Two roles exist during the GR process: Restarter and Helper. Accordingly, IS-IS GR is divided into the IS-IS GR Restart capability and IS-IS GR Help capability. A device with the GR Restart capability can send a GR request and execute GR. A device with the GR Help capability can receive a GR request and help its neighbor with GR implementation. The GR process starts when the Restarter sends a GR request. After receiving the GR request, the neighboring device enters Help mode to help the Restarter reestablish its LSDB while maintaining the neighbor relationship with the Restarter. The main GR working mechanism is as follows:

When an IS-IS device needs to perform GR, it instructs its neighbor to maintain their neighbor relationship so that other devices in the network cannot sense the change in the topological relationship and the neighbor will not recalculate the route and update its forwarding table. The IS-IS device synchronizes and restores the LSDB to its pre-GR state with the help of the neighbor to ensure that the route and forwarding table remain unchanged before and after GR implementation and data forwarding is not interrupted.

The Restarter performs the following operations during the GR process:

1. The GR Restarter notifies the GR Helpers that it will be restarted.

Figure 6-14 Restart Notification by the GR Restarter

Switch A is a GR Restarter, and Switch B and Switch C are the GR Helpers for Switch A. Switch A sends a GR request instructing all its neighbors not to delete the neighbor relationships with Switch A when it is restarted. After receiving the GR request, the neighbors send GR responses to the GR Restarter, and will maintain their neighbor relationships with the GR Restarter during the GR time (specified by **GR grace-period**) notified by the GR Restarter.

2. The GR Restarter is restarted.

Figure 6-15 Restart Performed by the GR Restarter

When the GR Restarter is restarted, its IS-IS interface goes from Down to Up. Because the GR Helpers know that the GR Restarter is in IS-IS restart state, they maintain their neighbor relationships with the GR Restarter during the GR time and retain the routes from the GR Restarter.

3. The GR Restarter synchronizes topology and routing information from the GR Helpers.

Figure 6-16 LSDB Synchronization

After IS-IS restart, the GR Restarter synchronizes topology or routing information from the GR Helpers and recalculates its routing table. During this process, any change in the routing table is not updated to the forwarding table.

4. GR is completed when the GR Restarter finishes LSDB synchronization. Then all devices enter IS-IS interaction state.

Figure 6-17 GR Completion

After the GR Restarter synchronizes all required data, all devices enter IS-IS interaction state. The GR Restarter's routing table is updated to the forwarding table and invalid entries are cleared. Because the GR Restarter is completely restored to the pre-restart state under stable network conditions, its routing table and forwarding table remain unchanged before and after GR.

Notes

- IS-IS GR is implemented based on RFC5306: Restart Signaling for IS-IS.

✓ All products support the IS-IS GR Helper capability.

Configuration Steps

➤ Enabling the IS-IS GR Restart Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

➤ Configuring the Maximum GR Time

- Perform this configuration based on requirements.
- Run the **graceful-restart grace-period** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

➤ Enabling the IS-IS GR Help Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart helper** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the routing table and forwarding table remain unchanged before and after GR.

Related Commands

➤ Enabling the IS-IS GR Restart Capability

Command	graceful-restart
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to enable the IS-IS GR Restart capability. As long as the network conditions remain unchanged, IS-IS can be restarted and restored to the pre-restart state without impact on data forwarding.

➤ Configuring the Maximum GR Time

Command	graceful-restart grace-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the GR time. The value range is 1s to 65,535s. The default value is 300s.
Command Mode	IS-IS routing process configuration mode

Usage Guide	N/A

➤ Enabling the IS-IS GR Help Capability

Command	graceful-restart helper disable
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use the graceful-restart helper disable command to disable the IS-IS GR Help capability. The command enables IS-IS to ignore the GR request sent by the device to be restarted.

Configuration Example

➤ Configuring IS-IS GR

Configuration Requirements	Two S8600 series high-end devices have the IS-IS GR Restart capability and are equipped with master/slave management boards for redundant backup at the control plane. IS-IS neighbor relationships are established between S86-1 and S3750/S3760 and between S86-2 and S3750/S3760. The system software of all devices supports the IS-IS GR Help capability. The following configuration requirements exist: Enable the IS-IS GR Restart capability with proper GR Time setting on S86-1 and S86-2 to realize uninterrupted forwarding and improve core device reliability. Disable the IS-IS GR Help capability on S3750 to exclude it from the Help process. By default, other device supports the IS-IS GR Help capability and require no additional configuration.
Figure 6-18 IS-IS GR Topology	
Configuration Steps	Configure IS-IS. (Omitted) Configure Ethernet interfaces. (Omitted)
S86-1	Configure IS-IS GR.
	<pre>S86-1 (config)# router isis CS86-1(config-router)# graceful-restart CS86-1(config-router)# graceful-restart grace-period 60</pre>
S86-2	Configure IS-IS GR.
	<pre>CS86-2(config)# router isis</pre>

	<pre>CS86-2(config-router)# graceful-restart CS86-2(config-router)# graceful-restart grace-period 80</pre>
S3750	Disable the IS-IS Help capability.
	<pre>S3750(config)# router isis S3750(config-router)# graceful-restart helper disable</pre>
Verification	Check whether the routing table and forwarding table remain unchanged before and after GR. Check whether S86-1 and S86-2 synchronize topology and routing information from S3760.
S86-1	<pre>S86-1# show isis neighbors S86-1# show isis database detail</pre>
S86-2	<pre>S86-2# show isis neighbors</pre>
S3760	<pre>S3760# show isis neighbors</pre>

6.4.8 Configuring IS-IS NSR

Configuration Effect

- IS-IS nonstop routing (IS-IS NSR) helps improve system reliability. During the active/standby switchover of devices in distributed or Virtual Switch Unit (VSU) mode, user data traffic keeps being forwarded without interruption.

Working Mechanism of IS-IS NSR

NSR backs up relevant IS-IS information from the master Supervisor Engine to the slave Supervisor Engine of the distributed device, or from the master device to the slave device in VSU mode, so that the device can automatically recover the link state and regenerate a route upon active/standby switchovers, without requiring help from neighbor devices during the recovery.

Notes

For the same IS-IS process, either NSP or GR is enabled, because they are exclusive.

