SAP Adaptive Server Enterprise 16.0 SP04 Document Version: 1.0 – 2021-08-12

Security Administration Guide

Content

1 Introduction to Security				
1.1	What is "Information Security?"	10		
1.2	Common Criteria Configuration Evaluation			
1.3	FIPS 140-2 Validated Cryptographic Module	. 12		
2	Security Administration in SAP ASE	13		
2.1	Recommendations for Setting up Security	14		
	Example of Setting up Security	14		
2.2	Security Features in SAP ASE	15		
	Identification and Authentication	16		
	Discretionary Access Control	17		
	Division of Roles	18		
	Auditing for Accountability	18		
	Confidentiality of Data	. 19		
2.3	Manage Deployed Source in Source Code Control Systems	19		
3	Data Protection in SAP ASE	. 20		
3.1	Deletion of Personal Data	. 24		
4	Manage SAP ASE Logins and Database Users	25		
4.1	Introduction to Logins	. 26		
	Create Login Accounts	. 26		
	Last Login and Managing Inactive Accounts	27		
	Authentication Mechanisms for Login	. 28		
	Change Login Accounts	. 28		
	Drop Login Accounts	. 29		
4.2	Choose and Create a Password	. 29		
	Maximum Login Attempts	. 30		
	Logging in After Losing a Password	31		
	Displaying Password Information for Logins	32		
	Displaying Password Information for Roles	33		
	Checking Passwords for at Least One Digit	34		
	Set or Change the Minimum Password Length	. 34		
	Password Complexity Checks	36		
	Enable Custom Password Checks	41		
	Set the Login and Role Expiration Interval for a Password	43		
	Secure Login Passwords Stored on Disk and in Memory	. 48		
	Character Set Considerations for Passwords	. 49		

	Upgrade Behavior
	Login Password Downgrade
	Retain Password Encryption After Upgrade then Downgrade
	Expire Passwords When allow password downgrade is Set to 0
4.3	Establish a Password and Login Policy
4.4	Login Failure
4.5	Lock Login Accounts and Roles
	Lock and Unlock Logins and Accounts
	Use syslogins to Track if an Account is Locked
	Track Locked Roles
	Locking and Unlocking Roles
	Lock Logins that Own Thresholds
4.6	Manage Login Profiles
	Login Profile Attributes
	Login Profile Attribute Precedence
	Create Login Profiles
	Create Default Login Profiles
	Associate Login Profiles with a Login Account
	Ignore Login Profiles
	Transfer Existing Login Account Values to a New Login Profile
	Manual Replication of Login Profiles
	Grant Roles to Login Profiles
	Invoke a Login Script
	Display Login Profile Information
	Modify Login Profiles
	Drop Login Profiles
4.7	Securely Automate Database Administration Tasks Using Secure User Store
	How Does the aseuserstore Utility Work?70
	Using the aseuserstore Utility With Other SAP ASE Utilities
	Using the aseuserstore Utility With the Client Applications
	Operating System Support
4.8	Add Users to Databases
	Add a "guest" User to a Database
	Add Guest Users to the Server
	Add Remote Users
4.9	Create Groups
	Change Group Membership
	Create Groups and Add Users
4.10	Aliases in Databases
	Add Aliases
	Drop Aliases

	Information About Aliases
4.11	Obtain Information About Users
	Report on Users and Processes
	Obtain Information about Login Accounts
	Obtain Information About Database Users
	Find User Names and IDs
4.12	Change User Information
	Change Passwords
	Change User Session Information
4.13	Drop Users and Groups
4.14	Monitor License Use
	How Licenses are Counted
	Configure the License Use Monitor
	Monitor License Use with the Housekeeper Task
	Log the Number of User Licenses
4.15	Number of User and Login IDs
4.16	Login Connection Limitations
4.17	Obtain Information About Usage: Chargeback Accounting
	Specify the Interval for Adding Accounting Statistics
5	Manage Roles
5.1	System-Defined Roles Overview
5.2	System Roles
5.3	Plan User-Defined Roles
5.4	Create a User-Defined Role
5.5	Add or Remove Passwords from a Role
5.6	Role Hierarchies and Mutual Exclusivity
	Define and Change Mutual Exclusivity of Roles
	Define and Change a Role Hierarchy
5.7	Default Activation at Login
5.8	Conditions for Role Activation
5.9	Drop User-Defined Roles
5.10	Activate or Deactivate Roles
5.11	Display Information About Roles
	Find Role IDs and Names
	View Active System Roles
	Display Role Hierarchy
	View User Roles in a Hierarchy
	Determine Mutual Exclusivity
	Determine Role Activation
	Check for Roles in Stored Procedures
5.12	Grant or Revoke Roles

	Grant Roles	. 107
	Understanding the grant Command and Roles	. 108
	Revoke Roles	. 109
5.13	Secure Role Passwords	. 109
	Character Set Considerations	. 109
	Locked Roles and syssrvroles	. 109
	Login Password Policy Checks Applied to Role Passwords	110
	Configure SAP ASE for Roles	
6	External Authentication	115
6.1	Configure SAP ASE for Network-Based Security	
0.1	SAP ASE Security Services	
	Administering Network-Based Security	
	Configuration Files for Security.	
	Identify Users and Servers to the Security Mechanism.	
	Configure SAP ASE for Security.	
	Add Logins to Support Unified Login.	
	Connect to a Server Using Security Services	
	Obtain Information About Available Security Services	
	Kerberos	
	Principal Names	
6.2	Configure SAP ASE for LDAP User Authentication	
	Composed DN Algorithm	
	Searched DN Algorithm	
	Configuring LDAP in New SAP ASE Installations	
	Migrating existing SAP ASE Servers to LDAP	.146
	LDAP User Authentication Administration	146
	Logins and LDAP User Accounts	. 149
	Secondary Lookup Server Support	149
	LDAP Server State Transitions	. 151
	LDAP User Authentication Tuning	. 153
	Add Tighter Controls on Login Mapping	. 153
	Troubleshoot LDAP User Authentication Errors	. 156
	Configuring an LDAP Server	. 157
6.3	LDAPS User Authentication	. 158
6.4	Automatic LDAP User Authentication and Failback	. 158
	LDAP Failback Time Interval	. 158
6.5	Configure SAP ASE for Authentication Using PAM	. 160
	Enable PAM in SAP ASE	. 160
6.6	Enhanced Login Controls	. 163
	Forced Authentication	163
	Map Logins Using sp_maplogin	. 164

7	Manage User Permissions
7.1	Granting Permissions for Creating Databases
	Change Database Ownership
7.2	Database Owner Privileges
7.3	Database Object Owner Privileges
7.4	Permissions on System Procedures
7.5	Grant or Revoke Permissions
	Object Access Permissions
	Grant Permissions on dbcc Commands
	Permissions on System Tables
	Combine grant and revoke Statements
	Permission Order and Hierarchy
7.6	Acquire the Permissions of Another User
	setuser Command
	Proxy Authorization
	Resolving Qualified Object Names on Behalf of Another User
7.7	Changing Database Object Ownership
	Supported Object Types
	Authorization to Transfer Ownership
	Transfer Ownership
7.8	Report on Permissions
	Query the sysprotects Table for Proxy Authorization
	Display Information About Users and Processes
	Report Permissions on Database Objects or Users
	Report Permissions on Specific Tables
7.9	Views and Stored Procedures as Security Mechanisms
	Using Views as Security Mechanisms
	Using Stored Procedures as Security Mechanisms
	Understanding Ownership Chains
	Permissions on Triggers
7.10	Execute a Procedure With execute as owner or execute as caller
	Creating a Procedure with References to an Object with an Unqualified Name
	Procedures that Invoke a Nested Procedure in Another Database with a Fully Qualified Name
	200
7.11	Row-Level Access Control
	Access Rules
	Using the Application Context Facility
	SYS_SESSION System Application Context
	Session Management for SAP HANA Syntax
	Using Login Triggers
	Export set Options from a Login Trigger

	Set Global Login Triggers	224		
8	Predicated Privileges	225		
8.1	Differences Between Access Rules and Predicated Privileges	225		
8.2	Commands Used for Predicated Privileges	226		
8.3	Configure SAP ASE to Use Predicated Privileges			
8.4	Grant Predicated Privileges	. 227		
	Grant Access to select Data	227		
	Grant Access to update Data	.228		
	Grant Access to delete Data	. 228		
	Use Predicated Privileges to Enforce a Data Privacy Policy	. 229		
8.5	Revoke Predicated Privileges	. 229		
8.6	How SAP ASE Saves Predicated Privileges in sysprotects	.230		
8.7	Predicated Role Activation	. 231		
8.8	Combine Predicates to Enforce Row-Level Privileges	232		
	Example 1: Combining Predicates From Multiple Grants for the Same Table Access	233		
	Example 2: Combining Predicates From Multiple Grants Applying to Different Sets of Columns			
		234		
	Example 3: Combining Predicates From Multiple Grants for Different Access	234		
8.9	SQL Behavior with Predicated Privileges	. 235		
8.10	Chain-of-Ownership Effect on Predicated Privileges	. 236		
8.11	ansi_permissions and Predicated Privileges	.237		
8.12	Permissions on Accesses Made by Predicates	. 238		
8.13	Predicated Privileges and Triggers.	239		
8.14	Recompile Predicated Privileges	.239		
8.15	Disallow Recursive Predicate Processing	.240		
8.16	Information Leakage Through Predicates	240		
9	Granular Permissions	. 242		
9.1	Configuring SAP ASE to Use Granular Permissions	.242		
9.2	System Privileges	. 242		
9.3	Effect of Privileges as Part of System-Defined Roles	. 243		
9.4	Permission Management	. 244		
	manage security permissions Privilege	244		
	manage server permissions Privilege	. 245		
	manage database permissions Privilege	. 247		
	manage any object permission Privileges	. 250		
9.5	Privileges Granted to System-Defined Roles	.251		
9.6	Privileges Assigned to the Database Owner	. 254		
9.7	Granular Permissions Adds the sa_serverprivs_role	. 256		
9.8	Default Roles Granted to the System Administrator	. 258		
9.9	Limiting the Power of the System Administrator and Database Owner	259		

9.10	Enable granular permissions and sybsecurity	260	
9.11	Logging in to a Locked-Out Server	260	
9.12	General Use Scenarios	261	
9.13	System Table master.dbo.sysprotects	263	
9.14	Database User usedb_user Account	264	
9.15	Grantable System Privileges		
10	Confidentiality of Data	292	
10.1	Public-Key Cryptography	292	
10.2	SAP Common Crypto Library	294	
10.3	SSL Overview	294	
	SSL in SAP ASE	295	
	Enabling SSL	298	
	Enabling SSL in the Backup Server	299

10.5	Kerberos Confidentiality	326	
10.6	Dump and Load Databases with Password Protection	326	
	Passwords and Character Sets	327	
10.7	Residual Data Removal	327	
	Operations That Can Result in Residual Data	328	
	Enabling the Removal of Residual Data	330	
	Examples of Residual Data Removal	331	
	Combinations of Settings for Removing Residual Data	334	
	Check Whether Residual Data Removal Is Enabled	335	
	Limitations	336	
11	Auditing	337	
11.1	The Audit System	337	
	The sybsecurity Database	338	
	The Audit Oueue	339	

11.2	Manage the Audit System
	Preinstallation Recommendations for Auditing Devices
	Install the Audit System
	Enable or Disable Auditing
	Restart Auditing
	Configure the Audit System
	Modifying the Audit System
	Audit Trail Management
	Truncate the Transaction Log
	Single-Table Auditing
11.3	Audit Tables
	Reading the extrainfo Column
	Values in event and extrainfo Columns
	Audit Event Values
	Monitoring Failed Login Attempts
	Auditing Login Failures

1 Introduction to Security

Information is possibly your company's greatest asset. Information needs protection just like any other asset. As a system administrator, determine how best to protect the information contained in company databases, and who may access the information. Individual database servers need strong, yet flexible, security support.

1.1 What is "Information Security?"

Users and the data they access may be located anywhere in the world, connected by untrusted networks. Ensuring the confidentiality and integrity of sensitive data and transactions in this environment is critical.

Information is useful only if it gets to the people who need it, when they need it. With complex and dynamically changing business relationships, it is critical that information gets only to authorized users.

These are some general guidelines when considering security for your enterprise:

- Sensitive information should be kept confidential determine which users should have access to what information.
- The system should enforce integrity the server should enforce rules and constraints to ensure that information remains accurate and complete.
- The information should be available even with all the safeguards in place, anybody who needs access to the information should have it available when the information is needed.

Identify what is it that your organization wants to protect, and what the outside world requires from your organization:

- Identify the information assets and the security risks associated with them if they become vulnerable or compromised.
- Identify and understand any laws, statutes, regulations, and contractual agreements that apply to your organization and the information assets.
- Identify your organization's business processes and the requirements they impose on information assets, to balance practical considerations with the security risks.

Security requirements change over time. Periodically reassess security requirements to make sure they still reflect your organization's needs.

Set up a series of controls and policies that meet the company's security objectives, the result of which is an information security policy document that clarifies decisions made for information security.

1.2 Common Criteria Configuration Evaluation

SAP Adaptive Server Enterprise (SAP ASE) has been evaluated and validated in accordance with the provisions of the Common Criteria Evaluation and Validation Scheme. SAP ASE also uses FIPS 140-2 certified modules for implementing encryption functionality.

Common Criteria for Information Technology Security Evaluation is an international standard (ISO/IEC 15408) for computer security certification. Common Criteria is developed by the governments of Canada, France, Germany, Netherlands, UK and the United States.

SAP ASE version 15.0.1 completed Common Criteria validation in September, 2007. The Evaluated configuration consists of version 15.0.1 with the security and directory services option. The evaluation for security was carried out in accordance with the Common Criteria Evaluation and Validation Scheme (CCEVS) process and scheme. The criteria against which SAP ASE was judged are described in the Common Criteria for Information Technology Security Evaluation, Version 2.3 and International Interpretations effective on August, 2005. If you configure SAP ASE as specified in the *Supplement for Installing Adaptive Server for Common Criteria Configuration*, SAP ASE satisfies all of the security functional requirements stated in the Adaptive Server Enterprise Security Target (Version 1.5).

SAP ASE supports eight security functions:

- Cryptographic support transparent encryption of data is supported at the column level. SQL statements and extensions provide secure key management.
- Security audit an audit mechanism that checks access, authentication attempts, and administrator functions. The security audit records the date, time, responsible individual, and other details describing the event in the audit trail.
- User data protection discretionary access control policy over applicable database objects is provided for these objects: databases, tables, views, stored procedures, and encryption keys.
- Identification and authentication an identification and authentication mechanism is provided in addition to the underlying operating system mechanism.
- Security management functions that allow you to manage users and associated privileges, access
 permissions, and other security functions such as the audit trail are provided. These functions are
 restricted based on discretionary access control policy rules, including role restrictions.
- Protection of the TOE Security Function (TSF) SAP ASE keeps its context separate from that of its users, and uses operating system mechanisms to ensure that memory and files used by SAP ASE have the appropriate access settings. SAP ASE interacts with users through well-defined interfaces designed to ensure that its security policies are enforced.
- Resource utilization resource limits are provided to prevent queries and transactions from monopolizing server resources.
- Target of Evaluation (TOE) access authorized administrators are allowed to construct login triggers that
 restrict logins to a specific number of sessions and restrict access based on time. Authorized
 administrators can also restrict access based on user identities.

1.3 FIPS 140-2 Validated Cryptographic Module

SSL is the standard for securing the transmission of sensitive information, such as credit card numbers, stock trades, and banking transactions over the Internet.

SAP ASE uses the proprietary SAP Common Crypto Library, as the SSL provider and cryptography library. Beginning with SAP ASE version 16.0 SP03, OpenSSL is not supported for encryption and decryption.

SAP Common Crypto Library is FIPS 140-2 compliant. For information about FIPS certification, see the *Computer Security Resource Center* at https://csrc.nist.gov.

The encrypted columns feature relies on symmetric-key cryptography, and uses the same FIPS 140-2 validated cryptographic modules as SSL. See *Database Encryption*.

A Security and Directory Services license is required to use SSL and to enable the FIPS login password encryption parameter. You must have an encrypted columns license to use the encrypted columns feature.

2 Security Administration in SAP ASE

Perform major tasks to securely administer SAP ASE.

- 1. Install SAP ASE, including auditing includes preparing for installation, loading files from your distribution medium, performing the actual installation, and administering required physical resources. See the installation documentation for your platform and *Auditing*.
- 2. Set up a secure administrative environment Set up system administrators and system security officers, create login profiles and establish password and login policies. See *Managing Logins and Database Users*.
- 3. Set up logins, database users and roles Add user logins to the server and assign login profiles to them. Create user defined roles, define role hierarchies and mutual exclusivity of roles, and assign roles to logins. Add users to databases. See *Managing Logins and Database Users* and *Create a User-Defined Role*.
- 4. Administer permissions for users, groups, and roles Grant and revoke permissions for certain SQL commands, executing certain system procedures, and accessing databases, tables, particular table columns, and views. Create access rules to enforce fine-grained access control. See *Managing User Permissions*.
- 5. Configure encryption in your database to encrypt sensitive data in tables. Encrypt sensitive data Configure SAP ASE to use column-level encryption, decide which columnar data to encrypt, perform a one-time key creation operation, and use alter table to perform initial data encryption. See *Database Encryption*.
- 6. Establish integrity controls over data Add check constraints, domain roles, and referential constraints to validate incoming data. See *Transact-SQL Users Guide* and *Reference Manual: Commands*
- 7. Set up and maintain auditing Determine what is to be audited, audit the use of SAP ASE, and use the audit trail to detect penetration of the system and misuse of resources. See *Auditing*.
- 8. Set up your installation for advanced authentication mechanisms and network security Configure the server to use services, such as LDAP, PAM, or Kerberos- based user authentication, data confidentiality with encryption, data integrity. See External Authentication and Confidentiality of Data.

2.1 Recommendations for Setting up Security

Security recommendations for setting up logins and auditing.

- Using the sa login when you install SAP ASE, a single login called "sa" is configured with the system administrator and system security officer roles, which means that the sa login has unlimited control over what occurs in the database.
 - Use the sa login only during initial setup. Instead of allowing several users to use the sa account, establish individual accountability by assigning specific roles to individual administrators.
- Changing the sa login password the sa login is configured initially with a NULL password. Use alter login to change the password immediately after installation.

When logging in to SAP ASE, do not use the -P option of isql to specify your password because another user may have an opportunity to see it.

- Enabling auditing enable auditing early in the administration process so that you have a record of privileged commands that are executed by system security officers and system administrators. You might also want to audit commands that are executed by those with other special roles, such as operators when they dump and load databases
- Assigning login names assign login names that are the same as their respective operating system login names. This makes logging in easier, simplifies management of server and operating system login accounts, and makes it easier to correlate the audit data generated with that of the operating system.

2.1.1 Example of Setting up Security

Security roles and specific commands are used to set up a secure operating environment.

This table shows special roles assigned to users.

Table 1: Users to whom you assign roles

Name	Privilege	Operating system login name
Rajnish Smith	sso_role	rsmith
Catherine Macar-Swan	sa_role	cmacar
Soshi Ikedo	sa_role	sikedo
Julio Rozanski	oper_role	jrozan
Alan Johnson	dbo	ajohnson

This table shows the sequence of commands you might use to set up a secure operating environment for SAP ASE, based on the role assignments listed above. After logging in to the operating system, issue these commands using the initial sa account. .

Table 2: Examples of commands used to set up security

Commands	Result
isql -Usa	Logs in to SAP ASE as "sa." Both sa_role and sso_role are active.
<pre>sp_audit "security", "all", "all", "on"</pre>	Sets auditing options for server-wide, security-relevant events, and the auditing of all actions that have sa_role or sso_role active.
<pre>sp_audit "all", "sa_role", "all", "on"</pre>	
<pre>sp_audit "all", "sso_role", "all", "on"</pre>	
sp_configure "auditing", 1	Enables auditing.

i Note

Before you enable auditing, set up a threshold procedure for the audit trail and determine how to handle the transaction log in sybsecurity.

create login	Adds logins and passwords.
grant role	Grant roles.
use sybsecurity sp_changedbowner rsmith	Grants access to the auditing database, sybsecurity, by making Rajnish, who is the system security officer, the database owner. Alan is not granted any system-defined roles.
sp_locklogin sa, "lock"	Locks the "sa" login so that no one can log in as "sa." Individuals can assume only the roles that are configured for them.

i Note

Do not lock the "sa" login until you have granted individual users the sa_role and sso_role roles and have verified that the roles operate successfully.

2.2 Security Features in SAP ASE

 $\ensuremath{\mathsf{SAP}}$ ASE provides security features that aid in protecting sensitive data.

- *Identification and Authentication* ensures that only authorized users can log in to the system. In addition to password-based login authentication, SAP ASE supports external authentication using Kerberos, LDAP, or PAM.
- Discretionary Access Control provides access controls that give object owners the ability to restrict access to objects, usually with the grant and revoke commands. This type of control is dependent on an object owner's discretion.

- Division of Roles allows an administrator to grant privileged roles to specified users so only designated users can perform certain tasks. SAP ASE has predefined roles, called "system roles," such as system administrator and system security officer. In addition, system security officers are allowed to define additional roles, called "user-defined roles."
- Auditing for Accountability provides the ability to audit events such as logins, logouts, server start
 operations, remote procedure calls, accesses to database objects, and all actions performed by a specific
 user or with a particular role active. SAP ASE also provides a single option to audit a set of server-wide
 security-relevant events.
- Confidentiality of Data maintains confidentiality of data using encryption for client/server communication, available with Kerberos or SSL. Column-level encryption preserves confidentiality of data stored in the database. Inactive data is kept confidential with a password-protected database backup.

2.2.1 Identification and Authentication

Both internal and external mechanisms can be used for authentication.

SAP ASE uses the server user identity (SUID) to uniquely identify a user with a login account name. This identity is linked to a particular user identity (UID) in each database. Access controls use the server user identity when determining whether to allow access for the user with this SUID to an object. Authentication verifies that a user is actually the person he or she claims to be.

External Authentication

Security is often enhanced in large, heterogeneous applications by authenticating logins with a central repository. SAP ASE supports a variety of external authentication methods:

- Kerberos provides a centralized and secure authentication mechanism in enterprise environments that includes the Kerberos infrastructure. Authentication occurs with a trusted, third-party server called a key distribution center to verify both the client and the server.
- LDAP user authentication Lightweight Directory Access Protocol (LDAP) provides a centralized authentication mechanism based on the user login name and password.
- PAM user authentication Pluggable Authentication Module (PAM) provides a centralized authentication mechanism that uses operating system interfaces for both administration and runtime application operations.

Managing Remote Servers

Internal mechanisms for administering logins and users between servers are described in *Managing Remote Servers* in the *System Administration Guide, Volume I*

2.2.2 Discretionary Access Control

With discretionary access control, you can give various permissions to users, groups, and roles.

Object owners can grant access to the objects they own to other users. Object owners can also grant other users the ability to pass the access permission to other users. Use the grant command to give permissions to users, groups, and roles. Use the revoke command to rescind these permissions. The grant and revoke commands give users permission to execute specified commands, and to access specified tables, procedures, views, encryption keys, and columns.

Some commands can be used at any time by any user, with no permission required. Others can be used only by users of a certain status, such as a system administrator, and are not transferable.

The ability to assign permissions for the commands that can be granted and revoked is determined by each user's status (as system administrator, system security officer, database owner, or database object owner), and whether a particular user is granted a permission with the option to grant that permission to other users.

Row-level Access Control

Administrators define access rules that are based on the value of individual data elements, and the server transparently enforces these rules. Once an administrator defines an access rule, it is automatically invoked whenever the affected data is queried through applications, ad hoc queries, stored procedures, views, and so on.

Using a rule-based access control simplifies both the security administration of an installation and the application development process because the server, rather than the application, enforces security. These features allow you to implement row-level access control:

- Access rules
- · Application context facility
- Login triggers
- Domain integrity rules

Predicated Privileges

With predicated privileges, the table owner provides row-level access to users, groups or roles by specifying a SQL where on the grant statement. You use the full power of SQL, including access to other tables, to implement a comprehensive row-level security policy.

2.2.3 Division of Roles

The roles supported by SAP ASE enable you to enforce and maintain individual accountability. SAP ASE provides system roles, such as system administrator and system security officer, and user-defined roles, which are created by a system security officer.

Roles are collections of privileges that allow the role assignee to do their job. Roles provide individual accountability for users performing operational and administrative tasks, and allow you to audit and attribute actions to these users.

Role Hierarchy

A system security officer can define role hierarchies such that if a user has one role, the user automatically has roles lower in the hierarchy. For example, the "chief_financial_officer" role might contain both the "financial_analyst" and the "salary_administrator" roles. The chief financial officer can perform all tasks and see all data that can be viewed by salary administrators and financial analysts.

Restrictions on Role Activation

The Security Administrator restricts the conditions under which a role may be activated by specifying a where clause on the grant role statement. SAP ASE evaluates the condition expressed by the where clause when the role is activated, either automatically during login, or when processing the set role statement.

Mutual Exclusivity

You can define roles to be mutually exclusive either at the membership level, or at the activation level. For example:

- You may not want to grant both the "payment_requestor" and "payment_approver" roles to the same user.
- A user might be granted both the "senior_auditor" and the "equipment_buyer" roles, but you may not want to permit the user to have both roles enabled at the same time.

You can define system roles, as well as user-defined roles, to be in a role hierarchy or to be mutually exclusive. For example, you might want a "super_user" role to contain the system administrator, operator, and technical support roles. Additionally, you may want to define the system administrator and system security officer roles to be mutually exclusive for membership; that is, a single user cannot be granted both roles.

2.2.4 Auditing for Accountability

SAP ASE includes a comprehensive auditing system.

The auditing system consists of:

- The sybsecurity database
- Configuration parameters for managing auditing
- sp audit to set all auditing options
- sp addauditrecord to add user-defined records to the audit trail

When you install auditing, you can specify the number of audit tables that SAP ASE uses for the audit trail. If you use two or more tables to store the audit trail, you can set up a smoothly running audit system with no manual intervention and no loss of records.

A system security officer manages the audit system and is the only user who can start and stop auditing, set up auditing options, and process the audit data. As a system security officer, you can establish auditing for events such as:

- Server-wide, security-relevant events
- Creating, dropping, and modifying database objects
- All actions by a particular user or all actions by users with a particular role active
- · Granting or revoking database access
- Importing or exporting data
- · Logins and logouts
- All actions related to encryption keys

2.2.5 Confidentiality of Data

You can maintain the confidentiality of data by encrypting client-server communications by using the Secure Sockets Layer (SSL) standard or Kerberos.

You can protect the confidentiality of data by using column-level encryption in the database and encrypting backups for offline data. The dump and load database commands include a password> parameter that allows you to password-protect your database dumps. For more information see Database Encryption, Backing Up and Restoring User Databases, in System Administration Guide: Volume 2.

2.3 Manage Deployed Source in Source Code Control Systems

SAP recommends that all user created source files associated with SAP ASE deployment be managed with a third party source control system (SCCS, RCS, Clearcase, Perforce, and so on).

It is further recommended that deployment of these files be done in an automated way such as use of a bill of materials and scripts to install the files in a reliable and repeatable way. The script source itself is recommended to be maintained within the source control system.

3 Data Protection in SAP ASE

SAP ASE provides the technical enablement and infrastructure to allow you run applications on SAP ASE to conform to the legal requirements of data protection in the different scenarios in which SAP ASE is used.

Introduction to Data Protection

Data protection is associated with numerous legal requirements and privacy concerns. In addition to compliance with general data privacy acts, it is necessary to consider compliance with industry-specific legislation in different countries. This section describes the specific features and functions that SAP ASE provides to support compliance with the relevant legal requirements and data privacy.

This section and any other sections in this guide do not give any advice on whether these features and functions are the best method to support company, industry, regional or country-specific requirements. Furthermore, this guide does not give any advice or recommendations with regard to additional features that would be required in a particular environment; decisions related to data protection must be made on a case-by-case basis and under consideration of the given system landscape and the applicable legal requirements.

i Note

In the majority of cases, compliance with data privacy laws is not a product feature. SAP software supports data privacy by providing security features and specific functions relevant to data protection, such as functions for the simplified blocking and deletion of personal data. SAP does not provide legal advice in any form. The definitions and other terms used in this guide are not taken from any given legal source.

Table 3: Glossary

Term	Definition
Blocking	A method of restricting access to data for which the primary business purpose has ended.
Business Purpose	A legal, contractual, or in other form justified reason for the processing of personal data . The assumption is that any purpose has an end that is usually already defined when the purpose starts.
Consent	The action of the data subject confirming that the usage of his or her personal data shall be allowed for a given purpose. A consent functionality allows the storage of a consent record in relation to a specific purpose and shows if a data subject has granted, withdrawn, or denied consent.
Deletion	Deletion of personal data so that the data is no longer available.

Term	Definition	
End of business	Date where the business with a data subject ends, for example the order is completed, the subscription is canceled, or the last bill is settled.	
End of purpose (EoP)	End of purpose and start of blocking period. The point in time, when the primary processing purpose ends (e.g. contract is fulfilled).	
End of purpose (EoP) check	A method of identifying the point in time for a data set when the processing of personal data is no longer required for the primary business purpose . After the EoP has been reached, the data is blocked and can only be accessed by users with special authorization (for example, tax auditors).	
Personal data	Any information relating to an identified or identifiable natural person ("data subject"). An identifiable natural person is one who can be identified, directly or indirectly, in particular by reference to an identifier such as a name, an identification number, location data, an online identifier or to one or more factors specific to the physical, physiological, genetic, mental, economic, cultural, or social identity of that natural person.	
Residence period	The period of time between the end of business and the end of purpose (EoP) for a data set during which the data remains in the database and can be used in case of subsequent processes related to the original purpose. At the end of the longest configured residence period, the data is blocked or deleted. The residence period is part of the overall retention period.	
Retention period	The period of time between the end of the last business activity involving a specific object (for example, a business partner) and the deletion of the corresponding data, subject to applicable laws. The retention period is a combination of the residence period and the blocking period.	
Sensitive personal data	 A category of personal data that usually includes the following type of information: Special categories of personal data, such as data revealing racial or ethnic origin, political opinions, religious or philosophical beliefs, trade union membership, genetic data, biometric data, data concerning health or sex life or sexual orientation, or personal data concerning bank and credit accounts. Personal data subject to professional secrecy Personal data relating to criminal or administrative offenses Personal data concerning insurances and bank or credit card accounts 	

Term	Definition
Where-used check (WUC)	A process designed to ensure data integrity in the case of potential blocking of business partner data. An application's where-used check (WUC) determines if there is any dependent data for a certain business partner in the database. If dependent data exists, this means the data is still required for business activities. Therefore, the blocking of business partners referenced in the data is prevented.

SAP ASE Approach to Data Protection

Many data protection requirements depend on how the business semantics or context of the data stored and processed in SAP ASE are understood.

i Note

Using capabilities to communicate with other data sources, SAP ASE may also be used to process data that is stored in other systems and accessed through virtual tables.

In SAP ASE installations, the business semantics of data are part of the application definition and implementation. SAP ASE provides the features for working with technical database objects, such as tables. It is therefore the application that "knows," for example, which tables in the database contain sensitive personal data, or how business level objects, such as sales orders, are mapped to technical objects in the database. Applications built on top of SAP ASE need to make use of features provided by SAP ASE to implement compliance requirements for their specific use case.

SAP ASE provides a variety of security-related features to implement general security requirements that are also required for data protection and privacy:

Aspect of Data Protection and Privacy	SAP ASE Feature	More Information
Access control	Several features in SAP ASE provide access control:	Section Manage SAP ASE Logins and Database Users [page 25]
	 Authentication Authorization Data encryption: Encrypted Columns for encrypting table columns Database Encryption for encrypting all data, indexes, and transaction logs in the database at rest 	 Section Manage Roles [page 93] Section Manage User Permissions [page 166] Section Confidentiality of Data [page 292] Document Database Encryption
	 Backup (dump) and Restore (load) of databases with pass- word protection and fully-en- crypted database backups 	

Aspect of Data Protection and Privacy	SAP ASE Feature	More Information
Access logging	Auditing	Section Auditing [page 337]
Transmission control/communication security	Support for encrypted communication on all internal and external channels	 Section External Authentication [page 115] Section SSL Overview [page 294] Section Kerberos Confidentiality [page 326] Section On-Demand Encryption [page 323]
Availability control	Several features in SAP ASE provide availability control: Backup and Recovery High Availability and Disaster Recovery (HADR)	 Section Mirroring Database Devices in the SAP ASE System Administration Guide: Volume 2 Section Developing a Backup and Recovery Plan in the SAP ASE System Administration Guide: Volume 2 Section Backup Up and Restoring User Databases in the SAP ASE System Administration Guide: Volume 2 Section Restoring the System Databases in the SAP ASE System Administration Guide: Volume 2 Section Archive Database Access in the SAP ASE System Administration Guide: Volume 2 Document HADR Users Guide
Separation by purpose	Separation by purpose is subject to the organizational model implemented and must be applied as part of the authorization concept. Data separation can be achieved in SAP ASE using: Multiple databases Separating ownership by database user	 Section Manage User Permissions [page 166] Section Granular Permissions [page 242]

⚠ Caution

The extent to which data protection is ensured depends on secure system operation. Network security, security note implementation, adequate logging of system changes, and appropriate usage of the system are the basic technical requirements for compliance with data privacy legislation and other legislation.

3.1 Deletion of Personal Data

SAP ASE supports the deletion of data in tables using SQL deletion commands. Applications running on SAP ASE must make use of such commands to implement deletion requirements of personal data.

End of purpose checks, including implementation of legally required retention periods and data blocking, are managed by the application. Applications can implement data blocking using SAP ASE mechanisms such as authorization and table creation. For example, an application could transfer blocked data to separate database tables that are protected by special authorizations.

Once data has been deleted, the delete operation cannot be undone using SQL statements.

i Note

Following standard practice, deletion of personal data is not enforced in backups.

4 Manage SAP ASE Logins and Database Users

The responsibility of adding new login accounts, adding users to databases, and granting users permission to use commands and access database objects is divided among the system security officer, system administrator, and database owner.

i Note

Permission requirements for operations assume that granular permissions is disabled. Operations may differ when granular permissions is enabled.

Table 4: Managing Users in SAP ASE

Task	Required role	Command or pro- cedure	Database, group, or role
Create login accounts	System security officer	create login	Master database
Alter login accounts	System security officer The exception is that users can change their own password and full name.	alter login	Master database
Drop login accounts	System security officer	drop login	Master database
Create groups	Database owner or system administrator	sp_addgroup	User database
Create and assign roles	System security officer	create role, grant role	Master database
Add users to database and assign groups	Database owner or system administrator	sp_adduser	User database
Alias users to other database users	Database owner or system administrator	sp_addalias	User database
Grant groups, users, or roles permission to create or access database objects and run commands	Database owner, system ad- ministrator, system security of- ficer, or object owner	grant	User database

Related Information

Granular Permissions [page 242]

4.1 Introduction to Logins

A login defines a name and a password for a user to allow access to SAP ASE.

When you execute create login, a row is added to master.dbo.syslogins, a unique system user ID (suid) is assigned for the new user, and specified attribute information is filled in. When a user logs in, SAP ASE looks in syslogins for the name and password provided by the user. The password column is encrypted with a one-way algorithm so it is not readable.

A login profile is a collection of attributes to be applied to a set of login accounts. The attributes define login characteristics, such as default roles or the login script associated with each login bound to the profile. Login profiles save time for the system security administrator because attributes of login accounts are set up and managed in one place.

4.1.1 Create Login Accounts

Use create login to add a new login name. Only the system security officer can execute create login.

The following steps describe creating a login account for a particular server and manage permissions for the users:

- 1. A system security officer creates a login account for a new user.
- 2. A system administrator or database owner adds a user to database or assigns a user to a group.
- 3. A system security officer grants specific roles to the user.
- 4. A system administrator, database owner, or object owner grants the user, or group specific permissions on specific commands and database objects.

See create login in the Reference Manual: Commands for complete syntax.

At login creation, the crdate column in syslogins is set to the current time.

The suid column in syslogins uniquely identifies each user on the server. A user's suid remains the same, no matter what database he or she is using. The suid 1 is always assigned to the default "sa" account that is created when SAP ASE is installed. Other users' server user IDs are integers assigned consecutively each time create login is executed.

The following statement sets up an account for the user "maryd" with the password "100cents," the default database (master), the default language (us_english), and no full name:

```
create login maryd with password "100cents"
```

The password requires quotation marks because it begins with 1.

After this statement is executed, "maryd" can log in to the server. She is automatically treated as a "guest" user in master, with limited permissions, unless she has been specifically given access to master.

The following statement sets up a login account "omar_khayyam" and password "rubaiyat" and makes "pubs2" the default database for this user:

create login omar_khayyam with password rubaiyat default database pubs2

4.1.2 Last Login and Managing Inactive Accounts

Manage and track SAP ASE accounts.

SAP ASE provides security for user accounts by:

- Tracking the creation date.
- Recording the last login time for an account.
- · Determining which accounts are stale and locked due to inactivity.
- Recording the reason an account is locked, when the account is locked, and the identity of the user who
 locked the account.

4.1.2.1 Defining a Stale Period

stale period is an attribute of login profiles which indicates the duration a login account is allowed to remain inactive before being locked due to inactivity.

If the login profile track lastlogin attribute is not set to 0 and the login account is not exempt from locking due to inactivity, then the syslogins.lastlogindate and syslogins.pwdate fields are checked to determine inactivity during the login process or during the execution of sp_locklogin.When login accounts are locked due to inactivity, the locksuid, lockreason and lockdate fields in syslogins will be set as follows:

Value of lockreason	Value for locksuid	Description of lockreason of account
4	NULL	Account locked automatically due to inactivity.

If a High Availability solution is setup, the syslogins.lastlogindate and syslogins.pwdate are synchronized on both the servers. Login accounts locked on one server are also locked on the companion server.

4.1.2.2 Tracking the Last Login

Tracking of the last login date time can be set through the track lastlogin attribute of a login profile.

create login profile general lp with track lastlogin true authenticate with ASE

4.1.2.3 Preventing Inactive Accounts from Being Locked

Login accounts can be set to be exempt login from being locked due to inactivity be using the exempt inactive lock clause.

The following statement creates the login account "user33" which is exempt from being lock due to inactivity.

create login user33 with password ATOu7gh9wd exempt inactive lock true

4.1.3 Authentication Mechanisms for Login

The supported authentication mechanisms are: ASE, LDAP, PAM, KERBEROS, and ANY.

When ANY is used, SAP ASE checks for a defined external authentication mechanism. If one is defined, SAP ASE uses the defined mechanism, otherwise the ASE mechanism is used.

4.1.4 Change Login Accounts

Use alter login to add, drop or change attributes of a login and their corresponding values.

alter login allows you to:

- Add or drop auto activated roles
- · Change a password
- Change the login profile association
- Change or add a full name
- Specify the password expiration and the minimum password length
- Specify the maximum failed attempts
- Specify an authentication mechanism
- Specify the default language and default database
- Invoke a login script
- Exempt inactive login accounts

A system administrator can use alter login to set password length and expiration, to limit failed login attempts, drop attributes, and to specify that a login script be run automatically when a user logs in.

After you execute alter login to change the default database, the user is connected to the new default database the next time he or she logs in. However, alter login does not automatically give the user access to the database. Unless the database owner has been assigned access with sp_adduser, sp_addalias, or with a guest user mechanism, the user is connected to master even after his or her default database has been changed.

This example changes the default database for the login account anna to pubs 2:

alter login anna modify default database pubs2

This example changes the default language for claire to French:

alter login claire modify default language french

4.1.5 Drop Login Accounts

The command drop login removes a user login by deleting the user's entry from master.dbo.syslogins.

You cannot drop a login who is a user in any database, and you cannot drop a user from a database if the user owns any objects in that database or has granted any permissions on objects to other users. The dropped login account's server user ID (suid) can be reused when the next login account is created. This only occurs when the dropped login holds the highest suid in syslogins, but could compromise accountability if execution of $drop\ login$ is not being audited. You cannot drop the last remaining System Security Officer's or System Administrator's login account.

The with override clause drops the login even if there are non-available databases that cannot be checked for login references.

The following example drops login accounts mikeb and rchin.

```
drop login mikeb, rchin
```

See the Reference Manual: Commands for complete drop login syntax.

4.2 Choose and Create a Password

The system security officer assigns each user a password using create login when adding the users. Users can modify their passwords at any time using the alter login statement.

When you create your password:

- Do not use information such as your birthday, street address, or any other word or number that has anything to do with your personal life.
- Do not use names of pets or loved ones.
- Do not use words that appear in the dictionary or words spelled backwards.

The most difficult passwords to guess are those that combine uppercase and lowercase letters and numbers. Never give anyone your password, and never write it down where anyone can see it.

Passwords must:

- Be at least 6 characters long. SAP recommends passwords of 8 characters or longer.
- Consist of any printable letters, numbers, or symbols. The complete special character set is: !@#\$
 %^&*()_-+={[}]|\:;"'<,>.?/~`
- Be enclosed in quotation marks in create login if they:
 - Include any character other than A Z, a z, 0 9,_, #, valid single-byte or multibyte alphabetic characters, or accented alphabetic characters

• Begin with a number 0 – 9

Related Information

Password Complexity Checks [page 36]

4.2.1 Maximum Login Attempts

Setting the maximum number of login attempts allowed provides protection against "brute-force" or dictionary-based attempts to guess passwords.

A system security officer can specify a maximum number of consecutive login attempts allowed, after which the login or role is automatically locked. The number of allowable failed login attempts can be set for the entire server, or for individual logins and roles. Individual settings override the server-wide setting.

The number of failed logins is stored in the logincount column in master..syslogins. A successful login resets the number of failed logins to 0.

Setting the Server-Wide Maximum Failed Logins

Use sp_passwordpolicy to set server-wide maximum number of failed logins for logins and roles.

To set the number of failed logins allowed, enter:

```
sp_passwordpolicy 'set', 'maximum failed logins', <'number'>
```

By default, ${\tt maximum}$ failed logins is turned off and this check is not applied to passwords.

See sp passwordpolicy in Reference Manual: Procedures.

Setting the Maximum Failed Logins for Logins

Use ${\tt create login}$ to set the maximum number of failed login attempts for a specific login.

This example creates the new login "joe" with the password "Djdiek3" and sets the maximum number of failed login attempts to 3:

```
create login joe with password Djdiek3 max failed attempts 3
```

See create login in Reference Manual: Commands.

Setting the Maximum Failed Logins for Roles

Use create role to set the maximum failed logins for a specific role.

This example creates "intern_role" with the password "temp244", and sets the maximum failed logins for "inter_role" to 20:

```
create role intern role with passwd "temp244", max failed logins 20
```

See create role in Reference Manual: Commands.

Changing the Maximum Failed Logins for Logins

Use alter login to set or change the maximum failed logins for an existing login.

This example changes the maximum failed logins for the login "joe" to 40:

```
alter login joe modify \max failed attempts 40
```

See alter login in Reference Manual: Commands.

Changing the Maximum Failed Logins for Roles

Use alter role to set or change the maximum failed logins for an existing role.

This example changes the maximum failed logins allowed for "physician_role" to 5:

```
alter role physician role set max failed logins 5
```

This example removes the overrides for the maximum failed logins for all roles:

```
alter role "all overrides" set max failed_logins -1
```

See alter role in Reference Manual: Commands.

4.2.2 Logging in After Losing a Password

Use dataserver -p to reset the password for sa_role and sso_role.

Context

Use the dataserver -p login_name parameter to specify the name of the system security officer or system administrator at the server start-up. This allows you to set a new password for these accounts if you cannot

recover a lost password. When you start the server with the -p parameter, SAP ASE generates, displays, and encrypts a random password and saves it in master..syslogins as that account's new password.

If sa_role does not have a password, and the server is started with -p sa_role, an error message is printed in the error log.

SAP recommends that you change the password for the login or role when the server is restarted.

Procedure

• Use dataserver -p when you have lost the password for either of these roles, that require a password to become active.

For example, if the server is started with:

```
xml:space="preserve">dataserver -p sa_role
```

This message is displayed:

```
xml:space="preserve">New password for role 'sa_role' : qjcdyrbfkxgyc0
```

4.2.3 Displaying Password Information for Logins

Display password information for logins using sp displaylogin.

Procedure

To display the login and password settings for a login, enter:

```
sp_displaylogin [<loginame >[, expand_up | expand_down]]
```

This example displays information about the login joe which is bound to a login profile:

```
sp displaylogin joe
Suid: 3
Loginame: joe
Fullname: Joe Williams
Configured Authorization:
      sa role (default ON)
     sso role (default ON)
     oper_role (default ON)
Locked: NO
Date of Last Password Change: Sep 22 2008 3:50PM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 1
Current failed login attempts: 2
Authenticate with: ANY
```

```
Login Profile: emp_lp
```

This example displays information about the login joe which is not bound to a login profile:

```
sp displaylogin joe
Suid: 3
Loginame: joe
Fullname:
Default Database: master
Default Language:
Auto Login Script:
Configured Authorization:
Locked: NO
Date of Last Password Change: Sep 22 2008 3:50PM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 1
Current failed login attempts: 2
Authenticate with: ANY
Login Password Encryption: SHA-256
Last login date: Sep 18 2008 10:48PM
```

See sp_displaylogin in Reference Manual: Procedures.

4.2.4 Displaying Password Information for Roles

Display password information for logins using sp displayroles

Procedure

• To display the login and password settings for a role, enter:

```
sp_displayroles
    [<grantee_name >[, <mode>]]
```

This example displays information about the physician_role role:

```
sp_displayroles physician_role, "display_info"
Role name = physician_role
Locked : NO
Date of Last Password Change : Nov 24 1997 3:35PM
Password expiration interval = 5
Password expired : NO
Minimum password length = 4
Maximum failed logins = 10
Current failed logins = 3
```

See $\operatorname{sp_displayroles}$ in Reference Manual: Procedures.

4.2.5 Checking Passwords for at Least One Digit

The system security officer can instruct the server to check for at least one digit in a password using the server-wide configuration parameter, check password for digit.

Context

If set, this parameter does not affect existing passwords. By default, checking for digits is off.

Procedure

• To active a password check for one digit, enter:

```
sp configure "check password for digit", 1
```

• To deactivate the password check, enter:

```
sp_configure "check password for digit", 0
```

See sp configure in Reference Manual: Procedures.

4.2.6 Set or Change the Minimum Password Length

The configurable password allows you to customize passwords to fit your needs such as using four-digit personal identification numbers (PINs) or anonymous logins with NULL passwords.

i Note

SAP ASE uses a default value of 6 for minimum password length and recommends that you use a value of 6 or more for this parameter.

The system security officer can specify:

- A globally enforced minimum password length
- A per-login or per-role minimum password length

The per-login or per-role value overrides the server-wide value. Setting the minimum password length affects only new passwords created after setting the value.

Setting the Minimum Password Length for a Specific Login

Use create login to set the minimum password length for a specific login.

This creates the login "joe", with the password "Djdiek3", and sets the minimum password length to 8:

create login joe Djdiek3 with password @minpwdlen min password length 8

See create login in Reference Manual: Commands.

Setting the Minimum Password Length for a Specific Role

Use create role to set the minimum password length for a specific role.

This creates the role "intern_role", with the password "temp244", and sets minimum password length to 0:

```
create role intern_role with passwd "temp244", min passwd length 0 \,
```

The original password is seven characters, but the password can be changed to any length because min passwd length is set to 0.

See create role in Reference Manual: Commands.

Changing the Minimum Password Length for a Specific Login

Use alter login to set or change minimum password length for an existing login.

This changes the minimum password length for the login "joe" to 8 characters:

```
alter login joe modify min password length 8
```

See alter login in Reference Manual: Commands.

Changing the Minimum Password Length for a Specific Role

Use alter role to set or change the minimum password length for an existing role.

This sets the minimum length for the role "physician_role" to 5 characters:

```
alter role physician role set min passwd length 5
```

This overrides the minimum password length for all roles:

```
alter role "all overrides" set min passwd length -1
```

See alter role in Reference Manual: Commands.

Removing the Minimum Password Length for a Specific Login

Use alter login to remove the minimum password length for an existing login.

This removes any restriction to minimum password length for login "joe":

```
alter login joe modify drop min password length
```

See alter login in Reference Manual: Commands.

4.2.7 Password Complexity Checks

Use sp passwordpolicy to activate password complexity checks.

Activating or Deactivating Password Complexity Checks

Login password complexity checks are extended to role passwords.

To turn off an individual password policy option, enter:

```
sp_passwordpolicy 'clear', <option>
```

To turn off all password policy options, enter:

```
sp passwordpolicy 'clear'
```

Disallow Simple Passwords

- 0 (default) turns off the option, and allows simple passwords.
- 1 turns the option on, and disallows simple passwords.

For example:

```
sp_passwordpolicy 'set', 'disallow simple passwords', '1'
```

Custom Password-Complexity Checks

You can custom-configure password checking rules using sp_extrapwdchecks and sp_cleanpwdchecks.

These stored procedures are defined and located in the master database and are automatically invoked during password complexity checks, and when dropping a login, respectively.

4.2.7.1 Specify Characters in a Password

Use sp_passwordpolicy parameters to specify the minimum number of characters (digits, upper and lower characters, and so on) in a password.

- min digits in password the minimum number of digits in a password. Disabled by default. Valid values are:
 - 0 through 16 the minimum number of digits that must exist in a password.
 - -1 the password cannot contain digits.
- min alpha in password the minimum number of alphabetic characters allowed in a password. This value must be at least the sum of minimum number of uppercase characters and minimum number of lowercase characters. Disabled by default. Valid values are:
 - 0 through 16 the minimum number of special characters required for a password.
 - -1 the password cannot contain special characters.
- min special char in password the minimum number of special characters for a password. Valid values are:
 - 0 through 16 the minimum number of special characters required for a password.
 - -1 the password cannot contain special characters.
- min upper char in password the minimum number of uppercase letters for a password. Disabled by default. Valid values are:
 - 0 through 16 the number of uppercase letters required for a password.
 - -1 the password cannot contain uppercase characters.
- min lower char in password the minimum number of lowercase letters for a password. Valid values are:
 - 0 through 16 the number of uppercase letters required for a password.
 - -1 the password cannot contain uppercase characters.
- minimum password length the minimum password length. You can set a minimum password length from 0 to 30. The value you specify with must be at least the sum of all other minimum requirements. For example, minimum password length must be set to at least 10 if you have set:
 - ullet minimum digits in password to 3
 - $^{\bullet}\,$ minimum special characters in password to $2\,$
 - minimum uppercase characters in password to 2
 - minimum lowercase characters in password to 3
- password expiration the number of days a password can exist before it expires. You specify this value on a global basis. Disabled by default. Valid values are:
 - 0 the password will never expire.
 - 1 through 32767 the number of days the password can exist without expiring.
- password exp warn interval the number of days before a password expires that the password expiration warning messages displays. These messages display with every successful login until the password is changed or it expires. This value must be less than or equal to the password expiration.
 Disabled by default.
 - Valid values are 0 to 365.
- maximum failed logins the maximum number of failed logins that can occur before the login is locked. Specify this value globally. Disabled by default. Valid values are:

- 0 logins are never locked, regardless of the number of failed login attempts.
- 1 through 32767 the number of failed logins that can occur before the login is locked.
- expire login changes the login status to expired when a system security officer creates or resets a login. The login is then required to change the password on the first login. Disabled by default. Valid values are:
 - 0 new or reset logins will not expire.
 - 1 new or reset logins expire; you must reset your password at the first login.

See sp passwordpolicy in the Reference Manual: Procedures.

4.2.7.2 Password Complexity Option Cross Checks

Some password complexity options have interaction implications.

- minimum password length must be at least the sum of min digits in password, min alpha in password, and min special characters in password.
- min alpha in password must be at least the sum of min upper char in password and min lower char in password.
- systemwide password expiration must be greater than password exp warn interval.

For the purpose of the above cross-checks, if SAP ASE encounters a password complexity option value of -1, it interprets that as a value of 0. If an option is not set, SAP ASE interprets the option value to be 0 as well.

SAP ASE prints warnings for each new password complexity option that fails to satisfy the cross-checks. Option setting, however, is successful.

4.2.7.3 Set Password Complexity Checks

Set the password complexity options at the login level using create login or alter login. Set the options at the global level using $sp_asswordpolicy or sp_configure$.

Password checks and policies for authentication	Configuration parameters specified using sp_configure	Password complexity options specified using sp_passwordpolicy	Per-login overrides speci- fied using alter login
Password expiration	system-wide password expiration	system-wide password expiration	password expiration
Digits in password	check password for digit	min digits in password	N/A
Alphabetic characters in password	N/A	min alpha in password	N/A

Password checks and policies for authentication	Configuration parameters specified using sp_configure	Password complexity options specified using sp_passwordpolicy	Per-login overrides speci- fied using alter login
Password length	minimum password length	minimum password length	min passwd length
Failed logins lockout	maximum failed logins	maximum failed logins	max failed attempts
Disallow simple passwords	N/A	disallow simple passwords	N/A
Special characters in password	N/A	min special char in password	N/A
Uppercase letters in password	N/A	min upper char in password	N/A
Lowercase letters in password	N/A	min lower char in password	N/A
Password expiration warning interval	N/A	password exp warn interval	N/A
Resetting your password at first login	N/A	expire login	N/A
Custom password complexity checks	N/A	N/A	N/A

Because you can set password configuration options on a global and per-login basis, the order of precedence in which the password options is applied is important.

When applying password options, the order of precedence is:

- 1. Existing per-login parameters
- 2. Password complexity options
- 3. Existing global password options

Example: Example 1

Creates a new login and sets the minimum password length for "johnd" to 6:

create login johnd with password complex_password min
 password length '6'

These global options for login "johnd" create two minimum password length requirements for login "johnd", and sets restrictions about digits in the password:

```
sp_configure 'minimum password length', '8'
sp_configure 'check password for digit', 'true'
sp_passwordpolicy 'set', 'min digits in password', '2'
```

If you then try to alter the password for login "johnd":

```
alter login johnd with password complex_password modify password 'abcd123'
```

Passwords are checked in the following order:

- 1. Per-login existing options check: minimum password length must be greater than 6. This is true and the check passes.
- 2. New options: minimum digits in password must be greater than 2. This is true and the check passes.
- 3. Existing global options: minimum password length specified here is not checked because there is already a per-login check for the login "johnd".
- 4. The check password for digit option is redundant because it is already checked when the minimum number of digits is turned on and set to 2.

Once the designated sequence is checked, and the new password for login "johnd" passes these checks, the password is successfully change.

Example: Example 2

If you enter the following for user "johnd", SAP ASE first checks the per-login existing options, and determines the minimum password length is set to 6, but that you have attempted to alter the password to use only 4 characters:

```
alter login johnd with password complex_password modify password abcd
```

The check fails, and an error message is printed. Once one password complexity check fails, no additional options are checked.

Example: Example 3

Creates a new login with the following password configuration options and sets the minimum password length for login johnd to 4:

```
create login johnd with password complex_password min
  password length 4
```

This is a per-login, existing option. When you add the following, you have created a global requirement that the minimum number of digits for a password must be 1:

```
sp_passwordpolicy 'set', 'min digits in password', '1'
```

If you then attempt to alter the password for login johnd as follows:

```
alter login johnd with password complex password modify
     password abcde
```

These checks are performed in the following order:

- 1. Per-login existing options check: the minimum password length of a new password is 4. The password "abcde" is greater than 4, so this check passes.
- 2. New global requirement check: the minimum digits in a password is set to 1, globally. This check fails.

The password is not changed and an error message is printed.

To alter a password, all the checks must pass.

4.2.8 Enable Custom Password Checks

A system security officer can write user-defined stored procedures that enable custom password checks.

To implement password history checks, create a new user table to store password histories:

```
create table pwdhistory
      name varchar(30) not null, -- Login name.
     password varbinary(30) not null, -- old password.
      pwdate datetime not null, -- datetime changed.
      changedby varchar(30)not null -- Who changed.
)
ao
```

Create a new stored procedure master.dbo.sp extrapwdchecks which saves previously used passwords in an encrypted form in the pwdhistory table and disallows reuse of used passwords. The sp extrapwdchecks user-defined stored procedure is called automatically when either the create login or alter login ... modify password commands are executed. You need the sa role to create this stored procedure. The following is an example of the implementation of sp extrapwdchecks:

```
create proc sp extrapwdchecks
@caller password varchar(30) = NULL, -- the current password of caller
\underline{\underline{\underline{\underline{\underline{\underline{0}}}}}} enew password of the target acct
@loginame
                  varchar(30) = NULL -- user to change password on
as
begin
declare @current time datetime,
        @encrypted_old_pwd varbinary(30),
        @encrypted_new_pwd varbinary(30),
        @salt varchar(\overline{8}),
        @changedby varchar(30),
        @cutoffdate datetime
        select @changedby = suser name()
        select @salt = null
        -- NOTE : caller password and/or loginame arguments can be null.
        -- In these cases, password history checks should be skipped.
        -- @loginame is null when SSO creates a new login account
        -- using "create login" command.
```

```
-- @caller password is null when
        -- 1. SSO creates a new login account using
        -- "create login" command.
        -- 2. SSO modifies the login account's password using
        -- "alter login ... modify password" command.
        -- Business logic for custom password checks should be
        -- implemented here.
        -- If there is no need to maintain password history, return
        -- from here.
        if (@loginame is NULL)
        begin
           return 0
        end
        -- Change this line according to the needs of your installation.
        -- This checks below keep history of 12 months only.
        select @current time = getdate(),@cutoffdate = dateadd
           (month, -12, getdate())
        delete master..pwdhistory
        where name = @loginame
        and pwdate < @cutoffdate
        select @salt = substring(password, 1, 8) from master..pwdhistory
            where pwdate =
                (select max(pwdate) from master..pwdhistory where
                name=@loginame) and name=@loginame
        if @salt is null
        begin
            select @salt = substring(hash
                (password random(8), 'shal'), 1, 8)
        end
        select @encrypted new pwd = @salt + hash
                (@salt + @new_password, 'sha1')
        if not exists ( select 1 from master..pwdhistory
            where name = @loginame and password = @encrypted new pwd )
        begin
            -- new password has not been used before
            if (@loginame != @changedby)
            begin
                return 0
            end
            -- Save old password
            select @encrypted_old_pwd = @salt + hash
                (@salt + @caller password, 'shal')
            insert master..pwdhistory
                select @loginame,
                    @encrypted old pwd,@current time, @changedby
            return (0)
        end
        else
        begin
               raiserror 22001 --user defined error message
        end
   end
   qo
grant execute on sp_extrapwdchecks to public
```

Use sp addmessage to add the user-defined message 22001. A raiserror 22001 indicates a custom password-complexity check error.

sp_extrapasswordchecks must use raiserror to signal a failure to the SAP ASE server. Use sp_addmessage to add error message for this failure in the SAP ASE server.

i Note

Do not use raiserror to get the expected behavior. raiserror updates the @@error global variable. @@error is also updated each time you execute a T-SQL statement, including print and if. If raiserror is followed by any T-SQL statement, @@error gets overwritten, and sp_extrapwdchecks fails to return an error for a failed password if raiserror is followed by any TSQL statement.

The following user-defined stored procedure (sp_cleanpwdchecks) can be used to clean-up the password history using sp_extrapwdchecks.

Once the two procedures above are defined and installed in the master database, they are called dynamically during the password complexity checks.

4.2.9 Set the Login and Role Expiration Interval for a Password

System administrators and system security officers can set the login or role expiration when the login or role is created, or change an existing login or role expiration.

Command	Expiration option
create login	Specify the expiration interval for a login password at creation.
alter login	Change the expiration interval for a login password.
create role	Specify the expiration interval for a role password at creation (only the system security officer can issue create role).
alter role	Change the expiration interval for a role password (only the system security officer can issue alter role).

These rules apply to password expiration for logins and roles:

A password expiration interval assigned to individual login accounts or roles overrides the global password
expiration value. This allows you to specify shorter expiration intervals for sensitive accounts or roles, such
as system security officer passwords, and more relaxed intervals for less sensitive accounts such as an
anonymous login.

- A login or role for which the password has expired is not directly activated.
- The password expires at the time of day when the password was last changed after the number of days specified by password expiration interval has passed.

For details on the syntax and rules for the commands and system procedures, see the appropriate *Reference Manual*.

4.2.9.1 Circumvent Password Protection

Circumventing the password-protection mechanism may be necessary in automated login systems. You can create a role that can access other roles without passwords.

A system security officer can bypass the password mechanism for certain users by granting the password-protected role to another role, and grant the password-protected role to one or more users. Activation of this role automatically activates the password-protected role without having to provide a password.

For example:

Jane is the system security officer for ABC Inc., which uses automated login systems. Jane creates the following roles:

• financial assistant

```
create role financial_assistant with passwd "L54K3j"
```

accounts_officer

```
create role accounts officer with passwd "9sF6ae"
```

• chief_financial_officer

```
create role chief_financial_officer
```

Jane grants the roles of financial_assistant and accounts_officer to the chief financial officer role:

```
grant role financial assistant, accounts officer to chief financial officer
```

Jane then grants the chief_financial_officer role to Bob:

```
grant role chief_financial_officer to bob
```

Bob logs in to the server and activates the chief financial officer role:

```
set role chief_financial_officer on
```

The roles of financial_assistant and accounts_officer are automatically activated without Bob providing a password. Bob can now access everything under the financial_assistant and accounts_officer roles without having to enter the passwords for those roles.

4.2.9.2 Create a Password Expiration Interval for a New Login

Use create login to set the password expiration interval for a new login.

This example creates the new login "joe" with the password "Djdiek3", and sets the password expiration interval for "joe" to 2 days:

```
create login joe with password Djdiek3 password expiration 30
```

The password for "joe" expires after 30 days from the time of day the login account was created, or 30 days from when the password was last changed.

See create login in Reference Manual: Procedures.

4.2.9.3 Create a Password Expiration Interval for a New Role

Use create role to set the password expiration interval for a new role.

This example creates the new role intern_role with the password "temp244", and sets the password expiration interval for intern_role to 7 days:

```
create role intern_role with passwd "temp244", passwd expiration 7
```

The password for intern_role expires after 7 days from the time of day you created the role, or 2 days from when the password was last changed.

See create role in Reference Manual: Commands.

4.2.9.4 Creation Date Added for Passwords

Passwords are stamped with a creation date equal to the upgrade date of a given server.

The creation date for login passwords is stored in the pwdate column of syslogins. The creation date for role passwords is stored in the pwdate column of syssrvroles.

4.2.9.5 Change or Remove Password Expiration Interval for Login or Role

Use alter login to change the password expiration interval for an existing login, add a password expiration interval to a login that did not have one, or remove a password expiration interval.

alter login only effects login passwords, not role passwords.

This example changes the password expiration interval for the login "joe" to 30 days:

alter login joe modify password expiration 30

The password expires 30 days from the time of day you ran password expiration.

See alter login in Reference Manual: Commands.

4.2.9.6 Secure Login Passwords on the Network

The use of asymmetric encryption is allowed to securely transmit passwords from client to server using the RSA public key encryption algorithm.

SAP ASE generates the asymmetric key pair and sends the public key to clients that use a login protocol. For example, the client encrypts the user's login password with the public key before sending it to the server. The server decrypts the password with the private key to begin the authentication of the client connecting.

You can configure SAP ASE to require clients to use a login protocol. Set the configuration parameter net password encryption require all user name- and password-based authentication requests to use RSA asymmetric encryption.

The sp_configure parameter net password encryption reqd supports a value of 3, which indicates the server should only allow incoming clients that are using EPEP login protocol. The values 0, 1, and 2 also allow EPEP login protocol to be used when a client that supports the login protocol attempts to use it with an SAP ASE that implements the EPEP login protocol.

Setting the value to 2 or 3 increases network memory to support the maximum configured connections using this protocol. The additional network memory configuration parameter dynamically adds more memory to the network memory pool used by EPEP. When the value of net password encryption reqd is set to 3, the KPP Handler goes into sleep status, because there is no need to provide new RSA key pair for every connection. This means that you will avoid spending CPU cycles generating unique RSA keypairs for each connection, resulting in a more efficient CPU utilization.

You can use the ${\tt sp_who}$ command to check the KPP Handler status.

Two versions of the login protocol using RSA asymmetric encryption are supported. One ensures a unique keypair per login session and the second employs a random number during the login protocol. When there are many user connections using network password encryption, the unique keypair per session may cause computation peaks due to computation of new keypairs. The second approach is less computationally demanding. The second approach requires a recompiled client program that supports the newer login protocol that uses RSA asymmetric encryption with a random number.

Generating an Asymmetric Key Pair

For RSA asymmetric encryption with random number, SAP ASE generates a new key pair:

- At each server start-up,
- Automatically at 24-hour intervals using the housekeeper mechanism, and

• When an administrator with sso_role requests key pair regeneration.

The key pair is kept in memory. A message is recorded in the error log and in the audit trail when the key pair is regenerated.

For RSA asymmetric encryption without random number, by default, a key pair is generated for each connection.

Procedure sp_passwordpolicy option unique keypair per session may be used to turn on or off the generation of a key pair for each connection with this login protocol. However this should only be used in environments where network password security is not a concern because the key pair is reused without the benefit of the random number component.

To generate the key pair on demand, use:

```
sp_passwordpolicy "regenerate keypair"
```

i Note

Depending on the system load, there may be a delay between the time this command is executed and the time the key pair is actually generated. This is because the housekeeper task runs at a low priority and may be delayed by higher priority tasks.

To generate the key pair at a specific time, use:

```
sp_passwordpolicy "regenerate keypair", <datetime>
```

where <datetime> is the date and time you want to regenerate the key pair.

For example, a datetime string of "Jan 16, 2007 11:00PM" generates the key pair at the specified time. The datetime string can also just be a time of day, such as "4:07a.m.". When only time of day is specified, key-pair regeneration is scheduled for that time of day in the next 24-hour period.

 ${\tt sp_passwordpolicy}\ lets\ you\ configure\ the\ frequency\ of\ key-pair\ regeneration,\ as\ well\ as\ what\ should\ be\ done\ when\ a\ key\ pair\ generation\ fails:$

- 'keypair regeneration period', { ([<keypair regeneration frequency>], datetime of first generation) | (keypair regeneration frequency, [<datetime of first generation>]) }
- "keypair error retry [wait | count]", "<value>"

See sp_passwordpolicy in Reference Manual: System Procedure.

Server Option "net password encryption"

also acts as a client when establishing a remote procedure call (RPC).

When connecting to remote servers, the net password encryption option is used to determine whether it will use password encryption.

Either RSA or proprietary algorithms are used when this server option is set to true. The command to enable net password encryption is:

```
sp_serveroption server, "net password encryption", "true"
```

The setting is stored in master..sysservers and you can display the value of server options using the sp helpserver stored procedure.

The default value for net password encryption is true for any new server added using sp_addserver. During upgrade, the net password encryption is set to true for sysservers entries with an ASEnterprise class value. No other server classes are modified. This improves password security between two communicating SAP ASE servers.

i Note

The administrator can optionally reset net password encryption to false if you encounter problems establishing a connection to a server. However, if the option is set to false, passwords are transmitted in clear text on the network.

Backward Compatibility

- SAP recommends that you use the RSA algorithm to protect passwords on the network.
- To use the RSA algorithm with random number, you must have SAP ASE version 15.7 ESD #1 or later and use new Connectivity SDK clients version 15.7 ESD #1 or later.
- To use the RSA algorithm, without random number, you must have SAP ASE version 15.0.2 and new Connectivity SDK clients version 15.0 ESD #7 and later.
- SAP provides the net password encryption reqd configuration parameter and the net password encryption server option to allow settings equivalent to versions earlier than 15.0.2 and maintain backward compatibility with older clients and older servers.
- Older clients that do not support the RSA algorithm can set the property to encrypt passwords using the proprietary algorithm, which has been available since version 12.0.
- New clients that support both RSA and proprietary algorithms can set properties for both algorithms. When communicating with such clients, SAP ASE 15.0.2 and later uses RSA encryption. A pre-15.0.2 SAP ASE uses the proprietary algorithm.

