serves as the reporter molecule, which are readily detected by the intense blue color after cells are fixed and stained with the histochemical staining kit.</p> |

| Virus Direct Detection ^{1,2} | Nasopharyngeal swab, throat swab, nasal aspirate, transtracheal aspirate, bronchoalveolar lavage (BAL), lung tissue, lesions, exanthems, urine, CSF. | Many monoclonal and polyclonal antibodies are available for direct detection of viral agents in clinical specimens by means of immunofluorescence stain. FA stains are available for direct detection of the following viruses: adenovirus, cytomegalovirus, enterovirus, herpes simplex, influenza, measles, mumps, parainfluenza, rabies, respiratory syncytial virus, and varicella-zoster virus. Similarly, amplification-based assays, such as PCR, with excellent sensitivity and specificity are also available for direct detection of virtually all viral agents in clinical specimens. In fact the availability of real time PCR and other automated “closed” amplification systems that are not prone to amplification carry-over contamination have eliminated most of the initial concerns (except for cost) that had limited the use of these assays in clinical laboratories. |
| FA, PCR | See <i>Virus Culture</i> . | |
| | | Sensitivity of these tests depends on the amount of antigen and/or viral DNA or RNA in the collected sample. |
| | | Selection of one or more of these assays depends upon the clinical history, patient presentation, history of exposures, and the epidemiology of the area. Knowledge of local outbreaks is necessary as well. |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|--|---|
| West Nile Virus (WNV) Serological Test¹ <i>ELISA, Plaque reduction neutralization test (PRNT)</i> | CSF, Serum, acute and convalescent. See <i>General Information</i> . | <p>WNV is a member of the family Flaviviridae (genus <i>Flavivirus</i>). Serologically, it is a member of the Japanese encephalitis virus antigenic complex, which includes St. Louis, Japanese, Kunjin, and Murray Valley encephalitis viruses. WNV was first isolated in the WN province of Uganda in 1937. In 1999 the first domestically acquired human cases of West Nile encephalitis (WNE) were documented in the U.S.</p> <p>Serological testing IgM and IgG ELISA are available from CDC, public health laboratories, and few commercial reference laboratories. The West Nile virus IgM is usually detected early when symptoms appear. IgG may not be detectable for 4-5 days of the illness. Because ELISA can cross-react between flaviviruses (e.g., SLE, dengue, and yellow fever), it should be viewed as a screening test only. Initial serologically positive samples should be confirmed by neutralization test.</p> |

| | | |
|---|------------|--|
| Zygomycosis Serological Test¹ <i>EIA, ID</i> | CSF, serum | <p>Patients with diabetic ketoacidosis, evidence of rhinocerebral disease, immunocompromised patients with renal disease, patients with acute leukemia, and debilitated patients with symptoms of pulmonary or systemic infection can be tested. Both EIA and ID tests can be used to detect antibodies in patients with active zygomycosis. The ID and EIA demonstrate a sensitivity of 70% and 80%, respectively. ID and EIA specificity are 90% and 94%, respectively. More sensitive methods would be more useful, but available assays may aid in the diagnosis of zygomycosis in patients with signs of pulmonary or systemic infection.</p> |

PART B: SUSCEPTIBILITY TESTS

| | | |
|--|---|--|
| Disk Diffusion for Antimicrobial Susceptibility Test (AST) (Bauer-Kirby Test) ¹⁻⁴ | Isolate of bacteria causing the infection | <p>A qualitative test performed and interpreted according to CLSI guidelines. Zones of growth inhibition for each antimicrobial agent tested are interpreted as susceptible (S), intermediate (I), or resistant (R).</p> |
|--|---|--|

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|---|
| Cefoxitin Disk Diffusion Test for Prediction of <i>mecA</i>-mediated Oxacillin/Methi- cillin Resistance in <i>Staph</i>⁴ (ORSA/MRSA) | <i>Staphylococcus aureus</i> or coagulase-negative staph isolate | <p>30-μg cefoxitin disk is used with alternate breakpoints to predict <i>mecA</i>-mediated resistance to oxacillin/methicillin in <i>Staph</i> spp. <i>S. aureus</i> and coagulase-negative staph with zone sizes ≤19 mm and ≤24 mm, respectively, should be reported as oxacillin resistant. Note that the same zone interpretation used for <i>S. aureus</i> should be applied to <i>S. lugdenensis</i>.</p> <p>Other tests, such as a latex agglutination test, to detect protein binding site (PBP) 2' (product of <i>mecA</i> gene); molecular tests including polymerase chain reaction and CHROMagar designed to detect ORSA/MRSA generally provide more rapid results. As a surveillance and infection control tool, the Cepheid Smart Cycler may be used to directly test nasal swabs for ORSA without prior culturing. Patients who are colonized or infected with ORSA should be placed on Contact Precautions. Patients treated with clindamycin may not respond to this therapy.</p> |
| D-Zone or Blunting Test for Inducible Clindamycin Resistance⁴ | <i>Staphylococcus</i> spp. isolate | According to CLSI, erythromycin and clindamycin disks are used to identify inducible <i>erm</i> gene positive, clindamycin resistant isolates that would otherwise be reported as susceptible. A blunted or D-zone of inhibition around the clindamycin disk is interpreted as resistant. These isolates express the methylase enzyme that blocks the antibiotic binding site on the bacterial ribosome. Patients treated with clindamycin may not respond to this therapy. |
| Oxacillin Disk Diffusion Test for Penicillin and Cephalosporin Resistant <i>S. pneumoniae</i>⁴ | <i>Streptococcus pneumoniae</i> isolate | According to CLSI guidelines, this test is used to predict penicillin resistance in <i>S. pneumoniae</i> . Zone sizes ≤19 mm are interpreted as resistant to B-lactam drugs. Results should be confirmed using an MIC method before reporting isolates as penicillin resistant. |
| Chromogenic Cefinase Disk Test¹⁻³ | Aerobic or anaerobic bacterial isolate | A chromogenic cephalosporin substrate is used to identify the production of a B-lactamase enzyme in organisms, such as <i>Staphylococcus</i> , <i>Haemophilus</i> , <i>Neisseria</i> , and <i>Bacteroides</i> . Organisms that are positive should be considered resistant to all of the B-lactam drugs. |
| ESBL Confirmatory Synergy Disk Diffusion Test^{2,4,5} | <i>Klebsiella pneumoniae</i> , <i>K. oxy-</i> <i>toca</i> , <i>Escherichia coli</i> , <i>Proteus</i> <i>mirabilis</i> isolate | According to CLSI guidelines, all <i>Klebsiella</i> and <i>E. coli</i> isolates, as well as <i>Proteus mirabilis</i> isolates from closed body sites, should be screened to determine if they are extended-spectrum B-lactamase enzyme (ESBL) producers. Resistance to a third-generation cephalosporin constitutes a positive screening test result for an ESBL and should be confirmed using a synergy test. According to CLSI guidelines, an isolate can be confirmed as a B-lactamase producer by testing ceftazidime and cefotaxime disks with and without the B-lactamase inhibitor clavulanic acid. An increase in zone size of at least ≥5 mm in the presence of clavulanic acid confirms the presence of an ESBL. |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--------------------------------------|--|
| | | <p>If a screening result has been confirmed, all cephalosporins, penicillins, and aztreonam should be reported as resistant even if the initial susceptibility test result was susceptible. Since these isolates are multidrug resistant, patients should be placed on Contact Precautions, and an infectious disease specialist may be consulted.</p> |

| | | |
|--|--|---|
| Etest ^{1,5} | An aerobic or anaerobic isolate | <p>A quantitative continuous concentration gradient of an antimicrobial agent applied to one side of a numerically labeled plastic strip. Appropriate Etest strips are placed on a seeded agar plate similar to the Disk Diffusion Test and incubated for 18-24 hr depending on the organism being tested. The minimum inhibitory concentration (MIC) value can be obtained by determining where the elliptical zone of growth inhibition intercepts the Etest strip.</p> |
| ESBL Confirmatory Synergy Test ^{1,2} (see ESBL Confirmatory Synergy Disk Diffusion Test.) | <i>Klebsiella pneumoniae</i> , <i>K. oxytoca</i> , <i>Escherichia coli</i> , or <i>Proteus mirabilis</i> isolate | <p>A synergy test is performed to confirm a positive ESBL screening test result based on resistance to one or more of the third-generation cephalosporins. At least two Etest strips, each containing a third-generation cephalosporin (e.g., ceftazidime and cefotaxime) with and without a B-lactamase inhibitor (e.g., clavulanic acid) are used. A screening result is confirmed for the presence of an ESBL, if there is at least a 3 twofold decrease in MIC for either agent tested in combination with clavulanic acid versus the MIC when tested alone.</p> <p>Additional markers to identify an ESBL-producing organism include susceptibility to one or more cephamycins, such as ceftoxitin or cefotetan, and to the carbapenems (i.e., imipenem, meropenem, or ertapenem).</p> <p>ESBL-producing organisms are multidrug resistant. Patients with these organisms should be placed on Contact Precautions. An infectious disease consult may be indicated.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--------------------------------------|--|
| Minimum Bactericidal Concentration ¹⁻⁴ (See <i>Minimum Inhibitory Concentration</i> .) | Log phase bacterial isolate | <p>The MBC is the minimum concentration of an antimicrobial agent that will kill $\geq 99.9\%$ of the initial inoculum of the organism being tested.</p> <p>Initially a macrodilution or microdilution minimum inhibitory concentration (MIC) test is performed. After 18-24 hr, the tubes or wells with no visible growth are subcultured onto solid medium and incubated 18-24 hr. The lowest antimicrobial concentration showing bactericidal activity for $\geq 99.9\%$ of the test inoculum is defined as the MBC and is expressed in $\mu\text{g/mL}$. Results obtained from MBC tests may be used to predict bacterial eradication in patients with certain conditions, e.g., endocarditis, osteomyelitis, and neutropenia.</p> <p>A significant discrepancy ($\text{MBC/MIC} \geq 32$) between the MIC and MBC for typical bactericidal drugs, e.g., the B-lactams and aminoglycosides, has been termed "tolerance." There is no evidence that tolerance in microorganisms other than enterococci has any predictive value for clinical outcome.</p> |

| | | |
|--|---|--|
| Minimum Inhibitory Concentration ¹⁻³ | Log phase or stationary phase bacterial isolate | <p>A semiquantitative test using CLSI (NCCLS) guidelines to determine the minimum inhibitory concentration (MIC) of an antimicrobial agent tested against an isolate and expressed as the concentration of an antimicrobial that will inhibit the growth of the test organism.</p> <p>Results can be reported in $\mu\text{g/mL}$, and using CLSI interpretation, as susceptible, intermediate, or resistant.</p> <p>Tests may be performed using agar dilution, Etest gradient agar diffusion, a manual or automated broth dilution test. Either a full-range MIC test using five to eight antimicrobial dilutions or breakpoint MICs using one to three concentrations of each agent may be used. The test is performed by adding known concentrations of an antimicrobial agent into a series of tubes or microwells when performing a broth microdilution or by employing a series of agar plates, each with a different concentration of the antimicrobial. A standard inoculum is then added to each antimicrobial concentration. In the case of an agar dilution test, up to 36 different isolates may be inoculated onto each plate using a replicator. The agar dilution test is considered the "gold standard," but is quite laborious and generally reserved for research-orientated laboratories.</p> |

| TEST NAME AND METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|---|--|--|
| Schlichter Test (Serum Inhibitory and Bactericidal Titers, SIT and SBT) ¹⁻³ | 2-5 mL of serum or body fluid and an isolate of bacteria caus- ing the infection | <p>Patient's isolate and sera collected no more than 30 min before the next dose (trough), 60 min after a 30-min intravenous infusion, 60 min after an intramuscular dose, or 90 min after an oral dose of the antimicrobial agent.</p> <p>Schlichter tests are used to determine the efficacy of treatment by testing the patient's serum bacteriostatic (SIT) and bactericidal (SBT) activities of an antimicrobial agent(s) when tested against the patient's isolate. The SIT is defined as the highest dilution of serum that inhibits visible growth following incubation for 24 hr. Tubes showing no growth are subcultured and incubated for 24-72 hr. The SBT is the highest dilution of serum or body fluid that kills ≥99.9% of the patient's isolate. An approved CLSI (NCCLS) document is available for performing this test although there is controversy regarding the choice of diluent used in the test (e.g., patient serum versus broth).</p> <p>Clinical indications for performing this test are limited to monitoring effective therapy in patients with osteomyelitis; closed-space infections, such as meningitis; and the use of oral agents after intravenous therapy. The precise value of the SBT is controversial since there has not been a clear-cut correlation between any particular titer and efficacy. Most often this assay is used for the following: to monitor therapy of infections that require bactericidal activity (e.g., endocarditis, osteomyelitis, and meningitis), to evaluate antimicrobial combinations subsequent to their administration, and to monitor the antibacterial activity of serum after changing from parenteral to oral therapy.</p> |

TABLE V-1 **NORMAL MICROBIAL FLORA**

Microorganisms normally residing on body surfaces or in various cavities of the body without invasion or harm to the host are referred to as “normal flora.” The types and numbers vary according to the environment of the surfaces and cavities. These organisms help prevent colonization, invasion, and infection by pathogenic microorganisms. Some of the normal flora in the alimentary tract synthesize vitamin K, aid in nutrient absorption, and help convert bile pigments and acids in the intestine. Although harmless in their usual sites, normal flora may produce disease if introduced into other areas (especially those cavities that are normally sterile) as opportunists.

The following is a compilation of microorganisms that constitute normal flora encountered in various body sites.¹

MOUTH AND OROPHARYNX

Viridans streptococci
Coagulase-negative staphylococci
Veillonella spp.
Fusobacterium spp.
Treponema spp.
Bacteroides spp.
Prevotella spp.
Propionibacterium spp.
Peptostreptococcus spp.
Neisseria spp. and *Moraxella catarrhalis*
Streptococcus pneumoniae
β-Hemolytic streptococci (not group A)
Candida spp.
Haemophilus spp.
Diphtheroids
Actinomyces spp.
Eikenella corrodens
Staphylococcus aureus
Lactobacillus spp.

NOSE AND NASOPHARYNX

Coagulase-negative staphylococci
Viridans streptococci
Staphylococcus aureus
Neisseria spp.
Haemophilus spp.
Streptococcus pneumoniae

OUTER EAR

Coagulase-negative staphylococci
Diphtheroids
Bacillus spp. (occasionally)
Micrococcus spp.
Saprophytic *Neisseria* spp. (occasionally)
Saprophytic *Mycobacterium* spp. (occasionally)
Aspergillus spp.
Alternaria spp.
Penicillium spp.
Candida spp.

CONJUNCTIVAE

Coagulase-negative staphylococci
Diphtheroids
Saprophytic *Neisseria* spp. (occasionally)
Viridans streptococci

SKIN

Coagulase-negative staphylococci
Diphtheroids (including *Propionibacterium acnes*)
Micrococcus spp.
Staphylococcus aureus
Streptococci (various species)
Bacillus spp.
Acinetobacter spp.
Malassezia spp.
Candida spp.
Saprophytic *Mycobacterium* spp. (occasionally)

URETHRA

Coagulase-negative staphylococci
Diphtheroids
Streptococci (various species)
Enterococcus spp.
Enterobacteriaceae
Lactobacillus spp.
Mycobacterium smegmatis
Bacteroides spp.
Peptostreptococcus spp.
Candida spp.

VAGINA

Lactobacillus spp.
Peptostreptococcus spp.
Diphtheroids
Micrococcus spp.
Coagulase-negative staphylococci
Streptococci (various species)
Enterococcus spp.
Clostridium spp.
Bacteroides spp.
Candida spp.
Gardnerella vaginalis

GASTROINTESTINAL TRACT

Small Intestine

Lactobacillus spp.
Bacteroides spp.
Clostridium spp.
Enterococcus spp.
Enterobacteriaceae
Peptostreptococcus spp.
Candida spp.

Large Intestine

Bacteroides spp.
Prevotella spp.
Porphyromonas spp.
Fusobacterium spp.
Clostridium spp.
Bifidobacterium spp.
Eubacterium spp.
Peptostreptococcus spp.
Escherichia coli
Klebsiella spp.
Proteus spp.
Lactobacillus spp.
Enterococcus spp.
Streptococci (various species)
Coagulase-negative staphylococci
Staphylococcus aureus
Actinomyces spp.
Candida spp.

**TABLE V-2 SPECIMENS FOR VIRAL ISOLATION
IN SELECTED CLINICAL SYNDROMES**

| INFECTION | VIRUS | PREFERRED SPECIMEN |
|---|---|---|
| Central nervous system (encephalitis, aseptic meningitis) | Enterovirus HSV Mumps Rabies, arbovirus | Throat or rectal swab, CSF CSF, vesicle fluid, brain biopsy Throat swab, urine, CSF Usually not cultured |
| Congenital/perinatal | CMV Enterovirus HSV | Throat swab, urine, blood (leukocytes) Throat, stool, or rectal swab; CSF Throat swab, CSF, vesicle fluid |
| Eye (conjunctivitis, keratitis) | Adenovirus, enterovirus, HSV | Throat or conjunctival swab, corneal scrapings |
| Gastrointestinal tract | Adenovirus Rotavirus, Norwalk agent | Stool or rectal swab Usually not cultured; EIA or EM on stool |
| Genital tract | HSV | Vesicle fluid, endocervical swab |
| Heart | Coxsackievirus B CMV Influenza A, B | Throat, stool, or rectal swab; pericardial fluid Throat swab, urine, pericardial fluid throat swab |
| Hepatitis | EBV; Hepatitis A, B, and C CMV | Not cultured Throat, urine, liver |
| Mononucleosis | CMV, HIV EBV | Urine, throat wash, blood Not cultured |
| Rash Maculopapular | Adenovirus, enterovirus Parainfluenza, RSV Rubella, rubeola Coxsackievirus A, echovirus | Throat or rectal swab, stool Nasopharyngeal aspirate Usually not cultured Throat or rectal swab, stool, vesicle fluid |
| Vesicular | HSV, VZV, vaccinia | Vesicle fluid |
| Respiratory tract | Adenovirus, coxsackievirus, echovirus HSV CMV Enterovirus Influenza Parainfluenza, RSV Rhinovirus | Throat swab or wash Oral swab Throat swab, urine Throat swab Throat swab and nasal wash Nasopharyngeal aspirates Nasal swab or wash |
| Urinary tract | Adenovirus, CMV | Urine |

HSV, herpes simplex virus; CMV, cytomegalovirus; EBV, Epstein-Barr virus; HIV, human immunodeficiency virus; VZV, varicella-zoster virus; RSV, respiratory syncytial virus; CSF, cerebrospinal fluid; EIA, enzyme immunoassay; EM, electron microscopy.