The switchover of distributed devices and VSU devices takes a period of time. If the IS-IS neighbor keepalive duration is less than the switchover duration, IS-IS neighbor relationship with the neighbor device is removed, and the services are interrupted during the switchover. Therefore, it is recommended to set the IS-IS neighbor keepalive duration not less than the default value. When Fast Hello is enabled, the IS-IS neighbor keepalive duration is less than 1 second and the IS-IS neighbor relationship times out during the switchover, causing NSR failures. Therefore, it is recommended to disable Fast Hello when NSR is enabled.

Configuration Steps

Configuring IS-IS NSR

- Optional. IS-IS NSR is disabled by default. Perform this configuration as required.
- Configure NSR in IS-IS routing process configuration mode on the required devices unless otherwise specified.

Verification

- Verify that user data traffic keeps being forwarded without interruption during the hot-backup switchover of devices in distributed or VSU mode.

Related Commands

▾ Enabling NSR

Command	nsr
Parameter	N/A
Description	
Configuration Mode	IS-IS routing process configuration mode
Usage Guide	NSR backs up relevant IS-IS information from the master Supervisor Engine to the slave Supervisor Engine of the distributed device, or from the master device to the slave device in VSU mode, so that the device can automatically recover the link state and regenerate a route upon active/standby switchovers, without requiring help from neighbor devices during the recovery. Information such as the neighbor relationship and link status needs to be backed up. For the same IS-IS process, either NSP or GR is enabled, because they are exclusive. The switchover of distributed devices and VSU devices takes a period of time. If the IS-IS neighbor keepalive duration is less than the switchover duration, IS-IS neighbor relationship with the neighbor device is removed, and the services are interrupted during the switchover. Therefore, it is recommended to set the IS-IS neighbor keepalive duration not less than the default value. When Fast Hello is enabled, the IS-IS neighbor keepalive duration is less than 1 second and the IS-IS neighbor relationship times out during the switchover, causing NSR failures. Therefore, it is recommended to disable Fast Hello when NSR is enabled. By default, if the DIS is a Ruijie device, the neighbor relationship between the neighbor device and the Ruijie device is maintained for 10 seconds at most (the DIS interface sends one HELLO packet every 3.3 seconds). However, the active/standby switchover of Ruijie devices takes at least 7 seconds. If the switchover takes place when the interface is to send HELLO packets, the period for the neighbor device to receive HELLO packets again may be greater than 10 seconds, leading to neighbor down. To avoid neighbor down, when NSR is enabled, increase the time for maintaining the neighbor relationship with the neighbor device that is to send HELLO packets by 10 seconds.

Configuration Example

▾ Configuring IS-IS NSR

Configuration Requirements	Two high-end RG-S8600 devices are required and both support IS-IS NSR and are equipped with master and slave Super Engines to implement redundancy backup on control plane. IS-IS neighbor relationships are established between S86-1 with S86-2, S3760, and S3750. The S86-1 device supports nonstop forwarding to improve high availability of the core device.

IS-IS NSR Topology	
Configuration Steps	Configure the IS-IS routing protocol. Configure Ethernet ports.
S86-1	Configure IS-IS NSR <pre>S86-1(config)# router isis S86-1(config-router)# nsr</pre>
Verification	Verify that data traffic keeps being forwarded without interruption during the hot-backup switchover. Verify that S86-2, S3760, and S3750 do not perceive the hot-backup switchover of S86-1.
S86-1	<pre>S86-1# show isis neighbors S86-1# show isis database detail S86-1# show isis nsr</pre>
S86-2	<pre>S86-2# show isis neighbors S86-2# show isis database detail</pre>
S3760	<pre>S3760# show isis neighbors S3760# show isis database detail</pre>
S3750	<pre>S3750# show isis neighbors S3750# show isis database detail</pre>

Common Errors

-

6.4.9 Configuring BFD Support for IS-IS

Configuration Effect

- IS-IS dynamically discovers neighbors through Hello packets. After IS-IS enables the BFD function, a BFD session will be set up with the neighbor in Up state. The BFD mechanism is used to detect the neighbor state. Once a neighbor failure is detected through BFD, IS-IS performs network convergence immediately. The convergence time can be reduced from 30s to less than 1s. By default, IS-IS Hello packets are sent at an interval of 10s in a P2P network, and the time required to detect a neighbor failure is three times the packet interval, that is 30s.

Notes

- You must set BFD session parameters before you enable BFD support for IS-IS.
- When you run the **bfd up-dampening** command on an interface with BFD support for IS-IS, you need to run the **bfd all-interfaces** command with the *[anti-congestion]* option selected.
- When you run the **bfd all-interfaces** command with the *[anti-congestion]* option selected, run the **bfd up-dampening** command on the interface.
- IP routing may cause a neighbor's interface for BFD session setup to be inconsistent with the interface for outgoing BFD packets. If this happens, the BFD session cannot be set up.
- If a neighbor's interface for BFD session setup is inconsistent with the interface for outgoing BFD packets, the BFD session cannot be set up.

Configuration Steps

✚ Enabling BFD Support for IS-IS on All Interfaces

- Perform this configuration based on requirements.
- Run the **bfd all-interfaces** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

✚ Enabling BFD Support for IS-IS on the Current Interface

- Perform this configuration based on requirements.
- Run the **isis bfd** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

- Build a topology with two parallel lines. Typically, IS-IS selects one line as the master line and the other as the backup line. Enable BFD on the master line.
- Make the master line fail. Check whether IS-IS performs route convergence based on the BFD monitoring state and starts the backup line.

Related Commands

✚ Enabling BFD Support for IS-IS on the Current Interface

Command	bfd all-interfaces <i>[anti-congestion]</i>
Parameter Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command Mode	IS-IS routing process configuration mode
Usage Guide	You can enable or disable BFD on an IS-IS interface by using any of the following two methods: Method 1: Run the bfd all-interfaces command in IS-IS routing process configuration mode to enable BFD on all IS-IS interfaces, and then run the no bfd all-interfaces command to disable BFD on all IS-IS interfaces.

Method 2: Run the **isis bfd [disable]** command in interface configuration mode to enable BFD on the specified IS-IS interface, and then run the **isis bfd disable** command to disable BFD on the interface.