See Reference Manual: Configuration Parameters > net password encryption required.

4.2.10 Secure Login Passwords Stored on Disk and in Memory

Login passwords used to authenticate client connections are stored securely on disk as SHA-256 hash digest.

The SHA-256 algorithm is a one-way encryption algorithm. The digest it produces cannot be decrypted, making its storage on disk secure. To authenticate the user connection, the SHA-256 algorithm is applied to the password sent by the client, and the result compared with the value stored on disk.

To prevent dictionary-based attacks on login passwords stored on disk, a salt is mixed with the password before the SHA-256 algorithm is applied. The salt is stored along with the SHA-256 hash, and used during login authentication.

SAP recommends using only SHA-256 as soon as you are certain that there will be no downgrades to an earlier versions. Consider the trade-offs when making this decision; should there be a need to downgrade to a pre-15.0.2 release, it requires administrator intervention to unlock user login passwords.

4.2.11 Character Set Considerations for Passwords

Passwords and other sensitive data that is encrypted must determine the character set of the clear text to accurately interpret the result when it is decrypted, or when hash values are compared during authentication.

For example, a client connects to SAP ASE using isql and establishes a new password. Regardless of the character set used in the client, characters are always converted to the server's default character set for processing within SAP ASE. Assuming the default character set is "iso_1," consider the command:

alter login loginName with password <oldPasswd> modify password <newPasswd>

The password parameters are varchar, and are expressed as a quoted string and stored with "iso_1" encoding before encryption. If the default character set changes later, the encrypted password remains an encrypted string of characters encoded with the original default character set. This may result in authentication failure due to mismatched character mapping. Although changing the default character set is a rare occurrence, it becomes more important when migration occurs between platforms.

The clear text password is converted to canonical form before encryption so that the password can be used across platforms, chip architectures, and character sets.

To use canonical form for storage in syslogins:

- 1. Convert the clear text password string to UTF-16.
- 2. Convert the UTF-16 string to network byte order.
- 3. Append a small buffer (the salt) with random bytes to the password.
- 4. Apply the SHA-256 hash algorithm.
- 5. Store digest, salt, and version in the password column.

At authentication time:

- 1. Convert the clear text password string to UTF-16.
- 2. Convert the UTF-16 string to network byte order.
- 3. Append the salt from the password column in syslogins to the password.
- 4. Apply the hash algorithm.
- 5. Compare results with password column in syslogins, if they match then authentication is successful.

4.2.12 Upgrade Behavior

Behavior changes are made on the master database when upgrading.

Behavior Changes on an Upgraded master Database

When you upgrade the master database, encrypted passwords are maintained in syslogins catalogs using algorithms from the earlier- and the upgraded version in the password column.

Users can call sp displaylogin to determine which "Login password encryption" a login uses.

On first authentication of a login after an upgrade:

- The user authenticates using the contents of the password column and the old algorithm.
- The password column is updated with the old encryption algorithm followed by the new encryption algorithm.

On subsequent authentication of a login after upgrade, before "allow password downgrade" is set to 0, the user authenticates using the new algorithm.

Behavior Changes on a New master Database

In a new master database, or in an upgraded master database after allow password downgrade is set to 0, the server maintains encrypted passwords in syslogins using only the new algorithm in the password column. Only the SHA-256 algorithm authenticates the connection requests and stores the password on disk.

Issue sp_passwordpolicy to determine if a server was upgraded (for example, from version 15.0 to 15.0.2) and maintains passwords using algorithms from the pre- and post-upgraded server, or if the server is newly installed and includes a master database that uses the most recent algorithm (from the 15.0.2 version):

sp passwordpolicy 'list', 'allow password downgrade'

4.2.13 Login Password Downgrade

To ease the transition to the on-disk encryption algorithm when migrating from versions earlier than 15.0.2, the password policy allow password downgrade is available.

After an upgrade from versions earlier than 15.0.2, the policy has a value of 1 to indicate that passwords are stored in both the proprietary algorithm used in earlier versions and the SHA-256 algorithm used in 15.0.2 and later.

As long as passwords are stored in both old and new forms, you can downgrade to 15.0 without resetting user passwords. When the policy allow password downgrade is set to 0, passwords are stored only in SHA-256 form, which is incompatible with older versions. When downgrading to previous releases, only passwords stored in SHA-256 are reset to random passwords and stored in the old form compatible with older versions.

To end the period when password downgrade is allowed, execute:

```
sp_passwordpolicy 'set', 'allow password downgrade', '0'
```

Before executing this command, examine login accounts with <code>sp_displaylogin</code> to determine if the login account has been used, and whether the password is stored in SHA-256 encoding. If is not, the account is automatically locked and reset with a generated password. To use the account again, you must unlock the account and give the user a newly generated password.

You may want to save the output from this command because it can contain information about locked login accounts and generated passwords for those accounts.

When the password downgrade period ends:

- The datetime when the password downgrade period ended is recorded in master.dbo.sysattributes.
- The value of each password column in syslogins is rewritten to use only the new password on-disk structure
- The logins that have not transitioned to the new algorithm have the password reset to a new server-generated password in SHA-256 format, and the login is locked. The generated password is displayed only to the administrator executing the sp_passwordpolicy procedure above. The lock reason is set to 3 ("Login or role not transitioned to SHA-256").

After the sp passwordpolicy procedure completes:

- Login authentication uses only SHA-256.
- Only the new password on-disk structure for the password column is used.
- Attempts to use the locked logins fail authentication. To use the locked logins, you must unlock the login with sp_locklogin and the user must use the password generated by sp_passwordpolicy. Alternatively, you may prefer to assign a new password instead of the generated password for locked login accounts.

Example 1

This example prepares an upgraded server to use only SHA-256. Examine login accounts to determine which encryption is used by the account using sp_displaylogin.

```
1> sp displaylogin login993
2> go
Suid: 70
Loginame: login933
Fullname:
Default Database: master
Default Language:
Auto Login Script:
Configured Authorization:
Locked: NO
Date of Last Password Change: Apr 20 2007 2:55PM
Password expiration interval: 0
Password expired: NO
Minimum password length: 0
Maximum failed logins: 3
Current failed login attempts:
Authenticate with: ANY
```

```
Login Password Encryption: SYB-PROP
Last login date:
(return status = 0)
```

The value SYB-PROP from the line Login Password Encryption: SYB-PROP indicates that only the SAP-proprietary encryption is used for this account. This login has not been used before the upgrade to 15.0.2 and later, and will be locked, and its password reset if sp_passwordpolicy 'set', 'allow password downgrade', '0' is executed.

After the first login to the account after upgrading to 15.0.2, the line changes to show that both old and new encryption is used:

```
Login Password Encryption: SYB-PROP, SHA-256
```

This is the desired state for all active login accounts, so that executing sp_passwordpolicy 'set', 'allow password downgrade', '0' does not lock and reset the password for accounts.

After you execute sp_passwordpolicy 'set', 'allow password downgrade', '0', only SHA-256 encryption is used, and you see:

```
Login Password Encryption: SHA-256
```

Login accounts that show this value are now using the stronger, on-disk encryption algorithm.

When all passwords have been changed to use the new algorithm, re-executing sp_passwordpolicy shows no accounts reset or locked:

```
1> sp_passwordpolicy 'set', 'allow password downgrade', '0'
2> go

Old password encryption algorithm usage eliminated from 0 login accounts, changes are committed.
(return status = 0)
```

Example 2

In this example, 990 out of 1000 login accounts have transitioned to the SHA-256 algorithm, but 10 accounts are still using SYB-PROP algorithm:

```
1> sp_passwordpolicy 'set', 'allow password downgrade', '0'
2> go

Old password encryption algorithm found for login name login1000, suid 3, ver1 =5, ver2 = 0, resetting password to EcJxKmMvOrDsC4
Old password encryption algorithm found for login name login999, suid 4, ver1 =5, ver2 = 0, resetting password to MdZcUaFpXkFtM1
Old password encryption algorithm found for login name login998, suid 5, ver1 =5, ver2 = 0, resetting password to ZePiZdSeMqBdE6
Old password encryption algorithm found for login name login997, suid 6, ver1 =5, ver2 = 0, resetting password to IfWpXvGlBgDgW7
Old password encryption algorithm found for login name login996, suid 7, ver1 =5, ver2 = 0, resetting password to JhDjYnGcXwObI8
Old password encryption algorithm found for login name login995, suid 8, ver1 =5, ver2 = 0, resetting password to QaXlRuJlCrFaE6
```

```
Old password encryption algorithm found for login name login994, suid 9, ver1 =5, ver2 = 0, resetting password to HlHcZdRrYcKyB2
Old password encryption algorithm found for login name login993, suid 10, ver1 =5, ver2 = 0, resetting password to UvMrXoVqKmZvU6
Old password encryption algorithm found for login name login992, suid 11, ver1 =5, ver2 = 0, resetting password to IxIwZqHxEePbX5
Old password encryption algorithm found for login name login991, suid 12, ver1 =5, ver2 = 0, resetting password to HxYrPyQbLzPmJ3
Old password encryption algorithm usage eliminated from 10 login accounts, changes are committed.
(return status = 1)
```

i Note

The login name, suid, and generated password appear to the administrator executing the procedure. The output of the command shows all 10 accounts that have not transitioned are reset (and locked).

4.2.14 Retain Password Encryption After Upgrade then Downgrade

If you upgrade SAP ASE, then downgrade to an earlier version, use <code>sp_downgrade_esd</code> to retain and use the password encryption functionality.

By default, you can downgrade passwords after an upgrade, until you end the password downgrade period.

4.2.14.1 Add Space Before You Upgrade

Additional space is required in the master database, and transaction log. Use alter database to add additional space to the master database, and transaction log.

Encryption algorithms and password policies:

- Increase the space required for syslogins by about 30%.
- Increase the maximum row length by 135 bytes per login account.
- Decrease the ratio of rows per page from about 16 rows per 2K page to 12 rows per 2K page between SAP ASE versions 15.0.1 and 15.0.2. There is a period of time during the downgrade when the value for allow password downgrade is 1 (when both old and new password encryption algorithms are used); the ratio further decreases to about 10 rows per 2K page.
 - For example, if version 15.0.1 has 1,000 login accounts, and the data fits into 59 pages, the same number of login accounts may require approximately 19 additional pages in version 15.0.2 on a new master database, or 33 additional pages if you upgraded from 15.0.1 (with allow password downgrade set to 1).

The transaction log requires additional space for the updated password column. When users first log in, about 829 2K pages per 1,000 logins is required, and about 343 pages per 1,000 logins for password changes users make during the upgrade and downgrade. To ensure there is sufficient log space, verify that there is approximately one 2K page of free log space per login before starting the password upgrade or downgrade, and when users first login to SAP ASE version 15.0.2 and later.

4.2.14.2 Downgrade

SAP ASE supports downgrading from version 16.x to earlier versions of 16.x. If you are downgrading to an earlier version, you may need to perform additional actions.

If allow password downgrade is O or NULL, or if a password has been stored in syslogins with only the SHA-256 algorithm, use $sp_displaylogin$ on login accounts to determine which algorithm is used, or $sp_displaylogin$ to determine which accounts are reset.

The prepare option reports whether the server is ready to be downgraded. If the prepare option fails, it reports errors that must be fixed. If a downgrade is performed on the server before the errors are fixed, the downgrade fails. For login passwords, prepare reports which passwords are reset during the downgrade.

Run sp downgrade esd "prepare" to verify whether you should run sp downgrade esd:

```
sp_downgrade_esd 'prepare','<version>',1
```

```
Checking databases for downgrade readiness.

There are no errors which involve encrypted columns.

Allow password downgrade is set to 0. Login passwords

may be reset, if old encryption version of password is

not present.

Warning: New password encryption algorithm found for

login name user103, suid 103.

Password will be reset during the downgrade phase.

sp_downgrade 'prepare' completed.

(return status = 0)
```

```
drop login probe
```

If the login has user entries in databases, from the master database, drop users from databases, and then drop the login:

```
use master sp_dropuser 'probe'
```

The probe login is re-created when you run installmaster on the downgraded server.

Before executing <code>sp_downgrade_esd</code>, SAP recommends that you drop statistics for <code>syslogins</code>, and <code>syssrvroles</code>. Doing this avoids invalid column information, such as the length of password column, in <code>sysstatistics</code> from being recorded during the downgrade.

To drop statistics for syslogins, and syssrvroles, enter:

```
delete statistics master..syslogins delete statistics master..syssrvroles
```

In this example, the execution of <code>sp_downgrade_esd</code> locks, and resets the login password for <code>user103</code>. The random password generated by SAP ASE is shown only to the client who executes <code>sp_downgrade_esd</code>. The administrator can redirect this output to a file so that these passwords are retained, or the administrator can manually reset them once the downgrade is complete, and the server is restarted.

```
sp_downgrade_esd 'downgrade','<version>',1
Checking databases for downgrade readiness.
```

```
There are no errors which involve encrypted columns.

Allow password downgrade is set to 0. Login passwords may be reset, if old encryption version of password is not present.

Warning: New password encryption algorithm found for login name user103, suid 103.

Password is reset during the downgrade phase.

Executing downgrade step 1 [sp_passwordpolicy 'downgrade'] for:

- Database: master (dbid: 1)

New password encryption algorithm found for login name user103, suid 103.

Resetting password to 'ZdSuFpNkBxAbW9'.

Total number of passwords reset during downgrade = 1

[ ... output from other downgrade steps ..]

(return status = 0)
```

Additional messages appear in the error log to identify steps that occurred during sp downgrade esd:

```
00:00000:00006:2007/05/21 05:35:59.19 server Starting downgrading ASE.

00:00000:00006:2007/05/21 05:36:03.90 server ASE downgrade completed.
```

sp_downgrade_esd makes catalog changes, and modifies password data. The server must be in single user mode to successfully execute sp_downgrade_esd. To start the server in single user mode, and to allow only the System Administrator to log in, use the -m command line option to start the server.

After running sp_downgrade_esd, shut down the server to avoid new logins or other actions that may modify data or system catalogs. If you restart the server after running sp_downgrade_esd, the earlier version shuts down and you are again upgraded to the later version.

4.2.15 Expire Passwords When allow password downgrade is Set to 0

Expire passwords in syslogins at the end of the password downgrade period.

To configure login passwords to expire, use:

```
sp_passwordpolicy "expire login passwords"[, "[<loginame> | <wildcard>]"
```

To configure role passwords to expire, use:

```
sp_passwordpolicy "expire role passwords"[, "[<rolename> | <wildcard>]"
```

To configure stale login passwords to expire, use:

```
sp_passwordpolicy "expire stale login passwords", "<datetime>"
```

To configure stale role passwords to expire, use:

```
sp_passwordpolicy "expire stale role passwords", "<datetime>"
```

Passwords that are not changed since the date you set in the <datetime> parameter of the sp_passwordpolicy "expire stale login passwords," expire when you execute the command. Users are automatically required to change their passwords after the password downgrade period ends.

You can also lock stale logins or roles; however this requires you to reset the password manually for legitimate users to access their login account again.

4.2.15.1 Show the Current Value of allow password downgrade

Obtain the current value of allow password downgrade.

To obtain the value of allow password downgrade, enter:

```
sp_passwordpolicy 'list', 'allow password downgrade'
```

The result set includes the current value, and a message indicating its meaning.

If you have upgraded the master database, and are maintaining passwords with the old and new encodings, the result is:

For an upgraded master database that only uses new password encryption, the result is:

For a new master database on Adaptive Server 15.0.2 that only uses new password encryption, the result is:

```
sp_passwordpolicy 'list', 'allow password downgrade'
go

value message

NULL New master database.
(1 row affected)
```

4.3 Establish a Password and Login Policy

Several controls are available for setting policies for logins, roles, and passwords for internal authentication.

The system security officer can:

- Specify the maximum allowable number of times an invalid password can be entered for a login or role before that login or role is automatically locked
- · Log in after a lost password
- Manually log and unlock logins and roles
- Display login password information
- Specify the minimum password length required server-wide, or for a specific login or role
- Check for password complexity of logins
- Enable custom password checks of logins
- Set the password expiration interval
- Consider login password character set
- Lock inactive login accounts
- Use passwords in a high availability environment

4.4 Login Failure

Users must be successfully authenticated before he or she can access data.

If the authentication attempt fails, the following message is returned and the network connection is terminated:

```
isql -U bob -P badpass
Msg 4002, Level 14, State 1:
Server 'ACCOUNTING'
Login failed.
CT-LIBRARY error:
ct_connect(): protocol specific layer: external error:
The attempt to connect to the server failed
```

This message is a generic login failure message that does not tell the connecting user whether the failure resulted from a bad user name or a bad password.

Although the client sees a generic message for a login failure to avoid giving information to a malicious user, the system administrator may find the reason for the failure to be important to help detect intrusion attempts and diagnose user authentication problems.

The reason for the login failure is provided in the Errornumber. Severity. State of the Other Information section of sysaudits.extrainfo column. Login failure audits have event number 45 and eventmod 2.

Set the sp_audit login parameter to on or fail to enable auditing for login failure:

```
sp_audit "login", "all", "all", "fail"
sp_audit "login", "all", "all", "on"
```

4.5 Lock Login Accounts and Roles

To prevent a user from logging in to an SAP ASE server, you can either lock or drop an login account.

Locking a login account maintains the suid so that it cannot be reused.

Execute sp_locklogin to lock login accounts

Audit records with audit event AUD_EVT_LOGIN_LOCKED (112) are generated under the $login_locked$ audit option when the login account is locked because login attempts have reached a configured maximum failed $login_locked$ value.

⚠ Caution

SAP ASE may reuse the server user ID (suid) of a dropped login account when the next login account is created. This occurs only when the dropped login holds the highest suid in syslogins; however, it can compromise accountability if execution of drop login is not being audited. Also, it is possible for a user with the reused suid to access database objects that were authorized for the old suid.

You cannot drop a login when:

- The user is in any database.
- The login is the last remaining user who holds the system security officer or system administrator roles.

The system security officer can lock or drop a login using $sp_locklogin$ or drop login. If the system procedure is being logged for replication, the system security officer must be in the master database when issuing the command.

4.5.1 Lock and Unlock Logins and Accounts

Use sp locklogin to lock and unlock logins and accounts or to display a list of locked accounts.

You must be a system security officer to use sp locklogin.

A login can be locked when:

- Its password expires, or
- The maximum number of failed login attempts occur, or
- The system security officer manually locks it, or
- Accounts are locked due to account inactivity

The syntax is:

```
sp_locklogin [ {<login_name> }, { "lock" | "unlock" } ]
```

where:

- <login_name> is the name of the account to be locked or unlocked. The login name must be an existing valid account.
- all indicates to lock or unlock all login accounts, except those with sa_role.
- lock | unlock specifies whether the account is to be locked or unlocked.

The system security officer can use sp_locklogin to manually lock or unlock a login. For example:

```
sp_locklogin "joe" , "lock"
sp_locklogin "joe" , "unlock"
```

Information about the lock status of a login is stored in the status column of syslogins.

Display Locked Logins

To display a list of all locked logins, use sp locklogin with no parameters.

You can lock an account that is currently logged in, and the user is not locked out of the account until he or she logs out. You can lock the account of a database owner, and a locked account can own objects in databases. In addition, you can use sp_changedbowner to specify a locked account as the owner of a database.

There is always at least one unlocked system security officer's account and one unlocked system administrator's account.

Information about the lock status of a login is stored in the status column of syslogins.

4.5.2 Use syslogins to Track if an Account is Locked

syslogins includes columns to track information about locked accounts.

syslogins includes the lastlogindate, crdate, locksuid, lockreason, and lockdate columns to support the last login, and locking inactive accounts, letting an account owner or administrator know if an account is locked, when it was locked, who locked it, and the reason why it was locked.

At login creation, the crdate column is set to the current time.

If the enable last login updates password policy option is set to 1, the lastlogindate column is set to the datetime of the login, and the previous value of the column is stored in the process status structure of the login session. The update to syslogins and the process status structure can occur at each login to SAP ASE. The default value for enable last login updates a new master database or an upgraded database is 1. To disable this option execute the procedure using administrator privileges:

```
sp_passwordpolicy 'set', 'enable last login updates', '0'
```

<@@lastlogindate> is specific to each user login session, and can be used by that session to determine the
date and time of the previous login to the account. If the account has not been previously used or if enable
last login updates is 0, the value of <@@lastlogindate> is NULL.

The transaction log does not log updates to syslogins..lastlogindate.

Administrators with sso_role can lock login accounts that are inactive for a given number of days, using:

```
sp_locklogin 'all', 'lock', [@except], '<number of inactive days>'
```

This command has no effect if enable last login updates is set to 0 or the value of the lastlogindate column is NULL. The range of values for <number of inactive days> is 1-32767 (days).

The lockreason column specifies the reason a login was locked. The value of the lockdate column is set to the current datetime.

When an account is unlocked, columns lockreason, lockdate, and locksuid are reset to NULL.

The lockdate, locksuid, and lockreason columns are set internally by SAP ASE.

Table 5: The Reasons and Values of locksuid

Values for lockreason	Values for locksuid	Description of lockreason account
NULL	NULL	Account has not been locked.
0	suid of caller of sp_locklogin	Account locked by locksuid by manually executing sp_locklogin.

Values for lockreason	Values for locksuid	Description of lockreason account
1	suid of caller of sp_locklogin	Account locked due to account inactivity, locksuid has manually executed sp_locklogin 'all', 'lock', 'ndays'.
2	suid of attempted login	Account locked due to failed login attempts reaching maximum failed logins.
3	<pre>suid of caller of sp_passwordpolicy set, "allow password downgrade", 0</pre>	Account locked by locksuid as the password downgrade period has ended, and login or role has not transitioned to SHA-256.
4	NULL	Account locked due to account inactivity.

4.5.3 Track Locked Roles

Accounting information such as when the role was locked, why it was locked, and who locked is stored in syssrvroles, and can be useful for role locking accounting.

There are several reasons roles may be locked:

- Entering the wrong role password a specified number of times. 'max failed_logins' option can be associated with roles during their creation or alteration. It specifies the number of failed role activation attempts after which a role is locked.
- Manually locking the role using alter role:

```
alter role <rolename> lock
```

These columns are included in syssrvroles for lock information:

- lockdate indicates when the role was locked.
- locksuid indicates who locked the role.
- lockreason gives a reason why it was locked. This is in the form of codes:

Values for lockrea-

son	Value for locksuid	Description of lockreason of role
NULL	NULL	Role is not locked
1	suid of caller of alter role	Role locked by suid by manually executing alter role rolename lock
2	suid of user whose last attempted role activation led to the role getting locked	Role locked due to failed role activation attempts reading max failed logins.

4.5.4 Locking and Unlocking Roles

Use alter role to lock and unlock roles.

As system security officer, use alter role to manually lock or unlock a role.

For example:

```
alter role physician_role lock alter role physician_role unlock
```

Information about the lock status of a role is stored in the status column of syssrvroles.

i Note

In high-availability environments, these syssrvroles columns are updated on both the primary and secondary servers.

See alter role in Reference Manual: Commands.

4.5.5 Lock Logins that Own Thresholds

Thresholds are affected by locked user logins.

- As a security measure, threshold stored procedures are executed using the account name and roles of the login that created the procedure.
 - You cannot drop the login of a user who owns a threshold.
 - · If you lock the login of a user who owns a threshold, the user cannot execute the stored procedure.
- The last-chance threshold, and thresholds created by the "sa" login are not affected by sp_locklogin. If you lock the "sa" login, the last chance threshold and thresholds created or modified by the "sa" user still fire.

4.6 Manage Login Profiles

System security officers can define, alter, and drop login profiles.

This table summarizes the system procedures and commands used to create and manage login profiles.

Task	Required role	Command or pro- cedure	Database
Create login profiles	System security officer	create login profile	Master database

Task	Required role	Command or pro- cedure	Database
Alter login profiles	System security officer	alter login profile	Master database
Drop login profiles	System security officer	drop login profile	Master database
Return login profile ID	System security officer	lprofile_id	Any database
Return login profile name	System security officer	lprofile_name	Any database
Display the name login profiles	System security officer	sp_displaylogi n	Any database
Displays information about login profiles	System security officer	sp_securitypro	Any database

4.6.1 Login Profile Attributes

Login profile attributes are stored in syslogins, sysloginroles and master.dbo.sysattributes.

This table summarizes the attributes of login profiles.

Attribute	Description
default database	Default database.
default language	Default language.
login script	Valid stored procedure. Stored procedures used as a login script through create login, alter login, create login profile, and alter login profile, is restricted to 120 characters.
auto activated roles	Previously granted user-defined roles that are not password-protected that must be automatically activated on login. An error is generated if the role specified is not granted to the login. By default, user-defined roles are not automatically activated on login.
authenticate with	Specifies the mechanism used for authenticating the login account. If authenticate with <authentication mechanism=""> is not specified, the value ANY will be used for the login account.</authentication>

Attribute	Description
track lastlogin	Enables last login updates.
stale period	Indicates the duration a login account is allowed to remain inactive before it is locked due to inactivity.
profile id	Specifies the login profile ID.

4.6.2 Login Profile Attribute Precedence

The attributes of login profiles are associated with login accounts and applied based on their precedence.

The attributes of login profiles are associated with login accounts using the following precedence:

- 1. Attribute values from a login profile bound to the login
- 2. Attribute values from a default login profile
- 3. Values which have been specified using sp passwordpolicy under the following circumstances:
 - A default login profile does not exit
 - A login profile has not been defined and bound to the account
 - The login profile is set to be ignored (the parameter with login profile ignore is specified for the command create login)
- 4. The default value for the attribute

4.6.3 Create Login Profiles

The attributes of a large number of login accounts can be managed by defining a login profile as the default for all login accounts, a subset of login accounts, or individual login accounts.

- 1. A system security officer creates a login profile for login accounts.
- 2. A system security officer creates a login account for a new user and associates the login profile to the new login account.
- 3. A system administrator or database owner adds a user to database or assigns a user to a group.
- 4. A system security officer grants specific roles to the user or to a login profile.
- 5. A system administrator, database owner, or object owner grants the user or group specific permissions on specific commands and database objects.

This example creates a login profile mgr lp:

```
create login profile mgr_lp
```

See create login profile in the Reference Manual: Commands.

4.6.4 Create Default Login Profiles

You can defining a login profile as the default profile for all login accounts.

The following example creates a default login profile named emp_lp. If another login profile is currently configured as the default login profile, the default property is removed and applied to emp_lp:

```
create login profile emp_lp as default
```

See create login profile in the Reference Manual: Commands.

4.6.5 Associate Login Profiles with a Login Account

If a login profile is not specified when creating a login account, the default login profile is associated with the new account.

If a default login does not exist, SAP ASE applies password policy attributes specified by sp_passwordpolicy or default attributes.

The following example creates the login account omar_khayyam with password rubaiyat and associates the account with the login profile emp lp:

```
create login khayyam with password rubaiyat login profile emp_lp
```

The following example modifies the login account omar_khayyam and associates the account with the login profile staff lp:

alter login khayyam modify login profile staff lp

4.6.6 Ignore Login Profiles

The ignore login profile clause is used to disable login profiles associated directly or through a default login profile.

Precedence rules are followed for applying the corresponding attributes of the login account.

The following example creates a login account and specifies to ignore any login profiles.

create login maryb with password itsAsecur8 login profile ignore

4.6.7 Transfer Existing Login Account Values to a New Login Profile

Transfer existing login account values to a new login profile.

This example shows you how to transfer existing login account values to a new login profile. The login profile sa_lp is created with default database, default language, and authenticate with attribute values set to the same values of the login account ravi.

```
create login profile sa lp with attributes from ravi
```

4.6.8 Manual Replication of Login Profiles

The profile ID is an attribute that specifies an ID for a new login profile and is used for manual replication of login profiles across SAP ASE.

For example, if the profile emp_1p with a profile ID of 25 is to be created on the replicate master, execute the following command:

```
create login profile emp_lp with profile id 25
```

4.6.9 Grant Roles to Login Profiles

Grant roles to login profiles when creating a login profile.

This example creates the login profile def 1p and grants the role access role to the login profile.

```
create login profile def_lp
grant role access_role to def_lp
```

Any login bound to def_lp will be implicitly granted access_role. The system security officer can specify a role granted to a login profile to behave as a default role for the bound logins, that is, the role is automatically activated in the user's session upon login.

If the default role has been granted to the login using a where clause to express an activation predicate, the default role is activated only if the activation predicate evaluates to true.

Related Information

Add or Drop Auto Activated Roles [page 69]

4.6.10 Invoke a Login Script

A login script can be specified to be invoked on login through a login profile.

The syntax is:

```
create login profile ravi_lp with login script 'empNew.script'
```

- A login script can be qualified by specifying the database where it resides and the owner name. When not qualified with a database name, the default database takes precedence over the master database.
- If the specified login script is not qualified with an owner name, the owner of the login trigger, which is the current login, takes precedence over the database owner where the login trigger resides.
- Stored procedures used as a login script through alter login, create login profile, and alter login profile, is restricted to 120 characters.

If a global login trigger is specified through $sp_logintrigger$, the login script is invoked after the global login trigger.

Related Information

Using Login Triggers [page 215]

4.6.11 Display Login Profile Information

Display information about login profiles such as the name, ID, and binding information.

Display a Login Profile Name

To display the login profile name of a specified login profile ID or login suid, use:

```
<lprofile_name>([{<login profile id> | <login suid>}])
```

System security officer role is required to view the profile name of the specified login ID if it is not the current user's login ID.

This example displays the login profile name of the specified login profile ID:

```
select lprofile_name(3)
-----
intern_lr
```

If no parameter is specified the login profile name of the current user is returned. If a login profile is not associated with the specified login account, then the login profile name of the default login profile is returned. The login profile ignore parameter must not be set.

The login profile name can also be displayed using sp_displaylogin. If a login profile is not directly associated with the login account and a default login profile exist, the name of the default login profile is displayed.

Display the Login Profile ID

To display the login profile ID of a specified login profile name or login name, use:

```
<lprofile>_id([{<login profile name> | <login name>}])
```

System security officer role is required to view the profile ID of the specified login name if it is not the current user's login name.

This example displays the login profile name of the specified login profile ID:

If a login profile is not associated with the specified login account, then the profile ID of the default login profile is returned. The login profile ignore parameter must not be set.

Display Login Profile Binding Information

Use sp securityprofile to display the login profile attributes associated with a login account.

i Note

A non-privileged login account can only display the attributes of a login profile that it is directly associated with, or the attributes of the default login profile. System security officer role is required to see attributes and bindings of all login profiles.

For more syntax information, see sp securityprofile, in Reference Manual: System Procedures.

4.6.12 Modify Login Profiles

The alter login profile command can be used to add, drop or change attributes of a login profile and their corresponding values.

If the attributes have not been specified, they will be added to the login profile.

This example removes the login script attribute from the login profile mgr_lp. If a login script is specified for the default login profile, it will be invoked on login, otherwise no login script will be invoked.

```
alter login profile mgr_lp drop login script
```

See alter login profile in the Reference Manual: Commands for complete syntax.

Related Information

Login Profile Attributes [page 63]

4.6.12.1 Add or Drop Auto Activated Roles

Previously granted user defined roles that are not password protected can be automatically activated on login.

The following modifies the login profile mgr_1p and automatically activates the roles mgr_role and eng_role when users associated with mgr_1p log in.

```
alter login profile mgr_lp add auto activated roles
    mgr_role, eng_role
```

The auto activated roles status of user defined roles granted to login profiles is indicated in the sysloginroles.status column. A value of '1' indicates the granted role must be automatically activated on login. Revoking a role will remove its corresponding row in sysloginroles and the role will not be automatically activated on login. Roles are automatically granted to a user's login profile as follows:

- 1. If a default login profile is associated with the account, any auto activated roles specified in the default login profile are applied.
- 2. If both a login profile that is directly associated with an account and a default login profile exist, only the auto activated roles specified in a login profile associated directly with the account are applied.

4.6.12.2 Change a Login Profile to be the Default Login Profile

The as [not] default clause is used to assign or remove a login profile as the default login profile.

The following statement alters the login profile named emp 1p as the default login profile.

```
alter login profile emp_lp as default
```

The following statement removes the login profile named emp 1p as the default login profile.

```
alter login profile userGroup_lp as not default
```

4.6.13 Drop Login Profiles

The command <code>drop login profile</code> removes the login profile if it is not bound to a login account.

Use drop login profile with override to forcefully remove a login profile that is bound to a login account. If the login profile is bound with a login account, the login account will be bound to the default login account, if one exist. If the login profile ignore clause has been specified, the clause is removed and the default login profile, if it exists, will be associated with the login account.

This example forcefully removes the login profile eng 1p even if it is bound to one or more login accounts.

drop login profile eng lp with override

4.7 Securely Automate Database Administration Tasks Using Secure User Store

With secure user store feature, you can connect to the SAP ASE server without explicitly entering username and password in the command line interface; instead, you can establish the connection between a client application and the SAP ASE server using a user-generated key that retrieves the connection information (username, password, host, and port number) from the secure store.

Use the aseuserstore utility to create and manage the secure store, generate user keys, and add those keys to the secure store. The feature is supported for ADO.NET, ODBC, jConnect, and SAP ASE native client applications.

Each client category (for example, ADO.NET or ODBC) requires its own entry in the secure store, even when the connection parameters are the same.

This password-less connection option lets you automate database administration tasks without compromising data confidentiality. The aseuserstore utility is located in:

- (UNIX) \$SYBASE/OCS-16 0/bin
- (Windows) %SYBASE%\OCS-16_0\bin

4.7.1 How Does the aseuserstore Utility Work?

The assuserstore utility provides commands to store client connection information in the secure store.

Use the aseuserstore utility commands to insert, list, and delete connection information in the form of user keys in the secure store. Each user key consists of a username and password, and optionally a hostname, port number, and a database name.

Users are encouraged to periodically change the secure store's encryption key using the aseuserstore utility's CHANGEKEY command. If there are changes to the client connection parameters (change in the port number, for instance), re-run the aseuserstore utility for that key with its new key value (that is, the new port number). Its corresponding entry is then updated in the secure store.

i Note

The assuserstore utility stores the secure user store in \$HOME/.ase/<hostname>, where <hostname> is the name of the host where you have executed the command. If you need to override the default hostname, use the utility's -H option.

4.7.2 Using the aseuserstore Utility With Other SAP ASE Utilities

isql, bcp, defncopy, and optdiag utilities include the -k parameter, which retrieves username, password, and server connection information from the secure store. With the -k parameter, you need to provide the key name while using these utilities to connect to the SAP ASE server.

In the following example, user ralph creates a secure store key to connect to SAP ASE:

```
aseuserstore -i
Command: set
Key: ralphkey
Connection info: ralph_server 5000
Username: ralph
Password:
```

User ralph now uses this secure store key with the isql utility to connect to ralph_server instead of the standard -U<username> -P<password> -S<servername> parameters:

```
isql -k ralphkey
1>
```

4.7.3 Using the aseuserstore Utility With the Client Applications

To use the secure user store feature, client applications use the following properties in their respective connection strings. It retrieves the connection information from the secure store:

- For CT-Library Connection property CS SECSTOREKEY
- For JDBC/jConnect Connection property SECURE STORE KEY
- For ODBC Connection property SecStoreKey
- For ADO.NET Connection property SecStoreKey

i Note

When using the secure store option, username and password are always retrieved from the secure store. If you specify the username and/or password in the connection string also, it results in an error. Other connection parameters are optional, and may be specified in the connection string if they are not set in the secure store. If you specify connection parameters in both the connection string and secure store, their values must match for the connection to succeed.

4.7.4 Operating System Support

The 64-bit versions of the following platforms support the aseuserstore utility and the client applications that use the secure user store feature:

- Microsoft Windows x86-64 64-bit
- HP HP-UX Itanium 64-bit
- Linux x86-64 64-bit
- Solaris SPARC 64-bit (SVR4)
- Solaris x86-64 64-bit
- IBM AIX 64-bit

4.8 Add Users to Databases

The database owner or a system administrator can use sp adduser to add a user to a specific database.

The user must already have an SAP ASE login. The syntax is:

```
sp_adduser <loginame> [, <name_in_db >[, <grpname>]]
```

Where:

- <loginame> is the login name of an existing user.
- <name_in_db> specifies a name that is different from the login name by which the user is to be known inside the database.

Use <name_in_db> to accommodate users' preferences. For example, if there are five users named Mary, each must have a different login name. Mary Doe might log in as "maryd", Mary Jones as "maryj", and so on. However, if these users do not use the same databases, each might prefer to be known simply as "mary" inside a particular database.

If no <name_in_db> parameter is given, the name inside the database is the same as loginame.

i Note

This capability is different from the alias mechanism described in "Using Aliases in Databases," which maps the identity and permissions of one user to another.

<grpname> – is the name of an existing group in the database. If you do not specify a group name, the user
is made a member of the default group "public." Users remain in "public" even if they are a member of
another group.

sp_adduser adds a row to the sysusers system table in the current database. When a user has an entry in the sysusers table of a database, he or she:

- Can issue use <database name> to access that database
- Will use that database by default, if the default database parameter was issued as part of create login
- Can use alter login to make that database the default

This example shows how a database owner can give access permission to "maryh" of the engineering group "eng," which already exists:

```
sp_adduser maryh, mary, eng
```

This example shows how to give "maryd" access to a database, keeping her name in the database the same as her login name:

```
sp adduser maryd
```

This example shows how to add "maryj" to the existing "eng" group, keeping her name in the database the same as her login name by using null in place of a new user name:

```
sp adduser maryj, null, eng
```

Users who have access to a database still need permissions to read data, modify data, and use certain commands. These permissions are granted with the grant and revoke commands.

Related Information

Change Group Membership [page 76]

4.8.1 Add a "guest" User to a Database

Creating a user named "guest" in a database enables any user with an account to access the database as a guest user.

If a user who has not been added to the database as a user or an aliased user issues the use <database_name> command, SAP ASE looks for a guest user. If there is one, the user is allowed to access the database, with the permissions of the guest user.

The database owner can use sp adduser to add a guest entry to the sysusers table of the database:

```
sp_adduser guest
```

The guest user can be removed with sp dropuser...

If you drop the guest user from the master database, server users who have not yet been added to any databases cannot log in to the server.

i Note

Although more than one individual can be a guest user in a database, SAP ASE can still use the user's server user ID, which is unique within the server, to audit each user's activity.

4.8.1.1 "guest" User Permissions

When you install SAP ASE, master..sysusers contains a guest entry.

The database owner and the owners of database objects can use grant and revoke to make the privileges of "guest" either more or less restrictive than those of "public." "guest" inherits the privileges of "public."

4.8.1.2 "guest" User in User Databases

In user databases, the database owner adds a guest user that permits all Adaptive Server users to use that database, which saves the owner from having to use <code>sp_adduser</code> to explicitly name each user as a database user.

You can use the guest mechanism to restrict access to database objects while allowing access to the database.

For example, the owner of the titles table can grant select permission on titles to all database users except "guest" by executing:

```
grant select on titles to public
sp_adduser guest
revoke all on titles from guest
```

4.8.1.3 "guest" User in Installed System Databases

SAP ASE creates the system tempdb database and user-created temporary databases with a guest user.

Temporary objects and other objects created in tempdb are automatically owned by user "guest." sybsystemprocs, sybsystemdb, and sybsyntax databases automatically include the "guest" user.

4.8.1.4 "guest" User in pubs2 and pubs3

The "guest" user entry in the sample databases allows new users to follow the examples in the Transact-SQL Users Guide.

The guest is given a wide range of privileges, including:

- select permission and data modification permission on all of the user tables
- execute permission on all of the procedures
- create table, create view, create rule, create default, and create procedure permissions

4.8.2 Add Guest Users to the Server

The system security officer can use create login to enter a login name and password that visiting users are instructed to use.

Typically, such users are granted restricted permissions. A default database may be assigned.

A visitor user account is not the same as the "guest" user account. All users of the visitor account have the same server user ID; therefore, you cannot audit individual activity. Each "guest" user has a unique server ID, so you can audit individual activity and maintain individual accountability. SAP recommends that you do not set up a visitor account to be used by more than one user because you cannot maintain individual accountability.

You can use create login to add a visitor user account named "guest" to master..syslogins. This "guest" user account takes precedence over the system "guest" user account. If you add a visitor user named "guest" with sp_adduser, this impacts system databases such as sybsystemprocs and sybsystemdb, which are designed to work with system "guest" user in them.

4.8.3 Add Remote Users

You can allow users on another SAP ASE server to execute stored procedures on your server by enabling remote access.

Working with the system administrator of the remote server, you can also allow users of your server to execute remote procedure calls to the remote server.

To enable remote procedure calls, you must reconfigure both the local and the remote servers. See "Managing Remote Servers" in the *System Administration Guide, Volume I.*

4.9 Create Groups

Groups let you grant and revoke permissions to more than one user in a single statement, as well as allow you to provide a collective name to a group of users.

Groups are especially useful if you administer an SAP ASE installation that has a large numbers of users.

Create groups before adding users to a database, since sp_adduser can assign users to groups as well as add them to the database.

You must have the system administrator or system security officer role, or be the database owner to create a group with sp addgroup. The syntax is:

sp_addgroup <grpname>

The group name, a required parameter, must adhere to the rules for identifiers. The system administrator, system security officer, or the database owner can use <code>sp_changegroup</code> to assign or reassign users to groups.

For example, to set up the Senior Engineering group, use this command while using the database to which you want to add the group:

```
sp_addgroup senioreng
```

sp_addgroup adds a row to sysusers in the current database. Therefore, each group in a database, as well as each user, has an entry in sysusers.

4.9.1 Change Group Membership

A system administrator, system security officer, or the database owner can use sp_changegroup to change a user's group affiliation.

Each user can be a member of only one group other than "public," of which all users are always members.

Before you execute sp changegroup:

- The group must exist.
- The user must have access to the current database (must be listed in sysusers).

The syntax for sp changegroup is:

```
sp_changegroup <grpname>, <username>
```

For example, to change the user "jim" from his current group to the group "management," use:

```
sp_changegroup management, jim
```

To remove a user from a group without assigning the user to another group, you must change the group affiliation to "public":

```
sp_changegroup "public", jim
```

The name "public" must be in quotes because it is a reserved word. This command reduces Jim's group affiliation to "public" only.

When a user changes from one group to another, the user loses all permissions that he or she had as a result of belonging to the old group, but gains the permissions granted to the new group.

The assignment of users into groups can be changed at any time.

4.9.2 Create Groups and Add Users

The system security officer, the system administrator, or the database administrator creates a group using sp addgroup <group name>.

You can grant and revoke permissions at the group level. Group permissions are automatically passed to group members. Every database is created with a group named "public" to which all users automatically belong. Add a user to a group using sp_adduser and change a user's group with sp_changegroup.

Groups are represented by an entry in the sysusers table. You cannot use the same name for creating a group and a user in the database (for example, you cannot have both a group and a user named "shirley").

4.10 Aliases in Databases

The alias mechanism allows you to treat two or more users as the same user inside a database so that they all have the same privileges.

This mechanism is often used so that more than one user can assume the role of database owner. A database owner can use the setuser command to impersonate another user in the database. You can also use the alias mechanism to set up a collective user identity.

For example, suppose that several vice presidents want to use a database with identical privileges and ownerships. If you add the login "vp" to the server and the database and have each vice president log in as "vp," there is no way to tell the individual users apart. Instead, alias all the vice presidents, each of whom has his or her own account, to the database user name "vp."

i Note

Although more than one individual can use the alias in a database, you can still maintain individual accountability by auditing the database operations performed by each user.

The collective user identity from using aliases implies set-ownership for database objects. For example, if user "loginA" is aliased to dbo in database db1, all objects created by "loginA" in db1 are owned by dbo. However, an object's ownership is concretely recorded in terms of the login name and the creator's database user ID. An alias cannot be dropped from a database if he or she concretely owns objects in that database.

i Note

You cannot drop the alias of a login if that login created objects in the database. In most cases, use aliases only for users who do not own tables, procedures, views, or triggers.

Related Information

Auditing [page 337]
Concrete Identification [page 171]

4.10.1 Add Aliases

Use sp_addalias to add an alias for a user. Executing sp_addalias maps the user name specified by <loginame > to the user name specified by <name in db>.

The syntax is:

```
sp_addalias <loginame>, <name_in_db>
```

where:

- <loginame> is the name of the user who wants an alias in the current database. This user must have an account but cannot be a user in the current database.
- <name_in_db> is the name of the database user to whom the user specified by <loginame> is to be linked. The <name in db> must exist in sysusers in the current database.

Adding an alias adds a row to the system table sysalternates.

When a user tries to use a database, a check is performed for the user's server user ID number in sysusers. If it is not found, then sysalternates is checked. If the user's <suid> is found there, and it is mapped to a database user's <suid>, the first user is treated as the second user while the first user is using the database.

For example, suppose that Mary owns a database. She wants to allow both Jane and Sarah to use the database as if they were its owner. Jane and Sarah have logins but are not authorized to use Mary's database. Mary executes the following commands:

```
sp_addalias jane, dbo
exec sp_addalias sarah, dbo
```

Users who are aliased to the database owner have all the permissions and can perform all the actions that can be performed by the database owner, with respect to the database in question. A database owner should carefully consider the implications of vesting another user with full access to a database.

4.10.2 Drop Aliases

Use sp dropalias to drop the mapping of an alternate <suid> to a user ID.

Dropping the mapping of an alternate <suid> to a user ID deletes the relevant row from sysalternates.

The syntax is the following, where <loginame> is the name of the user specified by <loginame> when the name was mapped with sp addalias:

```
sp_dropalias< loginame>
```

After a user's alias is dropped, the user no longer has access to the database.

You cannot drop an alias if the aliased login created any objects or thresholds. Before using sp_dropalias to remove an alias that has performed these actions, remove the objects or procedures. If you still need them after dropping the alias, re-create them with a different owner.

4.10.3 Information About Aliases

To display information about aliases, use sp_helpuser.

For example, to find the aliases for "dbo," execute:

```
Users_name ID_in_db Group_name Login_name

dbo 1 public sa
(1 row affected)

Users aliased to user.
Login_name
andy
christa
howard
linda
```

4.11 Obtain Information About Users

Obtain information about users, groups, and current usage using these procedures.

Task	Procedure
Report current users and processes	sp_who
Display information about login accounts	sp_displaylogin
Report users and aliases in a database	sp_helpuser
Report groups within a database	sp_helpgroup

4.11.1 Report on Users and Processes

Use sp_who to report information about current users and processes.

The syntax is:

```
sp_who [<loginame> | "<spid>"]
```

where:

• <loginame> – is the user's login name. If you provide a login name, sp_who reports information about processes being run by that user.

<spid> – is the number of a specific process.

For each process run, sp_who reports the security-relevant information for the server process ID, its status, the login name of the process user, the real login name (if $<login_name>$ is an alias), the name of the host computer, the server process ID of a process that is blocking this one (if any), the name of the database, and the command being run.

If you do not provide a login name or spid>, sp_who reports on processes being run by all users.

The following example shows the security-relevant results from executing sp who without a parameter:

```
fid spid status loginame origname hostname blk spid dbname tempdbname cmd block xloid threadpool
                                   sunbird 0 pubs2 tempdb
                                                                 SELECT
   1 running
                                                                                   0 syb default pool
                                              0 master tempdb METWORK HANDLER 0 syb default pool 0 master tempdb MIRROR HANDLER 0 syb default pool
      sleeping
  3 sleeping
Ω
                  NULL
                           NULL
                                                                                   0 syb_default_pool
                                                                 AUDIT PROCESS
       sleeping
                  NULL
                           NULL
                                              0 master tempdb
                                              0 master tempdb CHECKPOINT SLEEP 0 syb_default_pool
    5 sleeping NULL
                           NULL
```

sp who reports NULL for the <loginame> for all system processes.

4.11.2 Obtain Information about Login Accounts

Use sp_displaylogin to display information about a specified login account—or login names matching a wild-card pattern—including any roles granted, where <loginame> (or the wildcard matching pattern) is the user login name pattern about which you want information.

The syntax is:

```
sp_displaylogin [<loginame> | <wildcard>]
```

If you are not a system security officer or system administrator, you can display information only about your own account. If you are a system security officer or system administrator, you can use the <loginame> | <wildcard> parameter to access information about any account.

sp_displaylogin displays your server user ID, login name, full name, any roles that have been granted to you, date of last password change, default database, default language, whether your account is locked, any auto-login script, password expiration interval, whether password has expired, the login password encryption version used, and the authentication mechanism specified for the login.

 $sp_displaylogin$ displays all roles that have been granted to you, so even if you have made a role inactive with the set command, that role appears. For example, this displays the roles for the sa:

```
Suid: 121
Loginame: mylogin
Fullname:
Default Database: master
Default Language:
Auto Login Script:
Configured Authorization:
    sa_role (default ON)
    sso_role (default ON)
    oper role (default ON)
```

```
sybase_ts_role (default ON)
Locked: NO
Date of Last Password Change: Aug 10 2006 11:17AM
Password expiration interval: 0
Password expired: NO
Minimum password length: 6
Maximum failed logins: 0
Current failed login attempts:
Authenticate with: NONE
Login password encryption: SYB-PROP, SHA-256
Last login date: Aug 17 2006 5:55PM
(return status = 0)
```

4.11.3 Obtain Information About Database Users

Use sp helpuser to report information about authorized users of the current database.

Where <name_in_db> is the user's name in the current database:

```
sp_helpuser [<name_in_db>]
```

If you give a user's name, $sp_helpuser$ reports information about that user. If you do not give a name, it reports information about all users.

The following example shows the results of executing sp_helpuser without a parameter in the database pubs2:

```
Users_name ID_in_db Group_name Login_name

dbo 1 public sa
marcy 4 public marcy
sandy 3 public sandy
judy 5 public judy
linda 6 public linda
anne 2 public anne
jim 7 senioreng jim
```

4.11.4 Find User Names and IDs

To find a user's server user ID or login name, use suser_id and suser_name.

lo find	Use	With the argument
Server user ID	suser_id	(["server_user_name"])
Server user name (login name)	suser_name	([server_user_ID])

The arguments for these system functions are optional. If you do not provide one, information about the current user is shown.

This example shows how to find the server user ID for the user "sandy:"

```
select suser_id("sandy")
-----
3
```

This example shows how a system administrator whose login name is "mary" issues the commands without arguments:

```
select suser_name(), suser_id()

-----
mary 4
```

To find a user's ID number or name inside a database, use user_id and user_name.

Table 6: System functions user_id and user_name

To find	Use	With the argument
User ID	user_id	(["db_user_name"])
User name	user_name	([db_user_ID])

The arguments for these functions are optional. If you do not provide one, information about the current user is shown. For example:

4.12 Change User Information

Commands and system procedures used to change passwords, default database, default language, full name, or group assignment.

Task	Required role	System procedure	Master database for: al- ter/create/drop login/ login profile commands
Change your password	User	alter login	Any database
Change another user's password	System security officer	alter login	Any database
Change authentication mechanism	System security officer	alter login alter login profile	Any database
Change full name	System security officer	alter login	Any database
Change your own full name	User	alter login	Any database
Change default language or default database	System security officer	alter login profilealter login	Any database
Change the group assignment of a user	System administrator, data- base owner, or system se- curity officer	sp_changegroup	User database
Changing a login profile	System security officer	alter login profile	Any database
Configuring a login trigger	System security officer	alter login profile	Any database

4.12.1 Change Passwords

All users can change their passwords at any time using alter login. The system security officer can use alter login to change any user's password.

For example, to the password of the login account named ron, enter:

alter login ron with password watsMypaswd modify password 8itsAsecret $\,$

See alter login in Reference Manual: Commands.

4.12.1.1 Require New Passwords

You may choose to use the systemwide password expiration configuration parameter to establish a password expiration interval, which forces all users to change their passwords on a regular basis.

Even if you do not use systemwide password expiration, it is important, for security reasons, that users change their passwords periodically. See *Reference Manual: Configuration Parameters*..

The configuration parameter is superseded by the password policy settings.

password expiration interval specifies the password expiration interval in days. It can be any value between 0 and 32767, inclusive. For example, if you create a new login on August 1, 2012 at 10:30 a.m., with a password expiration interval of 30 days, the password expires on August 31, 2012 at 10:30 a.m.

The column pwdate in the syslogins table records the date of the last password change. The following query selects all login names whose passwords have not changed since September 15, 2012:

```
select name, pwdate
from syslogins
where pwdate < "Sep 15 2012"
```

4.12.1.2 Null Passwords

Secure login accounts with a non-null password.

Do not assign a null password. When SAP ASE is installed, the default "sa" account has a null password. This example shows how to change a null password to a valid one:

```
alter login sa with password null modify password 8M4LNC
```

i Note

Do not enclose "null" in quotes in the statement.

4.12.1.3 Log in After Lost Password

Use the dataserver command to set new passwords sa and sso accounts and roles that are locked or when passwords have been lost.

You can use dataserver -p<login name> if your site encounters any of these situations:

- All system administrator login accounts are locked.
- All system security officer login accounts are locked.
- The password for sa role or sso role has been lost.

The dataserver parameter, with the -p parameter allows you to set a new password for these accounts and roles. <login_name> is the name of the user or the name of the role (sa_role or sso_role) for which the password must be reset.

When you start with the -p parameter, SAP ASE generates, displays, and encrypts a random password and saves it in master..syslogins or in master...

Sybase strongly recommends that you change the password when the server restarts. For example, to reset the password for user rsmith who has sa role:

```
dataserver -prsmith
```

To reset the password of the sso role:

```
dataserver -psso_role
```

4.12.2 Change User Session Information

The set command includes options that allow you to assign each client an individual name, host name, and application name.

This is useful for differentiating among clients in a system where many clients connect to an SAP ASE server using the same name, host name, or application name.

The partial syntax for the set command is:

```
set [clientname <client_name> | clienthostname <host_name> | clientapplname
<application_name>]
```

where:

- <cli><cli>name> is the name you are assigning the client.
- <host name> is the name of the host from which the client is connecting.
- <application name> is the application that is connecting to SAP ASE.

These parameters are stored in the clientname, clienthostname, and clientapplname columns of the sysprocesses table.

For example, if a user logs in as "client1," you can assign them an individual client name, host name, and application name using commands similar to:

```
set clientname 'alison'
set clienthostname 'money1'
set clientapplname 'webserver2'
```

This user now appears in the <code>sysprocesses</code> table as user "alison" logging in from host "money1" and using the "webserver2" application. However, although the new names appear in <code>sysprocesses</code>, they are not used for permission checks, and <code>sp_who</code> still shows the client connection as belonging to the original login (in the case above, client1). <code>set clientname</code> does not perform the same function as <code>set proxy</code>, which allows you to assume the permissions, login name, and <code>suid></code> of another user.

You can set a client name, host name, or application name for only your current client session (although you can view the connection information for any client connection). Also, this information is lost when a user logs out. These parameters must be reassigned each time a user logs in. For example, the user "alison" cannot set the client name, host name, or application name for any other client connection.

Use the client's system process ID to view their connection information. For example, if the user "alison" described above connects with a \mathtt{spid} of 13, issue the following command to view all the connection information for this user:

```
select * from sysprocesses where spid = 13
```

To view the connection information for the current client connection (for example, if the user "alison" wanted to view her own connection information), enter:

```
select * from sysprocesses where spid = @@spid
```

4.13 Drop Users and Groups

A system administrator, system security officer, or database owner can use <code>sp_dropuser</code> or <code>sp_dropgroup</code> to drop users and groups from databases.

Dropping Users

A database owner, system security officer, or a system administrator can use sp_dropuser to deny a user access to the database in which sp_dropuser is executed. (If a "guest" user is defined in that database, the user can still access that database as "guest.")

The following is the syntax, where <name_in_db> is usually the login name, unless another name has been assigned with sp adduser:

```
sp_dropuser <name_in_db>
```

You cannot drop a user who owns objects. For tables owned by the user, you can use alter table modify owner to change the ownerships to other users before you drop the user. For other types of objects, you cannot transfer ownership of objects, you must drop objects owned by a user before you drop the user. To deny access to a user who owns objects, use sp locklogin to lock his or her account.

You also cannot drop a user who has granted permissions to other users. Use revoke with cascade to revoke permissions from all users who were granted permissions by the user to be dropped, then drop the user. You must then grant permissions to the users again, if appropriate.

Dropping Groups

The system security officer, the system administrator, or the database administrator uses $sp_dropgroup$ to drop a group. The syntax is:

```
sp_dropgroup <grpname>
```

You cannot drop a group that has members. If you try to do so, the error report displays a list of the members of the group you are attempting to drop.

Related Information

Change Group Membership [page 76]

4.14 Monitor License Use

The License Use Monitor allows a system administrator to monitor the number of user licenses used in SAP ASE, and to securely manage the license agreement data.

You can ensure that the number of licenses used on your SAP ASE server does not exceed the number specified in your license agreement. The License Use Monitor tracks the number of licenses issued; it does not enforce the license agreement. If the License Use Monitor reports that you are using more user licenses than specified in your license agreement, see your SAP sales representative.

You must have system administrator privileges to configure the License Use Monitor; by default the monitor is turned off when SAP ASE is installed or upgraded.

4.14.1 How Licenses are Counted

A license is the combination of a host computer name and a user name. If a user logs in multiple times from the same host machine, one license is used. However, if the user logs in once from host A, and once from host B, two licenses are used.

If multiple users log in from the same host, but with different user names, each distinct combination of user name and host name uses one license.

4.14.2 Configure the License Use Monitor

Use sp configure to specify the number of licenses in your license agreement.

Where <number > is the number of licenses:

```
sp_configure "license information" , <number>
```

This example sets the maximum number of user licenses to 300, and reports an overuse for license number 301:

```
sp_configure "license information", 300
```

If you increase the number of user licenses, you must also change the license information configuration parameter.

4.14.3 Monitor License Use with the Housekeeper Task

After you configure the License Use Monitor, the housekeeper task determines how many user licenses are in use, based on the user ID and the host name of each user logged in to SAP ASE.

The License Use Monitor updates a variable that tracks the maximum number of user licenses in use:

- If the number of licenses in use is the same or has decreased since the previous housekeeper run, the License Use Monitor does nothing.
- If the number of licenses in use has increased since the previous housekeeper run, the License Use Monitor sets this number as the maximum number of licenses in use.
- If the number of licenses in use is greater than the number allowed by the license agreement, the License Use Monitor issues this message to the error log:

```
Exceeded license usage limit. Contact SAP Sales for additional licenses.
```

The housekeeper chores task runs during idle cycles. Both the housekeeper free write percent and the license information configuration parameter must be set to values greater than or equal to 1 for the License Use Monitor to track license use.

For more information about the housekeeper chores task, see "Using Engines and CPUs," in the *Performance* and *Tuning Series:Basics*.

4.14.4 Log the Number of User Licenses

The syblicenseslog system table is created in the master database when you install or upgrade SAP ASE. The License Use Monitor updates the columns in syblicenseslog at the end of each 24-hour period.

These are the columns in the syblicenseslog table.

Column	Description	
status	-1 – housekeeper cannot monitor licenses.	
	0 – number of licenses not exceeded.	
	1 – number of licensees exceeded.	
logtime	Date and time the log information was inserted.	
maxlicenses	Maximum number of licenses used during the previous 24 hours.	

syblicenseslog looks similar to this:

1	Jul 19 2012 11:51AM	154
0	Jul 20 2012 11:55AM	142
0	Jul 21 2012 11:58AM	138
0	Jul 21 2012 3:14PM	133

In this example, the number of user licenses used exceeded the limit on July 19, 2012.

If SAP ASE is shut down, License Use Monitor updates syblicenseslog with the current maximum number of licenses used. SAP ASE starts a new 24-hour monitoring period when it is restarted.

The second row for July 21, 2012 was caused by a shutdown and restart of the server.

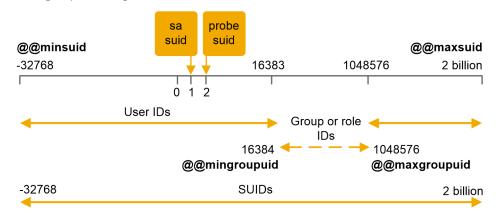

4.15 Number of User and Login IDs

SAP ASE supports over 2,000,000,000 logins per server and users per database. Negative numbers as well as positive numbers are used to increase the range of possible numbers available for IDs.

These are the valid ranges for the ID types:

ID type	Server limits
Logins per server (<suid>)</suid>	2 billion plus 32K
Users per database (<uid>)</uid>	2 billion less 1032193
Groups or roles per database (<gid>)</gid>	16,384 to 1,048,576

Users, groups, and logins available:

You may use negative values for user IDs (<uid>).

The server user ID (<suid>) associated with a group or a role in sysusers is not equal to the negation of their user ID (<uid>). Every <suid> associated with a group or a role in sysusers is set to -2 (INVALID_SUID).

4.16 Login Connection Limitations

Although you are allowed to define more than two billion logins per server, the actual number of users that can connect at one time is limited.

The actual number of users is limited by the:

- Value of the number of user connections configuration parameter, and
- Number of file descriptors available. Each login uses one file descriptor for the connection.

i Note

The maximum number of concurrent tasks running on the server is 32,000.

Allowing the Maximum Number of Logins and Simultaneous Connections

Configure the operating system on which SAP ASE is running for at least 32,000 file descriptors, then the value of number of user connections to at least 32,000.

i Note

To have more than 64K logins and simultaneous connections, you must first configure the operating system for more than 64K file descriptors. See your operating system documentation for information about increasing the number of file descriptors.

These are the global variables for logins, users, and groups:

Name of variable	What it displays	Value
<@@invaliduserid>	Invalid user ID	-1
<@@minuserid>	Lowest user ID	-32768
<@@guestuserid>	Guest user ID	2
<@@mingroupid>	Lowest group or role user ID	16384
<@@maxgroupid>	Highest group or role user ID	1048576
<@@maxuserid>	Highest user ID	2147483647
<@@minsuid>	Lowest server user ID	-32768
<@@probesuid>	Probe server user ID	2
<@@maxsuid>	Highest server user ID	2147483647

To issue a global variable, enter:

select <variable_name>

For example:

4.17 Obtain Information About Usage: Chargeback Accounting

When a user logs in, the server begins accumulating CPU and I/O usage for that user. Total usage is reported for an individual, or for all users.

Information for each user is stored in the syslogins system table in the master database.

Reporting Current Usage Statistics

The system administrator can use sp_reportstats or sp_clearstats to get or clear current total usage data for individuals or for all users.

Displaying Current Accounting Totals

sp_reportstats displays current accounting totals for users. It reports total CPU and total I/O, as well as the percentage of those resources used. It does not record statistics for the "sa" login (processes with an <suid> of 1), checkpoint, network, and mirror handlers.

Initiating a New Accounting Interval

CPU and I/O statistics are accumulated until you clear the totals from syslogins by running $sp_clearstats$. $sp_clearstats$ initiates a new accounting interval for users and executes $sp_reportstats$ to print out statistics for the previous period.

Choose the length of your accounting interval by deciding how to use the statistics at your site. For example, to do monthly cross-department charging for the percentage of CPU and I/O usage, run $sp_clearstats$ once a month

For detailed information about these stored procedures, see the *Reference Manual: Procedures*.

4.17.1 Specify the Interval for Adding Accounting Statistics

A system administrator can use configuration parameters to decide how often accounting statistics are added to syslogins.

To specify how many machine clock ticks accumulate before accounting statistics are added to syslogins, use the cpu accounting flush interval configuration parameter. The default value is 200. For example:

```
sp_configure "cpu accounting flush interval", 600
```

To find out how many microseconds a tick is on your system, run the following query:

```
select @@timeticks
```

To specify how many read or write I/Os accumulate before the information is added (flushed) to syslogins, use the i/o accounting flush interval configuration parameter. The default value is 1000. For example:

```
sp_configure "i/o accounting flush interval", 2000
```

I/O and CPU statistics are flushed when a user accumulates more I/O or CPU usage than the specified value. The information is also flushed when the user exits a session.

The minimum value allowed for either configuration parameter is 1. The maximum value allowed is 2.147.483.647.

5 Manage Roles

Roles are collections of privileges that allow the role assignee to perform their job. The roles supported by SAP ASE let you enforce individual accountability.

SAP ASE provides system roles, such as system administrator and system security officer, and user-defined roles, which are created and granted to users, login profiles, or other roles by a system security officer. Object owners can grant database access as appropriate to a role.

The final steps in adding database users are assigning them special roles, as required, and granting permissions.

i Note

Permission requirements for operations mentioned in this chapter assume that granular permissions is disabled. Operations may differ when granular permissions is enabled.

Related Information

Granular Permissions [page 242] Manage User Permissions [page 166]

5.1 System-Defined Roles Overview

System roles, values, and tasks.

These are the system roles, the value to use for the role_name option of the grant role or revoke role command, and the tasks usually performed by a person with that role.

Role	Value for role_granted	Description
System administrator	sa_role	Manage and maintain databases and disk storage
System security officer	sso_role	Perform security-related tasks
Operator	oper_role	Back up and load databases server-wide
Technical Support	sybase_ts_role	Analysis and repair of database structures
Replication	replication_role	Replicate user data

Role	Value for role_granted	Description
Distributed transaction manager	dtm_tm_role	Coordinate transactions across servers
High availability	ha_role	Administer and execute failover
Monitor and diagnosis	mon_role	Administer and execute performance and diagnostic monitoring
Job Scheduler administration	js_admin_role	Administer Job Scheduler
Job Scheduler user	<pre>js_user_role, js_client_role</pre>	Create and run jobs through Job Scheduler
Real-time messaging	messaging_role	Administer and executer real-time messaging
Web Services	webservices_role	Administer Web services
Key custodian	keycustodian_role	Create and manage encryption keys
Navigation Server	navigator_role	Though navigator_role is present in syssrvroles, this role is not used in SAP ASE and is obsolete.

i Note

sa_role is grantable by a user who has sa_role. All other system role are grantable by a user with sso_role. If a user defined role has been granted both sa_role and other system roles, that role may be granted only by a user who has both sa_role and sso_role.

sa_serverprivs_role is a user defined role that is enabled automatically for the system administrator.

Related Information

Granular Permissions Adds the sa_serverprivs_role [page 256]

5.2 System Roles

System-defined roles restrict system access to authorized users.

System Administrator Privileges

System administrators handle tasks that are not application-specific and work outside the SAP ASE discretionary access control system.

The role of system administrator is usually granted to individual logins. All actions taken by that user can be traced to his or her individual server user ID. If the server administration tasks at your site are performed by a single individual, you may instead choose to use the "sa" account that is installed with SAP ASE. At installation, the "sa" account user can assume the system administrator, system security officer, and operator roles. Any user who knows the "sa" password can log in to that account and assume any or all of these roles.

Having a system administrator operate outside the protection system serves as a safety precaution. For example, if the database owner accidentally deletes all the entries in the sysusers table, the system administrator can restore the table (as long as backups exist). There are several commands that can be issued only by a system administrator. They include disk init, disk refit, disk reinit, shutdown, kill, disk mirror, mount, unmount and several monitoring commands.

In granting permissions, a system administrator is treated as the object owner. If a system administrator grants permission on another user's object, the owner's name appears as the grantor in sysprotects and in sp_helprotect output.

System administrators automatically assume the identity of a database owner when they log in to a database, and assume all database owner privileges. This automatic mapping occurs, regardless of any aliases assigned to the user. The system administrator can perform tasks usually reserved for the database owner such as dbcc commands, diagnostic functions, reading data pages, and recovering data, or indexes.