SECTION VI

IMMUNOPHENOTYPING MARKERS

INTRODUCTION

The evaluation of hematopoietic and lymphoid neoplasms requires a variety of methods. Although morphological features remain the cornerstone of the evaluation of leukemias and malignant lymphomas, ancillary studies including immunophenotyping, cytogenetics, and/or molecular genetic testing are needed in most, if not all, cases.

Immunophenotyping, by multiparameter flow cytometry and/or immunohistochemistry, now is an integral part of the modern diagnosis and classification systems for leukemias and malignant lymphomas. There is a growing list of immunophenotyping markers, and many of them are currently used in clinical flow cytometry and immunohistology laboratories. Knowledge of these markers, its normal distribution and biological functions in particular, is essential for appropriate interpretation of immunophenotyping test results.

The majority of immunophenotyping markers are the cluster of differentiation antigens, or CD antigens. All cells involved in hematopoietic, immune, and phagocytic functions express a number of surface and cytoplasmic antigens unique to the cell lineage and stage of development. For standardization purposes, international workshops were held to assign a cluster of differentiation numbers, or CD number, to each antigen that is recognized by a cluster of monoclonal antibodies. If only one antibody defines a cluster or if all antibodies defining a cluster originate from the same laboratory, a suffix *w* is added to the CD designation. All CD antigens defined at the first to seventh international workshops on Human Leukocyte Differentiation Antigens (HLDA) are presented in Part I, along with any common names used before a CD number was assigned, molecular size, normal tissue distribution, and known or suspected physiological function. A few key primary papers and review articles for each CD antigen are also included. The eighth HLDA workshop was held in Adelaide, Australia in December 2004, and an additional 95 molecules were assigned CD numbers which are not included in this section.

In addition to the CD antigens, other commonly used immunophenotyping markers are also presented in Part I. It is worth noting that ZAP-70 is a new marker and currently not available in most flow cytometry laboratories, but is on the horizon to become a key prognostic marker for chronic lymphocytic leukemia and/or small lymphocytic lymphoma.

Typical immunophenotypes of hematopoietic and lymphoid neoplasms are summarized and listed in Part II. A brief summary of clinical, morphological, and/or genetic features of each disease is provided. The lists of diseases are based on the currently used World Health Organization (WHO) classification system, which was published in 2001.

PART I: IMMUNOPHENOTYPING MARKERS

1. THE CLUSTER OF DIFFERENTIATION ANTIGENS
(THE CD ANTIGENS)

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|------------|---|------------------------|--|---|
| CD1a | R4; HTA1; T6; Leu-6 | 49 | Cortical thymocytes (strong), B-cell subset, dendritic cells, Langerhans cells | CD1 is a member of immunoglobulin superfamily on chromosome 1q22-23. There are five different CD1 isoforms (CD1a-e), all noncovalently associated with a 12 kDa β_2 microglobulin. Each isoform is involved in presentation of antigens including lipids, restricting T-cell responses to certain antigens. CD1 may also mediate thymic T-cell development. |
| CD1b | | 45 | Cortical thymocytes (moderate), B-cell subset, dendritic cells, Langerhans cells | |
| CD1c | | 43 | Cortical thymocytes (weak), B-cell subset, dendritic cells, Langerhans cells | |
| CD2 | E-rosette receptor; LFA-2 (leukocyte function antigen-2); T11 | 50 | Thymocytes, T cell, NK cells | CD2 serves as the ligand for CD58, CD48, and CD59. It binds to CD58 on antigen-presenting cells and induces co-stimulatory signals in T cells. CD2 also regulates T- and NK-mediated cytotoxicity, induces apoptosis in activated peripheral T cells, mediates T-cell cytokine production, and regulates T-cell energy. <i>Immunol Rev 147:5, 1995</i> <i>Curr Opin Immunol 11:100, 1999</i> |
| CD3 | T3; Leu-4 | 16, 20, 25-28 | T cells, NK cells (cytoplasmic only) | CD3 is considered the lineage-specific T-cell marker. CD3 is composed of a family of proteins (γ , δ , ϵ), which form the membrane signal transduction complex linked to T-cell receptor (TCR). CD3 itself does not bind antigen, but is involved in the transduction of signals into the T cell after the TCR has bound the antigen. <i>Immunol Rev 163:217, 1998</i> <i>Immunol Today 17:177, 1996</i> |
| CD4 | T4; Leu-3 | 55 | Helper and/or inducer T cells, monocytes, macrophages, dendritic cells | CD4 serves as co-receptor in MHC class II-restricted antigen-induced T-cell activation. It binds to MHC class II molecules expressed on antigen-presenting cells, facilitating recognition of peptide antigens. In addition, CD4 is also a co-receptor for HIV gp120. |

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|-----------------|-----------------------|------------------------------|--|---|
| CD4—CONT | | | | |
| | | | | <i>Transplant Proc 31:820, 1999</i> <i>Curr Issues Mol Biol 6:1, 2004</i> |
| CD5 | Leu-1; B4; Ly-1; Tp67 | 67 | T cells, B-cell subset | CD5 belongs to ancient scavenger receptor family and is physically and functionally coupled with the membrane T-cell receptor (TCR)-CD3 complex. CD5 appears to be ligand for CD72 and serves as a dual receptor, giving either stimulatory or inhibitory signals depending both on the cell type and the development stage. CD5 is a phenotypic marker for some B-cell lymphoproliferative disorders (chronic lymphocytic leukemia and/or small lymphocytic lymphoma, mantle cell lymphoma, etc.). <i>Int J Biochem Cell Biol 36:2105, 2004</i> <i>Immunol Res 26:255, 2002</i> <i>Cur Opin Hematol 6:30, 1999</i> <i>Immunol Today 19:106, 1998</i> |
| CD6 | T12 | 105 or 130 | T cells, B-cell subset | CD6 is a cell surface receptor belonging to the scavenger receptor cysteine-rich (SRCR) protein superfamily. It binds cell adhesion molecule CD166 and is involved in T-cell development and activation. <i>Eur J Immunol 34:930, 2004</i> <i>Transplant Proc 31:795, 1999</i> <i>Proteins 40:420, 2000</i> <i>Immunol Today 18:498, 1997</i> |
| CD7 | Leu-9; 3A1; Gp40 | 40 | T cells, NK cells, some myeloid precursor cells | CD7 is considered the earliest marker for T-cell differentiation. CD7 is a membrane glycoprotein and Fc receptor for IgM. It associates with PI-3 kinase and is involved in T-cell and NK-cell activation. <i>Immunol Res 24:31, 2001</i> <i>Crit Rev Immunol 19:331, 1999</i> <i>J Clin Immunol 17:265, 1997</i> |
| CD8 | Leu-2; T8; Lyt2/3 | 68 (32-34) | Cytotoxic and/or suppressor T cells, NK cells, most thymocytes | CD8 serves as co-receptor in T-cell activation. It is composed of α and β chains and facilitates the recognition of cell-bound, MHC class I antigens. <i>Immunol Rev 182:201, 2001</i> <i>Sem Immunol 9:87, 1997</i> <i>J Immunol 157:4287, 1996</i> |

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|------------|--|------------------------|--|--|
| CD9 | p24; MRP-1; BA-2; DRAP-27 | 24, 26 | Megakaryocytes, platelets, monocytes, activated T cells, pre-B cells, eosinophils, basophils, vascular endothelial cells and smooth muscle cells, some epithelia, cardiac muscle cells | CD9 plays role in signal transduction leading to cell activation, adhesion, aggregation, and/or cell migration. <i>Immunol Today 15:588, 1994</i> <i>Mol Biol Cell 7:193, 1996</i> <i>Leuk Lymphoma 38:147, 2000</i> |
| CD10 | Common ALL antigen (CALLA); neutral endopeptidase; enkephalinase | 100 | Lymphoblasts (pre-B cells and pre-T cells), germinal center B cells (centroblasts and centrocytes), some T cells, neutrophils, intestinal epithelial cells, myoepithelial cells, hepatocytes, etc. | CD10 is a cell membrane zinc-binding metallopeptidase that cleaves peptides on the amino side of hydrophobic amino acids, thereby inactivating bioactive peptides. CD10 is considered the earliest marker for lymphoid differentiation and a characteristic marker for acute lymphoblastic leukemia (ALL), follicular lymphoma, Burkitt's lymphoma and/or leukemia, and angioimmunoblastic T cell lymphoma. CD10 is also used as a marker for breast myoepithelial cells. CD10 is positive in a variety of solid tumors. <i>J Exp Med 181:2271, 1995</i> <i>Blood 82:1052, 1993</i> <i>Blood 99:627, 2002</i> |
| CD11a | α L chain of β_2 integrins; leukocyte function-associated antigen-1 α (LFA-1 α) (in complex with CD18) | 180 | Granulocytes, monocytes, macrophages, lymphocytes | CD11a is an alpha integrin chain that binds to CD18 to form receptor for CD54 (intercellular adhesion molecule-1, ICAM-1) and CD102 (ICAM-2). By forming complex with CD18, it mediates leukocyte adhesion and transendothelial migration and lymphocyte recirculation through lymph nodes. Patients with leukocyte adhesion deficiency (mutations in CD18) often have severe immunodeficiency with recurrent bacterial and/or fungal infections early in life. <i>Curr Opin Cell Biol 9:643, 1997</i> <i>Immunol Rev 146:82, 1995</i> |
| CD11b | α M chain of β_2 integrins; complement receptor-3 (CR3); iC3b receptor; Mac-1 | 170 | Granulocytes, monocytes, macrophages, dendritic cells, NK cells, some B cells and T cells | CD11b assembles with CD18 to form a receptor for iC3b, fibrinogen, clotting factor X, and CD54. It facilitates adhesion to endothelium and platelets, phagocytosis of particles opsonized with iC3b, and/or chemotaxis. <i>Cell 80:631, 1995</i> <i>Immunol Res 25:219, 2002</i> |

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|--------------|--|------------------------|---|--|
| CD11c | α X chain of β_2 integrins; Leu-M5; gp150/95; complement receptor-4 (CR4) | 150 | Granulocytes, monocytes, macrophages, NK cells, some B cells and T cells | <p>CD11c assembles with CD18 to form a receptor for iC3b and fibrinogen. It facilitates the clearance of opsonized particles and immune complex. It also binds to fibrinogen and thereby is involved in adhesion of neutrophils and monocytes to endothelium and induces neutrophil respiratory burst. In addition to most acute myeloid leukemias (AML), CD11c is also positive in hairy cell leukemia and a subset of chronic lymphocytic leukemia and/or small lymphocytic lymphoma (CLL/SLL).</p> <p><i>Immunol Today 5:209, 1996</i> <i>J Immunol 156:3780, 1996</i></p> |
| CD13 | Aminopeptidase N (APN); Leu-M7; My7 | 150 | Myeloid cells (granulocytic cells), monocytes, some NK cells | <p>CD13 is a zinc-binding metalloprotease that catalyzes removal of N-terminal amino acids from peptides, thereby inactivating bioactive peptide hormones. CD13 is considered a characteristic marker for myeloid differentiation, although is less specific than CD33. In addition to most myeloid leukemias, CD13 is positive in some pre-B acute lymphoblastic leukemias and rare pre-T acute lymphoblastic leukemias. CD13 is also positive in bile duct canaliculi, central nervous system synapses, endothelial cells, osteoclasts, small intestinal epithelial cells, etc.</p> <p><i>J Exp Med 184:183, 1996</i> <i>J Exp Med 194:1183, 1996</i> <i>Immunol Today 20:83, 1999</i></p> |
| CD14 | LPS receptor, endotoxin receptor; GPI-linked glycoprotein | 55 | Monocytes, macrophages, dendritic cells, Langerhans cells, some myeloid cells | <p>CD14 is the receptor for lipopolysaccharide (LPS) that can transduce signal(s), leading to oxidative burst and/or synthesis of tumor necrosis factor alpha. CD14 is used as a marker for monocytic differentiation. CD14 may be deficient in patients with paroxysmal nocturnal hemoglobinuria.</p> <p><i>Trend Immunol 23:301, 2002</i> <i>Curr Opin Immunol 11:19, 1999</i></p> |
| CD15 | Leu-M1; Lewis ^x (Lex) | 185-260 | Neutrophils, monocytes, eosinophils, activated T-cells and B cells | <p>CD15 is a carbohydrate determinant that is found on many cell surface glycolipids and glycoproteins (e.g., CD11 and/or CD18, CD66) and is dependent on the activity of</p> |

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |

|------------------|----------------|------------------------------|--|--|
| CD18—CONT | | | | |
| | | | | <p>nal transduction. Mutations in CD18 gene cause leukocyte adhesion deficiency type 1 (LAD-1). Patients typically have recurrent bacterial or fungal infections, pronounced leukocytosis in the absence of infection, reduced expression of all members of the CD18 or β_2 integrin family on circulating leukocytes, and diminished CD18-dependent leukocyte functions, including cell adhesion, chemotaxis, transendothelial migration, and oxidative burst activation in response to iC3b-coated particles.</p> <p><i>Blood</i> 103:1105, 2004 <i>Int J Biochem Cell Biol</i> 30:179, 1998 <i>Curr Opin Cell Biol</i> 9:643, 1997</p> |
| CD19 | B4 | 95 | B cells, B-cell precursors, follicular dendritic cells | <p>CD19 forms a noncovalent complex with CD21, CD81, and CD225 that modulates signal transduction by B-cell antigen receptors. It regulates B-cell development, differentiation, and activation. CD19 is considered the earliest marker for B-cell differentiation. Plasma cells lack CD19.</p> <p><i>Science</i> 256:105, 1992 <i>Sem Immunol</i> 10:267, 1998 <i>Immunol Res</i> 26:45, 2002</p> |
| CD20 | B1; L26 | 95 (33, 35, 37) | B cells | <p>The structure of CD20 is similar to that of an ion channel. It may act as a Ca^{2+} channel involved in regulating cell cycle progression and activation. CD20 is one of the pan-B-cell markers. Its expression is behind CD10 and CD19, but earlier than CD21, CD22, and immunoglobulins. Plasma cells lack CD20. The majority of B-cell non-Hodgkin's lymphomas and nodular lymphocyte predominant Hodgkin's lymphomas are positive for CD20. Monoclonal anti-CD20 antibodies (e.g., rituximab, Bexxar, Zevalin) are currently widely used for the treatment of B-cell lymphomas.</p> <p><i>Curr Opin Hematol</i> 5:237, 1998 <i>Semin Oncol</i> 27(S12):17, 2000 <i>Semin Cancer Biol</i> 13:211, 2003</p> |

| CD MARKERS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|---------------|---|------------------------------|--|--|
| CD21 | CD2; EBV receptor; C3d receptor | 145 | B cells, follicular den- dritic cells, some epithe- lial cells, astrocytes, some T cells | <p>CD21 is the cell surface receptor for C3d and Epstein-Barr virus (EBV). It forms a signaling complex with CD19, CD81, and CD225. Binding of C3d to CD21 enhances B-cell antigen receptor signal transduction. EBV-infected B cells trigger a reactive process called infectious mononucleosis with increase in circulating reactive T cells. EBV-infected B cells may also transform into malignant lymphomas. Like CD23, CD21 is used as a dendritic cell marker. Nodular lymphocyte predominant Hodgkin's lymphoma and angioim- munoblastic T-cell lymphoma characteristi- cally demonstrate expansion and/or disrup- tion of follicular dendritic meshwork.</p> <p><i>Adv Exp Med Biol 452:181, 1998</i> <i>Sem Immunol 10:279, 1998</i> <i>Int Rev Immunol 20:739, 2001</i></p> |
| CD22 | B lymphocyte cell ad- hesion molecule (BL- CAM); Leu-14 | 135 | B cells (surface expres- sion), B-cell precursors (cytoplasmic expression) | <p>The CD22 antigen is a transmembrane sialoglycoprotein of the immunoglobulin superfamily. It is initially present in the cytoplasm of developing B cells, but is later expressed on the surface during B-cell maturation once IgD expression occurs. Most circulating IgM⁺IgD⁺ cells express CD22. CD22 is strongly expressed in follicular, mantle, and marginal zone B cells, but is weakly present in differentiating B cells. CD22 plays a role in a number of biological activities, including cellular adhesion and homing and regulation of the B-cell activa- tion. CD22 is considered a target for im- munotherapy.</p> <p><i>Adv Exp Med Biol 452:181, 1998</i> <i>Ann Rev Immunol 15:481, 1997</i> <i>Semin Oncol 30:253-257, 2003</i></p> |
| CD23 | Fc epsilon R II (IgE re- ceptor); Leu-20; B6 | 45 | Mature B cells expressing surface IgM and IgD, monocytes, macrophages, T-cell subsets, platelets, eosinophils, follicular dendritic cells | <p>CD23 is a Ca²⁺-dependent lectin with low affinity for IgE, CD11, and CD21-CD19- CD81 complex, which plays a role in the regulation of IgE synthesis and in cell-cell adhesion. Secreted form of CD23 may act as growth factor. CD23 is also used as a dendritic cell marker. CD23 is characteristi- cally positive in chronic lymphocytic leuke-</p> |

| | | | | <i>Immunol Today 19:313, 1998</i> <i>Cell Mol Life Sci 59:648, 2002</i> |
| CD24 | Heat stable antigen (HSA); BA-1 | 35-45 | B cells, B-cell precursors, neutrophils, epithelial cells, early T cells | CD24 a cell surface GPI-anchored adhesion protein. It may serve as ligand for CD62p and play a role in antigen-dependent B-cell proliferation and/or differentiation. CD24 is positive in a variety of epithelial carcinomas, and its expression is associated with a worse clinical outcome. <i>Blood 89:3385, 1997</i> <i>Int Immunol 7:155, 1995</i> |
| CD25 | IL-2 receptor alpha chain; TAC antigen | 55 | Activated T cells and B cells, some thymocytes, early myeloid cells | CD25 is a low-affinity receptor for interleukin-2 (IL-2). It can associate with CD122 and CD132 to form a heterotrimeric receptor with high affinity for IL-2. CD25 is characteristically positive in hairy cell leukemia and HTLV-1-associated adult T-cell leukemia and/or T-cell lymphoma. <i>Adv Immunol 59:225, 1995</i> <i>Cell 75:5, 1995</i> |
| CD26 | Depeptidyl peptidase IV; ADA binding protein | 110 | T-cell subset, macrophages, activated B cells, renal proximal tubular epithelial cells, small intestinal epithelial cells, biliary canaliculi | CD26 is a cell surface serine-type exopeptidase that cleaves dipeptides from the N-terminal of proteins. With an intracellular domain that associates with adenosine deaminase (ADA), CD26 also can function as a T-cell costimulatory molecule. It co-stimulates both the CD3- and the CD2-dependent T-cell activation and tyrosine phosphorylation of TCR-CD3 signal transduction pathway proteins. CD26 in vivo has integral membrane protein and soluble forms. Soluble CD26 is at significant levels in serum with its levels altered in many diseases. CD26 is also a cofactor of CD4 for HIV entry into cells. Normally, more than 90% of peripheral CD4 ⁺ cells are positive for CD26. For patients with Sézary syndrome, CD26 is useful for therapy monitoring since Sézary cells are characteristically |