✚ Enabling BFD Support for IS-IS on the Current Interface

Command	isis bfd [disable anti-congestion]
Parameter	<i>disable</i> : Disables BFD support for IS-IS on the current interface.
Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command Mode	Interface configuration mode
Usage Guide	You can enable or disable BFD on an IS-IS interface by using any of the following two methods: Method 1: Run the [no] bfd all-interfaces [anti-congestion] command in IS-IS routing process configuration mode to enable or disable BFD on all IS-IS interfaces. Method 2: Run the isis bfd [disable anti-congestion] command in interface configuration mode to enable or disable BFD on the specified interface. Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With the introduction of new techniques such as the Multi-Service Transport Platform (MSTP), link congestion tends to occur during peak hours of data communication. BFD quickly detects the link exception and instructs IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping. The anti-congestion option is used to avoid routing flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping. When you run the bfd all-interfaces [anti-congestion] command, run the bfd up-dampening command on the interface. The two commands must be used together. If you run only one command, the route flap dampening feature may not take effect or other network exceptions may occur.

Configuration Example

✚ Enabling BFD Support for IS-IS on the Current Interface

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Set BFD session parameters. (Omitted) ● Enable BFD support for IS-IS on the current interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis bfd</pre>
Verification	Enable S1 (192.168.1.10) and S2 (192.168.2.10) to send packets to G1 (229.1.1.1) and G2 (229.1.2.1). Add User to the G1 and G2 groups. ● Check the multicast packet that User receives. User should only receive the (S1, G1) packet. ● Check that the PIM-SM routing table does not have the (S1, G2), (S2, G1), and (S2, G2) entries.
	<pre>A# show bfd neighbors detail</pre>

Common Errors

- BFD support for IS-IS is not enabled on neighbors.

6.4.10 Setting the IS-IS Overload Bit

Configuration Effect

The overload bit is used in the following three situations:

- Device overload

The local IS-IS node has overload issues, such as insufficient memory or full CPU load; as a result, its routing table has incomplete routes or does not have resource forwarding data. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. When the local IS-IS node is restored, manually cancel the command configuration; otherwise, the node is always in overload state.

- Instantaneous black hole

In the scenario described by RFC3277, the IS-IS convergence speed is faster than the BGP speed; as a result, after an IS-IS node is restarted, a route may be instantaneously unreachable, which is called an instantaneous black hole. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device until the specified time has elapsed.

To set the overload bit, run the **set-overload-bit** command with the **on-startup** keyword. The overload bit can be configured or canceled automatically by the IS-IS node based on the configuration. If the **on-startup** keyword is selected, the IS-IS node automatically enters instantaneous black hole state after restart. When a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit to notify the neighbor that the local node enters instantaneous black hole (or overload)

state and instruct the neighbor not to use the local node as a forwarding device. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify the neighbor that the local node has exited instantaneous black hole (or overload) state and can work as a forwarding device.

- Disabling real data forwarding on the local IS-IS node

If you only need to connect the local IS-IS node to a production network for testing or to meet other functional requirements, but does not require the node to forward real data in the network, you can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. You can set the **suppress** keyword based on requirements to limit the routing information carried in an LSP in case of overload. For example, internal and external routes can be suppressed, and only the local direct route is advertised.

Notes

- At the same Level, the configuration with the **on-startup** keyword is mutually exclusive with the configuration without the **on-startup** keyword.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **set-overload-bit** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Capture packets and check that the neighbor does not forward LSPs from the local node.

Related Commands

Command	set-overload-bit [on-startup { <i>seconds</i> wait-for-bgp [<i>bgpseconds</i>] }] [suppress { [<i>interlevel</i>] [<i>external</i>] }] [<i>level-1</i> <i>level-2</i>]
Parameter Description	on-startup <i>seconds</i>: Indicates the duration when an IS-IS node remains in overload state after restart. The value range is 5s to 86,400s. wait-for-bgp <i>bgpseconds</i>: Indicates the duration in which an IS-IS node automatically enters and remains in the wait-for-BGP convergence state after restart. The value ranges from 5–86,400 in seconds. The default value is 600. suppress: Indicates not to advertise internal routes (intra-area and inter-area routes) or external routes to neighbors when the IS-IS node is in overload state. interlevel: Indicates not to advertise intra-area and inter-area routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword. external: Indicates not to advertise external routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword. level-1: Sends LSPs with the overload bit only to Level-1 neighbors.

	level-2: Sends LSPs with the overload bit only to Level-2 neighbors.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to force an IS-IS node to set the overload bit in a non-virtual LSP to instruct its IS-IS neighbors not to use the local node as a forwarding device. If you select the on-startup keyword, the IS-IS node automatically enters overload state after restart. If you do not select the on-startup keyword, the IS-IS node enters overload state immediately after restart.

Configuration Example

Configuring the Overload Bit in Case of an Instantaneous Black Hole

Configuration Steps	- Configure IS-IS neighbors. (Omitted) - Verify that the IS-IS node enters instantaneous black hole state immediately after restart and remains in this state until the specified time (300s) has elapsed, and the IS-IS node only advertises local direct links to its neighbors during the specified time.
	<pre>A(config)# router isis A(config-router)#set-overload-bit on-startup 300 suppress interlevel external</pre>
Verification	Capture packets to check LSPs. - Verify that the IS-IS node automatically enters instantaneous black hole state after restart. Once a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit. - After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify its neighbors that the local node has exited instantaneous black hole (or overload) state.
	<pre>A# show isis neighbors</pre>

Disabling Real Data Forwarding on the Local IS-IS Node

Configuration Steps	- Configure IS-IS neighbors. (Omitted) - Connect the local IS-IS node as a test device to a production network. The node is not required to forward real data in the network to avoid impact on production.
	<pre>A(config)# router isis A(config-router)#set-overload-bit suppress interlevel external</pre>
Verification	Capture packets to check LSPs. Verify that the LSPs carry the overload bit and only advertise local direct routes.

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Connect the local IS-IS node as a test device to a production network. The node is not required to forward real data in the network to avoid impact on production.
	<pre>A(config)# router isis A(config-router)#set-overload-bit suppress interlevel external</pre>
Verification	Capture packets to check LSPs. Verify that the LSPs carry the overload bit and only advertise local direct routes.
	<pre>A# show isis neighbors</pre>

6.4.11 Configuring IS-IS VRF

Configuration Effect

- Each VRF table can be seen as a virtual device or a dedicated PE device.
- The virtual device contains the following elements: an independent routing table, as well as an independent address space; a set of interfaces that belong to the VRF table; a set of routing protocols applicable only to the VRF table.
- Each device can maintain one or more VRF tables and a public-network routing table (also called a global routing table). Multiple VRF instances are separated from each other.