System Security Officer Privileges

System security officers perform security-sensitive tasks, including:

- Granting the system security officer, operator, and key custodian roles
- Administering the audit system
- Changing passwords
- · Adding new logins
- Dropping logins
- Locking and unlocking login accounts
- Creating and granting user-defined roles
- Administering network-based security
- Granting permission to use the set proxy or set session authorization commands
- Creating login profiles
- Managing encryption

The system security officer can access any database—to enable auditing —but, in general, has no special permissions on database objects (except for encryption keys and decrypt permission on encrypted columns. See *Database Encryption*). An exception is the sybsecurity database, where only a system security officer can access the sysaudits table. There are also several system procedures that can be executed only by a system security officer.

System security officers can repair any changes inadvertently done to the protection system by a user. For example, if a database owner forgets the password, a system security officer can change the password to allow the database owner to log in.

The system security officers share login management responsibilities with system administrators. System security officers are responsible for managing logins and login profiles.

System security officers can grant all system roles except sa_role. They can also create and grant user-defined roles to users, other roles, login profiles, or groups.

Operator Privileges

Users who have been granted the operator role can back up and restore databases on a server-wide basis without having to be the owner of each database. The operator role allows a user to use these commands on any database:

- dump database
- dump transaction
- load database
- load transaction
- checkpoint
- online database

Technical Support

A Technical Support engineer can use the Technical Support role to display internal memory and on-disk data structures using trace output, consistency checking, and patching data structures.

This role is used for analyzing problems and manually recovering data. Some actions necessary for resolving these issues may require additional system roles for access. SAP recommends that the system security officer grant this role to a knowledgeable SAP engineer only while this analysis or repair is being done.

Replication Role

The user maintaining Replication Server and ASE Replicator requires the replication role. See the *Replication Server Administration Guide* and the *ASE Replicator Users Guide* for information about this role.

Distributed Transaction Manager Role

The distributed transaction manager (DTM) transaction coordinator uses this role to allow system stored procedures to administer transactions across servers. Clients using the DTM XA interface require this role. See *Using Adaptive Server Distributed Transaction Management Features*

High Availability Role

You must have the high availability role to configure the high availability subsystem to administer primary and companion servers through commands and stored procedures. See *Using Sybase Failover in a High Availability System*

Monitoring and Diagnosis

This role is required to administer the monitoring tables. You must have this role to execute a monitoring table remote procedure call and to administer the collection of monitored data. See the *Performance and Tuning Series: Monitoring Tables*

Job Scheduler Roles

The Job Scheduler has three system roles to manage permissions for its operation:

- js_admin_role required to administer Job Scheduler, and provides access to the stored procedures and allow you to modify, delete, and perform Job Scheduler administrative operations.
- js_user_role required for a user to create, modify, delete, and run scheduled jobs using the Job Scheduler stored procedures.
- js client role allows users to work with predefined jobs but not to create or alter jobs.

See the Job Scheduler Users Guide for more information.

Real-time Messaging Role

Used by the real-time messaging subsystem (RTMS) execute msgsend, msgrecv, and certain sp_msgadmin commands. See the Messaging Services User's Guide for more information.

Web Services Role

Used by the Web services subsystem to execute create service, create existing service, drop service, and alter service commands. See the Web Services Users Guide.

Key Custodian Role

The key custodian role is responsible for key management: creating and altering encryption keys, setting up the system encryption password, setting up key copies for users, and so on. See *Database Encryption*.

5.3 Plan User-Defined Roles

Plan responsibility and positions before implementing roles.

Before you implement user-defined roles, decide:

- The roles you want to create
- The responsibilities for each role
- The position of each in the role hierarchy
- Which roles in the hierarchy are mutually exclusive and if so, at the membership or activation level

Avoid name conflicts when you create user-defined roles by following a naming convention. For example, you can use the "_role" suffix for role names. SAP ASE does not check for such restrictions.

The names of user-defined roles granted directly to users or to login profiles cannot duplicate the name of any login or login profile. If a role must have the same name as a user, avoid conflict by creating a new role, having it contain the original role, and then granting the new role to the user.

After you have planned the roles to create and the relationships among them, decide how to allocate roles according to business requirements and the responsibilities of your users.

The maximum number of roles that a user can activate per user session is 127.

The maximum number of user-defined roles that can be created server-wide is 992.

i Note

The sa_serverprivs_role is a user defined role that is enabled automatically on login for system administrator.

5.4 Create a User-Defined Role

A user with sso_role uses the create role command to create a role.

The create role command can only be used in the master database. If a password is used, any user activating the role must specify the password. Roles with passwords cannot be used if the role is to be activated during login as the login's default role or as an automatically activated role granted to a login profile.

For example, to create the intern role without a password, enter:

```
create role intern role
```

To create the doctor role and assign the password "physician", enter:

```
\verb|create role < doctor_role>| with passwd "<physician>"|
```

Only the system security officer can create user-defined roles.

See create role in the Reference Manual: Commands.

5.5 Add or Remove Passwords from a Role

Only a system security officer can add or drop a password from a role.

Use the alter role command to add or drop a password from either a system or user-defined role:

```
alter role <role_name >
[add passwd <password> | drop passwd]
```

For example, to require the password "oper8x" for the open role, enter:

```
alter role oper_role add passwd oper8x
```

To drop the password from the role, enter:

```
alter role oper_role drop passwd
```

i Note

When you assign a password to a role, any user granted the role must specify the password when activating the role.

5.6 Role Hierarchies and Mutual Exclusivity

A system security officer can define role hierarchies such that if a user has one role, the user also has roles lower in the hierarchy.

When you grant a role, role1, to another role, say, role2, you set up a hierarchy where role2 contains role1. For example, the "chief_financial_officer" role might contain both the "financial_analyst" and the "salary_administrator" roles.

The chief financial officer can perform all tasks and see all data that can be viewed by salary administrators and financial analysts.

Additionally, you can define a role's mutual exclusivity to enforce static or dynamic separation of duty policies. Roles can be defined to be mutually exclusive for:

- Membership one user cannot be granted two different roles. For example, you might not want the "payment_requestor" and "payment_approver" roles to be granted to the same user.
- Activation one user cannot activate, or enable, two different roles. For example, a user might be granted both the "senior_auditor" and the "equipment_buyer" roles, but not permitted to have both roles enabled at the same time.

System roles, as well as user-defined roles, can be defined to be in a role hierarchy, or to be mutually exclusive. For example, you might want a "super_user" role to contain the system administrator, operator, and Technical Support roles. To enforce a separation of roles, you may want to define the system administrator and system security officer roles to be mutually exclusive for membership; that is, one user cannot be granted both roles.

5.6.1 Define and Change Mutual Exclusivity of Roles

To define mutual exclusivity between two roles, use the alter role command.

The syntax is:

```
alter role <role1> { add | drop } exclusive { membership | activation } <role2>
```

For example, to define intern_role and specialist_role as mutually exclusive at the membership level, enter:

```
alter role <intern_role> add exclusive membership< specialist_role>
```

The example above restricts users who have membership in intern_role from also being members of specialist role.

To define the sso_role and sa_role as mutually exclusive at the activation level, enter the following command, which prohibits a user who is a member of sso_role and sa_role from assuming both roles simultaneously:

```
alter role sso_role add exclusive activation sa_role
```

5.6.2 Define and Change a Role Hierarchy

Defining a role hierarchy involves choosing the type of hierarchy and the roles, then implementing the hierarchy by granting roles to other roles.

For example:

```
grant role intern_role to specialist_role
grant role doctor_role to specialist_role
```

This grants to "specialist" all the privileges of both "doctor" and "intern."

To establish a hierarchy with a "super_user" role containing the sa_role and oper_role system roles, specify:

```
grant role sa_role to super_user
grant role oper_role to super_user
```

i Note

If a role requires a password to be contained within another role, the user with the role that contains the other does not need to use the password for the contained role. In the example above, assume that the "doctor" role usually requires a password. The user who has the "specialist" role does not need to enter the "doctor" password because "doctor" is contained within "specialist." Role passwords are only required for the highest level role.

When creating role hierarchies:

• You cannot grant a role to another role that directly contains it. This prevents duplication.

In the example above, you cannot grant "doctor" to "specialist" because "specialist" already contains "doctor."

• You can grant a role to another role that does not directly contain it.

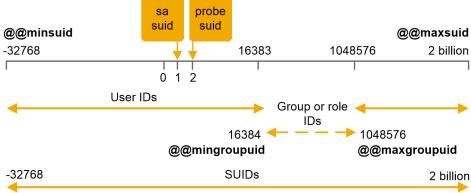

For example, in the Explicitly and implicitly granted privileges figure, you can grant the "intern" role to the "specialist" role, even though "specialist" already contains the "doctor" role, which contains "intern." If you subsequently dropped "doctor" from "specialist," then "specialist" still contains "intern."

In the Explicitly and implicitly granted privileges figure, "doctor" has "consultant" role permissions because "consultant" has been granted to "doctor." The "specialist" role also has "consultant" role permissions because "specialist" contains the "doctor" role, which in turn contains the "consultant."

However, "intern" does not have "consultant" role privileges, because "intern" does not contain the

"consultant" role, either directly or indirectly.

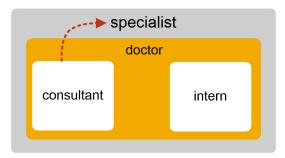

sa probe

• You cannot grant a role to another role that is contained by the first role. This prevents "loops" within the hierarchy.

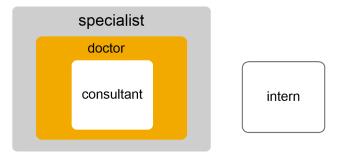

For example, in the Granting a role to a role contained by grantor figure, you cannot grant the "specialist" role to the "consultant" role; "consultant" is already contained in "specialist."

NOT ALLOWED

- When the system security officer grants to a user a role that contains other roles, the user implicitly gets membership in all roles contained by the granted role. However, a role can be activated or deactivated directly only if the user has explicit membership in that role.
- The system security officer cannot grant one role to another role that is explicitly or implicitly mutually exclusive at the membership level with the first role.

For example, in Mutual exclusivity at membership figure, if the "intern" role is defined as mutually exclusive at the membership level with the "consultant" role, the system security officer cannot grant "intern" to the "doctor."

The user can activate or deactivate only directly granted roles.
 For example, in the hierarchy shown in the Mutual exclusivity at membership figure, assume that you have been granted the "specialist" role. You have all the permissions of the "specialist" role, and, implicitly, because of the hierarchy, you have all the permissions of the "doctor" and "consultant" roles. However, you

because of the hierarchy, you have all the permissions of the "doctor" and "consultant" roles. However, you can activate only the "specialist" role. You cannot activate "doctor" or "consultant" because they were not directly granted to you.

Revoking roles from other roles is similar to granting roles to other roles. It removes a containment relationship, and the containment relationship must be a direct one.

For example:

- If the system security officer revokes the "doctor" role from "specialist," "specialist" no longer contains the "consultant" role or the "intern" role.
- The system security officer cannot revoke the "intern" role from "specialist" because "intern" is not directly contained by "specialist."

Related Information

Activate or Deactivate Roles [page 104]

5.7 Default Activation at Login

A system security officer can change role activation using alter login or alter login profile.

When a user logs in to SAP ASE, the user's roles are not necessarily active, depending upon how the role is set up as a default role. If a role has a password associated with it, the user must use the set role command to activate the role.

The system security officer determines whether to activate roles granted by default at login and uses the auto activated roles attribute of alter login profile or alter login to set the default status of user roles individually for each user. Individual users can change only their own default settings. auto activated roles only affects user roles, not system roles.

By default, user-defined roles that are granted are not activated at login, but system roles that are granted are automatically activated, if they do not have passwords associated with them.

The following example shows how to automatically activate roles on login if they are not password protected.

```
alter login mgr add auto activated roles
mgr_role, eng_role
```

The following example shows how to use the login profile to automatically activate roles on login if they are non password protected. The mgr role and eng role must be granted to mgr lp:

```
alter login profile mgr_lp add auto activated roles mgr_role, eng_role
```

5.8 Conditions for Role Activation

By specifying a where clause on the grant role statement, the system security officer can control the conditions under which a user can assume a given role.

SAP ASE evaluates the condition, termed a role activation predicate, when the user sets the role on or, for default or automatically activated roles, during login. Only if the role activation predicate evaluates to true is the role activated.

Related Information

Predicated Role Activation [page 231]

5.9 Drop User-Defined Roles

As system security officer, drop a role using the drop role command.

The syntax is:

```
drop role <role_name> [with override]
```

where <role_name> is the name of a user-defined role.

with override revokes all access privileges granted to the role in every database on the server.

If you do not use with the override option, you must revoke all privileges granted to the role in all databases before you can drop the role. If you do not, the command fails. To revoke privileges, use the revoke command

You need not drop memberships before dropping a role. Dropping a role automatically removes any user's membership in that role, regardless of whether you use the with override option.

5.10 Activate or Deactivate Roles

Roles must be active to have access privileges.

A default role is activated during login. Roles with passwords are always inactive at login. If the activation predicate on a default role evaluates to false during login, the role is silently ignored and remains inactive.

To activate or deactivate a role:

```
set role <role_name> [with passwd "<password>"] {on | off}
```

Include the with passwd parameter only if you are activating role. See the Reference Manual: Commands.

For example, to activate the "financial_analyst" role with the password "sailing19", enter:

```
set role financial_analyst with passwd "sailing19" on
```

If the role was granted using an activation predicate, the predicate is evaluated. If the predicate evaluates to true, the role is enabled; otherwise, the role remains inactive and the server returns an error message.

Activate roles only when you need them, and deactivate them when the roles are no longer necessary. Keep in mind that, when the sa_role is active, you assume the identity of database owner within any database that you use.

5.11 Display Information About Roles

Use these system procedures and functions to find information about roles.

To display information about	Use
The role ID of a role name	role_idsystemfunction
The role name of a role ID	role_name system function
System roles	show_role system function
Role hierarchies and roles that have been granted to a user or users	sp_displayroles system procedure
Whether one role contains another role in a role hierarchy	role_contain system function
Whether two roles are mutually exclusive	mut_excl_roles system function
Roles that are active for the current session	sp_activeroles system procedure
Whether you have activated the correct role to execute a procedure	has_role system function
Logins, including roles that have been granted	sp_displayloginsystem procedure
Permissions for a user, group, or role	sp_helprotect system procedure

5.11.1 Find Role IDs and Names

To find a role ID or role name, use the role_id and role_name functions.

To find a role ID when you know the role name, use: role_ID:

```
role_id(<role_name>)
```

Any user can execute role_id. If the role is valid, role_id returns the server-wide ID of the role (srid). The syssrvroles system table contains an srid column with the role ID and a name column with the role name. If the role is invalid, role id returns NULL.

To find a role name when you know the role ID, use: role name:

```
role_name(<role_id>)
```

Any user can execute role_name.

5.11.2 View Active System Roles

Use show role to display the currently active system roles for the specified login.

The syntax is:

```
show_role()
```

If you have not activated any system role, <code>show_role</code> returns NULL. If you are a database owner, and you execute <code>show_role</code> after using <code>setuser</code> to impersonate another user, <code>show_role</code> returns your own active system roles, not those for whom you are impersonating.

Any user can execute show role.

i Note

The show role function does not include information about user-defined roles.

5.11.3 Display Role Hierarchy

You can use sp_displayroles to see all roles granted to your login name or see the entire hierarchy tree of roles displayed in table format.

The syntax is:

```
sp_displayroles {login_name | <rolename >[, expand_up | expand_down]}
```

Any user can execute <code>sp_displayroles</code> to see his or her own roles. Only the system security officer can view information about roles granted to other users.

5.11.4 View User Roles in a Hierarchy

Use role contain to determine whether any role you specify contains any other role you specify.

The syntax is:

```
role_contain (["<role1>", "<role2>"])
```

If $< role1 > is contained by < role2 >, role_contain returns 1.$

Any user can execute role_contain.

5.11.5 Determine Mutual Exclusivity

Use the mut_excl_roles function to determine whether any two roles assigned to you are mutually exclusive, and the level at which they are mutually exclusive.

The syntax is:

```
mut_excl_roles(<role1>, <role2>, {membership | activation})
```

Any user can execute mut_excl_roles. If the specified roles, or any role contained by either specified role, are mutually exclusive, mut_excl_roles returns 1; if the roles are not mutually exclusive, mut_excl_roles returns 0.

5.11.6 Determine Role Activation

To find all active roles for the current login session, use ${\tt sp_activeroles}.$

The syntax is:

```
sp_activeroles [expand_down]
```

expand down displays the hierarchy of all roles contained by any roles granted to you.

Any user can execute $sp_active roles$.

5.11.7 Check for Roles in Stored Procedures

Use has role within a stored procedure to allow only users with a specific role to execute the procedure.

has role prevents inappropriate access to a particular stored procedure.

You can use grant execute to grant execute permission on a stored procedure to all users who have been granted a specified role. Similarly, revoke execute removes this permission.

However, grant execute permission does not prevent users who do not have the specified role from being granted execute permission on a stored procedure. To ensure, for example, that all users who are not system administrators cannot execute a stored procedure, use has_role within the stored procedure to check whether the invoking user has the correct role to execute the procedure.

has_role takes a string for the required role and returns 1or 2 if the invoker possesses it. Otherwise, it returns 0.

For example, here is a procedure that uses has role to determine if the user has sa role role:

```
create proc test_proc
as
if (has_role("sa_role",0) = 0)
begin
    print "You do not have the correct role"
    return -1
end
else
    print "You have System Administrator role"
    return 0
```

5.12 Grant or Revoke Roles

After a role is defined, it can be granted to any login account or role on the server, provided that it does not violate the rules of mutual exclusivity and hierarchy.

Task	Required role	Command
Grant the sa_role role	System administrator	grant role
Grant the sso_role role	System security officer	grant role
Grant the oper_role role	System security officer	grant role
Grant user-defined roles	System security officer	grant role
Create role hierarchies	System security officer	grant role
Modify role hierarchies	System security officer	revoke role
Revoke system roles	System security officer	revoke role
Revoke user-defined roles	System security officer	revoke role

5.12.1 Grant Roles

To grant roles to users, roles, or login profiles, use the grant role command.

The syntax is:

```
grant role <role_name>
    [where <pred_expression>] to {<username> | <rolename> |
    <login_profile_name> }
```

All roles listed in the grant statement are granted to all grantees. If you grant one role to another, it creates a role hierarchy.

For example, to grant Susan, Mary, and John the "financial_analyst" and the "payroll_specialist" roles, enter:

```
grant role financial_analyst, payroll_specialist
  to susan, mary, john
```

i Note

A role granted to a login profile can be activated by any user assigned that profile.

See grant role in the Reference Manual: Commands.

Related Information

Grant Roles to Login Profiles [page 66]

5.12.2 Understanding the grant Command and Roles

Use the grant command to grant permission on objects to all users who have been granted a specified role, whether system or user-defined.

This allows you to restrict use of an object to users who have been granted any of these roles:

- Any system-defined role
- Any user-defined role

A role can be granted only to a login account, another role, or login profile.

Grant permission to a role does not prevent users who do *not* have the specified role from being granted the same permission, directly or through a group. To ensure, for example, that only system administrators can successfully execute a stored procedure, use the has_role system function within the stored procedure itself to check that the user has been granted and has activated the requisite role.

Permissions granted to roles override permissions granted to users or groups. For example, assume John has been granted the system security officer role, and sso_role has been granted permission on the sales table. If John's individual permission on sales is revoked, he can still access sales when he has sso_role active because his role permissions override his individual permissions.

Related Information

Display Information About Roles [page 104]

5.12.3 Revoke Roles

Use revoke role to revoke roles from users, other roles, and login profiles.

The syntax is:

```
revoke role <role_name> [{<,> <role_name>}...]from <grantee> [{<,> <grantee>}...]
```

All roles listed in the revoke statement are revoked from all grantees.

5.13 Secure Role Passwords

In versions of SAP ASE earlier than 15.7, role passwords were stored using proprietary encryption in the syssrvroles system table. In version 15.7, role passwords are stored securely on-disk as SHA-256 digests.

When you upgrade to version 15.7 or later, and activate a role password for the first time after the upgrade, A the role password is encrypted and stored as an SHA-256 digest.

You cannot downgrade a role password that has been encrypted in SHA-256; instead, upon downgrade, the role password is truncated and the role is locked. The administrator must then reset the password and unlock the role after the downgrade.

i Note

In a high availability environment, those role passwords that are upgraded on first use on a primary server are also upgraded on its companion server.

5.13.1 Character Set Considerations

Passwords are automatically converted to a canonical—that is, a universal standardized form.

This automatic conversion prevents role-activation failures due to mismatched character mapping when you change the default character set. In versions earlier than 15.7, passwords used the server's default character set before they were encrypted.

5.13.2 Locked Roles and syssrvroles

You can configure a role to lock automatically after a certain number of failed role-activation attempts using the max failed_logins option, or manually using alter role <rolename> lock.

Information about locked roles is stored in the syssrvroles system table:

• lockdate - indicates when the role was locked. lockdate is set to the datetime when the role was locked.

- locksuid indicates who locked the role.
- lockreason indicates why the role was locked. lockreason is coded into an integer that can be represented with an internationalized message. Each reason has a message in the MSGDB database added to identify the reason in the local language.

These are reset to NULL when a role is unlocked.

The values and descriptions are:

Values for lockreason	Value for locksuid	Description of lockreason of role
NULL	NULL	Role has not been locked
1	suid of caller of alter role	Role locked by suid by manually executing alter role <rolename> lock</rolename>
2	suid of user whose last attempted role activation led to the role getting locked	Role locked due to failed-role activation attempts reaching maximum number of failed logins

i Note

If you are using high availability functionality, both the primary and companion servers are updated when you update the syssrvroles columns.

5.13.3 Login Password Policy Checks Applied to Role Passwords

Password complexity options that are applicable to login passwords are also applied to role passwords.

The following options check which are extended to role passwords:

- disallow simple passwords
- min digits in password
- min alpha in password
- min special char in password
- min upper char in password
- min lower char in password
- systemwide password expiration
- password exp warn interval
- minimum password length
- maximum failed logins
- expire login

5.13.4 Configure SAP ASE for Roles

Before using the role functionality, make sure SAP ASE has additional disk space in the master database and transaction log for the columns added to the syssrvroles table.

A database administrator can use the alter database command to add the additional space.

To identify the density of roles per page and log space you need for role password changes, use sp_help syssrvroles and sp_helpdb. You can then compare the values of:

- The values of the log space from before and after a specific number of password changes
- The specific number of set role with passwd commands that update syssrvroles with dates

5.13.4.1 Upgrade SAP ASE

During the upgrade process, SAP ASE automatically adds the columns locksuid, lockreason, and lockdate into syssrvroles.

These columns are nullable, and have a default value of NULL after the upgrade. Values are set only when needed.

5.13.4.2 Downgrade SAP ASE

When you downgrade SAP ASE, role passwords are truncated and locked.

In addition, SAP ASE does not support the use of allow password downgrade for role passwords. After a downgrade, the administrator should reset the role passwords and unlock the role accounts before using them again.

During the downgrade process, SAP ASE:

- Truncates role passwords and locks roles
- Removes any attributes in sysattributes under class 35, as well as class 35 itself
- Removes locksuid, lockreason, and lockdate columns from syssrvroles

The actions to downgrade a password occur when you execute $sp_downgrade_esd$. in single-user mode. A dataserver started with a "-m" command line option starts the server in single-user mode and allows only the system administrator to log in.

In this example, executing $sp_{downgrade_esd}$ results in the password of the "doctor_role" role becoming locked and truncated. The administrator can redirect this output to a file so that the passwords for these roles can be reset:

```
1> sp_downgrade_esd 'downgrade','16.1',1
2> go

Checking databases for downgrade readiness.
There are no errors which involve encrypted columns.
Executing downgrade step 2 [dbcc markprocs(@dbid)] for :
```

```
- Database: master (dbid: 1)
sql command is: dbcc markprocs(@dbid)
Executing downgrade step 26 [delete statistics syssrvroles(password) if exists
 (select 1
from syssrvroles where password is not
null) begin print "Truncating password and locking following role(s)" select

database
downgrade indicator.
00:0006:00000:00006:2011/06/28 06:21:26.21 server Downgrade : Resetting
database version
indicator.
00:0006:00000:00006:2011/06/28 06:21:26.21 server ASE downgrade completed.
```

After running sp_downgrade_esd, shut down the server to avoid new logins or other actions that may modify data or system catalogs.

You can enable locked roles and truncated password. In this example, the output of sp_displayroles shows that the downgrade process has locked "doctor_role" and truncated its password:

```
select srid, status, name, password from syssrvroles go
```

```
suid status name password

33 2 doctor_role NULL
```

This unlocks the role:

```
alter role doctor_role unlock
```

This sets a new password for the role:

```
alter role doctor_role add passwd "dProle1"
```

Running $\mathtt{sp_displayroles}$ now displays that the role is unlocked and has a password:

```
select srid,status,name,
"vers"=substring(password,2,1) from syssrvroles
go
```

suid	status	name	vers
33	0	doctor_role	0x05

6 External Authentication

You can authenticate users with authentication data stored in repositories that are external to SAP ASE.

You can enhance the security for large, heterogeneous applications by authenticating logins with a central repository. These external authentication methods are supported:

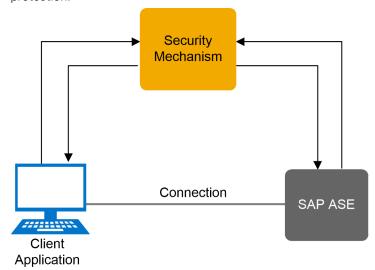

- Kerberos provides a centralized and secure authentication mechanism in enterprise environments that
 employ the Kerberos infrastructure. Authentication occurs with a trusted, third-party server called a key
 distribution center (KDC) that verifies both the client and the server.
- LDAP user authentication Lightweight Directory Access Protocol (LDAP) provides a centralized authentication mechanism based on a user's login name and password.
- PAM user authentication Pluggable Authentication Module (PAM) provides a centralized authentication mechanism that uses interfaces provided by the operating system for administration and runtime application interfaces.

i Note

To use these external authentication methods, you must obtain the ASE_SECDIR security and directory services license package.

6.1 Configure SAP ASE for Network-Based Security

The secure connection between a client and a server can be used for login authentication and message protection.

If a client requests authentication services:

1. The client validates the login with the security mechanism. The security mechanism returns a credential, which contains security-relevant information.

- 2. The client sends the credential to SAP ASE.
- 3. SAP ASE authenticates the client's credential with the security mechanism. If the credential is valid, a secure connection is established between the client and SAP ASE.

If the client requests message protection services:

- The client uses the security mechanism to prepare the data packet it sends to SAP ASE.
 Depending upon which security services are requested, the security mechanism might encrypt the data or create a cryptographic signature associated with the data.
- 2. The client sends the data packet to SAP ASE.
- 3. Upon receiving the data packet, SAP ASE uses the security mechanism to perform any required decryption and validation.
- 4. SAP ASE returns results to the client, using the security mechanism to perform the security functions that were requested; for example, SAP ASE may return the results in encrypted form.

6.1.1 SAP ASE Security Services

Depending on the security mechanism you choose, SAP ASE allows you to use one or more security services.

You can use:

- Unified login authenticates users once, without requiring them to supply a name and password every time they log in to an SAP ASE server.
- Message confidentiality encrypts data over the network.
- Mutual authentication verifies the identity of the client and the server. Mutual authentication can be requested only by the client; it cannot be required.
- Message integrity verifies that data communications have not been modified.
- Replay detection verifies that data has not been intercepted by an intruder.
- Out-of-sequence check verifies the order of data communications.
- Message origin checks verifies the origin of the message.
- Credential delegation allows the client to delegate the credential to the server to enable secure connection with remote servers. This service is supported by Kerberos security mechanism. This currently supported for connections to remote servers through CIS.
- Remote procedure security establishes mutual authentication, message confidentiality, and message integrity for remote procedure communications through CIS for Kerberos connections.

i Note

The security mechanism you are using may not employ all of these services.

Related Information

Obtain Information About Available Security Services [page 130]

6.1.2 Administering Network-Based Security

How to administer network-based security.

Procedure

- 1. Edit the configuration files: libtcl.cfg, objectid.dat, and interfaces (or directory service).

 See Configuration Files for Security and the Open Client/Server Configuration Guide for your platform.
- 2. Make sure the security administrator for the security mechanism has created logins for each user and for the SAP ASE and Backup Server.
 - See *Identifying Users and Servers to the Security Mechanism* and the documentation supplied with your security mechanism.
- 3. Use sp configure to configure security for your installation.
- 4. Restart the server to activate the use security services parameter.
- 5. Use create login to add login accounts to support enterprise-wide login. Optionally, specify a default secure login with sp configure.
 - See Adding Logins to Support Unified Login.
- 6. Use security mechanism option of sp_serveroption to enable security mechanism for required remote servers.
 - See Establish Kerberos Security for Remote Connections.
- 7. Use isq1_r or Open Client Client-Library to connect to SAP ASE, specifying the security services you want to use
 - See Connect to the Server and Using the Security Services. Also see Security Features in the Open Client Client-Library/C Reference Manual and the Open Client/Server Configuration Guide for your platform.
- 8. Use the functions <code>show_sec_services</code> and <code>is_sec_services_on</code> to check which security services are available. For a list of security mechanisms and their security services supported by SAP ASE, use <code>select</code> to query the <code>syssecmechs</code> system table.

6.1.3 Configuration Files for Security

Configuration files are created during installation at a default location in the directory structure.

These are the names and locations for configuration files:

File name	Description	Location
libtcl.cfg (libtcl64.cfg for 64-bit)	The driver configuration file contains information regarding directory, security, and network drivers, and any required initialization information.	UNIX platforms: \$SYBASE/ \$SYBASE_OCS/config Windows platforms: \$SYBASE%\ \$SYBASE_OCS%\ini
	·	

File name	Description	Location
objectid.dat	The object identifiers file maps global object identifiers to local names for character set, collating sequence, and security mechanisms.	UNIX platforms: \$SYBASE/config
		Windows platforms: %SYBASE%\ini
UNIX: interfaces	The interfaces file contains connection and security information for each server listed in the file.	UNIX platforms: \$SYBASE
		Desktop platforms: SYBASE_home\ini
Desktop platforms: sql.ini		

For a detailed description of the configuration files, see the *Open Client/Server Configuration Guide* for your platform.

6.1.3.1 Security Information for the Server

Use an interfaces file or a Directory Service to provide information about the servers in your installation.

The interfaces file contains network and security information for servers. To use security services, the interfaces file must include line for "secmech" that specifies the global identifier or identifiers of the security services you plan to use.

SAP ASE supports Directory Services to keep track of information about servers. A Directory Service manages the creation, modification, and retrieval of information about network servers. The advantage of using a Directory Service is that you do not need to update multiple interfaces files when a new server is added to your network or when a server moves to a new address. To use security services with a Directory Service, you must define the secmech security attribute to point to one or more global identifiers of the security services you plan to use.

UNIX Tools for Specifying the Security Mechanism

To specify the security mechanism or mechanisms:

- If you are using the interfaces file, use the dscp utility.
- If you are using a Directory Service, use the dscp rutility.

i Note

The dsedit tool, which helps you create entries for either the interfaces file or a Directory Service, is available on UNIX platforms. However, it does not support the creation of secmech entries for security mechanisms.

For more information about dscp, see the Open Client/Server Configuration Guide for UNIX.

Desktop Tools for Specifying Server Attributes

To provide information about the servers for your installation in the sql.ini file or a Directory Service, use the dsedit utility. This utility provides a graphical user interface for specifying server attributes such as the server version, name, and security mechanism. For the security mechanism attribute, you can specify one or more object identifiers for the security mechanisms you plan to use. For information about using dsedit, see the Open Client/Server Configuration Guide for Desktop Platforms.

6.1.3.2 Prepare libtcl.cfg to Use Network-Based Security

Edit the libtcl.cfg or libtcl64.cfg for network-based security.

The libtcl.cfg and libtcl64.cfg (for 64-bit applications) contain information about three types of drivers:

- Network (Net-Library)
- Directory Services
- Security

A driver is a library that provides an interface to an external service provider. Drivers are dynamically loaded so that you can change the driver used by an application without relinking the application.

Entries for Network Drivers

The syntax for a network driver entry is:

<driver>=<protocol> <description>

where:

- <driver> is the name of the network driver.
- cprotocol> is the name of the network protocol.
- <description> is a description of the entry. This element is optional.

i Note

If you do not specify a network driver, an appropriate driver for your application and platform is automatically used. For example, for UNIX platforms, a driver that can handle threads is automatically chosen when security services are being used.

Entries for Directory Services

Directory Services entries apply if you want to use a Directory Service instead of the interfaces file. See the configuration documentation for your platform, and the *Open Client/Server Configuration Guide* for your platform.

Entries for Security Drivers

The syntax for a security driver entry is:

where:

The default local names are:

- "csfkrb5" for the CyberSAFE or MIT Kerberos security mechanism.
- "LIBSMSSP" for Windows LAN Manager on Windows NT or Windows 95 (clients only).

If you use a local mechanism name other than the default, change the local name in the objectid.dat file.

- <driver >is the name of the security driver. The default location of all drivers for UNIX platforms is \$SYBASE/\$SYBASE_OCS/lib. The default location for Windows platform is \$SYBASE\\$SYBASE_OCS\ \dll.
- <init-string> is an initialization string for the driver. This element is optional. The value for <init-string> varies by driver:
 - Kerberos driver the following is the syntax for <init-string>, where <realm> is the default Kerberos realm name:

```
secbase=@<realm>
```

• Windows NT LAN Manager - <init-string> is not applicable.

UNIX Platform Information

No special tools for editing the libtcl.cfg file are available. Use your favorite editor to comment and uncomment the entries that are already in place after you install SAP ASE.

After you install SAP ASE on a UNIX platform, the libtcl.cfg file already contains entries for the three sections of the file:

- [DRIVERS]
- [DIRECTORY]
- [SECURITY]

The sections do not have to be in a specific order.

Make sure that the entries you do not want to use are commented (begin with ";") and the entries you want are uncommented (do not begin with ";").

For more information, see the Open Client/Server Configuration Guide for UNIX

Sample libtcl.cfg for Sun Solaris

```
[DRIVERS]
;libtli.so=tcp unused; This is the non-threaded tli driver.
;libtli_r.so=tcp unused; This is the threaded tli driver.
[SECURITY]
csfkrb5=libsybskrb.so secbase=@MYREALM libgss=/krb5/lib/libgss.so
```

This file does not use Directory Services because all [DIRECTORY] section entries are commented.

Because all entries in the [DRIVERS] section for network drivers are also commented, appropriate drivers are automatically chosen by the system. SAP ASE automatically chooses a threaded driver when you use security services, and chooses an unthreaded driver for applications that cannot work with threaded drivers. For example, Backup Server does not support security services and does not work with a threaded driver.

Desktop Platform Information

The ocscfg utility automatically creates section headings for the libtcl.cfg file; you can also use osccfg to edit the libtcl.cfg file.

This is a sample libtcl.cfg file for desktop platforms:

```
[NT_DIRECTORY]
ntreg_dsa=LIBDREG ditbase=software\sybase\serverdsa
[DRIVERS]
NLWNSCK=TCP Winsock TCP/IP Net-Lib driver
NLMSNMP=NAMEPIPE Named Pipe Net-Lib driver
NLNWLINK=SPX NT NWLINK SPX/IPX Net-Lib driver
NLDECNET=DECNET DecNET Net-Lib driver
[SECURITY]
NTLM=LIBSMSSP
```

See the Open Client/Server Configuration Guide for Desktop Platforms.

6.1.3.3 objectid.dat File

The objectid.dat file maps global object identifiers to local names and the file contains sections such as [CHARSET] for character sets and [SECURITY] for security services.

This is a sample objected.dat file:

```
secmech] 1.3.6.1.4.1.897.4.6.3 = NTLM
```

```
1.3.6.1.4.1.897.4.6.6 = csfkrb5
```

The mapping of global object identifiers to local names, for example, is the Kerberos service (such as the identifier 1.3.6.1.4.1.897.4.6.6) to local names, such as "csfkrb5".

Use a text editor to change this file only if you have changed the local name of a security service in the libtal.cfg file.

For example, if you changed:

```
[SECURITY] csfkrb5=libsybskrb.so secbase=@MYREALM libgss=/krb5/lib/libgss.so
```

to:

```
[SECURITY]
csfkrb5_group=libsybskrb.so secbase=@MYREALM libgss=/krb5/lib/libgss.so
```

Change the objected.dat in libtcl.cfg to reflect the change. Simply change the local name in the line for Kerberos in objected.dat:

```
1.3.6.1.4.1.897.4.6.6 = csfkrb5 group
```

i Note

You can specify only one local name per security mechanism.

6.1.4 Identify Users and Servers to the Security Mechanism

The security administrator for the security mechanism must define principals (both users and servers) to the security mechanism.

The tools you can use to add users and servers are:

- Kerberos see your Kerberos vendor-specific tools for information about defining users and servers.
- Windows NT LAN Manager run the User Manager tool to define users to the Windows NT LAN Manager.
 Define the SAP ASE server name as a user to Windows NT LAN Manager and display SAP ASE as that user name.

i Note

In a production environment, control access to files that contain the keys of the servers and users. If users can access the keys, they can create a server that impersonates your server.

See the documentation available from the third-party provider of the security mechanism for detailed information about how to perform required administrative tasks.

6.1.5 Configure SAP ASE for Security

Adaptive Server includes several configuration parameters for administering network-based security. To set these parameters, you must be a system security officer. All parameters for network-based security are part of the "Security-Related" configuration parameter group.

6.1.5.1 Enable Network-Based Security

To enable or disable network-based security, use <code>sp_configure</code> to set the use <code>security services</code> configuration parameter.

If use security services is set to 1, SAP ASE supports a security mechanism when both of the following circumstances are true:

- The security mechanism's global identifier is listed in the interfaces file or Directory Service.
- The global identifier is mapped in objectid.dat to a local name that is listed in libtcl.cfg.

6.1.5.2 Require Users to be Authenticated

To require all users, other than the system security officer, to be authenticated by a security mechanism, set the unified login required configuration parameter to 1.

Only the user with the sso_role can log in to the server with a user name and password when this configuration parameter is set:

```
sp_configure "unified login required", [0|1]
```

For example, to require all logins to be authenticated by a security mechanism, execute:

```
sp configure "unified login required", 1
```

6.1.5.3 Establish a Secure Default Login

SAP ASE uses a default login for any user who is not defined in master..syslogins, but who is preauthenticated by Kerberos security mechanism.

When a user with a valid credential from a security mechanism logs in to SAP ASE, the server checks whether the user name exists in master..syslogins. If it does, SAP ASE uses that user name. For example, if a user logs in to the Kerberos security mechanism as "ralph," and "ralph" is in master..syslogins, SAP ASE uses all roles and authorizations defined for "ralph" in the server.

However, if a user with a valid credential logs in to SAP ASE, but is unknown to the server, the login is accepted only if a secure default login is defined with <code>sp_configure</code>. SAP ASE uses the default login for any user who is not defined in <code>master..syslogins</code>, but who is preauthenticated by Kerberos. The syntax is:

```
sp_configure "secure default login", 0, <login_name>
```

The default value for secure default login< >is "guest."

A secure default login must also be a valid login in master..syslogins. For example, to set the "gen_auth" as the default login:

1. Use create login to add the login as a valid user:

```
create login gen_auth with password pwgenau
```

This procedure sets the initial password to "pwgenau".

2. Designate the login as the security default:

```
sp_configure "secure default login", 0, gen_auth
```

SAP ASE uses this login for a user who is preauthenticated by Kerberos but is unknown to SAP ASE.

i Note

More than one user can assume the suid associated with the secure default login. Therefore, you might want to activate auditing for all activities of the default login. You may also want to consider using create login to add all users to the server.

6.1.5.4 Map Security Mechanism Login Names to Server Names

All login names must be valid identifiers.

Some security mechanisms may allow login names that are invalid in Adaptive Server. For example, login names that are longer than 30 characters, or login names containing special characters such as !, %, *, and & are invalid in Adaptive Server.

This table shows how invalid characters in login names are converted:

Invalid characters	Converts to
Ampersand &	Underscore _
Apostrophe '	
• Backslash \	
• Colon:	
• Comma ,	
• Equals sign =	
• Left quote '	
Percent %	
 Right angle bracket > 	
Right quote '	
• Tilde ~	
Asterisk *	Pound sign #
• Minus sign -	
• Pipe	
• Plus sign +	
Quotation marks "	
• Semicolon;	
• Slash /	
Square brackets []	

See Expressions, Identifiers, and Wildcard Characters, in the Reference Manual.

6.1.5.5 Require Message Confidentiality with Encryption

To require all messages into and out of SAP ASE to be encrypted, set the ${\tt msg}$ confidentiality reqd configuration parameter to 1.

If this parameter is 0 (the default), message confidentiality is not required but may be established by the client. The syntax is:

```
sp_configure <configuration_parameter>, [0 | 1]
```

For example, to require that all messages be encrypted, execute:

```
sp_configure "msg confidentiality reqd", 1
```

6.1.5.6 Require Data Integrity

SAP ASE allows you to use the msg integrity reqd configuration parameter to require that one or more types of data integrity be checked for all messages.

Set msg integrity reqd to 1 to require that all messages be checked for general tampering. If msg integrity reqd is 0 (the default), message integrity is not required but may be established by the client if it is supported by the security mechanism.

6.1.5.7 Memory Requirements for Network-Based Security

Allocate approximately 2K additional memory per secure connection. The value of the max total_memory configuration parameter specifies the amount of memory that the server requires at start-up.

For example, if your server uses 2K logical pages, and if you expect the maximum number of secure connections occurring at the same time to be 150, increase the \max total_memory parameter by 150, which increases memory allocation by 150 2K blocks.

The syntax is:

```
sp_configure "max total_memory", <value>
```

For example, if the server requires 75,000 2K blocks of memory, including the increased memory for network-based security, execute:

```
sp_configure "max total_memory", 75000
```

See Configuring Memory, in System Administration Guide: Volume 2.

6.1.5.8 Using NT Lan Manager Security Services on Windows 64-bit

NT Lan Manager security services are supported on Windows 64-bit.

Context

In order to use the NTLM Security Services on Windows 64bit, changes are required in the libtcl64.cfg, libtcl.cfg, and sql.ini files.

Procedure

- 1. Update the [SECURITY] section of the %SYBASE%\%SYBASE OCS%\ini\libtc164.cfg file.
 - a. Add the following to the [SECURITY] section:

```
NTLM=LIBSYBSMSSP64
```

This change allows 64-bit ASE and 64-bit Open Client applications to use the security driver library libsybsmssp64.dll at runtime. The libsybsmssp64.dll library is located in %SYBASE%\%SYBASE OCS%\dll, along with other Open Client dynamic link libraries.

- 2. Update the [SECURITY] section in the %SYBASE%\%SYBASE OCS%\ini\libtcl.cfg file.
 - a. Add the following to the [SECURITY] section:

```
NTLM=LIBSYBSMSSP
```

The libtcl.cfg is used by the 32bit isql utility and 32-bit OpenClient applications.

- 3. Choose one of the following methods to specify the OID value for NTLM.
 - Update the [SECMECH] section of the %SYBASE%\ini\sql.ini file. Add the following to the sql.ini file:

```
[ASENAME]
master=TCP,<host>,<port>
query=TCP,<host>,<port>
secmech=1.3.6.1.4.1.897.4.6.3
```

• Use the dsedit utility to add the 'Server Security' attribute value of '1.3.6.1.4.1.897.4.6.3' to your server.

i Note

This OID value derived from the %SYBASE%\ini\objectid.dat file which should not be modified

4. Make sure Adaptive Server is configured for security services. For example, to enable services with LAN Manager, execute:

```
sp\_configure "use security services", 1
```

For more information, see *Using Security Services with NT LAN Manager* in the *Configuration Guide for Windows NT*.

- 5. Make sure you have a login on the Adaptive Server that corresponds with your Windows login.
- 6. Connect to the Adaptive Server without a user name and password. For example:
 - isql -V -SASENAME
 - isql64 -V -SASENAME

6.1.6 Add Logins to Support Unified Login

Consider whether you want to allow only those users who are defined as valid logins to use SAP ASE, or whether you want users to be able to log in with the default login.

When users log in with a preauthenticated credential, SAP ASE:

- 1. Checks whether the user is a valid user in master..syslogins. If the user is listed in master..syslogins, the login is accepted without requiring a password.
- 2. If the user name is not in master..syslogins, a check is performed as to whether a default secure login is defined. If the default login is defined, the user is logged in successfully using the default. If a default login is not defined, the user cannot log in.

To define a default login, add the default login in master..syslogins and use sp configure.

6.1.6.1 General Procedure for Adding Logins

Add logins to the server and, optionally, to add users with appropriate roles and authorizations to one or more databases.

Context

Follow this general procedure to add logins to the server and, optionally, to add users with appropriate roles and authorizations to one or more databases.

Procedure

- System security officer uses create login to add a login for the user.
 See Create Login Accounts.
- 2. The system administrator or database owner uses sp_adduser to add the user to one or more databases. See Add Users to Databases.
- 3. The system administrator or database owner uses sp_changegroup to add the user to group in the database.
 - See Change Group Membership.
- 4. The system administrator or system security officer uses grant role to grant system roles to the user. See *Grant or Revoke Roles*.
- 5. The system security officer uses create role and grant role to create user-defined roles and grant the roles to users.
 - See Grant Roles.
- 6. The Database object owners grant access to database objects. See *Manage User Permissions*.

Related Information

Create Login Accounts [page 26]
Add Users to Databases [page 72]
Change Group Membership [page 76]
Grant or Revoke Roles [page 107]
Grant Roles [page 107]
Manage User Permissions [page 166]

6.1.7 Connect to a Server Using Security Services

The isql and bcp utilities enable network-based security services on the connection.

The isql and bcp utilities include the following command line options:

- -R <remote server principal>
- -V <security options>
- -Z <security mechanism>

These options are described in the following paragraphs.

- -R <remote_server_principal> specifies the principal name for the server as defined to the security mechanism. By default, a server's principal name matches the server's network name (which is specified with the -s option or the DSQUERY environment variable). The -R option must be used when the server's principal name and network name are not the same.
- -V <security_options> specifies network-based user authentication. With this option, the user must log in to the network's security system before running the utility. In this case, if a user specifies the -U option, the user must supply the network user name known to the security mechanism; any password supplied with the -P option is ignored. -V can be followed by a <security_options> string of key-letter options to enable additional security services. These key letters are:
 - c enables data confidentiality service.
 - d requests credential delegation and forwards client credentials.
 - i enables data integrity service.
 - m enables mutual authentication for connection establishment.
 - o enables data origin stamping service.
 - r enables data replay detection.
 - q enables out-of-sequence detection.
- -Z <security mechanism> specifies the name of a security mechanism to use on the connection.

Security mechanism names are defined in the libtcl.cfg configuration file. If no <security_mechanism> name is supplied, the default mechanism is used. See the *Open Client/Server Configuration Guide* for your platform.

If you are using Client-Library to connect to SAP ASE, you can define security properties before connecting to the server. For example, to check message sequencing, set the CS_SEC_DETECTSEQ property. For information about using security services with Client-Library, see the *Open Client Client-Library/C Reference Manual*.

6.1.7.1 Security Mechanisms for the Client

SAP ASE, when it is started, determines the set of security mechanisms it supports. From the list of supported security mechanisms, SAP ASE must choose the one to be used for a particular client.

If the client specifies a security mechanism (for example with the -z option of isql), SAP ASE uses that security mechanism. Otherwise, it uses the first security mechanism listed in the libtol.cfq file.

6.1.8 Obtain Information About Available Security Services

You can determine which security mechanisms and services are supported, what security services are active for the current session, and whether a particular security service is enabled for the session

Determining Supported Security Services and Mechanisms

A system table, syssecmechs, provides information about the security mechanisms and security services supported. The table, which is dynamically built when you query it, contains these columns:

- sec_mech_name is the name of the security mechanism; for example, the security mechanism might be "NT LANMANAGER."
- available_service is the name of a security service supported by the security mechanism; for example, the security service might be "unified login."

The table may have several rows for a single security mechanism: one row for each security service supported by the mechanism.

To list all the security mechanisms and services supported, run:

```
select * from syssecmechs
```

Determining Active Security Services

To determine which security services are active for the current session, use the function show_sec_services:

```
select show_sec_services()

------
unifiedlogin mutualauth confidentiality
(1 row affected)
```

Determining Whether a Security Service is Enabled

To determine whether a particular security service, such as "mutualauth" is enabled, use the function is sec service on, where <security service nm> is a security service that is available:

```
is_sec_service_on(<security_service_nm>)
```

Use the security server that is returned when you query <code>syssecmechs</code>.

For example, to determine whether "mutualauth" is enabled, execute:

```
select is_sec_service_on("mutualauth")
-----
1
(1 row affected)
```

A result of 1 indicates the security service is enabled for the session. A result of 0 indicates the service is not in use.

6.1.9 Kerberos

Kerberos is a network authentication protocol that uses secret-key cryptography so that a client can prove its identity to a server across a network connection.

User credentials are obtained when the user logs in to the operating system, or by executing an authentication program. Each application uses these credentials to perform authentication. Users only have to log in once, instead of having to log in to each application.

Kerberos assumes the key distribution center (KDC) is running and properly configured for your realm, and the client libraries are installed under or on each client host in your realm. For configuration information, consult the documentation and the reference pages that come with the Kerberos software.

SAP ASE supports Kerberos through:

- CyberSafe Kerberos libraries, version 2.1
- MIT Kerberos libraries, version 1.4.3 (version 4.0.1 for Windows 64-bit)
- Native libraries

i Note

To enable Kerberos security options, you must have ASE_SECDIR, the "Security and directory services" package.

6.1.9.1 Concurrent Kerberos Authentication

SAP ASE supports concurrent Kerberos authentication.

When there are concurrent logins using Kerberos authentication, SAP ASE establishes multiple Kerberos authentication sessions.

SAP ASE versions earlier than 15.0.3 used locking mechanisms during Kerberos authentication to protect internal data structures.

6.1.9.2 Start an SAP ASE Server Under Kerberos

To start an SAP ASE server under Kerberos, add the server name to the KDC and extract the service key to a key table file.

For example:

```
/krb5/bin/admin admin/ASE -k -t /krb5/v5srvtab -R" addrn my_ase; mod my_ase attr nopwchg; ext -n my_ase eytabfile.krb5"
Connecting as: admin/ASE
Connected to csfA5v01 in realm ASE.
Principal added.
Principal modified.
Key extracted.
Disconnected.
```

i Note

The administrator can also be authenticated using a password on the command line. In this example, the – k option is used, which tells the administrator to search the /krb5/v5srvtab file (specified using the –t option) for the administrator and the SAP ASE server key, instead of prompting for a password, which is useful for writing shell scripts.

6.1.9.3 Configuring Kerberos

The configuration process is similar, regardless of which variety of Kerberos you use.

Procedure

- 1. Set up Kerberos third-party software and create a Kerberos administrative user. To do this, you must:
 - a. Install Kerberos client software on machines where Open Client Server clients or SAP ASE will run. The following client packages have been verified to work with:
 - CyberSafe TrustBroker 2.1
 - MIT Kerberos version 1.4.3 (version 4.0.1 for Windows 64-bit)

- b. Install the Kerberos KDC server on a separate, dedicated machine.
 - KDCs from CyberSafe TrustBroker version 2.1, MIT Kerberos version.1.8.2, and Microsoft Windows Active Directory have been verified for use with SAP ASE.
- c. Create an administrator account with administration privileges on the Kerberos server. This account is used for subsequent client actions such as creating principals from the client machines.

Execute the remainder of these steps on the Kerberos client machine.

- 2. Add Kerberos principal for SAP ASE <ase120srv> or <ase120srv@MYREALM>.
- 3. Extract the keytab file for principal <ase120srv@MYREALM> and store it as a file:

```
/krb5/v5srvtab
```

The following UNIX examples use the command line tool kadmin, available with CyberSafe or MIT Kerberos (there are also GUI tools available to administer Kerberos and users):

```
CyberSafe Kadmin:
% kadmin aseadmin
Principal - aseadmin@MYREALM
Enter password:
Connected to csfA5v01 in realm ASE.
Command: add ase120srv
Enter password:
Re-enter password for verification:
Principal added.
Command: ext -n ase120srv
Service Key Table File Name (/krb5/v5srvtab):
Key extracted.
Command: quit
Disconnected.
```

In a production environment, control the access to the keytab file. If a user can read the keytab file, he or she can create a server that impersonates your server.

Use chmod and chgrp so that /krb5/v5srvtab is:

```
-rw-r---- 1 root sybase 45 Feb 27 15:42 /krb5/v5srvtab
```

When using Active Directory as the KDC, log in to the Domain Controller to add users and SAP ASE principals. Use the Active Directory Users and Computers wizard to guide you through creating users and principals.

Extracting the keytab file for use with SAP ASE requires an optional tool called ktpass, which is included in the Microsoft Support Tools package.

With Active Directory, extracting the keytab with ktpass is a separate step from creating the principal. The keytab file on Windows for SAP ASE is located with the CyberSafe program files. For example, c: $\label{eq:cyberSafe} $$ \end{array} $$$

- 4. Add a Kerberos principal for the user "sybuser1" as "sybuser1@MYREALM".
- 5. Start the SAP ASE server and use isql to log in as "sa". The following steps configure SAP ASE parameters to use Kerberos security services, and create the user login account. These are the same on both Windows or UNIX machines:

a. Change configuration parameter use security services to 1:

```
sp_configure 'use security services', 1
```

b. Add a new login for user, "sybuser1" and then add the user:

```
create login sybuser1 with password <password>
```

- 6. Shut down the SAP ASE server and modify administrative files and connectivity configuration files.
 - On UNIX platforms the interfaces file is under \$SYBASE/ and has an entry that looks similar to:

```
ase120srv
master tli tcp myhost 2524
query tli tcp myhost 2524
secmech 1.3.6.1.4.1.897.4.6.6
```

On Windows platforms – the sql.ini file is in %SYBASE%\ini, and has an equivalent server entry that looks like:

```
[ase120srv] master=TCP,myhost,2524 query=TCP,myhost,2524 secmech=1.3.6.1.4.1.897.4.6.6
```

• The libtcl.cfg or libtcl64.cfg file is located in \$SYBASE/\$SYBASE_OCS/config/ on UNIX platforms. The SECURITY section should have an entry that looks similar to the following for CyberSafe Kerberos client libraries: (the lines starting with "csfkrb5" are single lines in these examples, but are split for space purposes)

```
[SECURITY] csfkrb5=libsybskrb.so secbase=@MYREALM libgss=/krb5/lib/libgss.so
```

A 64-bit CyberSafe Kerberos client library entry follows:

```
[SECURITY] csfkrb5=libsybskrb64.so secbase=@MYREALM libgss=/krb5/appsec-rt \//lib/64/libgss.so
```

For a machine that uses MIT Kerberos client libraries, the entry looks something like:

```
[SECURITY]
csfkrb5=libsybskrb.so secbase=@MYREALM libgss=/opt/mitkrb5/lib/ \
libgssapi_krb5.so
```

For a machine that uses Native OS provided libraries, such as Linux, it looks similar to:

```
[SECURITY]
csfkrb5=libsybskrb.so secbase=@MYREALM libgss=/usr/kerberos/lib/ \
libgssapi_krb5.so
```

On Windows - the %SYBASE%\%SYBASE OCS%\ini\libtcl.cfg file contains an entry like:

```
[SECURITY] csfkrb5=libskrb secbase=@MYREALM libgss=C:\WinNT\System32\ ^ gssapi32.dll
```

i Note

The libgss=<gss shared object path> specifies the GSS API library to be used. You must distinctly locate the Kerberos Client libraries being used, especially when multiple versions are installed on a machine.

• Also check the objectid.dat under \$SYBASE/\$SYBASE_OCS/config/ and make sure the [secmech] section has an entry for csfkrb5:

```
[secmech]
1.3.6.1.4.1.897.4.6.6 = csfkrb5
```

7. You can use environment variables to override default locations of keytab files, Kerberos configuration, and realm configuration files. This is Kerberos-specific behavior and may not work consistently on all platforms.

For example, use the CSFC5KTNAME environment variable on CyberSafe UNIX platforms to specify the keytab file:

```
% setenv CSFC5KTNAME /krb5/v5srvtab
```

For MIT Kerberos, the equivalent environment variable is KRB5_KTNAME.

See the vendor documentation for information about these environment variables.

You may need to modify the environment variable for dynamic library search paths. On UNIX, the most commonly used environment variable is LD_LIBRARY_PATH; on Windows, PATH is typically set to include DLL locations. You may need to modify these environment variables to enable applications to load the third-party objects correctly. For example, this command adds the location of CyberSafe 32-bit libgss.so shared object to the search path in a C-shell environment:

```
% set path = ( /krb5/lib $path )
```

8. Restart the server. You should see:

```
00:00000:00000:2001/07/25 11:43:09.91 server
Successfully initialized the security mechanism
'csfkrb5'. The SQL Server will support use of this
security mechanism.
```

9. Use $isql\ r$ as UNIX user "sybuser1" (without the -U and -P arguments) to connect:

```
% $SYBASE/$SYBASE_OCS/bin/isql_r -Sase120srv -V
1>...
```

You can also use the encryption option:

```
$SYBASE/$SYBASE_OCS/bin/isql_r -Sase120srv -Vc
```

6.1.9.4 Passing Caller Passwords As Null

Use the allow kerberos null password configuration parameter to configure the server to allow Kerberos administrators to pass caller passwords.

The caller password is the password for the user executing alter login .. modify password.

Set the allow kerberos null password configuration parameter to 1 to enable the server to pass caller passwords as null:

```
sp configure "allow kerberos null password", 1
```

i Note

Instead of resetting the login password to null, allow kerberos null password allows you to pass the caller password as null so that you can reset login passwords.

In this example, user1, with sso_role and a non-null password of abc123, logs into SAP ASE with the -v option (Kerberos authentication):

```
isql_r -U user1 -P abc123 -V -Sbig_server
1> select @@authmech
2> go
______kerberos
```

If another login, user2, needs to change their password, user1 can issue this command, using a null password:

```
alter login user2 with password null modify password password123
```

6.1.9.5 Using MIT Kerberos Security Services on Windows 64-bit

MIT Kerberos security services are supported on Windows 64-bit.

Context

In order to use the MIT Kerberos Security services on Windows 64bit, changes are required in libtcl64.cfg, libtcl.cfg, and sql.ini files.

Procedure

- 1. Update the [SECURITY] section of the %SYBASE%\%SYBASE OCS%\ini\libtc164.cfg file.
 - a. Add the following to the [SECURITY] section:

```
csfkrb5=LIBSYBSKRB64 secbase=@<REALM>
libgss=<MIT_KRB_64_INSTALL_DIR> \bin\gssapi64.dll
```

i Note

For the above example:

<REALM> should be replaced with the Kerberos realm name.

<MIT_KRB_64_INSTALL_DIR> should be replaced with the directory where MIT Kerberos version 4.0.1 for Windows 64-bit is installed.

The path to the gssapi library, used in the libtcl64.cfg file, cannot contain whitespaces.

This change allows 64-bit ASE and 64-bit Open Client applications to use the security driver library libsybsmssp64.dll at runtime. The libsybsmssp64.dll library is located in %SYBASE%\%SYBASE OCS%\dll, along with other Open Client dynamic link libraries.

- 2. Update the [SECURITY] section in the %SYBASE%\%SYBASE OCS%\ini\libtcl.cfg file.
 - a. Add the following to the [SECURITY] section:

```
csfkrb5=LIBSYBSKRB secbase=@<REALM>
libgss=<MIT_KRB_32_INSTALL_DIR> \bin\gssapi32.dll
```

i Note

For the above example:

<REALM> should be replaced with the Kerberos realm name.

<MIT_KRB_32_INSTALL_DIR> should be replaced with the directory where MIT Kerberos version
4.0.1 for Windows 32-bit is installed.

The path to the gssapi library, used in the libtcl64.cfg file, cannot contain whitespaces.

The libtcl.cfg is used by the 32bit isql utility and 32-bit OpenClient applications.

- 3. Choose one of the following methods to specify the OID value for MIT Kerberos.
 - Update the [SECMECH] section of the %SYBASE%\ini\sql.ini file. Add the following to the sql.ini file:

```
[ASENAME]
master=TCP,<host>,<port>
query=TCP,<host>,<port>
secmech=1.3.6.1.4.1.897.4.6.6
```

• Use the dsedit utility to add the 'Server Security' attribute value of '1.3.6.1.4.1.897.4.6.6' to your server.

i Note

This OID value derived from the %SYBASE%\ini\objectid.dat file which should not be modified

4. Make sure Adaptive Server is configured for security services. For example, to enable services with LAN Manager, execute:

```
sp configure "use security services", 1
```

For more information, see *Using Security Services with NT LAN Manager* in the *Configuration Guide for Windows NT*.

- 5. Connect to the Adaptive Server without a user name and password. For example:
 - isql -V -SASENAME
 - isql64 -V -SASENAME

6.1.9.6 Establish Kerberos Security for Remote Connections

SAP ASE acts as the client when it connects to another server to execute a remote procedure call (RPC) and for remote connections through Component Integration services (CIS).

For remote server logins through SAP ASE for RPC execution, one physical connection is established between the two servers. The servers use the physical connection to establish one or more logical connections—one logical connection for each RPC.

SAP ASE supports end-to-end Kerberos authentication for Kerberos logins that attempt remote server connections through CIS using the credential delegation feature provided by Kerberos version 5.

The credential delegation or ticket forwarding allows a Kerberos client to delegate the credential when connecting to a server, thereby allowing the server to initiate Kerberos authentication for further connections to other servers on behalf of Kerberos client.

A Kerberos client connected to SAP ASE can request a Remote Procedure Call (RPC) to SAP ASE, and for general distributed query processing requests to a remote server through CIS by using the Kerberos credential delegation feature. The Kerberos authentication feature used for connections to remote servers is not supported for remote server logins. For information about configuring CIS Kerberos Authentication, see *Configuration for Component Integration Services Remote Procedure Calls*, in the *Component Integration Services User Guide*.

i Note

If the ID of any server gets changed after configuring high availability (HA) with SAP ASE, you may experience issues with Kerberos authentication for remote connections to those servers with IDs that have changed. Restart the SAP ASE server to reconnect.

6.1.9.6.1 Unified Login and the Remote Server Logins

If the local server and remote server are set up to use security services, you can use unified login on both servers.

Use one of these two methods:

- The system security officer defines a user as "trusted" with sp_remoteoption on the remote server. The user gains access to the local server using a "unified login" and executes an RPC on the remote server. The user is trusted on the remote server and does not need to supply a password.
- A user specifies a password for the remote server when he or she connects to the local server. The facility to specify a remote server password is provided by the ct_remote_pwd routine available with Open Client Client-Library/C. See the Open Client Client-Library/C Reference Manual.

6.1.9.6.2 Obtain Information About Remote Servers

sp helpserver displays information about servers.

When you run sp_helpserver without an argument, it provides information about all the servers listed in sysservers. You can specify a particular server to receive information about that server. The syntax is:

```
sp_helpserver [<server>]
```

For example, to display information about the GATEWAY server, execute:

```
sp helpserver GATEWAY
```

6.1.10 Principal Names

The principal name is the name the server uses to authenticate with the Kerberos key distribution center (KDC).

6.1.10.1 Server Principal Name

Use the DSLISTEN and DSQUERY environment variables, or the dataserver <code>-s<server_name></code> command line option to specify the server name.

Use either the setenv command or the -k dataserver option to set the principal name.

By default, the principal name is the name of the SAP ASE server. To specify a different name, set SYBASE_PRINCIPAL before starting SAP ASE to use Kerberos:

```
setenv SYBASE_PRINCIPAL <<name of principal>>
```

Once you have set a principal name, the value of this variable is used to authenticate itself to Kerberos.

To specify a principal name when starting the server, use:

```
-k <<server principal name>>
```

When you start a server with the Kerberos security mechanism enabled, the principal name specified with the -k option is used for Kerberos authentication. If the -k option is not specified, the principal name in the environment variable SYBASE_PRINCIPAL is used. If neither is specified, the server name is used for authentication.

Kerberos Open Client connections that use different server principal names are accepted if the entry for the principal name is present in the keytab file. To allow connections with different principal names:

- Pass an empty string as a parameter for the -k option, or
- Set the SYBASE_PRINCIPAL environment variable to "". For example:

```
export SYBASE_PRINCIPAL=""
```

Example

In this example, the server name is "secure_ase" and the realm name is "MYREALM.COM." The server name is specified on the command line with -s parameter to the dataserver. The current realm is specified in libtcl.cfg by a secbase attribute value:

```
[SECURITY] csfkrb5=libskrb.so libgss=/krb5/lib/libgss.so secbase=@MYREALM.COM
```

The default principal name is "secure_ase@MYREALM.COM." If the principal name defined in the keytab file is "aseprincipal@MYREALM.COM," you can override the default principal name by setting a server principal name using options 1 or 2 below:

• Option 1, specify -k '':

```
%
$SYBASE/$SYBASE_ASE/bin/dataserver -dmaster.dat
-s secure_ase -k aseprincipal@MYREALM.COM
```

The principal name used to authenticate with Kerberos is "aseprincipal@MYREALM.COM."

• Option 2, set SYBASE_PRINCIPAL:

```
setenv SYBASE_PRINCIPAL aseprincipal@MYREALM.COM
$SYBASE/$SYBASE_ASE/bin/dataserver -dmaster.dat
-s secure_ase
```

The principal name used to authenticate with Kerberos is "aseprincipal@MYREALM.COM," the value of \$SYBASE PRINCIPAL.

• Option 3, neither -k nor SYBASE_PRINCIPAL is set:

```
% $SYBASE/$SYBASE_ASE/bin/dataserver -dmaster.dat
-s secure_ase
```

The principal name used to authenticate with Kerberos is "secure_ase@MYREALM.COM."

6.1.10.2 Use sybmapname to Handle User Principal Names

sybmapname converts external user principal names used in the Kerberos environment to the namespace of user logins.

You can customize the sybmapname shared object and map names specified in the Kerberos input buffer to names suitable for a login to the server output buffer.

Use the sybmapname shared object to perform the custom mapping between the user principal name and the login name. This shared object is optionally loaded at server start-up, and the function syb_map_name contained in the shared object is called after a successful Kerberos authentication and just before the user principal is mapped to a login in the syslogins table. This function is useful when the user principal name and the login name to be mapped are not identical.

```
syb__map_name(NAMEMAPTYPE *protocol, char *orig,
int origlen, char *mapped, int *mappedlen)
```

where:

- NAMEMAPTYPE *protocol refers to a structure reserved for usage of this function.
- char *orig is an input buffer that is not null-terminated.
- int origlen is the input buffer length, which should be less than or equal to 255 characters.
- char *mapped is an output buffer that should not be null-terminated.
- int *mappedlen is an output buffer length, which should be less than or equal to 30.

syb__map_name returns a value greater than 0 if the mapping succeeds, or returns a value of 0 if no mapping occurred, and it returns a value less than 0 when an error occurs in syb__map_name. When an error occurs, reporting the mapping failure is written to the error log.

For example, to authenticate a Kerberos user on SAP ASE:

- Configure SAP ASE to use the Kerberos security mechanism.
 A sample sybmapname.c file is located in \$SYBASE_ASE/sample/server/sybmapname.c.
- $2. \ \ Modify \ {\tt sybmapname.c} \ to \ implement \ your \ logic. \ See \ \textit{Precautions When Using sybmapname}.$
- 3. Build the shared object or DLL using the generic platform-specific makefile supplied. You may need to modify the makefile to suit your platform-specific settings.
- 4. Place the resulting shared object generated in a location specified in your \$LD_LIBRARY_PATH on UNIX machines, and PATH variable on Windows machines. The file should have read and execute permissions for the "sybase" user.

i Note

SAP recommends that only the "sybase" user is allowed read and execute permissions, and that all other access should be denied.