| | | | | positive for CD4 and negative for CD26. <i>Crit Rev Clin Lab Sci 40:209, 2003</i> <i>Scand J Immunol 54:249-264, 2001</i> |
| CD27 | S152; T14 | 110(55) | Medullary thymocytes, T cells, NK cells, memory B cells | CD27 is a ligand for CD70 and a member of the nerve-growth-factor superfamily. CD27-CD70 interactions regulate T- and B-cell activation and differentiation. CD27 is T-cell activation marker. <i>Immunol Res 21:23, 2000</i> <i>Sem Immunol 10:491, 1998</i> <i>Immunol Today 15:307, 1994</i> |
| CD28 | Tp44 antigen | 90(44) | 95% CD4 T cells, 50% CD8 T cells, activated B cells, plasma cells | CD28 interacts with CD80 (B7-1) and CD86 (B7-2) expressed on antigen-presenting cells and activated B cells. The interactions provide co-stimulatory signal in activation of naïve T cells, and interleukin-2 expression. The opponent of CD28 is CD152 (CTLA-4), which mediates the negative signaling in T-cell activation. <i>Nat Rev Immunol 3:939, 2003</i> <i>Immunol Rev 165:287, 1998</i> <i>Crit Rev Immunol 18:389, 1998</i> |
| CD29 | Platelet gpIIa, integrin β_1 subunit; fibronectin receptor, VLA-beta chain | 130 | Platelets, all leukocytes with higher levels on memory T cells | CD29 assembles into a heterodimer with one of the several alpha chains (CD49a-f) to form the transmembrane β_1 integrins. The extracellular domains of integrin alpha and/or beta heterodimers mediate cell-matrix and cell-cell contacts, and their cytoplasmic tails associate with the cytoskeleton. Integrins are capable of transducing information in a bidirectional manner, and the beta subunit is recognized to play an important role in the process. <i>Int J Biochem Cell Biol 30:179, 1998</i> <i>J cell Biol 132:211, 1996</i> |
| CD30 | Ki-1 antigen; Ber-H2 | 105 | Activated T cells, B cells, and NK cells; monocytes | CD30 is a member of the TNF receptor family. CD30 binds to CD30 ligand (CD153) and plays a role in cell activation, differentiation, and/or proliferation. Signal- |

|---------------|---|------------------------------|--|---|
| CD39 | Vascular nucleoside triphosphate diphosphohydrolase (NTPDase) | 78 | Endothelial cells, macrophages, dendritic cells, activated cells of the NK-cell, B-cell, or T-cell lineage (not on resting cells or germinal center B cells); placenta | CD39 is a membrane-bound ectoenzyme that hydrolyzes extracellular ATP and ADP to AMP. It inhibits platelet adhesion and aggregation by digesting ADP. It may also facilitate the homotypic adhesion of B cells and play roles in regulating a variety of vascular and inflammatory processes. <i>J Biol Chem</i> 271:9898, 1996 <i>J Immunol</i> 153:3574, 1994 |
| CD40 | Bp50 | 48 | Mature B cells, monocytes, dendritic cells, basal epithelial cells, endothelial cells, fibroblasts, keratinocytes | CD40 is a member of the nerve growth factor receptor superfamily. It binds CD154 (CD40L) expressed on activated T-helper cells and serves as receptor for co-stimulatory signal for B cells; promotes growth, differentiation, and isotype switching of B cells; and regulates cytokine production by macrophages and dendritic cells. It is worth emphasizing that CD40-CD154 interaction is essential for B-cell differentiation, maturation, and secretion of IgG, IgA, and IgE antibodies. Patients with mutations in CD40L have an immunodeficiency called <i>X-linked hyper-IgM syndrome</i> . CD40 is positive in most B-cell lymphomas. <i>Immunol Res</i> 24:311, 2001 <i>Immunol Today</i> 19:502, 1998 |
| CD41 | GpIIb of the gpIIb-gpIIIa complex; α IIb integrin | 120 | Platelets and megakaryocytes | CD41 associates with CD61 (gpIIIa) to form receptor for fibrinogen, fibronectin, vitronectin, vWF, and thrombospondin. It facilitates platelet adhesion and aggregation. Deficiency of CD41 and/or CD61 causes thromboasthenia (<i>Glanzmann disease</i>). Patients' platelets do not aggregate with ADP, epinephrine, thrombin, collagen, and arachidonic acid in vitro. CD41 and CD61 are used as markers for megakaryocytic differentiation (e.g., AML FAB-M7). <i>N Engl J Med</i> 332:1553, 1995 <i>J Biol Chem</i> 271:6017, 1996 <i>J Biol Chem</i> 271:18610, 1996 |

|---------------|---|------------------------------|---|---|
| CD55 | Decay accelerating factor (DAF) | 70 | All hematopoietic cells, all cells in contact with serum, CNS, epithelial cells lining body fluid cavities | CD55 neutralizes complement activation on autologous tissue by preventing the assembly of C3 convertase (C3bBb and C4b2a) or accelerating disassembly of preformed convertase. It also serves as the receptors for CD97, echovirus, and Coxsackie B virus. CD55 is deficient in blood cells from patients with paroxysmal nocturnal hemoglobinuria (PNH) and thereby is used as a marker for the diagnosis of PNH. <i>Clin Lab Sci 17:172, 2004</i> <i>J Lab Clin Med 123:485, 1994</i> |
| CD56 | Neural cell adhesion molecule-1 (N-CAM); Leu-19; NKH1 | 175-220 | NK cells, embryonic cells, muscle, neural cells, epithelium, some activated T cells | CD56 is a cell surface adhesion molecule that facilitates homophilic adhesion and plays a role in contact-dependent growth inhibition, NK-cell cytotoxicity, and neural development. CD56 is the prototypic marker for NK cells. It is also present on subsets of CD4 and CD8 T cells. It is positive in a variety of hematological and/or lymphoid malignancies, such as NK-cell and/or T-cell leukemia and/or NK-cell or T-cell lymphoma, anaplastic large cell lymphoma, and plasma cell myeloma. Plasma cell leukemia is characteristically negative for CD56. <i>Leuk Lymphoma 45:61, 2004</i> <i>Ann Hematol 74:51, 1997</i> <i>Proc Natl Acad Sci USA 93:6421, 1996</i> <i>Neuron 17:413, 1996</i> |
| CD57 | Human natural killer-1 (HNK-1); Leu 7 | 110 | Subsets of NK cells, T cells, B cells, and monocytes; some Schwann cells; neuroectodermal tissue; brain; prostate; proximal tubules of kidney | CD57 is a cell surface glycoprotein with cell adhesion functions. It is a NK-and/or T-cell marker and neuroendocrine marker. Cells that are positive for CD56 but not CD57 have substantial NK-cell activities. Cells that are positive for CD56 and CD57 have variable (weak) NK-cell activities. CD57 is usually positive in T-cell large granular lymphocyte leukemia, but is negative in aggressive NK-cell leukemia. <i>Oncologist 9:247, 2004</i> <i>Trend Neurosci 18:183, 1995</i> |

| CD82 | R2; IA4; 4F9; KAI-1 | 50-53 | Epithelia, endothelium, monocytes, neutrophils, platelets, activated lymphocytes | CD82 is a highly glycosylated protein that belongs to the transmembrane 4 (tetraspanin) superfamily. It associates with CD4 or CD8 and delivers co-stimulatory signals for T-cell receptor pathway. It is down-regulated in tumor progression and may function as a suppressor of tumor metastasis. Its expression appears to correlate with p53 expression. <i>Eur J Immunol 32:1328, 2002</i> <i>Curr Biol 24:1009, 2000</i> <i>Immunol Today 15:588, 1994</i> |
| CD83 | HB15 | 45 | Dendritic cells (not FDC), Langerhans cells, B cells (weak), interdigitating reticular cells | CD83 is involved in antigen presentation and the cellular interactions that follow lymphocyte activation. CD83 is strongly up-regulated together with co-stimulatory molecules, such as CD80 and CD86 during dendritic cell (DC) maturation, and is best known as a marker for mature DCs. Studies with herpes simplex virus type 1 (HSV-1)-infected DCs and the inhibition of the CD83 mRNA-specific transport from the nucleus to the cytoplasm have provided evidence that CD83 is important for DC biology. <i>Trends Immunol 23:273, 2002</i> <i>J Immunol 156:541, 1996</i> |
| CD84 | | 72-86 | Monocytes, platelets, germinal center B cells (strong), mantle zone B cells (weak), T-cell subset | CD84 is a member of the CD2 subgroup of immunoglobulin receptor superfamily (e.g., CD2, CD48, CD58, 2B4, Ly9, etc.). CD84 is involved in the activation of T cells via an SAP (signaling lymphocyte activation molecule-associated protein)-independent mechanism. In addition, the proliferative potential of CD34 ⁺ progenitor cells decreases with increasing CD84 expression, suggesting that CD84 may serve as a |

|----------|-------------------------|------------------------|---|--|
| Bcl-1 | Cyclin D1; PRAD1; CCND1 | 36 | Some epithelial cells (no expression in normal lymphocytes) | <p>Bcl-1 is one of the cell cycle regulatory proteins involved in restriction point control between G1 and S phase (G1-S transition). It forms complexes with cyclin-dependent kinases (CDK) 4 and 6 and further with retinoblastoma protein (pRB). Phosphorylation of pRB by Bcl-1/CDK4/6 leads to release of the E2F transcription factor, which then leads to progression of the cell cycle into the S phase. The Bcl-1/CDK4/6 activity is inhibited by p15/16, p18/19, p21, and p27. Bcl-1 is characteristically up-regulated in mantle cell lymphoma caused by t(11;14)(q13;q32), where the Bcl-1 gene at 11q13 is brought under the control of IgH gene enhancer. The translocation is also seen in subsets of B-cell prolymphocytic leukemia, plasma cell leukemia, splenic lymphoma with villous lymphocytes, chronic lymphocytic leukemia, and multiple myeloma.</p> <p><i>Am J Pathol 154:1449, 1999</i> <i>Arch Pathol Lab Med 123:1182, 1999</i></p> |
| Bcl-2 | 124 | 26 | Resting B cells and T cells, but not normal germinal center B cells, cortical thymocytes, or monocytoid B cells | <p>Bcl-2 is a well-characterized inhibitor of apoptosis. It functions to prevent the release of cytochrome C from mitochondria and sequester procaspase-8 and procaspase-9 and thereby to block the signaling pathway leading to activation of the caspase cascades. The Bcl-2 gene is located at chromosome 18q21. Bcl-2 is positive in all cases of follicular lymphoma caused by t(14;18)(q32;q21) or rare t(2;18)(p12;q21). Most other B-cell lymphomas and T-cell lymphomas are also positive for Bcl-2. Clinically, Bcl-2 is a highly sensitive marker for distinguishing follicular hyperplasia from follicular lymphoma and reactive monocytoid B-cell hyperplasia from marginal zone lymphoma, respectively.</p> <p><i>Mod Pathol 11:864, 1998</i> <i>Am J Clin Pathol 103:472, 1995</i> <i>Proc Natl Acad Sci USA 88:6961, 1991</i></p> |

|----------|-------------|------------------------|---|---|
| Bcl-6 | | 79 | Germinal center B cells and T cells, skeletal muscle cells, keratinocytes | <p>Bcl-6 is a sequence-specific DNA binding transcriptional factor that mediates transcriptional repression by recruiting the SMRT (silencing mediator of retinoid and thyroid receptors), NCoR (nuclear receptor co-repressor), and BCoR (Bcl-6 co-repressor) co-repressors in a mutually exclusive manner. Bcl-6 is required for the formation of germinal centers and the Th2-mediated responses. Its gene is located at chromosome 3q27. Bcl-6 gene is frequently dysregulated in B-cell lymphomas. It is expressed in germinal center cell-derived lymphomas, including follicular lymphoma, diffuse large B-cell lymphoma, nodular lymphocyte predominant Hodgkin's lymphoma, and angioimmunoblastic T-cell lymphoma.</p> <p><i>Histol Histopathol</i> 19:637, 2004 <i>Leuk Lymphoma</i> 44:S5, 2003 <i>Hum Pathol</i> 30:403, 1999 <i>N Engl J Med</i> 331:74, 1994</p> |
| FMC-7 | | 105 | B cells | <p>FMC-7 is a glycoprotein found on circulating B lymphocytes. FMC-7 identifies the same cell type as CD22, but is a superior alternative for characterization of B-cell lymphomas. It is negative to weakly positive in chronic lymphocytic leukemia (CLL), but strongly positive in B-cell prolymphocytic leukemia (PLL), hairy cell leukemia (HCL), and splenic marginal zone lymphoma with villous lymphocytes (SLVL). It is thereby used for the differentiation of PLL from CLL (e.g., progression of CLL to PLL) and for confirmation of the diagnosis of other disorders, such as HCL and SLVL.</p> <p><i>Am J Clin Pathol</i> 120:754, 2003 <i>Am J Clin Pathol</i> 115:285, 2001</p> |
| HLA-DR | Ia/7.2 | 63 | B cells and B-cell precursors, activated T cells, monocytes and/or macrophages and their precursors, myeloid precursors, dendritic cells, endothelial cells | <p>HLA-DR is one of the MHC (major histocompatibility complex) class II antigens. It consists of two glycoprotein chains, designated α and β, both of which are attached to the membrane. It is positive in B-cell acute lymphoblastic leukemia (ALL), some T-cell ALL, and acute myeloid leukemias (AML), except acute promyelocytic leukemia.</p> |

| ANTIGENS | OTHER NAMES | MOLECULAR WEIGHT (KDA) | KNOWN NORMAL DISTRIBUTION | REMARKS |
|-----------------------------------|-------------|------------------------|---|--|
| Immuno-globulin (Ig) heavy chains | | ~50 | B cells (surface membrane expression), pre-B cells (cytoplasmic μ chain), plasma cells (cytoplasmic expression) | <p>There are five different heavy (H) chains, μ, δ, γ, α, and ϵ, which bind to kappa or lambda light (L) chain to form IgM, IgD, IgG, IgA, and IgE, respectively. The five H chains are produced through rearrangement of the Ig H chain gene, located at chromosome 14q32. Each H chain contains about 440 amino acids and is divided into variable (V) and constant (C) regions. Heavy chains are distinguished from each other on the basis of amino acid sequences in their C region (isotypic determinants) and by the number of domains. Molecular testing for Ig H chain gene rearrangement is routinely used for the determination of clonality and diagnosis of B-cell neoplasms.</p> <p><i>J Mol Diagn 2:178, 2000</i> <i>Leukemia 11:852, 1997</i></p> |
| Immuno-globulin (Ig) light chains | | ~25 | B cells (surface membrane expression), plasma cells (cytoplasmic expression) | <p>There are two different Ig light (L) chains, kappa (κ) and lambda (λ) L chains, encoded by two different genes located on chromosomes 2 and 22, respectively. The L chain contains about 220 amino acids. The κ and λ L chains are distinguished by the amino acid sequences in their C regions (isotypic determinants). The κ L chain has four subgroups, and λ has six subgroups. Each Ig molecule contains either κ or λ L chain, but not both. Neoplastic B cells and plasma cells characteristically express only κ or λ L chain (L chain restriction), an important feature for the confirmation of B-cell neoplasms and plasma cell neoplasms.</p> |
| Ki-67 | MIB-1 | 320, 359 | Proliferating cells | <p>Ki-67 is a nuclear protein involved in cell proliferation regulation. Ki-67 protein is used as a cell proliferation marker in research and diagnostics. It is present in the nuclei of cells in G₁, S, and G₂ phases of cell division and in mitosis. Quiescent or resting cells in the G₀ phase do not express the Ki-67 protein. The fraction of Ki-67-positive tumor cells (the Ki-67 labeling index) is often correlated with the grade and clinical course of the disease.</p> <p><i>Histopathology 40:2, 2002</i> <i>Cancer 94:2151, 2002</i> <i>J Pathol 182:145, 1997</i></p> |

|----------|---|------------------------------|---------------------------------------|---|
| ZAP-70 | Zeta-chain (TCR) as- sociated protein kinase | 70 | T cells and NK cells (cytoplasmic) | <p>ZAP-70 is a member of the Syk–ZAP-70 protein tyrosine kinase family. It is nor- mally expressed in T cells and natural killer cells and has a critical role in the initiation of T-cell signaling and activation. The ex- pression of ZAP-70 is observed in a subset of chronic lymphocytic leukemia (CLL) and some other B-cell leukemias and/or lym- phomas. Of interest, the ZAP-70 expression by CLL cells serves as a surrogate marker for the unmutated status of immunoglobulin heavy-chain variable-region gene (IgV_H). Patients with Binet stage A CLL who had at least 20% ZAP-70–positive leukemic cells had more rapid progression and poorer sur- vival than those with less than 20% ZAP- 70–positive cells. Thus, like CD38, ZAP-70 expression appears to be a prognostic marker for CLL.</p> <p><i>N Engl J Med</i> 351:893, 2004 <i>Am J Clin Pathol</i> 122:582, 2004</p> |