Notes

- Note the following constraints or conventions when you bind IS-IS instances and VRF tables:
- The IS-IS instances bound with the same VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip router isis [tag]** interface configuration and the redistribution configuration in routing process configuration mode will be deleted.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **vrf** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.

Related Commands

Configuring IS-IS VRF

Command	<code>vrf vrf-name</code>
Parameter Description	<i>vrf-name</i> : Indicates the name of an existing VRF table.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Before you bind an IS-IS instance to a VRF table, ensure that the VRF table has been configured. If you need to establish an IS-ISv6 neighbor relationship, enable IPv6 and ensure that the table to be bound is a multiprotocol VRF table. Note the following constraints or conventions when you bind IS-IS instances and VRF tables: • The IS-IS instances bound with the same non-default VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID. • One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances. • When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the ip (or ipv6) router isis [<i>tag</i>] interface configuration and the redistribution configuration in routing process configuration mode will be deleted.

Configuration Example

Configuring IS-IS VRF

Configuration Steps	• Bind an IS-IS instance to a VRF table. • Add interfaces to the VRF table and IS-IS instance. (Omitted)
	<pre> A(config)#vrf definition vrf_1 A(config-vrf)#address-family ipv4 A(config-vrf-af)#exit-address-family A(config)# router isis A(config-router)# vrf vrf_1 </pre>
Verification	Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.
	<pre> A# show isis neighbors </pre>

Common Errors

- Interfaces are not added to the VRF table.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.

- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level-1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

6.4.12 Configuring IS-IS MTR

Configuration Effect

- If the **multi-topology** command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the **multi-topology** command is executed without the **transition** parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the **multi-topology** command is executed with the **transition** parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.

Notes

Note the following constraints or conventions when you configure the IS-IS MTR feature:

- Set **metric-style** to **Wide** or **Transition** before you run the **multi-topology** command.
- The MTR feature will be disabled if **metric-style** is set to **Narrow** or only one Level is configured to support the Wide or Transition mode.

Configuration Steps

- Perform this configuration based on requirements.
- Configure the MTR feature in IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices.

Related Commands

📄 Configuring IS-IS MTR

Command	multi-topology [<i>transition</i>]

Parameter Description	<i>transition</i> : Configures the MTT mode, which supports smooth migration from an IPv4-IPv6 hybrid topology to separate IPv4 and IPv6 topologies.
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	If the multi-topology command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the multi-topology command is executed without the transition parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the multi-topology command is executed with the transition parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur. Set metric-style to Wide or Transition before you run the command. The MTR feature will be disabled if metric-style is set to Narrow or only one Level is configured to support the Wide or Transition mode.

Configuration Example

Configuring IS-IS MTR

Configuration Requirements	The typical application scenario of MTR is to retain devices that only support IPv4 services in a network where IPv6 service extension will be performed. In Figure 1-20, Router 2 only supports the IPv4 protocol stack but does not support the MTR feature; therefore, it can only run IPv4 services. The network capacity needs to be scaled to support IPv6 services in order to meet service extension requirements. (Router 1, Router 3, and Router 4 that support the MTR feature will be added.) The device (Router 2) that supports only one protocol stack must be replaced to maintain the stability of the network running IPv4 and IPv6 dual protocol stacks; otherwise, IPv6 routing black holes may occur. If you need to retain Router 2, you can configure the MTR feature on Router 1, Router 3, and Router 4. The MTR feature enables Router 2 to continue to run IPv4 services without interference on the IPv4 and IPv6 services on Router 1, Router 3, and Router 4. The MTR feature improves networking flexibility, indirectly prolongs the service life of old devices, and meets service extension requirements while maximizing the values of old devices. The configuration requirements are as follows: ● Retain Router 2, which only supports IPv4 services. ● Add devices that support IPv4 and IPv6 dual topologies, and separate IPv4 route calculation and IPv6 route calculation based on different topologies.

Figure 6-19
IS-IS MTR
Topology

Router 1

Configure IS-IS and Ethernet interfaces.

Configure IS-IS:

```
Ruijie(config)# router isis
Ruijie(config-router)# net 49.0001. 0000.0000.0001.00
Ruijie(config-router)# is-type level-1
Ruijie(config-router)# metric-style wide
Ruijie(config-router)# address-family ipv6
Ruijie(config-router-af)# multi-topology
```

Configure Ethernet interfaces:

```
Ruijie(config)# interface gigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 enable
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 address 1002: : 1/112
Ruijie(config-if-GigabitEthernet 0/1)# ipv6 router isis
Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Ruijie(config-if-GigabitEthernet 0/1)# ip router isis
Ruijie(config-if-GigabitEthernet 0/1)# interface gigabitEthernet 0/2
Ruijie(config-if-GigabitEthernet 0/2)# ipv6 enable
Ruijie(config-if-GigabitEthernet 0/2)# ipv6 address 1003: : 1/112
Ruijie(config-if-GigabitEthernet 0/2)# ipv6 router isis
Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
```

	<pre>Ruijie(config-if-GigabitEthernet 0/2)# ip router isis Ruijie(config-if-GigabitEthernet 0/2)#isis wide-metric 11</pre>
Router 2	Configure IS-IS and Ethernet interfaces. Configure IS-IS: <pre>Ruijie(config)# router isis Ruijie(config-router)# net 49.0001. 0000.0000.0002.00 Ruijie(config-router)# is-type level-1 Ruijie(config-router)# metric-style wide Ruijie(config-router)#address-family ipv6 Ruijie(config-router-af)#no adjacency-check</pre> Configure Ethernet interfaces: <pre>Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0 Ruijie(config-if-GigabitEthernet 0/1)# ip router isis Ruijie(config-if-GigabitEthernet 0/1)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.3.2 255.255.255.0 Ruijie(config-if-GigabitEthernet 0/2)# ip router isis</pre>
Router 3	Configure IS-IS and Ethernet interfaces. Configure IS-IS: <pre>Ruijie(config)# router isis Ruijie(config-router)# net 49.0001. 0000.0000.0003.00 Ruijie(config-router)# is-type level-1 Ruijie(config-router)# metric-style wide Ruijie(config-router)# address-family ipv6 Ruijie(config-router-af)# multi-topology</pre> Configure Ethernet interfaces: <pre>Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ipv6 enable Ruijie(config-if-GigabitEthernet 0/1)# ipv6 address 3001: : 1/112 Ruijie(config-if-GigabitEthernet 0/1)# ipv6 router isis Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.2.3 255.255.255.0</pre>