Precautions When Using sybmapname

When coding for sybmapname:

• Use caution when making modifications to the sample sybmapname.c program. Avoid using code that may create a segmentation fault, that may call exit, that may call system calls, that may change UNIX signals, or that makes any blocking calls. Improper coding or calls may interfere with the SAP ASE server engine.

i Note

SAP bears no responsibility for coding errors in sybmapname.

- Code defensively, check all pointers before dereferencing them, and avoid system calls. The functions you write must be quick name-filtering functions.
- Do not use goto statements since, depending on the platform, they may cause unexpected side effects.
- If you use multiple realms, use caution when mapping the user principal names to a suitable login name to reflect the realm information. For example, if you have two users whose user principal names are userA@REALMONE and userB@REALMTWO, respectively, map them to the login names userA_REALMONE and userB_REALMTWO, instead of userA or userB. This distinguishes the two users who belong to different realms.

Verifying Your login to SAP ASE Using Kerberos Authentication

To verify your login to SAP ASE using Kerberos authentication, assume that:

- \$SYBASE refers to your release and installation directory.
- \$SYBASE ASE refers to the SAP ASE version directory that contains your server binary.
- \$SYBASE OCS refers to the Open Client/Server version directory.

Example: Example 1

If a client's principal name is user@REALM, and the corresponding entry in syslogins table is user_REALM, you can code sybmapname to accept the input string user@realm and to convert the input string to the output string user REALM.

Example: Example 2

sybmapname is loaded by SAP ASE at runtime and uses its logic to do the necessary mapping.

The following actions and output illustrate the sybmapname function. The sybmapname.c file containing the customized definition for syb__map_name() should be compiled and built as a shared object (or DLL), and finally placed in the appropriate path location. Start SAP ASE with the Kerberos security mechanism enabled.

To initialize the Ticket Granted Ticket (TGT), which is a encrypted file that provides identification:

```
$ /krb5/bin/kinit johnd@public
Password for johnd@public:
$
```

To list the TGT:

```
$ /krb5/bin/klist
  Cache Type: Kerberos V5 credentials cache
  Cache Name: /krb5/tmp/cc/krb5cc_9781
Default principal: johnd@public
```

Log in as "sa" and verify the user login for "johnd":

```
$ $SYBASE/$SYBASE OCS/bin/isql -Usa -P
      -Ipwd`/interfaces
1> sp_displaylogin johnd
2> go
No login with the specified name exists.
(return status = 1)
1> sp displaylogin JOHND
2> go
Suid: 4
Loginame: JOHND
Fullname:
Default Database: master
Default Language:
Auto Login Script:
Configured Authorization:
Locked: NO
Password expiration interval: 0
Password expired: NO
Minimum password length:
Maximum failed logins: 0
Current failed login attempts:
Authenticate with: ANY
(return status = 0)
```

Successful Kerberos authentication, maps lower-case johnd to uppercase JOHND using the sybmapname utility, and allows user johnd to log in to SAP ASE:

```
$ $SYBASE/$SYBASE_OCS/bin/isql -V -I'pwd'/interfaces
1>
```

6.2 Configure SAP ASE for LDAP User Authentication

The LDAP user authentication allows client applications to send user name and password information to SAP ASE for authentication by the LDAP server instead of syslogins.

Authentication using the LDAP server allows you to use server-wide passwords instead of SAP ASE or application-specific passwords.

LDAP user authentication is ideal if you want to simplify and centralize user administration, or want to avoid unnecessary complexities for user administration.

LDAP user authentication works with directory servers that meet Version 3 of the LDAP protocol standard, including Active Directory, iPlanet, and OpenLDAP Directory Server.

Use one of these authentication algorithms with LDAP user authentication:

- Composed DN for authentication, available for SAP ASE version 12.5.1 or later, or,
- Searched DN for authentication, available for SAP ASE version 12.5.2 and later.

These algorithms differ in how they obtain a user's distinguished name (DN).

The primary data structure used with the LDAP protocol is the LDAP URL.

An LDAP URL specifies a set of objects or values on an LDAP server. SAP ASE uses LDAP URLs to specify an LDAP server and search criteria to use to authenticate login requests.

The LDAP URL uses this syntax:

```
ldapurl::=ldap://host:port/node/attributes [base | one | sub] filter
```

where:

- <host> is the host name of the LDAP server.
- <port> is the port number of the LDAP server.
- <node> specifies the node in the object hierarchy at which to start the search.
- <attributes> is a list of attributes to return in the result set. Each LDAP server may support a different list of attributes.
- base | one | sub qualifies the search criteria. base specifies a search of the base node; one specifies a search of the base node and one sublevel below the base node; sub specifies a search of the base node and all node sublevels.
- filter specifies the attribute or attributes to be authenticated. The filter can be simple, such as uid=*, or compound, such as (uid=*) (ou=group).

6.2.1 Composed DN Algorithm

When you use the composed DN algorithm, this is login sequence used.

- 1. Open Client connects to an listener port.
- 2. The listener accepts the connection.
- 3. Open Client sends an internal login record.
- 4. The SAP ASE server reads the login record..
- 5. SAP ASE binds to the LDAP server with a DN composed from the primary URL and the login name from the login record. This bind also uses the password from the login record.
- 6. The LDAP server authenticates the user, returning either a success or failure message.
- 7. If the Primary URL specifies a search, then SAP ASE sends the search request to the LDAP server.
- 8. The LDAP server returns the results of the search.
- 9. The login is accepted or rejected based on the search results.

6.2.2 Searched DN Algorithm

When you use the searched DN algorithm, this is the login sequence used.

- 1. Open Client connects to an SAP ASE listener port.
- 2. The SAP ASE listener accepts the connection.
- 3. Open Client sends an internal login record.
- 4. SAP ASE reads the login record.
- 5. SAP ASE binds to the LDAP server with a directory server access account.

 The connection established in steps 5 and 6 may persist between authentication attempts from SAP ASE to reuse connections to DN searches.
- 6. The LDAP server authenticates the user, returning either a success or failure message.
- 7. SAP ASE sends search requests to the LDAP server based on the login name from the login record and the DN lookup URL.
- 8. The LDAP server returns the results of the search.
- 9. SAP ASE reads the results to obtain an a value of attribute from the DN lookup URL.
- SAP ASE uses the value of attribute as the DN and the password from the login record to bind to the LDAP server.
- 11. The LDAP server authenticates the user, returning either a success or failure message.
- 12. If the primary URL specifies a search, SAP ASE sends the search request to the LDAP server.
- 13. The LDAP server returns the results of the search.
- 14. SAP ASE accepts or rejects the login, based on the search results.

SAP ASE reports a generic login failure to the client if any of these authentication criteria are not met.

You may skip steps 12 and 13 by not specifying search criteria in the primary or secondary URL strings. The authentication completes, displaying the success or failure returned by step 11.

6.2.3 Configuring LDAP in New SAP ASE Installations

You can configure SAP ASE for LDAP authentication.

Procedure

- 1. Specify the LDAP URL search strings and access account values.
- 2. Set enable ldap user auth to 2.
- 3. Add users in the LDAP directory server using LDAP vendor-supplied tools.
- 4. Add users using create login. You can also use sp_maplogin to automatically create login accounts upon authentication or apply other login controls.

6.2.4 Migrating existing SAP ASE Servers to LDAP

To avoid disruption of service in existing server installations, migrate SAP ASE to LDAP.

Procedure

- 1. Specify an LDAP URL search string to SAP ASE.
- 2. Set the configuration parameter enable ldap user auth to 1.
- 3. Add users in the LDAP directory server.
- 4. When all users are added to the LDAP server, set enable ldap user auth to 2 to require all authentications to be performed with LDAP, or use sp_maplogin to override configuration parameters with login controls.

6.2.5 LDAP User Authentication Administration

Use sp_ldapadmin to create or list an LDAP URL search string, verify an LDAP URL search string or login, and specify the access accounts and tunable LDAP user authentication (LDAPUA) related parameters.

You must have the SSO role to execute ${\tt sp_ldapadmin}.$

Composed DN Examples

If you use a simple LDAP server topology and schema, you can use a composed DN algorithm for user authentication. If you use commercially available schemas (for example, iPlanet Directory Servers or OpenLDAP Directory Servers), users are created as objects in the same container in the LDAP server tree, and SAP ASE determines the user's DN from the object's location. However, there are restrictions on the LDAP server's schema:

- You must specify the filter with the attribute name that uniquely identifies the user to be authenticated.
- You must specify the filter with the attribute name=*. The asterisk is a wildcard character. The appropriate attribute name to use in the filter depends on the schema used by the LDAP server.
- The login name is the same as the short user name for example, a UNIX user name.
- The DN uses the short user name rather than a full name with embedded spaces or punctuation. For example, jqpublic meets the restriction for a DN, but "John Q. Public" does not.

iPlanet Example

LDAP vendors may use different object names, schema, and attributes than those used in these examples. There are many possible LDAP URL search strings, and valid sites may also extend schemas locally or use them in ways that differ from each other:

• This example uses the uid=* filter. To compose the DN, SAP ASE replaces the wildcard with the login name to be authenticated, and appends the resulting filter to the node parameter in the LDAP URL. The resulting DN is:

```
uid=myloginname,ou=People,dc=mycomany,dc=com
```

• After a successful bind operation, the connection is used to search for attribute names, such as uid, that are equal to the login name:

```
sp_ldapadmin set_primary_url, 'ldap://myhost:389/
ou=People,dc=mycompany,dc=com??sub?uid=*'
```

• This example uses the schema defined in OpenLDAP 2.0.25, with an attribute name of cn. The composed DN is cn=myloginname, dc=mycompany, dc=com:

```
sp_ldapadmin set_primary_url, 'ldap://myhost:389/dc=mycompany,dc=com??sub?
cn=*'
```

Searched DN Examples

Use the searched DN to use an Active Directory server or other LDAP server environment that does not meet the restrictions to use the composed DN algorithm.

- Perform these steps for an Active Directory server using a commercially available user schema from a Windows 2000 Server.
 - 1. Set the access account information:

```
sp_ldapadmin set_access_acct,
'cn=Admin Account, cn=Users, dc=mycompany, dc=com',
'Admin Account secret password'
```

2. Set the primary URL:

```
sp_ldapadmin set_primary_url, 'ldap://hostname:389/
```

3. Set the DN lookup URL search string:

```
sp_ldapadmin set_dn_lookup_url, 'ldap://hostname:389/
cn=Users,dc=mycompany,dc=com?distinguishedName?one?samaccountname=*'
```

On Windows, the short name is typically referred to as the "User Logon Name" and is given the attribute name samaccountname in the default schema. This is the attribute name used to match the login name. The DN for a user contains a full name with punctuation and embedded spaces (for example, cn=John Q. Public, cn=Users, dc=mycomany, dc=com. The DN on Windows does not use the short name, so the searched DN algorithm is appropriate for sites using the Active Directory schema (the default) as the LDAP server. The primary URL does not specify a search. Instead, it relies on the bind operation for authentication.

Examples Using Search Filters to Restrict Access

You can use LDAP URL search strings to restrict access to groups of users on LDAP servers. For example, to restrict logins to users in an accounting group. use a compound filter to restrict access to the group of users where attribute group=accounting.

• The following LDAP URL string uses the composed DN algorithm for an iPlanet server:

```
sp_ldapadmin set_primary_url, 'ldap://myhost:389/ou=People,dc=mycompany,
dc=com??sub?(&(uid=*)(group=accounting))'
```

SAP ASE binds with DN uid=mylogin, ou=People, dc=mycompany, dc=com. After successfully binding with this identity, it searches for:

```
"ou=People,dc=mycompany,dc=com??sub?(&(uid=mylogin)(group=accounting))"
```

Authentication succeeds if this search returns any objects.

• These examples use LDAP URL strings with compound filters:

```
sp_ldapadmin set_primary_url, 'ldap://myhost:389/
ou=people,dc=mycompany,dc=com??sub?(&(uid=*)(ou=accounting) (l=Santa Clara))'

sp_ldapadmin, set_primary_url, 'ldap://myhost:389/
ou=people,dc=mycompany,dc=com??sub?(&(uid=*)(ou=Human%20Resources))'
```

6.2.5.1 LDAP User Authentication Password Information Changes

There are two LDAP user authentication-related informational messages that SAP ASE obtains from the LDAP server and passes to the client.

• If you log in to an SAP ASE server using an LDAP authentication mechanism with an LDAP user authentication password that is about to expire, you see:

```
Your password will expire in <<number>>> days.
```

• If you attempt to log in to SAP ASE using an LDAP authentication mechanism after the LDAP server administrator resets your password or after your LDAP server password has expired, you see message 4002:

```
Login failed
```

If auditing is enabled and the errors auditing option is turned on, message 4099 is sent to the audit log:

```
Your LDAP password has expired.
```

i Note

Configure your LDAP server to give this additional information. Additionally, SAP ASE must support the transmission of LDAP password controls to an LDAP client.

6.2.5.2 Failover Support

When a major failure occurs in the LDAP directory server specified by the primary URL, and the server no longer responds to network requests, SAP ASE attempts to connect to the secondary LDAP directory server specified by the secondary URL.

SAP ASE uses the LDAP function <code>ldap_init</code> to determine if it can open a connection to the LDAP directory server. A null or invalid primary URL string causes an SAP ASE server to attempt to fail over to a secondary URL. Failures returned by LDAP bind or search operations do not cause a fail over to the secondary URL.

6.2.6 Logins and LDAP User Accounts

Once you enable LDAP user authentication, choose and set an authentication algorithm and URL strings, you must configure the user accounts.

The LDAP administrator creates and maintain accounts in the LDAP server, and the database administrator creates and maintains accounts in SAP ASE. Alternatively, the database administrator can choose administration options that allow flexibility with login accounts when integrating SAP ASE with external authentication mechanisms such as LDAP server. The database administrator continues to administer the account roles, default database, default language, and other login-specific attributes using traditional commands and procedures.

Updates to syslogins from LDAP describes the updates that SAP ASE makes at login time to the syslogins table. These updates assume that LDAP user authentication is configured, the login is not restricted from using LDAP, and you have not set the create login mapping.

These are the updates to syslogins from LDAP:

Does the row	exist in	syslo-
--------------	----------	--------

gins?	LDAP server authentication succeeds?	Changes in syslogins
No	Yes	No change, login fails
No	No	No change, login fails
Yes	Yes	Update row if password has changed
Yes	No	No change

6.2.7 Secondary Lookup Server Support

Uninterrupted support is provide for clients that are authenticated by an LDAP server. You can specify a secondary LDAP lookup server to fail over from a primary LDAP server in the event of the LDAP server failure or planned downtime.

The health of the URL set is monitored through the following states:

- INITIAL indicates that LDAP user authentication is not configured.
- RESET indicates that the URL has been entered with administrative commands.

- READY indicates that the URL is ready to accept connections.
- ACTIVE indicates that the URL has performed a successful LDAP user authentication.
- FAILED indicates that there is a problem connecting to the LDAP server.
- SUSPENDED indicates that the URL is in maintenance mode, and will not be used.

The following sequence of events describe the failover and manual failback:

- 1. The primary and secondary URL sets are configured and in a READY state.
- 2. The connections are authenticated using the primary server infrastructure.
- 3. The primary server fails, and its state is changed to FAILED.
- 4. Connections automatically begin authentication through the secondary server infrastructure.
- 5. The primary server is repaired and brought back online by an LDAP administrator. The primary LDAP server state is changed by an administrator to READY.
- 6. New connections are authenticated using the primary server.

i Note

Once the SAP ASE server has failed over to the secondary LDAP server, a database administrator must manually activate the primary LDAP server before it can be used again.

When SAP ASE encounters errors connecting to an LDAP server, it retries the authentication three times. If the errors persist, the LDAP server is marked as FAILED.

Use sp ldapadmin to configure secondary lookup LDAP servers.

- To set the secondary DN lookup URL, enter: sp_ldapadmin set_secondary_dn_lookup_url, <URL>
- To set the administrative access account for the secondary DN lookup URL, enter:

```
sp ldapadmin set secondary access acct, <DN>, <password>
```

• To suspend the use of a primary or secondary URL for authentication, enter:

```
sp_ldapadmin suspend, {primary | secondary}
```

• To activate the set of primary or secondary URLs for authentication, enter:

```
sp_ldapadmin activate, {primary | secondary}
```

• To display details about the primary and secondary LDAP server settings and status, enter:

```
sp ldapadmin list
```

sp_ldapadmin list combines previous outputs from list_access_acct and list_urls. It has the following expected output for the primary and secondary servers:

- Search URL
- Distinguished name lookup URL
- Access account DN
- Active [true | false]
- Status [ready | active | failed | suspended | reset]
- To display DN lookup URLs for the secondary server, enter:

```
sp_ldapadmin list_urls
```

• To display the administrative account for the secondary DN lookup URL, enter:

```
sp ldapadmin list access acct
```

• To display subcommands, enter:

```
sp ldapadmin help
```

6.2.8 LDAP Server State Transitions

Use the ${\tt sp_ldapadmin}$ command to show LDAP server state transitions.

Table 7: State Transitions When sp_Idapadmin set_URL is Executed

Initial state	Final state
INITIAL	RESET
RESET	RESET
READY	READY
ACTIVE	RESET
FAILED	RESET
SUSPENDED	RESET

 $\mathtt{set}_\mathtt{URL}$ represents one of these commands

- set_dn_lookup_url
- set_primary_url
- set_secondary_dn_lookup_url
- set_secondary_url

Table 8: State Transitions When sp_Idapadmin Suspend is Executed

Initial state	Final state	
INITIAL	Error	
RESET	SUSPENDED	
READY	SUSPENDED	
ACTIVE	SUSPENDED	
FAILED	SUSPENDED	
SUSPENDED	SUSPENDED	

Table 9: State Transitions When sp_Idapadmin Activate is Executed

Initial state	Final state
INITIAL	Error
RESET	READY
READY	READY

Initial state	Final state
ACTIVE	ACTIVE
FAILED	READY
SUSPENDED	READY

The following tables show the LDAP server state transitions carried out implicitly by SAP ASE.

Table 10: State Transitions When SAP ASE is Restarted

Initial state	Final state
INITIAL	INITIAL
RESET	RESET
READY	READY
ACTIVE	READY
FAILED	FAILED
SUSPENDED	SUSPENDED

SAP ASE only attempts an LDAP login if the LDAP server is in a READY or ACTIVE state.

Table 11: State Transitions When an LDAP Login Succeeds

Initial state	Final state
READY	ACTIVE
ACTIVE	ACTIVE
Table 12: State Transitions When an LDAP Login Fails	

lable 12: State Transitions When an LDAP Login Fails
--

Initial state	Final state
READY	FAILED
ACTIVE	FAILED

6.2.9 LDAP User Authentication Tuning

Configure and tune SAP ASE options based on the load of incoming connections and the SAP ASE/LDAP server infrastructure.

Configure these options based on the number of simultaneous incoming requests:

- Use sp_configure to set max native threads, which indicates the number of native threads per engine.
- Use sp_ldapadmin to configure max_ldapua_native_threads, which indicates the number of LDAP user authentication native threads per engine.

Configure the set_timeout option (which indicates the LDAP server bind and search timeouts) based on the network and the health of the SAP ASE/LDAP server infrastructure.

Configure the set_abandon_ldapua_when_full option to specify the behavior when incoming connections have consumed max ldapua native threads:

Use these sp ldapadmin options to configure the LDAP server for better performance:

- set_max_ldapua_desc manages the concurrency of the LDAPUA connection requests. If you are using a distinguished name algorithm, setting set_max_ldapua_desc to a larger number expedites the LDAPUA connections SAP ASE is processing.
- set_num_retries sets the number of attempts. Tune this number according to the number of transient errors between SAP ASE and the LDAP server. You can nullify transient errors by configuring the number of retries.
- set_log_interval controls the number of messages sent to the error log for diagnostic purposes.

 Using a low number clutters the error log may be helpful in identifying specific errors. Using a large number sends fewer messages to the error log, but does not have the same investigative value. Tune set log interval according to your error log size.

6.2.10 Add Tighter Controls on Login Mapping

Use sp maplogin to map users that are authenticated with LDAP or PAM to the local login.

i Note

To map a user authenticated with Kerberos, use sybmapname instead of sp maplogin.

Only users with sso role can create or modify login mappings using sp maplogin.

SAP ASE avoids conflicts between an authentication mechanism setting for a login and a mapping that uses the login. Potential mapping conflicts are detected by the stored procedure <code>sp_maplogin</code> or the commands alter login, Or create login.

These controls do not allow maps:

- From one login name to another login name
- From an external name that already exists as a local login
- To a nonexistent login name

Additionally, when the authentication mechanism is specified with a mapping, the mechanism is checked with the authentication mechanism set in the target login.

If a target login's authentication mechanism restricts the login to use a particular authentication mechanism, then the mechanism specified with the mapping must match either that specified for the login or match the "ANY" authentication mechanism.

When $sp_{maplogin}$ detects that a conflict exists, $sp_{maplogin}$ fails and reports an error that identifies the conflict.

Similarly, alter login and create login check for an existing mapping that may conflict with the authenticate with option for the user login. When alter login or create login detect a conflict, an error is reported to identify any conflicts with a login mapping.

Example: Example 1

Maps an LDAP user to the "sa" login. A company has adopted LDAP as their repository for all user accounts and has a security policy that requires LDAP authentication of all users including database administrators, "adminA" and "adminB," who may manage hundreds of servers. Auditing is enabled, and login events are recorded in the audit trail.

To map these administrator accounts to "sa," enter:

```
sp_maplogin LDAP, 'adminA', 'sa'
go
sp_maplogin LDAP, 'adminB', 'sa'
go
```

Require all users to authenticate using LDAP authentication:

```
sp_configure 'enable ldap user auth', 2
go
```

When "adminA" authenticates during login to a server, the distinguished name associated with "adminA" rather than only "sa" is recorded in the login audit event. This allows each individual performing an action to be identified in the audit trail.

Because the "adminA" and "adminB" password is set in the LDAP server, there is no need to maintain the "sa" password on all servers being managed.

This example also allows different external identities and passwords to be used for authentication, while their actions within the server still require the special privileges associated with "sa" account.

Example: Example 2

Uses both PAM and LDAP to map users to application logins. A company has adopted both PAM and LDAP authentication but for different purposes. The company security policy defines LDAP as the authentication mechanism for general user accounts, and PAM for special users, such as for a middle-tier application. A middle-tier application may establish a pool of connections to SAP ASE to handle requests on behalf of users of the middle-tier application.

Configure SAP ASE for both LDAP and PAM user authentication:

```
sp_configure 'enable ldap user auth', 2
go
sp_configure 'enable pam user auth', 2
go
```

Establish a login appx locally with permissions that are appropriate for the middle-tier application:

```
create login appX with password myPassword go alter login appX authenticate with PAM go
```

Instead of hard-coding a simple password in "appX" and maintaining the password consistently in several different servers, develop a custom PAM module to authenticate the application in a centralized repository using additional facts to verify the middle-tier application.

Client application login "appY" requires LDAP authentication of the user with its LDAP identity and password. Use sp maplogin to map all LDAP authenticated users to login "appY,"

```
create login appY with password myPassword go sp_maplogin LDAP, NULL, 'appY' go
```

Users of "appY" are authenticated with their company identity and password, then mapped to a local login "appY" to execute database actions. Authentication has occurred with the identity of the LDAP user, which is recorded in the audit trail, and executes with permissions appropriate to the application login "appY."

6.2.10.1 Login Mapping of External Authentication

When you configure an external authentication mechanism, if there is a single mapping of an external user to an internal login, and if the mapping is successfully authenticated, the internal login password is updated to match the external user's password.

For example:

- A user has an login name of user_ase (with password user_password), and an LDAP login name of user_ldap (with password user_ldappasswd).
 The produces a one to one mapping for user ldap to user ase.
- 2. When user_ldap logs into the server using the user_ldappassword, the password for user_ase is updated to user ldappassword

The benefit of mapping the login name to the LDAP password is that the user can log in with the most recently used LDAP password if the LDAP server crashes. That is, when a user has a one-to-one mapping of a user name to an LDAP password for authentication, the user appears to have uninterrupted authentication because the password is updated locally when it is used to authenticate the login.

However, the password is not updated locally when more than one external user is mapped to the local user. If the LDAP server crashes, multiple external users cannot be mapped to a single user.

6.2.11 Troubleshoot LDAP User Authentication Errors

SAP ASE may experience the following transient errors when communicating with the LDAP server.

These errors are generally resolved by retrying the connection. If the errors persist after three retry attempts, SAP ASE marks the LDAP server as FAILED.

- LDAP_BUSY server is busy.
- LDAP_CONNECT_ERROR error during a connection.
- LDAP LOCAL ERROR error on the client side.
- LDAP_NO_MEMORY cannot allocate memory on the client side.
- LDAP OPERATIONS ERROR error on the server side.
- LDAP_OTHER unknown error code.
- LDAP_ADMINLIMIT_EXCEEDED a search has exceeded a limit.
- LDAP_UNAVAILABLE server cannot process the request.
- LDAP_UNWILLING_TO_PERFORM server is not going to process the request.
- LDAP_LOOP_DETECT a loop has been detected during a referral.
- LDAP_SERVER_DOWN server is not reachable (connection fails).
- LDAP_TIMEOUT LDAP API fails because operation does not complete in the user-specified amount of time

Transient errors and a large number of simultaneous login requests may lead to a large number of repeated error messages in the error log. To increase the readability of the log, this error message logging algorithm is used:

- 1. If a message is being logged for the first time, log it.
- 2. If the last time the message was logged was greater than 3 minutes:
 - · Log the error message.
 - Log the number of times the message was repeated since the message was last printed.
 - Log the time elapsed, in minutes, since the message was printed.

Authentication failures arising from the following are not considered LDAP errors and are not conditions for retrying the authentication request:

- Bind failure due to bad password or an invalid distinguished name.
- A search after a successful bind that returns a result set of 0 or no attribute value.

Syntax errors found while parsing the URL are caught when an LDAP URL is set, and therefore do not fall into any of the above categories.

6.2.12 Configuring an LDAP Server

User authentication for Lightweight Directory Access Protocol (LDAP) supports the Secure Sockets Layer/ Transport Layer Security (SSL/TLS) protocol, providing secure data transmission between SAP ASE and an LDAP server.

Procedure

1. Make sure that all trusted root certificates are located in the same file.

After you define the trusted servers, a secure connection is configured, where servername is the name of the current server. If you:

- Have defined \$SYBASE_CERTDIR, certificates are loaded from \$SYBASE_CERTDIR/servername.txt (for UNIX) or \$SYBASE_CERTDIR\servername.txt (for Windows).
- Have not defined \$SYBASE_CERTDIR, certificates are loaded from \$SYBASE_ASE/ certificates/servername.txt (for UNIX) or %SYBASE%\\$SYBASE_ASE%\certificates \servername.txt (for Windows).
- 2. Restart the server to change the trusted root certificate file.
- 3. Use sp_ldapadmin, specifying ldaps://URLs instead of ldap://URLs, to establish a secure connection to a secure port of the LDAP server.
- 4. Establish a TLS session over a plain TCP connection:

```
sp_ldapadmin 'starttls_on_primary', {<true> | <false>}

or

sp_ldapadmin 'starttls_on_secondary', {<true> | <false>}
```

Results

i Note

LDAP server connections do not have a connect timeout option; if the LDAP server stops responding, all login connections also stop responding.

6.3 LDAPS User Authentication

The command, reinit_descriptors unbinds the LDAP server descriptors and reinitializes the user authentication subsystem.

- This command requires System Security Officer permissions.
- If the Certifying Authority (CA) trusted root file is modified without execution of this command by a user with System Security Officer permissions, the housekeeping utility chores task uses a new chore, designed to reinitialize the user authentication subsystem every 60 minutes.

 SAP ASE supports modifications to the trusted root file, so that restarting the server is unnecessary.

6.4 Automatic LDAP User Authentication and Failback

SAP ASE provides support for a secondary LDAP server.

The set_failback_interval option in sp_ldapadmin set_failback_interval sets the interval between attempts to activate failed LDAP servers; if you do not set this parameter, the default value is 15 minutes. See sp_ldapadmin in the *Reference Manual: Procedures*.

If the primary URL is marked FAILED, the housekeeper task attempts to activate it, using the primary access account distinguished name (DN) and password. If you have not configured a primary access account, the housekeeper task attempts to use an anonymous bind. If the bind operation fails on the first attempt, the housekeeper task retries the bind operation for the number of retry times configured. If the bind operation succeeds, the primary URL is marked READY.

If the secondary URL is marked FAILED, the housekeeper task attempts to activate the secondary URL in a similar way.

The $reinit_descriptors$ option in $sp_ldapadmin$ executes when the certificate file is modified, in which case it reinitializes the LDAP user authentication subsystem every 60 minutes.

After you set the failback interval, the housekeeper task checks for failed LDAP servers each time it sweeps through its chores. When it finds a failed LDAP server, it attempts to activate the LDAP server when the failback time interval expires.

6.4.1 LDAP Failback Time Interval

To activate an LDAP server automatically, use 'set failback interval'.

The syntax is:

```
sp_ldapadmin 'set_failback_interval', <time_in_minutes>
```

where:

<time in minutes> is the value from -1 to 1440 minutes (24 hours):

- A value of 0 indicates that failing back is manual. That is, the housekeeper task does not attempt to automatically fails back the LDAP server. You must perform this task manually.
- A value of -1 sets the fail over time interval to 15 minutes, the default.
- If you issue sp_ldapadmin 'set_failback_interval' without any parameters, sp_ldapadmin displays the value to which the fail back interval is set.
- If you issue sp_ldapadmin without any parameters, sp_ldapadmin includes the failback time interval in the output:

```
sp ldapadmin
Primary:
                         1 1
   URL:
   DN Lookup URL:
                         1.1
                         1.1
   Access Account:
   Active:
                         'FALSE'
    Status:
                         'NOT SET
   StartTLS on Primary LDAP URL: 'TRUE'
Secondary:
    URL:
   Access Account:
Active:
Status:
Startmr
                         'FALSE'
                        'NOT SET'
   StartTLS on Secondary LDAP URL: 'FALSE'
Timeout value:
                         '-1'(10000) milliseconds
                         '3' minutes
Log interval:
Number of retries:
                       131
Maximum LDAPUA native threads per Engine: '49'
Maximum LDAPUA descriptors per Engine: '20'
Abandon LDAP user authentication when full: 'false'
                        '-1'(15) minutes
Failback interval:
(return status = 0)
```

This example sets the LDAP failback time interval to 60 minutes:

```
sp_ldapadmin 'set_failback_interval' 60
```

This example sets the LDAP failback

time interval to the default, 15 minutes:

```
sp_ldapadmin 'set_failback_interval' -1
```

This example displays the value to which the failback interval is set:

```
sp_ldapadmin 'set_failback_interval'
The LDAP property 'set_failback_interval' is set to '15
    minutes'.
```

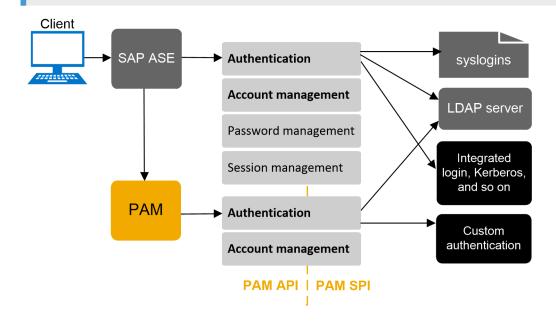

6.5 Configure SAP ASE for Authentication Using PAM

Pluggable Authentication Module (PAM) support allows multiple authentication service modules to be stacked and made available without modifying the applications that require authentication.

PAM integrates SAP ASE with Unix operating systems and simplifies the management and administration of user accounts and authentication mechanisms, thus reducing the total cost of ownership. Users can customize or write their own authentication and authorization modules.

i Note

PAM is available on all platforms except Windows. For more information on PAM user authentication, see your operating system documentation.

SAP ASE passes the login name and credentials obtained from the login packet to the PAM API. PAM loads a service provider module as specified in the operating system configuration files and calls appropriate functions to complete the authentication process.

6.5.1 Enable PAM in SAP ASE

PAM is available on all operating systems except Windows.

You can use one of these modules, or create one of your own. When creating your own modules, follow the guidelines in your operating system documentation on creating a PAM module.

i Note

PAM modules you create should comply with RFC 86.0 "Unified Login With Pluggable Authentication Modules (PAM)." SAP ASE supports the authentication management module of the RFC. It does not support the account management, session management, or password management modules.

6.5.1.1 Configuring Operating Systems

Configure your operating system to enable PAM support.

• For Solaris, add the following line to /etc/pam.conf:

```
ase auth required /user/lib/security/$ISA/pam_unix.so.1
```

• For Linux, create a new file called /etc/pam.d/ase, and add:

```
auth required /lib/security/pam_unix.so
```

i Note

PAM is available on all platforms except Windows. For more information on PAM user authentication, see your operating system documentation.

For more information on how to create these entries, see your operating system documentation.

6.5.1.2 Running a 32- and 64-bit Server on the Same Machine

\$ISA is an environment variable that allows 32- and 64-bit libraries to run together.

Context

On Solaris 32-bit machines, \$ISA is replaced by an empty string, while on 64-bit machines, it is replaced by the string "sparcv9".

To use both 32- and 64-bit servers, place the 32-bit PAM module in a directory, and place the 64-bit version in a subdirectory of this directory.

The entry in pam.conf should look similar to:

```
$ ls /usr/lib/security/pam_sec.so.1
pam_sec.so.1 -> /SYBASE/pam_whatever_32bits.so.1
$ ls /usr/lib/security/sparcv9/pam_sec.so.1
pam_sec.so.1 -> /SYBASE/pam_sec_64bits.so.1
ase auth required /usr/lib/security/$ISA/pam_sec.so.1
```

i Note

\$ISA is the only variable allowed in pam.conf.

6.5.1.3 Configure SAP ASE for PAM User Authentication

enable pam user auth enables PAM user authentication support.

The syntax is:

```
sp_configure "enable pam user auth", 0 | 1 | 2
```

where:

- 0 disables PAM authentication. This is the default.
- 1 indicates SAP ASE first attempts PAM authentication, and then uses syslogins authentication if PAM authentication fails.
- 2 indicates only PAM authentication may be used.

i Note

When PAM is enabled, password management is delegated to the PAM service providers.

6.5.1.4 Logins and PAM User Accounts

After you have set enable PAM user authentication and completed the PAM configuration for both SAP ASE and the operating system, you must configure the user accounts.

The operating system or network security administrator creates and maintains user accounts in the PAM service provider, and the database administrator creates and maintains accounts in SAP ASE. Alternatively, the database administrator can choose administration options that allow flexibility with login accounts when integrating SAP ASE with external authentication mechanisms such as PAM. The database administrator continues to administer the account roles, default database, default language, and other login-specific attributes using traditional commands and procedures.

The following table describes updates to syslogins made at login time. It assumes that PAM user authentication is configured, the login is not restricted from using PAM, and you have not set the create login mapping

Does the row exist in syslo-

gins?	PAM authentication succeeds?	Changes in syslogins
No	Yes	No change, login fails
No	No	No change, login fails
Yes	Yes	Update row if password has changed
Yes	No	No change

6.6 Enhanced Login Controls

Configure SAP ASE to allow the server-wide authentication mechanism according to the methods discussed in the LDAP and PAM sections earlier.

You can also configure SAP ASE to specify the authentication mechanism for each individual login on the server using enhanced login controls.

Login-specific controls may be useful when a server is transitioning between authentication mechanisms or for server-specific logins that local server administration may require; they are not associated with a centrally managed user login.

6.6.1 Forced Authentication

You can force a login to use a specific authentication process by using alter login and create login

Use these parameters for alter login and create login:

- ASE use SAP ASE internal authentication using passwords from syslogins table.
- LDAP use external authentication with an LDAP server.
- PAM use external authentication with PAM.
- ANY by default, users are authenticated using this authentication method. A user with ANY
 authentication means that SAP ASE checks if there is any external authentication mechanism defined, and
 if there is, it is used. Otherwise, it uses SAP ASE authentication.

SAP ASE checks for external authentication mechanisms in the following order:

- 1. LDAP.
- 2. Pluggable Authentication Modules (PAM). If both LDAP and PAM are enabled, PAM authentication is never attempted for a user.
- 3. If neither PAM nor LDAP is enabled, SAP ASE uses syslogins to authenticate the login.

Login accounts such as "sa" continue to be validated using the syslogins catalog. Only the SSO role can set authenticate for a login.

For example, the following authenticates the login with alter login:

```
alter login nightlyjob modify authenticate with ASE sp_displaylogin "nightlyjob"
```

Displays output similar to:

```
Suid: 1234
Loginname: nightlyjob
Fullname: Batch Login
Default Database: master
...
Date of Last Password Change: Oct 2 2003 7:38 PM
Password expiration interval: 0
Password expired: N
Minimum password length:
Maximum failed logins: 0
Current failed login attempts:
```

6.6.2 Map Logins Using sp_maplogin

Use sp maplogin to map logins.

The syntax is:

```
sp_maplogin (authentication_mech | null),
(<client_username> | null), (<action> | <login_name> | null)
```

This example maps external user "jsmith" to the user "guest." Once authenticated, "jsmith" has the privileges of "guest." The audit login record shows both the <client username> and the user name:

```
sp_maplogin NULL, "jsmith", "guest"
```

This example creates a new login for all external users authenticated with LDAP, if a login does not already exist:

```
sp_maplogin LDAP, NULL, "create login"
```

For more information, see Reference Manual: Procedures.

6.6.2.1 Display Mapping Information

 $\verb"sp_helpmaplogin" displays mapping information.$

The syntax is:

```
sp_helpmaplogin [ (authentication_mech | null), (client_username | null) ]
```

where:

<client_username> - is an external user name.

If you do not include any parameters, <code>sp_helpmaplogin</code> displays login information about all users currently logged in to SAP ASE. You can restrict the output to specific sets of client user names or authentication mechanisms by using the parameters listed above.

This displays information about all logins:

```
authentication client name login name

NULL jsmith guest
LDAP NULL create login
```

6.6.2.2 Determine the Authentication Mechanism

Use the <@@authmech> global variable to determine the authentication mechanism SAP ASE uses.

For example, if SAP ASE is enabled for LDAP user authentication with failover (enable ldap user auth = 2) and user "Joe" is an external user with authentication set to ANY, when Joe logs in, SAP ASE attempts to authenticate Joe, using LDAP user authentication. If Joe fails authentication as a user in LDAP, Joe is authenticated using SAP ASE authentication, and if that succeeds, he logs in successfully.

<@@authmech> global has this value:

If SAP ASE is configured for strict LDAP user authentication (enable ldap user auth = 2) and Joe is added as a valid user in LDAP, when Joe logs in, the value for @@authmech is:

select @@authmech
ldap

7 Manage User Permissions

Discretionary access controls (DACs) allow you to restrict access to objects and commands based on a user's identity, group membership and active roles.

The controls are "discretionary" because a user with a certain access permission, such as an object owner, can choose whether to pass that access permission on to other users.

The discretionary access control system recognizes the following types of users:

- Users possessing one or more system defined roles: system administrator, system security officer, operator, and other roles
- Database owners
- Database object owners
- Other users

System administrators (those users with sa_role) operate outside the DAC system and have access permissions on all database objects at all times except encryption keys (see *Database Encryption*). System security officers can always access the audit trail tables in the sybsecurity database to track accesses by system administrators.

If you have the sa_role, all grants permissions for create database, set tracing, and connect as well, if you issue the grant command in the master database.

Database owners do not automatically receive permissions on objects owned by other users; however, they can:

- Temporarily acquire all permissions of a user in the database by using the setuser command to assume the identity of that user.
- Permanently acquire permission on a specific object by using the setuser command to assume the identity of the object owner, and then using grant commands to grant the permissions.

Object owners can grant access to those objects to other users and can also grant other users the ability to pass the access permission to other users. You can give various permissions to users, groups, and roles with the grant command, and rescind them with the revoke command. Use grant and revoke to give users permission to:

- Create databases
- · Create objects within a database
- Execute certain commands such as dbcc and set proxy
- Access specified tables, views, stored procedures, encryption keys, and columns

grant and revoke can also be used to set permissions on system tables.

For permissions that default to "public," no grant or revoke statements are needed.

Some commands can be used at any time by any user, with no permission required. Others can be used only by users of a particular status and they are not transferable.

The ability to assign permissions for the commands that can be granted and revoked is determined by each user's role or status (as system administrator, database owner, system security officer, or database object

owner), and by whether the user was granted a role with permission that includes the option to grant that permission to other users.

You can also use views and stored procedures as security mechanisms.

Operations may differ when granular permissions is enabled.

Related Information

Views and Stored Procedures as Security Mechanisms [page 190] Granular Permissions [page 242]

7.1 Granting Permissions for Creating Databases

Only a system administrator can grant permission to use the create database command.

Context

The user that receives create database permission must also be a valid user of the master database because all databases are created while using master. In many installations, the system administrator maintains a monopoly on create database permission to centralize control of database placement and database device space allocation. In these situations, a system administrator creates new databases on behalf of other users, and then transfers ownership to the appropriate user.

Procedure

- 1. Issue the create database command in the master database.
- 2. Switch to the new database with the use command.
- 3. Execute sp changedbowner.

7.1.1 Change Database Ownership

Use sp_changedbowner to change the ownership of a database.

Often, system administrators create the user databases, then give ownership to another user after some of the initial work is complete. Only the system administrator can execute sp changedbowner.

SAP suggests that you transfer ownership before the user has been added to the database, and before the user has begun creating objects in the database. The new owner must already have a login name on the server, but cannot be a user of the database, or have an alias in the database. You may have to use <code>sp_dropuser</code> or <code>sp_dropalias</code> before you can change a database's ownership, and you may have to drop objects before you can drop the user.

Issue sp changedbowner in the database whose ownership is to be changed. The syntax is:

```
sp_changedbowner <loginame> [, true ]
```

This example makes "albert" the owner of the current database and drops aliases of users who could act as the old "dbo:"

```
sp changedbowner albert
```

Include the true parameter to transfer aliases and their permissions to the new "dbo."

i Note

You cannot change the ownership of the master, model, tempdb, or sybsystemprocs databases and should not change the ownership of any other system databases.

7.2 Database Owner Privileges

The database owner has full privileges to do anything inside that database, and must explicitly grant permissions to other users with the grant command.

Database owners and system administrators are the only users who can grant object creation permissions to other users (except for create encryption key and create trigger permission which can only be granted by the system security officer).

Permission to use the following commands is automatically granted to the database owner and cannot be transferred to other users:

- checkpoint
- dbcc
- alter database
- online database
- drop database
- dump database
- dump transaction
- grant (object creation permissions)
- load database
- load transaction
- revoke (object creation permissions)
- setuser

Database owners can grant or revoke permission to:

- Use these commands: create default, create procedure, create rule, create table, create view.
 - Database owners can grant permission to use create database, set tracing, and connect if they have the sa role and are in the master database.
- all if you are the database owner, all grants permissions for all create commands except create database, create trigger and create encryption key.
- default permissions on system tables
- Use dbcc commands:checkalloc, checkcatalog, checkdb, checkindex, checkstorage, checktable, checkverify, fix_text, indexalloc, reindex, tablealloc, textalloc, tune

Permissions are granted to or revoked from other database users by object owners, database owners, users who were granted permissions with grant option, the system administrator, or a system security officer. These users are specified by user name, group name, or the keyword public. All users inherit the permissions granted to the roles assigned to them after they have activated those roles.

7.3 Database Object Owner Privileges

A user who creates a database object (a table, view, encryption key, or stored procedure) owns the object and is automatically granted all object access permissions on it.

Users other than the object owner, including the owner of the database, are automatically denied all permissions on that object, unless they are explicitly granted by either the owner or a user who has grant permission on that object.

As an example, suppose that Mary is the owner of the pubs2 database, and has granted Joe permission to create tables in it. Now Joe creates the table new authors; he is the owner of this database object.

Initially, object access permissions on new_authors belong only to Joe. Joe can grant or revoke object access permissions for this table to other users.

The following object altering permissions default to the owner of a table and cannot be transferred to other users:

- alter table
- drop table
- create index

Permission to use the grant and revoke commands to grant specific users select, insert, update, delete, references, decrypt, truncate table, update statistics, delete statistics, and execute permissions on specific database objects can be transferred, using the grant with grant option command.

Permission to drop an object—a table, view, index, stored procedure, rule, encryption key, trigger, or default—defaults to the object owner and cannot be transferred.

7.4 Permissions on System Procedures

Set permissions on system procedures in the sybsystemprocs database, where the system procedures are stored.

Security-related system procedures can be run only by system security officers. Certain other system procedures can be run only by system administrators.

Some of the system procedures can be run only by database owners. These procedures make sure that the user executing the procedure is the owner of the database from which they are being executed.

Other system procedures can be executed by any user who has been granted permission. A user must have permission to execute a system procedure in all databases, or in none of them.

Users who are not listed in sybsystemprocs..sysusers are treated as "guest" in sybsystemprocs, and are automatically granted permission on many of the system procedures. To deny a user permission on a system procedure, the system administrator must add him or her to sybsystemprocs..sysusers and issue a revoke statement that applies to that procedure. The owner of a user database cannot directly control permissions on the system procedures from within his or her own database.

7.5 Grant or Revoke Permissions

Use the grant and revoke commands to control permissions.

These permissions are controlled with the grant and revoke commands:

- Object access permissions
- Permission to select from functions
- Permission to execute commands
- Permission to execute dbcc commands
- Permission to execute some set commands
- Default permissions on system tables

Each database has its own independent protection system. Having permission to use a certain command in one database does not give you permission to use that command in other databases.

7.5.1 Object Access Permissions

Object access permissions regulate the use of certain commands that access certain database objects.

For example, you must explicitly be granted permission to use the select command on the authors table. Object access permissions are granted and revoked by the object owner (and system administrators or system security officers), who can grant them to other users.

Table 13: Permissions and the objects to which they apply

Permission	Object	
select	Table, view, column	
update	Table, view, column	
insert Table, view		
delete	Table, view	
references	Table, column	
execute	Stored procedure	
truncate table	Table	
delete statistics	Table	
update statistics	Table	
decrypt	Table, view, column	
select	Encryption key	

The references permission refers to referential integrity constraints that you can specify in an alter table or create table command. The decrypt permission refers to the permission required to decrypt an encrypted column. An encryption key's select permission refers to the permissions required to use encryption keys in create table, alter table or select into command to encrypt columns. The other permissions refer to SQL commands. Object access permissions default to the object's owner, or system administrators or system security officers for decrypt on an encrypted column and select on an encryption key, and can be granted to other users.

If several users grant access to an object to a particular user, the user's access remains until access is revoked by all those who granted access. If a system administrator revokes access, the user is denied access, even though other users have granted access.

Use the grant command to grant object access permissions. See the Reference Manual: Commands.

You can grant select, update and delete permission using a where clause that can restrict access on a row by row basis based on the condition in the where clause.

7.5.1.1 Concrete Identification

When the user creates an object, the server associates both the owner's database user ID (<uid>) and the creator's login name with the object in the sysobjects table. This information concretely identifies the object as belonging to that user.

Concrete identification allows the server to recognize when permissions on an object can be granted implicitly.

i Note

SAP ASE identifies users during a session by login name. This identification applies to all databases in the server.

If a user creates a table and then creates a procedure that accesses the table, any user who is granted permission to execute the procedure does not need permission to access the object directly. For example, by giving user "mary" permission on proc1, she can see the id and descr columns from table1, though she does not have explicit select permission on the table:

```
create table table1 (id int, amount money, descr varchar(100))

create procedure proc1 as select id, descr from table1

grant execute on proc1 to mary
```

There are, however, some cases where implicit permissions are only useful if the objects can be concretely identified. One case is where aliases and cross-database object access are both involved.

7.5.1.2 Special Requirements for SQL92 Standard Compliance

When you use the set command to turn ansi_permissions on, additional permissions are required for update and delete statements.

These are the ANSI permissions for update and delete:

	Permissions required: set ansi_permissions off	Permissions required: set ansi_permissions on
updat	update permission on columns	update permission on columns where values are being set
е	where values are being set	and
		select permission on all columns appearing in the where clause
		select permission on all columns on the right side of the set clause
delet e	delete permission on the table	delete permission on the table from which rows are being deleted
		and
		select permission on all columns appearing in the where clause

If ansi_permissions is on and you attempt to update or delete without having all the additional select permissions, the transaction is rolled back and you receive an error message. If this occurs, the object owner must grant you select permission on all relevant columns.

7.5.1.3 Grant Object Access Permissions Examples

Examples of granting object access permissions.

This statement gives Mary and the "sales" group permission to insert into and delete from the titles table:

```
grant insert, delete
on titles
to mary, sales
```

This statement gives Harold permission to use the stored procedure makelist:

```
grant execute
on makelist
to harold
```

This statement grants permission to execute the custom stored procedure sa_only_proc to users who have been granted the system administrator role:

```
grant execute
on sa_only_proc
to sa_role
```

This statement gives Aubrey permission to select, update, and delete from the authors table and to grant the same permissions to other users:

```
grant select, update, delete
on authors
to aubrey
with grant option
```

This statement grants permission to the payroll employees to update salaries during December:

```
grant update (salary)
on employee
where date_part(month, getdate()) = 12
to payroll_role
```

7.5.1.4 Revoke Object Access Permissions Examples

Examples of Revoking Object Access Permissions.

These two statements both revoke permission for all users except the table owner to update the price and total_sales columns of the titles table:

```
revoke update
on titles (price, total_sales)
from public
```

This statement revokes permission from Clare to update the authors table, and simultaneously revokes that permission from all users to whom she had granted that permission:

```
revoke update on authors
```

from clare cascade

This statement revokes permission from operators to execute the custom stored procedure new sproc:

revoke execute on new_sproc from oper_role

7.5.2 Grant Permissions on dbcc Commands

System administrators can grant the permission to execute dbcc commands to users and roles that do not have system administrator-level privileges in Adaptive Server.

This discretionary access control allows system administrators to control access to database objects or to certain database- and server-level actions.

See the Reference Manual: Commands for the complete dbcc syntax.

7.5.2.1 Server-wide and Database-Specific dbcc Commands

dbcc commands are either database specific or server-wide.

- Database-specific dbcc commands are execute on a particular target database (for example, checkalloc, checktable, checkindex, checkstorage, checkdb, checkcatalog, checkverify, fix_text, indexalloc, reindex, tablealloc, and textalloc). Although these commands are database-specific, only system administrators can grant or revoke them.
- Server-wide dbcc commands such as tune are effective server-wide and are not associated with any particular database. These commands are granted server-wide by default and are not associated with any database.

System administrators can allow users to execute the dbcc command in all databases by making them valid users in those databases. However, it may be more convenient to grant dbcc to roles instead of individual users, since this allows users to use databases as a "guest" user instead of requiring that they each be added manually to the database.

Since roles are automatically added as users in a database on their first grant in a database, there are no additional requirements when roles are granted dbcc privileges. Logins must be valid users in the database where permissions are granted. Valid users include "guest."

For server-wide dbcc commands, the login must be a valid user in master, and the system administrator must be in master when granting the permission.

For database-specific dbcc commands the login should be a valid user in the target database.

From a security administration perspective, system administrators may prefer to grant permission to execute database-specific dbcc commands server-wide. For example, you can execute grant dbcc checkstorage

on all databases to a user-defined role called storage_admin_role, thereby eliminating the need to execute grant dbcc checkstorage to storage admin role in every database.

The following commands are effective server-wide, but are not database-specific:

- Server-wide dbcc commands such as tune.
- Database-specific dbcc commands that are granted server-wide, such as grant dbcc checkstorage granted to storage admin role.

7.5.3 Permissions on System Tables

Permissions for use of the system tables can be controlled by the database owner, just like permissions on any other tables.

When a database is created, select permission on some system tables is granted to public, and select permission on some system tables is restricted to administrators. For some other tables, a few columns have restricted select permissions for public.

To determine the current permissions for a particular system table, execute:

```
sp_helprotect <system_table_name>
```

For example, to check the permissions of syssrvroles in the master database, execute:

```
use master
go
sp_helprotect syssrvroles
go
```

By default, no user—including the database owner—can modify the system tables directly. Instead, the T-SQL commands and the system procedures supplied with SAP ASE modify the system tables. This helps guarantee integrity.

Although SAP ASE provides a mechanism that allows you to modify system tables, SAP strongly recommends that you do not do so.

7.5.3.1 Grant Default Permissions to System Tables and Stored Procedures

The grant and revoke commands include the default permissions parameter.

installmodel or installmaster do not grant default permissions on any system tables (see the table below). Instead, the default permissions on the system tables are assigned when SAP ASE builds a new database. The partial syntax is:

```
grant default permissions on system tables
```

revoke default permissions on system tables

where default permissions on system tables specifies that you grant or revoke the default permissions for the following system tables when you issue it from any database:

sysalternates	sysjars	sysquerymatrics	systhresholds
sysattributes	syskeys	sysqueryplans	systypes
syscolumns	syslogs	sysreferences	sysusermessages
syscomments	sysobjects	sysroles	sysusers
sysconstraints	syspartitionkeys	syssegments	sysxtypes
sysdepends	syspartitions	sysslices	
sysgams	sysprocedures	sysstatistics	
sysindexes	sysprotects	systabstats	

Default permissions applies select to public on all system tables, with these exceptions:

- Revokes select on syscolumns (encrkeyid) from public
- Revokes select on syscolumns (encrkeydb) from public
- Grants select on syscolumns to sso role
- Revokes sysobjects (audflags) permissions from public
- Grants permissions for sysobjects to sso role
- Revokes select on all columns of sysencryptkeys from public
- Grants select on all columns of sysencryptkeys to sso_role

If you run this command from the master database, default permissions for the following system tables are granted or revoked:

syscharsets	syslanguages	sysmessages	sysservers
sysconfigures	syslisteners	sysmonitor	syssessions
syscurconfigs	syslocks	sysprocesses	syssrvroles
sysdatabases	syslogin	sysremotelogins	systimeranges
sysdevices	sysloginrole	sysresourcelimits	systransactions
sysengines	syslogshold	syssecmechs	sysusages

The command also makes the following changes:

- Revokes select on sysdatabases(audflags) from public
- Revokes select on syscolumns (encrkeyid) from public
- Revokes select on syscolumns (encrkeydb) from public
- Grants select on syscolumns to sso_role
- Revokes select on sysdatabases(deftabaud) from public
- Revokes select on sysdatabases(defvwaud) from public
- Revokes select on sysdatabases(defpraud) from public

- Revokes select on sysdatabases(audflags2) from public
- Grants select on sysdatabases to sso role.
- Revokes select on syslogins(password) to public
- Revokes select on syslogins (audflags) from public
- Grants select on syslogins to sso_role
- Revokes select on syslisteners(net type) from public
- Revokes select on syslisteners(address info) from public
- grant select on syslisteners to sso_role
- Revokes select on syssrvroles(srid) from public
- Revokes select on syssrvroles(name) from public
- Revokes select on syssrvroles(password) from public
- Revokes select on syssrvroles(pwdate) from public
- Revokes select on syssrvroles(status) from public
- Revokes select on syssrvroles(logincount) from public
- grant select on syssrvroles to sso_role
- Revokes select on sysloginroles(suid) from public
- Revokes select on sysloginroles(srid) from public
- Revokes select on sysloginroles(status) from public
- Revokes select on sysloginroles to sso_role

7.5.4 Combine grant and revoke Statements

Assign specific permissions to specific users, or, if most users are going to be granted most privileges, it may be easier to assign all permissions to all users, and then revoke specific permissions from specific users.

For example, a database owner can grant all permissions on the titles table to all users by issuing:

```
grant all on titles to public
```

The database owner can then issue a series of revoke statements, for example:

```
revoke update
on titles (price, advance)
from public
```

```
revoke delete
on titles
from mary, sales, john
```

grant and revoke statements are order-sensitive: in case of a conflict, the most recently issued statement supersedes all others.

i Note

Under SQL rules, you must use the grant command before using the revoke command, but the two commands cannot be used within the same transaction. Therefore, when you grant "public" access to

objects, and then revoke that access from an individual, there is a short period of time during which the individual has access to the objects in question. To prevent this situation, use the create schema command to include the grant and revoke clauses within one transaction.

7.5.5 Permission Order and Hierarchy

grant and revoke statements are sensitive to the order in which they are issued.

For example, if Jose's group has been granted select permission on the titles table and then Jose's permission to select the advance column has been revoked, Jose can select all the columns except advance, while the other users in his group can still select all the columns.

A grant or revoke statement that applies to a group or role changes any conflicting permissions that have been assigned to any member of that group or role. For example, if the owner of the titles table has granted different permissions to various members of the sales group, and wants to standardize, he or she might issue the following statements:

Similarly, a grant or revoke statement issued to public changes, for all users, all previously issued permissions that conflict with the new regime.

The same grant and revoke statements issued in different orders can create entirely different situations. For example, the following set of statements leaves Jose, who belongs to the public group, without any select permission on titles:

```
grant select on titles(title_id, title) to jose
revoke select on titles from public
```

In contrast, the same statements issued in the opposite order result in only Jose having select permission and only on the $title_id$ and title columns:

```
revoke select on titles from public grant select on titles(title_id, title) to jose
```

When you use the keyword public with grant, you are including yourself. With revoke on object creation permissions, you are included in public unless you are the database owner. With revoke on object access permissions, you are included in public unless you are the object owner. You may want to deny yourself permission to use your own table, while giving yourself permission to access a view built on it. To do this, you must issue grant and revoke statements explicitly setting your permissions. You can reinstitute the permission with a grant statement.

i Note

grant dbcc and set proxy issue the following warning when they are issued while set fipsflagger option is enabled:

 $\ensuremath{\text{SQL}}$ statement on line number 1 contains Non-ANSI text. The error is caused due to the use of DBCC.

7.6 Acquire the Permissions of Another User

Two ways are provided to acquire another user's identity and permissions status.

- A database owner can use the setuser command to "impersonate" another user's identity and permissions status in the current database.
- proxy authorization allows one user to assume the identity of another user on a server-wide basis.

7.6.1 setuser Command

The Database Owner uses setuser to adopt the identity of another user.

Use setuser to:

- Access an object owned by another user
- Grant permissions on an object owned by another user
- Create an object that will be owned by another user
- Temporarily assume the DAC permissions of another user for some other reason

While the setuser command enables the database owner to automatically acquire another user's DAC permissions, the command does not affect the roles that have been granted.

setuser permission defaults to the database owner and cannot be transferred. The user being impersonated must be an authorized user of the database. SAP ASE checks the permissions of the user being impersonated.

System administrators can use setuser to create objects that will be owned by another user. However, system administrators operate outside the DAC permissions system; therefore, they need not use setuser to acquire another user's permissions. The setuser command remains in effect until another setuser command is given, the current database is changed, or the user logs off.

i Note

setuser requires that you disable quoted identifiers with set <code>quoted_identifier</code> off, and that the target user against whom you are issuing <code>setuser</code> already exists in the database.

The syntax is:

```
setuser ["<user_name>"]
```

where <user name> is a valid user in the database that is to be impersonated.

To reestablish your original identity, use setuser with no value for <user name>.

This example shows how the database owner would grant Joe permission to read the authors table, which is owned by Mary:

```
setuser "mary"
grant select on authors to joe
setuser /*reestablishes original identity*/
```

7.6.2 Proxy Authorization

With the proxy authorization capability of SAP ASE, system security officers can grant selected logins the ability to assume the security context of another user, and an application can perform tasks in a controlled manner on behalf of different users.

If a login has permission to use proxy authorization, the login can impersonate any other login in SAP ASE.

The ability to assume another user's identity is extremely powerful and should be limited to trusted administrators and applications. grant set proxy ... restrict role can be used to restrict which roles users cannot acquire when switching identities.

A user executing set proxy or set session authorization operates with both the login name and server user ID of the user being impersonated. The login name is stored in the name column of master..syslogins and the server user ID is stored in the suid column of master..syslogins. These values are active across the entire server in all databases.

i Note

set proxy and set session authorization are identical in function and can be used interchangeably. The only difference between them is that set session authorization is ANSI-SQL92-compatible, and set proxy is a Transact-SQL extension.

7.6.2.1 Use set proxy to Restrict Roles

Grant set proxy...restrict role to restrict which roles cannot be acquired when switching identities.

The syntax for set proxy is:

```
grant set proxy to <user> | <role>
  [restrict role <role_list> | all | system]
```

where:

• <role_list> - list of roles you are restricting for the target login. The grantee must have all roles on this
list, or the set proxy command fails.

- <all> ensures the grantee can run set proxy only for those users who have the same roles, or a subset of the roles, as the grantee.
- <system> ensures the grantee has the same set of system roles as the target login.

For example, this grants set proxy to user "joe" but restricts him from switching identities to any user with the sa, sso, or admin roles (however, if he already has these roles, he can set proxy for any user with these roles):

```
grant set proxy to joe
restrict role sa_role, sso_role, admin_role
```

When "joe" tries to switch his identity to a user with admin_role (in this example, Our_admin_role), the command fails unless he already has admin_role:

```
Msg 10368, Level 14, State 1:
Server 's', Line 2:Set session authorization permission denied because the target login has a role that you do not have and you have been restricted from using.
```

After "joe" is granted the admin role and retries the command, it succeeds:

```
grant role admin_role to joe
set proxy Our_admin_role
```

For more information about the set proxy command, see the Reference Manual: Commands.

7.6.2.2 Execute Proxy Authorization

Follow these rules when executing set proxy or set session authorization.

- You cannot execute set proxy or set session authorization from within a transaction.
- You cannot use a locked login for the proxy of another user. For example, if "joseph" is a locked login, the following command is not allowed:

```
set proxy "joseph"
```

- You can execute set proxy or set session authorization from any database you are allowed to use. However, the <login_name> you specify must be a valid user in the database, or the database must have a "guest" user defined for it.
- Only one level is permitted; to impersonate more than one user, you must return to your original identity between impersonations.
- If you execute set proxy or set session authorization from within a procedure, your original identity is automatically resumed when you exit the procedure.

If you have a login that has been granted permission to use set proxy or set session authorization, you can set proxy to impersonate another user. The following is the syntax, where <login_name> is the name of a valid login in master..syslogins:

```
set proxy <login_name>
```

```
set session authorization <login name>
```

Enclose the login name in quotation marks.

For example, to set proxy to "mary," execute:

```
set proxy "mary"
```

After setting proxy, check your login name in the server and your user name in the database. For example, assume that your login is "ralph" and that you have been granted set proxy authorization. You want to execute some commands as "sallyn" and as "rudolph" in pubs2 database. "sallyn" has a valid name ("sally") in the database, but Ralph and Rudolph do not. However, pubs 2 has a "guest" user defined. You can execute:

```
set proxy "sallyn"
ao
use pubs2
go
select suser_name(), user_name()
sallyn
```

To change to Rudolph, you must first change back to your own identity. To do so, execute:

sally

```
set proxy "ralph"
select suser name(), user name()
```

```
ralph
                                 guest
```

Notice that Ralph is a "guest" in the database.

Then execute:

```
set proxy "rudolph"
select suser name(), user name()
rudolph
                                guest
```

Rudolph is also a guest in the database because Rudolph is not a valid user in the database.

Now, impersonate the "sa" account. Execute:

```
set proxy "ralph"
set proxy "sa"
select suser name(), user name()
go
```

sa dbo

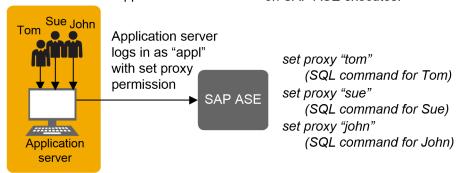

7.6.2.3 Proxy Authorization for Applications

Using proxy authorization, an application server can log in to an SAP ASE server with a generic login to execute procedures and commands for users.

The diagram below shows an application server logging in to SAP ASE server with the generic login "appl" to execute procedures and commands for several users. While "appl" impersonates Tom, the application has Tom's permissions. Likewise, when "appl" impersonates Sue and John, the application has only Sue's and John's permissions, respectively.

Tom, Sue, and John establish sessions with the application server:

The application server ("appl") on SAP ASE executes:

7.6.3 Resolving Qualified Object Names on Behalf of Another User

SAP ASE allows a database owner to specify object name resolution for a specified user so that SAP ASE resolves qualified object names on behalf of this user.

Context

That is, a database owner can specify object name resolution for a user so that SAP ASE resolves qualified object names on behalf of another user, allowing the first user to execute the command even though they have read-only permission on the object.

Use sp_modifyuser to map one user to resolve qualified objects as another user. The syntax is:

```
sp_modifyuser '<username_1>', 'resolve as', '<username_2>'
```

i Note

You must enable the enable functionality group before issuing sp_modifyuser ... resolve as.

Procedure

For example, if you issue this for user_A_RO:

```
sp_modifyuser 'user_A_RO', 'resolve as', 'user_B'
```

When user user_A_RO issues this command:

```
select cname from customer c, orders o
where c.cid = o.oid and o.date = 'today'
```

SAP ASE processes the command as if user_A_RO issued:

```
select cname from user_B.customer c, user_B.orders o
where c.cid = o.oid and o.date = 'today'
```

7.7 Changing Database Object Ownership

A system security officer or database owner can transfer the ownership of database objects using the alter... modify owner command.

The command lets a database administrator manage the assignment of objects due to employee changes or to separate the creation ownership of database objects. For example, a key custodian can create an encryption key and then transfer the ownership of the encryption key to another user.

7.7.1 Supported Object Types

The ownership of objects can be transferred from one owner to another.

Objects for which the ownership can be changed explicitly:

- User tables
- Proxy tables
- Views
- · Stored procedures
- User-defined functions
- Defaults
- Rules
- User-defined datatypes
- Encryption keys

i Note

The ownership of objects not listed below cannot be changed.

Dependent objects for which the ownership cannot be changed explicitly. These objects are transferred implicitly when the ownership is the same as the explicitly transferred object:

Triggers

The ownership of a dbo-owned trigger cannot be altered if the trigger was created for a non-dbo-owned table (view

- Declarative objects that are defined during the table/view creation
 - Defaults
 - Decrypt_defaults
 - Check constraints
 - Reference constraints
 - · Partition conditions
 - · Computed columns

7.7.2 Authorization to Transfer Ownership

System security officers have authorization to transfer ownership of all objects for which ownership transfer is supported. Database owners have authorization to transfer ownership of objects, other than encryption keys.

- Database owners can transfer ownership with these restrictions:
 - The database object owner cannot transfer the ownership of objects concretely owned by the database owner.
 - An object is identified as concretely owned by a database owner if it carries the database owner user ID as sysobjects.uid, and null or the database owner's user name as sysobjects.loginame.
 - A user aliased to the database owner cannot transfer the ownership of objects created by the database owner or concretely owned by the user.
 - Database owner-created objects have a null value in sysobjects.loginame. Objects concretely owned by a user carries the user's username in sysobjects.loginame.

Use sp helpuser to search for and list objects and corresponding owners.

7.7.3 Transfer Ownership

Ownership transfer can be specific to an individual object, or multiple objects can be transferred in one command. Use preserve permissions to preserve explicitly granted permissions of an object.

For syntax, see alter...modify owner in Reference Manual: Commands.

In this example, the database owner transfers a table owned by john to eric.

```
alter table john.table audit modify owner eric
```

To transfer the ownership of all tables owned by john to eric, a system security officer can execute:

```
alter table john.* modify owner eric
```

To transfer the ownership of all objects owned by john to eric, a system security officer can execute:

alter all john.* modify owner eric

7.7.3.1 Transfer Ownership of Objects in the System Database

Change the ownership of objects in system databases supplied by SAP.