PART II: IMMUNOPHENOTYPES OF NEOPLASMS OF HEMATOPOIETIC AND LYMPHOID TISSUES

1. IMMUNOPHENOTYPES OF ACUTE MYELOID LEUKEMIAS

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|---|---|
| AML with t(8;21)(q22;q22), (<i>AML1-ETO</i>) | In addition to CD34 and HLA-DR, the blasts typically express myeloid markers CD13, CD33, CD15, MPO, and CD117. Aberrant expression of CD19 is frequently present. CD56 is often expressed. | The translocation t(8;21)(q22;q22) involves the <i>AML1</i> gene, which encodes <i>CBFα</i> , and the <i>ETO</i> (8-21) gene. The <i>AML1/ETO</i> fusion transcript is consistently detected in patients with t(8;21) AML. AML with t(8;21) is usually associated with good response to chemotherapy and high complete remission rate with long-term disease-free survival. Some factors appear to adversely affect survival, including CD56 expression and secondary karyotypic abnormalities. |
| AML with inv(16)(p13;q22) or t(16;16)(p13;q22), (<i>CBFβ-MYH11</i>) | In addition to myeloid markers (CD13, CD33, MPO, CD117), the blasts frequently express monocytic markers (CD14, CD4, CD11b, CD11c, CD64, CD36, lysozyme). Co-expression of CD2 is often present. | Inv(16)(p13;q22) and t(16;16)(p13;q22) both result in the fusion of the <i>CBFβ</i> gene at 16q22 to the smooth muscle myosin heavy chain (<i>MYH11</i>) at 16p13. By conventional cytogenetics, the inv(16) is a subtle rearrangement that may be overlooked. Trisomy 22 is a frequent secondary karyotypic abnormality. AML with inv(16) or t(16;16) typically shows myeloid and monocytic differentiation and the presence of eosinophilia, referred to as AMML-Eo. The disease usually responds well to chemotherapy with high complete remission rate. |
| AML with t(15;17)(q22;q12), (<i>PML-RARα</i>) and variants (FAB AML-M3) | The leukemic cells express CD13 (variable), CD33 (bright), MPO, and CD117 (variable). CD34 and HLA-DR are characteristically absent. There is frequent co-expression of CD2 and/or CD9. | AML with t(15;17), acute promyelocytic leukemia (APL), is caused by fusion of the retinoic acid receptor alpha (<i>RARα</i>) gene on 17q12 and the <i>PML</i> gene on 15q22, giving rise to a <i>PML-RARα</i> fusion product. APL has a particular sensitivity to treatment with all-trans retinoic acid (ATRA), which acts as a differentiating agent. APL is frequently associated with DIC. Rare variant translocations seen in APL include t(11;17)(q23;q12) (<i>PLZF-RARα</i>), t(5;17)(q35;q12) (<i>NPM-RARα</i>), and t(11;17)(q13;q12) (<i>NuMA-RARα</i>). APL with <i>PLZF-RARα</i> fusion is resistant to ATRA. |
| AML with 11q23 (MLL) abnormalities | The leukemic cells variably express CD13, CD33, CD117, and MPO. CD34 is generally absent. Cases with monoblastic morphology usually express monocytic differentiation markers (CD4, CD14, CD11b, CD11, CD64, CD36, lysozyme). | AML with 11q23 (<i>MLL</i>) abnormalities is usually associated with monocytic features. There are two clinical subgroups: one is AML in infants, and the other group is therapy-related AML usually occurring after treatment with DNA topoisomerase II inhibitors. The <i>MLL</i> (mixed lineage leukemia) gene on 11q23 is involved in a number of translocations with different partner chromosomes. AML with 11q23 abnormalities have an intermediate survival. |
| AML with multilineage dysplasia | Blasts are generally positive for CD34 and HLA-DR and express myeloid markers (CD13, CD33, MPO, CD117). There is frequent aberrant expression of CD56 and/or CD7. | AML with multilineage dysplasia is an acute leukemia with 20% or more blasts in blood or marrow and dysplasia in two or more myeloid cell lines, generally including megakaryocytes. Dysplasia must be present in 50% or more of the cells of at least two lines. These features must be present in a pre-treatment specimen. The disease entity may occur de novo or following MDS or MDS/MPD. |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|---|---|
| AML, therapy related | <p>This AML is alkylating agent and/or radiation related. Blasts are generally positive for CD34 and HLA-DR and express myeloid markers (CD13, CD33, MPO, CD117). There is frequent aberrant expression of CD56 and/or CD7.</p> <p>It is also topoisomerase II inhibitor related. This is same as AML with 11q23 abnormalities.</p> | <p>Alkylating-agent and/or radiation-related AML usually occur 5-6 years following exposure. Cytogenetic abnormalities are primarily unbalanced translocations or deletions involving chromosomes 5 and/or 7. This type of therapy-related AML is generally refractory to chemotherapy and is associated with short survival.</p> <p>Topoisomerase II inhibitor-related AML usually occurs 1-3 years after exposure and characteristically has a significant monocytic component. The primary cytogenetic finding is a balanced translocation involving chromosome 11q23 (the MLL gene). Most cases respond to initial therapy in a manner similar to that of a patient with de novo AML.</p> |
| AML, minimally differentiated (FAB AML-M0) | Blasts express panmyeloid markers (CD13, CD33, CD117), but not MPO. Most cases express precursor cell-associated antigens (CD34, CD38, HLA-DR). TdT may be positive in some cases. | The differential diagnosis includes ALL, acute megakaryoblastic leukemia, and biphenotypic or mixed lineage acute leukemia. Flow cytometric immunophenotyping is required for the confirmation of the diagnosis. |
| AML without maturation (FAB AML-M1) | Blasts express myeloid markers (CD13, CD33, CD117) and MPO. CD34 is often positive. | More than 20% blasts in the marrow. At least 3% of the blasts are positive for MPO. Blasts constitute more than 90% of the nonerythroid nucleated marrow cells. |
| AML with maturation (FAB AML-M2) | Blasts express myeloid markers (CD13, CD33, CD15, CD117) and MPO. CD34 and HLA-DR are often positive. | Blasts constitute more than 20% of all bone marrow cells and 20%-89% of nonerythroid cells. Monocytes constitute less than 20% of bone marrow cells. |
| Acute myelomonocytic leukemia (FAB AML-M4) | The blasts variably express CD13, CD33, CD117, HLA-DR and show some markers of monocytic differentiation, including CD14, CD4, CD11b, CD11c, CD64, CD36, and lysozyme. A subset of blasts expresses CD34. | Blasts constitute more than 20% of all bone marrow cells and nonerythroid cells. Monocytic component (monoblasts to monocytes) composes 20%-79% of bone marrow cells. |
| Acute monoblastic leukemia (FAB AML-M5a) and acute monocytic leukemia (FAB AML-M5b) | The leukemic cells variably express CD13, CD33, CD117, HLA-DR and show some markers of monocytic differentiation, including CD4, CD14, CD11b, CD11c, CD64, CD68, CD36, and lysozyme. CD34 is usually negative. | Blasts constitute more than 20% of all bone marrow cells and nonerythroid cells. Monocytic component (monoblasts to monocytes) composes 80% or more of bone marrow cells. |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|---|---|
| Acute erythroid leukemia (FAB AML-M6) and pure erythroid leukemia | The erythroblasts in acute erythroid leukemia generally lack myeloid markers, but are positive for CD36 and glycophorin A. The myeloblasts express many myeloid antigens, including CD13, CD33, CD117, and MPO, with or without expression of precursor-cell markers, such as CD34 and HLA-DR. The erythroid cells in pure erythroid leukemia express CD36 and glycophorin A, and the more immature forms may also express CD34 and HLA-DR. | The diagnostic criteria for acute erythroid leukemia include: (1) erythroblasts constitute more than 50% of the nucleated marrow cells and (2) myeloblasts compose more than 20% of the nonerythroid cells. Pure erythroid leukemia is defined as a neoplastic proliferation of erythroid precursors (>80% of nucleated marrow cells) without a significant myeloblastic component. |
| Acute megakaryocytic leukemia (FAB AML-M7) | The blasts express CD36 and one or more of the platelet glycoproteins (CD41, CD61, and CD42). The blasts may or may not express HLA-DR, CD34, CD117, CD13, CD33, CD11c, CD14, and CD15. | Blasts constitute more than 20% of nucleated marrow cells and express one or more of the markers for megakaryocytic differentiation. Flow cytometric immunophenotyping is required for the confirmation of the diagnosis. |
| Acute leukemia of ambiguous lineage | <p>Undifferentiated acute leukemia: The blasts often express HLA-DR, CD34, CD38 and may express TdT and CD7. The blasts generally lack lineage-specific markers, such as cCD79a, cCD22, cIgM, CD3, and MPO.</p> <p>Bilineal acute leukemia: There is a dual population of blasts with each population expressing markers of a distinct lineage, such as myeloid and lymphoid or B cell and T cell.</p> <p>Biphenotypic acute leukemia: The blasts co-express myeloid and T-cell or B-cell lineage-specific antigens or concurrent B-cell and T-cell antigens.</p> | Cases of bilineal and biphenotypic acute leukemia usually have cytogenetic abnormalities. The common abnormalities include Philadelphia chromosome, t(4;11)(q21;q23) or other 11q23 abnormalities. The prognosis of acute leukemia of ambiguous lineage is unfavorable. |

2. IMMUNOPHENOTYPES OF ACUTE LYMPHOBLASTIC LEUKEMIAS AND/OR LYMPHOMAS

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|---|---|
| Precursor B lymphoblastic leukemia and/or lymphoblastic lymphoma (precursor B-cell acute lymphoblastic leukemia) (B-ALL/LBL) | <p>The lymphoblasts in B-ALL/LBL are generally positive for TdT, HLA-DR, CD19, CD20, cCD79a. CD45 expression is usually dim and may be negative. The blasts in most cases are positive for CD10 and CD34. Cases with t(4;11)(q21;q23) or other 11q23 abnormalities are usually negative for CD10 and CD20, and CD15 is frequently expressed. Aberrant expression of CD13 and/or CD33 may be present.</p> <p>Early precursor B-ALL/LBL: TdT⁺, HLA-DR⁺, CD34⁺ and/or Cd34⁺, CD10[−], CD45[−] and/or CD45⁺, CD19⁺, cCD22⁺, CD20[−], CD15⁺, cIg[−], sIg[−].</p> <p>Common B-ALL/LBL: TdT⁺, HLA-DR⁺, CD34⁺, CD10⁺, CD45⁺(dim), CD19⁺, CD20⁺, cIg[−], sIg[−].</p> <p>Pre-B-ALL/LBL: TdT[−] and/or TdT⁺, CD34[−] and/or CD34⁺, HLA-DR⁺, CD45⁺(dim), CD19⁺, CD20⁺, cIgM⁺, sIg[−].</p> | <p>The cytogenetic abnormalities in B-ALL/LBL include several groups: hypodiploid, hyperdiploid (<50), hyperdiploid (>50), translocations, and pseudodiploid. The commonly seen translocations include t(9;22)(q34;q11) (<i>BCR-ABL</i>), t(12;21)(p13;q22) (<i>TEL-AML1</i>), t(5;14)(q31;q32) (<i>IL-3-IgH</i>), t(1;19)(q23;p13) (<i>PBX-E2A</i>), t(17;19)(q21;p13) (<i>HLF-E2A</i>), t(4;11)(q21;q23) (<i>AF4-MLL</i>), and other translocations involving 11q23. The cytogenetic findings are prognostically important.</p> |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|--|--|
| Precursor T lymphoblastic leukemia and/or lymphoblastic lymphoma (precursor T-cell acute lymphoblastic leukemia) (T-ALL/LBL) | T-ALL/LBL most often has an immunophenotype that corresponds to the common thymocyte stage of differentiation. The blasts are positive for TdT and often CD10 and variably express CD1a, CD2, CD3, CD4, CD5, CD7, and CD8. CD4 and CD8 are frequently co-expressed on the blasts. Myeloid markers CD13 and CD33 are often present. CD79a and CD117 expression has been observed in some cases. | In about one third of T-ALL/LBL, translocations have been detected involving the alpha and delta T-cell receptor loci at 14q11.2, the beta locus at 7q35, and the gamma locus at 7p14-15, with a variety of partner genes. Genes include the transcription factors MYC (8q24), TAL1 (1p32), RBTN1 (11p15), RBTN2 (11p13), and HOX11 (10q24), and the cytoplasmic tyrosine kinase LCK (1p34-35). In most cases these translocations lead to a dysregulation of transcription of the partner gene by juxtaposition with the regulatory region of one of the T-cell receptor loci. |
| | Some T-ALL/LBL has an immunophenotype that corresponds to prothymocyte stage of differentiation. The blasts are positive for TdT and early T-cell antigens (CD7, CD3, CD5 and CD2). Both CD4 and CD8 are characteristically absent. | It is worth noting that T-ALL/LBL can be part of a unique disease entity known as the 8p11 myeloproliferative syndrome caused by constitutive activation of FGFR1. FGFR1 is a receptor tyrosine kinase for fibroblast growth factors and is encoded by a gene on chromosome 8p11. Disruption of FGFR1 gene is associated with a chronic myeloproliferative disorder that frequently has eosinophilia and associated T-cell lymphoblastic lymphoma. Four gene fusions associated with distinct translocations have been described in this syndrome: the t(8;13)(p11;q12), t(8;9)(p11;q33), t(6;8)(q27;p11), and t(8;22)(p11;q22) that fuse ZNF198, CEP110, FOP, and BCR, respectively, to FGFR1. The resulting fusion proteins have constitutive tyrosine kinase activity and activate multiple signal transduction pathways. These pathways and the fusion proteins are attractive targets for targeted signal transduction therapy. |
| | Occasional T-ALL/LBL cases show an immunophenotype that corresponds to that of mature thymocytes. The blasts often express TdT, CD2, CD3 (surface expression), CD5 and CD7. However, the blasts express either CD4 or CD8 but not both. | |