	<pre> Ruijie(config-if-GigabitEthernet 0/1)# ip router isis Ruijie(config-if-GigabitEthernet 0/1)#isis wide-metric 11 Ruijie(config-if-GigabitEthernet 0/1)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# ipv6 enable Ruijie(config-if-GigabitEthernet 0/2)# ipv6 address 3004: : 1/112 Ruijie(config-if-GigabitEthernet 0/2)# ipv6 router isis Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.4.3 255.255.255.0 Ruijie(config-if-GigabitEthernet 0/2)# ip router isis Ruijie(config-if-GigabitEthernet 0/2)#isis wide-metric 12 </pre>
Router 4	Configure IS-IS and Ethernet interfaces.
	Configure IS-IS: <pre> Ruijie(config)# router isis Ruijie(config-router)# net 49.0001.0000.0000.0004.00 Ruijie(config-router)# is-type level-1 Ruijie(config-router)# metric-style wide Ruijie(config-router)# address-family ipv6 Ruijie(config-router-af)# multi-topology </pre> Configure Ethernet interfaces: <pre> Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ipv6 enable Ruijie(config-if-GigabitEthernet 0/1)# ipv6 address 4002: : 1/112 Ruijie(config-if-GigabitEthernet 0/1)# ipv6 router isis Ruijie(config-if-GigabitEthernet 0/1)# ip address 192.168.3.4 255.255.255.0 Ruijie(config-if-GigabitEthernet 0/1)# ip router isis Ruijie(config-if-GigabitEthernet 0/1)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# ipv6 enable Ruijie(config-if-GigabitEthernet 0/2)# ipv6 address 4003: : 1/112 Ruijie(config-if-GigabitEthernet 0/2)# ipv6 router isis Ruijie(config-if-GigabitEthernet 0/2)# ip address 192.168.4.4 255.255.255.0 Ruijie(config-if-GigabitEthernet 0/2)# ip router isis </pre>
Verification	● Run the show command on Router 1 to check whether the next hop of the IPv4 route destined for

	Router 4 is Router 2. Run the show command on Router 1 to check whether the next hop of the IPv6 route destined for Router 4 is Router 3.
Checking the IPv4 route	<pre> Ruijie#show ip route Codes: C - connected, S - static, R - RIP, B - BGP O - OSPF, IA - OSPF inter area N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 ia - IS-IS inter area, * - candidate default Gateway of last resort is no set C 192.168.1.0/24 is directly connected, GigabitEthernet 0/1 C 192.168.1.1/32 is local host. ```

Common Errors

- **metric-style** is not set to **Wide** or **Transition**.
- The protocol types used by two neighbors do not match; therefore, a neighbor relationship cannot be established.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level 1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

6.4.13 Configuring SNMP for IS-IS

Configuration Effect

- By default, the SNMP software can perform the MIB operation on the first IS-IS instance. To perform the MIB operation on other instances, you need to manually specify these instances.

Notes

- By default, the SNMP software can perform the MIB operation on the first displayed IS-IS instance.

Configuration Steps

📌 Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

- Perform this configuration based on requirements.
- Run the **enable mib-binding** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Enabling IS-IS Trap Globally

- Perform this configuration based on requirements.
- Run the **snmp-server enable traps isis** command in global configuration mode on the desired device, unless otherwise specified.

↘ Configuring an SNMP Host Globally

- Perform this configuration based on requirements.
- Run the **snmp-server host** command in global configuration mode on the desired device, unless otherwise specified.

↘ Allowing the Sending of all IS-IS Trap Messages to the SNMP Host

- Perform this configuration based on requirements.
- Run the **enable traps all** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Use the MIB tool to read and write IS-IS settings.

Related Commands

↘ Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

Command	enable mib-binding
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	The latest standards stipulate that the MIB operation can be performed on a single instance. By default, the MIB operation is performed on the first displayed IS-IS instance. Because multiple IS-IS instances can be configured, the administrator can use this command to specify the instances on which the MIB operation will be performed.

↘ Enabling IS-IS Trap Globally

Command	snmp-server enable traps [isis]
Parameter Description	<i>isis</i> : Enables IS-IS event trap.
Command Mode	Global configuration mode
Usage Guide	This command must be used with the snmp-server host command in global configuration mode so that trap messages can be sent.

Configuring an SNMP Host Globally

Command	snmp-server host { <i>host-addr</i> ipv6 <i>ipv6-addr</i> } [vrf <i>vrfname</i>] [traps] [version { 1 2c 3 { auth noauth priv }] <i>community-string</i> [udp-port <i>port-num</i>] [<i>notification-type</i>]
Parameter Description	<i>host-addr</i>: Indicates the address of the SNMP host. <i>ipv6-addr</i>: Indicates the IPv6 address of the SNMP host. <i>vrfname</i>: Indicates the name of a VRF table. version: Indicates the SNMP version, which can be set to V1, V2C, or V3 auth noauth priv: Indicates the security level of V3 users. <i>community-string</i>: Indicates the community string or user name (V3 version). <i>port-num</i>: Indicates the port number of the SNMP host. <i>notification-type</i>: Indicates the type of trap messages that are actively sent, for example, snmp.
Command Mode	Global configuration mode
Usage Guide	This command is used with the snmp-server enable traps command to actively send trap messages to a Network Management System (NMS). You can configure different SNMP hosts to receive trap messages. A host supports different trap types, ports, and VRF tables. For the same host (with the same port configuration and VRF configuration), the last configuration is combined with the previous configurations. That is, to send different trap messages to the same host, configure a type of trap messages each time. These configurations are finally combined.

Allowing the Sending of Trap Messages

Command	enable traps { all <i>traps set</i> }
Parameter Description	all: Indicates all trap messages. <i>traps set</i>: Indicates a trap message type in any set.
Command Mode	IS-IS routing process configuration mode
Usage Guide	IS-IS packets are classified into 18 types of trap messages, which are grouped into several sets, with each set containing several trap message types. To enable the sending of IS-IS trap messages, run the snmp-server enable traps isis command in global configuration mode and specify the recipient host and the type of trap messages that can be sent.

Configuration Example

Configuring IS-IS SNMP

Configuration Steps	- Bind the instances on which the IS-IS MIB operation will be performed. - Complete trap message-related settings.