Use caution to change the ownership of objects in the following system databases that are supplied and managed by SAP:

- sybsecurity
- sybsystemdb
- model
- sybsystemprocs
- sybsyntax
- dbccdb
- tempdb

Do not change the ownership of these system objects that are supplied and managed by SAP:

- User tables with spt_prefix
- System stored procedures with sp_ prefix

Changing the ownership of these objects can make the system unusable.

7.7.3.2 Transfer Ownership of Database Owner Objects

The database owner of nonsystem objects can transfer ownership using the parameter $dbo.object_name$. You cannot transfer the ownership of multiple objects using \star .

7.7.3.3 preserve permissions Command

 $Specify\ \texttt{preserve}\ \ \texttt{permissions}\ \ \textbf{to}\ \ \textbf{preserve}\ \ \textbf{all}\ \ \textbf{explicitly}\ \ \textbf{granted}\ \ \textbf{or}\ \ \textbf{revoked}\ \ \textbf{permissions}\ \ \textbf{on}\ \ \textbf{an}\ \ \textbf{object}.$

For example, bill granted select permission of table bill_table to mark. mark then granted select permission on table bill_table to john. If the ownership of the table is then transferred to eric with preserve permissions specified, mark and john retain their permission of bill_table.

In the following example, the system security officer transfers the ownership of view bill.vw_author to eric while keeping all existing explicitly granted permissions.:

```
alter view bill.vw author in ca modify owner eric
```

preserve permissions

Implicit permissions are not preserved when preserve permissions is specified.

For example, bill owns table bill.encr_table which has encrypted columns and the restricted decrypt permission configure option is set to 1. If the system security officer explicitly granted decrypt permission on bill.encr_table to bill, bill has the permissions alter, delete, insert, references, select, and update which he accrued through his ownership. He also has decrypt permission which he accrued through explicit granting by the system security officer. After the system security officer transfers the ownership on bill.encr_table to eric with preserve permissions, bill loses all permissions on the table except the decrypt permission.

When preserve permissions is not specified, after the ownership transfer, the previous owner loses permissions on the object, that are implicitly accrued through ownership. The new implicitly accrues permissions by being given ownership of the object.

i Note

For permissions that cannot be accrued through ownership, such as decrypt permissions, the system security officer or database owner must explicit again grant permission of the objects to the new owner.

7.7.3.4 Security Issues

The system security officer or database owner should be aware of possible security issues.

For example, alice is a user in the Accounting database and has no access to the payroll data. She could create the procedure alicep that selects name and salary from Accounting.dbo.payroll, and then grant execute on alicep to public. If the system security officers accidentally changes the ownership of alicep to bill, a privileged user with access to the payroll data with preserve permissions option, all users can access the payroll information by executing the malicious procedure alicep because all the permissions are set to be preserved after the ownership change.

To avoid unauthorized usage, the system security officers or database owner can check existing permissions on an object using sp helprotect.

7.7.3.5 Transfer Ownership of Encryption Keys

System security officers and key owners can use alter encryption key or alter... modify owner to transfer encryption keys.

For information about the alter encryption key command, see Reference Manual: Commands.

7.7.3.5.1 Encryption Key Copy Owners

When using the alter... modify owner command, the user that has been assigned a key copy cannot be the new owner of the encryption key.

After the owner of a encryption key changes, the assignees of key copies do not change. For example, user bill owns an encryption key named bill.encrkey and creates one key copy of the key, which he assigns to mark. After bill transfers the ownership of bill.encrkey to eric, mark still owns a copy of bill.encrkey.

7.8 Report on Permissions

Use system procedures and system tables to report information about proxies, object creation, and object access permissions.

To report information on	Use
Proxies	system tables
Users and processes	sp_who
Permissions on database objects or users	sp_helprotect
Permissions on specific tables	sp_helprotect

7.8.1 Query the sysprotects Table for Proxy Authorization

To display information about permissions that have been granted to—or revoked from—users, groups, and roles, query the sysprotects table.

The action column specifies the permission. For example, the action value for set proxy or set session authorization is equal to 167.

When executing this query:

```
select * from sysprotects where action = 167
```

The results provide the user ID of the user who granted or revoked the permission (column grantor), the user ID of the user who has the permission (column uid), and the type of protection (column protecttype). The protecttype column can contain these values:

- Oforgrant with grant
- 1 for grant
- 2 for revoke

For more information about the sysprotects table, see the Reference Manual: Building Blocks.

7.8.2 Display Information About Users and Processes

sp_who displays information about all current SAP ASE users and processes or about a particular user or process.

The results of sp_who include the loginame and origname. If a user is operating under a proxy, origname contains the name of the original login. For example, assume that "ralph" executes the following, then executes some SQL commands:

```
set proxy susie
```

sp who returns "susie" for loginame and "ralph" for origname.

sp_who queries the master..sysprocesses system table, which contains columns for the server user ID (suid) and the original server user ID (origsuid).

For more information, see sp who in the Reference Manual: Procedures.

7.8.3 Report Permissions on Database Objects or Users

Use sp_helprotect to report on permissions by database object or by user, and (optionally) by user for a specified object. Any user can execute this procedure.

For example, suppose you issue the following series of grant and revoke statements:

```
grant select on titles to judy
grant update on titles to judy
revoke update on titles(contract) from judy
grant select on publishers to judy
with grant option
```

To determine the permissions Judy now has on each column in the titles table, enter:

```
sp helprotect titles, judy
grantor grantee type action object
                                        column predicate
                                                           grantable
                                      -----
All
       judy Grant Select titles
                                                 NULL
                                                            FALSE
                                      advance NULL
notes NULL
price NULL
pub_id NULL
dbo
       judy Grant Update titles
                                                            FALSE
            Grant
                    Update
Update
                             titles
dbo
       judy
                                                             FALSE
dbo
       judy
             Grant
                             titles
                                                             FALSE
             Grant Update titles
dbo
       judy
                                                             FALSE
             Grant
                                      pubdate
                    Update titles
                                                  NULL
dho
       judy
                                                             FALSE
dbo
             Grant
                     Update
                             titles
                                        title
                                                   NULL
                                                             FALSE
       judy
       judy
                                        title id NULL
             Grant Update titles
                                                             FALSE
dbo
dbo
       judy
             Grant
                     Update
                             titles
                                        total sales NULL
                                                             FALSE
                             titles
dbo
       judy
             Grant
                     Update
                                        type
                                                   NULL
                                                              FALSE
```

The first row shows that the database owner ("dbo") gave Judy permission to select all columns of the titles table. The rest of the lines indicate that she can update only the columns listed in the display. Judy cannot give select or update permissions to any other user.

To see Judy's permissions on the publishers table, enter:

```
sp_helprotect publishers, judy
```

In this display, the grantable column indicates TRUE, meaning that Judy can grant the permission to other users.

grantor gr	antee type	action	object	column	predicate	grantable
dbo ju	dy Grant	Select	publishers	all	NULL	TRUE

See Reference Manual: Procedures for syntax.

7.8.4 Report Permissions on Specific Tables

Use sp helprotect to return permissions information about a specified table.

To see permissions on the sales table, enter:

sp_help	rotects						
grantor	grante	e type	action	object	column	predicate	grantable
dbo	guest	Grant	Delete	sales	All	NULL	FALSE
dbo	guest	Grant	Delete Statistics	sales	All	NULL	FALSE
dbo	guest	Grant	Insert	sales	All	NULL	FALSE
dbo	guest	Grant	References	sales	All	NULL	FALSE
dbo	guest	Grant	Transfer Table	sales	All	NULL	FALSE
dbo	guest	Grant	Transfer Table	sales	All	NULL	FALSE
dbo	guest	Grant	Update	sales	All	NULL	FALSE
dbo	guest	Grant	Update Statistics	sales	All	NULL	FALSE
•	public affected status	d)	Select	sales	All	NULL	FALSE

For more information about the output of sp helprotect, see the Reference Manual: Procedures.

7.9 Views and Stored Procedures as Security Mechanisms

Views and stored procedures can serve as security mechanisms. You can give users controlled access to database objects via a view or stored procedure without granting them direct access to the data.

For example, you might give a clerk execute permission on a procedure that updates cost information in a projects table without letting the user see confidential data in the table. To use this feature, you must own the procedure or view as well as its underlying objects. If you do not own the underlying objects, users must have permission to access the objects. For more information about when permissions are required, see *Understanding Ownership Chains*.

SAP ASE makes permission checks, as required, when the view or procedure is used. When you create the view or procedure, SAP ASE makes no permission checks on the underlying objects.

Related Information

Understanding Ownership Chains [page 193]

7.9.1 Using Views as Security Mechanisms

Through a view, users can query and modify only the data they can see. The rest of the database is neither visible nor accessible.

Permission to access the view must be explicitly granted or revoked, regardless of the permissions on the view's underlying tables. If the view and underlying tables are owned by the same owner, no permissions need to be given on the underlying tables. Data in an underlying table that is not included in the view is hidden from users who are authorized to access the view but not the underlying table.

By defining different views and selectively granting permissions on them, a user (or any combination of users) can be restricted to different subsets of data. Access can be restricted to:

- A subset of the rows of a base table (a value-dependent subset). For example, you might define a view that contains only the rows for business and psychology books to keep information about other types of books hidden from some users.
- A subset of the columns of a base table (a value-independent subset). For example, you might define a view that contains all the rows of the titles table, but omits the price and advance columns, since this information is sensitive.
- A row-and-column subset of a base table.
- The rows that qualify for a join of more than one base table. For example, you might define a view that joins the titles, authors, and titleauthor tables. This view hides personal data about authors and financial information about the books.
- A statistical summary of data in a base table. For example, you might define a view that contains only the average price of each type of book.
- A subset of another view, or of some combination of views and base tables.

If you want to prevent some users from accessing the columns in the titles table that display money and sales amounts, you can create a view of the titles table that omits those columns, then give all users permission on the view but only the Sales Department permission on the table:

```
grant all on bookview to public grant all on titles to sales
```

An equivalent way of setting up these privilege conditions, without using a view, is to use the following statements:

One possible problem with the second solution is that users not in the sales group who enter the select * from titles command might be surprised to see the message that includes the phrase:

```
permission denied
```

SAP ASE expands the asterisk into a list of all the columns in the titles table, and since permission on some of these columns has been revoked from nonsales users, access to these columns is denied. The error message lists the columns for which the user does not have access.

To see all the columns for which they do have permission, the nonsales users must name them explicitly. For this reason, creating a view and granting the appropriate permissions on it is a better solution.

You can also use views for context-sensitive protection. For example, you can create a view that gives a data entry clerk permission to access only those rows that he or she has added or updated. To do so, add a column to a table in which the user ID of the user entering each row is automatically recorded with a default. You can define this default in the create table statement, like this:

```
create table testtable

(empid int,
startdate datetime,
username varchar(30) default user)
```

Next, define a view that includes all the rows of the table where uid is the current user:

```
create view context_view
as
    select *
    from testtable
    where username = user_name()
with check option
```

The rows retrievable through this view depend on the identity of the person who issues the select command against the view. By adding with <code>check option</code> to the view definition, you make it impossible for any data entry clerk to falsify the information in the username column.

Related Information

Understanding Ownership Chains [page 193]

7.9.2 Using Stored Procedures as Security Mechanisms

If a stored procedure and all underlying objects are owned by the same user, that owner can grant users permission to use the procedure without granting permissions on the underlying objects.

For example, you might give a user permission to execute a stored procedure that updates a row-and-column subset of a specified table, even though that user does not have any other permissions on that table.

You can create a procedure using execute as owner or execute as caller, which checks runtime permissions, executes DDL, and resolves objects names on behalf of the owner or caller respectively.

Procedures defined with execute as owner, execute as caller, or with no execute as clause, can be nested inside procedures defined with execute as owner or execute as caller. Similarly procedures defined with execute as owner execute as caller can be nested inside procedures defined without the execute as clause.

set session authorization statement is not allowed inside the procedure created with execute as owner even if the statement is in a nested procedure which is not defined as execute as owner.

For syntax see, create procedure in Reference Manual: Commands.

7.9.2.1 Roles and Stored Procedures

Use the grant execute command to grant execute permission on a stored procedure to all users who have been granted a specified role.

revoke execute removes this permission. But grant execute permission does not prevent users who do not have the specified role from being granted execute permission on the stored procedure.

For further security, you can restrict the use of a stored procedure by using the has_role system function within the procedure to guarantee that a procedure can be executed only by users who have a given role. has_role returns 1 if the user has a specific role (sa_role , sso_role , $oper_role$, or any user-defined role) and returns 0 if the user does not have that role. For example, here is a procedure that uses has_role to see if the user has the system administrator role:

```
create proc test_proc
as
if (has_role("sa_role") = 0)
begin
    print "You don't have the right role"
    return -1
end
else
    print "You have SA role"
    return 0
```

See "System Functions" in Reference Manual: Building Blocks for more information about has role.

7.9.3 Understanding Ownership Chains

Views can depend on other views or tables. Procedures can depend on other procedures, views, or tables. These dependencies can be thought of as an ownership chain.

Typically, the owner of a view also owns its underlying objects (other views and tables), and the owner of a stored procedure owns all the procedures, tables, and views referenced by the procedure.

A view and its underlying objects are usually all in the same database, as are a stored procedure and all the objects it references; however, this is not required. If objects are in different databases, a user wanting to use the view or stored procedure must be a valid user or guest user in all of the databases containing the objects. This prevents users from accessing a database unless the database owner has authorized it.

When a user who has been granted execute permission on a procedure or view uses it, SAP ASE does not check permissions on any of the underlying objects if:

- These objects and the view or procedure are owned by the same user, and
- The user accessing the view or procedure is a valid user or guest user in each of the databases containing the underlying objects.

However, if all objects are not owned by the same user, SAP ASE checks object permissions when the ownership chain is broken. That is, if object A references object B, and B is not owned by the user who owns object A, SAP ASE checks the permissions for object B. In this way, the owner of the original data is allowed to retain control over who is authorized to access it.

Ordinarily, a user who creates a view needs to worry only about granting permissions on that view. For example, say Mary has created a view called auview1 on the authors table, which she also owns. If Mary grants select permission to Sue on auview1, Sue is allowed to access it without checking permissions on authors.

However, a user who creates a view or stored procedure that depends on an object owned by another user must be aware that any permissions he or she grants depend on the permissions allowed by those other owners.

7.9.3.1 Example of Views and Ownership Chains

Examples of ownership chains and permission checks.

As example of an ownership chain, Joe creates a view called auview2, which depends on Mary's view auview1. Joe grants Sue select permission on auview2.

The ownership chain looks like this:

Sue's permission	Objects	Ownership	Checks
select	auview2	Joe	Different owner Check permissions
select	auview1	Mary	Different owner Check permissions
none	authors	Mary	Same owner No permission check

SAP ASE checks the permissions on auview2 and auview1, and finds that Sue can use them. SAP ASE checks ownership on auview1 and authors and finds that they have the same owner. Therefore, Sue can use auview2.

Taking this example a step further, suppose that Joe's view, auview2, depends on auview1, which depends on authors. Mary decides she likes Joe's auview2 and creates auview3 on top of it. Both auview1 and authors are owned by Mary.

The ownership chain looks like this:

Sue's permission	Objects	Ownership	Checks
select	auview3	Mary	Sue not owner Check permissions
select	auview2	Joe	Different owner Check permissions
select	auview1	Mary	Different owner Check permissions
none	authors	Mary	Same owner No permission check

When Sue tries to access auview3, SAP ASE checks permissions on auview3, auview2, and auview1. If Joe has granted permission to Sue on auview2, and Mary has granted her permission on auview3 and auview1, SAP ASE allows the access. SAP ASE checks permissions only if the object immediately before it in the chain has a different owner (or if it is the first object in the chain). For example, it checks auview2 because the object before it—auview3—is owned by a different user. It does not check permission on authors, because the object that immediately depends on it, auview1, is owned by the same user.

7.9.3.2 Example of Procedures and Ownership Chains

Examples of ownership chains and permission checking for stored procedures.

Procedures follow the same rules as views. For example, suppose the ownership chain looks like this:

Sue's permission	Objects	Ownership	Checks
execute	proc4	Mary	Sue not owner Check permissions
none	proc3	Mary	Same owner No permission check
execute	proc2	Joe	Different owner Check permissions
execute	proc1	Mary	Different owner Check permissions
none	authors	Mary	Same owner No permission check

To execute proc4, Sue must have permission to execute proc4, proc2, and proc1. Permission to execute proc3 is not necessary because proc3 and proc4 have the same owner.

Sue's permissions are checked on proc4 and all objects it references each time she executes proc4. SAP ASE knows which referenced objects to check: it determined this the first time Sue executed proc4, and it saved the information with the procedure's execution plan. Unless one of the objects referenced by the procedure is dropped or redefined, SAP ASE does not change its initial decision about which objects to check.

This protection hierarchy allows every object's owner to fully control access to the object. Owners can control access to views and stored procedures, as well as to tables.

7.9.4 Permissions on Triggers

A trigger is a special kind of stored procedure used to enforce integrity, especially referential integrity. Triggers are never executed directly, but only as a side effect of modifying a table. You cannot grant or revoke permissions for triggers.

Only an object owner can create a trigger. However, the ownership chain can be broken if a trigger on a table references objects owned by different users. The protection hierarchy rules that apply to procedures also apply to triggers.

While the objects that a trigger affects are usually owned by the user who owns the trigger, you can write a trigger that modifies an object owned by another user. If this is the case, any users modifying your object in a way that activates the trigger must have permission on the other object as well.

If SAP ASE denies permission on a data modification command because a trigger affects an object for which the user does not have permission, the entire data modification transaction is rolled back.

See Triggers: Enforcing Referential Integrity, in the Transact-SQL User's Guide.

7.10 Execute a Procedure With execute as owner or execute as caller

You can create a procedure using execute as owner or execute as caller, which checks runtime permissions, executes DDL, and resolves objects names on behalf of the owner or caller respectively.

If you create a procedure using execute as caller, SAP ASE performs these operations as the procedure caller. If you create a procedure using execute as owner, these operations are performed on behalf of the procedure owner.

When the execute $\,$ as clause is omitted, the behavior is the same as in versions earlier than SAP ASE 15.7 ESD #2.

Creating procedures for execution as the procedure owner is useful for applications that require all actions in a procedure to be checked against the privileges of the procedure owner. Implicit grant checking due to ownership chains does not apply to procedures created with execute as owner. The application end user requires no privilege in the database other than execute permission on the stored procedure. Additionally, any DDL executed by the procedure is conducted on behalf of the procedure owner, and any objects created in the procedure are owned by the procedure owner. This relieves the administrator of the requirement of having to grant privilege on DDL commands to the application user.

Creating the procedures for execution as the session user or caller is necessary if permissions must be checked on behalf of the individual user. For example, use execute as caller if a table accessed by the procedure is subject to fine-grained access control through predicated privileges, such that one user is entitled to see one set of rows and another user another set of rows. Implicit grant checking due to ownership chains

does not apply for procedures which are created with execute as caller; if predicated privileges are present on tables referenced in the procedure, they will be applied.

If the execute as clause is omitted:

- Object names are resolved on behalf of the procedure owner.
- DDL commands and cross-database access are on behalf of the procedure caller.
- Permission checks for DML, execute, transfer table, truncate table, delete statistics, and update statistics are made on behalf of the caller unless there exists an ownership chain between the referenced object and the procedure, in which case permission checks are bypassed.

If the execute as owner clause is specified, the procedure behavior conforms to the expected behavior following an implicit set session authorization to the owner at the beginning of execution. This behavior includes:

- Object names are resolved on behalf of the procedure owner. If the procedure references a table or other
 object without qualifying the name with an owner name, SAP ASE will look up a table of that name
 belonging to the procedure owner. If no such table exists, SAP ASE will look for a table of that name owned
 by the Database Owner.
- DDL commands and cross-database access are on behalf of the procedure owner.
- No implicit granting of permissions through ownership chains occurs.
- All access control checks are based on the permission of the procedure owner, and the owner's group, system roles, default user-defined roles, also those roles granted to the owner that are activated in the procedure body. Roles granted to the owner's login profile are also considered. Only those roles activated by the procedure owner during execution of the procedure are considered.
- Procedures defined with execute as owner, execute as caller, or with no execute as clause, can be
 nested inside procedures defined with execute as owner. Similarly procedures defined with execute
 as owner can be nested inside procedures defined without the execute as clause.
 Procedures called from an execute as owner procedure are executed as the owner of the calling
 procedure unless the nested procedure is defined as execute as owner.
- Dynamic SQL statements inside a procedure are executed with permissions of procedure owner regardless of the 'Dynamic Ownership Chain' setting of sp procxmode.
- Because temporary tables are owned by the session, temporary tables created outside the procedure by the caller are available inside the procedure to the procedure owner. This behavior reflects temporary table availability after a set session authorization command is executed in a session.
- Audit records for the execution of a procedure show the execute as owner clause and the name of the procedure owner in the extrainfo column.
- Audit records of statements executed within the procedure show the name of the procedure owner in the loginname column.
- set session authorization statement is not allowed inside the procedure created with execute as owner even if the statement is in a nested procedure which is not defined as execute as owner.

If the execute as caller clause is specified,

- Objects are resolved on behalf of caller. If the procedure references a table or other object without qualifying the name with an owner name, SAP ASE will look up a table of that name belonging to the user who called the procedure. If no such table exists, SAP ASE will look for a table of that name owned by the Database Owner.
- DDL commands and cross-database access are on behalf of the caller.
- No implicit granting of permissions through ownership chains occurs.

- Permissions are checked on behalf of caller, caller's group, active roles, and system roles.
- Procedures defined with execute as owner, execute as caller, or with no execute as clause, can be
 nested inside procedures defined with execute as caller. Similarly procedures defined with execute
 as caller can be nested inside procedures defined without the execute as clause.
 Procedures called from an execute as caller procedure are executed on behalf of the caller of the
 parent procedure unless the nested procedure is defined as execute as owner.
- Dynamic SQL executes as caller regardless of the 'Dynamic Ownership Chain' setting on sp procxmode.
- Temporary tables created outside the procedure are available inside the procedure.
- Object references by the procedure are not entered into sysdepends, as the objects are resolved according to each caller of the procedure.
- select * is not expanded in syscomments.
- Plans in the procedure cache for the same procedure are not shared across users, as the objects in the procedure must be resolved to the user executing the procedure. Because of this, procedure cache usage may increase if many users are executing the procedure. The plan for a particular user is reused when the user executes the procedure again.
- Audit records for the execution of a procedure show the execute as caller clause and the name of the procedure caller in the extrainfo column.
- Audit records of statements executed within the procedure show the name of the session owner in the loginname column.

In the following example, the procedure created by user Jane has no execute as clause. The procedure selects from jane.employee into an intermediate table named emp interim:

```
create procedure p_emp

select * into emp_interim
from jane.employee

grant execute on p_emp to bill
```

Bill executes the procedure:

```
exec jane.p_emp
```

- Bill is not required to have select permission on jane.employee because Jane owns p_emp and employee. By granting execute permission on p_emp to Bill, Jane has implicitly granted Bill select permission on employee.
- Bill must have been granted create table permission. The emp interim table will be owned by Bill.

In the following example, Jane creates a procedure with an identical body using the <code>execute as owner</code> clause and Bill executes the procedure:

```
create procedure p_emp

with execute as owner as

select * into emp_interim
from jane.employee
```

```
grant execute on p emp to bill
```

- Bill requires only execute permission to run the procedure successfully.
- The emp_interim table is created on behalf of Jane, meaning Jane is the owner. If Jane does not have create table permission, the procedure will fail.

In the following example, Jane creates the same procedure with the execute as caller clause:

```
create procedure p_emp

with execute as caller as

select * into emp_interim
from jane.employee

grant execute on p_emp to bill
```

- Bill must have select permission on jane.employee. No implicit grant checking is done though jane owns both p_emp and employee. If jane.employee has predicated privileges granted to Bill, the predicates will be added to the query.
- Bill must have create table permission. The emp_interim is created on behalf of Bill, meaning Bill is the owner.

7.10.1 Creating a Procedure with References to an Object with an Unqualified Name

Examples of creating procedures without the execute as clause, and with the execute as owner or execute as caller clause.

In the following example, the procedure does not have an execute as clause:

```
create procedure insert p
  insert t1 (c1) values (100)
grant execute on insert p to bill
```

Bill executes the procedure:

```
exec jane.insert p
```

- A search is performed to look for a table named t1 owned by Jane. If jane.t1 does not exist, a search is performed to look for dbo.t1.
- If t1 resolves to dbo.t1, Bill must have insert permission for t1.
- If t1 resolves to jane.t1, Bill will have implicit insert permission because of the ownership chain between jane.insert p and jane.t1.

In the following example, Jane creates the same procedure as above with execute as owner:

```
create procedure insert p

with execute as owner as

insert t1 (c1) values (100)

grant execute on insert p to bill
```

Bill executes the procedure:

```
exec jane.insert p
```

- A search is performed to look for a table named t1 owned by Jane. If jane.t1 does not exist, a search is performed to look for dbo.t1.
- If t1 resolves to dbo.t1, permission to insert into t1 must have been granted to Jane.
- If t1 resolves to jane.t1, since the procedure is being executed as owner, Jane has the permission.

In the following example, Jane creates the same procedure as above with execute as caller:

```
create procedure insert p

with execute as caller as

insert t1 (c1) values (100)

grant execute on insert p to bill
```

Bill executes the procedure:

```
exec jane.insert p
```

- A search is performed to look for a table named t1 owned by Bill. If bill.t1 does not exist, a search is performed to look for dbo.t1.
- If t1 resolves to dbo.t1, Bill must have permission to insert into t1.

7.10.2 Procedures that Invoke a Nested Procedure in Another Database with a Fully Qualified Name

Examples of creating a nested procedure with execute as owner and execute as caller.

In the following example, Jane creates a procedure that invokes a nested procedure in another database with a fully qualified name. The login associated with Jane resolves to user Jane in otherdb. This example uses execute as owner:

```
create procedure p master
```

with execute as owner

as exec otherdb.jim.p child

grant execute on p master to bill

Bill executes the procedure:

- SAP ASE checks that user Jane in otherdb has execute permission on jim.p child.
- If jim.p_child has been created with no execute as clause, then p_child will be executed on behalf of lane
- If jim.p_child has been created with execute as owner then p_child will be executed on behalf of lim
- If jim.p_child has been created with execute as caller then p_child will execute on behalf of Jane.

In the following example, Jane creates the same procedure as above using execute as caller. The login associated with user Bill in the current database resolves to user Bill in otherdb:

create procedure p master

with execute as caller

as exec otherdb.jim.p_child

grant execute p master to bill

Bill executes the procedure:

exec jane.p_master

- $\bullet \quad \mathsf{SAP}\,\mathsf{ASE}\,\mathsf{checks}\,\mathsf{that}\,\mathsf{Bill}\,\mathsf{in}\,\mathsf{otherdb}\,\mathsf{has}\,\mathsf{execute}\,\mathsf{permission}\,\mathsf{on}\,\,\mathsf{jim}.\mathsf{p}_\mathsf{child}.$
- If jim.p_child has been created with no execute as clause, then p_child will be executed on behalf of Bill.
- If jim.p_child has been created with execute as owner then p_child will be executed on behalf of Jim.
- If jim.p child has been created with execute as caller then p child will execute on behalf of Bill.

7.11 Row-Level Access Control

Row-level access control enables the database owner or table owner to create a secure data access environment automatically.

Row-level access control provides:

- · More granular data security: you can set permissions for individual rows, not just tables and columns
- · Automatic data filtering according to group, role, and application

Data-level security encoded in the server

Row-level access control restricts access to data in a table's individual rows, through three features:

- Access rules that the database owner defines and binds to the table
- Application Context Facility, which provides built-in functions that define, store, and retrieve user-defined contexts
- Login triggers that the database owner, sa role, or the user can create

SAP ASE enforces row-level access control for all data manipulation languages (DMLs), preventing users from bypassing the access control to get to the data.

The syntax for configuring your system for row-level access control is:

```
sp_configure "enable row level access", 1
```

This option slightly increases the amount of memory used, and you need an ASE_RLAC license option. Row-level access control is a dynamic option, so you need not restart the server.

Row-level access can also be granted using a where clause on the grant statement. Use this method of row-level access control if your privacy policy depends on data in other tables or on the full expression of SQL through a subquery.

7.11.1 Access Rules

To use the row-level access control feature, add the access option to the existing create rule syntax. Access rules restrict any rows that can be viewed or modified.

Access rules are similar to domain rules, which allow table owners to control the values users can insert or update on a column. The domain rule applies restrictions to added data, functioning on update and insert commands.

Access rules apply restrictions to retrieved data, enforced on select, update, and delete operations. SAP ASE enforces the access rules on all columns that are read by a query, even if the columns are not included in the select list. In other words, in a given query, SAP ASE enforces the domain rule on the table that is updated, and the access rule on all tables that are read.

For example:

```
insert into orders_table
select * from old_orders_table
```

In this query, if there are domain rules on the $orders_table$ and access rules on the old_orders_table , SAP ASE enforces the domain rule on the orders_table, because it is updated, and the access rule on the old_orders_table , because it is read.

Using access rules is similar to using views, or using an ad hoc query with where clauses. The query is compiled and optimized after the access rules are attached, so it does not cause performance degradation. Access rules provide a virtual view of the table data, the view depending on the specific access rules bound to the columns.

Access rules can be bound to user-defined datatypes, defined with sp_addtype. SAP ASE enforces the access rule on user tables, which frees the table owner or database owner from the maintenance task of binding

access rules to columns in the normalized schema. For instance, you can create a user-defined type, whose base type is varchar (30), call it username, and bind an access rule to it. SAP ASE enforces the access rule on any tables in your application that have columns of type username.

7.11.1.1 Syntax for Access Rules

Use the access parameter in the create rule syntax to create access rules.

```
create [or|and] access rule (<access_rule_name>)
as (<condition>)
```

7.11.1.1.1 Creating a Sample Table with Access Rules

You can create a table and bind an access rule to the table.

Creating a Table

A table owner creates and populates table T (username char(30), title char(30), classified_data char(1024)):

```
AA, "Administrative Assistant", "Memo to President"

AA, "Administrative Assistant", "Tracking Stock Movements"

VP1, "Vice President", "Meeting Schedule"

VP2, "Vice President", "Meeting Schedule"
```

Creating and Binding Access Rules

The table owner creates access rule uname_acc_rule and binds it to the username column on table T.

```
create access rule uname_acc_rule
as @username = suser_name()
------
sp_bindrule uname_acc_rule, "T.username"
```

Querying the Table

When you issue the following query:

```
select * from T
```

SAP ASE processes the access rule that is bound to the username column on table T and attaches it to the query tree. The tree is then optimized and an execution plan is generated and executed, as though the user had executed the query with the filter clause given in the access rule. In other words, SAP ASE attaches the access rule and executes the query as:

```
select * from T where T.username = suser_name().
```

The condition where T.username = suser_name() is enforced by the server. The user cannot bypass the access rule.

The result of an Administrative Assistant executing the select query is:

```
AA, "Administrative Assistant", "Memo to President"
AA, "Administrative Assistant", "Tracking Stock Movements"
```

Dropping an Access Rule

Before you drop an access rule, you must unbind it from any columns or datatypes, using sp_unbindrule, as in the following example:

```
sp_unbindrule "T.username",
NULL, "all"
```

sp_unbindrule unbinds any domain rules attached to the column by default.

After you unbind the rule, you can drop it:

```
drop rule "rule_name"
```

For example:

```
drop rule "T.username"
```

7.11.1.1.2 Syntax for Extended Access Rule

Each access rule is bound to one column, but you can have multiple access rules in a table. create rule provides AND and OR parameters to handle evaluating multiple access rules.

To create AND access rules and OR access rules, use extended access rule syntax:

AND access rule:

```
create and access rule rule_name
```

OR access rule

```
create or access rule rule_name as
```

You can bind AND access rules and OR access rules to a column or user-defined datatype. With the extended access rule syntax, you can bind multiple access rules to the table, although you can bind only one per column.

When the table is accessed, the access rules go into effect, the AND rules bound first by default, and then the OR access rules.

If you bind multiple access rules to a table without defining AND or OR access, the default access rule is AND.

If there is only one access rule on a row of the table and it is defined as an OR access rule, it behaves as an AND access rule.

7.11.1.2 Access and Extended Access Rules Examples

Examples for creating access rules.

Create Access Rules

The following steps create access rules:

```
create access rule empid1_access
as @empid = 1

create access rule deptno1_access
as @deptid = 2
```

The following steps create OR access rules:

```
create or access rule name1_access
as @name = "smith"

create or access rule phone_access
as @phone = "9999"
```

Create a Table

This step creates a test table:

```
create table testtabl (empno int, deptno int, name char(10), phone char(4))
```

Bind Rules to Table

The following steps bind access rules to the test table columns:

```
sp_bindrule empidl_access, "testtabl.empno"
/*Rule bound to table column.*/
```

```
(return status = 0) sp_bindrule deptnol_access, "testtabl.deptno"
/*Rule bound to table column.*/(return status = 0) sp_bindrule
namel_access, "testtabl.name"
/*Rule bound to table column.*/(return status = 0) sp_bindrule
phone_access, "testtabl.phone"
/*Rule bound to table column.*/(return status = 0)
```

Insert Data into Table

The following steps insert values into the test table:

```
insert testtab1 values (1,1,"smith","3245")
(1 row affected)insert testtab1 values(2,1,"jones","0283")
(1 row affected)insert testtab1 values(1,2,"smith","8282")(1 row affected)insert
testtab1 values(2,2,"smith","9999")(1 row affected)
```

These examples show how access rules return specific rows containing information limited by access rules.

Example 1

Returns information from two rows:

Example 2

Returns information from four rows:

Example 3

Returns information from six rows:

```
/* return the rows when name = "smith" or phone = "9999" */
select * from testtab1
```

empno	deptno	name	phone
		1	
	T	1 smit	
	1	2 smit	h 8282
	2	2 smit	h 9999
	3	2 smit	h 8888
	1	2 jone	s 9999
	2	3 jone	s 9999

7.11.1.3 Access Rules and the alter table Command

When a table owner uses the alter table command, access rules are disabled during the execution of the command and enabled upon completion of the command. The access rules are disabled to avoid filtering the table data during the alter table command.

7.11.1.4 Access Rules and bcp

SAP ASE enforces access rules when data is copied out of a table using the bcp. SAP ASE cannot disable access rules, as it does with alter table, because any user can use bcp who has select permission on the table.

For security purposes, the database owner should lock the table exclusively and disable access rules during bulk copy out. The lock disables access to other users while the access rules are disabled. The database owner should bind the access rules and unlock the table after the data has been copied.

7.11.1.5 Access Rules as User-Defined Java Functions

Access rules can use user-defined Java functions. For example, you can use Java functions to write sophisticated rules using the profile of the application, the user logged in to the application, and the roles that the user is currently assigned for the application.

The following Java class uses the method GetSecVal to demonstrate how you can use Java methods that use JDBC as user-defined functions inside access rules:

```
if (con == null)
 return (-1);
 pstmt = con.prepareStatement("select classification from sec tab where id = ?");
 if (pstmt == null)
 return (-1);
pstmt.setInt(1, c1);
 rs = pstmt.executeQuery();
 rs.next();
 pno val = rs.getInt(1);
 rs.close();
 pstmt.close();
 con.close();
 return (pno val);
 catch (SQLException sqe)
 return(sqe.getErrorCode());
 catch (ClassNotFoundException e)
 System.out.println("Unexpected exception : " + e.toString());
System.out.println("\nThis error usually indicates that " + "your Java CLASSPATH
 environment has not been set properly.");
 e.printStackTrace();
 return (-1);
 catch (Exception e)
 System.out.println("Unexpected exception : " + e.toString());
 e.printStackTrace();
 return (-1);
```

After compiling the Java code, you can run the same program from isql, as follows.

For example:

```
javac sec_class.java
jar cufo sec_class. jar sec_class.class
installjava -Usa -Password -f/work/work/FGAC/sec_class.jar -
-D testdb
```

From isql:

```
/*to create new user datatype class_level*/
sp_addtype class_level, int
/*to create the sample secure data table*/
create table sec_data (c1 varchar(30),
c2 varchar(30),
c3 varchar(30),
clevel class_level)
/*to create the classification table for each user*/
create table sec_tab (userid int, clevel class-level int)
insert into sec_tab values (1,10)
insert into sec_tab values (2,9)
insert into sec_tab values (3,7)
insert into sec_tab values (4,7)
insert into sec_tab values (5,4)
insert into sec_tab values (6,4)
insert into sec_tab values (7,4)
```

```
declare @v1 int
select @v1 = 5
while @v1 > 0
begin
insert into sec_data values('8', 'aaaaaaaaaa',
                                                      'aaaaaaaaaa', 8)
insert into sec_data values('7', 'aaaaaaaaaaa', 'aaaaaaaaaa',
insert into sec_data values('5', 'aaaaaaaaaaa', 'aaaaaaaaaaa', 5) insert into sec_data values('5', 'aaaaaaaaaaa', 'aaaaaaaaaaa', 5)
insert into sec_data values('2', 'aaaaaaaaaaa', 'aaaaaaaaaaa', 2)
insert into sec data values ('3', 'aaaaaaaaaa', 'aaaaaaaaaa', 3)
select @v1 = @v\overline{1} - 1
end
create access rule clevel rule
@clevel <= sec class.GetSecVal(suser id())</pre>
create default clevel def as sec class.GetSecVal(suser id())
sp bindefault clevel def, class level
sp bindrule clevel, class level
grant all on sec data to public
grant all on sec tab to public
```

7.11.2 Using the Application Context Facility

Applications on a database server must limit access to the data. Applications are carefully coded to consider the profile of the user. For example, a Human Resources application is coded to know which users are allowed to update salary information.

The attributes that enable this coding comprise an application context. The Application Context Facility (ACF) consists of three built-in functions that provide a secure environment for data access, by allowing access rules to compare against the intrinsic values assigned to users in a session.

An application context consists of context_name, attribute_name, and attribute_value. Users define the context name, the attributes, and the values for each context. You can use the default application context that SAP provides, <code>SYS_SESSION</code>, to access some session-specific information. All <code>SYS_SESSION</code> attributes are read-only except the attribute <code>INFMSG</code>.

The user profile, combined with the application profile, which is defined in a table created by the system administrator, permits cumulative and overlapping security schemes.

ACF allows users to define, store, and retrieve:

- User profiles (the roles authorized to a user and the groups to which the user belongs)
- Application profiles currently in use

Any number of application contexts per session are possible, and any context can define any number of attribute/value pairs. ACF context rows are specific to a session, and not persistent across sessions; however, unlike local variables, they are available across nested levels of statement execution. ACF provides built-in functions that set, get, list, and remove these context rows.

7.11.2.1 Setting Permissions for Using Application Context Functions

You execute an application context function in a select statement. The owner of the function is the system administrator of the server.

You can create, set, retrieve, and remove application contexts using these built-in functions.

- set_appcontext sets an application context name, attribute name, and attribute value, defined by the attributes of an application, for a specified user session.
- get_appcontext sets an application context name, attribute name, and attribute value, defined by the attributes of an application, for a specified user session.
- list appcontext lists all the attributes of all the contexts in the current session.
- rm appcontext removes a specific application context, or all application contexts.

For syntax, see Reference Manual: Building Blocks.

The data used in the functions is defined in a table that contains all logins for all tables, which created by the system administrator.

• set appcontext() stores:

```
select set_appcontext ("titles", "rlac", "1")
```

• get appcontext() supplies two parts of a context in a session, and retrieves the third:

Granting and Revoking

Grant and revoke privileges to users, roles, and groups in a given database to access objects in that database. The only exceptions are create database, set session authorization, and connect. A user granted these privileges should be a valid user in the master database. To use other privileges, the user must be a valid user in the database where the object is located.

Using of functions means that unless special arrangements are made, any logged-in user can reset the profiles of the session. Although SAP ASE audits built-in functions, security may be compromised before the problem is noticed. To restrict access to these built-in functions, use grant and revoke privileges. Only users with the sa_role can grant or revoke privileges on the built-in functions. Only the select privilege is checked as part of the server-enforced data access control checks performed by the functions.

Valid Users

Because built-in functions do not have object IDs or home databases, database owners must grant select privileges for functions to the appropriate user or role. SAP ASE uses the user's default database as a template

to determine privileges for additional databases. However, only the owner of the users' default database may grant select privileges. If using a built-in function in one databases prevents a user from using an additional database, the owner of the additional databases must explicitly revoke permission from the user or role in these databases.

Privileges granted to public affect only users named in the table created by the system administrator. Guest users have privileges only if the sa role specifically grants it by adding them to the table.

A system administrator can execute the following commands to grant or revoke select privileges on specific application context functions:

- grant select on set_appcontext to user_role
- grant select on set appcontext to joe user
- revoke select on set appcontext from joe user

7.11.3 SYS_SESSION System Application Context

The SYS_SESSION context shows the default predefined application context, which provides session-specific pairs of attributes and values.

The syntax for using the context is:

```
select list_appcontext ("SYS_SESSION", "*")
```

Then:

```
select get_appcontext ("SYS_SESSION", "<attribute>")
```

Table 14: SYS_SESSION Attributes and Values

Attribute	Value
username	Login name
hostname	Host name from which the client has connected
applname	Name of the application as set by the client
suserid	User ID of the user in the current database
groupid	Group ID of the user in the current database
dbid	ID of the user's current database
dbname	Current database
spid	Server process ID
proxy_suserid	The server user ID of the proxy

Attribute	Value
client_name	Client name set by the middle-tier application, using set client_name
client_applnam	Client application name set by the middle-tier application, using set client_applname
client_hostnam	Client host name set by the middle-tier application, using set client_hostname
language	Current language the client is using by default or after using set language (@@language)
character_set	Character set the client is using (@@client_csname)
dateformat	Date expected by the client, set using set dateformat
is_showplan_on	Returns YES if set showplan is on, NO if it is off
is_noexec_on	Returns YES if set no exec is on, NO if it is off
infmsg	Returns a string with the latest informational messages sent to the client.

7.11.3.1 Solving a Problem Using an Access Rule and ACF

Problem solutions using Access Rule and ACF.

This shows the solution of a problem: each of five users, on different security levels, should see only rows with a value less than or equal to his or her security level. This solution uses access rules, with the Application Context Facility, to display only the rows that one of the users, Dave, sees.

There are five logins:

- Anne has security level 1.
- Bob has security level 1.
- Cassie has security level 2.
- Dave has security level 2.
- Ellie has security level 4.

Users should see only rows with a value in rlac that is less than or equal to their own security level. To accomplish this, create an access rule and apply ACF.

The rlac column is type integer, and appcontext arguments are type char.

```
select title id, rlac from titles
title id
            rlac
PC8888
             1
BU1032
PS7777
              1
PS3333
BU1111
PC1035
BU2075
PS2091
              1
PS2106
              1
BU7832
PS1372
(11 rows affected)
```

7.11.3.2 Using infmsg to Return Informational Messages

infmsg is an attribute in the $sys_session$ system application context that returns the latest informational messages sent to the client as a string.

infmsg informational messages use a varchar (16384) data type. Text which exceeds 16384 bytes is truncated. infmsg is the only attribute in the SYS SESSION context that is writable.

To start recording the printed informational messages, initialize the infmsq attribute:

```
SELECT set_appcontext("SYS_SESSION","INFMSG","")
```

To append a string to the end of the recorded message, execute the following command:

```
SELECT set_appcontext("SYS_SESSION","INFMSG","<string>")
```

To retrieve messages stored by the infmsg attribute, execute the following command:

```
SELECT get_appcontext("SYS_SESSION","INFMSG")
```

To clear the messages, execute the following command:

```
SELECT rm_appcontext("SYS_SESSION","INFMSG")
```

Example 1

This example runs a script called database model that dumps a database schema to file, and then loads the file to create a new copy of the database. By initializing the infmsg attribute between the dump and load commands, you can capture and review the informational messages generated:

```
DUMP database model to "/tmp/model.dmp"
GO

SELECT set_appcontext("SYS_SESSION","INFMSG","")
```

```
GO
LOAD DATABASE MODEL WITH listonly=(create_sql,load_sql)
GO
SELECT get_appcontext("SYS_SESSION","INFMSG")
GO
```

The returned result is:

Example 2

This example initializes the infmsg attribute to return informational messages and then appends the strings abc and pqr to the end of the returned message:

The returned result of the informational message with the appended text is:

```
select get_appcontext("SYS_SESSION", "INFMSG")
-----
abcpqr
(1 row affected)
```

Example 3

Clear the recorded messages:

Once cleared, no text is returned when you get the informational message:

```
select get_appcontext("SYS_SESSION", "INFMSG")
----
NULL

(1 row affected)
```

7.11.4 Session Management for SAP HANA Syntax

Set variables for your database session using the SAP HANA session management style.

• Use the set command to define a session variable. For example:

```
set 'abc' = '123'
```

Use the set command to rewrite a session variable. For example:

```
set 'abc' = '456'
```

• Use unset to delete a session variable. For example:

```
unset 'abc'
```

• Use the session context function to retrieve a variable. For example:

```
select session_context('abc')
```

7.11.5 Using Login Triggers

Login triggers execute a specified stored procedure every time a user logs in.

The login trigger is an ordinary stored procedure, except it executes in the background. It is the last step in a successful login process, and sets the application context for the user logging in.

Only the system security officer can register a login trigger to users in the server.

To provide a secure environment, the system administrator must:

- 1. Revoke select privilege on the set_appcontext function. The owner of a login trigger must have explicit permission to use set appcontext, even if the owner has sa role.
- 2. Configure a login trigger from a stored procedure for each user, and register the login trigger to the user.
- 3. Provide execute privilege to the login trigger that the user executes.

7.11.5.1 Create Login Triggers

Create a login trigger as a stored procedure.

Do not use the create trigger command. The following sample requires the you first create the lookup table in the pubs2 database:

```
create table lookup (
  appname varchar(20),
  attr varchar(20),
  value varchar(20),
  login varchar(20)
)
```

Then create a login trigger stored procedure in the pubs2 database:

```
create procedure loginproc as
 declare @appnamevarchar(20)
  declare @attr varchar(20)
 declare @value varchar(20)
 declare @retvalue int
declare apctx cursor for
select appname, attr, value from
pubs2.dbo.lookup where login = suser_name()
open apctx
fetch apctx into @appname, @attr, @value
While (@@sqlstatus = 0)
   select f@retval =
      set_appcontext (rtrim (@appname),
      rtrim(@attr), rtrim(@value))
 fetch apctx into @appname, @attr, @value
end
go
```

Grant permission to execute loginproc to public:

```
grant execute on loginproc to public
```

To associate the login trigger with a specific user, run alter login in the user's default database.

7.11.5.2 Configure Login Triggers

You must have sso_role enabled to set, change, or drop a login trigger.

The object ID of the login trigger is stored in the syslogins.procid column. Login triggers do not exist by default. They must be registered using alter login.

Run this command from the user's default database. The stored procedure you are registering as a login trigger must be available in the user's default database, because SAP ASE searches the sysobjects table in the user's default database to find the login trigger object.

The following example configures the stored procedure my_proc (which must exist in the database you want to configure) as a login trigger for login my login:

```
alter login my_login modify login script "my_proc"
```

Again, you must execute the command from within the user's default database. SAP ASE checks to see whether the login has execute permissions on the stored procedure, but not until the user actually logs in and executes the login trigger.

7.11.5.2.1 Display Login Triggers

To display the current login trigger, use sp displaylogin.

```
sp_displaylogin my_login
go
(...)
Default Database: my_db
Default Language:
Auto Login Script: my_proc
....
```

7.11.5.2.2 Drop and Change Login Triggers

Once you have configured a stored procedure as a login trigger, it cannot be dropped. You must first unconfigure the stored procedure, either by dropping the login trigger altogether, or by changing the login trigger to a different stored procedure.

To drop the login trigger, enter:

```
alter login my_login drop login script
```

To change the login trigger to a different stored procedure, enter:

```
alter login my_login modify login script "diff_proc"
```

7.11.5.3 Execute Login Triggers

Login triggers are different from ordinary stored procedures in that once they are registered they execute in the background, without active user connections.

Once you have configured a login trigger, SAP ASE automatically executes it in the background as soon as the user logs in, but before the server executes any commands from the client application.

If one login makes multiple concurrent connections, the login trigger executes independently during each session. Similarly, multiple logins can configure the same stored procedure to be a login trigger.

Background execution means that you cannot use some standard features of stored procedures in a stored procedure configured as a login trigger. For instance, you cannot pass any parameters without default values to or from the procedure, nor does the procedure pass back any result values.

This special execution mode affects any stored procedures that are called by the login trigger stored procedure, as well as any output generated by the login trigger stored procedure itself.

You can also execute a login trigger stored procedure as a normal stored procedure, for example, from isql. The procedure executes and behaves normally, showing all output and error messages as usual.

7.11.5.4 Login Trigger Output

The main effect of executing the stored procedure as a background task is that output from the login trigger is not written to the client application, but to the error log file, as are some, but not all, error messages.

Output from print or raiserror messages is prefixed by the words background task message or background task error in the error log. For example, the statements print "Hello!" and raiserror 123456 in a login trigger appear in the error log as:

```
(....) background task message: Hello!
(....) background task error 123456: This is test
message 123456
```

However, not all output goes to the error log:

- No result sets from select statements (which are normally sent to a client connection) appear anywhere, not even in the error log. This information disappears.
- The following statements execute normally: insert...select and select...into statements, as well as other DML statements which do not ordinarily send a result set to the client application, and DDL statements ordinarily allowed in a stored procedure.

7.11.5.5 Use Login Triggers for Other Applications

Login triggers are part of the row-level access control feature in SAP ASE.

In this context, you can use a login trigger in combination with the features for access rules and application contexts to set up row-level access controls, once a session logs in to an SAP ASE server. However, you can use login triggers for other purposes as well.

7.11.5.5.1 Limiting the Number of Concurrent Connections

You can create a stored procedure to limit the number of concurrent connections.

Procedure

```
create procedure limit user sessions
 declare @cnt int,
   @limit int,
  @loginname varchar(32)
 select @limit = 2 -- max nr. of concurrent logins
/* determine current #sessions */
select @cnt = count(*)
from master.dbo.sysprocesses
 where suid = suser_id()
/* check the limit *\overline{/}
if @cnt > @limit
begin
 select @loginname = suser name()
 print "Aborting login [%1!]: exceeds session
   limit [%2!]",
     @loginname, @limit
    /* abort this session */
    select syb quit()
end
grant exec on limit_user_sessions to public
```

2. As system security officer, configure this stored procedure as a login trigger for user "bob":

```
alter login bob modify login script
"limit_user_sessions"
go
```

Now, when user "bob" creates a third session for SAP ASE, this session is terminated by the login trigger calling the syb quit () function:

```
% isql -SASE125 -Ubob -Pbobpassword
1> select 1
2> goCT-LIBRARY error:
ct_results(): network packet layer: internal net library error:
Net-Library operation terminated due to disconnect
```

This message appears in the error log file:

```
(...) background task message: Aborting login
[ my_login]: exceeds session limit [2]
```

7.11.5.5.2 Enforcing Timed-Based Restrictions

You can limit the number of concurrent connections for a specific login and restrict access to specific times of day for that login.

Procedure

1. As system administrator, create this table:

```
create table access_times (
suid int not null,
dayofweek tinyint,
shiftstart time,
shiftend time)
```

2. As system administrator, insert the following rows in table access_times. These rows indicate that user "bob" is allowed to log into the server on Mondays between 9:00am and 5:00pm, and user "mark" is allowed to login to the server on Tuesdays between 9:00am and 5:00pm.

```
insert into access_times
select suser_id('bob'), 1, '9:00', '17:00'
go
insert into access_times
select suser_id('mark'), 2, '9:00', '17:00'
go
```

3. As system administrator, create the limit_access_time stored procedure, which references the access time table to determine if login access should be granted:

```
create procedure limit access time as
declare @curdate date,
    @curdow tinyint,
    @curtime time,
    @cnt int,
   @loginname varchar(32)
-- setup variables for current day-of-week, time
select @curdate = current date()
select @curdow = datepart(cdw,@curdate)
select @curtime = current_time()
select @cnt = 0
-- determine if current user is allowed access
select @cnt = count(*)
from access times
where suid = suser id()
and dayofweek = @curdow
and @curtime between shiftstart and shiftend
if @cnt = 0
begin
   select @loginname = suser_name()
print "Aborting login [%1!]: login attempt past normal working
hours", @loginname
   -- abort this session
   return -4
end
grant exec on limit access time to public
```

4. As system security officer, configure the limit_access_time stored procedure as a login trigger for users "bob" and "mark":

```
alter login bob login script
"limit_access_time"
go
alter login mark login script
"limit_access_time"
go
```

On Mondays, user "bob" creates a session:

However, user "mark" is denied access:

```
isql -Umark -Ppassword
1> select 1
2> go
CT-LIBRARY error:
ct_results(): network packet layer: internal net
library error: Net-Library operation terminated
due to disconnect
```

The following message is logged in the error log:

```
(...) server back-ground task message: Aborting
login [mark]: login attempt past normal working
hours
```

Results

The above examples show how you can limit the number of concurrent connections for a specific login and restrict access to specific times of day for that login, but it has one disadvantage: the client application cannot easily detect the reason the session was terminated. To display a message to the user, such as "Too many users right now—please try later," use a different approach.Instead of calling the built-in function $syb_quit()$, which causes the server to simply terminate the current session, you can deliberately cause an error in the stored procedure to abort the login trigger stored procedure.

For example, dividing by zero aborts the login trigger stored procedure, terminates the session, and causes a message to appear.

7.11.5.6 Login Trigger Restrictions

These login trigger actions are restricted.

• You cannot create #temp tables to use later in the session. Once the procedure completes, #temp tables are automatically dropped and the original session settings are restored, as in any other stored procedure.

- Do not use login triggers on the sa login; a failing login trigger can lock you out of SAP ASE.
- Do not use a login trigger for anything that may take longer than a few seconds to process, or that risks processing problems.

Issues and Information

- If you do not have access to the error log, do not use login triggers. Always check the error log for error messages.
- For SAP ASE version 15.0.2 and later, any exportable option set or unset in a login trigger take effect in the login process when the server starts.
 - To disable this behavior, execute set export_options off inside the login trigger. SAP ASE versions 15.0.1, 12.5.4, and earlier required that you start the server with trace flag 4073 to enable the options for a login trigger.
- A client application, like <code>isql</code>, is unaware of the existence or execution of a login trigger; it presents a command prompt immediately after the successful login, though SAP ASE does not execute any commands before the login trigger successfully executes. This <code>isql</code> prompt displays even if the login trigger has terminated the user connection.
- The user logging in to the server must have execute permission to use the login trigger stored procedure. If no execute permission has been granted, an error message appears in the error log and the user connection closes immediately (though isql still shows a command prompt).

The error log shows a message similar to the following:

```
EXECUTE permission denied on object my_proc, database my_db, owner dbo
```

• The login trigger stored procedure cannot contain parameters without specified default values. If parameters without default values appear in the stored procedure, the login trigger fails and an error similar to the following appears in the error log:

```
Procedure my_proc expects parameter @param1, which was not supplied...
```

7.11.5.7 Disable the execute Privilege on Login Triggers

A database owner or administrator can disable execute privilege on the login trigger, or code the login trigger to permit access only at certain times.

For example, you may want to prohibit regular users from using the server while the database owner or administrator is updating the table.

i Note

If the login trigger returns a negative number, the login fails.

7.11.6 Export set Options from a Login Trigger

SAP ASE allows options for the set command that are inside login triggers to remain valid for the entire user session.

The following set options are automatically exported:

- showplan
- arithabort [overflow | numeric_truncation]
- arithignore [overflow]
- colnames
- format
- statistics io
- procid
- rowcount
- altnames
- nocount
- quoted_identifier
- forceplan
- fmtonly
- close on endtran
- fipsflagger
- self recursion
- ansinull
- dup in subquery
- or_strategy
- flushmessage
- ansi permissions
- string_rtruncation
- prefetch
- triggers
- replication
- sort_resources
- transactional_rpc
- cis_rpc_handling
- strict dtm enforcement
- raw_object_serialization
- textptr parameters
- remote indexes
- explicit transaction required
- statement_cache
- command_status_reporting

- proc_return_status
- proc_output_params

7.11.7 Set Global Login Triggers

Use ${\tt sp_logintrigger}$ to set a global login trigger that is executed at each user login.

To take user-specific actions, set a user specific login trigger using alter login or create login.

8 Predicated Privileges

Predicated privileges include a system of flexible row-level access controls, allowing you to grant select, update, and delete privileges on data for different users, groups, or roles based on a predicate that is evaluated by SAP ASE during data access.

If the condition expressed by the predicate is not met for any row of data, that row is withheld from the result set.

Predicated privileges offer data privacy protection based on row-level access controls that dynamically grant privileges to a user based on data content or context information, allowing you to implement a privacy policy in the server instead of the client or a Web server.

A predicate may access other objects, such as tables, SQL functions, or built-in functions. Access to these other objects is checked against the permissions and roles of the predicate owner (the grantor of the predicated privilege). The user who executes the select, update, or delete command on the object targeted by the grant does not require explicit permission on the objects referenced by the predicate.

Predicated privileges allow a service provider to store data in a single database, and share the same tables for multiple customers instead of requiring separate views and instead of triggers for each customer. The data is filtered for specific users according to the predicated privileges granted directly to the user, or granted indirectly through the user's groups or roles.

8.1 Differences Between Access Rules and Predicated Privileges

Compare the advantages of predicated privileges over the access rules provided by versions of SAP ASE earlier than 15.7 ESD#2.

	Access rules	Predicated privileges
Predicate scope	Can refer only to the column to which the rule is bound. Multiple access rules are required to reference more than one column.	Can refer to any column in the table or, using a sub-select, any other table or function in the current database or in other databases.
Statement scope	All rules apply to select, update, and delete. Does not allow different restrictions across different kinds of access.	Grantor specifies which predicate applies to which access. For example, stricter access control may be imposed for updating and deleting rows than for selecting rows.

	Access rules	Predicated privileges
Combining predicates	Gives a way to combine individual rules using and or or, but does not give a way to express precedence grouping; for example, ((<rule1> and <rule2>) or <rule3>).</rule3></rule2></rule1>	A predicated privilege can construct an arbitrarily complex Boolean expression. You may combine multiple privileges against the same object based on well-defined rules.
Restricting the scope to a subject	Any restriction directed at a specific subject must be expressed as part of the rule, such as where name = <user>.</user>	You can apply a predicate to selected users, groups, or roles without the administrator needing to introduce complicated logic into the predicate.
Integration with permissions system	Decoupled from SQL authorization. Requires rule analysis to understand how users are restricted from some action.	Strongly enforced through the permission system. Diagnostic commands allow an application developer to predict how the predicates modify a query .

8.2 Commands Used for Predicated Privileges

Use these commands for granting and revoking predicated privileges.

- grant ... where grant row-level access control to a group, role, or individual user based on conditions expressed through the where clause.
- grant role ... where grant roles whose activation is conditional on the evaluation of a where clause
- revoke ... [with { <pred name> | {all |no} predicates}] revoke predicated privileges.
- set show_transformed_sql displays the full SQL text, including the added predicates for row-level filtering.

See the Reference Manual: Commands.

8.3 Configure SAP ASE to Use Predicated Privileges

Configure SAP ASE to use predicated privileges.

- 1. Enable the ASE_SECDIR license, required for SAP ASE Security and Directory Services.
- 2. Configure the enable predicated privileges configuration parameter.
- 3. Set the value for permission cache entries. Granting access to a single table restricted by multiple predicated privileges increases the number of protection cache entries required. Allow one extra protection cache entry for any access that requires more than one predicate evaluation.
- 4. Consider whether to increase the size of the procedure cache. If users executing a stored procedure each have different predicated access to the tables referenced by the procedure, a separate plan is created for each user executing the procedure. In this case, you may need to increase the size of the procedure cache.

8.4 Grant Predicated Privileges

grant allows you to grant row-level access control on a table based on conditions specified by a where clause.

The syntax is:

```
grant {all [privileges] | permission_list}
on table_name [<correlation_name>]
[(<column_name_list>)]
[where search_conditions
    [as pred_name]]
to {public | <name_list> | <role_list>}
[with grant option]
```

See the Reference Manual: Commands.

The grant ... where statement on a table allows you to define conditions on select, update, or delete commands against that table that qualify or disqualify rows from the result set. The <search_conditions> act as a row filter, working with the where clause specified on the select, update, or delete. You can compose search_conditions that contain complex SQL conditions and reference functions, tables, and SQL functions. However, predicated privileges cannot reference a view.

This example gives engineers permission to see their own salary and the salary of the workers reporting to them:

```
grant select on employee (salary)
  where ename = USER or
  emgr = USER to eng_role
```

The statement filters rows on the select command (including selects that are part of compound commands such as select into, insert select, and update from, and select commands wrapped by a view), as well as on select, update, and delete commands that reference the salary column in their where clauses. The predicate, effectively, restricts workers from seeing another worker's salary.

SAP ASE applies the where clause from the grant statement when a query against the table is processed, and evaluates the conditions when a query is executed.

8.4.1 Grant Access to select Data

The where clause on a grant select command combines with any end user's where clause in the select command to qualify the rows returned from a select operation.

Use the grant ... where statement on a table without a column list to filter rows regardless of the individual columns selected. This grant statement allows project_leaders read and write access to information only for those projects they manage:

```
grant select on projects
  where user_id() = p_mgrid
  to proj_leader_role
```

Use a column or column list with the grant command to filter rows when the select accesses a specific column. These grant statements allows all engineers access to the names and departments of all engineers, while restricting access to engineers' phone numbers to their manager:

```
grant select on employee(ename, edept)
  to eng_role

grant select on employee(ephone)
  where user_id() = emgr to eng_role
```

8.4.2 Grant Access to update Data

The where clause on a grant update command combines with the end user's where clause in the select command to qualify the rows targeted for an update operation.

Use a column or column list with the grant ... update statement to filter rows that update only specific columns. This example allows all administrative and medical staff to update patients' addresses, but restricts modifications to the medical status to only the patient's physician:

```
grant update on patients (address, phone)
  to public
grant update on patients (medical_status)
  where USER = primary_md
  to doctor_role
```

The update command raises a permissions error if any user other than one with doctor_role attempts to update a patient's medical status. It also restricts the rows and columns that a doctor may update.

8.4.3 Grant Access to delete Data

The where clause on a grant update command combines with the end user's where clause to qualify the rows to be deleted.

This example grants permission for Bob to delete sales data:

```
grant delete on employee
where edept = 'sales'
to Bob
```

Now when Bob runs this statement:

```
delete employee
  where status = 'terminated'
```

SAP ASE runs the statement internally as:

```
delete employee
  where status = 'terminated' and edept = 'sales'
```

8.4.4 Use Predicated Privileges to Enforce a Data Privacy Policy

The grant statements can be used to enforce a policy that restricts employees from viewing private data.

The grant statements in this example enforce a policy that restricts employees from viewing any salaries but their own, allows managers to view their group members' salaries, and restricts salary updates to the HR department during any month except December:

```
grant select on employee as e (esalary)
  where e.ename = USER
  or USER in
    (select username(mgrid) from depts d
  where d.deid = e.eid)
    to public
grant update on employee (esalary)
  where datepart(month, current_date()) <> 12
  to hr_role
```

8.5 Revoke Predicated Privileges

Use the revoke command to revoke row-level access on a table.

The syntax is:

• If <column_list> is used with <pred_name>, the predicated row-level access is revoked for the named columns. If there are remaining columns that are referenced by this row-level privilege, the privilege and its related named predicate remain in sysprotects. For the following revoke examples, assume permission was initially granted as:

```
grant select on t1(col1,col2,col3)
  where col4 > 99 as pred1
  to user1
```

This revokes select permission on t1.col2 with pred1:

```
revoke select on t1 (col2)
with pred1
from user1
```

However, if user1 selects t1.col3, then pred1 is still applied:

If the grantor also issued:

```
revoke select on t1 (col1, col3)
with pred1
from user1
```

or,

```
revoke select on t1 with pred1
```

then all permissions on t1 using pred1 would be revoked from user1.

• Use with cause to revoke all predicates, name predicates, or remove only unpredicated grants for the given access from the named grantee. If the with clause is omitted, both predicated and non-predicated grants are revoked. This example revokes all predicated row-level privileges granted to user1.

```
revoke select on t1 with all predicates from user1
```

The following omits the with clause and revokes all non-predicated select access non-predicated grants granted to user1.

```
revoke select on t1 with no predicates
```

See the Reference Manual: Commands.

8.6 How SAP ASE Saves Predicated Privileges in sysprotects

For grant commands that do not include predicates, the precedence rule of granted privileges with respect to the grantee, specifies that a grant at a higher level can remove a grant at a lower level. However, if the higher precedence grant is predicated, generally lower-precedence rows are retained in sysprotects.

In this example, the second non-predicated grant to public causes SAP ASE to remove the earlier grant to an individual user1:

```
grant select on t1 to user1 grant select on t1 to public
```

However, grants with predicates allow grants that are lower in precedence to remain. For example, the first grant, below, to user1 is general, but the second grant to public on t1 is conditional. SAP ASE does not remove the grant to user1, even though the grantee, public, has a higher precedence:

```
grant select on t1
  to user1
grant select on t1
  where col1 = 4 to public
```

In this example, the second grant is added but the privilege is recorded as conditional access on all columns in t1 except col1:

```
grant select on t1 (col1)
  to user2
grant select on t1
  where col1 = 4
  to user2
```

The first grant is not removed because it gives user2 unconditional access on column col1, which is stronger than the conditional access on col1 from the second grant.

8.7 Predicated Role Activation

Use the grant role ... where command to restrict role activation according to certain conditions.

Only active roles can have access privileges. The grantee of a role with an activation predicate may be a user or a login profile (a login profile is a template of attributes that is applied to assigned users when they log in).

The syntax is:

```
grant role <role_name>
        [where <pred_expression>]
    to {<username>< | ><login_profile_name >}
```

The where cpred_expression clause is a role-activation predicate or SQL condition that must be satisfied when the named role is activated. Use cpred_expression when granting a role to a user or login profile.

i Note

You must be in the master database to grant a role with an activation predicate.

Role activation predicates, like predicated privileges, can access database objects such as tables, views, SQL functions, and built-in functions. These accesses are checked against the permissions and roles of the predicate owner (the grantor of the role) instead of requiring explicit permission on the objects accessed by the predicate by the user who executes the set role statement.

i Note

Although you can reference a view with an activation predicate, you cannot reference a view with a row-filtering predicate.

The following example allows login "Bob" to perform maintenance duties on the server during off-peak hours. If Bob attempts to enable the oper role between 8 am and 6 pm, an error is returned.

```
grant role oper_role
  where datepart(hour, current_time())
  not between 8 and 18
  to Bob
```

If an activation predicate is used on a grant role to a user or login profile, the predicate is evaluated either:

- During login, if the role is designated as a default role for the user, or
- During login, if the role is granted to a login profile and has been added as an auto-activated role, or
- When the user attempts to set the role.

Roles granted to a login profile apply to all users assigned to that profile, and can be specified for automatic activation at login, based on evaluation of the predicate. For example, this allows users associated with the admin login profile to assume the sa_role when they use the resource monitor application:

```
grant role sa_role
```

```
where
  (select get_appcontext('SYS_SESSION', 'applname'))
  = 'mon_resource' to loginprof_admin
```

If a role activation predicate evaluates to false, an error is returned for the set role command, or silently does not set a default or automatically activated role during login.