3. IMMUNOPHENOTYPES OF MATURE B-CELL NEOPLASMS

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|---|---|
| Chronic lymphocytic leukemia and/or small lymphocytic lymphoma (CLL/SLL) | The malignant cells express weak or dim surface IgM or IgM and IgD, but not surface IgG. They express CD5, CD19, CD20 (weak), CD22 (weak), CD79a, CD23, CD43 and are negative for CD10, Bcl-1 (cyclin D1), FMC-7, and CD79b. A subset of cases expresses CD11c (weak). Cases with unmutated Ig variable region genes have been reported to be positive for CD38 and ZAP-70. Some cases may have an atypical immunophenotype (e.g., CD5 ⁺ or CD23 ⁺ , FMC7 ⁺ or CD11c ⁺ , or strong sIg or CD79b ⁺). | <p>The clinical course is often indolent but incurable. The disease may progress and/or transform to prolymphocytic leukemia (PLL) or large B-cell lymphoma (Richter's syndrome). CD38 and/or ZAP-70 positivity is associated with worse prognosis.</p> <p>About 80% of the CLL/SLL cases have abnormal karyotypes. Trisomy 12 is reported in ~20% of cases and deletions at 13q14 in up to 50% of cases. Trisomy 12 in CLL/SLL correlates with a worse prognosis.</p> <p>In addition to CLL/SLL, aberrant CD5 expression is also characteristic of mantle cell lymphoma and/or leukemia (MCL).</p> |
| B-cell prolymphocytic leukemia (B-PLL) | The cells of B-PLL strongly express surface IgM and B-cell antigens CD19, CD20, CD22, CD79a, CD79b, and FMC-7. CD5 is present in about one third of cases, and CD23 is typically negative. | B-PLL can be divided into CD5 ⁺ B-PLL (arising in CLL/SLL) and CD5 [−] B-PLL (de novo PLL). CD5 ⁺ B-PLL has a longer median survival than CD5 [−] B-PLL. |
| Lymphoplasmacytic lymphoma and/or Waldenström's macroglobulinemia (LPL) | The cells express strong surface and cytoplasmic (some cells) immunoglobulin, usually of IgM type (rarely IgG or IgA), are typically IgD [−] , and express B-cell antigens (CD19, CD20, CD22, CD79a), and are CD5 [−] , CD10 [−] , CD23 [−] , CD43 ⁺ and/or CD43 [−] , and CD38 ⁺ . Lack of CD5 and strong immunoglobulin expression are useful in distinction from CLL/SLL. | Characteristic features include IgM monoclonal gammopathy; spectrum of small lymphocytes, plasmacytoid lymphocytes, and plasma cells, with or without PAS ⁺ intranuclear pseudoinclusions (Dutcher bodies); interstitial, nodular, or diffuse pattern of bone marrow involvement; and typical immunophenotype (sIgM ⁺ , CD19 ⁺ , CD20 ⁺ , CD5 [−] , CD23 [−] , CD10 [−]). |
| Splenic marginal zone lymphoma (SMZL) | The tumor cells express surface IgM and are positive for CD19, CD20, CD79a and negative for CD5, CD10, CD23, CD25, CD43, CD103, and Bcl-1 (cyclin D1). | <p>Circulating lymphoma cells are usually, but not always, characterized by the presence of short polar villi (villous lymphocytes).</p> <p>The absence of CD5 and CD43 are useful in excluding CLL/SLL and MCL (mantle cell lymphoma). The absence of CD103 is useful in excluding hairy cell leukemia, and the absence of CD10 is useful in excluding follicular lymphoma. On tissue sections, Bcl-1 (cyclin D1) is also useful in distinguishing between SMZL and MCL.</p> <p>The clinical course is indolent, even with bone marrow involvement. The disease is incurable with available therapy.</p> |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|---|--|
| Hairy cell leukemia (HCL) | The leukemic cells express surface Ig (IgM, IgD, IgG, or IgA), pan-B-cell markers (CD19, CD20, CD22, CD79a, but usually not CD79b), and are typically negative for CD5, CD10, and CD23. The cells are characteristically positive for CD11c, CD25, FMC-7, and CD103. In tissue sections, the cells are typically positive for DBA-44 and negative for Bcl-1 (cyclin D1). | <p>Patients with HCL usually have splenomegaly, pancytopenia (monocytopenia is characteristic), and may have circulating hairy leukemic cells. The cells in bone marrow biopsy sections may produce a “fried-egg” appearance because of abundant cytoplasm and prominent cell borders. Bone marrow reticulin fibers are characteristically increased, often resulting in “dry tap” during aspirate procedure.</p> <p>Interferon alpha, deoxycoryformycin (pentostatin), or 2-chlorodeoxyadenosine (2-CdA, cladribine) can induce long-term remissions.</p> |
| Plasma cell myeloma and/or plasmacytoma | The malignant cells typically express monotypic cytoplasmic immunoglobulin (Ig) (IgG, IgA, light chain only, rare IgD, IgM, or IgE) and lacks surface Ig. The cells generally lack CD45 and pan-B-cell antigens (CD19, CD20, CD22), but CD79a is positive in the majority of cases. The cells are typically positive for CD38, CD138 and often express CD56, CD43, and rarely CD10. The phenotype of plasma cell leukemia is similar to that of myeloma, but CD56 is characteristically negative. | Plasma cells do not express surface immunoglobulin. For the clonality (or light chain restriction) determination by flow cytometry analysis, cell permeabilization procedure is necessary. The procedure gives antibodies access to intracellular structures and/or molecules and leaves the morphological scatter characteristics of the cells intact. |
| Extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT lymphoma) | The lymphoma cells typically express IgM \pm IgD, and less often IgA or IgG and show light chain restriction. The cells are positive for CD19, CD20, CD79a, CD43 and negative for CD5, CD10, CD23, and Bcl-1. | <p>Trisomy 3 is found in \sim60%, and t(11;18)(q21;q21) has been detected in 25%-50% of MALT lymphoma cases. Analysis of the t(11;18) breakpoint has shown fusion of the apoptosis-inhibitor gene API2 to a novel gene at 18q21, named MLT. Neither t(14;18) nor t(11;14) is present. Cases with t(11;18) appear to be resistant to <i>H. pylori</i> eradication therapy.</p> <p>In small biopsy tissue sections, the co-expression of CD20 and CD43 and lack of CD5, CD10, and Bcl-1 (cyclin D1) are characteristic for MALT lymphoma.</p> |
| Nodal marginal zone B-cell lymphoma (NMZL) | The immunophenotype of most cases is similar to that of extranodal MALT lymphoma. Some cases are IgD ⁺ and CD43 ⁺ , similar to SMZL. | NMZL is a primary nodal B-cell neoplasm that morphologically resembles lymph nodes involved by marginal zone lymphomas of extranodal or splenic types, but without evidence of extranodal or splenic disease. Monocytoid B cells may be prominent. |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|---|---|
| Follicular lymphoma (FL) | The lymphoma cells are usually positive for pan-B-cell antigens (CD19, CD20, CD22, CD79a), sIg (IgM \pm IgD, IgG, or rarely IgA), CD10, Bcl-2, Bcl-6 and negative for CD5. Rare cases may express CD5 and/or CD43. Bcl-2 is expressed in the majority of cases, ranging from nearly 100% in grade 1 to 75% in grade 3 FL. | Virtually all cases of FL have cytogenetic abnormalities. The most common translocation, t(14;18)(q32;q21), involving rearrangement of the Bcl-2 gene and IgH gene, is present in 80%-95% of FL. Rare cases have a t(2;18)(p12;q21), which places the Bcl-2 gene with the light chain gene on chromosome 2. Clonal evolution in FL has been reported. FL may transform into precursor B-ALL, and c-myc (8q24) rearrangement is often associated with the transformation. In addition to FL, Bcl-2 is expressed by resting B cells and T cells, but not by normal germinal center cells, cortical thymocytes, or monocytoid B cells. Bcl-2 is particularly useful in distinguishing reactive follicular hyperplasia and FL. |
| Mantle cell lymphoma (MCL) | The lymphoma cells usually express surface IgM \pm IgD, pan-B-cell antigens (CD19, CD20, CD79a), Bcl-2, FMC-7, CD5, CD43 and are typically negative for CD10, CD23, and Bcl-6. Virtually all cases express Bcl-1 (cyclin D1). Rare CD5-negative cases have been reported. | MCL and CLL/SLL are the two common CD5-positive B-cell lymphoproliferative disorders. But unlike CLL/SLL, MCL cells express bright surface immunoglobulin, bright CD20 and FMC-7, and are characteristically CD23 negative. Virtually all MCL cases show rearrangement involving the cyclin D1 (Bcl-1) gene and IgH gene using FISH (fluorescence in situ hybridization). The t(11;14)(q13;q32) translocation is demonstrable in about 75% of MCL cases by conventional cytogenetic study. |
| Diffuse large B-cell lymphoma (DLBCL) | DLBCL cells typically express various pan-B-cell antigens (CD19, CD20, CD22, CD79a), sIg and/or cIg (IgM>IgG>IgA), Bcl-6, and CD10. Bcl-2 is positive in 30%-50% of cases. CD5 is expressed in about 10% of cases. DLBCL with anaplastic morphology also express CD30. | Morphological variants of DLBCL include centroblastic, immunoblastic, T-cell and/or histiocyte-rich, anaplastic, and plasmablastic DLBCL. Translocation of the Bcl-2 gene (e.g., t[14;18], a hallmark of follicular lymphoma [FL]) occurs in 20%-30% of cases. Up to 30% of cases show abnormalities of 3q27 region involving Bcl-6 gene. Bcl-2 expression has been reported to be associated with an adverse disease-free survival, and expression of Bcl-6 appears to be associated with a better prognosis. |
| Mediastinal (thymic) large B-cell lymphoma (Med-DLBCL) | The lymphoma cells express CD45 and B-cell antigen (CD19, CD20). Immunoglobulin (Ig) and HLA class I and II molecules (e.g., HLA-DR) are frequently absent. The cells do not express CD5 and CD10 and lack Bcl-2, Bcl-6, and c-myc rearrangements. | Med-DLBCL is a subtype of DLBCL arising in the mediastinum of putative thymic B-cell origin with distinct clinical, immunophenotypic, and genotypic features. Tissue sections usually show diffuse lymphoid proliferation, compartmentalized into groups by fine and/or delicate fibrotic bands. |
| Intravascular large B-cell lymphoma | The lymphoma cells express pan-B-cell antigens (CD19, CD20, CD22, CD79a). CD5 co-expression is seen in some cases. | Intravascular large B-cell lymphoma is a rare subtype of extranodal DLBCL characterized by the presence of lymphoma cells only in the lumina of small vessels, particularly capillaries. The intravascular growth pattern appears to be due to a defect in homing receptors (e.g., CD29, CD54) on the lymphoma cells. |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|-----------------------------------|---|--|
| Primary effusion lymphoma (PEL) | The lymphoma cells usually express CD45, but are usually negative for pan-B-cell markers (CD19, CD20, CD79a). Surface and cytoplasmic immunoglobulin is likewise often absent. Activation and plasma cell-related markers, such as CD30, CD38, and CD138 are usually positive. Aberrant cytoplasmic CD3 expression has been reported. | PEL is a neoplasm of large B cells usually having serous effusions without detectable tumor masses. It is universally associated with human herpes virus 8 (HHV-8), most often occurring in the setting of immunodeficiency. Rare cases of PEL of T-cell origin have been reported. |
| Lymphomatoid granulomatosis (LYG) | The lymphoma cells usually express CD20 and are variably positive for CD79a and CD30, but negative for CD15. The cells generally lack cytoplasmic and surface immunoglobulin expression. The background small lymphocytes are CD3-positive T cells, with CD4-positive cells more frequent than CD8-positive cells. | LYG is an angiocentric and angiodestructive lymphoproliferative disease involving extranodal sites, comprised of Epstein-Barr virus (EBV)-positive B cells admixed with reactive T cells, which usually are preponderant. LYG may progress to an EBV-positive DLBCL. The common sites of involvement are lung, kidney, brain, liver, and skin. |
| Burkitt's lymphoma (BL) | The lymphoma cells express surface IgM with light chain restriction, pan-B-cell antigens (CD19, CD20, CD22, CD79a), CD10, CD77, and Bcl-6. The cells are negative for CD5, CD23, CD34, and TdT. Nearly 100% of the cells are positive for Ki-67 (MIB-1). Bcl-2 is not expressed. | All BL cases show a translocation of <i>c-myc</i> gene at chromosome 8q24 to the IgH gene at 14q32 or less commonly to light chain loci at 2p12 or 22q11. Genetic abnormalities involving the <i>c-myc</i> gene play an essential role in BL pathogenesis. The expression of CD10 and Bcl-6 indicates a germinal center origin of the tumor cells. BL is highly aggressive, but potentially curable. |

4. IMMUNOPHENOTYPES OF MATURE T-CELL AND NK-CELL NEOPLASMS

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|--|--|
| T-cell prolymphocytic leukemia (T-PLL) | <p>The leukemic cells express CD2, CD3, and CD7, but not TdT and CD1a. In about two thirds of patients with T-PLL, the cells are CD4⁺ and CD8⁻. In ~25% of cases, the cells co-express CD4 and CD8, a feature almost unique to T-PLL. In ~15% of cases, the cells are CD4⁻ and CD8⁺.</p> | <p>T-PLL is an aggressive T-cell leukemia characterized by the proliferation of small to medium sized prolymphocytes with a mature postthymic T-cell phenotype involving the blood, bone marrow, lymph nodes, spleen, and skin. The most frequent chromosome abnormality in T-PLL involves inversion of chromosome 14 with breakpoints in the long arm at q11 and q32, seen in ~80% of patients. In ~10% of cases, there is a reciprocal tandem translocation t(14;14)(q11;q32). These translocations juxtapose the TCR-α/β locus with the oncogenes TCL1 and TCL1b at 14q32, which are activated through the translocation.</p> |
| T-cell large granular lymphocyte leukemia (T-LGL) | <p>T-LGL cells have a mature T-cell immunophenotype. Based on the predominant cell markers, T-LGL can be subdivided into:</p> <ol style="list-style-type: none">1. Common type (80% of cases): CD3⁺, TCR$\alpha\beta$⁺, CD4⁻, CD8⁺2. Rare variants:<ol style="list-style-type: none">(1) CD3⁺, TCR$\alpha\beta$⁺, CD4⁺, CD8⁻(2) CD3⁺, TCR$\alpha\beta$⁺, CD4⁺, CD8⁺(3) CD3⁺, TCR$\gamma\delta$⁺ <p>CD11b, CD56, and CD57 are variably expressed. CD57 is often expressed in the common type. TIA-1 is usually positive.</p> | <p>T-LGL is a heterogeneous disorder characterized by a persistent (>6 mo) increase in the number of peripheral blood large granular lymphocytes (LGLs), usually between 2-20 $\times 10^3$/mL, without a clearly identified cause. Severe neutropenia with or without anemia is a characteristic clinical feature. Pure red cell hypoplasia has been reported in association with T-LGL leukemia. Moderate splenomegaly, rheumatoid arthritis, and the presence of autoantibodies are commonly seen in patients with T-LGL.</p> |
| Aggressive NK-cell leukemia | <p>The leukemic cells are CD2⁺, surface CD3⁻, cytoplasmic CD3ϵ⁺, CD56⁺ and positive for cytotoxic molecules (TIA-1, granzyme B, and/or perforin). This immunophenotype is identical to that of extranodal NK- and/or T-cell lymphoma, nasal type. CD11b and CD16 may be expressed, whereas CD57 is usually negative.</p> | <p>Aggressive NK-cell leukemia is characterized by a systemic proliferation of NK cells. The disease has an aggressive clinical course. T-cell receptor (TCR) genes are in germline configuration. Clonality therefore has to be established by other methods, such as cytogenetic studies and pattern of X chromosome inactivation in female patients. A variety of clonal cytogenetic abnormalities have been reported, such as del(6)(q21q25).</p> |
| Adult T-cell leukemia and/or lymphoma (ATLL) | <p>The tumor cells express T-cell antigens (CD2, CD3, CD5), but usually lack CD7. Most cases are CD4⁺, CD8⁻. Rare cases are CD4⁻, CD8⁺, or double negative for CD4 and CD8. CD25 is expressed in virtually all cases. TIA-1 and granzyme B are negative.</p> | <p>ATLL is a peripheral T-cell neoplasm most often composed of highly pleomorphic lymphoid cells. The disease is usually widely disseminated and is caused by the human T-cell leukemia virus type 1 (HTLV-1). Clonally integrated HTLV-1 is found in all cases. ATLL is endemic in Japan, the Caribbean basin, and parts of Central Africa. T-cell receptor genes are clonally rearranged.</p> |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|---|---|
| Extranodal NK/T-cell lymphoma, nasal type | The typical immunophenotype is CD2 ⁺ , CD56 ⁺ , surface CD3 ⁻ , and cytoplasmic CD3ε ⁺ . Most cases are positive for cytotoxic molecules (TIA-1, granzyme B, perforin). The tumor cells are usually negative for CD4, CD5, CD8, CD16, and CD57. But CD43, CD45RO, HLA-DR, CD95 are commonly expressed. | The disease entity is designated NK/T-(rather than NK) cell lymphoma because although most cases appear to be NK-cell neoplasms (EBV ⁺ , CD56 ⁺), rare cases show an EBV ⁺ , CD56 ⁻ cytotoxic T-cell phenotype. T-cell receptor and immunoglobulin genes are in germline configuration in a majority of cases. EBV can be demonstrated in the tumor cells in nearly all cases. The prognosis is variable, with some patients responding well to therapy and others dying of disseminated disease despite aggressive therapy. |
| Enteropathy-type T-cell lymphoma | Tumor cells are CD3 ⁺ , CD5 ⁻ , CD7 ⁺ , CD8 ⁻ and/or CD8 ⁺ , CD4 ⁻ , CD103 ⁺ and contain cytotoxic molecules (TIA-1, granzyme B). A varying proportion of the tumor cells express CD30. In a subset of cases, the tumor cells are CD8 ⁺ and CD56 ⁺ . | The lymphoma is a tumor of intraepithelial T lymphocytes, showing varying degrees of transformation, but usually having a tumor composed of large lymphoid cells. TCRβ and TCRγ genes are clonally rearranged. The tumor occurs most commonly in the jejunum or ileum, and there is a clear association with celiac disease. The prognosis is usually poor. |
| Hepatosplenic T-cell lymphoma | The tumor cells are CD3 ⁺ , CD4 ⁻ , CD8 ⁻ , CD5 ⁻ , CD56 ⁺ and/or CD56 ⁻ . The cells are usually TCRδ1 ⁺ , TCRαβ ⁻ and express TIA-1. | Hepatosplenic T-cell lymphoma is an extranodal and systemic neoplasm derived from cytotoxic T cells usually of γδ T-cell receptor type, medium in size, demonstrating marked sinusoidal infiltration of spleen, liver, and bone marrow. TCRδ genes are clonally rearranged. TCRβ genes are usually in germline configuration. Isochromosome 7q is present in nearly all cases, sometimes in conjunction with other abnormalities, most commonly trisomy 8. The clinical course is aggressive. |
| Subcutaneous panniculitis-like T-cell lymphoma (SPTCL) | The tumor cells are usually CD3 ⁺ , TCRαβ ⁺ , CD5 ⁻ , CD4 ⁻ , CD8 ⁻ and express cytotoxic molecules, including granzyme B, perforin, and TIA-1 (T-cell intracellular antigen). Cases of γδ origin may express CD56 and CD16. | SPTCL is a cytotoxic T-cell lymphoma, which preferentially infiltrates subcutaneous tissue. It is composed of atypical lymphoid cells of varying size, often with marked tumor necrosis and karyorrhexis. Some patients may have a hemophagocytic syndrome with pancytopenia. The clinical course is aggressive. |
| Blastic NK-cell lymphoma | The neoplastic cells are CD4 ⁺ , CD56 ⁺ , and CD43 ⁺ . The cells lack surface CD3 and are usually negative for CD2, CD7, cytoplasmic CD3ε, and cytotoxic molecules. All cases studied have been EBV negative. | Blastic NK-cell lymphoma is composed of cells with a lymphoblast-like morphology and evidence of commitment to the NK lineage. TCR genes are germline in configuration. The clinical course is usually aggressive. |
| Mycosis fungoides and Sézary syndrome (MF/SS) | The typical phenotype is CD2 ⁺ , CD3 ⁺ , TCRβ ⁺ , CD5 ⁺ , CD4 ⁺ and CD8 ⁻ (rarely CD4 ⁻ and CD8 ⁺). Virtually all cases are negative for CD26. CD7 is usually negative. | MF is a mature T-cell lymphoma with Th2-like immunophenotype, occurring in the skin with patches and/or plaques and characterized by epidermal and dermal infiltration of small to medium sized T cells with cerebriform nuclei. SS is a generalized mature T-cell lymphoma characterized by the presence of erythroderma, lymphadenopathy, and neoplastic T lymphocytes in the blood ($>1 \times 10^3/\mu\text{L}$). Similar to MF, the neoplastic T cells in SS also have cerebriform nuclei. TCR genes are clonally rearranged. |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|--|--|--|
| Primary cutaneous CD30-positive T-cell lymphoproliferative disorders | <p>Primary cutaneous anaplastic large cell lymphoma (C-ALCL):</p> <p>The tumors cells express T-cell anti-gens (CD2, CD3, CD5, CD7) and are usually positive for CD4. CD30 is ex-pressed in the majority (>75%) of the cells. Cytotoxic molecules (granzyme B, perforin, TIA-1) are usually positive. Aberrant T-cell phe-notype with loss of one or more T-cell antigens (CD2, CD5, or CD7) is common, but null cell phenotype is rare. CD56 is expressed in some cases. Unlike systemic ALCL, the tu-mor cells are negative for EMA (ep-ithelial membrane antigen, also called CD227) and ALK (anaplastic large cell lymphoma kinase, also called CD246).</p> <p>Lymphomatoid papulosis (LyP): The atypical T cells are CD4⁺, CD8⁻. The cells often express aber-rant phenotypes with variable loss of pan-T-cell antigens (e.g., CD2, CD5, or CD7). CD30 is positive in a LyP subtype (type A). Cytotoxic mole-cules are often expressed, but ALK (CD246) is absent.</p> | <p>LyP and C-ALCL constitute a spectrum of related conditions originating from transformed or activated CD30-positive T lymphocytes. They may co-exist in individual patients; they can be clonally related, and they often show overlapping clinical and/or histological features.</p> |
| Angioimmunoblastic T-cell lymphoma (AITL) | <p>The neoplastic cells express T-cell antigens (CD2, CD3, CD5, CD7), usually without aberrant antigen loss. The tumor cells are CD4⁺ and CD8⁻, but admixed reactive CD8⁺ T cells are usually present. The neoplastic T cells are characteristically positive for CD10 and Bcl-6. CD21 stain high-lights the intact or disrupted follicular dendritic meshwork.</p> | <p>AITL is a T-cell lymphoma with Th1-like immunophenotype. It is characterized by systemic disease, a polymorphous infil-trate involving lymph nodes, with a prominent proliferation of high endothelial venules and follicular dendritic cells. TCR genes are rearranged in the majority (>75%) of cases. Sec-ondary EBV-related B-cell lymphoma may occur.</p> <p>Recent studies showed that almost all cases are positive for CD10 and Bcl-6, suggesting a germinal center derivation of the tumor cells.</p> <p>The clinical course is aggressive with a median survival of less than 3 years.</p> |

| DISEASE | TYPICAL IMMUNOPHENOTYPE | REMARKS |
|---|---|---|
| Peripheral T-cell lymphoma, unspecified | The neoplastic cells express T-cell antigens (CD2, CD3, CD5, CD7), but aberrant T-cell phenotypes with antigen loss (e.g., CD7, CD5) are frequent. Most nodal cases are CD4 ⁺ , CD8 ⁻ . CD30 is expressed by a majority of tumor cells in large cell variants. CD56 may be positive in some cases. Expression of cytotoxic molecules is rare. | TCR genes are clonally rearranged in most cases. Complex karyotypes, consistent with clonal evolution, are frequent. Trisomy 3 is frequent in the lymphoepithelioid cell (Lennert's) variant. EBV (Epstein-Barr virus) is usually absent in the tumor cells. The diseases are among the most aggressive of the non-Hodgkin's lymphomas. |
| Anaplastic large cell lymphoma (ALCL) | The tumor cells express one or more T-cell antigens (CD2, CD3, CD5, CD7), but apparent "null cell" phenotype has been reported. The cells usually express CD30 (membrane and in the Golgi region), ALK (CD246, cytoplasmic and/or nuclear), EMA, cytotoxic molecules (TIA-1, granzyme B, and/or perforin), CD43, and CD45. Clusterin is expressed in all cases of systemic ALCL, but not primary cutaneous ALCL (C-ALCL) or classical Hodgkin's lymphoma. | Nearly all ALCL cases show clonal rearrangement of the T-cell receptor genes irrespective of whether they express T-cell antigens or not. Expression of ALK (CD246) in ALCL is due to genetic alteration of the ALK locus on chromosome 2. The most frequent alteration is t(2;5)(p23;q35), resulting in fusion of the ALK gene and nucleophosmin (NPM) gene on 5q35. The classic t(2;5) leads to positive staining for ALK in both the nucleolus, nucleus, and the cytoplasm. In other variant translocations, often only cytoplasmic staining is observed. ALK positivity is an important prognostic indicator, which is associated with a favorable prognosis. |