	<pre> A(config)# router isis A(config-router)# enable mib-binding A# configure terminal A(config)#snmp-server enable traps isis A(config)#snmp-server host 10.1.1.1 traps version 2c public A(config)#router isis A(config-router)# enable traps all </pre>
Verification	Run the MIB tool to read and write IS-IS settings.
	<pre> A# show running-config </pre>

6.4.14 Configuring IS-IS Two-way Maintenance

Configuration Effect

- Enable IS-IS two-way maintenance.

Notes

- The IS-IS basic functions must be configured.
- The neighbor relationship is successfully established.

Configuration Steps

📌 Configuring IS-IS Two-way Maintenance

- Configure the two-way maintenance function as required.
- Run the **two-way-maintain** command in IS-IS routing process configuration mode on the required devices unless otherwise specified.

Verification

- Run the **show isis neighbor** command to check the neighbor update time.
- Run the **show isis protocol** command to check whether the two-way maintenance function is enabled.

Related Commands

📌 Configuring IS-IS Two-way Maintenance

Command	two-way-maintain
Parameter	N/A
Description	

Command Mode	IS-IS routing process configuration mode
Usage Guide	In a large-scale network, a large number of packets are sent and received, which occupies lots of CPU and memory resources, causing some IS-IS packets to be delayed or discarded. If the time required for processing HELLO packets exceeds the neighbor relationship maintenance time, the corresponding neighbor relationship times out and is removed. When the two-way maintenance function is enabled, if a large number of packets exist on the network, the LSP packets, CSNP packets, and PSNP packets from a neighbor in addition to HELLO packets can also be used to maintain the two-way relationship with the neighbor, preventing neighbor failure caused by delay or discard of HELLO packets.

Configuration Example

- i** The following example is implemented based on IS-IS basic functions. For details about the IS-IS basic functions, see preceding description

Configuring IS-IS Two-way Maintenance

Scenario	Area 49.0001 
Configuration Steps	- Configure the ISIS basic functions on all devices. - The neighbor relationship is successfully established.
Verification	Verify that an ISIS interface neighbor is established on device A. Check the status of an ISIS instance on device A.

Common Errors

6.4.15 Configuring Other IS-IS Parameters

Configuration Effect

- maximum-paths:** Configures the maximum number of IS-IS equal-cost paths to be installed to a routing table.
- lsp-length receive:** Configures the maximum length allowed for received LSPs.
- lsp-length originate:** Configures the maximum length allowed for sent LSPs.
- passive-interface:** Prevents passive interfaces from receiving and sending IS-IS packets. That is, IS-IS neighbor relationships will not be established on passive interfaces. The IP addresses of passive interfaces are flooded through other interfaces.

- **bandwidth-reference:** Configures the bandwidth reference for IS-IS to automatically calculate the link metric. If a metric is configured, the metric prevails. If no metric is configured, the metric is automatically calculated based on the configured bandwidth reference.
- **interface-protocol-compatible:** Configures the TLV field of the IS-IS protocol to be padded based on protocols supported by an interface.
- **is-name:** Replaces the system ID of an instance with the configured name.
- **isis metric:** Stores the metric, which is used in SPF calculation, in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation.
- **isis passive:** Prevents the interface from sending or receiving IS-IS packets, but the corresponding IP address will be flooded through other interfaces.
- **isis priority:** In a broadcast network, IS-IS needs to elect a DIS among all devices. The DIS will generate a pseudonode and related LSPs. The device with the highest priority is elected as the DIS. You can configure different priorities for different Levels.
- **default-information originate:** Generates a Level-2 default route, which will be advertised through LSPs.
- **spf-interval:** Configures the exponential backoff algorithm of SPF.
- **summary-address** and **summary-prefix:** Creates a summary route to represent a group of routes in a routing table. A summary route can include multiple routes of the specified Level. The interface metric of the summary route follows the smallest interface metric among all routes.
- **log-adjacency-changes:** Enables neighbor relationship event output to log IS-IS neighbor relationship changes.
- **redistribute:** Redistributes other routes to IS-IS; redistributes Level-1 routes to Level-2; redistributes Level-2 routes to Level-1.

Configuration Steps

📌 Configuring the Maximum Number of Equal-Cost Paths

- Perform this configuration based on requirements.
- Run the **maximum-paths** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

📌 Configuring the Maximum Length Allowed for Received LSPs

- Perform this configuration based on requirements.
- Run the **lsp-length receive** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

📌 Configuring the Maximum Length Allowed for Sent LSPs

- Perform this configuration based on requirements.
- Run the **lsp-length originate** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ **Configuring a Passive Interface**

- Perform this configuration based on requirements.
- Run the **passive-interface** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ **Configuring the IS-IS Interface Bandwidth Reference**

- Perform this configuration based on requirements.
- Run the **bandwidth-reference** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ **Configuring the TLV Field of the IS-IS Protocol to Be Padded Based on Protocols Supported by an Interface**

- Perform this configuration based on requirements.
- Run the **interfaces-protocol-compatible** command in IS-IS routing process configuration mode on the desired devices, unless otherwise specified.

↘ **Configuring the IS-IS Instance Alias**

- Perform this configuration based on requirements.
- Run the **is-name** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ **Configuring the IS-IS Interface Metric**

- Perform this configuration based on requirements.
- Run the **isis metric** command in interface configuration mode on the desired device, unless otherwise specified.

↘ **Configuring an Interface as a Passive Interface**

- Perform this configuration based on requirements.
- Run the **isis passive** command in interface configuration mode on the desired device, unless otherwise specified.

↘ **Configuring the Priority of the DIS**

- Perform this configuration based on requirements.
- Run the **isis priority** command in interface configuration mode on the desired device, unless otherwise specified.

↘ **Generating a Default Route**

- Perform this configuration based on requirements.
- Run the **default-information originate** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

↘ **Configuring the SPF Calculation Cycle**

- Perform this configuration based on requirements.
- Run the **spf-interval** command in interface configuration mode on the desired device, unless otherwise specified.