8.8 Combine Predicates to Enforce Row-Level Privileges

SAP ASE combines and attaches predicates to update, delete, or select commands on a specific table.

This done while taking into account:

- Multiple grantors grant commands are applied across all affected columns to a specific grantee, or to his group or roles, for the same access from one or more grantors.
- Multiple column sets grant commands are applied across different column sets, to a specific grantee, or to his group or roles, for the same access from one or more grantors.
- Different access granted privileges on the same object for different accesses.

If a revoke row exists for a specific user access at the user or group level, the aggregated grants consist of predicates that apply to the user's set of roles.

SAP ASE obeys a set of rules when combining predicates.

Examples

The following examples assume you create this table:

```
create table employee (
   eid int not null,
   ename char(8) not null,
   eaddr varchar(20) not null,
   ecity char(10) not null,
   ezip char(5) not null,
   ephone int not null,
   esalary money not null,
   edept char(10) not null
)
```

And insert these values:

```
insert employee values (1001, 'Bill','6 Tree St','Baytown','97364',3973465,100000, 'eng') insert employee values (1009, 'Sally', '2 Sun Dr', 'Henton', '97821', 1239786, 50000, 'sales') insert employee values (1005, 'Drew','7 Inn Rd','Denville','29052',4960034,110000, 'payroll') insert employee values (1010, 'Navid', '1 Bat Ave', 'Busitown', '60734', 3094509,175000, 'hr') insert employee values (1004, 'Pat', '5 Dot Ln', 'Toytown', '33109', 4247184, 90000, 'eng') insert employee
```

8.8.1 Example 1: Combining Predicates From Multiple Grants for the Same Table Access

Predicates from multiple grants for the same table access are combined using a Boolean or operator when all predicates apply to the columns referenced by the user command.

If a user is directly, or indirectly, granted (for example, through a role) multiple predicated privileges for the same access and on the same object, the predicates from the individual grant commands are combined using the or parameter. Additional grants with predicates for a single access usually results in more rows being made visible to the user.

For example, user Ben, a sale manager, has been granted these permissions on the employee table:

```
grant select on employee
  where edept = "sales"
  to sales_mgr_role
grant select on employee (eid, ename, eaddr,
  ezip)
  where ezip like "97%"
  to ben
```

When Ben with sales_manager_role active, executes this statement, the columns eid and ename are affected by the two predicated grant commands:

```
select eid, ename from employee
```

SAP ASE internally executes:

```
select eid, ename from employee
where edept = "sales" or
ezip like "97%"
```

SAP ASE then returns:

```
eid ename
---- ----
1001 Bill
1009 Sally
1006 Sue
```

8.8.2 Example 2: Combining Predicates From Multiple Grants Applying to Different Sets of Columns

Predicates from multiple grants applying to different sets of columns are combined using the boolean or and and operators.

When a result set is affected non-uniformly by a set of predicates, SAP ASE combines all predicates for a given access on each column using the boolean or operator. These Boolean expressions are combined across all columns using the Boolean and operator.

For example, Ben has been granted the same privileges as in Example 1, except the first grant affects a subset of employee columns:

```
grant select on employee (esalary)
  where edept = "sales"
  to sales_mgr_role
grant select on employee (eid, ename, eaddr,
  ezip)
  where ezip like "97%"
  to ben
```

When Ben executes this statement, SAP ASE notices that columns <code>ename</code> and <code>esalary</code> are affected by the different <code>grant</code> commands:

```
select ename, esalary from employee
```

SAP ASE internally executes:

```
select ename, esalary from employee
where edept = "sales" and ezip like "97%"
```

SAP ASE then returns:

```
ename esalary sally 50000
```

8.8.3 Example 3: Combining Predicates From Multiple Grants for Different Access

Predicates from multiple grants for different accesses are combined using the Boolean and operator.

If select access on an object is granted to a subject using a predicate, update access is allowed using a different predicate, and both predicated grants are required for access, the two predicates are combined using the Boolean and operator.

For example, the first grant allows California administrators to see employees who live in the "97..." area code. Through the second grant, those administrators are allowed to update only employees whose salary is less than \$100,000 per year:

```
grant select on employee
where ezip like "97%"
to calif_admin
```

```
grant update on employees (esalary)
where esalary < $100000
to calif_admin</pre>
```

When a user with calif admin role executes:

```
select eid, ename, esalary from employee
```

SAP ASE returns:

```
eid ename esalary
---- 1001 Bill 100,000.00
1009 Sally 50,000.00
```

When a user with calif admin executes:

```
update employees
set esalary = esalary + (esalary * 0.05)
```

SAP ASE internally executes:

```
update employees
set esalary = esalary + (esalary * 0.05)
where ezip like "97%"
and esalary < $100000</pre>
```

SAP ASE then updates the row as:

```
eid ename esalary
1009 Sally $52500
```

8.9 SQL Behavior with Predicated Privileges

Use these set parameters and system procedures to display information about predicated privileges.

These set parameters display information about predicated privileges:

- set show_transformed_sql command displays the full SQL query, including the added predicates for row-level filtering. When used with set noexec on, you can validate the final SQL query after the relevant predicates for the user, group, and active roles have been added, without executing the query.
- set show_permission_source displays the grantee, type of grantee, grantor, action, object and predicate in tabular form.

See the Reference Manual: Commands.

These system procedures display information about predicated privileges:

• sp_helptext displays the predicate text. Include the predicate's user-defined name, if there is one, or its internal name with sp_helptext:

```
sp_helptext pred1
# Lines of Text
-----
```

```
text
grant select on tab1 where col1 = 5 as pred1 to robert
```

sp helptext only displays results not previously hidden by sp hidetext.

This example displays the predicate with the source text hidden by sp hidetext:

```
Msg 18406, Level 16, State 1:
Procedure 'sp_helptext', Line 313:
Source text for compiled object pred1 (id = 592002109) is hidden.
```

sp helprotect lists the name of the predicated privilege, if any, in the predicate column.

See the Reference Manual: Procedures.

8.10 Chain-of-Ownership Effect on Predicated Privileges

A chain of ownership exists between a stored procedure, SQL function, view, or trigger and a table accessed by that object if the same user owns the calling object and the table.

With this chain of ownership, the owner of a stored procedure, view, SQL function, or trigger gives another user implicit access on the dependent object by granting explicit access to the user on the procedure, view, and so on. Granting access to the dependent object is unnecessary.

If a user has implicit permission on a table through a chain of ownership, the predicates are not applied from any row-filtering grant commands for this access.

For example, the owner of the employee table grants user "Priscilla" access to see the employee data in the payroll department:

```
grant select on employee
  where dept = 'payroll'
  to priscilla
```

When Priscilla enters:

```
select name, phone from employee
where city='SFO'
```

The names and phone numbers are returned of only those employees who live in San Francisco and work in the payroll department.

However, if the owner of the employee table creates the following procedure and grants execute access to priscilla, the ownership chain between employee and employee addresses is detected:

```
create procedure employee_addresses as
select name, phone from employee
```

Priscilla is given implicit access to all rows in employee in the context of the procedure without restrictions from the predicate on the previous grant.

8.11 ansi_permissions and Predicated Privileges

If an update or a delete command includes a where clause that references columns in a table that has rows being updated or deleted, SAP ASE checks for select permission privileges on these columns only if ansi permissions is enabled for the session.

SAP ASE applies predicated privileges on the update and delete statements according to whether:

- ansi_permissions is enabled predicated privileges from grant select are applied in addition to any predicate specified in the grant update statement if the table owner granted predicated select access on the columns in the where clause. Verify that applying both predicates does not unexpectedly restrict the row set.
- ansi_permissions is disabled select permission is not required on the columns of the updated or deleted table referenced in the where clause. Any predicates granted for select access on the table are not applied to the update or delete statement.

This example illustrates how ansi permissions affects predicated privileges:

• The first grant allows user "Bob" to update employee salaries in the sales department, while the second grant allows Bob to select the employee ID and address of only those employees who are his direct reports:

```
grant update on employee (salary)
  where edept = "sales"
  to bob
grant select on employee (eid, eaddress)
  where user_name(mgrid) = USER
  to bob
```

If Bob attempts to update an employee's salary based on eid, one or both of the predicates from grant commands in the examples above are applied:

```
update employee
  set salary = salary * 0.1
  where eid = 1006
```

• If the session has set ansi_permissions enabled, SAP ASE executes the update command after adding the predicates for both the update and the select statements:

```
update employee
  set salary = salary * 0.1
  where eid = 1006
  and edept = "sales"
  and user_name(mgrid) = USER
```

Since Bob's predicated select permission allows him to search IDs only of employees who are his direct reports, Bob's predicated select access does not restrict the rows he can update or delete.

If ansi permissions are disabled, SAP ASE executes the update command as follows:

```
update employee
  set salary = salary * 0.1
  where eid = 1006
  and edept = 'sales'
```

To summarize, if ansi permissions is:

- Disabled Bob can update and delete rows that he is not allowed to select.
- Enabled the where clause on a predicated grant for select access qualifies the row set that may be updated or deleted.

i Note

Either one or both of the predicates from the grant commands in the examples above are applied.

8.12 Permissions on Accesses Made by Predicates

The grantor of a predicated privilege must have authorization to access any tables build-in or SQL functions referenced by the predicate.

For row-filtering predicates, SAP ASE verifies accesses made by the predicate at the same point in execution that is verifies accesses made by the user's select, update or delete commands. Accesses made by role activation predicates are checked when the user activates a role. The user who enters the command to which a predicate is attached is not required to have authorization on the predicate's referenced objects.

For example, enforcing data privacy requires you specify predicates that access tables and columns that contain the data owner's privacy policies. Access to these privacy policies should be restricted to a small set of users; data consumers should not necessarily have the right to view the internal data used to enforce policies.

SAP ASE enforces permissions on accesses made by predicated privileges against the grantor of the privilege, taking into account the grantor's direct and indirect permissions through group and default role membership. A user's default roles include roles granted through login profiles for automatic activation.

You may want to create an application security role that has permission on privacy metadata tables. You can then assign object owners this role as a default or automatically activated role so that the grant predicates have access to the necessary data.

In this example Bob, the owner of the purchases table, grants permission to market analysts with the market_role to view product purchasing information for those customers who opted to share their data (customer preferences are stored in the privacy db).

When user Alice, who has activated the market_role, selects from the purchases table, these access checks are performed:

- Alice's direct or indirect select permission on purchases
- Bob's direct or indirect permission to select from the privacy db..choices table

i Note

The ownership of a predicated privilege is modified when the object to which the predicated grant applies changes ownership by the alter .. modify owner command. If the new owner has not been granted permission on the objects accessed by the predicate, application of the predicate causes a run time error.

8.13 Predicated Privileges and Triggers

SAP ASE does not apply row-filtering predicates to pseudo tables. The row-filtering predicates applied to the base table restricts the data in inserted and deleted tables.

Accesses made by a trigger against regular tables are subject to row-filtering through predicates.

8.14 Recompile Predicated Privileges

If a stored procedure, trigger, or SQL function accesses tables that are controlled by predicated privileges, SAP ASE may need to recompile the procedural object for access by different users, or by the same user with one or more roles activated when the active roles differ from those activated when the plan was last compiled.

To prevent constant recompiling for different users executing the same procedure, SAP ASE attempts to select a cached plan that has the right "profile" for the current user. For example, if a procedure is initially compiled for execution by Joe with role1 and role2 active, the same procedure is likely recompiled for Bob, who has role2 and role3 active, assuming that accesses by the procedure are controlled by separate predicated grants to role1, role2, and role3.

If the procedure cache contains plans compiled for Bob and Joe, a copy of the plan that is less likely to require compiling is chosen.

The initial choice of a plan that uses predicates from the cache depends on matching the protection "profile" of the user with that of the plan, which consists of:

- The user ID for whom the plan was compiled. The user ID is saved in the plan's protection profile only if one or more predicated privileges on tables accessed by the procedure are granted directly to the user.
- The group ID if one or more predicated privileges are granted to a group.
- A list of role IDs if one or more predicated privileges are granted to a role.

Choosing a plan that matches the user's profile does not guarantee the plan is up to date with the required predicates for the current user's accesses. SAP ASE verifies that each select, update, and delete command in the procedure has been compiled with where clauses that reflect the current user's predicated grants.

Otherwise, the procedure must be recompiled. Predicated privileges introduces protection checking as a new decision point for plan recompilation during the execution phase.

For efficient use of the procedure cache and the sharing of stored procedure plans, you should use a role-based privacy policy. Predicated access to the objects referenced by a stored procedure should be granted to a small number of roles that can be activated by the end users.

8.15 Disallow Recursive Predicate Processing

SAP ASE returns an error if the accesses made in a row-filtering predicate or a role activation predicate are controlled by predicated grants. For example, this situation results in recursive cycles of access checking, and is not allowed:

- table1 is protected by a grant with predicate1 that references table2.
- table2 is protected by a grant with predicate2, that references table1.

Role activation predicates have similar restrictions. For example, this situation returns an error when a user attempts to set role r1 on:

- table1 is protected by a predicated grant.
- A grant on r1 references table1 in an activation predicate.

When applying a user's default roles, for example, during login, when executing set proxy, or when evaluating predicate accesses on behalf of the grantor, SAP ASE ignores any default roles that have been granted with an activation predicate.

8.16 Information Leakage Through Predicates

Predicated privilege enforcement may leak information about rows in a table to a user who is not authorized to see the data, or may violate data consistency.

For example, if employee IDs are sensitive and unique, and user Joe is entitled to process IDs only for those employees who work in the sales department, when Joe updates the ID of an employee in the sales department, Joe can get confirmation about whether a particular ID exists in the entire table by whether or not SAP ASE issues a uniqueness-violation message.

Updateable views have the same potential for leaked information. Application designers who rely on access control through predicated privileges should disallow updates of primary keys, and should restrict the users with predicated update and delete privileges on tables with referential constraints.

In the following example, the column <code>cust_name</code> is a foreign key on the table <code>t_orders</code> that is constrained by the values of <code>customer.name</code>:

```
create table t_orders (ordernum int, orders_dt date, cust_name char(60)
references customer.name, state char(2))
```

An employee in the orders department has select and update permission on the t_orders table for those orders shipped to customers in the state of lowa.

```
grant select, update on t_orders
  where state = 'IA'
  to procure_role
```

The employee in the orders department may not have access to the customer table, which lists customers of the company nation-wide. The employee wants to know whether a certain customer from New York buys from this company. Using the customer name of the New York customer, the employee enters the following command to update an order placed in lowa:

```
update orders set cust_name = 'Ronald Crump'
where ordernum = 345
```

If above statement does not return a foreign key constraint violation, the employee knows that Ronald Crump is a customer of the company.

9 Granular Permissions

Granular permissions are used to grant system privileges, allowing you to construct site-specific roles with privileges to match your requirements, and restrict system administrators and database owners from accessing user data.

Grantable system privileges allow you to enforce "separation of duties," which requires that, for particular sets of operations no single individual is allowed to execute all operations within the set and "least privilege," which requires that all users in an information system should be granted as few privileges as are required to do the job.

You cannot revoke or grant one privilege from—or to—another privilege. However, privileges may overlap what the grantee can do. Possessing one privilege may imply possessing another, more granular, privilege.

Enabling granular permissions reconstructs system-defined roles (sa_role, sso_role, oper_role, and replication_role) as privilege containers consisting of a set of explicitly granted privileges. You can revoke explicitly granted system privileges from system-defined roles and regrant them to the roles.

9.1 Configuring SAP ASE to Use Granular Permissions

Configure SAP ASE to use granular permissions.

- 1. Enable the security and directory services license, ASE_SECDIRS.
- 2. Enable the enable granular permissions configuration parameter, which requires the sso_role, and checks out the ASE_SECDIRS license. Disabling enable granular permissions requires the granular system privilege, manage security configuration and checks the license back in.

When enable granular permissions is turned on, SAP ASE verifies that at least one unlocked account has the manage server permissions privilege, and at least one unlocked account has the manage security permissions privilege. When disabling enable granular permissions, SAP ASE verifies the server has at least one unlocked account with the sso_role, and that at least one unlocked account has the sa_role.

9.2 System Privileges

Granular permissions define server-wide and database-wide privileges.

You must grant or revoke server-wide privileges in the master database. The grantees must be roles, users, or groups in the master database. SAP ASE stores the permission information for server-wide privileges in master.dbo.sysprotects.

You must grant or revoke database-wide privileges in the database for which the command requiring the privilege is intended. The grantees can be users, groups, or roles in the database. SAP ASE stores the permission information for database-wide privileges in <database name>.dbo.sysprotects.

Use the grant or revoke commands to grant or revoke server- and database-wide privileges. For example, to allow user Joe to dump any database, a user with the proper privilege issues this command from the master database:

```
grant dump any database to joe
```

To allow Joe to create any object on behalf of himself and on behalf of other users in database db2, a user with the proper privilege issues this command from db2:

grant create any object to joe

9.3 Effect of Privileges as Part of System-Defined Roles

The effects of granting and revoking privilege as part of system-defined roles and the enable granular permissions parameter.

When granting and revoking privileges included as part of system-defined roles:

- Any privileges explicitly granted to a system defined role may be revoked from the role. Once a privilege is revoked, the role holder can no longer perform operations related to the privilege on the server.
- enable granular permissions configuration parameter should be enabled for explicitly granted privileges to take effect. If enable granular permissions is disabled, system defined roles have the same privileges as in SAP ASE versions earlier than 15.7 ESD #2. These privileges are implicitly vested in the roles and cannot be revoked.

Use sp_restore_system_role to restore a modified system-defined role to its default privilege configuration.

9.4 Permission Management

All system privileges are managed by users with manage server permissions, manage security permissions, or manage database permissions privileges. Object permissions are managed by the object owners or users with manage any object permission privilege.

9.4.1 manage security permissions Privilege

Users with manage security permissions privileges can grant or revoke security-related sever-wide privileges and security-related database-wide privileges.

Table 15: Server-Wide Privileges Managed by manage security permissions privilege

manage any encryption key

manage column encryption key

manage database permissions

manage master key

manage service key

update any security catalog

manage security permissions is initially explicitly granted to the sso_role on a newly installed server, and, by default, the sa account has manage security permissions privilege. Once you revoke manage server permissions from the sso_role, a user with this role cannot grant or revoke any security-related privilege.

To avoid having a user unintentionally causing the server to be locked, SAP ASE ensures the server contains at least one unlocked user account with manage security permissions privilege.

9.4.2 manage server permissions Privilege

Users with manage server permissions privilege can grant and revoke server-wide privilege.

Table 17: System Privileges Managed by manage server permissions privilege

manage server permissions is initially explicitly granted to the sa_role on a newly installed server. Once you revoke manage server permissions from the sa_role, a user with sa_role cannot grant or revoke any server-wide privilege.

To avoid a user unintentionally causing the server to be locked, SAP ASE ensures the server contains at least one unlocked user account with manage server permissions privileges.

9.4.3 manage database permissions Privilege

Users with manage database permissions privilege can grant or revoke database-wide privileges except encryption key related privileges, which are managed by users with the manage security permissions privilege.

Users with the manage database permissions privilege cannot grant or revoke the manage database permissions privilege to or from other users, including themselves.

When a database is created, the manage database permissions privilege is not initially granted to any role or user, including the Database Owner. A user with manage security permissions privilege must explicitly grant manage database permissions privilege to a database user before that user can grant or revoke database permissions.

manage any encryption key

Use sp_restore_system_role (which requires manage security permissions privileges) to restore a role or database owner to the default role privilege configuration.

9.6 Privileges Assigned to the Database Owner

Database owners are granted privileges by default.

Table 25: Privileges Granted to Database Owners by Default

alter any object owner

create default

create function

create procedure

create rule

create table

create trigger create view dbcc checkalloc dbcc checkcatalog dbcc checkdb dbcc checkindex dbcc checkstorage dbcc checktable dbcc checkverify dbcc fix_text dbcc indexalloc dbcc reindex dbcc tablealloc dbcc textalloc manage abstract plans manage any user manage checkstorage manage database $\label{eq:manage_database_permissions} \ \mbox{(sybsecurity only)}$ manage replication report checkstorage select any audit table(sybsecurityonly) setuser truncate any audit table(sybsecurity only)

These rules apply to the database owner:

- By default, no newly added database-wide privileges, other than the ones listed above, are granted to the database owner. You must use an explicit grant command to grant any additional privilege to the database owner.
- By default, setuser privilege is explicitly granted to the database owner. To prevent the database owner from impersonating other users, revoke the setuser privilege from the database owner.
- Any user with own any database privilege or own database privilege on a database logs in to the database as the database owner, regardless if the user is a valid user of the database. Any object created by this user has UID=1 in sysobjects.uid and their login name in sysobjects.loginame. If both own any databaseand own database privileges are revoked from this user, he or she enters the database with his or her own user ID or as a guest if he or she has not been added as a user in the database.

9.7 Granular Permissions Adds the sa_serverprivs_role

The sa_serverprivs_role is a user-defined role granted to the sa by default, and ensures the system administrator possesses all privileges necessary to run SAP ASE when enable granular permissions is enabled.

As a user-defined role, when granted to a login, sa_serverprivs_role is not activated automatically for the login during login by default.

You can use alter login to enable automatic activation of this role during login.

i Note

SAP recommends that you do not use sa_serverprivs_role as a regular user-defined role.

When you enable <code>granular permissions</code>, the sa login has the same privileges in a database as the database owner. The sa login can obtain other database-wide privileges by adding himself as a user of the database, and granting himself those privileges.

Table 26: Privileges Granted to sa_serverprivs_role by Default

9.8 Default Roles Granted to the System Administrator

By default, the login sa is granted these roles.

sa_role

```
sso_role

oper_role

mon_role

sybase_ts_role

sa_serverprivs_role
```

9.9 Limiting the Power of the System Administrator and Database Owner

Any granular permissions granted to a system defined role can be revoked from the role to limit the power of that role. See examples below for some typical use cases.

Example 1:

Users with the manage server permissions privilege can restrict users with the sa_role from accessing user databases by revoking the own any database and manage server permissions privileges:

```
use master
revoke own any database from sa_role
revoke manage server permissions from sa_role
```

Example 2:

By default, setuser privilege is granted to the database owner, which enables the database owner access other users' data by impersonating that user.

Revoke the setuser privilege from the database owners to restrict them from accessing other users' data. To prevent database owners from granting setuser privileges to themselves, make sure that the manage database permissions privilege is not granted to the database owners in the databases. By default, the manage database permissions privilege is not granted to the database owner.

For example, to revoke setuser privileges from the database owner in database db1:

```
use db1 revoke setuser from dbo
```

Change these privileges in the model database to make this the default behavior in any user database created in the future:

```
use model
revoke setuser from dbo
```

Example 3:

Any sa_role user may accidentally shut down the server. To prevent this, a system administrator with manage server permissions privilege can revoke shutdown privilege from sa_role and grant it only to the administrators responsible for shutting down the server operation.

For example, to grant users joe and bob (both with the sa_role) the shutdown privilege, and revoke it from all others, a user with the manage server permissions privilege issues:

```
use master
grant shutdown to joe, bob
revoke shutdown from sa_role
```

9.10 Enable granular permissions and sybsecurity

These restrictions apply to the sybsecurity database when you enable enable granular permissions.

- Only users with manage auditing privilege can create sybsecurity.
- Any user with manage auditing privilege can access sybsecurity as the database owner.
- By default, manage database permissions, select any audit table, and truncate any audit table privileges are granted to the database owner of sybsecurity.
- All server privileges that include the word "any" do not apply to sybsecurity. For example, own any database does not grant the privilege holder access to sybsecurity as the database owner.
- Only users with manage security permissions can grant own database, dump database, load database, checkpoint, and online database privileges on sybsecurity to other users.

9.11 Logging in to a Locked-Out Server

If enable granular permissions is enabled, a SAP ASE server can be locked out only if all logins with the change password privilege lose their passwords. The dataserver command line includes the following parameters to unlock the server.

- -p <login_name> specifies the login name when starting the server so this account's password may be reset. A random password is generated, displayed, encrypted, and saved in master..syslogins as a new password for this account. When granular permissions is disabled, the <login_name> must have sso_role. When granular permission is enabled, the <login_name> must have change_password privilege.
- -u <login_name> specifies a login name you want to unlock. When granular permissions is disabled, the <login_name> must have either sso_role or sa_role. When granular permissions is enabled, the <login_name> must have change_password privilege.
- -A system_role, --role-logins specifies the system role name so that a list of login accounts with this role is printed into log file.
- -n system_privilege, --permission-logins specifies the system privilege name so that a list of login accounts with this system privilege is printed into log file.

To unlock a locked-out server, the account name specified with the -u and -p parameters must be a login name that has the change password privilege. Once that user has logged in to the server with the new password, he or she should first reset their own password to a new password then they can reset passwords for other logins.

To generate a list of login accounts that have sso_role when granular permissions is not enabled, use the -A <system role> or --role-logins parameter. For example:

```
$SYBASE/$SYBASE_ASE/bin/dataserver -d master.dat -s server_name-A sso_role
```

To generate a list of login accounts that has change password privilege when granular permissions is enabled, use the $-n < system_privilege > or --permission-logins parameters.$ For example:

```
$SYBASE/$SYBASE_ASE/bin/dataserver -d master.dat -s server_name-n "change password"
```

9.12 General Use Scenarios

Examples of how to set permissions for general use scenarios.

Scenario 1: Permissions for an Application Server User

Example of allowing a user to execute DML commands on all user tables and execute any stored procedures and user-defined functions.

A user with manage database permissions privilege in database db1 issues the following to allow user app_user to execute DML commands on all user tables and execute any stored procedures and user-defined functions defined in db1:

```
use db1
grant insert any table to app_user
grant select any table to app_user
grant update any table to app_user
grant truncate any table to app_user
grant delete any table to app_user
grant identity_insert any table to app_user
grant identity_update any table to app_user
grant execute any procedure to app_user
grant execute any function to app_user
```

Scenario 2: Permissions for a Database Access Manager

Example of allowing a user to manage users, groups, aliases, and permissions on all objects.

A user with the manage database permissions privilege in database db2 issues the following to allow user Joe to manage users, groups, aliases, and permissions on all objects in db2:

```
use db2 grant manage any object permission to joe grant manage any user to joe
```

Scenario 3: Permissions for a Database Backup Manager

Example of allowing a user to run dump database, dump transaction, checkpoint, and quiesce database on all user databases.

A user with the manage server permissions privilege issues the following to allow user Mike, who is a user in master database, but not in other user databases, to run dump database, dump transaction, checkpoint, and quiesce database on all user databases:

```
use master
grant dump any database to mike
grant use any database to mike
grant checkpoint any database to mike
grant quiesce any database to mike
```

Scenario 4: Permissions for a Help Desk Operator

Example of allowing a help desk operator to reset passwords or kill processes.

A user with the manage security permissions privilege issues the following to allow help desk operator Alice to reset passwords for users who call in with password issues:

```
use master grant change password to alice
```

A user with the manage server permissions privilege issues the following to allow Alice to kill runaway user processes that are using system resources:

```
use master grant kill any process to alice
```

Scenario 5: Permissions for a Security Auditor

Example of allowing an information security department employee to generate daily reports from the SAP ASE auditing subsystem.

A user with the manage auditing privilege issues the following to allow information security department employee Jane to generate daily reports from the SAP ASE auditing subsystem:

```
use sybsecurity
```

9.13 System Table master.dbo.sysprotects

When a server-wide privilege such as own database is granted on a database, the permission is recorded in master.dbo.sysprotects, with the database ID (dbid) stored in the ID field.

All grantable permission values are stored in $master.dbo.spt_values$. The columns in spt_values are overloaded as:

Table 27: master.dbo.spt_values

Parameter	Value
name	Permission name string.
number	Internal token number of the permission (sysprotects.action).
type	Identifier for permission entries:
	${\tt T}$ – permissions available and grantable in releases prior to 15.7 ESD #1 and earlier and continue to be available and grantable in 15.7 ESD #2 and later whether the granular permissions option is on or off.
	GP – permissions only available and grantable when granular permissions option is on.
ansi_w	Execution scope of the permission:
	1 – server-wide
	2 – database-wide
	4 - object
low	SAP ASE version in which the permission is first introduced:
	0 – exist in versions earlier than 15.7 ESD #2.
	157002 – introduced in 15.7 ESD #2.
high	Token number of the permission that manages the current permission when granular permissions option is on:
	117 - manage server permissions
	114-manage security permissions
	106-manage database permissions

Parameter	Value		
	97-manage any object permission		
msgnum	Bitset of the permission token:		
	• 0x00000001 server-wide privilege		
	• 0x00000002 database-wide privilege		
	• 0x00000004 object permission		
	ullet 0x00000008 when granting the privilege a database name is required		
	 0x00000010 the privilege is managed by "manage server permissions" 		
	 0x00000020 the privilege is managed by "manage security permissions" 		
	• 0x00000040 the privilege is managed by "manage database permissions"		
	• 0x00000080 column level permission		
	ullet 0x00000100 the permission applies to system table object		
	ullet 0x00000200 the permission applies to view object		
	ullet 0x00000400 the permission applies to user table object		
	ullet 0x00000800 the permission applies to procedure object		

9.14 Database User usedb_user Account

By default, the database user account $usedb_user$ is added to each database. When granular permissions is enabled, a user accessing a database will assume the user name $usedb_user$ if the user is granted the $usedb_user$ if the $usedb_user$ if the $usedb_user$ if the $usedb_user$ is $usedb_user$ if the $usedb_user$ if the $usedb_user$ is $usedb_user$ if the $usedb_user$ is $usedb_user$ if $usedb_user$

The following conditions apply to the user:

- Does not have own database privilege on the database
- Does not hold an identity as a valid user in the database
- Is not aliased to another valid user in the database

The following rules apply to the user account usedb user:

- usedb_user is only authorized to perform operations in the database that are allowed for public. To perform any additional operations, the user must acquire the corresponding privileges. A user may acquire privileges in a database through roles when he or she is not a valid user in the database.
- To create an object, the user must be a valid user in the database.

Allowing a user to access a database as usedb_user will provide the user the ability to execute a server-wide privilege in a database without being added as a valid user in the database.

For example, Bob is a valid user in master database, but not a valid user for database db1 which does not have a guest user account. Bob has manage security permissions privileges in the master database.

To allow Bob to execute manage security permissions in db1, a user with manage server permissions privilege can issue:

```
grant use database on db1 to bob
```

Bob can now access database db1 and issue the commands to grant manage any encryption key privileges to user Alice:

```
use db1 grant manage any encryption key to alice
```

SAP ASE records the grantor of manage any encryption key in sysprotects as the user ID of usedb user.

9.15 Grantable System Privileges

These are the grantable server-wide and database-wide privileges.

Privileges marked with an asterisk (*) may be granted or revoked when enable granular permissions is disabled

For a list of all grantable privileges and permissions in alphabetic order, see *Privileges for grant* in the grant command section in *Reference Manual: Commands*.

i Note

Possessing one privilege may imply possessing another, more granular, privilege. For example, a user with select any table privilege implies the user has select permission on all user tables. See *Privileges for grant* in the grant command section of *Reference Manual: Commands* for a complete list of privileges pairs that have an implied relationship.

Table 28: Server-Wide Privileges

Privilege name	Operations the privilege authorizes	
Privileges management		
manage security permissions	Granting and revoking security privileges	
manage server permissions	Granting and revoking nonsecurity server-wide privileges not related to security.	
Audit management		

Privilege name	Operations the privilege authorizes	
manage auditing	Acting as the database owner of sybsecurity	
	Executing these commands:	
	• create database sybsecurity	
	• alter database sybsecurity	
	 drop database sybsecurity 	
	• set switch(7601)	
	• truncate table(audittable)	
	Executing these system store procedures:	
	• sp_addaudittable	
	• sp_audit	
	• sp_displayaudit	
Login and role management		
allow exceptional login	Granting login to the server when:	
	Server maximum connection limit exceeded	
	Master database is in restore mode	
	Server is in shutdown	
	 Recovery is in progress (during server restart) 	
change password	Executing this command:	
	• alter login change password	
	Executing these system store procedure:	
	<pre>sp_locklogin (unlock any login account which was locked because the user exceeded the limit of maximum failed logins)</pre>

		• load transaction	

Operations the privilege authorizes

manage any database

Performing database maintenance operations on any database

Executing these commands:

- install jar
- remove jar class

Executing these system procedures:

- sp_addobjectdef
- sp_addsegment
- sp_addthreshold
- sp checksource
- sp_dbextend 'simulate'
- sp dbextend 'execute'
- sp dbextend 'clear', 'threshold'
- sp dbextend 'check'
- sp dbextend 'set', 'threshold'
- sp dbextend 'modify', 'database'
- sp_dbextend 'set','database'
- sp_dbextend 'set', 'threshold'
- sp_dropobjectdef
- sp_dropsegment
- sp_dropthreshold
- sp_droptype
- sp_extendsegment
- sp hidetext
- sp_modifthreshold
- sp_placeobject
- sp_procxmode
- sp_rename
- sp_rebuild_text
- sp_spaceusage (for some parameters)

Drivil	000	name
PIIVII	lege	name

Operations the privilege authorizes

manage any database(continued)	Executing these dbcc commands:	
	• dbcc dbrepair(remap)	
	 dbcc dbrepair(newthreshold) 	
	 dbcc dbrepair(findstranded) 	
	 dbcc dbrepair(fixlogfreespace) 	
	• dbr_remap	
	• dbcc dbrepair(ltmignore)	
	dbcc dbrepair(upd_usg)	
	 dbcc dbrepair(auinit) 	
	dbcc dbrepair(dmap_unlock)	
	dbcc rebuild_text	
	• dbcc refreshids (placeobject)	
	• dbcc refreshpdes	
	• dbcc update_tmode	
	• dbcc upgrade_obj	
	Executing these functions:	
	• derived_stat	
	• identity_burn_max	
mount any database	Executing the mount database command for any database	
online any database	Executing the online database command for any database	
online database	Executing the online database command for a specified database	
own any database	Acting as database owner for the specified database	
	See ${\tt own}$ database for a list of operations the privilege is authorized to perform.	

Operations the privilege authorizes

own database

Acting as database owner for any database except sybsecurity

Executing these commands:

- alter database
- drop database
- grant (default)
- revoke (default)
- checkpoint
- dump database
- dump transaction
- load database
- load transaction
- online database
- use database

Privilege name	Operations the privilege authorizes
own database (continued)	Executing these system procedures:
	• sp_addmessage
	• sp_altermessage
	• sp_dboption
	• sp_dbremap
	• sp_dropmessage
	• sp_fixindex
	• sp_forceonline_db
	• sp_forceonline_page
	• sp_helptext
	• sp_logdevice
	• sp_post_xpload
	• sp_renamedb
	sp_setsuspect_granularity
	• sp_tempdb_markdrop
	• sp_version
	• xp_cmdshell
	• xp_enumgroups
	• xp_logevent
	Executing these dbcc commands:
	• dbcc addtempdb
	• dbcc dbrepair

	• dbcc reindex
quiesce any database	Executing the quiesce database command for any database
unmount any database	Executing the unmount database command for any database
Server Maintenance	
manage any thread pool	Executing these commands:
	• create thread pool
	• alter thread pool
	• drop thread pool

Privilege name Operations the privilege authorizes	
manage cluster	Managing cluster-related configurations and operations
	Executing the shutdown cluster command (requires shutdown privilege)
	Executing these system procedures:
	• sp_addserver
	• sp_cluster
	• sp_clusterlockusage
	• sp_dropserver
	• sp_serveroption
	sp_tempdb_markdrop
	Executing these dbcc commands:
	• dbcc quorum
	 dbcc set_scope_in_cluster
manage disk	Executing these commands:
	• disk init
	• disk refit
	• disk reinit
	• disk mirror
	• disk unmirror
	• disk remirror
	Executing these system procedures:
	• sp_addumpdevice
	• sp_diskdefault
	• sp_deviceattr
	• sp_dropdevice
	• sp_refit_admin
	 sp_dbextend (required by some options)

Operations the privilege authorizes

manage	security	configura	ation

Enable or disable security related configurations

Executing these system procedures:

- sp_configure (to set security-related configuration options)
- sp_encryption
- sp_logintrigger
- sp_ldapadmin
- sp passwordpolicy
- sp_ssladmin

Operations the privilege authorizes

manage server

Manage server maintenance operations

Executing these system procedures:

- sp addlanguage
- sp_addserver (current security system officer)
- sp_clearstats
- sp countmetadata
- sp dbrecovery order
- sp_displaylogin
- sp_displayroles
- sp_droplanguage
- sp dropserver (current security system officer)
- sp_engine
- sp errorlog
- sp_extengine
- sp helpapptrace
- sp_metrics
- sp_monitorconfig
- sp_object_stats
- sp_reportstats
- sp_serveroption
- sp_setlangalias
- sp_tempdb

Executing these dbcc commands:

- dbcc complete_xact
- dbcc engine
- dbcc forget_xact
- dbcc traceflags

Executing these functions:

- passinfo
- valid_user

Privilege name	Operations the privilege authorizes	
manage server configuration	Enable or disable server configurations not related to security	
	Executing these system procedures:	
	 sp_configure (set security related configuration options) 	
	• sp_displaylevel	
	• sp_jreconfig	
	sp_lmconfigsp pciconfig	
	sp_perconing	
shutdown	Shutting down the:	
	• Server	
	 Cluster (also requires manage cluster privilege) Instance 	
	Backup Server	
	Execute the shutdown command.	
dbcc		
dbcc checkalloc any database	Executing dbcc checkallocin any database	
dbcc checkcatalog any database	Executing dbcc checkcatalog in any database	
dbcc checkdb any database	Executing dbcc checkdb in any database	
dbcc check index any database	Executing dbcc checkindex in any database	
dbcc checkstorage any database	Executing dbcc checkstorage in any database	
dbcc checktable any database	Executing dbcc checktable in any database	
dbcc checkverify any database	Executing dbcc checkverify in any database	
dbcc fix_text any database	Executing dbcc fix_text in any database	
dbcc indexalloc any database	Executing dbcc indexallocin any database	
dbcc reindex any database	Executing dbcc reindex in any database	
dbcc tablealloc any database	Executing dbcc tableallocin any database	
dbcc textalloc any database	Executing dbcc textallocin any database	
dbcc tune	Executing dbcc tune	
Application Management		

Privilege name	Operations the privilege authorizes
manage any execution class	Executing these system procedures: • sp_addengine • sp_addexeclass • sp_bindexeclass • sp_clearpsexe • sp_dropengine • sp_dropexeclass • sp_setpsexe • sp_unbindexeclass
manage any ESP	Executing these system procedures: • sp_addextendedproc • sp_dropextendedproc • sp_freedll • sp_helpextendedproc
manage data cache	Executing these system procedures: • sp_bindcache • sp_cacheconfig • sp_cachestrategy • sp_logiosize • sp_poolconfig • sp_unbindcache • sp_unbindcache_all
manage dump configuration	Managing dump configuration for a backup server Executing these commands: • dump configuration Executing these system procedures: • sp_config dump • sp_dump history
manage lock promotion threshold	Executing these system procedures: • sp_dropglockpromote • sp_droprowlockpromote • sp_setpglockpromote • sp_setrowlockpromote

D : "		
Privi	lege	name

Operations the privilege authorizes

Monitoring query processing performance
Executing these commands:
• set switch (3604, 3605)
• set tracefile
• set plan for plan_list
<pre>• set option <><optimizer_show_option> {value on off}</optimizer_show_option></pre>
Executing these system procedures:
• sp_cmp_all_qplans
• sp_cmp_qplans
• sp_find_qplans
sp_flush_query_tuning
• sp_flushmetrics
• sp_flushstats
<pre>• sp_metrics (for 'filter', 'show', 'help')</pre>
• sp_showplan
Executing these dbcc commands:
• dbcc traceoff(3604, 3605)
• dbcc traceon(3604, 3605)
• dbcc nodetraceoff(3604, 3605)
• dbcc nodetraceon(3604, 3605)
Executing these system procedures:
sp_add_resource_limit
• sp_add_time_range
sp_drop_resource_limit
• sp_drop_time_range
• sp_help_resource_limit
sp_modify_resource_limit
• sp_modify_time_range
Connecting to any server using the connect command
Killing processes owned by the privilege holder

Privilege name Operations the privilege authorizes map external file Mapping a proxy table to a directory or file on a remote server monitor server replication Displaying replication status Executing these system procedures: • sp config rep agent (no configure value specified, with or without database name specified) sp help rep agent (with or without the database name specified) Executing set proxy to change the identity to another user set proxy set tracing* Executing these commands: • set tracefile (for your own session) set plan for <plan_list> on|off set option <><optimizer show option>on|off Executing these dbcc commands: • dbcc traceoff(3604, 3605) dbcc traceon(3604, 3605) dbcc nodetraceoff(3604, 3605) dbcc nodetraceon(3604, 3605) set tracing any process Executing these commands: set tracefile (for any session) set plan for <plan list> on|off set option <><optimizer_show_option> on|off Executing these dbcc commands: dbcc traceoff(3604, 3605)

dbcc traceon(3604, 3605)

dbcc nodetraceoff(3604, 3605) dbcc nodetraceon(3604, 3605)

Privilege name	Operations the privilege authorizes
set switch	Enabling or disabling any trace flag
	Executing these commands:
	• set switch
	• show switch
	Executing these dbcc commands:
	• dbcc traceon
	• dbcc traceoff
	• dbcc nodetraceon
	• dbcc nodetraceoff
	Executing this stored procedure:
	• sp_dbextend 'trace'
show switch	Displays traceflags that are on
	Execute the show switch command
use any database	Accessing any database when the privilege holder is not a valid user of the database and there is no "guest" account in the database
	Execute the use database command
use database	Accessing the specified database when the privilege holder is not a valid user of the database and there is no guest account in the database
	Execute the use database command
Table 29: Database-Wide Privileges	
Privilege name	Operations this privilege authorizes
Permission management	
manage any object permission	Granting and revoking object permissions
manage database permissions	Granting and revoking database privileges
Manage user	

Privilege name Operations this privilege authorizes Executing these system procedures: manage any user sp_addalias sp_addgroup sp_adduser sp_changegroup sp dropalias sp_dropgroup sp_dropuser Set user setuser Impersonating another user Replication Management Managing replication settings in a database manage replication Executing these commands: • set replication set repmode • set repthreshold Executing these system procedures: sp_config_rep_agent (with database name specified) sp_help_rep_agent (with database name specified) sp_replication_path sp reptostandby sp_setrepcol sp setrepdb sp_setrepdbmode sp setrepdefmode sp_setreplicate sp setrepproc sp_setreptable sp start rep agent sp_stop_rep_agent Executing these dbcc commands: dbcc gettrunc

dbcc settrunc

Operations this privilege authorizes

Maintains database	
manage database	Performing database maintenance operations without accessing dbo-owned data
	Executing these commands:
	• install jar
	• remove jar class
	Executing these system procedures:
	• sp_addobjectdef
	• sp_addsegment
	• sp_addthreshold
	• sp_checksource
	sp_dropobjectdef
	• sp_dropsegment
	sp_dropthreshold
	• sp_droptype
	• sp_extendsegment
	• sp_hidetext
	sp_merge_dup_inline_default

sp_modifthreshold
sp_placeobject
sp_procxmode
sp_rebuild_text

sp_spaceusage (for some parameters)

Operations this privilege authorizes

manage database (continued)

Executing these dbcc commands:

- dbcc dbrepair(remap)
- dbcc dbrepair(newthreshold)
- dbcc dbrepair(findstranded)
- dbcc dbrepair(fixlogfreespace)
- dbcc dbrepair(ltmignor)
- dbcc dbrepair(updusg_anchors)
- dbcc dbrepair(auinit)
- dbcc dbrepair(dmap_unlock)
- dbcc rebuild_text
- dbcc refreshids (placeobject)
- dbcc refreshpdes
- dbcc update_tmode
- dbcc upgrade_obj

Executing these built-in functions:

- derived_stat
- identity_burn_max
- lct_admin
- next_identity

Manage query plan

Privilege name	Privi	lege	name
----------------	-------	------	------

Operations this privilege authorizes

manage abstract plans	Executing these system procedures:
	• sp_add_qpgroup
	• sp_cmp_all_qplans
	• sp_cmp_qplans
	• sp_copy_all_qplans
	• sp_drop_all_qplans
	• sp_drop_qpgroup
	• sp_drop_qplan
	• sp_export_qpgroup
	• sp_find_qplan
	• sp_help_qpgroup
	• sp_help_qplan
	sp_import_qpgroupsp_rename_qpgroup
	• sp_set_qplan
dbcc	
dbcc checkalloc*	Executing dbcc checkalloc in the database
dbcc checkcatalog*	Executing dbcc checkcatalog in the database
dbcc checkdb*	Executing dbcc checkdb in the database
dbcc checkindex*	Executing dbcc checkindex in the database
dbcc checkstorage*	Executing dbcc checkstorage in the database
dbcc checktable*	Executing dbcc checktable in the database
dbcc checkverify*	Executing dbcc checkverify in the database
dbcc fix_text*	Executing dbcc fix_text in the database
dbcc indexalloc*	Executing dbcc indexallocin the database
dbcc reindex*	Executing dbcc reindex in the database
dbcc tablealloc*	Executing dbcc tableallocin the database
dbcc textalloc*	Executing dbcc textallocin the database

Privilege name	Operations this privilege authorizes
manage checkstorage	Managing dbcc checkstorage-related settings on the database (specified with the procedures in which the privilege is granted)
	Executing these dbcc stored procedures:
	• sp_dbcc_deletedb
	• sp_dbcc_deletehistory
	• sp_dbcc_evaluatedb
	• sp_dbcc_exclusions
	• sp_dbcc_patch_finishtime
	• sp_dbcc_updateconfig
report checkstorage	Executing dbcc procedures to generate reports about dbcc checkstorage results on the database (specified with the procedures in which the privilege is granted)
	Executing these dbcc stored procedures:
	• sp_dbcc_configreport
	 sp_dbcc_differentialreport
	• sp_dbcc_faultreport
	• sp_dbcc_fullreport
	• sp_dbcc_recommendations
	• sp_dbcc_statisticsreport
	• sp_dbcc_summaryreport
System Catalog	
select any audit table	Selecting any audit table in sybsecurity (available only in sybsecurity database)
select any system catalog	Selecting all columns from any system table in the current database
truncate any audit table	Truncating any audit table in sybsecurity (available only in the sybsecurity database)

Operations this privilege authorizes

update any security catalog

Updating, inserting, and deleting these security-related system catalogs, which are restricted from direct update:

- master.dbo.syslogins
- master.dbo.syssrvroles
- master.dbo.sysloginroles
- db.dbo.sysroles
- db.dbo.sysprotects

i Note

Configuration parameter allow updates to system tables must be enabled before any catalogs can be updated.

Manage	objects
--------	---------

alter any object owner

Altering ownership for any object in the database

Execute the alter \dots modify owner command.

create any object

Creating any of these objects owned by anyone:

- tables
- views
- procedures
- functions
- defaults
- rules
- indexes
- triggers

Executing these commands:

- create table
- create view
- create procedure
- create function
- create rule
- create default
- create trigger
- create index

Privilege name	Operations this privilege authorizes	
drop any object	Dropping any of these objects owned by anyone:	
	 tables views procedures functions defaults rules indexes 	
	• triggers	
	Executing these commands:	
	• drop default	
	• drop function	
	• drop index	
	• drop procedure	
	• drop rule	
	drop tabledrop trigger	
	• drop view	
Built-in functions		
select *		
Manage encryption		
create encryption key*	Creating encryption keys in the database	
manage any encryption key	Creating, altering, and dropping column encryption keys, master keys, and service keys owned by anyone	
	Executing these commands:	
	• create encryption key	
	• alter encryption key	
	 drop encryption key 	
	Executing sp_encryption	
manage column encryption key	Creating, altering, and dropping column encryption keys	
manage master key	Creating, altering, and dropping master keys	
manage service key	Creating, altering, and dropping service keys	

Privilege name	Operations this privilege authorizes
Defaults	
create default*	Creating self-owned default
	Execute the create default command
create any default	Creating defaults owned by anyone
	Execute the create default command
drop any default	Dropping defaults owned by anyone
	Execute the drop default command
Functions	
create function*	Creating self-owned user-defined function
	Executing these commands:
	• create function
	create function (SQLJ)
create any function	Creating functions owned by anyone
	Executing these commands:
	• create function
	• create function (SQLJ)
drop any function	Dropping functions owned by anyone
	Executing these commands:
	• drop function
	drop function (SQLJ)
execute any function	Running user-defined functions owned by anyone
	Execute the execute command
Indexes	
create any index	Creating indexes on tables owned by anyone
	Execute the create index command
Procedures	
create procedure	Creating self-owned procedures
	Execute the create procedure command

Privilege name	Operations this privilege authorizes
create any procedure	Creating procedures owned by anyone
	Execute the create procedure command
execute any procedure	Execute procedures owned by anyone
	Execute the execute command.
drop any procedure	Dropping procedures owned by anyone
	Execute the drop procedure command
Rules	
create rule*	Creating self-owned rule
	Execute the create rule command
create any rule	Creating rule owned by anyone
	Execute the create rule command
drop any rule	Dropping rules owned by anyone
	Execute the drop rule command.
Tables	
alter any table	Altering user tables owned by anyone
	Execute the alter table command.
create any table	Creating user tables owned by anyone
	Execute the create table command.
create table*	Creating self-owned user tables
	Execute the create table command
decrypt any table	Decrypting any encrypted table
delete any table	Delete rows of user tables owned by anyone
	Executing these commands:
	• delete table
	• lock table
drop any table	Dropping user tables owned by anyone
	Execute the drop table command.

identity_insert any table	Enabling or disabling identity_update on any user table
	Execute the set identity_insert command
identity_update any table	Enabling or disabling identity_insert on any user table
	Execute the set identity_update command
insert any table	Inserting user tables owned by anyone
	Executing these commands:
	• insert
	• lock table
manage any statistics	Update or delete statistics on any table owned by anyone
	Executing these commands:
	• delete statistics
	• update statistics
	Executing sp_modifystats
references any table	Referencing user tables owned by anyone
reorg any table	Reorganizing user tables owned by anyone
	Execute the reorg command
select any table	Selecting user tables owned by anyone
	Execute these commands:
	• select
	• lock table (for share lock)
	• readtext
transfer any table	Transferring data to or from user tables owned by anyone
	Execute the transfer table command
truncate any table	Truncating user tables owned by anyone
	Execute the truncate table command
update any table	Updating user tables owned by anyone
	Execute these commands:
	• update
	• lock table
	• writetext

Privilege name

Operations this privilege authorizes

Trigger	
create trigger*	Creating self-owned trigger.
	Execute the create trigger command.
create any trigger	Creating triggers owned by anyone
	Execute the create trigger command
drop any trigger	Dropping triggers owned by anyone
	Execute the drop trigger command
Views	
create view*	Creating self-owned view
	Execute the create view command
create any view	Creating views owned by anyone
	Execute the create view command.
drop any view	Dropping views owned by anyone
	Execute the drop view command.

10 Confidentiality of Data

SAP ASE security services support Secure Sockets Layer (SSL) session-based security.

SSL is the standard for securing the transmission of sensitive information, such as credit card numbers, stock trades, and banking transactions, over the Internet.

While a comprehensive discussion of public-key cryptography is beyond the scope of this document, the basics are worth describing so that you have an understanding of how SSL secures Internet communication channels. This document is not a comprehensive guide to public-key cryptography.

The implementation of SSL features assume that there is a knowledgeable system security officer who is familiar with the security policies and needs of your site, and who has general understanding of SSL and public-key cryptography.

TCP/IP is the primary transport protocol used in client/server computing, and is the protocol that governs the transmission of data over the Internet. TCP/IP uses intermediate computers to transport data from sender to recipient. The intermediate computers introduce weak links to the communication system where data may be subjected to tampering, theft, eavesdropping, and impersonation.

10.1 Public-Key Cryptography

Several mechanisms, known collectively as public-key cryptography, have been developed and implemented to protect sensitive data during transmission over the Internet. Public-key cryptography consists of encryption, key exchange, digital signatures, and digital certificates.

Encryption

Encryption is a process wherein a cryptographic algorithm is used to encode information to safeguard it from anyone except the intended recipient. There are two types of keys used for encryption:

- Symmetric-key encryption is where the same algorithm (key) is used to encrypt and decrypt the message. This form of encryption provides minimal security because the key is simple, and therefore easy to decipher. However, transfer of data that is encrypted with a symmetric key is fast because the computation required to encrypt and decrypt the message is minimal.
- Public/private key encryption also known as asymmetric-key, is a pair of keys that are made up of public and private components to encrypt and decrypt messages. Typically, the message is encrypted by the sender with a private key, and decrypted by the recipient with the sender's public key, although this may vary. You can use a recipient's public key to encrypt a message, who then uses his private key to decrypt the message.

The algorithms used to create public and private keys are more complex, and therefore harder to decipher. However, public/private key encryption requires more computation, sends more data over the connection, and noticeably slows data transfer.

Key Exchange

The solution for reducing computation overhead and speeding transactions without sacrificing security is to use a combination of both symmetric key and public/private key encryption in what is known as a key exchange.

For large amounts of data, a symmetric key is used to encrypt the original message. The sender then uses either his private key or the recipient's public key to encrypt the symmetric key. Both the encrypted message and the encrypted symmetric key are sent to the recipient. Depending on what key was used to encrypt the message (public or private) the recipient uses the opposite to decrypt the symmetric key. Once the key has been exchanged, the recipient uses the symmetric key to decrypt the message.

Digital Signatures

Digital signatures are used for tamper detection and non-repudiation. Digital signatures are created with a mathematical algorithm that generates a unique, fixed-length string of numbers from a text message; the result is called a hash or message digest. To ensure message integrity, the message digest is encrypted by the signer's private key, then sent to the recipient along with information about the hashing algorithm. The recipient decrypts the message with the signer's public key. This process also regenerates the original message digest. If the digests match, the message proves to be intact and tamper free. If they do not match, the data has either been modified in transit, or the data was signed by an impostor. Further, the digital signature provides non-repudiation—senders cannot deny, or repudiate, that they sent a message, because their private key encrypted the message. Obviously, if the private key has been compromised (stolen or deciphered), the digital signature is worthless for non-repudiation.

Digital Certificates

Digital Certificates are like passports: once you have been assigned one, the authorities have all your identification information in the system. Like a passport, the certificate is used to verify the identity of one entity (server, router, Web sites, and so on) to another.

SAP ASE uses two types of certificates:

- Server certificates a server certificate authenticates the server that holds it. Certificates are issued by a trusted third-party Certificate Authority (CA). The CA validates the holder's identity, and embeds the holder's public key and other identification information into the digital certificate. Certificates also contain the digital signature of the issuing CA, verifying the integrity of the data contained therein and validating its use.
- CA certificates (also known as trusted root certificates) is a list of trusted CAs loaded by the server at start-up. CA certificates are used by servers when they function as a client, such as during remote procedure calls (RPCs). SAP ASE loads its CA trusted root certificate at start-up. When connecting to a remote server for RPCs, SAP ASE verifies that the CA that signed the remote server's certificate is a "trusted" CA listed in its own CA trusted roots file. If it is not, the connection fails.

Certificates are valid for a period of time and can be revoked by the CA for various reasons, such as when a security breach has occurred. If a certificate is revoked during a session, the session connection continues. Subsequent attempts to login fail. Likewise, when a certificate expires, login attempts fail.

The combination of these mechanisms protect data transmitted over the Internet from eavesdropping and tampering. These mechanisms also protect users from impersonation, where one entity pretends to be another (spoofing), or where a person or an organization says it is set up for a specific purpose when the real intent is to capture private information (misrepresentation).

10.2 SAP Common Crypto Library

SAP ASE uses the proprietary SAP Common Crypto Library as the SSL provider and cryptography library. Beginning with SAP ASE version 16.0 SP03, the OpenSSL library is not supported for encryption and decryption.

i Note

The SAP Common Crypto Library is FIPS 140-2 compliant.

10.3 SSL Overview

SSL is an industry standard for sending wire- or socket-level encrypted data over secure network connections.

Before the SSL connection is established, the server and the client exchange a series of I/O round trips to negotiate and agree upon a secure encrypted session. This is called the SSL handshake.

SSL Handshake

When a client requests a connection, the SSL-enabled server presents its certificate to prove its identity before data is transmitted. Essentially, the handshake consists of the following steps:

- The client sends a connection request to the server. The request includes the SSL (or Transport Layer Security, TLS) options that the client supports.
- The server returns its certificate and a list of supported cipher suites, which includes SSL/TLS support options, algorithms used for key exchange, and digital signatures.
- A secure, encrypted session is established when both client and server have agreed upon a Cipher Suite.

For more specific information about the SSL Handshake and the SSL/TLS protocol, see the Internet Engineering Task Force Web site \nearrow .

10.3.1 SSL in SAP ASE

The implementation of SSL provides several levels of security.

- The server authenticates itself—proves that it is the server you intended to contact—and an encrypted SSL session begins before any data is transmitted.
- Once the SSL session is established, the client requesting a connection can send his user name and password over the secure, encrypted connection.
- A comparison of the digital signature on the server certificate can determine whether the data received by the client was modified before reaching the intended recipient.

SAP ASE uses the proprietary SAP Common Crypto Library as the SSL provider and cryptography library. Beginning with SAP ASE version 16.0 SP03, the OpenSSL library is not supported for encryption and decryption.

SAP Common Crypto Library is FIPS 140-2 compliant. For information about FIPS certification, see the *Computer Security Resource Center* at https://csrc.nist.gov.

10.3.1.1 SSL Filter

The SAP ASE directory service, such as the interfaces file, Windows Registry, or LDAP service, defines the server address and port numbers, and determines the security protocols that are enforced for client connections. SAP ASE implements the SSL protocol as a filter that is appended to the master and query lines of the directory services.

The addresses and port numbers on which SAP ASE accepts connections are configurable, so you can enable multiple network and security protocols for a single server. Server connection attributes are specified with directory services, such as LDAP, or with the traditional Sybase interfaces file.

All connection attempts to a master or query entry in the interfaces file with an SSL filter must support the SSL protocol. A server can be configured to accept SSL connections and have other connections that accept clear text (unencrypted data), or use other security mechanisms.

For example, the interfaces file on UNIX that supports both SSL-based connections and clear-text connections looks like this:

```
SYBSRV1
master tcp ether myhostname myport1 ssl="CN=my_server_common_name.mydomain.com"
query tcp ether myhostname myport1 ssl="CN=my_server_common_name.mydomain.com"
master tcp ether myhostname myport2
```

The SSL filter is different from other security mechanisms, such as Kerberos, which are defined with SECMECH (security mechanism) lines in the interfaces file (sql.ini on Windows).

10.3.1.2 Authentication Via the Certificate

The SSL protocol requires server authentication via a server certificate to enable an encrypted session. Likewise, when SAP ASE is functioning as a client during RPCs, there must be a repository of trusted CAs that a client connection can access to validate the server certificate.

The Server Certificate

Each SAP ASE server must have its own server certificate file that is loaded at start-up. The following is the default location for the certificates file, where servername> is the name of the server as specified on the command line during start-up with the -s flag, or from the environment variable \$DSLISTEN:

- UNIX \$SYBASE/\$SYBASE ASE/certificates/servername.crt
- Windows %SYBASE%\%SYBASE ASE%\certificates\servername.crt

The server certificate file consists of encoded data, including the server's certificate and the encrypted private key for the server certificate.

Alternatively, you can specify the location of the server certificate file when using sp ssladmin.

i Note

To make a successful client connection, the common name in the certificate must match the server name in the interfaces file.

The CA Trusted Roots Certificate

The list of trusted CAs is loaded by SAP ASE at start-up from the trusted roots file. The trusted roots file is similar in format to a certificate file, except that it contains certificates for CAs known to SAP ASE. A trusted roots file is accessible by the local server in the following, where servername is the name of the server:

- UNIX \$SYBASE/\$SYBASE_ASE/certificates/servername.txt
- Windows %SYBASE%\%SYBASE_ASE\certificates\servername.txt

The trusted roots file is only used by SAP ASE when it is functioning as a client, such as when performing RPC calls or Component Integration Services (CIS) connections.

The system security officer adds and deletes CAs that are to be accepted by SAP ASE, using a standard ASCII-text editor.

Use the system security officer role (sso_role) within SAP ASE to restrict access and execution on security-sensitive objects.

The \$SYBASE/\$SYBASE_ASE/certificate/servername.crt file is an SAP ASE server certificate and the \$SYBASE/\$SYBASE_ASE/certificates/servername.txt file is the CA trusted roots certificate that has signed the SAP ASE server certificate.

Both of these files are loaded by SAP ASE during start-up. The file \$SYBASE/config/trusted.txt contains list of CA trusted roots certificate that are used by the client (there could be many CA trusted roots certificates). This file should contains the CA trusted root certificate that is present in \$SYBASE/\$SYBASE_ASE/certificates/servername.txt. Note that the file extension "crt" is for the server certificate, and "txt" is for the CA trusted roots certificates.

10.3.1.3 Connection Types

Various client-to-server and server-to-server connections are available.

Client Login to SAP ASE

Open Client applications establish a socket connection to SAP ASE similarly to the way that existing client connections are established. Before any user data is transmitted, an SSL handshake occurs on the socket when the network transport-level connect call completes on the client side and the accept call completes on the server side.

Server-to-Server Remote Procedure Calls

SAP ASE establishes a socket connection to another server for RPCs in the same way that existing RPC connections are established. Before any user data is transmitted, an SSL handshake occurs on the socket when the network transport-level connect call completes. If the server-to-server socket connection has already been established, the existing socket connection and security context is reused.

When functioning as a client during RPCs, SAP ASE requests the remote server's certificate during connection. SAP ASE then verifies that the CA that signed the remote server's certificate is trusted; that is to say, on its own list of trusted CAs in the trusted roots file. It also verifies that the common name in the server certificate matches the common name used when establishing the connection.

Companion Server and SSL

You can use a companion server to configure SAP ASE for failover. You must configure both the primary and secondary servers with the same SSL and RPC configuration. When connections fail over or fail back, security sessions are reestablished with the connections.

Open Client Connections

Component Integration Services, RepAgent, Distributed Transaction Management, and other modules in SAP ASE use Client-Library to establish connections to servers other than SAP ASE servers. The remote server is authenticated by its certificate. The remote server authenticates the SAP ASE client connection for RPCs with user name and password.

10.3.2 Enabling SSL

SAP ASE determines which security service it will use for a port based on the interface file (sql.ini on Windows).

Procedure

- 1. Obtain an SAP ASE license for the SSL feature. You can use either the ASE_ASM or ASE_SECDIRS license.
- 2. Run the command:

```
sp_configure "enable ssl", 1
```

Check that the run value is 1 and there are no errors in the log file.

- 3. Request a signed server certificate for the SAP ASE server. See Request Certificates [page 303].
 - a. Make sure certificate file has the certificate's "private key" encrypted, encoded, and appended to the file.
 - b. The commonName of the subject certificate must match the exact case of the servername in the interfaces file. Optionally, you can specify the commonName in the certificate with the SSL filter. See Create Server Directory Entries [page 312].
- 4. Run the command:

```
sp_ssladmin addcert, <certificate_path>, <password>
```

- 5. Install the server CA certificate in: \$SYBASE_ASE/certificates/<servername>.txt
- 6. Add the server entry to the interfaces file. See Create Server Directory Entries [page 312].
- Copy CA certificates to the clients trusted.txt file location which defaults to \$SYBASE/config/ trusted.txt

Results

Unlike other security services, such as Kerberos, and NTLAN, SSL relies neither on the "Security" section of the Open Client/Open Server configuration file libtcl.cfg, nor on objects in objectid.dat.

The system administrator should consider memory use by SSL when planning for total physical memory. You need approximately 40K per connection (connections include user connections, remote servers, and network

listeners) in SAP ASE for SSL connections. The memory is reserved and preallocated within a memory pool and is used internally by SAP ASE and SSL Plus libraries as requested.

10.3.3 Enabling SSL in the Backup Server

The security mechanism used by the Backup Server is based on server directory entries for the security service (if any) set in the interfaces file for UNIX (sybase/interfaces) and Windows (sybase/interfaces) and Windows (sybase/interfaces) respectively.

Context

To enable the SSL security service in the Backup Server, use the following procedure:

Procedure

Obtain an SSL-enabled license for the SAP ASE server. You can use one of ASE_ASM, or ASE_SECDIRS licenses.

i Note

The SAP ASE server must be SSL-enabled to successfully perform dump and load operations.

2. Connect to the Backup Server with the administrator account (defined by the configuration parameter admin_user, and set to sa by default), and run the command:

```
set use ssl true
```

3. Request a signed server certificate for the SAP ASE server. See Requesting and Authorizing SSL Certificates Using Keytool and ExportPrivateKey Utility [page 304].

i Note

Ensure that the private key of the server certificate is encrypted, encoded, and appended to the certificate file.

4. Run the commands:

```
set ssl_identity_file <certificate_path>
set ssl_password <password>
```

- 5. Add the server entry to the interfaces file. See Create Server Directory Entries [page 312].
- 6. Append the CA certificates to the file trusted.txt (which defaults to the path \$SYBASE/config/trusted.txt). To specify a custom path for trusted.txt, run the command:

```
set ssl_ca_file <custom path for trusted.txt>
```

Example: Set up SSL Using a Direct Connection to the Backup Server

An illustration of how to set up SSL using a direct connection to the Backup Server.

Example

We use two Backup Servers here – **BkpSvr001** and **BkpSvr002**, each with their own commonName and certificate (although they can use the same certificate as well).

To set up SSL using a direct connection to these Backup Servers, we boot them with a non-SSL port:

First, let's look at how to set up SSL using a direct connection to BkpSvr001.

If you boot the Backup Server without specifying a configuration file, run the command:

```
$BACKUPSERVER -M$SYBMULTBUF -I$DEVDIR/interfaces -SBkpSvr001 -e$DEVDIR/backup.log
```

When the Backup Server boots for the first time, it creates the file \$SYBASE/BkpSvr001.cfg from defaultbs.cfg:

```
$ cat $SYBASE/defaultbs.cfg
server name=DEFAULT
admin user=DEFAULT
admin password=DEFAULT
interfaces_file=DEFAULT
errorlog_file= DEFAULT
sybmultbuf binary=DEFAULT
library_path=DEFAULT
hosts_allow_file=DEFAULT
tape_config_file=DEFAULT
language=DEFAULT
character set=DEFAULT
network connections=DEFAULT
server connections=DEFAULT
service_threads=DEFAULT
warn level=DEFAULT
notify_lang_warn=DEFAULT
packet_size=DEFAULT
max shared memory=DEFAULT
allocation threshold=DEFAULT
reserved_threshold=DEFAULT
pll_scan_threads=DEFAULT compress_level=DEFAULT
use ssl=DEFAULT
ssl_password=DEFAULT
ssl identity file=DEFAULT
```

Backup Server: 9.18.1.1: Configuration option 'admin password' changed. The

Backup Server: 9.9.1.1: Configuration file '/FolderZ/User666/sapase/release/

Backup Server: 9.17.1.1: Configuration option 'ssl identity file' changed.

to be rebooted for this option to take effect since the option is static. 1> set ssl ca file /FolderZ/User666/sapase/release/config/trusted.txt

Backup Server: 9.18.1.1: Configuration option 'ssl ca file' changed. The

to be rebooted for this option to take effect since the option is dynamic.