SECTION VII

PHARMACOGENOMICS

Pharmacogenomics, a clinical and scientific discipline, is based on the phenotype and genotype and/or haplotype correlation. It uses genetic information to predict the drug efficacy and toxicity and to identify responders and nonresponders.¹⁻⁹ Pharmacogenomics may be regarded as one of the tangible outcomes of the completion of the human genome project.^{10,11} As such, pharmacogenomics constitutes the genomic component for personalized medicine, which also encompasses personalized laboratory medicine. Other personalized laboratory medicine components would include: clinical chemistry, such as creatinine, as a renal biomarker; TDM biomarker; and possibly future proteomics biomarkers. Together this combination of personalized laboratory medicine tests would enable the benefit of drug therapy and/or discovery based on an individual's genetic, proteomic, and metabolic profiles. Even though pharmacogenomics and pharmacogenetics are used interchangeably, the proposed definition of pharmacogenetic testing is concerned with using genotyping for identifying interindividual DNA sequence variation, whereas pharmacogenomic testing is concerned with identifying variation in whole genomes, haplotypes, and gene expression or inactivation.^{11,12} Since FDA-approved pharmacogenomic product is limited, the majority of the testing is performed in "home-brew" settings by developing or adopting published procedures. Currently the testing may be more readily characterized as pharmacogenetics in that the majority of the clinical protocols identify mutations and/or single nucleotide polymorphisms (SNPs). The top ten pharmacogenetic tests, according to a recent AACC survey, are: *CYP 2D6*, *TPMT*, *CYP 2C9*, *CYP 2C19*, *NAT-2*, *CYP 3A5*, *UGT1A1*, *MDR1*, *CYP 2B6*, and *MTHFR*.¹³ These procedures may be performed by a variety of molecular techniques by using genomic DNA. Readers are referred to review papers for technical details.¹⁴⁻²⁰ Pharmacogenomics testing for the gene expressions of drug-metabolizing enzymes, transporters, and receptors are limited to drug discovery and clinical research laboratories. Currently, they are not yet offered clinically for patient services.

This section attempts to provide a database for pharmacogenomics and/or pharmacogenetics testing and is divided into four sections: Phase I drug-metabolizing enzymes, phase II drug-metabolizing enzymes, drug transporters, and drug receptors and/or targets. Currently the majority of the interest is focused on phase I and II drug-metabolizing enzymes genes, with emerging interest in drug transporters and receptors and/or targets. The tables are organized by each gene with the known mutations, representative and/or selected drug substrates, inhibitors, inducers, nucleotide changes, amino changes, frequencies, and clinical effects. References are provided to guide the readers. Since the practice of personalized medicine—personalized laboratory medicine—and pharmacogenomics are rapidly evolving, representative websites are listed below:

GSTM1 and GSTT1

*Adapted from Weinshilbaum R: Inheritance and <https://CafePezeshki.IR>⁰⁰³.

| DRUGS | MUTATIONS AND PREVALENCE | CLINICAL EFFECTS |
|--|--|---|
| Mercaptopurine ^{10,81} Azathioprine | These three mutations account for 80%-95% of TPMT deficiency ⁹⁴⁻⁹⁹ 460G>A, Ala154Thr, and 719A>G, Tyr240Cys 100 | 6-Mercaptopurine (6-MP) is used in the treatment of acute lymphoblastic leukemia (ALL). 6-MP, a prodrug, is converted to both active thioguanine triphosphate nucleotides (6-TGN) and inactive metabolites. TPMT is responsible for metabolism of 6-MP and indirectly regulates 6-TGN. ^{10, 83-91} TPMT-deficient patients might receive half or fifteenfold reduction in dose. ^{92,93} |
| Irinotecan ¹⁰² Bilirubin ¹⁰⁶ | 211G>A, G71R 1456T>G, Y486D 686C>A, P229Q (TA)7TAA, TA insertion | Irinotecan is initially metabolized by carboxylesterase-2 to 7-ethyl-10-hydroxycamptothecin (SN-38), a topoisomerase I inhibitor. ¹⁰³⁻¹⁰⁵ This is glucuronidated to inactive SN-38G by UGT1A1. UGT1A1 deficiency would result in accumulation of SN-38, causing diarrhea. ¹⁰⁹ Enhanced drug effect, ¹¹² Gilbert syndrome, ^{106,115,116} Crigler-Najjar syndrome ¹¹⁷ |
| Amonafide ¹¹⁹⁻¹²¹ Isoniazid ¹²² Hydralazine ¹²³ Procainamide ¹²⁷ | 191G>A 282 C>T 341T>C 481C>T 590G>A 803A>G 857G>A | NAT acetylates amonafide, a topoisomerase II inhibitor, to an active metabolite, N-acetyl-amonafide. Rapid acetylator would result in myelosuppression. ^{119,120} NAT2 mutants account for 55% of slow acetylators. ^{124,125} WT has much higher acetylation rate. ¹²⁶ Enhanced drug effects ¹²⁸ |
| Levodopa ^{81,129} | | Enhanced drug effect |
| Alkylating agents and/or cyclophosphamide metabolites ¹³¹ Cisplatin ¹⁰¹ Thiotepa ¹³⁸ | Duplication Deletion ¹³⁷ SNP Ile114 Val, Ala 114 Val | Cyclophosphamide metabolites ^{101,119,120,131-135} Null genotypes correlate to poorer survival of ovarian cancer patients. ¹³⁹ GSTM increases risks of relapse in childhood acute lymphoblastic leukemias (ALL). ¹⁴⁰ GSTT1 genotype affects outcome using prednisone I Berlin-Frankfurt-Munster protocols with null GSTT1 for a 7.6 risk reduction. Null GSTM1, null GSTT1, and GSTp1 Val105 /val105 are “low-risk” genotypes. For acute myeloid leukemia (AML) patients, null GSTT1 genotype results in lower survival and toxic drug deaths. ¹⁴¹ |

PART III: DRUG TRANSPORTERS*

| PROTEIN TRANSPORTER GENES | PROTEIN TRANSPORTERS | SUBSTRATES | INHIBITORS |
|--|---|--|------------|
| Albumin | Albumin | Warfarin, salicylate, diazepam | |
| Multidrug resistance-associated proteins | MRP1 | Anticancer drug glucuronide, sulfate and glutathione conjugates | |
| | MRP2 Canalicular multidrug resistance-associated protein (cMRP, also known as cMOAT) | Bilirubin glucuronide conjugates, ¹⁴⁵ glutathione conjugates, vinblastine, ¹⁴⁶ and telmisartan ¹⁴⁷ | |
| | MRP3 | Glucuronide and glutathione conjugates, ^{148,149} MTX, ¹⁴⁹ bile acid conjugates, ¹⁴⁹ etoposide, ^{148,150} vincristine ¹⁵⁰ | |
| | MRP4 | 9-(2-phosphonyl methoxyethyl) adenine PMEAs (cytotoxic acyclic nucleoside phosphonates), AZT, 3TC, d4T, MTX, ¹⁵¹ CMP, 6-TG ¹⁵² | |
| | MRP5 | PMEA, 6MP, and 6 TG | Sildenafil |
| | MRP6 | Anthracycline | |
| Multidrug resistance family (MDR) | | | |
| Multidrug-resistance gene, human MDR1 | P-glycoprotein P-gp ¹⁵⁴ (ABCB1) | Lipophilic and/or amphipathic, with one or more aromatic rings | |

*Adapted from Tirona RG, Kim RB: Pharmacogenomics of drug transporters; and Fromm MF, Eichelbaum M: The pharmacogenomics of human P-glycoprotein. In Licinio J, Wong ML, editors: *Pharmacogenomics*, Weinheim, Germany, 2002, Wiley-VCH.

| MUTATIONS | GENOTYPING FREQUENCIES | CLINICAL EFFECTS |
|---|------------------------|--|
| | | Reduced warfarin affinity of some albumin variants ¹⁴² |
| 1 gene deletion and 17 SNPs ¹⁴³ | | It may change tissue drug level. Effect pending. ¹⁴⁴ |
| 11 mutations: Point mutation, base pair deletion, premature stop codons, and aberrant RNA splicing ¹⁴³ | | Effect pending. ¹⁴³ |
| 10 SNPs | | Effect pending. ¹⁴³ |
| 2 mutations | | High expression results in drug resistance to PMEA and nucleoside analogues. Other effects pending ¹⁴³ |
| 11 SNPs | | High expression results in drug resistance to PMEA and nucleoside analogs. Other effects pending ^{143,153} |
| 25 mutations: missense, splice, deletions, and insertions | | Effects pending. ¹⁴³ |
| 20 SNPs in Caucasian ¹⁵⁵⁻¹⁵⁷ | | P-gp, an ATP-binding cassette (ABC) superfamily of membrane proteins and ATP-dependent xenobiotics exporter from cells, is expressed in intestine, liver, kidneys, brain, placenta and testis. ^{154,158-165} and protects against xenobiotics. Intestinal P-gp limits absorption of immunosuppressants, cardiac glycoside and some β -adrenoceptor antagonists. Drug interactions may be caused by P-gp induction and inhibition. |

| PROTEIN TRANSPORTER GENES | PROTEIN TRANSPORTERS | SUBSTRATES | INHIBITORS |
|---------------------------------|-------------------------|--|---|
| | | Chemotherapeutics ¹⁵⁴ Actinomycin D ¹⁶⁸ Etoposide ¹⁶⁹ Daunorubicin ¹⁷⁰ Docetaxel ¹⁷¹ Doxorubicin ¹⁷⁰ Irinotecan ¹⁷² Mitomycin C ¹⁷³ Mitoxantrone ¹⁷³ Paclitaxel ¹⁷⁴ Teniposide ¹⁷³ Topotecan ¹⁷³ Vinblastine ¹⁷⁵ Vincristine ¹⁷⁶ | |
| | | Immunosuppressants ¹⁵⁴ Cyclosporine A ¹⁷⁷ FK 506 ¹⁷⁷ Rapamycin(?) RAD (?) | Immunosuppressants Cyclosporine A ^{19,154} |
| | | Steroids ¹⁵⁴ Aldosterone ¹⁹ Hydrocortisone ¹⁹ Cortisol ¹⁹ Corticosterone ¹⁹ Dexamethasone ¹⁹ | Antiestrogen Tamoxifen ¹⁹ Mefipristone ^{19,154} |
| | | HIV protease inhibitors ¹⁵⁴ Amprenavir ¹⁷⁸ Indinavir ¹⁷⁹ Nelfinavir ¹⁷⁹ Ritonavir ¹⁷⁹ Saquinavir ¹⁸⁰ | Nelfinavir ^{19,154} Ritonavir ^{19,154} Saquinavir ^{19,154} |
| | | Digitalis glycoside ^{154,181} Digoxin ¹⁸² | Antifungal agent Ketoconazole ^{19,154} |
| | | Antiarrhythmic agent ¹⁵⁴ Quinidine ¹⁶⁵ | Sedative agent Midazolam ^{19,154} |

| PROTEIN TRANSPORTER GENES | PROTEIN TRANSPORTERS | SUBSTRATES | INHIBITORS |
|--|-------------------------|--|------------|
| | | Antibiotic ^{154,183-185} Erythromycin ¹⁸³ | Warfarin |
| | | Antituberculous agent Rifampin ¹⁸⁷ Rhodamine ¹⁹ | |
| MDR3 | | Digoxin, paclitaxel, and vinblastine ¹⁸⁸ | |
| Sister of P-glycoprotein | SPGP | Vinblastine ¹⁹⁵ and sulindac ^{196?} | |
| Novel organic cation transporters | OCTN1 | Tetraethylammonium (TEA), quinidine, pyrilamine, and verapamil ¹⁹⁹ | |
| | OCTN2 | TEA, ²⁰⁰ quinidine, verapamil, ²⁰¹ cephalosporins ²⁰⁷ | |
| Organic anion polypeptide transporters | OATP-A | Steroid sulfates, ^{208,209} fexofenadine ²¹⁰ | |
| | OATP-B | Unknown | |
| | OATP-C | Sulfate and glucuronide conjugates, ²¹¹ pravastatin, ²¹² MTX ^{213,214} | |
| | OATP-E | Taurocholate ²¹⁵ | |
| | OATP8 | Similar to OATP-C | |
| Organic anion transporter | OAT1 | Cidofovir, adefovir ²¹⁶ | |
| | OAT2 | Unknown | |
| | OAT3 | Methotrexate, cimetidine, and setrone sulfate ²¹⁷ | |
| | OAT4 | Steroid sulfates and ochratoxin A ²¹⁸ | |
| Organic cation transporter | OCT1 | TEA, 1-methyl 1,4-phenylpyridinium (MPP ⁺) N-1-methylnicotinamide | |
| | OCT2 | MAOI and amantadine | |
| | OCT3 | Adrenaline, noradrenaline, MPP ⁺ | |
| | OCTN1 | TEA, quinidine, pyrilamine, and verapamil ¹⁹⁹ | |
| | OCTN2 | TEA, ²⁰⁰ quinidine, ²⁰¹ verapamil ²⁰¹ cephalosporins ²⁰⁷ | |
| | | | |

| MUTATIONS | GENOTYPING FREQUENCIES | CLINICAL EFFECTS |
|--|------------------------|--|
| | | Variable warfarin affinity of some P-gp variants ¹⁸⁶ |
| 23 mutations include deletions, insertions, and missense mutations | | Polymorphisms result in low or nondetectable MDR3 protein expression in liver, and hence change hepatic drug elimination rate. ¹⁸⁴ Mutations cause progressive familial intrahepatic cholestasis type 3 (PFIC3), intrahepatic cholestasis of pregnancy, and cholesterol gallstone disease. ^{143,189-194} |
| 14 mutations: frameshift, missense and premature stop codon ^{197,198} | | Mutations cause PFIC2. ¹⁹⁷ Effect pending on further study. ¹⁴⁷ |
| 5 mutations ¹⁴³ | | Effect unknown. ¹⁴³ |
| 15 mutations ²⁰²⁻²⁰⁶ | | Mutations may affect drug metabolism. ¹⁴³ |
| Unknown 4 mutations 16 mutations | | Unknown Unknown Unknown |
| 1 mutation | | Unknown |
| 1 mutation | | Unknown |
| 5 mutations Unknown Unknown Unknown | | Unknown Unknown Unknown Unknown |
| Unknown Unknown Unknown Unknown 5 mutations 15 mutations | | Unknown Unknown |

| PROTEIN TRANSPORTER GENES | PROTEIN TRANSPORTERS | SUBSTRATES | INHIBITORS |
|---|--|--|------------|
| Peptide transporter family | PepT1 | β -Lactam antibiotics, ^{219,220} valaciclovir ²²¹ valganciclovir, ²²² captopril ²²³ | |
| | PepT2 | Similar to PepT1 with different affinity ²²⁴ | |
| Serotonin transporter (5-hydroxytryptamine) | 5-HTTs (short variant) | Antidepressants: clomipramine, fluoxetine, paroxetine | |
| | 5-HTT1 (long variant) | | |
| “White” ABC transporter family | BCRP (or MXR or ABCP) (breast cancer resistance protein) | Topotecan, overlaps with MDR1 and MRPs ²²⁸ | |

| MUTATIONS | GENOTYPING FREQUENCIES | CLINICAL EFFECTS |
|------------------------|------------------------|---|
| Unknown | | Unknown |
| 6 mutations | | Unknown |
| 44 bp deletion | | 5-Hydroxytryptamine neurotransmission, antidepressant response. ^{11,225-227} Reduced transcriptional efficiency and subsequent 5-HTT expression and uptake in lymphoblasts, higher risk of a manic phase in bipolar disorder |
| 44 bp insertion | | Higher response to fluvoxamine and paroxetine |
| 34 SNPs ²²⁹ | | May explain interindividual variability. |