↘ **Configure a Summary Route**

- Perform this configuration based on requirements.
- Run the **summary-address** and **summary-prefix** commands in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

📌 Enabling Neighbor Relationship Event Output

- Perform this configuration based on requirements.
- Run the **log-adjacency-changes** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

📌 Configuring Route Redistribution

- Perform this configuration based on requirements.
- Run the **redistribute** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- **maximum-paths**: Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
- **lsp-length receive**: Capture packets to check the length of LSPs.
- **lsp-length originate**: Capture packets to check the length of LSPs.
- **passive-interface**: Capture packets to check whether the interface receives and sends IS-IS packets.
- **bandwidth-reference**: Check the metric of the routing table.
- **interfaces-protocol-compatible**: Check the neighbor relationship establishment status.
- **is-name**: Check the database details of IS-IS.
- **isis metric**: Check the database details of IS-IS.
- **isis priority**: Check whether the device with the changed priority setting is elected as the DIS.
- **default-information originate**: Check whether a default route is generated.
- **spf-interval**: Check whether the SPF calculation cycle works.
- **summary-address** and **summary-prefix**: Capture packets to check whether the summary route instead of detailed routes is advertised through LSPs.
- **log-adjacency-changes**: Change the neighbor state and verify that the change is recorded when debugging is disabled.
- **redistribute**: Check IS-IS routing entries.

Related Commands

📌 Configuring the Maximum Number of Equal-Cost Paths

Command	maximum-paths <i>maximum</i>

Parameter Description	<i>maximum</i> : Indicates the maximum number of IS-IS equal-cost routes to be installed to a routing table. The value range is 1 to 32.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	This command is used by IS-IS to control the number of IS-IS equal-cost paths to be installed to a routing table. The routing table also has a command used to control the number of equal-cost paths. The number of effective equal-cost paths is determined by either of the two command values, whichever is smaller.

✚ Configuring the Maximum Length Allowed for Received LSPs

Command	lsp-length receive <i>size</i>
Parameter Description	<i>size</i> : Indicates the maximum length allowed for received LSPs. According to RFC, the value range is 1,492 to 16,000, in the unit of bytes.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to control the maximum length allowed for LSPs received by the local device. Intermediate nodes with sufficient memory are required to receive LSPs whose maximum length is equal to the interface MTU in order to avoid a route convergence failure. From this perspective, the command is meaningless. The maximum length allowed for received LSPs cannot be smaller than that allowed for sent LSPs; otherwise, the former will be automatically adjusted to be equal to the latter.

✚ Configuring the Maximum Length Allowed for Sent LSPs

Command	lsp-length originate <i>size</i> [level-1 level-2]
Parameter Description	<i>size</i> : Indicates the maximum length allowed for sent LSPs. The value range is 512 to 16,000, in the unit of bytes. level-1 : Applies the setting only to Level-1 LSPs. level-2 : Applies the setting only to Level-2 LSPs.
Command Mode	IS-IS routing process configuration mode
Usage Guide	In principle, the maximum length of LSPs and SNPs cannot be greater than the interface MTU; otherwise, the packets will be discarded when being sent.

✚ Configuring a Passive Interface

Command	passive-interface [default] { <i>interface-type</i> <i>interface-number</i> }
Parameter Description	default : Configures all IS-IS interfaces that are not enabled as passive interfaces. <i>interface-type</i> : Indicates the interface type. <i>interface-number</i> : Indicates the interface number.
Command Mode	IS-IS routing process configuration mode
Usage Guide	This command prevents the specified interface from receiving and sending IS-IS packets, but the IP address of the interface will be flooded by other interfaces. If the default option is selected and there are more than 255 IS-IS interfaces not enabled, only the first 255

interfaces will be configured as passive interfaces. The remaining interfaces are non-passive interfaces.

✚ Configuring the Bandwidth Reference

Command	bandwidth-reference value
Parameter Description	<i>value</i> : Indicates the bandwidth value. The value ranges from 1 to 4294967 , in the unit of Mbps. The default value is 100 .
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to calculate the interface metric in an instance according to the bandwidth reference configured in the instance. If a metric is configured, the metric prevails.

✚ Configuring the TLV Field of the IS-IS Protocol to Be Padded Based on Protocols Supported by an Interface

Command	interfaces-protocol-compatible
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	When devices supporting IS-IS for IPv4 or IS-IS for IPv6 and those supporting both IS-IS for IPv4 and IS-IS for IPv6 on a network are configured to establish a neighbor relationship, the calculated routes may be unreachable, resulting in routing black holes. To prevent routing black holes, the TLV (#129) field of Ruijie IS-IS protocol is padded based on protocols supported by an instance, that is, IS-IS instances that establish a neighbor relationship need to support the same protocol. The TLV (#129) field of the IS-IS protocol supported by devices of some vendors is padded based on protocols supported by an interface. In single topology mode, a Ruijie device connects to a device of another vendor, a loopback interface is configured on both devices, both IS-IS for IPv4 and IS-IS for IPv6 are enabled, and only a single protocol stack (IS-IS for IPv4 or IS-IS for IPv6) is configured on the interface for interconnecting the two devices. The device of the other vendor sends TLV#129 (supporting only a single protocol stack) based on interfaces whereas Ruijie device sends TLV#129 (supporting dual protocol stacks) based on instances. As a result, the displayed neighbor status on the device of the other vendor is "Init" but Ruijie device cannot establish a neighbor relationship with the device of the other vendor. For this, the interfaces-protocol-compatible command can be configured to enable Ruijie devices to establish a neighbor relationship with devices of other vendors.

✚ Configuring an IS Name

Command	is-name name
Parameter Description	<i>name</i> : Indicates the name for replacing the system ID. The name contains a maximum of 64 characters.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to replace the system ID of an instance with the configured name. All system IDs displayed in the command output of show isis database and show isis neighbors are replaced with the configured name.

✚ Configuring the IS-IS Interface Metric

Command	isis metric <i>metric</i> [level-1 level-2]
Parameter Description	<i>metric</i> : Indicates the metric value. The value range is 1 to 63. The default value is 10. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric belongs to the narrow type and is valid only when metric-style is set to Narrow .

✚ Configuring the Wide Metric of an Interface

Command	isis wide-metric <i>metric</i> [level-1 level-2]
Parameter Description	<i>metric</i> : Indicates the metric value. The value range is 1 to 16,777,214. The default value is 10. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric is valid only when metric-style is set to Wide .

✚ Configuring an Interface as a Passive Interface

Command	isis passive
Parameter	-
Description	
Command Mode	Interface configuration mode
Usage Guide	This command prevents the interface from sending or receiving ISIS packets, but the corresponding IP address will be flooded through other interfaces. It only takes effect on the generated ISIS interface.