 EDE_CBC_SHA,TLS_RSA_WITH_RC4_128_SHA,TLS_RSA_WITH_RC4_128_MD5TLS_DHE_DSS_WITH
 3DES EDE CBC SHA, TLS DHE DSS WITH RC4 128 SHA, TLS DHE RSA WITH 3DES EDE CBC SH
TLS RSA WITH DES CBC SHA, TLS DHE DSS WITH DES CBC SHA, TLS DHE RSA WITH DES CBC
 This is what the configuration file now looks like:
 ********************
 * * *
$ cat $SYBASE/BkpSvr001.cfg
 server name=BkpSvr001
admin user=DEFAULT
admin password=0x02c38047d4d41e84a0e0d8dfdd71b57a99ac5907ee9f5948c1d86175d7f76
c61
interfaces file=DEFAULT
{\tt errorlog\_f\overline{i}le=DEFAULT}
 sybmultbuf_binary=DEFAULT
library_path=DEFAULT
hosts_allow_file=DEFAULT
tape_config_file=DEFAULT
language=DEFAULT
character set=DEFAULT
network connections=DEFAULT
server connections=DEFAULT
service threads=DEFAULT
warn level=DEFAULT
notify_lang_warn=DEFAULT
packet_size=DEFAULT
max shared memory=DEFAULT
allocation_threshold=DEFAULT
reserved threshold=DEFAULT
pll_scan_threads=DEFAULT
compress_level=DEFAULT
use ssl=DEFAULT
```

After you create the configuration file, you can boot the Backup Server without any parameters. If any parameter is passed, it overwrites the corresponding value in the Backup Server configuration file.

To enable SSL on BkpSvr001 from the command line, run the command:

At this point, the non-SSL listeners can be removed from the interfaces file, requiring users to connect only through SSL. This enables both isql and SAP ASE to act as SSL clients of an SSL-enabled Backup Server.

The CA root certificate must be present in the file \$\$YBASE/config/trusted.txt. The configuration option ssl_ca_file allows the Backup Server to change the location of the CA root certificate, and also (by default) of \$\$YBASE/config/trusted.txt, so that it can act as an SSL client when working as the client of a remote Backup Server, in a remote dump or load.

You have now successfully set up SSL on BkpSvr001.

To set up SSL on BkpSvr002, repeat the tasks you performed for BkpSvr001.

After you complete those tasks, run the following command:

```
2> dump database model to "/tmp/model.dmp" at BkpSvr002
3> go
```

As an option, you can specify the hostname (asestore1) and port (8892) with the command itself:

```
1> dump database model to "/tmp/model.dmp" at 'asestore1 8892 ssl="CN=BkpSvr002"' 2> go
```

You have successfully set up SSL using a direct connection to both Backup Servers, BkpSvr001 and BkpSvr002.

10.3.4 Certificate Request Overview

The system security officer installs server certificates and private keys for SAP ASE.

To generate a certificate, you can use a third party tool, such as the openssl utility, or use the keytool and ExportPrivateKey utility provided with SAP ASE.

To obtain a certificate, you must request a certificate from a certificate authority (CA). SAP ASE requires SSL certificates to use the PEM format. However, the certificate authority may deliver certificates in a format other than PEM. You must convert the certificate to the PEM format.

If you request a certificate from a third party and that certificate is in PKCS #12 format, use the openssl or any other third party tool to convert the certificate into a format that is understood by SAP ASE.

When FIPS is configured, MD5 hash algorithms cannot be used for certificate generation. The private key must be in PKCS #8 encrypted format.

The main steps to creating a certificate for use with SAP ASE are:

- 1. Generate the public and private key pair.
- 2. Securely store the private key.
- 3. Generate the certificate request.
- 4. Send the certificate request to the CA.
- 5. After the CA signs and returns the certificate, store it in a file and append the private key to the certificate.
- 6. Store the certificate in the SAP ASE installation directory.

Most third-party PKI vendors and some browsers have utilities to generate certificates and private keys. These utilities are typically graphical wizards that prompt you through a series of questions to define a distinguished name and a common name for the certificate.

Follow the instructions provided by the wizard to create certificate requests. Once you receive the signed PKCS #12-format certificate, use openssl tool or any other tool to generate a certificate file and a private key file. Concatenate the two files into a servername.crt file, where <servername> is the name of the server, and place it in the certificates directory under \$SYBASE /\$SYBASE ASE.

10.3.5 Requesting and Authorizing SSL Certificates Using Keytool and ExportPrivateKey Utility

Use the ExportPrivateKey utility to encrypt a server private key in Public-Key Cryptography Standards (PKCS) 8 format.

To generate an SSL certificate, use keytool (a key and certificate management tool) with ExportPrivateKey utility. The process of creating an SSL certificate involves multiple steps. Some steps, such as generating a key pair, exporting certificate, and creating a root certificate require you to use the keytool, whereas encrypting a server private key in PKCS8 format requires the ExportPrivateKey utility.

The ExportPrivateKey utility is bundled with the SAP ASE installer and is installed at \$sybase/\$sybase_ocs/bin. The keytool is also provided with the SAP ASE installer. The utility can be used to create SSL certificates with Java Runtime Environment (JRE) version 7 or later.

i Note

While using the ExportPrivateKey utility with the keytool, it is recommended to provide the full directory path to the keytool.

After you create an SSL certificate, use the sp_ssladmin addcert, <certificate_path>, <password> system procedure to install the certificate. SAP ASE installs SSL certificates at \$SYBASE/\$SYBASE_ASE/ certificates.

10.3.5.1 Creating a Self-signed Root Certificate

Generating a self-signed root certificate involves creating a key pair and exporting the certificate from the keystore to a text file.

Procedure

1. Create a key pair (public-private keys). The private key is then used to sign the certificate. Run the following command:

```
keytool -genkeypair -alias ca -keyalg RSA -keysize 1024 -dname "cn=TestCA, o=SAP, l=Dublin, st=CA, c=US, ou=Support" -keypass sap123 -ext bc:c -validity 3650 -keystore ca.jks -storepass sap123
```

After the successful execution of this command, a key pair is created for CA and is stored in the keystore (ca.jks).

2. Export the certificate from the keystore (ca.jks) to a text file (trusted.txt). Run the following command:

```
keytool -exportcert -alias ca -file trusted.txt -keystore ca.jks -storepass sap123 -rfc
```

After the successful execution of this command, the certificate is exported to a text file.

i Note

The CA trusted root certificate used to sign the ASE server certificate present in trusted.txt file should be copied to \$SYBASE /\$SYBASE ASE/certificates/servername.txt.

See Authentication Via the Certificate for more information.

- 3. Create the trusted roots file, server.txt:
 - UNIX:

```
cp trusted.txt $SYBASE/$SYBASE_ASE/certificates/server.txt
```

Windows:

```
copy trusted.txt %SYBASE%\%SYBASE_ASE%\certificates\server.txt
```

10.3.5.1.1 Generate Key Pair Using genkeypair Option

Use the genkeypair option of keytool to generate a key pair and store it in the keystore.

A sample command to generate a key pair is as follows:

```
keytool -genkeypair -alias ca -keyalg RSA -keysize 1024 -dname "cn=TestCA, o=SAP, l=Dublin, st=CA, c=US, ou=Support" -keypass sap123 -ext bc:c -validity 3650 -keystore ca.jks -storepass sap123
```

Where

- -genkeypair The keytool command to generate a public key and an associated private key.
- -alias The alias (ca) to access the keystore (ca.jks). The keystore stores the key pair. Each entry in the keystore is identified by a unique name or an alias.
- -keyalg The name of the algorithm (RSA) used to generate the key pair.
- -keysize The size (1024 bits) of the generated key pair.
- -dname Specifies the X.500 distinguished name to be associated with the alias. It is used as the issuer and subject fields in the self-signed certificate. In this example, the values are as follows:
 - (common name) cn=TestCA
 - (organization) o=SAP
 - (locality) l=Dublin
 - (state) st=CA
 - (country) c=US
 - (organization unit) ou=Support
- -keypass The password (sap123) to recover the key pair. If you do not specify the option on the command line, keytool will first attempt to use the keystore password to recover the private key, and if it fails, will then prompt you for the private key password.
- -ext Denotes an X.509 certificate extension (BasicContraints:critical).
- -validity Certificate validity (3650 days)
- -keystore The keystore (ca.jks) that stores the key pair.
- -storepass The password (sap123) to access the keystore.

After the successful execution of this command, a key pair is created for the CA and stored in the keystore (ca.jks).

10.3.5.1.2 Export Certificate Using exportcert Option

Use the exportcert option of keytool to export a certificate from the keystore.

A sample command to export a certificate from the keystore (ca.jks) to a text file (trusted.txt) is as follows:

```
keytool -exportcert -alias ca -file trusted.txt -keystore ca.jks -storepass sap123 -rfc
```

- -exportcert The keytool command to export a certificate.
- -alias The alias (ca) to access the keystore (ca.jks).
- -file The text file (trusted.txt) that contains the exported certificate.
- -keystore The keystore (ca.jks) that stores the key pair.
- -storepass The password (sap123) to access the keystore (ca.jks).
- -rfc Indicates that the certificate is exported in PEM format.

10.3.5.2 Creating a Private Key and a Certificate Request for Server

Generate a key pair and a certificate request for a server.

Procedure

1. Create a key pair for the server by running the following command:

```
keytool -genkeypair -alias server -keyalg RSA -keysize 1024 -dname
"cn=<server>, o=SAP, l=Dublin, st=CA, c=US" -keypass sybase -ext bc:c -
validity 3650 -keystore server.jks -storepass sybase
```

After the successful execution of this command, a key pair is created for the server and is stored in the server keystore as server.jks.

2. Generate a certificate request for a server. Run the following command:

For Open Server 15.7 and later version:

```
keytool -certreq -alias server -file <server>.req -keypass sybase -keystore
server.jks -storepass sybase
```

For Open Server 15.5 and earlier versions:

```
keytool -certreq -alias server -sigalg SHA1withRSA -file <server>.req - keypass sybase -keystore server.jks -storepass sybase
```

A successful execution of this command generates a certificate request file (file <server>.req).

10.3.5.2.1 Generate Key Pair For Server Using genkeypair Option

Use the genkeypair option of keytool to generate a key pair for the server and store the key pair in the server keystore.

A sample command to generate a key pair is as follows:

```
keytool -genkeypair -alias server -keyalg RSA -keysize 1024 -dname "cn=<server>,
o=SAP, l=Dublin, st=CA, c=US" -keypass sybase -ext bc:c -validity 3650 -keystore
server.jks -storepass sybase
```

- -genkeypair The keytool command to generate a public key and an associated private key.
- -alias The alias (server) to access the keystore (server.jks). The keystore stores the key pair. Each entry in the keystore is identified by a unique name or an alias.
- -keyalg The name of the algorithm (RSA) used to generate the key pair.

- -keysize The size (1024 bits) of the generated key pair.
- -dname Specifies the server (server) for which a key pair is being generated. Other values are as follows:
 - (common name) cn=server
 - (organization) o=SAP
 - (locality) l=Dublin
 - (state) st=CA
 - (country) c=US
 - (organization unit) ou=Support
- -keypass The password (sybase) to recover the key pair. If you do not specify the option on the command line, keytool will first attempt to use the keystore password to recover the private key, and if it fails, will then prompt you for the private key password.
- -ext Denotes an X.509 certificate extension (BasicContraints:critical).
- -validity Certificate validity (3650 days)
- -keystore The keystore (server.jks) that stores the server key pair.
- -storepass The password (sybase) to access the server keystore.

A successful execution of this command creates a key pair for the server, which is stored in the server keystore (server.jks).

10.3.5.2.2 Generate a Certificate Request For Server Using certreq Option

Use the certreg option of keytool to generate a certificate request for the server.

A sample command to generate a certificate request for the server is as follows:

```
keytool -certreq -alias server -file <server>.req -keypass sybase -keystore
server.jks -storepass sybase
```

- -certreq The keytool command to generate a certificate request for a server.
- -alias The alias (server) to access the server keystore (server.jks).
- -file <server>.req Generated certificate request file for the server.
- -keypass The password (sybase) to access the key pair.
- -keystore The server keystore (server.jks).
- -storepass The password (sybase) to access the server keystore.

10.3.5.3 Converting a Certificate Request to a CA-signed Server Certificate

Generate a server certificate signed by CA.

Procedure

Generate a certificate as a response to a certificate request file by running the following command:

For Open Server 15.7 and later version:

```
keytool -gencert -rfc -infile <server>.req -outfile <server>.crt -alias ca -ext
bc:c -keystore ca.jks - storepass sap123
```

For Open Server 15.5 and earlier versions:

```
keytool -gencert -rfc -infile <server>.req -outfile <server>.crt -alias ca -
sigalg SHAlwithRSA -ext bc:c -keystore ca.jks -storepass sap123
```

10.3.5.3.1 Convert a Certificate Request to a CA-signed Server Certificate

Use the gencert option of keytool to accept a certificate request file as an input and generate a server certificate signed by a CA.

A sample command to generate a CA-signed certificate is as follows:

```
keytool -gencert -rfc -infile <server>.req -outfile <server>.crt -alias ca -ext
bc:c -keystore ca.jks -storepass sap123
```

- -gencert Generate a certificate as a response to a certificate request file.
- -infile The input file is the certificate request file (<server>.reg).
- -outfile The output file is the server certificate (<server>.crt).
- -alias The alias (ca) to access the keystore.
- -ext Denotes an X.509 certificate extension (bc:c).
- -keystore The CA keystore (ca.jks).
- -storepass The password (sap123) to access the CA keystore.

10.3.5.4 Encrypting the Server Private Key in PKCS8 Format

Use the ExportPrivateKey.jar utility to extract the server private key from the server keystore and then encrypt the key in Public-Key Cryptography Standards (PKCS) 8 format.

Procedure

Set <CLASSPATH> environment variable to \$SYBASE/\$SYBASE_OCS/bin/ExportPrivateKey.jar, and run the following command:

java com.sap.security.ExportPrivateKey -keystore server.jks -alias server -file <server>.prk -storepass sybase

10.3.5.4.1 Encrypt the Server's Private Key in PKCS8 Format

Use the ExportPrivateKey utility to encrypt a server's private key in PKCS8 format.

java com.sap.security.ExportPrivateKey -keystore server.jks -alias server -file <server>.prk -storepass sybase

Where

- java com.sap.security.ExportPrivateKey The command to encrypt the server private key in PKCS8 format using the ExportPrivateKey utility.
- -keystore The server keystore (server.jks).
- -alias The alias (server) to access the keystore.
- -file The generated file that stores the encrypted private key.
- -storepass The password (sybase) to access the server keystore.

10.3.5.5 Appending Private Key to the Server Certificate

Append the generated private key to the server certificate.

Procedure

Run the following command to append the generated private key (<server>.prk) to the server certificate (<server>.crt).

```
cat <server>.prk >> <server>.crt
```

10.3.5.6 ExportPrivateKey

Use the ExportPrivateKey utility to encrypt a server private key in Public-Key Cryptography Standards (PKCS) 8 format. To generate an SSL certificate, you need to use keytool (a key and certificate management tool) with the ExportPrivateKey utility. The process of creating an SSL certificate involves multiple steps. Some steps, such as generating a key pair, exporting certificate, and creating a root certificate require you to use the keytool, whereas encrypting a server private key in PKCS8 format requires the ExportPrivateKey utility.

Syntax

```
ExportPrivateKey
[-keystore <server_keystore>]
[-alias <alias>]
[-file <server_file.prk>]
[-storepass <password>]
[-keypass <password>]
```

Parameters

```
-keystore <server keystore>
```

Specifies the server keystore.

```
-alias <alias>
```

Specifies the alias to access the keystore.

```
-file <server file.prk>
```

File that stores the encrypted private key.

```
-storepass <password>
```

Password to access the keystore.

```
-keypass <password>
```

Specifies a password that is different from the one specified for keystore. The password used for the keystore is used to access the private key if you do not include keypass,

Example

In this example, the <code>ExportPrivateKey</code> utility extracts the server private key from the server keystore (<code><server.jks></code>) using the alias (<code><server></code>), and then encrypt the key and stores it in the <code><server.prk></code> file. It uses <code><sapl23></code> as the password to access the server keystore.

```
java com.sap.security.ExportPrivateKey -keystore <server.jks> -alias <server> -
file <server.prk> -storepass <sap123>
```

10.3.6 Create Server Directory Entries

SAP ASE accepts client logins and server-to-server RPCs. The address and port numbers where SAP ASE accepts connections are configurable so you can specify multiple networks, different protocols, and alternate ports.

In the interfaces file, SSL is specified as a filter on the master and query lines. The following example shows an entry for an server using SSL in a UNIX environment:

```
[SYBSRV1]
master tcp ether myhostname myport ssl="CN=my_server_common_name.mydomain.com"
query tcp ether myhostname myport ssl="CN=my_server_common_name.mydomain.com"
```

In this example, the SSL security service is specified on port number myport.

An entry for the server with SSL and Kerberos security mechanisms on Windows might look like:

```
[SYBSRV2]
query=nlwnsck, 18.52.86.120,2748,ssl
master=nlwnsck 18.52.86.120,2748,ssl
master=nlwnsck 18.52.86.120,2749
secmech=1.3.6.1.4.897.4.6.6
```

In this example, the SSL security service is specified on port number 2748 (0x0abc).

The SECMECH line in the example contains an object identifier (OID) that refers to the security mechanism Kerberos, respectively. The OID values are defined in:

- UNIX \$SYBASE/\$SYBASE_OCS/config/objectid.dat
- Windows %SYBASE%\%SYBASE OCS\ini\objectid.dat

i Note

The use of SSL concurrently with a SECMECH security mechanism is intended to facilitate migration from SECMECHs to SSL security.

10.3.7 Administer Certificates

To administer SSL and certificates in SAP ASE, use <code>sp_ssladmin.sso_role</code> is required to execute the stored procedure.

sp ssladmin is used to:

- Add local server certificates. You can add certificates and specify the password used to encrypt private keys, or require input of the password at the command line during start-up.
- Delete local server certificates.
- List server certificates.

For example:

This adds an entry for the local server, <server1.crt>, in the certificates file in the absolute path to
\$SYBASE/ASE-16_0/certificates. The private key is encrypted with the password "<mypassword>". The
password should be the one specified when you created the private key.

Before accepting the certificate, sp ssladmin verifies that:

- The private key can be decrypted using the provided password (except when NULL is specified).
- The private key and public key in the certificate match.
- The certificate chain, from root CA to the server certificate, is valid.
- The common name in the certificate matches the common name in the interfaces file.

If the common names do not match, sp_ssladmin issues a warning. If the other criteria fails, the certificate is not added to the certificates file.

Passwords are limited to 64 characters.

The use of NULL as the password is intended to protect passwords during the initial configuration of SSL, before the SSL-encrypted session begins. Since you have not yet configured SSL, the password travels unencrypted over the connection. You can avoid this by specifying the password as NULL during the first login.

When NULL is the password, you must start dataserver with a -y flag, which prompts the administrator for the private-key password at the command line.

After restarting the server with an SSL connection established, use <code>sp_ssladmin</code> again, this time using the actual password. The password is then encrypted and stored by SAP ASE. Any subsequent starts of the server from the command line use the encrypted password; you do not have to specify the password on the command line during start-up.

An alternative to using a NULL password during the first login is to avoid a remote connection to SAP ASE via isql. You can specify "localhost" as the <hostname> in the interfaces file (sql.ini on Windows) to prevent clients from connecting remotely. Only a local connection can be established, and the password is never transmitted over a network connection.

SAP ASE has sufficient memory in its network memory pool to allow sp_ssladmin addcert to set the certificate and private key password with its default memory allocations. However, if another network memory

consumer has already allocated the default network memory, sp_ssladmin may fail and display this error to the client:

```
Msg 12823, Level 16, State 1:
Server 'servername', Procedure 'sp_ssladmin', Line 72:
Command 'addcert' failed to add certificate path
/work/REL125/ASE-16_0/certificates/servername.crt, system error: ErrMemory.
(return status = 1)
```

Or the following message may appear in the error log:

```
... ssl_alloc: Cannot allocate using ubfalloc(rnetmempool, 131072)
```

As a workaround, you can increase the additional network memory configuration parameter. About 500K bytes of memory is needed for <code>sp_ssladmin</code> addcert to succeed, so increasing additional network memory by this amount may allow it to succeed. This memory is reused by the network memory pool when needed, or you can return additional network memory to its previous value after <code>sp_ssladmin</code> has successfully completed.

See Reference Manual: Procedures for a complete sp ssladmin syntax.

10.3.7.1 Updating an Expired Certificate

Use sp ssladmin to replace an expired certificate on your local server.

Procedure

1. Use the dropcert parameter of the sp_ssladmin system stored procedure to drop the expired certificate. For example:

```
sp_ssladmin dropcert , "/sybase/ASE-16_0/certificates/Server1.crt"
```

2. Use the addcert parameter to add a certificate, for example:

```
sp_ssladmin addcert, "/sybase/ASE-16_0/certificates/Server1_new.crt",
"mypassword"
```

3. Activate the certificate:

```
sp_ssladmin refreshcert
```

10.3.8 Performance

There is additional overhead required to establish a secure session, because data increases in size when it is encrypted, and it requires additional computation to encrypt or decrypt information.

The additional memory requirements for SSL increases the overhead by 50-60 percent for network throughput or for establishing a connection. You must have approximately 40K more memory for each user connection.

10.3.9 Cipher Suites

During the SSL handshake, the client and server negotiate a common security protocol via a Cipher Suite. Cipher Suites are preferential lists of key-exchange algorithms, hashing methods, and encryption methods used by SSL-enabled applications.

For a complete description of Cipher Suites, visit the Internet Engineering Task Force (IETF) organizationhttp://tools.ietf.org/html/rfc5246 .

By default, the strongest Cipher Suite supported by both the client and the server is the Cipher Suite that is used for the SSL-based session.

i Note

The Cipher Suites listed conform to the Transport Layer Specification (TLS). TLS is an enhanced version of SSL 3.0, and is an alias for the SSL version 3.0 Cipher Suites.

10.3.9.1 Display or Set SSL Cipher Suites

You can display, set, or restrict the set of cipher suites that SAP ASE uses.

Display Cipher Suite Preferences

You can display cipher suite preferences that have been set using <code>sp_ssladmin lsciphers</code>. If no preferences have been set, <code>sp_ssladmin lsciphers</code> returns 0 rows to indicate no preferences are set and SAP ASE uses its default (internal) preferences.

The Transact-SQL global variable <@@ssl_ciphersuite> can be used to display the cipher suite that was chosen by the SSL handshake and verify that an SSL or a non-SSL connection was established.

For example, an isql connection using SSL protocol displays the cipher suite chosen for it.

SAP ASE sets <@@ssl_ciphersuite> when the SSL handshake completes. The value is either NULL, indicating a non-SSL connection, or a string containing the name of the cipher suite chosen by the SSL handshake.

Set Cipher Suite Preferences

The set of cipher suites that SAP ASE uses can be restricted, giving control to the system security officer over the types of encryption algorithms that can be used by client connections to the server, or outbound connections from the SAP ASE server. SAP ASE uses an internally defined set of preferences for cipher suites.

To set a specific cipher suite preference, enter:

```
sp_ssladmin setciphers, { "TLS1.2" | "TLS1.0" | "FIPS" | "Strong" | "Weak" |
"All" | quoted_list_of_ciphersuites }
```

sp_ssladmin setciphers sets cipher suite preferences for a given ordered list. This restricts the available SSL cipher suites to the specified set of "TLS1.2", "TLS1.0", "FIPS", "Strong", "Weak", "All", or a quoted list of cipher suites. This takes effect on the next listener started, and requires that you restart the server to ensure that all listeners use the new settings.

Non-zero numbers indicate the preference order that SAP ASE uses during the SSL handshake. The client side of the SSL handshake chooses one of these cipher suites that matches its list of accepted cipher suites. An output preference of O (zero) indicates a cipher suite is not used by SAP ASE.

The following example specifies the set of cipher suites that use FIPS algorithms.

```
1> sp_ssladmin setcipher, 'FIPS'

The following cipher suites and order of preference are set for SSL connections:
Cipher Suite Name Preference

TLS_RSA_WITH_AES_256_GCM_SHA384 1
TLS_RSA_WITH_AES_128_GCM_SHA256 2
TLS_RSA_WITH_AES_256_CBC_SHA 3
TLS_RSA_WITH_AES_128_CBC_SHA 3
TLS_RSA_WITH_AES_128_CBC_SHA 4
```

This example sets a quoted list of cipher suite preferences:

```
1> sp_ssladmin setciphers, 'TLS_RSA_WITH_AES_128_CBC_SHA,
TLS_RSA_WITH_AES_256_CBC_SHA'
2> go

The following cipher suites and order of preference are set for SSL connections:
Cipher Suite Name Preference

TLS_RSA_WITH_AES_128_CBC_SHA 1
TLS_RSA_WITH_AES_256_CBC_SHA 2
2
```

The system security officer should consider the security policies employed at his or her site and the available SSL cipher suites to decide whether to restrict cipher suites and which cipher suites are appropriate for the security policies.

For more information, see Reference Manual: Procedures > sp_ssladmin.

Remove Cipher Suite Preferences

If you have set SSL cipher suite preferences and want to remove all preferences from the server and use default preferences, delete the preferences from their storage location in system catalogs using the following commands:

```
1> sp_configure 'allow updates to system tables', 1
2> go
1> delete from master..sysattributes where class=24
2> go
1> sp_configure 'allow updates to system tables', 0
2> go
```

These commands can be executed only by the system security officer or system administrator.

Attempts to use any dropped cipher suite results in an SSL handshake failure and a failure to connect to SAP ASE.

10.3.9.2 Predefined Cipher Suites in SAP ASE

SSL cipher suites use an internally defined set of preferences for cipher suites.

The logical groups for cipher suite are as follows:

Logical Group	Cipher Suite
FIPS	• TLS_RSA_WITH_AES_256_GCM_SHA384
	• TLS_RSA_WITH_AES_128_GCM_SHA256
	• TLS_RSA_WITH_AES_256_CBC_SHA
	TLS_RSA_WITH_AES_128_CBC_SHA
TLS 1.2	 TLS_RSA_WITH_AES_256_GCM_SHA384
	TLS_RSA_WITH_AES_128_GCM_SHA256
Strong	• TLS_RSA_WITH_AES_256_GCM_SHA384
	 TLS_RSA_WITH_AES_128_GCM_SHA256
	 TLS_RSA_WITH_AES_256_CBC_SHA
	TLS_RSA_WITH_AES_128_CBC_SHA
TLS 1.0	TLS_RSA_WITH_AES_256_CBC_SHA
	 TLS_RSA_WITH_AES_128_CBC_SHA
	 TLS_RSA_WITH_3DES_EDE_CBC_SHA
	 TLS_RSA_WITH_RC4_128_SHA
	• TLS_RSA_WITH_RC4_128_MD5
Weak	TLS_RSA_WITH_3DES_EDE_CBC_SHA

Logical Group	Cipher Suite
	TLS_RSA_WITH_RC4_128_SHATLS_RSA_WITH_RC4_128_MD5
All	 TLS_RSA_WITH_AES_256_GCM_SHA384 TLS_RSA_WITH_AES_128_GCM_SHA256 TLS_RSA_WITH_AES_256_CBC_SHA TLS_RSA_WITH_AES_128_CBC_SHA TLS_RSA_WITH_3DES_EDE_CBC_SHA TLS_RSA_WITH_RC4_128_SHA TLS_RSA_WITH_RC4_128_MD5

i Note

Diffie-Hellman Ephemeral Digital Signature Standard (DHE_DSS) is no longer supported for DSA certificates and cipher suites.

SAP ASE version 16.0 SP03 and later no longer supports these cipher suites:

- TLS_RSA_WITH_DES_CBC_SHA
- TLS_DHE_DSS_WITH_3DES_EDE_CBC_SHA
- TLS_DHE_DSS_WITH_RC4_128_SHA
- TLS_DHE_RSA_WITH_3DES_EDE_CBC_SHA
- TLS_DHE_DSS_WITH_DES_CBC_SHA
- TLS_DHE_RSA_WITH_DES_CBC_SHA
- TLS_RSA_EXPORT1024_WITH_RC4_56_SHA
- TLS_RSA_EXPORT1024_WITH_DES_CBC_SHA
- TLS_DHE_DSS_EXPORT1024_WITH_RC4_56_SHA
- TLS_DHE_DSS_EXPORT1024_WITH_DES_CBC_SHA
- TLS_RSA_EXPORT_WITH_RC4_40_MD5
- TLS_RSA_EXPORT_WITH_DES40_CBC_SHA
- TLS_DHE_DSS_EXPORT_WITH_DES40_CBC_SHA
- TLS_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA
- TLS_DH_anon_EXPORT_WITH_DES40_CBC_SHA
- TLS_DH_anon_EXPORT_WITH_RC4_40_MD5
- TLS_RSA_WITH_NULL_SHA
- TLS_RSA_WITH_NULL_MD5

10.3.10 Display or Set the TLS Protocol

You can display or set the TLS protocol version for client connections.

Display the TLS Protocol

To display the TLS protocol version, use sp ssladmin lsprotocol or @@ssl protocol.

In this example, a value of 0 is returned by sp ssladmin 1sprotocol when the protocol is set to NULL:

In this example, the Transact-SQL global variable <code>@@ssl_protocol</code> is used to identify that version TSL1.2 is negotiated by client and server:

```
1> select @@ssl_protocol
2> go
------
TLSv1.2
(1 row affected)
```

Set the TLS Protocol

Set the TLS protocol version to TLS1.2 or NULL using $sp_ssladmin$ setprotocol. When you set the TLS protocol to TLS 1.2, the client must use the TLS 1.2 protocol version to successfully connect. Setting $sp_ssladmin$ setprotocol to NULL allows backward compatibility by accepting TLS 1.0 and TLS 1.2 protocol versions from clients (this is the default value).

For example:

```
1> sp_ssladmin setprotocol,'TLS1.2'
2> go
TLS Protocol Version
------
TLSv1.2
(1 row affected)
(return status = 0)
1> sp_ssladmin lsprotocol
2> go
TLS Protocol Version
------
TLSv1.2
(1 row affected)
(return status = 0)
```

i Note

Cipher suites are independent of the TLS protocol version.

For more information, see Reference Manual: Procedures > sp_ssladmin.

10.3.11 Use SSL to Specify a Common Name

The server name specified in the directory service entry can be different from the common name the SSL server certificate uses to perform an SSL handshake.

This allows you to use a fully-qualified domain name for the SSL certificate common name (for example, server1.bigcompany.com).

To add a common name to the interfaces file, use:

```
ase1
  master tcp ether <host_name> <port_number> ssl="CN='<common_name>'"
  query tcp ether <host_name> <port_number> ssl="CN='<common_name>'"
```

When clients use SSL to connect to an SAP ASE server that also uses SSL, the SSL filter is placed after the port number in the interfaces file. The directory service includes the common name, which you add either by using dsedit or a text editor.

10.3.11.1 Specify a Common Name with sp_listener

sp_listener includes the CN=<common_name> parameter, which allows you to specify a common name for the SSL certificate.

The syntax is:

```
sp_listener 'command','[protocol:]<machine_name>:<port_number>:
"CN=<common_name>"', '<engine_number>'
```

Where CN=<common_name> is used only if you specify ssltcp as the protocol. The <common_name> you specify here is validated against the <common_name> in the SSL certificate. If you do not include CN=<common_name>, SAP ASE uses <server_name> to validate against the common name in the SSL certificate. If you include a fully-qualified domain name in the certificate, it must match the CN=<common_name>.

The attribute name "CN" is case insensitive (it can be "CN", "cn" or "Cn"), but the attribute value for the common name is case sensitive.

For example, to specify the common name ase1.big server 1.com:

```
sp_listener 'start','ssltcp:blade1:17251:"CN=ase1.big server 1.com"','0'
```

See the Reference Manual: Procedures for more information about sp listener.

10.3.12 Using isql to Connect to an SSL-enabled SAP ASE Server

You can connect to an SSL-enabled SAP ASE server.

Procedure

Issue a command similar to:

```
isql -Usa -Pbigsecret96 -S'myhost 5000 ssl="CN=awsase1"'
```

where:

- <user name> sa
- <password> bigsecret96
- <host name> myhost
- <port number> 5000
- The ASE server common name (CN) as used in the SSL server certificate awsase

10.3.13 Viewing a Certificate Expiration Date

Use the monSSLCertInfo monitoring table to view the expiration date of the SSL certificate loaded into SAP ASE.

Context

You must add the SSL certificate in SAP ASE server and activate the certificate first before you can view the certificate details.

Procedure

1. Use the sp ssladmin addcert stored procedure to add the SSL certificate for the SAP ASE server:

```
sp_ssladmin addcert, <certificate_path>,<password>
```

- <certificate_path>
 - Specify the absolute path to the certificates file on the local server.
- <password>

The password used to encrypt the private key when adding the new server certificate to the certificates file.

This example adds the SSL certificate path $/sybase/ASE-16_0/certificates/asel.crt$ for the SAP ASE server:

```
sp_ssladmin addcert,'/sybase/ASE-16_0/certificates/asel.crt',<password>
go
```

2. Activate the SSL certificate on the SAP ASE server:

```
sp_ssladmin refreshcert
go
```

3. View certificate details in the monSSLCertInfo monitoring table:

```
select * from monSSLCertInfo
go
```

The result is:

You can also view the certificate valid dates in the errorlog file once the certificate is activated, or after you restart the server. For example:

```
00:0006:00000:00015:2019/02/06 21:47:45.97 kernel SSL Certificate '/sybase/ASE-16_0/certificates/ase1.crt' with validity from 'Aug 19 2016 11:58AM' up to 'May 16 2019 11:58AM' is loaded successfully.
```

10.4 Encryption

SAP ASE comes with several encryption options to allow you to comply with security and privacy requirements. The differing methods allow you to choose whichever feature is easiest for you to deploy.

SAP ASE supports these forms of encryption:

Туре	Description
Database encryption	A fully encrypted database encrypts all of its data, indexes, and transaction logs. This is done transparently, so you can perform operations as usual.
Column encryption	You can encrypt table columns by adding the encrypt column qualifier to the create table statement.
Session-level encryption using isql	Executing thecommand_encrypt command line option encrypts the commands for the full active isql

Туре	Description
	session. Executing theconceal command line option hides and encrypts user input during the isql session.
Command-level encryption using isql	Adding encrypt to the command executor go encrypts commands on a per-command basis during an isql session.
Bulk copy encryption using the bcp utility	In versions of SAP ASE 16.0 SP03 and later, bcp automatically encrypts the initstring, colpasswd, and keypasswd options.
Encrypting commands between servers using CIS	Executing the set remote command encryption {on off} command activates encryption for those commands that process sensitive data during the active command session.

For more information, see *Database Encryption > Overview of Encryption* and *Utility Guide > bcp and Encryption*.

10.4.1 On-Demand Encryption

On-demand encryption allows you to issue encrypted commands and system procedures as needed, for a full isql session, and on an ad hoc basis when you want to run individual commands that contain sensitive data.

When you use on-demand encryption, the client encrypts the command before sending it to the server. The server decrypts the command before processing it. However, the result returned by the server is not encrypted.

On-demand encryption requires both the client and server to run SAP ASE versions 16.0 SP03 or later, or the system returns an error. No permissions are required to use on-demand encryption.

10.4.1.1 @@prev_batch_encrypted

Use the $<@@prev_batch_encrypted>$ global variable to find out whether your previously executed commands were sent encrypted.

This global variable checks the encryption status of the most recently executed batch of commands in the current user session. A return of 0 indicates that the server received the command as plain text; a return of 1 indicates that the commands were received encrypted.

This example encrypts a command to create a login named "test_login," with successful encryption indicated by the return value "1":

```
create login test_login with password '<password>'
go encrypt
select @@prev_batch_encrypted
go
```

1

This example shows the same command and is not encrypted, which is indicated by the return value "0":

```
create login test_login with password '<password>'
go
select @@prev_batch_encrypted
go
0
```

10.4.1.2 Session-Level Encryption

Encrypt all of your commands in a session using the --command_encryption or --conceal command line options.

i Note

On-demand command encryption only encrypts the commands send by the client to the SAP ASE server. The result returned by the server is not encrypted.

Specifying the --command encryption option encrypts every command sent during the isql session.

In this example, the guest login encrypts the entire isql session:

```
isql -Uguest -P<password> -Smyase --command_encryption
```

Specifying the --conceal option hides and encrypts your input during the isql session.

For example:

```
isql -Uguest -P<password> -Smyase --conceal
```

Use --command encryption when the isql session contains sensitive data.

Use --conceal when inputting visually sensitive data (such as passwords).

10.4.1.3 Command-Level Encryption

You can encrypt individual commands by adding encrypt to the go command terminator for isql.

i Note

On-demand command encryption only encrypts the commands send by the client to the SAP ASE server. The result returned by the server is not encrypted.

Add encrypt after the go command terminator to encrypt the command you just specified. Only that command is encrypted; no subsequent command sent by go is encrypted unless you add encrypt.

For example, this encrypted command modifies the password for a login from "master" to "password123":

10.4.1.3.1 List of Commands and System Procedures that Transmit Sensitive Data

Use on-demand encryption to encrypt commands transmitting sensitive data.

A number of commands transmit data that your site may deem sensitive, and should be encrypted.

- alter encryption key
- alter login
- alter role
- connect
- create cluster
- create encryption key
- create login
- create role
- deploy plugin
- drop encryption key
- dump database
- dump transaction
- load database
- load transaction
- set cluster
- set encryption passwd
- set role
- show agent
- upgrade server
- sp_addexternlogin
- sp addlogin
- sp_companion
- sp_encryption
- sp extrapwdchecks
- sp_ldapadmin
- sp_password
- sp_ssladmin

10.4.2 Encrypting Commands Between Local and Remote Servers Using CIS

CIS supports encryption for some commands and system procedures between servers by enabling command encryption for the session.

To encrypt commands sent between the servers, use the following set command for the active session:

```
set remote command encryption {on|off}
```

You can use this command as long as both the local and remote servers use SAP ASE version 16.0 SP03 or higher; the client need not use this version.

This encrypts the following:

- connect to <server_name>
- execute <server name>...<proc name>
- sp autoconnect
- sp passthru
- sp remotesql

If one of the servers does not support encryption, the command is sent unencrypted.

For more information, see Reference Manual: Commands > set, and the Component Integration Services Users Guide.

10.5 Kerberos Confidentiality

To require all messages into and out of SAP ASE to be encrypted, set the msg confidentiality reqd configuration parameter to 1.

If this parameter is 0 (the default), message confidentiality is not required but may be established by the client.

For example, to require that all messages be encrypted, execute:

```
sp_configure "msg confidentiality reqd", 1
```

10.6 Dump and Load Databases with Password Protection

You can protect your database dump from unauthorized loads using the password parameter of the dump database command. If you include the password parameter when you make a database dump, you must also include this password when you load the database.

The partial syntax for the password-protected dump database and load database commands are:

```
dump database <database_name> to <file_name> [ with passwd = <password> ]
```

```
load database <database name> from <file name> [ with passwd = <password> ]
```

where:

- <database name> is the name of the database that is being dump or loaded.
- <file name> is the name of the dump file.
- <password> is the password you provide to protect the dump file from unauthorized users.

Your password must be between 6 and 30 characters long. If you provide a password that is less than 6 or greater than 30 characters, an error message is issued. If you provide an incorrect password when you attempt to load the database, an error message is issued and the command fails.

For example, the following uses the password "bluesky" to protect the database dump of the pubs2 database:

```
dump database pubs2 to "/Syb_backup/mydb.db" with passwd = "bluesky"
```

The database dump must be loaded using the same password:

```
load database pubs2 from "/Syb_backup/mydb.db" with passwd = "bluesky"
```

10.6.1 Passwords and Character Sets

You can load the dump only to another server with the same character set. For example, if you attempt to load a dump from a server that uses an ASCII character set to a server that uses a non-ASCII character set, the load fails because the value of the ASCII password is different from the non-ASCII password.

Passwords entered by users are converted to the local character set. Because ASCII characters generally have the same value representation across character sets, if a user's password is in an ASCII character set, the passwords for dump and load are recognized across all character sets.

10.7 Residual Data Removal

To strengthen the security of database data, remove residual data.

Some database operations that delete space do not always physically erase the data. This can pose a security threat, as this residual data may be visible to a user using the dbcc utility. You can automatically zero out residual data when users perform such database operations.

You cannot remove residual data from system databases such as master, sybsystemdb, and sybsystemprocs, or from system tables present in each database.

i Note

Deallocated space is unavailable for reuse until SAP ASE finishes zeroing out the residual data. Depending on the amount of data that SAP ASE has to remove, this might take a long time.

10.7.1 Operations That Can Result in Residual Data

Any operation that results in space deallocation can cause residual data.

Table 30: Operations That Can Result in Residual Data

Operation	Description
drop table and drop index	Dropping a table or index can result in the deallocation of extents, which can then be directly reused for other objects, allowing a user who runs dbcc to see the contents of a deleted table.
	Residual data is removed if you set the erase residual data option at the session, database, or table level.
alter table	alter table commands such as alter table encryption delete the physical copy of existing data and store it in encrypted form, but do not delete old ASCII (or clear text) data pages; these can be viewed by directly looking at the database devices or by using the dbcc page command.
	Residual data is removed if you set the erase residual data option at the session, database, or table level.
Worktable deallocation	If the user query involves aggregations on the columns, there might be column data in the worktables. These worktables process the user query, and are deallocated at the end of query execution.
	These worktables are deallocated while closing the table, and the task deallocates the pages. You can remove the residual data by setting/enabling the erase residual data option at the session/database level.
Sort page deallocation	sort allocates pages from disk for merging the internal runs of internal list merge sorts. The extents used for external merge are cached in sort metadata structures and are reused to write the final result of the sort. If the external merge allocates more extents than the size of the table, the cached extents are deallocated at the end of the sort operation, and should be zeroed out.
Page deallocation after a page becomes empty	A delete query on a table can result in page deallocation; that is, if all the rows of a page are deleted, the page is then deallocated, and such a page has residual data.
Dropping or shrinking a database	Physical data can remain in dropped pages after a drop/ shrink database operation, but this data is not visible via a database utility. The only way to reuse this space is by run- ning create database or alter database, after which the pages are initialized with zero.

Operation	Description
reorg rebuild	Replicates the data into another space, then re-creates the indexes on the table and organizes the data. reorg rebuild then deallocates the old data (using the data it replicated). If the table/session/database-level option is not set and the table contains sensitive information, the old data still has residual data.
reorg compact	Deallocates the page if it finds that all the rows on the page are committed deletes. This happens if you run reorg compact before the SAP ASE mechanism for automatic garbage collection executes. If the pages that are queued for reorg compact are from the tables that have the option erase residual data turned on, the residual data in such pages should be removed.
Deleting a temporary table	Since a temporary table is similar to any other table, dropping a temp table that contains sensitive data results in the removal of residual data. For temp tables, set the removal of residual data at the session or table level; the database-level option does not work, as these tables reside in tempdb, for which the database option cannot be set.

10.7.2 Enabling the Removal of Residual Data

You can mark data as sensitive, and configure SAP ASE to erase residual data after performing delete or update operations.

Table 31: Enabling the Removal of Residual Data at Different Levels

Level	Description	
Database level	Use:	
	<pre>sp_dboption <dbname>, "erase residual data", true</dbname></pre>	
	When you set erase residual data to true, SAP ASE automatically removes all residual data after any operation resulting in deallocation.	
	i Note	
	Using sp_dboption does not allow for granular control, and may impact performance. If possible, consider enabling the feature at the session level by using the set command instead.	
	By default, when you enable the option at a database level, all the tables you create are set to erase residual data unless you explicitly turn it off.	
	To set the database-level option using sp_dboption, the user must be a system administrator or database owner.	
Session level	Use:	
	set erase_residual_data {on off}	
	Using set allows you to enable or disable the removal of residual data based on your needs.	
	When you enable the option at a session level, all page deal- locations during that session have their residual data re- moved. This includes page deallocations of tables that have the erase residual data option turned off explicitly.	
	This option can be set by any user for the particular session; no special permissions are required.	

Level Description

Table level

To create a new table, use:

```
create table <table_name> with "erase
residual data" {on | off}
```

By default, nothing is set or enabled, which means that the feature is off for this table.

To change the settings of an existing table to enable or disable the removal of residual data, use:

```
alter table <table_name> set "erase
residual data" {on | off}
```

When you set the erase residual data option for a table, SAP ASE cleans up deallocated space after any operation on the table, such as drop table, delete row (which causes page deallocation), alter table, or drop index, that results in residual data.

When you set the option for a table to on/off explicitly, you enable/disable data erasure for any operation that leaves residual data in the table respectively, regardless of its database settings.

To set the table-level option using create table or alter table, the user must be listed in the sysusers table for that database and should have create table permissions. For alter table, the user must be a table owner or the database owner (who can impersonate as table owner using the setuser command) to be able to set this option.

10.7.3 Examples of Residual Data Removal

Examples show the removal of residual data.

The examples use these two tables:

- create table t1 (col1 int) with "erase residual data" on
- create table t2 (col1 int) with "erase residual data" off

Example: Example 1

Residual data is automatically removed for t1 since it has the erase residual data option on, but not for t2, since it does not have the erase residual data option set, and the dboption/session-level option is not set:

```
drop table t1
go
drop table t2
go
```

Example: Example 2

Residual data is removed for both t1 and t2, because erase_residual_data is set at the session level, which overrides the table-level option that was set to explicitly turn erase_residual_data off:

```
set erase_residual_data on
go
drop table t1
go
drop table t2
go
set erase_residual_data off
go
```

Example: Example 3

The option to erase residual data is turned on for table t1 because it is set at the database level, so that both the drop table and truncate table commands for t1 result in the cleanup of all residual data from its pages.

Table t2, however, has the erase residual data option turned off explicitly, as it was created with the erase residual data off clause. For this reason, residual data is not removed, even though the erase residual data option is set to true at the database level. As a result, residual data remains, even after running drop table and truncate table on t2:

```
create database db1
go
sp_dboption db1, "erase residual data", true
go
use db1
go
create table t1 (col int)
go
insert t1 values ...
go
create table t2 (col1 int, col2 char(10)) with "erase residual data" off
go
truncate table t1
go
drop table t1
```

```
go
truncate table t2
go
drop table t2
go
```

Example: Example 4

In this example:

- Table t1 does not have erase residual data off set explicitly, but does have it set at the database level, resulting in the removal of residual data from t1 when you run truncate table t1.
- Table t2 has the erase residual data option set at the time it was created because the option was set at the database level. This results in the removal of residual data from t2 when you run truncate table t2.
- Table t3 is marked with erase residual data off explicitly, so that even though sp_dboption sets erase residual data to true, residual data is not removed when SAP ASE runs truncate table t3.

```
create database db1

go
use db1
go
create table t1 (col int)
go
sp_dboption db1, "erase residual data", true
go
create table t2 (col1 int, col2 char(10))
go
create table t3 (col1 int, col2 char(10)) with "erase residual data" off
go
truncate table t1
go
truncate table t2
go
truncate table t3
go
```

Example: Example 5

In this example,

- Although both t1 and t2 tables had the erase residual data option not set by default, because erase_residual_data was turned on at the session level just before the truncate table command was executed, the residual data is removed on both t1 and t2
- Although table t3 has the erase residual data option explicitly set to off, residual data is still removed when the truncate command is executed because the erase_residual_data option is set at session level.

```
create database db1
go
use db1
go
```

```
create table t1(col int)
go
create table t2 (col1 int, col2 char(10))
go
create table t3 (col1 int, col2 char(10)) with "erase residual data" off
go
set erase_residual_data on
go
truncate table t1
go
truncate table t2
go
truncate table t3
go
```

10.7.4 Combinations of Settings for Removing Residual Data

SAP ASE removes residual data depending on what the settings are at the various levels.

Table 32: Combinations of Settings and Residual Data Removal Behavior

Table Level	Session Level	Database Level	Cleanup
Off	Off	On	Yes
Off	On	Off	Yes
On	Off	Off	Yes
On	Off	On	Yes
On	On	Off	Yes
Off	On	On	Yes
Off, set explicitly	On	Off	Yes
Off, set explicitly	On	On	Yes
Off, set explicitly	Off	On	No

Of these settings, note these two combinations in particular:

• Combination 1:

Table Level	Session Level	Database Level	Clean-up
Off, set explicitly	On	Off	Yes

When the session-level option is on, the removal of residual data for the deallocated pages of the table happens even when the table-level option for erase residual data is explicitly set to off. For this reason, enable the session-level option only if the current session involves sensitive data that requires removal, as the tables involved in the session that do not possess this property also remove residual data, causing a performance degradation.

• Combination 2:

Table Level	Session Level	Database Level	Clean-up
Off, set explicitly	Off	On	No

Even though the database-level option is on, the removal of residual data for the deallocated pages of the table is not performed, because the table-level option is explicitly turned off.

For this reason, if a table contains sensitive data, do not turn the table-level option explicitly off, as the deallocated pages contain residual data even if the database-level option is turned on.

10.7.5 Check Whether Residual Data Removal Is Enabled

Use system procedures to see whether you have enabled the removal of residual data at the table, database, and session levels.

Checking at the Table Level

Use sp help to check whether the erase residual data option is set at the table level. For example:

Checking at the Database Level

Use sp_helpdb to check whether the erase residual data option is set at the database level. For example:

```
use master

go
sp_dboption db1, "erase residual data", true
go
sp_helpdb db1
go
name db_size owner dbid created durability
lobcomplvl inrowlen status

db1 700.0 MB sa 4 Jul 22, 2013 full
0 NULL erase residual data
(1 row affected)
```

Checking at the Session Level

Use $sp_show_options$ to check whether the erase residual data option is set at the session level. For example:

```
set erase_residual_data on
go
sp_show_options
go
number name
----
[...]
110 erase_residual_data
(13 rows affected)
(return status = 0)
```

10.7.6 Limitations

There are some objects from which you cannot remove residual data.

Table 33: Limitations and Restrictions for Removing Residual Data

Limitation	Description	
Page-level deallocation cleanups	You can remove residual data at the page deallocation level as long as you enable the feature. When you do, however, residual data is removed only for the page deallocation itself; residual data is not removed as a result of any row-level deletion that does not cause page deallocation.	
Log records	Residual data is not removed from syslogs after deallocation, and log records are not cleaned up.	
In-memory databases	You cannot remove residual data from pages that belong to an in-memory database.	
Proxy tables	You cannot remove residual data from proxy tables.	
System databases	You cannot remove residual data from system databases such as master, system tempdb, and sybsystemprocs. In addition, residual data is not removed at the database level when you perform deallocation operations that involve tables created in systemtempdb.	
Worktables and sort pages	If any operation creates worktables or sort pages, those pages are deallocated if you set the database- or session-level option to remove residual data.	
Dropping databases	A fully durable database with the erase residual data option on may experience data loss—that is, data recovery cannot be fully ensured—if the drop database operation is aborted or rolled back for any reason.	

11 Auditing

A principal element of a secure system is accountability. One way to ensure accountability is to audit events on the system. Many events that occur in SAP ASE can be recorded.

Auditing is an important part of security in a database management system. An audit trail can be used to detect penetration of the system and misuse of resources. By examining the audit trail, a system security officer can inspect patterns of access to objects in databases and can monitor the activity of specific users. Audit records are traceable to specific users, which may act as a deterrent to users who are misusing the system.

Each audit record can log the nature of the event, the date and time, the user responsible for it, and the success or failure of the event. Among the events that can be audited are log ins and log outs, server starts, use of data access commands, attempts to access particular objects, and a particular user's actions. The audit trail, or log of audit records, allows the system security officer to reconstruct events that occurred on the system and evaluate their impact.

The system security officer is the only user who can start and stop auditing, set up auditing options, and process the audit data. As a system security officer, you can establish auditing for events such as:

- Server-wide, security-relevant events
- Creating, deleting, and modifying database objects
- All actions by a particular user or all actions by users with a particular role active
- Granting or revoking database access
- Importing or exporting data
- · Log ins and log outs

i Note

Permission requirements for operations mentioned in this book assume that granular permissions is disabled. Operations may differ when granular permissions is enabled.

Related Information

Manage User Permissions [page 166]

11.1 The Audit System

The audit system consists of the sybsecurity database, an audit queue, configuration parameters, and system procedures.

• The sybsecurity database – contains global auditing options and the audit trail

- The in-memory audit queue to which audit records are sent to the audit queue before they are written to the audit trail
- Configuration parameters used for managing auditing
- System procedures used for managing auditing

11.1.1 The sybsecurity Database

The sybsecurity database is created during the auditing installation process. In addition to all the system tables found in the model database, it contains sysauditoptions, a system table for keeping track of server-wide auditing options, and system tables for the audit trail.

sysauditoptions contains the current setting of global auditing options, such as whether auditing is enabled for disk commands, remote procedure calls, ad hoc user-defined auditing records, or all security-relevant events. These options affect the entire SAP ASE server.

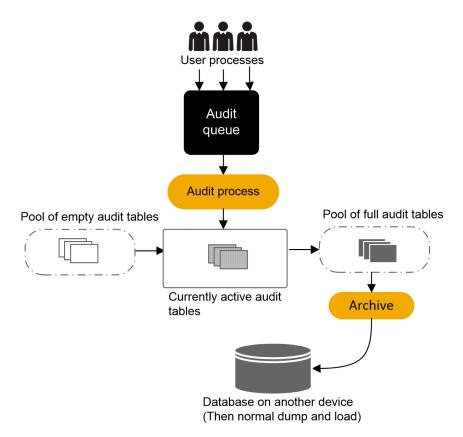

11.1.1.1 The Audit Trail

SAP ASE stores the audit trail in system tables named sysaudits_01 through sysaudits_08.

When you install auditing, you determine the number of audit tables for your installation. For example, if you choose to have two audit tables, they are named <code>sysaudits_01</code> and <code>sysaudits_02</code>. At any given time, only one audit table is current. SAP ASE writes all audit data to the current audit table. A system security officer can use <code>sp_configure</code> to set (or change) which audit table is current.

SAP recommends two or more audit tables, with each table on a separate audit device. This allows you to set up a smoothly running auditing process in which audit tables are archived and processed with no loss of audit records and no manual intervention.

SAP strongly recommends against using a single audit table on production systems. If you use only a single audit table, you may lose audit records.

The auditing system writes audit records from the in-memory audit queue to the current audit table. When the current audit table is nearly full, a threshold procedure can automatically archive the table to another database. The archive database can be backed up and restored with the dump and load commands. Use archive database access for read-only access to archived audit tables from backup. See *Archive Database Access*, in the *System Administration Guide, Volume 2*.

Related Information

Single-Table Auditing [page 380]
Audit Trail Management [page 371]

11.1.2 The Audit Queue

When an audited event occurs, an audit record first goes to the in-memory audit queue. The record remains in memory until the audit process writes it to the audit trail.

You can configure the size of the audit queue with the audit queue size parameter of sp configure.

Before you configure the size of the audit queue, consider the trade-off between the risk of losing records in the queue if the system crashes and the loss of performance when the queue is full. As long as an audit record is in the queue, it can be lost if the system crashes. However, if the queue repeatedly becomes full, overall system

performance is affected. If the audit queue is full when a user process tries to generate an audit record, the process sleeps until space in the queue becomes available.

i Note

Because audit records are not written directly to the audit trail, you cannot count on an audit record being stored immediately in the current audit table.

11.2 **Manage the Audit System**

Task for managing the audit system.

- 1. Install auditing set the number of audit tables and assign devices for the audit trail and the syslogs transaction log in the sybsecurity database.
- 2. Set up audit trail management write and establish a threshold procedure that receives control when the current audit table is nearly full. The procedure automatically switches to a new audit table and archives the contents of the current table. In addition, this step involves setting the audit queue size and the suspend audit when device full configuration parameters.
- 3. Set up transaction log management in the sybsecurity database determine how to handle the syslogs transaction log in the sybsecurity database, how to set the trunc log on chkpt database option and establishing a last-chance threshold procedure for syslogs if trunc log on chkpt is off.
- 4. Set auditing options use sp audit to establish the events to be audited.
- 5. Enable auditing use sp configure to turn on the auditing configuration parameter. SAP ASE begins writing audit records to the current audit table.
- 6. Restart auditing use sp_audit restart to restart auditing if the audit process is forced to terminate due to an error.

11.2.1 Preinstallation Recommendations for Auditing Devices

Complete the preinstallation recommendations before installing auditing.

- ullet Determine the location of the devices for the sybsecurity, syslogs, and sysaudits table devices. You will need to provide this information later.
- · Configure your system with the minimum number of auditing devices you require you must configure at least three devices. You can use sp addaudittable to add more auditing devices later. See the Reference Manual: Procedures.
- Install auditing tables and devices in a one-to-one ratio. Tables that share the same device also share the same upper threshold limit. These tables cannot be used sequentially when a device fills up, because they both reside on the same device.
- Install each auditing table on its own device. This enables you to set up a smoothly running auditing system with no loss of auditing records. With two auditing tables, when one fills up, you can switch to the other. With a third auditing table, if one device fails, the system security officer can install a new threshold procedure that changes the device rotation to skip the broken device until the device is repaired.

• Make the device larger than the table. When you use only three auditing tables and devices, the size of the table and the size of the device can be similar, because you can obtain more auditing capacity by adding more auditing tables and devices. When you are working toward the upper table and device limit (six to eight), you may want to make the device considerably larger than the table. You can later expand the table size toward the upper size of the device when a larger auditing capacity is desired, and few or no device additions are available.

If you are using a file system device, either set the <code>dsync</code> attribute on, or use the <code>directio</code> attribute with that device.

11.2.2 Install the Audit System

There are two methods for installing auditing for the first time in SAP ASE.

You can use the auditinit utility or an install script to install the audit system. The utilities and install scripts are located here:

- On UNIX, use one of the following:
 - \$SYBASE/\$SYBASE ASE/bin/auditinit
 - \$SYBASE/\$SYBASE ASE/scripts/installsecurity
- On Windows, use one of the following:
 - %SYBASE%\%SYBASE ASE%\bin\auditinit.exe
 - %SYBASE%\%SYBASE ASE%\scripts\instsecu

i Note

After auditing is installed, no auditing occurs until a System Security Officer enables auditing using sp configure.

11.2.2.1 Install Auditing on UNIX with installsecurity

Install the SAP ASE auditing system on the UNIX platform using the installsecurity script. After you complete this step, you can enable auditing.

Context

The \$SYBASE/ASE-16 O/scripts directory contains the installsecurity script for installing auditing.

i Note

Select your device size for data and log depending on the logical page size. This example assumes a server that uses a logical page size of 2K. Fore more information about device sizes, see the *Configuration Guide* for UNIX > SAP ASE Devices and System Databases > Determine the Size of a Database Device.

Procedure

- 1. Determine an available device number to use for the auditing device.
- 2. Create the auditing devices and auditing database with the disk init and create database commands. For example:

```
disk init name = "auditdev01",
    physname = "/dev/dsk/auditdev",
    size = "10M"

disk init name = "auditlogdev01",
    physname = "/dev/dsk/auditlog",
    size = "2M"

create database sybsecurity on auditdev01 log on auditlogdev01
```

3. Use isql to execute the installsecurity script:

```
cd $SYBASE/ASE-16_0/scripts
setenv DSQUERY <server_name>
isql -Usa -P<password> -S<server_name> -iinstallsecurity
```

4. Shut down and restart the SAP ASE server.

Results

When you have completed these steps, the sybsecurity database has one audit table (sysaudits_01) created on its own segment. You can enable auditing at this time, but should add more auditing tables with sp_addaudittable. For information about disk init, create database, and sp_addaudittable, see Reference Manual: Procedures and Reference Manual: Commands.

11.2.2.2 Install Auditing on Windows with instsecu

Install the SAP ASE auditing system on the Windows platform using the instsecu script. After you complete this step, you can enable auditing.

Context

The %SYBASE%\ASE-16 0\scripts directory contains the instsecu script for installing auditing.

Procedure

- 1. Determine the next available device number to use for the auditing device.
- 2. Open a Command Prompt window.
- 3. Start the isql program as user "sa":

```
isql -Usa -P<password> -S<server_name>
```

4. At the isql prompt, use the disk init command to create the auditing devices.

An example of configuring the auditing database:

```
declare @devno int
select @devno = max(low/16777216)+1 from sysdevices
disk init
name = "auditdev",
physname = "%SYBASE%\data\sybaud.dat",
vdevno = @devno,
size = 5120
```

An example of configuring the auditing database log:

```
declare @devno int
select @devno = max(low/16777216)+1 from sysdevices
disk init
name = "auditlogdev",
physname = "%SYBASE%\data\sybaudlg.dat",
vdevno = @devno,
size = 1024
```

5. Create the auditing database:

```
create database sybsecurity on auditdev log on auditlogdev
```

6. Exitisql:

```
exit
```

7. Change to the scripts directory:

```
cd %SYBASE%\ASE-16_0\scripts
```

8. Set the DSQUERY environment variable:

```
set DSQUERY = <server_name>
```

9. Start the isql program as user "sa" with the instsecu script as the input file:

```
isql -Usa -P<password> -S<server_name > -iinstsecu
```

10. Shut down and restart SAP ASE.

Results

Once you have completed these steps, the sybsecurity database has one audit table (sysaudits_01) created on its own segment. Add additional auditing tables with sp_addaudittable. No auditing occurs until a system security officer enables auditing with the auditing system procedures. For information about disk init, create database, and sp_addaudittable, see the Reference Manual: Procedures and Reference Manual: Commands.

11.2.2.3 Install Auditing with auditinit (Windows and UNIX)

Install auditing with the auditinit utility.

The auditinit process of installing an audit system involves:

- · Configuring the server
- Creating devices for the audit table
- Creating a device for the audit database transaction log

The auditinit utility is located here:

- UNIX: \$SYBASE/ASE-16 0/bin/auditinit
- Windows: %SYBASE%\ASE-16 0\bin\auditinit.exe

For more information about the auditinit utility, see the Utility Guide.

11.2.2.3.1 Configure a Server with auditinit

Configure the SAP ASE server for auditing with the auditinit utility.

Procedure

- 1. Do one of the following:
 - (On UNIX) Source the SYBASE.csh or SYBASE.sh environment variable file.
 - (On Windows) Go to the directory %SYBASE%\ASE-16_0\bin
- 2. Execute auditinit.

The following menu is displayed:

```
AUDITINIT

1. Release directory: /usr/u/sybase

2. Configure a Server product
```

3. Select Configure a Server product.

As a result, a list of available products is displayed.

- 4. From the product list, select Adaptive Server, or on Windows, SQL Server.
- 5. Select Configure an existing SAP Server.
- 6. Select the server to configure.
- 7. Provide the sa password for the server that you selected.
- 8. Type Ctrl+a and Enter to accept the sa account values.

As you proceed through the menus in auditinit, you can change any default values that appear. As you finish each menu, type Ctrl+a to accept the defaults or changed values and move to the next menu.

9. From the Sybase Server Configuration screen, select Configure Auditing.

The following menu is displayed:

```
CONFIGURE AUDITING

1. Configure auditing: no

2. create new device for the sybsecurity database: no

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry
```

Type *Ctrl+f* to scroll forward.

10. From the Configure Auditing screen, select Configure Auditing.

As a result, auditinit re-displays the Configure Auditing menu with the value "yes" displayed for Configure Auditing.

```
CONFIGURE AUDITING

1. Configure auditing: no

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry
```

Next Steps

To continue with the audit installation, you must add devices for the audit tables and then a device for the audit database transaction log.

Related Information

Create a Device for the Audit Transaction Log with auditinit [page 348]

11.2.2.3.2 Create a Device for an Audit Table with auditinit

Create audit table devices using auditinit.

Prerequisites

You must start the auditinit utility and configure the server before adding devices for an audit table See Configure a Server with auditinit.

Procedure

1. When the server is selected to be configured, the following auditinit menu is displayed:

```
CONFIGURE AUDITING
1. Configure auditing: yes

    create new device for the sybsecurity database:
    Add a device for audit table(s)

4. Add a device for the audit database transaction log

    Delete a device entry
    Change a device entry

List of devices for the audit tables:
Logical name Physical name Segment name
                                                       Table name
                                                                        Size
Device for the audit database transaction log:
Logical name Physical name
                                                       Table name
                                                                        Size
                                     Segment name
```

Press Ctlr+f to scroll forward.

2. From the same screen, select Add a device for sybsecurity database.

As a result, auditinit re-displays the Configure Auditing menu with the value "yes" displayed for Add a device for sybsecurity database. Type Ctrl+f to scroll forward.

3. From the Configure Auditing Screen, select Add a Device for Audit Table(s).

auditinit displays the following menu:

```
ADD/CHANGE A NEW DEVICE FOR AUDITING
1. sybsecurity physical device name:
2. Logical name of the device:
3. Size of the device (Meg):
4. Device size for auditing:
```

- 4. Select sybsecurity physical device name.
- 5. Enter the full path of the physical device (file system or raw partition).

```
Enter the physical name of the device to use for the audit database (default
is " "):
/dev/<path to partition>
```

6. Type Enter key to acknowledge the warning.

auditinit re-displays the Add/Change a New Device for Auditing menu, which displays the physical name of the device:

```
ADD/CHANGE A NEW DEVICE FOR AUDITING

1. sybsecurity physical device name: /secret1/sybase_dr/install/aud1.dat

2. Logical name of the device:

3. Size of the device:

4. Device size for auditing:
```

Type *Ctlr+f* to scroll forward.

7. Proceed through the remaining items on this menu.

i Note

The Size of the device value must be equal to or greater than the Device size for auditing value. If you are following SAP auditing guidelines, you need not change the value displayed in Device size for auditing.

8. Type *Ctrl+a* to accept the settings. auditinit returns to the Configure Auditing menu and displays the device you have created.

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry
List of devices for the audit tables:
Logical name Physical name Segment name Table name Size

7.Audit_01' secret1/sybase_dr/install/aud1.dat' sysaudits_01 5
```

9. To add multiple audit devices, repeat steps 1– 6. You can add as many as eight devices. SAP recommends adding three or more audit table devices.

After adding a device, auditinit returns to the Configure Auditing menu and displays all the devices you have created.

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry

List of devices for the audit tables:

Logical name Physical name Segment name Table name Size

7. Audit_01' /secret1/sybase_dr/install/aud1.dat' sysaudits_01 5

8. Audit_02' /secret1/sybase_dr/install/aud2.dat' sysaudits_02 5
```

Next Steps

To continue with the audit installation, you must add a device for the audit database transaction log.

Related Information

Create a Device for the Audit Transaction Log with auditinit [page 348]

11.2.2.3.3 Create a Device for the Audit Transaction Log with auditinit

Create a device for the audit transaction log using auditinit.

Prerequisites

You must start the auditinit utility, configure the server, and add devices for an audit table before adding a transaction log device. See Configure a Server with auditinit and Create a Device for an Audit Table with auditinit.

Procedure

1. When the audit table devices have been created, the following auditinit menu is displayed:

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry

List of devices for the audit tables:

Logical name Physical name Segment name Table name Size

7. Audit_01' /secret1/sybase_dr/install/aud1.dat' sysaudits_01 5

8. Audit_02' /secret1/sybase_dr/install/aud2.dat' sysaudits_02 5
```

Type *Ctlr+f* to scroll forward.

2. From the Configure Auditing menu, select Add a device for the audit database transaction log.

auditinit displays the Add/Change a New Device for Auditing menu.

```
ADD/CHANGE A NEW DEVICE FOR AUDITING

1. sybsecurity physical device name:

2. Logical name of the device:

3. Size of the new device (Meg):

4. Device size for auditing:
```

3. Select sybsecurity physical device name.

auditinit prompts for the physical name and supplies you with a default, if available:

```
Enter the physical name of the device to use for the sybsecurity database (default is''):
```

```
/dev/<path_to_partition>
```

where <path to partition >is the path to the raw partition for the device.

- 4. Enter the full path name of a physical device.
- 5. Type Enter.

auditinit displays the Add/Change a New Device for Auditing menu and the value you selected for the physical name of the device.

```
ADD/CHANGE A NEW DEVICE FOR AUDITING

1.sybsecurity physical device name:
    /secret1/sybase_dr/install/auditlog.dat

2.Logical name of the device:

3.Size of the device:

4.Device size for auditing:
```

Type *Ctlr+f* to scroll forward.