PART IV: DRUG RECEPTOR/TARGET SYSTEMS*

| RECEPTORS/TARGETS | SUBSTRATES | MUTATIONS/AMINO ACID CHANGES/CLINICAL EFFECT |
|---|---|---|
| Angiotensinogen-converting enzyme (ACE) | ACE inhibitors—enalapril, lisinopril, captopril | Renoprotective effects, blood pressure reduction, reduction in left ventricular mass, endothelial function ^{11,228-236} |
| | Fluvastatin | Lipid changes, progression or regression of coronary atherosclerosis ^{11,237} |
| Angiotensin I (angiotensinogen, AGT) | Salt intake and ACE inhibitors | Variation in the efficacy of reduced sodium intake ²³⁸ and of ACE inhibitors in hypertension treatment, susceptibility to hypertension ²³⁹ |
| Apolipoprotein E (APOE) | Cholinesterase inhibitor, tacrine | Variation in cognitive function improvements with tacrine in the treatment of Alzheimer's disease, ²⁴⁰ susceptibility to Alzheimer's disease, increased by the epsilon-4 allele and decreased by epsilon-2 allele ²⁴¹ |
| Arachidonate 5-lipoxygenase | Leukotriene inhibitors | Improvement in forced expiratory volume in 1 sec ^{11,242} |
| β ₂ -Adrenergic receptor (ADRB2) | β ₂ Agonists, albuterol | 16 SNPs, ²⁴³ Arg-to-Gly at codon 16, Gln-to-Glu at codon 27, ²⁴³⁻²⁴⁴ bronchodilatation, susceptibility to agonist-induced desensitization, cardiovascular effects ²⁴³⁻²⁵⁰ |
| Bradykinin B ₂ receptor | ACE inhibitors | ACE inhibitor-induced cough ^{11,251} |
| Cholesteryl ester transfer protein (CETP) | HMG-CoA reductase inhibitor, pravastatin | Efficacy of pravastatin in the treatment of coronary atherosclerosis and susceptibility to coronary atherosclerosis ²⁵² |
| Dopamine receptors (D2, D3, D4) | Antipsychotics—haloperidol | Antipsychotic response (D2, D3, D4), antipsychotic-induced tardive dyskinesia (D3), antipsychotic-induced acute akathisia (D3) ^{11,253-257} |
| Estrogen receptor-α | Conjugated estrogens | Increase in bone mineral density ^{11,258} |
| | Hormone-replacement therapy | Increase in high-density lipoprotein cholesterol ^{11,259} |
| Glycoprotein IIIa subunit of glycoprotein IIb/IIIa | Aspirin or glycoprotein IIb/IIIa inhibitors | Antiplatelet effect ^{11,260} |
| Guanine nucleotide binding protein ²⁶¹ (G-protein), α, β, γ subunits | | Coupling to opiate receptor to distinct cellular effector system |
| Opiates ²⁶¹ —μ, δ, κ μ δ κ | Opiates and endogenous enkephalins and endorphins | Naloxone as antagonist; Asp95Asn reduces δ receptor affinity for DPDPE, DSLET, and SIOM; eliminate buprenorphine as agonist |
| | Morphine, enkephalins, and endorphins | Asp114 to noncharged amino acid decreases binding of DAMGO and morphine |
| | Morphine, enkephalins, and endorphins | |
| | Dynorphin A | |

| RECEPTORS/TARGETS | SUBSTRATES | MUTATIONS/AMINO ACID CHANGES/CLINICAL EFFECT |
|---|---------------------------------------|---|
| Peroxisome proliferator activated receptor (PPAR-GAMMA-2) | Insulin | Variation of insulin efficacy in the treatment of diabetes, susceptibility to type II diabetes ²⁶² |
| 5-hydroxytryptamine 2A receptor HTR2A | Neuroleptics ²⁶³ | Variation of clozapine ²⁶⁴ and typical neuroleptics ²⁶⁵ efficacy in schizophrenia treatment, increased susceptibility to schizophrenia ²⁶⁶ |
| Sulfonylurea receptor 1 (SUR1) | Sulfonylurea (tolbutamide) | Decreased tolbutamide-stimulated insulin secretion in healthy subjects with sequence variants in the high-affinity sulfonylurea receptor gene, ²⁶⁷ susceptibility to type II diabetes ²⁶⁸ |
| Vitamin D (VDR) | 1, 25-dihydroxyvitamin D ₃ | Vitamin D response in patients affected with rickets, susceptibility to osteoporosis ²⁶⁹ and autosomal dominant rickets disease ²⁷⁰ |

SECTION VIII

ALLERGY TESTING

BACKGROUND AND INTRODUCTION

Allergic Disease: Significance and Extent of Disease

The allergic diseases include a spectrum of disorders: asthma, rhinitis, anaphylaxis, atopic dermatitis, and sinusitis. These diseases affect up to 20% of the population. Although there are a number of immunologic mechanisms that may be involved in the various disorders, the primary focus of this chapter is those allergic reactions that are classified as type I (or immediate-type hypersensitivities) according to the classical Gel Coombs scheme. These usually involve a special immunoglobulin, IgE, which circulates in the serum at low concentrations and is present on mast cells and basophils.¹

Allergy Diagnostics

Diagnostic testing for allergy has evolved over the years. Skin testing has been the primary method to confirm allergic sensitization since the early 1900s. With this method a small quantity of allergen extract is injected into the skin where it reacts with IgE on the surface of the tissue mast cells. The cross-linking of IgE on the surface of mast cells by the multivalent allergen results in rapid cellular changes, including degranulation. This degranulation event leads to a release of chemical mediators such as histamine in the skin. Histamine causes a visible wheal and flare reaction at the site of allergen injection. These reactions in the skin can be graded according to size.² The skin test method is a very sensitive bioassay for allergic sensitization and is still widely used, especially by allergy specialists in the United States.

The most common laboratory test methods to assess allergic sensitization are based on the measurement of allergen-specific IgE in serum rather than IgE on the surface of cells. The development of these *in vitro* methods followed the discovery of IgE in 1967.³ In these laboratory test methods, the allergenic proteins are usually coupled to a solid-phase (e.g., cellulose) or a soluble matrix polymer.^{4,5} Serum from the patient is incubated with the coupled allergen of interest so that the allergen-specific IgE can bind. After this incubation period, a washing step is used to remove any unbound IgE, and the amount of specific IgE is then measured by one of several methods with a labeled antihuman IgE antibody.⁶ The most widely used methods are outlined in the following section.

ALLERGENS

A variety of substances, derived from many different sources, can sensitize an individual and cause allergic disease. In the vast majority of cases, allergens are protein molecules, usually in the molecular weight range of 10,000 to 40,000 Da. The various types of allergenic substances are outlined and organized in Tables VIII-1 and VIII-2 by source (e.g., pollen, foods). The selection of the appropriate allergens for testing requires knowledge of the patient's environmental exposure, age, and clinical history. A limited selection or panel of indoor allergens (e.g., mites, animal dander, and fungi) and pollens (weeds, trees, and grasses) can be useful to the primary care physician who is trying to evaluate the possibility of allergy in patients with symptoms suggestive of allergy. Although there are literally hundreds of tests that may be ordered, large screening panels are seldom

indicated. In general, because of both specific geographic exposure charts and cross-reaction considerations, the panel of allergens should not need to total >12 to 15 tests. Laboratories should advise physicians to limit the number of allergy tests in screening evaluations. However, if foods are to be investigated, an additional 5 to 10 allergens may be appropriate. Often the clinical laboratory will have designed regional panels that can be used by the primary care physician.

TABLE VIII-1 INDIVIDUAL ALLERGENS AVAILABLE FOR ALLERGEN-SPECIFIC IGE TESTING*

| CATEGORY OF ALLERGEN AND ALLERGEN NAME | USUAL EXPOSURE |
|--|----------------|
| GRASS POLLENS | |
| Sweet vernal grass (<i>Anthoxanthum odoratum</i>) | Inhalation |
| Bermuda grass (<i>Cynodon dactylon</i>) | |
| Orchard grass (<i>Dactylis glomerata</i>) | |
| Meadow fescue (<i>Festuca elatior</i>) | |
| Rye grass (<i>Lolium perenne</i>) | |
| Timothy grass (<i>Phleum pratense</i>) | |
| Common reed grass (<i>Phragmites communis</i>) | |
| Kentucky blue grass (<i>Poa pratensis</i>) | |
| Redtop or Bent grass (<i>Agrostis stolonifera</i>) | |
| Johnson grass (<i>Sorghum halepense</i>) | |
| Brome grass (<i>Bromus inermis</i>) | |
| Cultivated rye grass (<i>Secale cereale</i>) | |
| Velvet grass (<i>Holcus lanatus</i>) | |
| Cultivated oat (<i>Avena sativa</i>) | |
| Cultivated wheat (<i>Triticum sativum</i>) | |
| Meadow foxtail grass (<i>Alopecurus pratensis</i>) | |
| Bahia grass (<i>Paspalum notatum</i>) | |
| Wild rye grass (<i>Elymus triticoides</i>) | |
| Canary grass (<i>Phalaris arundinacea</i>) | |
| Barley (<i>Hordeum vulgare</i>) | |
| Maize or corn (<i>Zea mays</i>) | |
| WEED POLLENS | |
| Common ragweed (<i>Ambrosia elatior</i>) | Inhalation |
| Western ragweed (<i>Ambrosia psilostachya</i>) | |
| Giant ragweed (<i>Ambrosia trifida</i>) | |
| False ragweed (<i>Franseria acanthicarpa</i>) | |
| Wormwood (<i>Artemisia absinthium</i>) | |
| Mugwort (<i>Artemisia vulgaris</i>) | |
| Ox-eye daisy (<i>chrysanthemum leucanthemum</i>) | |
| Dandelion (<i>Taraxacum vulgare</i>) | |
| English plantain (<i>Plantago lanceolata</i>) | |
| Lamb's quarters (<i>Chenopodium album</i>) | |
| Russian thistle (<i>Salsola kali</i>) | |
| Golden rod (<i>Solidago virgaurea</i>) | |
| Cocklebur (<i>Xanthium commune</i>) | |
| Wall pellitory (<i>Parietaria judaica</i>) | |

| CATEGORY OF ALLERGEN AND ALLERGEN NAME | USUAL EXPOSURE |
|--|----------------|
|--|----------------|

TREE POLLENS

| | |
|--|------------|
| Box-elder (<i>Acer negundo</i>) | Inhalation |
| Grey alder (<i>Alnus incana</i>) | |
| Common silver birch (<i>Betula verrucosa</i>) | |
| Hazel (<i>Corylus avellana</i>) | |
| American beech (<i>Fagus grandifolia</i>) | |
| Mountain juniper (<i>Juniperus sabinoides</i>) | |
| Oak (<i>Quercus alba</i>) | |
| Elm (<i>Ulmus americana</i>) | |
| Olive (<i>Olea europaea</i>) | |
| Walnut (<i>Juglans californica</i>) | |
| Maple leaf sycamore, London plane (<i>Platanus acerifolia</i>) | |
| Willow (<i>Salix caprea</i>) | |
| Cottonwood (<i>Populus deltoides</i>) | |
| White ash (<i>Fraxinus Americana</i>) | |
| White pine (<i>Pinus strobes</i>) | |
| Japanese cedar (<i>Cryptomeria japonica</i>) | |
| Eucalyptus, Gum tree (<i>Eucalyptus</i> spp.) | |
| Acacia (<i>Acacia longifolia</i>) | |
| Mesquite (<i>Prosopis juliflora</i>) | |
| Melaleuca, Cajeput-tree (<i>Melaleuca leucadendron</i>) | |
| Pecan, Hickory (<i>Carya pecan</i>) | |
| Italian/Funeral cypress (<i>Cupressus sempervirens</i>) | |
| Mulberry (<i>Morus alba</i>) | |
| Queen palm (<i>Arecastrum romanzoffianum</i>) | |
| Australian pine (<i>Casaurina equisetifolia</i>) | |
| Linden (<i>Tilia cordata</i>) | |
| Privet (<i>Ligustrum vulgare</i>) | |

MOLDS AND YEASTS

| | |
|--|------------------------------|
| <i>Penicillium notatum</i> | Usually inhalation of spores |
| <i>Cladosporium herbarum</i> (<i>Hormodendrum</i>) | |
| <i>Aspergillus fumigatus</i> | |
| <i>Mucor racemosus</i> | |
| <i>Candida albicans</i> | |
| <i>Alternaria alternata</i> (<i>A. tenuis</i>) | |
| <i>Botrytis cinerea</i> | |
| <i>Helminthosporium halodes</i> | |
| <i>Fusarium moniliforme</i> | |
| <i>Stemphylium botryosum</i> | |
| <i>Rhizopus nigricans</i> | |
| <i>Aureobasidium pullulans</i> | |
| <i>Phoma betae</i> | |
| <i>Epicoccum purpurascens</i> | |
| <i>Trichoderma viride</i> | |
| <i>Curvularia lunata</i> | |
| <i>Pityrosporum orbiculare</i> | |
| <i>Cephalosporium acremonium</i> | |
| <i>Trichophyton rubrum</i> | |
| <i>Aspergillus niger</i> | |

| CATEGORY OF ALLERGEN AND ALLERGEN NAME | USUAL EXPOSURE |
|---|----------------|
| MITES | |
| House dust mite (<i>Dermatophagoides pteronyssinus</i>) | Inhalation |
| House dust mite (<i>Dermatophagoides farinae</i>) | |
| House dust mite (<i>Dermatophagoides microceras</i>) | |
| Storage mite (<i>Acarus siro</i>) | |
| Storage mite (<i>Lepidoglyphus destructor</i>) | |
| Storage mite (<i>Tyrophagus putrescentiae</i>) | |
| Storage mite (<i>Glycyphagus domesticus</i>) | |
| House dust mite (<i>Euroglyphus maynei</i>) | |
| HOUSE DUST | |
| House dust, Greer Labs, Inc | Inhalation |
| House dust, Hollister-Stier Labs | |
| ANIMAL EPIDERMALS AND PROTEINS | |
| Cat dander | Inhalation |
| Dog epithelium | |
| Horse dander | |
| Cow dander | |
| Dog dander | |
| Guinea pig epithelium | |
| Pigeon droppings | |
| Goose feathers | |
| Mouse urine proteins | |
| Rat epithelium | |
| Rat urine proteins | |
| Rat serum proteins | |
| Mouse serum proteins | |
| Budgerigar droppings | |
| Budgerigar feathers | |
| Budgerigar serum proteins | |
| Goat epithelium | |
| Sheep epithelium | |
| Rabbit epithelium | |
| Swine epithelium | |
| Hamster epithelium | |
| Chicken feathers | |
| Duck feathers | |
| Canary bird feathers | |
| Parrot feathers | |

| CATEGORY OF ALLERGEN AND ALLERGEN NAME | USUAL EXPOSURE |
|---|----------------|
| FOODS | |
| Egg white | Ingestion |
| Milk | |
| Fish, cod (<i>Gadus morhua</i>) | |
| Wheat (<i>Triticum aestivum</i>) | |
| Rye (<i>Secale cereale</i>) | |
| Barley (<i>Hordeum vulgare</i>) | |
| Oat (<i>Avena sativa</i>) | |
| Maize, corn (<i>Zea mays</i>) | |
| Rice (<i>Oryza sativa</i>) | |
| Sesame seed (<i>Sesamum indicum</i>) | |
| Buckwheat (<i>Fagopyrum esculentum</i>) | |
| Pea (<i>Pisum sativum</i>) | |
| Peanut (<i>Arachis hypogaea</i>) | |
| Soybean (<i>Glycine max</i>) | |
| White bean (<i>Phaseolus vulgaris</i>) | |
| Hazelnut (<i>Corylus avellana</i>) | |
| Brazil nut (<i>Bertholletia excelsa</i>) | |
| Almond (<i>Amygdalus communis</i>) | |
| Crab (<i>Cancer pagurus</i>) | |
| Shrimp (<i>Pandalus borealis</i>) | |

| | Serum | CEIA | Normal <24 ng/mL | [<24 mcg/L] |

Specimen processing is critical. Collect the blood in a 4-mL Vacutainer Hemogard SST tube. The tube should be completely filled

| DIAGNOSTIC INFORMATION | REMARKS |
|---|--|
| See <i>Background and Introduction to Allergy Testing</i> . | There are many different scoring schemes used to report allergen-specific IgE. ³ Most academic investigators now prefer quantitative units (kU/L) rather than the use of class scores in reporting specific IgE results. However, most laboratories still report both class and quantitative units. |

| | |
|---|---|
| See <i>Background and Introduction to Allergy Testing</i> . | The reference range for ECP is the 95% confidence interval for a normal healthy population. Serum ECP measurements may be used to monitor asthma therapies and optimize drug dosing. ¹ |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| P ↑ In hyperalaninemia, mild increase in citrullinemia, Cushing's disease, gout, hyperornithinemia, kwashiorkor, septicemia, urea cycle enzyme defects, pyruvate carboxylase deficiency, and lysinuric protein intolerance | Glycine and proline, as well as alanine, may be increased in kwashiorkor. |
| P ↓ Chronic renal disease, wasting syndrome of HIV infection, ketotic hypoglycemia, and Huntington's chorea | |
| U ↑ Secondary lactic acidosis, acute leukemia, pyruvate dehydrogenase deficiency, glycogen synthase deficiency, other diseases with elevated plasma pyruvic acid, Hartnup disease, histidinemia, rheumatoid arthritis, and lead intoxication | Increase may be seen as a result of bacterial contamination of specimen. |

Values in children (3 mo-10 yr) were measured using reversed-phase liquid chromatography.

| DIAGNOSTIC INFORMATION | REMARKS |
|--|--|
| Plasma lactic acid and 15:0 and 17:0 fatty acids are increased in biotin deficiency. | <p>Biotin deficiency has been noted to occur in patients receiving long-term parenteral nutrition unsupplemented with biotin, and particularly in those with short small intestines (biotin is produced by the gut flora). Biotin deficiency also occurs in association with Leiner's disease and in infants with genetic defects of carboxylases and biotinidase. Carboxylase defects are usually multiple; treatment requires 5-10 mg/day of biotin and can be given prenatally. In biotin-deficient infants, urinary excretion of biotin is decreased to <6 mcg/day [<25 nmol/day], whereas excretion of toxic organic acids (methylcitrate, 3-methylcrotonylglycine, 3-OH-isovalerate) is increased. No toxicity to biotin has been described. See <i>Biotinidase</i>.</p> <p>Clinical symptoms include scaly dermatitis, pallor, irritability, lethargy, anorexia, nausea, and loss of hair. Altered T-cell and B-cell immunity can also occur.⁷</p> |

Biotinidase acts to recycle biotin by cleaving the covalently bound vitamin from CoA carboxylase enzymes during their degradation. Biotinidase deficiency can cause Leigh syndrome, which may result in death.⁴

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---------|
| <p>↓ Carnitine deficiencies either myopathic or systemic. Systemic deficiency presents acutely in early life; symptoms may mimic Reye's syndrome. The condition is frequently associated with inherited organic acidurias but may also be caused by dietary deficiency in infancy. The myopathic type develops later in life with the carnitine deficiency present only in muscle. Serum carnitine levels may be within the reference range.</p> <p>↑ Severe renal disease</p> | |

| DIAGNOSTIC INFORMATION | REMARKS |
|--|---|
| P ↑ Citrullinemia, liver disease, argininosuccinic aciduria, ammonia intoxication, pyruvate carboxylase deficiency, lysinuric protein intolerance, and chronic renal failure | Premature infants show a steady increase in citrulline concentrations during the first month of life. Citrullinemia is caused by a deficiency of arginosuccinate synthetase; however, arginosuccinate levels are not increased. |
| U ↑ Citrullinemia, Hartnup disease, argininosuccinic aciduria, and glutaric aciduria type II | In urine the concentration may fluctuate greatly, but the absolute amount remains very small. |
| CSF ↑↑ Citrullinemia | |

|---|--|---|
| P ↑ Methylmalonic acidemia, homocystinuria | | |
| U ↑ Cystathioninuria, cystinosis, secondary to pyridoxine deficiency, neuroblastoma, and hepatoblastoma | | Excretion of cystathionine is markedly increased in patients with both homocystinuria and methylmalonic aciduria. |