- 6. Proceed through the remaining items on this menu. As you do so, be aware of:
 - SAP recommends a minimum size of 2MB for the size of the transaction log.
 - auditinit displays the size in Size of the device and in Device size for auditing in the Add/Change a New Device for Auditing menu.
 - The Device size for auditing default value is equal to Size of the device, based on the assumption that you may want to devote the entire device to log for the auditing task. To use only a subset of the device, edit the Size of the device value.
- 7. Type Ctrl+a to accept the settings that appear in the Add/Change a New Device for Auditing menu.

auditinit returns to the Configure Auditing menu and displays all the devices you have created.

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry

List of devices for the audit tables:
Logical name Physical name Segment name Table name Size

7. Audit_01' /secret1/sybase_ dr/install/aud1.dat' sysaudits_01 5

8. Audit_02' /secret1/sybase_ dr/install/aud2.dat' sysaudits_02 5

9. auditlog /secret1/.../auditlog.dat logsegment syslogs 2
```

- 8. When you are ready to execute the audit configuration, type Ctrl+a.
- 9. On the SAP Server Configuration screen, type Ctrl+a again. You see:

```
Execute the SAP Server Configuration now?
```

10. Enter "y" (yes).

auditinitexecutes the tasks to install auditing. When installation completes successfully, you see:

```
Running task: install auditing capabilities.
......Done
Auditing capability installed.
Task succeeded: install auditing capabilities.
Configuration completed successfully.
Press <return> to continue.
```

Related Information

Configure a Server with auditinit [page 344]
Create a Device for an Audit Table with auditinit [page 346]

11.2.3 Enable or Disable Auditing

After auditing is installed, no auditing occurs until a System Security Officer enables auditing using sp_configure.

i Note

Before enabling auditing with sp configure, restart the server.

Use ${\tt sp_configure}$ with the auditing configuration parameter to enable or disable auditing.

The syntax is:

```
sp_configure "auditing", [0 | 1 ]
```

- 1 enables auditing.
- 0 disables auditing.

For example, to enable auditing, enter:

```
sp_configure "auditing", 1
```

i Note

When you enable or disable auditing, SAP ASE automatically generates an audit record.

You can also specify the location of audit records.

(Linux only) The syntax is:

```
sp_configure "audit trail type" [{"table" | "syslog"}]
```

• (Default) table – SAP ASE sends audit records to a table in the sybsecurity database. The log record looks like this:

```
event eventmod spid eventtime sequence suid dbid objid xactid loginname dbname objname objowner extrainfo

nodeid

10 1 15 Nov 19 2020 10:51PM 1 1 1 1 1 NULL 0x5f0b00007800 sa master test_tab NULL sa_role sso_role oper_role sybase_ts_role mon_role; create table test_tab (c int); ; ; ; sa/ase; NULL
```

 syslog – SAP ASE sends audit records to the operating system (OS) syslog file. For example, the /var/log/messages for Linux OS. Every audit record in the OS syslog file is identified with the string SAP_ASE_AUDIT. The log record looks like this:

```
2020-11-19T22:46:24.658425-08:00 asedg1lnx8 SAP_ASE_AUDIT: <> | 10 | 1 | 15 | Nov 19 2020 10:46PM | 1 | 1 | 1 | | | sa | master | test_tab | | sa_role sso_role oper_role sybase_ts_role mon_role; create table test_tab (c int); ; ; ; sa/ase; |
```

11.2.4 Restart Auditing

If the audit process is forced to terminate due to an error, it can be manually restarted.

Context

Enter:

```
sp_audit restart
```

The audit process can be restarted provided that no audit was currently running, but the audit process must be enabled with sp configure "auditing", 1.

11.2.5 Configure the Audit System

Configure the auditing system using ${\tt sp_configure}$ and system procedures.

Use the sp configure auditing parameters to manage the auditing process:

- auditing enables or disables auditing for the entire SAP ASE server. The parameter takes effect immediately upon execution of sp_configure. Auditing occurs only when this parameter is enabled.
- audit queue size establishes the size of the audit queue. Because the parameter affects memory allocation, the parameter does not take effect until the SAP ASE server is restarted.
- suspend audit when device full controls the behavior of the audit process when an audit device becomes full. The parameter takes effect immediately upon execution of sp_configure.
- current audit table sets the current audit table. The parameter takes effect immediately upon execution of sp configure.

Use these system procedures to manage the auditing process:

- sp_audit enables and disables auditing options. This is the only system procedure required to establish the events to be audited.
- sp displayaudit displays the active auditing options.
- sp_addauditrecord adds user-defined audit records (comments) into the audit trail. Users can add these records only if a system security officer enables ad hoc auditing with sp_audit.

11.2.5.1 Audit Configuration Changes

SAP also recommends that changes to SAP ASE configuration be audited.

There are two ways to enable audit of configuration changes made by sp configure:

- use the audit option <code>exec_procedure on the object of sp_configure to directly audit sp_configure,</code>
- use the audit option security which includes configuration changes made by sp_configure and other procedures.

To capture configuration changes made to the configuration file directly, use operating system provided file system auditing on the configuration files.

Follow the recommendations of your operating system vendor to enable auditing of configuration files.

For example:

- On Linux 2.6 kernel, use the auditd(8) daemon and related utilities auditctl, ausearch, and aureport.
- On AIX, the audit system is configured in /etc/security/audit/config and started using the audit start command. The IBM Redbook "Accounting and Auditing on AIX 5L" can be referenced for AIX systems.
- On Windows, auditing on files and folders is enabled by setting properties in the Security tab. For example, right-click the file or folder, then select *Properties > Security > Advanced > Auditing* and follow the dialog box. More information for Windows can be found on the Microsoft support site.

11.2.5.2 Correlate SAP ASE and Operating System Audit Records

The easiest way to link SAP ASE audit records with operating system records is to make SAP ASE login names the same as operating system login names.

Alternatively, the system security officer can map users' operating system login names to their SAP ASE login names. However, this approach requires ongoing maintenance, as login names for new users must be recorded manually.

11.2.5.3 Set Auditing Options

After you have installed auditing, use <code>sp_audit</code> to set auditing options.

The syntax for sp_audit is:

```
sp_audit <option>, <login_role_name>, <object_name> [,<setting>]
```

If you run sp audit with no parameters, it provides a complete list of the options.

For details about sp audit, see Reference Manual: Procedures > sp_audit.

i Note

Auditing does not occur until you activate auditing for the server.

Related Information

Enable or Disable Auditing [page 350]

11.2.5.3.1 Determine Current Auditing Settings

To determine the current auditing settings for a given option, use sp displayaudit.

The syntax is:

```
sp_displayaudit ["procedure" | "object" | "login" | "database" | "global" |
    "default_object" | "default_procedure" | "role" [, "<name>"]]
```

For more information, see sp displayaudit in Reference Manual: Procedures.

11.2.5.3.2 Full-Text Auditing

SAP ASE supports full-text auditing for DDL and DML commands, printing full command text in the second position of the extrainfo column when you enable relevant auditing options.

Full-text auditing also records parameters, printing them in the fifth position of the extrainfo column. Passwords, encryption key values, and encrypted column parameters are replaced with a fixed length string of asterisks in the audit records. Extra white space and comments are filtered to save space in the logs. Comments are included in the logs only if they are quoted such as: "/* audit comment */" or bracketed, such as "[/* audit comment */]".

i Note

When DML commands are executed from stored procedures, more procedure cache is required to store command text and parameter values. SAP recommends that you increase the size of the audit log and procedure cache to account for the extra space requirements of full-text auditing.

For a complete list of commands supported by full text auditing, see Reading the extrainfo Column [page 383].

11.2.5.3.2.1 Examples of Full-Text Auditing

In each of the examples of full text auditing, enable auditing option, execute a command or procedure, and view auditing record in sysaudits 01.

Example 1

Enable create auditing option for the "master" database:

```
sp_audit "create", "all", "master", "on"
go
```

Create a table:

```
create table t1(c1 int,c2 int)
```

Select the event from sysaudits 01. The full text of create statement is displayed (in **bold**):

```
select event, extrainfo from sybsecurity..sysaudits_01 where event = 10
go
event extrainfo

10    sa_role sso_role oper_role sybase_ts_role mon_role; create table t1
    (c1 int,c2 int) ; ; ; ; sa/ase;
```

Example 2

Enable dbcc auditing option:

```
sp_audit "dbcc", "all", "all", "on" go
```

Run dbcc checktable on t1:

```
dbcc checktable('master.dbo.t1')
go
```

The audit table contains the full text of the statement (in **bold**):

```
select event, extrainfo from sysaudits_01 where event = 81
go
event extrainfo

81    sa_role sso_role oper_role sybase_ts_role mon_role; dbcc checktable
    ('master.dbo.tl'); ; ; ; sa/ase;
```

Example 3

Enable auditing for executing drop on "test1" database:

```
sp_audit "drop", "all", "test1", "on"
go
```

Create and then drop tables t1 and t2:

```
create table t1(c1 int, c2 int)
create table t2(c1 int, c2 int)
go
drop table t1,t2
```

go

The audit table contains two full text audit records for the drop table command. Since the command is executed on two different objects (t1 and t2), two separate audits records are generated, one for each object identified by an **objid** and **objname**:

```
select event, dbid, objid, objname, extrainfo from sybsecurity..sysaudits_01
    where event = 27
go
    event    objid    objname
    extrainfo

27     992003534    t1
    sa_role sso_role oper_role sybase_ts_role mon_role; drop table t1, t2;
    ; ; ; sa/ase;
    27     1008003591    t2
    sa_role sso_role oper_role sybase_ts_role mon_role; drop table t1, t2;
    ; ; ; sa/ase;
}
```

Since create option has not been enabled for "test1" database, there are no audit records for this command.

Example 5

Enable security profile auditing option:

```
sp_audit "security_profile", "all", "all", "on"
```

Run:

```
create login profile joe_lp
go
alter login profile joe_lp modify default database "sybsystemprocs"
go
drop login profile joe_lp
go
```

The audit table contains the full text of the statements (in **bold**):

```
select event, extrainfo from sybsecurity..sysaudits_01 where event in (137, 140,
141)
go
event extrainfo

137 ; sa_role sso_role oper_role sybase_ts_role; create login profile joe_lp; ; ; ;
sa/ase;
140 ; sa_role sso_role oper_role sybase_ts_role; alter login profile joe_lp modify default
database "sybsystemprocs"; ; ; ; sa/ase;
141 ; sa_role sso_role oper_role sybase_ts_role; drop login profile joe_lp; ; ; ; sa/
ase;
```

For more examples, see Hide Sensitive Parameter Values [page 358], Print Parameter Values [page 356], and Filter Out Comments [page 360].

11.2.5.3.2.2 Print Parameter Values

In full-text auditing records, parameter names and values are printed in the fifth position of the extrainfo column.

Full-text auditing does not print parameter values for text, unitext and image datatypes. Instead, it prints the string: "Text data", "Unitext data", and "Image data" respectively in the result set. See example 5 below.

For a complete list of commands for which printing parameters is supported, see Reading the extrainfo Column [page 383].

Example 1

Enable update auditing option:

```
sp_audit "update", "all", "t1", "on"
```

And update table t1:

```
declare @val1 int
select @val1 = 1
update t1 set c1 = @val1
go
```

When you select the auditing event from sysaudits_01, SAP ASE displays full text of the update statement. In addition, parameters are displayed. The full text of the command and parameters are shown in **bold**:

Example 2

Enable disk auditing option:

```
sp_audit "disk", "all", "all", "on"
```

And issue disk resize on test_db_dev:

```
declare @p_name varchar(50)
declare @p_dsize varchar(50)
select @p_name='test_db_dev'
select @p_dsize='32m'
disk resize name = @p_name, size = @p_dsize
```

When you select the auditing event from sysaudits_01, SAP ASE displays the full text of the disk resize statement and all parameters:

Example 3

Enable select auditing option for table t1:

```
sp_audit "select", "all", "t1", "on"
go
```

Create a stored procedure that selects from t1:

```
create proc p1 @val1 int, @val2 int
as
select * from t1 where c1 = @val1
and c2 = @val2
go
sp_audit 'select', 'all', 't1', 'on'
go
exec p1 10, 20
go
```

The audit table contains the full text of the select statement and parameters:

Example 4

Enable auditing for the role option:

```
sp_audit "role", "all", "on"
```

Run:

```
declare @para1_role varchar(30)
declare @para2_grantee1 varchar(30)
select @para1_role='role1'
select @para2_grantee1 ='user4'
grant role @para1_role to @para2_grantee1
```

The audit table contains the full text of the statement and parameters:

```
select event, extrainfo from sybsecurity..sysaudits_01 where event = 85
go
event extrainfo

sso_role; grant role @para1_role to @para2_grantee1; ;
@para1_role = role1, @para2_grantee1 = user4; ; user1/ase;
```

Example 5

Full-text auditing does not print parameter values for text, unitext and image datatypes. Instead, it prints the string: "Text data", "Unitext data", and "Image data" respectively in the result set. In this example, "Text data" is printed:

```
values (10, @a); ; @a = Text data; ; sa/ase;
```

11.2.5.3.2.3 Hide Sensitive Parameter Values

In full-text auditing records, sensitive parameters such as passwords, encryption key values, and encrypted column parameter values are replaced with a fixed length string of asterisks.

Hide Passwords

Passwords are replaced with a fixed-length string of asterisks in the records contained in the audit logs.

Example 1

For example, if you enable login admin audit option:

```
sp_audit "login_admin", "all", "all", "on"
```

And then execute:

```
alter login johnd with password 'oldpasswd' modify password 'newpasswd'
```

The command will appear in the audit log as:

This protects passwords from being seen by others with access to the audit log.

Example 2

Enable role and password audit options:

```
sp_audit "role", "all", "all", "on"
go
sp_audit "password", "all", "all", "on"
go
```

And alter the role "role1" by adding password:

```
alter role role1 add passwd "sap78475984ulkmf"
```

The audit table contains two records, one for "role" (event 85) ad one for "password" (event 134) option. Each record includes the full text of the command with obfuscated password (in **bold**):

```
select event, extrainfo from sysaudits_01 where event in (85, 134) go event extrainfo
```

```
85 sa_role sso_role oper_role sybase_ts_role mon_role; alter role role1
add passwd "*****"; ; ; ; sa/ase;

134 sa_role sso_role oper_role sybase_ts_role mon_role; alter role role1
add passwd "*****"; ; ; ; sa/ase;
```

Example 3

Enable dump audit option:

```
sp_audit "dump" , "all", "tdb1", "on"
```

And execute dump database command::

```
create procedure dmpdb as
dump database tdb1 to "/tmp/tdb1.dmp" with passwd='sap12345'
go
exec dmpdb
go
```

When you select the auditing event from sysaudits_01, SAP ASE prints the full text of the command with obfuscated password:

```
select event, extrainfo from sybsecurity..sysaudits_01 where event = 132
go
event extrainfo

70     sa_role sso_role oper_role sybase_ts_role mon_role; dump database
    tdb1 to "/tmp/tdb1.dmp" with passwd='*****"; ; ; ; sa/ase;
```

Hide Encrypted Key Values

Encrypted key values are replaced with a fixed length string of asterisks in the audit records contained in the audit logs.

Example 1

Enable auditing for the encryption key auditing option:

```
sp_audit 'encryption_key', 'all', 'tdb1', 'on'
```

Create an encryption key:

```
CREATE ENCRYPTION KEY loginA_key FOR AES WITH KEYLENGTH 128 PASSWD 0x0000a91c0c68fcada09e0
INIT_VECTOR RANDOM PAD NULL KEYVALUE
0x54db068edf1b934726a7537fb1e660387a6da06f5ff7df04f80192d7a84fc66301 KEYSTATUS 33 go
```

The audit table contains the full text of the statement with obfuscated encryption key value (in **bold**):

```
NULL KEYVALUE ***** KEYSTATUS 33; ; ; ; sa/ase;
```

i Note

When a sensitive parameter with a binary value is used in a stored procedure, its value is not obfuscated in the audit record.

Hide Encrypted Column Parameters

Encrypted column parameter values are replaced with a fixed length string of asterisks in the audit records contained in the audit logs.

Example 1

In this example, the values of parameters which are used to insert or update data to encrypted columns are

For example, the second column in table t1 is encrypted:

```
declare @nr char(30)
declare @nr1 int
declare @nr2 char(30)
select @nr="aaa"
select @nr1=100
select @nr2="bbb"
insert t1 values(@nr, @nr1, @nr2)
```

The command appears in the audit log as:

```
select event, extrainfo from sysaudits 01 where event = 41
event extrainfo
     sa role sso role oper role sybase ts role mon role; insert t1 values
       (@nr, @nr1, @nr2); ; ; @nr = aaa, @nr1 = '******' , @nr2 = bbb;
        ; sa/ase;
```

11.2.5.3.2.4 Filter Out Comments

In full text auditing records, comments are filtered out unless they are quoted such as: "/* audit comment */" or bracketed, such as "[/* audit comment */]". Extra white space is filtered.

For example, if you enable auditing for executing create commands in "test1" database:

```
sp audit "create", "all", "test1", "on"
```

And run:

```
set quoted identifier on
create table "/* audit comment */" (col int)
```

```
create table /* audit comment */ "testtable" (col int)
go
```

The first audit record contains full text of the first create table command and the quoted comment. The second record includes full text of the create table command, but the comment is filtered out (since it was not quoted or bracketed):

The

11.2.5.3.3 Auditing Stored Procedures

In general, you can audit execution of stored procedures by issuing sp_audit "exec_procedure", which generates an audit record containing the name of the stored procedure and the parameters.

Some system stored procedures can be audited after enabling specific audit options. See procedure-specific documentation in the reference manual.

11.2.5.3.3.1 Enable Auditing of Stored Procedures

Enable $exec_procedure$ to audit execution of stored procedures. A majority of stored procedures can be audited using this option.

```
i Note
```

Before enabling exec procedure, run use sybsystemprocs.

Enables auditing for a specific procedure:

```
sp_audit "exec_procedure", "all", <object name>, procedure_name>, "on"
```

Enables auditing for audit all new procedures:

```
sp_audit "exec_procedure", "all", "default procedure", "on"
```

Example

This example audits sp_addmessage:

```
use sybsystemprocs
sp_audit "exec_procedure", "all", "sp_addmessage", "on"
go

sp_addmessage 220000, "Test Message"
go
```

All the parameters entered for sp addmessage are printed in position 5 of the extrainfo column:

```
select event, extrainfo from sybsecurity..sysaudits_01 where event = 38
go
event extrainfo
______
38    sa_role sso_role oper_role sybase_ts_role mon_role; ; ; ; 220000,
    Test Message; ; ;
```

11.2.5.3.3.2 Enable Auditing for Authorization Checks

The audit option <code>sproc_auth</code> enables auditing for authorization checks that are performed inside system stored procedures.

Granular Permissions Event

Enabled 146. The audit event 146 is only audited when the option sproc auth is enabled.

Disabled 80. The audit event 80 is audited when the sproc auth or security audit option is

enabled.

Enables sproc_auth:

```
sp_audit "sproc_auth", "all", "on"
```

 $The permission \, needed \, to \, run \, the \, stored \, procedure \, is \, included \, in \, the \, fifth \, position \, of \, {\tt extrainfo} \, column.$

Example

Enable granular permissions:

```
sp_configure "enable granular permissions", 1
go
```

Enable "sproc_auth":

```
sp_audit "sproc_auth", "all", "on"
```

Event 146 is recorded each time an authentication check is performed:

Example

Disable granular permissions:

```
sp_configure "enable granular permissions", 0
go
```

(Skip this step if you performed it in example 1) Enable "sproc auth":

```
sp_audit "sproc_auth", "all", "on"
```

Event 80 is recorded each time an authentication check is performed:

11.2.5.3.3 Auditing Stored Procedures Created with execute as owner or execute as caller

When auditing the execution of a stored procedure, if that procedure is created with execute as owner or execute as caller, the information is written to position 2 of the extrainfo section of the audit record.

In section 5 of the extrainfo column, the user name is written as either the owner or the caller, which ever applies.

Example

This is an example of an extrainfo column for a stored procedure that is owned by the database owner, executed by user Joe, and is created with execute as caller:

```
; EXECUTE AS CALLER; ; ; procedure caller = joe ; ;
```

Example

This is an example of an extrainfo column for a stored procedure that is owned by user Billy and is created with execute as owner:

```
; EXECUTE AS OWNER; ; ; procedure owner = billy ; ; ;
```

11.2.5.4 Granular Auditing

Granular auditing allows the auditing of options for a particular login or role. This reduces the number of audit records generated and minimizes unnecessary audits.

Granular auditing is supported for all global options and the user-specific all option. Records are generated for specified logins, and logins granted system roles or user defined roles. Audit records are generated only for those logins that have been granted the specified roles.

Audit Log in Attempts for Logins and Roles

In this example, there are five logins. Three are administrators and two are application logins. You can audit only the administrators who have logged in to the server by specifying the login option:

```
sp_audit "login", "admin1", "all", "on"
sp_audit "login", "admin2", "all", "on"
sp_audit "login", "admin3", "all", "on"
```

No audit records are generated for the application logins when they attempt to log in to the server.

You can audit at the role level for both system roles and user-defined roles, which reduces the number of audit records produced. This provides better performance, as extra processing for generating audit records for all logins is reduced. In this example, auditing is enabled to produce audit records of log-on attempts for all logins that are granted the user-defined roles role1 and role2:

```
sp_audit "login", "role1", "all", "on"
sp_audit "login", "role2", "all", "on"
```

Audit all Actions

The user-specifc all option supports auditing for all actions of logins, and logins that are granted system roles or user-defined roles. The following audits all actions for logins that are granted the user defined role role3:

```
sp_audit "all", "role3", "all", "on"
```

Global Audit Options

All global audit options support auditing at login and role level (both system defined and user defined roles). For example:

```
sp_audit "config_history", "sa_role", "all", "on"
```

For a list of global options, see Reference Manual: Procedures > sp_audit.

In this example, a new login is created and granted roles sa role and oper role:

```
1> create login userA with password myPassWord
2> go
1> grant role sa_role to userA
2> go
1> grant role oper_role to userA
2> go
```

Auditing is enabled for the global option dump config for userA:

```
1> sp_audit "dump_config", "userA", "all", "on"
2> go
Audit option has been changed and has taken effect immediately.
(return status = 0)
```

You can display the status of the enabled ${\tt dump_config}$ option using ${\tt sp_displayaudit}$:

```
1> sp displayaudit
2> go
No sprocs/triggers currently have auditing enabled.
No databases currently have default sproc/trigger auditing enabled.
No objects currently have auditing enabled.
No databases currently have default table/view auditing enabled.
Login Name Audit Option Value
userA
              dump_config
(1 row affected)
No databases currently have auditing enabled.
Audit Option Value Subject Name Type of Subject
dump config
                          userA
                                             login
(1 row affected)
(return status = 0)
```

Displaying Granular Audit Options

Use sp displayaudit to display the status of auditing for specific logins or roles.

To show whether the login option is set to enabled for login bob:

```
sp_displayaudit "login", "bob"

Subject Name Audit Option Value Type of Subject

bob login on login
(1 row affected) (return status = 0)
```

To show whether the login option is enabled for the role role1:

```
sp_displayaudit "login", "role1"

Subject Name Audit Option Value Type of Subject

role1 login on role

(1 row affected)
(return status = 0)
```

Viewing Events From sybsecurity

The columns id and status are updated in sybsecurity..sysauditoptions to indicate audit status. For example, when the option login is enabled for all logins and roles, then the column status in sybsecurity..sysauditoptions is updated to 1:

When the audit option <code>login</code> is enabled for a system role and a user-defined role, new rows for both roles are listed in <code>sybsecurity..sysauditoptions</code> to indicate the audit status. For example, 2 is listed in the <code>status</code> column to indicate that the <code>id</code> of the stored <code>srid</code> for the specified role name:

Upgrade and Downgrade

For a minor upgrade:

- The status is indicted in the sysauditoptions columns id and status.
- The upgraded rows show NULL for the id column for all audit options except the all audit option.
- The status column uses a bit set to denote the option that need to be audited for all logins and roles for global audit options.

• For the all audit option, rows are added for login level and role level options are indicated with the option number 59. The id column in sysauditoptions shows the ID of the role or login, and the status bit is set to indicate role or login.

For a downgrade:

- Downgrade of granular auditing is processed by sp_downgrade_esd. During downgrade, the rows with status!=1, or num=59 are deleted, and sysauditoptions columns id and status are removed.

 The information in the syslogins table for the all audit option, and the option numbers denoting system role-level auditing, are retained. These rows are not used in version 16.0 SPO3 and higher.
- The audit options <code>cmdtext</code>, <code>view_access</code>, and <code>table_access</code> maintain the login-specific audit information in <code>syslogins</code>.

For more information, see Reference Manual > sp_audit and sp_displayaudit.

11.2.6 Modifying the Audit System

Move the sybsecutity database to a different device, or change devices in the audit system.

11.2.6.1 Moving the sybsecurity Auditing Database

If you currently have the sybsecurity database on the same device as master, you can move sybsecurity to another device, with or without saving your existing global audit settings.

i Note

The sybsecurity database should be placed on its own device, separate from the master database. If you have more than one audit table, place each table on its own device. It can also be helpful to put each table on a separate segment which points to a separate device.

11.2.6.1.1 Moving sybsecurity Without Saving Global Audit Settings

You can move the sybsecurity database from the same device as master without saving your existing global audit settings.

Context

i Note

These steps include dropping the sybsecurity database, which destroys all audit records and global audit settings previously recorded in sybsecurity. Before you drop the sybsecurity database, make sure you

archive existing records with a backup or archive the audit table to avoid losing any historical data that remain in the sybsecurity tables.

Procedure

1. Execute the following to stop logging audit records for all logins to the syslogins system table:

```
sp_audit "all","all","all","off"
```

- 2. Drop the sybsecurity database.
- 3. Install sybsecurity again using the installation procedure described in either the configuration documentation for your platform, or *Installing Auditing with installsecurity*.
- 4. During the installation process, place the sybsecurity database on one or more devices, separate from the master device.

11.2.6.1.2 Moving sybsecurity and Saving Global Audit Settings

You can move the sybsecurity database from the same device as master and save your existing global audit settings.

Context

i Note

The sybsecurity database should be placed on its own device, separate from the master database. If you have more than one audit table, place each table on its own device. It can also be helpful to put each table on a separate segment which points to a separate device.

Procedure

1. Dump the sybsecurity database:

```
dump database sybsecurity to "/remote/sec_file"
```

2. Drop the sybsecurity database:

```
drop database sybsecurity
```

3. Initialize the first device on which you want to place the sybsecurity database:

```
disk init name = "auditdev",
    physname = "/dev/dsk/c2d0s4",
    size = "10M"
```

4. Initialize the device where you want to place the sybsecurity log:

```
disk init name = "auditlogdev",
    physname = "/dev/dsk/c2d0s5",
    size = "2M"
```

5. Create the new sybsecurity database:

```
create database sybsecurity on auditdev log on auditlogdev
```

6. Load the contents of the old sybsecurity database into the new database. The global audit settings are preserved:

```
load database sybsecurity from "/remote/sec_file"
```

7. Run online database, which upgrades sysaudits and sysauditoptions if necessary:

```
online database sybsecurity
```

8. Load the auditing system procedures using the configuration documentation for your platform.

11.2.6.2 Deleting a Device Entry with auditinit

Delete a device entry using auditinit.

Procedure

- 1. Do one of the following:
 - (On UNIX) Source the SYBASE.csh or SYBASE.sh environment variable file.
 - (On Windows) Go to the directory %SYBASE%\ASE-16_0\bin
- 2. In a command window, enter auditinit.

The following menu is displayed:

```
AUDITINIT

1. Release directory: /usr/u/sybase

2. Configure a Server product
```

- 3. Select Configure a Server product.
- 4. From the product list, select Adaptive Server, or on Windows, SQL Server.
- 5. Select Configure a Server product.
- 6. Select the server to configure.

- 7. Provide the sa password for the server you selected.
- 8. Type Ctrl+a and Enter to accept the sa account values.

As you proceed through the menus in auditinit, you can change any default values that appear. As you finish each menu, type Ctrl+a to accept the defaults or changed values and move to the next menu.

9. From the Sybase Server Configuration screen, select Configure Auditing.

The following menu is displayed:

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry
```

Type *Ctrl+f* to scroll forward.

- 10. Select Delete a Device Entry.
- 11. Enter the number of the device to delete.
- 12. Type Enter key.

11.2.6.3 Changing a Device Entry with auditinit

Change a device entry using auditinit.

Procedure

- 1. Do one of the following:
 - (On UNIX) Source the SYBASE.csh or SYBASE.sh environment variable file.
 - (On Windows) Go to the directory %SYBASE%\ASE-16_0\bin
- 2. In a command window, enter auditinit.

The following menu is displayed:

```
AUDITINIT

1. Release directory: /usr/u/sybase

2. Configure a Server product
```

- 3. Select Configure a Server product.
- 4. From the product list, select Adaptive Server, or on Windows, SQL Server.
- 5. Select Configure a Server product.
- 6. Select the server to configure.
- 7. Provide the sa password for the server you selected.
- 8. Type Ctrl+a and Enter to accept the sa account values.

As you proceed through the menus in auditinit, you can change any default values that appear. As you finish each menu, type Ctrl+a to accept the defaults or changed values and move to the next menu.

9. From the Sybase Server Configuration screen, select Configure Auditing.

The following menu is displayed:

```
CONFIGURE AUDITING

1. Configure auditing: yes

2. create new device for the sybsecurity database: yes

3. Add a device for audit table(s)

4. Add a device for the audit database transaction log

5. Delete a device entry

6. Change a device entry
```

Type *Ctrl+f* to scroll forward.

- 10. Select Change a Device Entry.
- 11. Enter the number of the device to change.

auditinit displays the Add/Change a New Device for Auditing menu with information on the device you selected:

```
ADD/CHANGE A NEW DEVICE FOR AUDITING

1. sybsecurity physical device name:
    /secret1/sybase_dr/install/audlog

2. Logical name of the device: aud.log

3. size of the new device (Meg): 5

4. Device size for auditing:5
```

- 12. Select each remaining entry that you want to change.
- 13. Type *Ctrl+a* to save the new entries.

11.2.7 Audit Trail Management

These general steps describe how to effectively manage the audit trail.

- Be sure that auditing is installed with two or more tables, each on a separate device. If not, consider adding additional audit tables and devices.
- Write a threshold procedure and attach it to each audit table segment.
- Set configuration parameters for the audit queue size and to indicate appropriate action should the current audit table become full.
- Query the audit trail
- Add user specified records to the audit trail

11.2.7.1 Creating more than one sysaudits table in sybsecurity

SAP strongly recommends that you not use single-device auditing for production systems. If you use only a single audit table, you create a window of time while you are archiving audit data and truncating the audit table during which incoming audit records are lost. There is no way to avoid this when using only a single audit table.

Procedure

1. Initialize the device where you want to place the additional table:

```
disk init name = "auditdev2",
    physname = "/dev/dsk/c2d0s6",
    size = "10M"
```

2. Extend the sybsecurity database to the device you initialized in step 1:

```
alter database sybsecurity on auditdev2 = "2M"
```

3. Run sp addaudittable to create the next sysaudits table on the device you initialized in step 1:

```
sp_addaudittable auditdev2
```

4. Repeat steps 1 – 3 for each sysaudits table.

11.2.7.2 Setting Up Threshold Procedures

Before enabling auditing, establish a threshold procedure to automatically switch auditing tables when the current table is full.

i Note

These instructions assume that you have installed auditing with two or more tables, each on a separate device. If you have only one device for the audit tables, see *Single-Table Auditing*.

The threshold procedure for the audit device segments should:

- Make the next empty audit table current using sp_configure to set the current audit table configuration parameter.
- Archive the audit table that is almost full using the insert...select command.

11.2.7.2.1 Change the Current Audit Table

The current audit table configuration parameter establishes the table where SAP ASE writes audit rows.

As a system security officer, you can change the current audit table with $sp_configure$, using the following syntax, where <n> is an integer that determines the new current audit table:

```
sp_configure "current audit table", <n>
[, "with truncate"]
```

The valid values for <n> are:

- 1 means sysaudits 01, 2 means sysaudits 02, and so forth.
- O tells the server to automatically set the current audit table to the next table. For example, if your installation has three audit tables, sysaudits_01, sysaudits_02, and sysaudits_03, SAP ASE sets the current audit table to:
 - 2 if the current audit table is sysaudits 01
 - 3 if the current audit table is sysaudits 02
 - 1 if the current audit table is sysaudits 03

The with truncate option specifies that the new table should be truncated if it is not already empty. If you do not specify this option and the table is not empty, sp configure fails.

i Note

If the current audit table is truncated and you have not archived the data, the table's audit records are lost. Archive the audit data before you use the with truncate option.

To execute sp_configure to change the current audit table, you must have the sso_role active. You can write a threshold procedure to automatically change the current audit table.

11.2.7.2.2 Archiving the Audit Table

You can use insert with select to copy the audit data into an existing table having the same columns as the audit tables in sybsecurity.

Procedure

- 1. Create the archive database on a separate device from the one containing audit tables in sybsecurity.
- 2. Create an archive table with columns identical to those in the sybsecurity audit tables. If such a table does not already exist, you can use select into to create an empty one by having a false condition in the where clause. For example:

```
use aud_db
go
select *
```

```
into audit_data
from sybsecurity.dbo.sysaudits_01
where 1 = 2
```

The where condition is always false, so an empty duplicate of sysaudits 01 is created.

The select into/bulk copy database option must be turned on in the archive database (using sp dboption) before you can use select into.

Results

The threshold procedure, after using sp_configure to change the audit table, can use insert and select to copy data to the archive table in the archive database. The procedure can execute commands similar to these:

```
insert aud_db.sso_user.audit_data
select * from sybsecurity.dbo.sysaudits_01
```

11.2.7.2.3 Example Threshold Procedure for Audit Segments

This sample threshold procedure assumes that three tables are configured for auditing.

```
declare @audit table number int
** Select the value of the current audit table
select @audit table number = scc.value
from master.dbo.syscurconfigs scc, master.dbo.sysconfigures sc
where sc.config=scc.config and sc.name = "current audit table"
** Set the next audit table to be current.
** When the next audit table is specified as 0,
** the value is automatically set to the next one.
*/
exec sp configure "current audit table", 0, "with truncate"
** Copy the audit records from the audit table
** that became full into another table.
if @audit_table_number = 1
   begin
        insert aud db.sso user.sysaudits
           select * from sysaudits_01
        truncate table sysaudits 01
   end
else if @audit table number = 2
       insert aud_db.sso_user.sysaudits
select * from sysaudits_02
        truncate table sysaudits 02
   end
return(0)
```

11.2.7.2.4 Attach the Threshold Procedure to Each Audit Segment

Use sp addthreshold to attach the threshold procedure to each audit table segment.

Before executing sp_addthreshold:

- Determine the number of audit tables configured for your installation and the names of their device segments
- Have the permissions and roles you need for sp_addthreshold for all the commands in the threshold procedure

sp_addthreshold and sp_modifythreshold check to ensure that only a user with sa_role directly granted can add or modify a threshold. All system-defined roles that are active when you add or modify a threshold are inserted as valid roles for your login in the systhresholds table. However, only directly granted roles are activated when the threshold procedure fires.

11.2.7.2.5 Audit Tables and Their Segments

When you install auditing, auditinit displays the name of each audit table and its segment. The segment names are "aud_seg1" for sysaudits 01, "aud_seg2" for sysaudits 02, and so on

You can find information about the segments in the sybsecurity database if you execute sp_helpsegment with sybsecurity as your current database. One way to find the number of audit tables for your installation is to execute the following SQL commands:

```
use sybsecurity
go
select count(*) from sysobjects
    where name like "sysaudit%"
go
```

Get additional information about the audit tables and the sybsecurity database by executing the following SQL commands:

```
sp_helpdb sybsecurity
go
use sybsecurity
go
sp_help sysaudits_01
go
sp_help sysaudits_02
go
...
```

11.2.7.2.6 Required Roles and Permissions

To execute sp addthreshold, you must be either the database owner or a system administrator.

A system security officer should be the owner of the sybsecurity database and, therefore, should be able to execute sp_addthreshold. In addition to being able to execute sp_addthreshold, you must have permission to execute all the commands in your threshold procedure. For example, to execute sp configure for current audit table, the sso role must be active. When the threshold procedure fires, Adaptive Server attempts to turn on all the roles and permissions that were in effect when you executed sp addthreshold.

To attach the threshold procedure audit thresh to three device segments:

```
use sybsecurity
sp_addthreshold sybsecurity, aud_seg_01, 250, audit_thresh
sp_addthreshold sybsecurity, aud_seg_02, 250, audit_thresh sp_addthreshold sybsecurity, aud_seg_03, 250, audit_thresh
```

The sample threshold procedure audit thresh receives control when fewer than 250 free pages remain in the current audit table.

For more information about adding threshold procedures, see Managing Free Space with Thresholds, in System Administration Guide: Volume 2.

11.2.7.2.7 Auditing with the Sample Threshold Procedure in **Place**

After you enable auditing, SAP ASE writes all audit data to the initial current audit table, sysaudits 01.

When sysaudits 01 is within 250 pages of being full, the threshold procedure audit thresh fires. The procedure switches the current audit table to sysaudits 02, and, immediately, SAP ASE starts writing new audit records to sysaudits 02. The procedure also copies all audit data from sysaudits 01 to the audit data archive table in the audit db database. The rotation of the audit tables continues in this fashion without manual intervention.

11.2.7.3 Audit Configuration Parameters

Use the audit queue size and suspend audit when device full configuration parameters for your auditing installation.

Set the following configuration parameters:

- audit queue size sets the number of records in the audit queue in memory.
- suspend audit when device full determines what SAP ASE does if the current audit table becomes completely full. The full condition occurs only if the threshold procedure attached to the current table segment is not functioning properly.

11.2.7.3.1 Manage the Size of the Audit Queue

The amount of memory consumed by the audit queue pool is defined by the audit queue size parameter, and includes data buffers and overhead for the memory pool. However, the amount of memory in the pool can vary between releases and chip architectures.

The default audit queue size is 100 bytes.

Use sp configure to set the length of the audit queue. The syntax is:

```
sp_configure "audit queue size", [<value>]
```

value is the number of records that the audit queue can hold. The minimum value is 1, and the maximum is 65,535. For example, to set the audit queue size to 300, execute:

```
sp_configure "audit queue size", 300
```

For more information about setting the audit queue size and other configuration parameters, see *Reference Manual: Configuration Parameters*.

11.2.7.3.2 Suspend Auditing if Devices are Full

If you have two or more audit tables, each on a separate device other than the master device, and have a threshold procedure for each audit table segment, the audit devices should never become full.

Only if a threshold procedure is not functioning properly would the "full" condition occur. Use sp_configure to set the suspend audit when device full parameter to determine what happens if the devices do become full. Choose one of these options:

- Suspend the auditing process and all user processes that cause an auditable event. Resume normal operation after a system security officer clears the current audit table.
- Truncate the next audit table and start using it. This allows normal operation to proceed without intervention from a system security officer.

Use sp_configure to set this configuration parameter. You must have the sso role active. The syntax is:

```
sp_configure "suspend audit when device full",
      [0|1]
```

- 0 truncates the next audit table and starts using it as the current audit table whenever the current audit table becomes full. If you set the parameter to 0, the audit process is never suspended; however, older audit records are lost if they have not been archived.
- 1 (the default value) suspends the audit process and all user processes that cause an auditable event. To resume normal operation, the system security officer must log in and set up an empty table as the current audit table. During this period, the system security officer is exempt from normal auditing. If the system security officer's actions would generate audit records under normal operation, SAP ASE sends an error message and information about the event to the error log.

If you have a threshold procedure attached to the audit table segments, set suspend audit when device full to 1 (on). If it is set to 0 (off), SAP ASE may truncate the audit table that is full before your threshold procedure has a chance to archive your audit records.

11.2.7.4 Query the Audit Trail

To guery the audit trail, use SQL to select and summarize the audit data.

If you follow the procedures discussed in *Audit Trail Management*, the audit data is automatically archived to one or more tables in another database. For example, assume that the audit data resides in a table called audit_data in the audit_db database. To select audit records for tasks performed by "bob" on July 5, 1993, execute:

```
use audit_db
go
select * from audit_data
  where loginname = "bob"
  and eventtime like "Jul 5% 93"
go
```

This command requests audit records for commands performed in the pubs2 database by users with the system security officer role active:

```
select * from audit_data
  where extrainfo like "%sso_role%"
  and dbname = "pubs2"
go
```

This command requests audit records for all table truncations (event 64):

```
select * from audit_data
  where event = 64
go
```

To query the audit trail using the name of an audit event, use the audit_event_name function. For example, to request the audit records for all database creation events, enter:

11.2.7.5 Add User-Specified Records to the Audit Trail

 $\verb"sp_addauditrecord" allows users to enter comments into the audit trail. The syntax is:$

```
sp_addauditrecord [<text>] [, <db_name>] [, <obj_name>]
   [, <owner_name>] [, <dbid>] [, <objid>]
```

All the parameters are optional:

- <text> is the text of the message that you want to add to the extrainfo audit table.
- <db_name> is the name of the database referred to in the record, which is inserted into the dbname column of the current audit table.
- <obj_name> is the name of the object referred to in the record, which is inserted into the objname column of the current audit table.
- <owner_name> is the owner of the object referred to in the record, which is inserted into the objowner column of the current audit table.

- <dbid> is an integer value representing the database ID number of db_name, which is inserted into the dbid column of the current audit table. Do not place it in quotes.
- <objid> is an integer value representing the object ID number of obj_name. Do not place it in quotes. <objid> is inserted into the objid column of the current audit table.

You can use sp addauditrecord if:

- You have execute permission on sp addauditrecord.
- The auditing configuration parameter was activated with sp configure.
- The adhoc auditing option was enabled with sp audit.

By default, only a system security officer and the database owner of sybsecurity can use sp addauditrecord. Permission to execute it may be granted to other users.

11.2.7.5.1 Examples of Adding User-Defined Audit Records

The following examples show how to add a record to the current audit table and inserting information into the extrainfo and dbname columns.

The following example adds a record to the current audit table. The text portion is entered into the extrainfo column of the current audit table, "corporate" into the dbname column, "payroll" into the objname column, "dbo" into the objowner column, "10" into the dbid column, and "1004738270" into the objid column:

```
sp_addauditrecord "I gave A. Smith permission to view the payroll table in the corporate database. This permission was in effect from 3:10 to 3:30 pm on 9/22/92.", "corporate", "payroll", "dbo", 10, 1004738270
```

The following example inserts information only into the extrainfo and dbname columns of the current audit table:

```
sp_addauditrecord @text="I am disabling auditing
briefly while we reconfigure the system",
@db_name="corporate"
```

11.2.8 Truncate the Transaction Log

If you enable the trunc log on chkpt option for the sybsecurity database, you do not need to worry about the transaction log becoming full. SAP ASE truncates the log whenever it performs a checkpoint.

With this option enabled, you cannot use dump transaction to dump the transaction log, but you can use dump database to dump the database.

If you follow the procedures in *Setting Up Threshold Procedures*, audit tables are automatically archived to tables in another database. You can use standard backup and recovery procedures for this archive database.

If a crash occurs on the sybsecurity device, you can reload the database and resume auditing. At most, only the records in the in-memory audit queue and the current audit table are lost because the archive database

contains all other audit data. After you reload the database, use sp_configure 'current audit table', <new current audit table>, 'with truncate' to set and truncate the current audit table.

If you have not changed server-wide auditing options since you dumped the database, all auditing options stored in sysauditoptions are automatically restored when you reload sybsecurity. If not, you can run a script to set the options prior to resuming auditing.

11.2.8.1 Manage a Transaction Log with No Truncation

Attaching a last-chance threshold procedure to the transaction log segment allows you to control when the amount of space remaining on the segment is less than a threshold amount.

If you use sp_dboption to turn the trunc log on chkpt off, the transaction log may fill up. Plan to attach a last-chance threshold procedure to the transaction log segment. This procedure takes control when the amount of space remaining on the segment is less than a threshold amount computed automatically by SAP ASE. The threshold amount is an estimate of the number of free log pages that are required to back up the transaction log.

The default name of the last-chance threshold procedure is sp_thresholdaction, but you can specify a different name with sp modifythreshold, as long as you have the sa role active.

i Note

 $sp_modifythreshold$ checks to ensure you have "sa_role" active. See Attaching the Threshold Procedure to Each Audit Segment for more information.

SAP ASE does not supply a default procedure, however, *Managing Free Space with Thresholds*, in *System Administration Guide: Volume 2* contains examples of last-chance threshold procedures. The procedure should execute the dump transaction command, which truncates the log. When the transaction log reaches the last-chance threshold point, any transaction that is running is suspended until space is available. The suspension occurs because the option abort xact when log is full is always set to false for the sybsecurity database. You cannot change this option.

With the trunc log on chkpt option disabled, you can use standard backup and recovery procedures for the sybsecurity database, but be aware that the audit tables in the restored database may not be in sync with their status during a device failure.

11.2.9 Single-Table Auditing

If you use only a single audit table, you create a window of time while you are archiving audit data and truncating the audit table during which incoming audit records are lost. There is no way to avoid this when using only a single audit table.

SAP strongly recommends that you not use single-device auditing for production systems.

If you use only a single audit table, your audit table is likely to fill up. The consequences of this depend on how you have set suspend audit when device full. If you have suspend audit when device full set to on, the audit process is suspended, as are all user processes that cause auditable events. If suspend audit

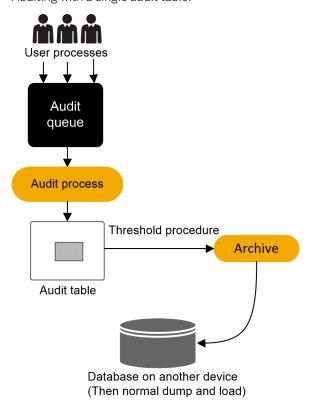

when device full is off, the audit table is truncated, and you lose all the audit records that were in the audit table.

For non-production systems, where the loss of a small number of audit records may be acceptable, you can use a single table for auditing, if you cannot spare the additional disk space for multiple audit tables, or you do not have additional devices to use.

The procedure for using a single audit table is similar to using multiple audit tables, with these exceptions:

- During installation, you specify only one system table to use for auditing.
- During installation, you specify only one device for the audit system table.
- The threshold procedure you create for archiving audit records is different from the one you would create if you were using multiple audit tables.

Auditing with a single audit table:

11.2.9.1 Threshold Procedure for Single-Table Auditing

The steps to configure for single-table auditing is the same as for multiple-table auditing.

For single-table auditing, the threshold procedure should:

- Archive the almost-full audit table to another table, using the insert and select commands.
- Truncate the audit table to create space for new audit records, using the truncate table command.

Before you can archive your audit records, create an archive table that has the same columns as your audit table. After you have done this, your threshold procedure can use insert with select to copy the audit records into the archive table.

Here is a sample threshold procedure for use with a single audit table:

```
create procedure audit thresh as
** copy the audit records from the audit table to
** the archive table
insert aud_db.sso_user.audit_data
   select * from sysaudits 01
return(0)
go
** truncate the audit table to make room for new
** audit records
truncate table "sysaudits 01"
```

After you have created your threshold procedure, you will need to attach the procedure to the audit table segment. For instructions, see Attaching the Threshold Procedure to Each Audit Segment.

On a multiprocessor, the audit table may fill up even if you have a threshold procedure that triggers before the audit table is full. For example, if the threshold procedure is running on a heavily loaded CPU, and a user process performing auditable events is running on a less heavily loaded CPU, the audit table may fill up before the threshold procedure triggers. The configuration parameter suspend audit when device full determines what happens when the audit table fills up. For information about setting this parameter, see Suspending Auditing if Devices are Full. .

11.2.9.2 What Happens when the Current Audit Table is Full?

These events occur when the current audit table is full.

- 1. The audit process attempts to insert the next audit record into the table. This fails, so the audit process terminates. An error message is written to the error log.
- 2. When a user attempts to perform an auditable event, the event cannot be completed because auditing cannot proceed. The user process terminates. Users who do not attempt to perform an auditable event are
- 3. If you have login auditing enabled, no one can log in to the server except a system security officer.
- 4. If you are auditing commands executed with the sso role active, the system security officer cannot execute commands.

11.2.9.3 Recover When the Current Audit Table is Full

If the current audit device and the audit queue become full, the system security officer becomes exempt from auditing.

Every auditable event performed by a system security officer after this point sends a warning message to the error log file. The message states the date and time and a warning that an audit has been missed, as well as the login name, event code, and other information that would normally be stored in the extrainfo column of the audit table.

When the current audit table is full, the system security officer can archive and truncate the audit table as described in *Archiving the Audit Table*. A system administrator can execute shutdown to stop the server and then restart the server to reestablish auditing.

If the audit system terminates abnormally, the system security officer can shut down the server after the current audit table has been archived and truncated. Normally, only the system administrator can execute shutdown.

11.3 Audit Tables

The system audit tables can be accessed only by a system security officer, who can read the tables by executing SQL commands. The only commands that are allowed on the system audit tables are select and truncate.

For content of audit tables sysaudits_01 - sysaudits_08, see Reference Manual: Tables > System Tables > sysaudits_01 - sysaudits_08.

11.3.1 Reading the extrainfo Column

The extrainfo column in the sysaudits table contains a sequence of data separated by semicolons. The data is organized in the following categories.

Table 34: Information in the extrainfo Column

Position	Category	Description
1	Roles	A list of active roles, separated by blanks.
2	Full command text	For commands supported by full text auditing, full text of an audited command.
	or	or
	Keywords or options	The name of the keyword or option that was used for the event. If multiple keywords or options are listed, they are separated by commas.
3	Previous value	If the event resulted in the update of a value, this item contains the value prior to the update.
4	Current value	If the event resulted in the update of a value, this item contains the new value.
5	Other information	Additional security-relevant information that is recorded for the event. For example, parameter names and values can be recorded here.
6	Proxy information	The original login name if the event occurred while a set proxy was in effect.

Position	Category	Description
7	Principal name	The principal name from the underlying security mechanism if the user's login is the secure default login, and the user logged in to SAP ASE via unified login. The value of this item is NULL if the secure default login is not being used.

This example shows an extrainfo column entry for the event of changing an auditing configuration parameter.

sso_role; suspend audit when device full; 1; 0; ; ; sa/ase;

This entry indicates that:

- 1 a user with sso_role (system security officer)
- 2-changed suspend audit when device full
- 3 from 1 (previous value)
- 4 to 0 (current value)
- 5 there is no other information for this entry
- 6 there is no proxy information, because set proxy was not in effect
- 7 the principal name is sa/ase.

The other fields in the audit record give other pertinent information. For example, the record contains the server user ID (suid) and the login name (loginname).

11.3.2 Values in event and extrainfo Columns

This table includes a complete list of sp_audit parameters and information displayed in event and extrainfo columns of sysaudits tables.

i Note

The fourth column in this table only lists information displayed in positions 2, 3, 4, and 5 of extrainfo column. The information in positions 1, 6, and 7 follows the rules described in Reading the extrainfo Column [page 383].

Audit option	Command or access to be audited	Event	Information in positions 2 — 5 of extrainfo
(Automatically audited event not controlled by an option)	<pre>Enabling auditing with: sp_configure "auditing", 1</pre>	73	_

Audit option	Command or access to be audited	Event	<pre>Information in positions 2 - 5 of extrainfo</pre>
(Automatically audited event not controlled by an option)	Disabling auditing with: sp_configure "auditing", 0	74	_
adhoc	User-defined audit record created using sp_addauditrecord	1	Only text parameter value is displayed in extrainfo.
all	All actions of a particular user, or logins of a particular role	62	_
allow	allow	164	2 — Full text of the command
alter	alter database	2	2 — Full text of the command (for alter
	alter index	155	role, password is obfuscated)
	alter role	85	
	alter table	3	
	<pre>altermodify owner(including alter encryption key modify owner)</pre>	132	
bcp	bcp inutility	4	-
bind	sp_bindefault	6	5 — Name of the default
	sp_bindmsg	7	5 — Message ID
	sp_bindrule	8	5 — Name of the rule
cluster	Cluster commands	124	-
cmdtext	Execution of a command or procedure by a specific user.	92	Only full text of command (for supported commands) or keywords are displayed in extrainfo. Sensitive parameters are obfuscated.
config_history	Configuration history using:	154	5 — Includes procedure name, parameter
	sp_audit		name, old value, new value, mode (static or active), and instance ID.
	sp_cacheconfig		
	sp_configure		
	sp_poolconfig		
	1 _1 11 11 11		

Audit option	Command or access to be audited	Event	<pre>Information in positions 2 — 5 of extrainfo</pre>
create	create database	9	2 — Full text of the command (for create
	create default	14	role, password is obfuscated
	create function	97	
	create index	104	
	create procedure	11	
	create role	85	
	create rule	13	
	create service	11	
	create table	10	
	create trigger	12	
	create view	16	
	sp_addmessage	15	5 — Message number
dbaccess	Direct or indirect access to the database by any user	17	2 — use cmd (direct access using use <dbname>)</dbname>
			outside reference (indirect access from another database)
dbcc	dbcc with all keywords	81	2 — Full text of the command
delete	delete from a table	18	2 — Full text of the command
	delete from a view	19	5 — Parameter names and values
deny	deny	163	2 — Full text of the command
disk	disk init	20	2 — Full text of the command
	disk resize	100	5 — Parameter names and values
	disk mirror	23	2 — Full text of the command
	disk refit	21	
	disk reinit	22	
	disk remirror	25	
	disk unmirror	24	

Audit option	Command or access to be audited	Event	Information in positions $2-5$ of extrainfo
drop	drop database	26	2 — Full text of the command
	drop default	31	
	drop function	98	
	drop index	105	
	drop procedure, drop service	28	
	drop role	85	
	drop rule	30	
	drop table	27	
	drop trigger	29	
	drop view	33	
	sp_dropmessage	32	5 — Message number
dump	dump database	34	2 — Full text of the command (for dump
	dump databasecumulative	150	database, password is obfuscated)
	dump transaction	35	
dump_config	dump configuration to	149	2 — Full text of the command
encryption_key	alter encryption key as not default	108	2 — Full text of the command (sensitive parameters are obfuscated)
	alter encryption key add encryption	119	-
	alter encryption key drop encryption	120	-
	alter encryption key modify encryption	118	-
	alter encryption key recover encryption	122	-
	alter encryption regenerate key	135	-
	create encryption key	107	-
	drop encryption key	109	-

Audit option	Command or access to be audited	Event	Information in positions 2 — 5 of extrainfo
	sp_encryption	106	2 — If password is set the first time:
			<pre>ENCR_ADMIN system_encr_passwd password ********</pre>
			If the password is subsequently changed:
			<pre>ENCR_ADMIN system_encr_passwd password ************************************</pre>
errorlog	sp_errorlog	127	5 — ERRORLOG_ADMIN, all input parameters
errors	Fatal error	36	5-
	Non-fatal error	37	<error number="">.<severity>.<state></state></severity></error>
exec_procedure	Execution of a system stored procedure	38	5 — Values of all input parameters
exec_trigger	Execution of a trigger	39	_
func_dbaccess	Access to a database using the following functions:	86	2 — Name of the function
	allocinfo		
	curunreservedpgs		
	dbencryption_status		
	db_instanceid		
	db_id		
	db_name		
	db_recovery_status		
	dol_downgrade_check		
	is_quiesced		
	hadr_mode		
	hadr_state		
	lct_admin		
	shrinkdb_status		

Audit option	Command or access to be audited	Event	Information in positions 2 — 5 of extrainfo
func_obj_acces	Access to an object using the following functions:	86	2 — Name of the function
	col_length		
	col_name		
	data_pages		
	defrag_status		
	derived_stat		
	identity_burn_max		
	index_col		
	index_colorder		
	index_name		
	lockscheme		
	next_identity		
	object_id		
	object_name		
	object_owner_id		
	pagesize		
	partition_id		
	partition_object_id		
	partition_name		
	reserve_identity		
	reserved_pages		
	row_count		
	spaceusage		
	used_pages		
grant	grant	40	2 — Full text of the command
	grant role	85	2 — Full text of the command
			5 — Parameter names and values

Audit option	Command or access to be audited	Event	Information in positions 2 — 5 of extrainfo
insert	insert into a table	41	2 — Full text of the command
	insert into a view	42	5 — Parameter names and values
install	installjava	93	_
load	load database	43	2 — Full text of the command (for load
	load databasecumulative	151	database, sensitive parameters are obfuscated)
	load transaction	44	cated)
load	<pre>loadwith [headeronly listonly verifyonly]</pre>	43	_
login	Audits login attempts into the SAP ASE server.	45	2 — Host name and IP address of the machine from which the login was performed.
			For failed logins: <error number.severity.state=""></error>
login_admin	alter login	138	2 — Full text of the command (for create
	create login	103	login and alter login, password is ob- fuscated)
	drop login	139	rasoutou)
login_locked	Audits the hostname and network IP address when a login account is locked due to exceeding the configured number of failed login attempts	112	5 — Host machine name, host machine IP address, network password encryption information, lock reason from syslogins table
logout	Any logouts from the SAP ASE server	46	5 — Host name
mount	mount database	101	2 — Full text of the mount database command
password	alter roleadd passwd	134	2 — Full text of the command (password is
	alter roledrop passwd		obfuscated)
	create role with passwd		
	sp_passwordpolicy and all its actions except list	115	5 — PASSWORD_ADMIN policy name and options

Audit option	Command or access to be audited	Event	Information in positions $2-5$ of extrainfo
quiesce	quiesce database,prepare	96	2 — Full text of the command
	database	113	
	<pre>quiesce databasehold security</pre>	114	
	quiesce databaserelease		
reference	References between tables	91	2 — Full text of the command
remove	remove java	94	_
revoke	revoke	47	2 — Full text of the command
	revoke role	85	2 — Full text of the command
			5 — Parameter names and values
role	alter role	55	2 — Full text of the command (password is
	create role		<pre>obfuscated for alter role, create role, and set role)</pre>
	drop role		
	grant role		
	revoke role		
	set role	55	
role_locked	alter rolelock	133	2 — Full text of the alter rolelock command
rpc	Remote procedure call from another	48	2 — Name of client program
	server		5 — Server name, host name of the machine from which the RPC was executed
	Remote procedure call to another server	49	2 — Procedure name
security	Audit table access	61	_
	Audit table change	77	_
	Audit table truncation	58	_
	Audit option change	78	_

Audit option	Command or access to be audited	Event	Information in positions $2-5$ of extrainfo
	Changes to the LDAP state	123	2 — Primary URL state and secondary URL state
			3 — Previous value
			4 — Current value
			5 — Indicates whether the state change happened automatically or because of a manually entered command
	Security command or access to be audited, specifically, starting SAP ASE with – u option to unlock the administrator's account	95	5-Unlocking admin account
	Server start	50	5 —
			-d <masterdevicename></masterdevicename>
			-i <interfaces file="" path=""></interfaces>
			-S <servername></servername>
			-e <errorfilename></errorfilename>
	Server shutdown	51	2-shut down
	alter login	138	2 — Full text of the command (password is
	create login	103	<pre>obfuscated for alter login and create login)</pre>
	drop login	139	109111)
	alter login profile	140	2 — Full text of the command
	create login profile	137	
	drop login profile	141	
	alter role	85	2 — Full text of the command (password is
	create role		<pre>obfuscated for alter role and create role)</pre>
	drop role	Totel	
	grant role		
	revoke role		
	connect to (CIS only)	90	2 — Full text of the connect to command
	kill (CIS only)	89	2 — Full text of the kill command

Audit option	Command or access to be audited	Event	<pre>Information in positions 2 — 5 of extrainfo</pre>
	online database	83	2 — Full text of the online database command
	set role	55	2 — Full text of the command (password is obfuscated)
	set session authorization/se t proxy	88	2 — Full text of the command
	sp_configure	82	2-SETCONFIG
			5 — If a parameter is being set: number of configuration parameter
			If a configuration file is being used to set parameters: name of the configuration file
	sp_hidetext	145	5 — Total number of objects for which sp_hidetext was executed, and object ids from syscomments table.
	Regeneration of a password by an SSO	76	2 - Setting SSO password
			5 — Login name
	Regeneration of asymmetric keypairs for network password encryption by the system or sp_passwordpolicy	117	_
	When sp_passwordpolicy 'set', 'disallow simple passwords', 1, and a login with a simple password is created using create login	125	-
	sp_ssladmin administration enabled	99	2—SSL_ADMIN addcert if adding a certification
	sp_webservices	110, 111	2 — deploy/undeploy if deploying/undeploying a web service.
			deploy_all/undeploy_all if deploy-ing/undeploying all web services

Audit option	Command or access to be audited	Event	<pre>Information in positions 2 - 5 of extrainfo</pre>
	Built-in functions:	86	2 — Name of the function
	authmech		
	show_cached_plan_in_xml		
	show_cached_text		
	<pre>show_cached_text_long, show_condensed_text</pre>		
	show_plan		
	valid_user		
	workload_metric		
	proc_role function when executed from within a system stored procedure	80	5 — Required roles
security_profi	alter login profile	140	2 — Full text of the command
le	create login profile	137	
	drop login profile	141	
select	select from a table	62	2 — Full text of the command
	select from a view	63	5 — Parameter names and values
setuser	setuser	84	5 — Name of the user being set
sproc_auth	Authorization checks that are performed inside system stored procedures. Event 80 is recorded when granular permissions are disabled. Event 146 is recorded when granular permissions are enabled.	80, 146	5 — Permission needed to run the stored procedure
table_access	delete	18	2 — Full text of the command
	insert	41	5 — Parameter names and values
	select	62	
	update	70	
thread_pool	alter thread pool	143	2 — Full text of the command
	create thread pool	142	
	drop thread pool	144	
transfor table	transfer table	136	2 — Full text of the command

Audit option	Command or access to be audited	Event	Information in positions 2 — 5 of extrainfo
truncate	truncate table	64	2 — Full text of the command
unbind	sp_unbindefault	67	_
	sp_unbindmsg	69	
	sp_unbindrule	68	
unmount	unmount database	102	2 — Full text of the command
	create manifest file	116	_
update	update to a table	70	2 — Full text of the command
	update to a view	71	
view_access	delete	19	2 — Full text of the command
	insert	42	5 — Parameter names and values
	select	63	
	update	71	

11.3.3 Audit Event Values

This figure includes all audit events in ascending order.

Table 35: Audit Event Values

Audit event ID	Audited command or access	Audit event ID	Audited command or access
1	ad hoc audit record	81	dbcc
2	alter database	82	sp_configure
3	alter table	83	online database
4	bcp in	84	setusercommand
5	Reserved	85	alter role, create role, drop role,
			grant role, or revoke role
6	sp_bindefault	86	Built-in functions
7	sp_bindmsg	87	Reserved

Audit event ID	Audited command or access	Audit event ID	Audited command or access
8	sp_bindrule	88	set proxy
			set session authorization
9	create database	89	kill
10	create table	90	connect to
11	create procedure, create service	91	Creation of references to tables
12	create trigger	92	Command text
13	create rule	93	installjava
14	create default	94	remove java
15	sp_addmessage	95	Unlock admin account
16	create view	96	quiesce database, prepare database
17	Access to database by any user	97	create function (SQLJ)
18	delete from a table	98	drop function (SQLJ)
19	delete from a view	99	sp_ssladmin
20	disk init	100	disk resize
21	disk refit	101	mount database
22	disk reinit	102	unmount database
23	disk mirror	103	create login
24	disk unmirror	104	create index
25	disk remirror	105	drop index
26	drop database	106	sp_encryption
27	drop table	107	create encryption key
28	drop procedure, drop service	108	alter encryption key as not default
29	drop trigger	109	drop encryption key
30	drop rule	110	sp_webservices(deploy)
			.

Audit event ID	Audited command or access	Audit event ID	Audited command or access
31	drop default	111	sp_webservices(undeploy)
32	sp_dropmessage	112	Login locked due to exceeding the configured number of failed attempts
33	drop view	113	quiesce databasehold security
34	dump database	114	quiesce databaserelease
35	dump transaction	115	<pre>sp_passwordpolicy and all of its actions ex- cept "list"</pre>
36	Fatal error	116	create manifest file
37	Non-fatal error	117	Regeneration of asymmetric keypairs for network password encryption by system or sp_passwordpolicy
38	Execution of stored procedure	118	alter encryption key modify encryption

11.3.4 Monitoring Failed Login Attempts

When the audit option <code>login_locked</code> is enabled, the event <code>Locked_Login_(value_112)</code> is recorded when a login account is locked due to exceeding the configured number of failed login attempts.

To enable login_locked, enter:

```
sp_audit "login_locked","all","all","ON"
```

If the audit tables are full and the event cannot be logged, a message with the information is sent to the error log.

The host name and network IP address are included in the audit record. Monitoring the audit logs for the Locked Login event number 112 helps to identify attacks on login accounts.

11.3.5 Auditing Login Failures

Although client applications may fail to login for many reasons, SAP ASE does not provide them with any detailed information about the login failure. This is done to avoid giving information to ill intentioned users attempting to crack passwords or otherwise breach the authentication mechanisms.

However, as a system administrator, detailed information is useful for diagnosing administrative or configuration problems, and it is useful to security officers for investigating attempts to breach security.

This enables auditing for all login failures:

```
sp audit "login", "all", "all", "fail"
```

In order to provide a barrier to inappropriate use of the information, only a user granted the SSO role can access the audit trail information containing this sensitive information.

Audits login failures for the following conditions:

- For SAP ASE started as a Windows Service, if the SQLServer service is paused (for example, by the Microsoft Management Console for Services).
- · If a remote server attempts to establish a site handler for server-to-server RPCs, but insufficient resources (or any of the other conditions listed here) cause the site handler initialization to fail.
- Using SAP ASE for Windows with the Trusted Login or Unified Login configuration, but the specified user is not a trusted administrator (that is, an authentication failure).
- SAP ASE does not support the SQL interface requested by the client.
- · A user is attempting to log into SAP ASE when it is in single-user mode. In single-user mode, exactly one user with the sa_role is allowed to log in to SAP ASE. Additional logins are prevented, even if they have the sa_role.
- The syslogins table in the master database fails to open, indicating the master database has an internal error.
- A client attempts a remote login, but sysremotelogins cannot be opened, or there is no entry for the specified user account and no guest account exists.
- A client attempts a remote login and, although it finds an entry referring to a local account for the specified user in sysremotelogins, the referenced local account does not exist.
- A client program requests a security session (for example, a Kerberos authentication), but the security session could not be established because:
 - The security subsystem was not initialized at startup.
 - Insufficient memory resources for allocated structures.
 - The authentication negotiation failed.
- An authentication mechanism is not found for the specified user.
- The specified password was not correct.
- syslogins does not contain the required entry for the specified login.
- The login account is locked.
- SAP ASE has reached its limit for the number of user connections.
- The configuration parameter unified login required is set, but the login has not been authenticated by the appropriate security subsystem.
- The network buffers are unavailable, or the requested packet size is invalid.

- A client application requests a host-based communication socket connection, but memory resources for the host-based communication buffers are not available.
- A shutdown is in progress, but the specified user does not have the sa role.
- SAP ASE could not open the default database for a login, and this login does not have access to the master database.
- A client makes a high availability login fail over request, but the high availability subsystem is does not have a high availability session for this login, or the login is unable to wait for the fail over to complete.
- A client requests a high availability login setup, but the high availability subsystem is unable to create the session or is unable to complete the TDS protocol negotiations for the high availability session.
- SAP ASE fails to setup tempdb for a login.
- TDS Login Protocol errors are detected.