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|--|
| <i>Chlamydia trachomatis</i> Identification | Aspiration of bubo or of pus from urethra, endocervix, or infected tissue. | Isolation of <i>C. trachomatis</i> in tissue culture is the most reliable method of making the diagnosis of LGV. The organism is isolated from pus in ~30% of patients with clinical and/or serological evidence of LGV. |
| Culture for <i>Lymphogranuloma venereum</i> (LGV)^{1,2} | Only cotton, rayon, or Dacron swabs should be used for swab collections. In addition, epithelial cell specimens should be collected by vigorous swabbing or scraping of the infected site. Transport to laboratory immediately in special transport medium such as 2SP or multi-purpose transport medium specific for Chlamydia, virus and mycoplasma. Antibiotics should be included in transport medium to reduce bacterial contamination. | The disease is relatively uncommon in the U.S.; most cases occur in travelers returning from Southeast Asia or Central or South America. There are, however, sporadic cases in the U.S. in individuals who have not had exposure abroad. When LGV is suspected in a patient with lymphadenopathy, perform a needle aspiration of the node through healthy adjacent tissue rather than directly into the bubo. Fluctuant nodes should yield frank pus, but if they do not, a small amount of sterile saline should be injected and aspirated back into the syringe. |
| Culture in Neonatal <i>Chlamydia</i> Infections^{1,2} | Conjunctival scrapings; nasopharyngeal aspirates; tracheobronchial aspirates. Transport to laboratory immediately at 4° C in special transport medium such as 2SP or multi-purpose transport medium specific for Chlamydia, virus and mycoplasma. Antibiotics should be included in transport medium to reduce bacterial contamination. | Inclusion conjunctivitis and pneumonia are the two principal manifestations of neonatal chlamydia infection. Approximately 30% of children born to women with genital chlamydia infection develop inclusion conjunctivitis. The course of this mucopurulent conjunctivitis is generally benign, and the disease resolves spontaneously within a few weeks to several months. Pneumonia occurs in 10-20% of infants born to infected mothers. <i>C. trachomatis</i> is responsible for up to 60% of all pneumonias during the first 6 mo of life, making it a major cause of pneumonia in this age group. Pneumonia is usually of mild to moderate severity. Approximately 50% of infants with pneumonia also have conjunctivitis. Culture for <i>C. trachomatis</i> routinely requires at least 2-3 days. |
| Culture for Adult Eye Infections of Chlamydial Origin¹⁻³ | Scrapings of the conjunctiva. | Ocular trachoma is the leading cause of preventable blindness in underdeveloped countries. Primary infection usually occurs early in life. In endemic areas, trachoma is transmitted via hand to eye contact. In developed countries, infection usually presents in adulthood as adult inclusion conjunctivitis. Spread of the disease depends on transmission from genital tract to eye and likely results from autoinoculation in patients with concurrent genital tract disease. Spread between individuals from eye to eye may also occur in the absence of sexual contact. |

| TEST METHOD | SPECIMEN AND SPECIAL REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
|--|---|--|
| <i>Culture for Nongonococcal Urethritis (NGU) and Cervicitis</i> ¹⁻³ | Urethral scrapings collected on a swab inserted 2-4 cm into the urethra; endocervical scrapings collected from the transitional zone of the cervix; fluids/aspirates or tissue collected from the epididymis, endometrium, or fallopian tubes. Transport to laboratory immediately at 4° C in special transport medium such as 2SP or multipurpose transport medium specific for Chlamydia, virus and mycoplasma. Antibiotics should be included in transport medium to reduce bacterial contamination. | <p>A definitive diagnosis can only be made by isolation of the organism in tissue culture.</p> <p>In the U.S., trachoma was once a very serious problem, but today it is usually found only in certain groups, such as the American Indians and immigrants from Mexico and the Far East.</p> <p><i>C. trachomatis</i> is the most common cause of nongonococcal urethritis in men. In addition up to 30% of males with gonorrhea may also have chlamydial infection. Asymptomatic urethral infection is also common in young, sexually active males.</p> <p><i>C. trachomatis</i> causes >20% of the cases of mucopurulent cervicitis in females; asymptomatic cases occur more frequently than symptomatic ones. Approximately 50% of women with gonorrhea have a concomitant chlamydial infection.</p> <p>Culture for <i>C. trachomatis</i> routinely requires at least 2-3 days. Discharge (pus/mucus) and urine are inadequate specimens for culture. Specimens containing epithelial cells should be collected directly from the surface of the involved tissue.</p> |
| <i>Direct Fluorescent Antibody (DFA)</i> ¹⁻³ | Conjunctival scrapings, urethral scrapings, and endocervical scrapings. Transport to laboratory on special slides made available for the test. | |
| <i>Nucleic Acid Hybridization (PACE 2/PACE 2C, Gen-Probe, San Diego, CA; Hybrid Capture II, Digene, Gaithersburg, MD)</i> ^{1,4,5} | Conjunctival, urethral, and endocervical swabs collected using manufacturer-specific swab collection devices. | <p>The DFA test utilizes a <i>C. trachomatis</i>-specific monoclonal antibody to detect the organism directly in clinical specimens.</p> <p>Published studies have shown a sensitivity of 75-85% and a specificity of 98-99% compared with culture and a lower sensitivity compared with nucleic acid amplification tests.</p> <p>Specimen quality greatly affects test performance. It is extremely important that cellular material be obtained. If cellular material is insufficient, the specimen is unsatisfactory.</p> |
| <i>EIA</i> ^{1,6} | Conjunctival, urethral, and endocervical swabs collected using manufacturer-specific swab collection devices; urine. Males should not urinate for at least 1 hr before specimen collection. | <p>The GenProbe assay is a probe test that utilizes DNA-RNA hybridization for detection of <i>C. trachomatis</i> directly in specimens from the genital tract or eye. Its reported sensitivity ranges from 77-96% depending on prevalence of the disease in the population being tested. The Hybrid Capture II assay utilizes a signal amplification component to improve test sensitivity, which has been reported as >95%.</p> <p>Both assays have the ability to simultaneously test for the presence of <i>N. gonorrhoeae</i>. Collection of specimens using these transport devices renders them unacceptable for culture; therefore specimens for culture must be collected separately.</p> |

| SPECIMEN AND SPECIAL | | |
|----------------------|--------------|--|
| TEST METHOD | REQUIREMENTS | CLINICAL COMMENTS AND REMARKS |
| | | Recent recommendations indicate that confirmatory testing on positive Chlamydia tests should be performed when the patient is from a low incidence population or if there would be adverse consequences of reporting a false-positive result. |
| | | The sensitivity and specificity of these assays range from 40-80% and 98-100%, respectively. The predictive value will depend on the prevalence of the disease in the population being tested. EIA tests are significantly less sensitive than nucleic acid hybridization or nucleic acid amplification tests. |

TEST INDEX

Alternate test name index

3-Methoxy-4-hydroxyphenylacetic acid, 578

Acetylcholine acetylhydrolase, 38

Acid load test, 100

Acid maltase, 458

Aminobenzene, 118

Anti-Fya (Duffy), 88

Anti-K (Kell), 88

Anti-Kla (Kidd), 88

Apolipoprotein H, 494

Arylamine, 118

Ascorbic acid, 1130

Bentiromide test, 802

Bone gla protein, 790

Borax, 182

Breath test, 168

Calciferol, 1134, 1136

Carbon bisulfide, 216

Carbonate dehydratase, 218

Carbonate hydrolyase, 218

C-erbB-2, 548

Choline esterase I, 38

Choline esterase II, 250

Chorionic somatomammotropin, 858

Clot solubility test, 384

Cold-insoluble cell surface protein, 404

Compound B, 298

Compound S, 340

Corticotropin, 56

Cross labs, 284

Cyanoethylene, 44

Diastase, 100

Diphosphoglyceromutase, 178

Direct coombs test, 126

Erythrocyte cholinesterase, 38

Factor V leiden, 48

Fairley's pigment, 730

Fibrin split products, 402

Fibrin-stablizing factor, 384

Fitzgerald Factor, 570

Flaujeac Factor, 570

Fletcher Factor, 892

Follicle stimulating hormone, 412

Gamma transpeptidase, 470

Glucanohydrolase, 100

Guanase, 510

Hemoglobin A1c, 480

Hemoglobin binding protein, 512

Hexachlorodiphenylmethane, 550

Indirect antiglobulin test, 92

Indrect Coombs test, 122

Ketone body, 34, 36, 580

Levulose, 420

Luteinizing hormone-releasing hormone,
496, 694

Methylcyanide, 38

Muramidase, 700

Orosmucoid, 42

Parathyrin, 822

Phosphoric monoester phosphohydrolase, 912

Phylloquinone, 1142

Porphobilinogen synthase, 96

Prealbumin, 1070

Pseudocholinesterase, 250

Pyridoxal phosphate, 1120

Retinol, 1116

Schilling test, 1128

Siderophilin, 1062

Somatocrinin, 504

Somatomedin, 626

Somatropin, 502

T fraction, 1064

Thymotaxin, 742

Tissue polypeptide-specific antigen, 1060

Tocopherol, 1140

Topoisomerase 1, 136

Transcortin, 296

Triacylglycerol acyl-hydrolase, 676

Trypsin inhibitor, 138

Tumor associated glycoprotein 72, 208

Vasopressin, 124

Vinyl cyanide, 44

Vitamin B₁, 1022

Vitamin B₂, 960

Vitamin B₅, 808

Williams Factor, 570

 Osteoporosis, 83, 85, 113, 205, 595, 791, 1135, 1670
 Ovarian failure, 113
 Paget's disease, 79, 81, 83, 85, 203, 205, 283, 595, 791
 Pancreatitis, 65, 101, 107, 155, 199, 213, 223, 239, 263, 265, 445, 459, 605, 649, 677, 681, 705, 707, 731, 803, 807, 995, 1021, 1089, 1141, 1190, 1417
 Paraganglioma, 227, 725, 1111
 Parinaud's ocular syndrome, 1531
 Parkinson's disease, 227
 Paroxysmal cold hemoglobinuria, 127, 352, 523, 527, 533, 731
 Paroxysmal nocturnal hemoglobinuria, 37, 523, 527, 533, 639, 731, 765, 791, 1103, 1105, 1638, 1654
 Peliosis hepatitis, 1531
 Pellega, 293, 767, 1091
 Peptic ulcer disease, 385, 783
 Phenylketonuria, 345, 585, 711, 841, 1095, 1164, 1232
 Pheochromocytoma, 203, 227, 229, 263, 279, 365, 389, 423, 445, 579, 725, 729, 1111, 1229
 Pickwickian syndrome, 797
 Pneumonia, 125, 127, 215, 273, 797, 837, 977, 987
 Polycystic nephritis, 69, 275, 365, 993, 1095, 1099
 Polycystic ovary disease, 113, 335, 337, 411, 695, 891, 983, 1011
 Polycythemia vera, 179, 183, 353, 361, 363, 365, 515, 525, 667, 701, 765, 861, 865, 1023, 1067, 1099, 1117, 1125, 1127, 1183, 1193, 1683
 Polyendocrine syndrome I or II, 587, 619
 Polymyositis, 73, 307, 313, 315
 Pompe's disease, 459, 461, 835
 Porphyrias, 97
 acute intermittent porphyria, 97, 235, 873, 875, 877, 993, 1051, 1055, 1178
 congenital erythropoietic porphyria, 1107, 1178
 erythropoietic protoporphyria, 223
 hepatoerythropoietic porphyria, 1105, 1178
 hereditary coproporphyria, 873, 875, 1178
 porphyria cutanea tarda, 873, 1105, 1178
 variegate porphyria, 97, 873, 875, 1178
 Portal hypertension, 605
 Post-transfusion purpura, 1669
 Prader-Willi syndrome, 1233
 Preeclampsia, 49, 51, 67, 319, 341, 441, 705, 797, 1021, 1029, 1121, 1190
 Prerenal azotemia, 995
 Primary biliary cirrhosis, 245, 293, 295, 747, 781, 991, 1051, 1075, 1137, 1143
 Primary hyperoxaluria, Type II, 487, 489
 Prolactinoma, 901, 903
 Prolymphocytic leukemia, 1187, 1188
 Propionic acidemia, 487
 Pseudohypoparathyroidism, 195, 199, 203, 325, 823, 845, 855, 1093, 1135
 Pseudomembranous colitis, 1547
 Psoriasis, 337, 1029, 1039, 1067, 1071, 1087, 1103, 1131
 Psychogenic polydipsia, 125, 789, 993, 1103, 1147
 Pulmonary embolism, 333, 403, 655, 853
 Pulmonary fibrosis/infarction, 117, 129, 137, 797
 Pyelonephritis, 371, 441, 563, 651, 833, 969, 971, 1103, 1105
 Q fever, 1594, 1595
 Rabies, 1595, 1632
 Raynaud's phenomenon, 125
 Refsum's disease, 857, 1473, 1508, 1769, 1779
 Reifenstein's syndrome, 413
 Renal failure, 93, 101, 143, 171, 195, 245, 263, 433, 441, 445, 447, 485, 487, 503, 565, 679, 681, 685, 737, 739, 755, 785, 795, 837, 845, 881, 901, 955, 967, 987, 1025
 Renal tubular acidosis, disease, 101, 215, 219, 235, 329, 441, 495, 881, 993, 1691
 Respiratory acidosis, 165, 167, 215, 217, 235, 837, 853
 Respiratory alkalosis, 165, 167, 217, 837, 853
 Respiratory distress syndrome, 141, 353, 399, 691, 845
 Retinoblastoma, 1218

- Reye's syndrome, 99, 307, 465, 469, 651, 937, 1765, 1777
 Rhabdomyolysis, 119, 307, 1251
 Rheumatic fever, 51
 Rheumatoid arthritis, 111, 117, 137, 139, 191, 275, 327, 329, 393, 469, 487, 497 563, 567, 601, 605, 705, 711, 713, 761, 1027, 1095, 1131, 1183, 1190, 1192, 1193, 1195, 1401, 1613, 1679, 1763, 1768
 Rickets, 79, 85, 205, 441, 487, 595, 853, 855, 1135, 1137, 1139
 Rocky Mountain spotted fever, 1105
 Rotavirus, 1601, 1602
 Rotor's syndrome, 175, 297
 Rubella virus/measles, 1603, 1604, 1667
 Salla's disease, 987
 Salt-losing nephritis, 235
 Sandhoff disease, 557, 561, 1177
 Sarcoidosis, 117, 205, 295, 595, 605, 701, 765, 795, 797, 823, 891, 959, 1099, 1103, 1105, 1192, 1194, 1195
 Sarcomas, 1235
 desmoplastic small round cell sarcoma, 1690
 Ewing's sarcoma, 1667
 Kaposi's sarcoma, 783, 1223
 lymphosarcoma, 649
 osteosarcoma, 1401
 rhabdosarcoma, 281
 Schinder disease, 1177
 Schizophrenia, 1073
 Schwachman's syndrome, 265
 Scleroderma, 959
 Scurvy, 783, 1131, 1133
 Septic thrombophlebitis, 1526
 Severe acute respiratory syndrome, 1215, 1605
 Severe combined immunodeficiency disease, 53
 Severe congenital neutropenia, 1670
 Severe exfoliative dermatitis, 411
 Sézary syndrome, 835
 Sheehan's syndrome, 901
 Sick euthyroid syndrome, 1041
 Sjögren syndrome, 137, 139, 601, 605, 701, 827, 959, 1103, 1117, 1133
 Spina bifida, 401
 Spotted fever group
 African tick bite fever, 1606
 boutonneuse fever, 1606
 Flinders Island spotted fever, 1606
 Japanese spotted fever, 1606
 North Asian tick typhus, 1606
 Queensland tick typhus, 1606
 rickettsialpox, 1606
 Rocky Mountain spotted fever, 1606
 Steatorrhea, 795, 803, 853, 1089, 1141
 Stein-Leventhal syndrome, 891
 Streptococcus, 1186, 1220, 1221, 1527, 1528
 Stress, 35
 Stroke, cerebrovascular accident, 447, 563, 649, 709, 715, 965, 1676
 Subacute sclerosing panencephalitis, 607, 751, 927, 1603
 Subarachnoid, cerebral hemorrhage, 451, 469, 649
 Sydenham's chorea, 1527
 Syndrome of inappropriate antidiuretic hormone, 119, 125, 235, 707, 789, 993, 995, 1001, 1099, 1147
 Syphilis, 127, 451, 1195, 1612-1614
 Takahara's disease, 225
 Tangiers disease, 143, 223, 245, 565, 923
 TAR syndrome, 865
 Tay Sachs disease, 553, 557, 561, 1177, 1236
 Thalassemia, 51, 155, 293, 361, 393, 475, 513, 515, 519, 523, 533, 635, 637, 639, 643, 717, 757, 789, 791, 835, 935, 939, 1067, 1089, 1153, 1155, 1183
 Thrombophilia, 49
 Thrush, 1616
 Thymoma, 759, 761, 763, 811, 817, 819, 1194
 Thyrotoxicosis, 35, 183, 861
 Transfusion related acute lung injury, 499, 501
 Tuberculosis, 51, 125, 293, 327, 667, 1117, 1153, 1192, 1194, 1229, 1477
 Turner's syndrome, 75, 783
 Typhoid fever, 155, 293, 667, 783, 1194, 1625
 Typhus, 1105
 Ulcerative colitis, 221, 411, 967, 997, 1193, 1195
 Ulcerative neutrophilic cutaneous panniculitis, 141
 Uremia, 353, 591, 1121
 Verner-Morrison syndrome, 263, 1115
 Von Gierke's disease, 155, 389, 447, 937
 Von Recklinghausen's disease, 1231
 Von Willebrand's disease, 181, 281, 865, 867, 937, 1143, 1145
 Waldenstrom's macroglobulinemia, 609, 675, 925, 951, 959, 1704
 Wegener's granulomatosis, 765, 929, 1103, 1194
 Werner syndrome, 433

Wernicke-Korsakoff syndrome, 1023
Whipple's disease, 223, 385, 411, 585, 1149,
1151
Whooping cough, 1212
Wilm's tumor, 629, 1218
Wilson's disease, 231, 233, 293, 1099, 1169
Wiskott-Aldrich syndrome, 599, 865, 1194
X-linked hyper-IgM syndrome, 1678

X-linked lymphoproliferative disease, 1689
X-linked SCID, 1674
Yaw, 1543
Yellow fever, 971, 1626
Zetterstrom's syndrome, 447
Zollinger-Ellison syndrome, 195, 223, 253, 429,
431, 433, 435, 807, 823, 831, 833, 967