✚ Configuring the Priority of the DIS

Command	isis priority <i>value</i> [level-1 level-2]
Parameter Description	<i>value</i> : Indicates the priority. The value range is 0 to 127. The default value is 64. level-1 : Applies the setting to Level-1 circuits. level-2 : Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode

Usage Guide	Use this command to change the priority carried in Hello packets in a LAN. The device with a lower priority is less likely to be elected as the DIS. The command is invalid on a P2P network interface. The no isis priority command, with or without parameters, restores the priority to its default value. To change the configured priority, run the isis priority command with the priority specified to overwrite the existing configuration, or you can first restore the priority to its default value and then configure a new priority.

Generating a Default Route

Command	default-information originate [route-map <i>map-name</i>]
Parameter Description	route-map <i>map-name</i> : Associates with a route map.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	Because Level-2 domains do not generate any default route, use this command to allow a default route to enter a Level-2 domain.

Configuring SPF Calculation Cycle

Command	spf-interval [level-1 level-2] <i>maximum-interval</i> [<i>initial-interval</i> <i>hold-interval</i>]
Parameter Description	level-1: Applies the configuration only to Level-1. level-2: Applies the configuration only to Level-2. <i>maximum-interval</i>: Indicates the maximum interval for performing two consecutive SPF calculations. The value range is 1 to 120 (in seconds). The default value is 10. <i>initial-interval</i>: Indicates the waiting time for performing the SPF calculation for the first time. The value range is 0 to 60000 (in milliseconds). The default value is 50. <i>hold-interval</i>: Indicates the minimum interval for performing the SPF calculation for the second time. The value range is 10 to 60000 (in milliseconds). The default value is 200.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Increasing the maximum interval for performing SPF calculations can avoid frequent SPF calculations and waste of CPU resources. However, a larger minimum interval also leads to slower responses to route changes.
	The waiting time for performing the SPF calculation for the first time is the initial interval. If the network becomes unstable, the SPF calculation interval is less than the maximum interval, and the interval for performing the SPF calculation for the second time becomes the hold interval. A corresponding penalty is added to this interval: The next interval for the SPF calculation doubles the previous interval for the same SPF calculation, until the SPF calculation interval reaches the maximum interval. Subsequent SPF calculations are performed at the maximum interval. When the network becomes stable, the interval for performing the SPF calculation becomes greater than the maximum interval, and the waiting time for performing the SPF calculation is restored to the initial interval. Link changes have high requirements for convergence. The initial interval can be set to a small value. The preceding parameters can also be adjusted to larger values to reduce CPU consumption.

	The value of initial-interval cannot be greater than that of maximum-interval. Otherwise, the value of initial-interval will be used as the value of maximum-interval. The value of hold-interval cannot be greater than that of maximum-interval. Otherwise, the value of hold-interval will be used as the value of maximum-interval. The value of initial-interval cannot be greater than that of hold-interval. Otherwise, the value of initial-interval will be used as the value of hold-interval.

📌 Configuring an IPv4 Summary Route

Command	summary-address <i>ip-address net-mask</i> [level-1 level-2 level-1-2] [<i>metric number</i>]
Parameter	<i>ip-address</i> : Indicates the IP address of the summary route.
Description	<i>net-mask</i>: Indicates the subnet mask of the summary route. level-1: Applies the setting only to Level-1. level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2. level-1-2: Applies the setting to Level-1 and Level-2. <i>number</i>: Indicates the metric of the summary route.
Command Mode	IS-IS routing process configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

📌 Configuring an IPv6 Summary Route

Command	summary-prefix <i>ipv6-prefix/prefix-length</i> [level-1 level-2 level-1-2]
Parameter	<i>ipv6-prefix/prefix-length</i> : Indicates the network address of the summary route and its IPv6 prefix length. The address format is X:X:X:X::X/<0-128>.
Description	level-1: Applies the setting only to Level-1. level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2. level-1-2: Applies the setting to Level-1 and Level-2.
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

📌 Enabling Neighbor Relationship Event Output

Command	log-adjacency-changes
Parameter	N/A
Description	
Command Mode	IS-IS routing process configuration mode
Usage Guide	You can also use the debug command to record IS neighbor state changes, but the command consumes many system resources.

Redistributing Other Routes to IS-IS

Command	redistribute { bgp ospf process-id [match { internal [external [1 2]] [nssa-external [1 2]] external [1 2] [internal] [nssa-external [1 2]] nssa-external [1 2] [internal] [external [1 2]] }] rip connected static } [metric metric-value] [metric-type type-value] [route-map map-tag] [level-1 level-1-2 level-2]
Parameter Description	<i>process-id</i>: Indicates the OSPF process ID. The range is 1 to 65,535. match { internal external [1 2] nssa-external [1 2] }: When OSPF routes are redistributed, the routes are filtered by subtype. If the match option is not selected, routes of all OSPF types will be received. If match external is not followed by the number 1 or 2, OSPF routes specified by external 1 and external 2 will be redistributed. If match nssa-external is not followed by the number 1 or 2, OSPF routes specified by nssa-external 1 and nssa-external 2 will be redistributed. metric metric-value: Indicates the metric of redistributed routes. The value range is 0 to 4,261,412,864. The metric of external routes is used when the metric option is not specified. metric-type { internal external }: Indicates the metric type of redistributed routes. internal: Indicates that the metric belongs to the internal type. external: Indicates that the metric belongs to the external type. If metric-type is not specified, the metric belongs to the internal type. route-map map-tag: Indicates the route map used for external route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>map-tag</i> cannot exceed 32 characters. By default, route-map is not configured. level-1 level-1-2 level-2: Indicates the Level of redistributed routes received by IS-IS. If no Level is specified, routes are redistributed to Level-2. level-1: Redistributes routes to Level-1. level-1-2: Redistributes routes to Level-1 and Level-2. level-2: Redistributes routes to Level-2.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	The no redistribute { bgp ospf process-id rip connected static } command is used to cancel the redistribution of routes mapped to the specified protocol. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution. For example, no redistribute bgp cancels BGP route redistribution, whereas no redistribute bgp route-map aa cancels the route map named aa used for BGP route redistribution. When external routes are redistributed in IPv4 mode, the routing information is stored in LSPs' IP External Reachability Information TLV. When external routes are redistributed in IPv6 mode, the routing information is stored in LSPs' IPv6 Reachable TLV. In the old versions of some vendors, if metric-type is set to external, the metric of redistributed routes is added by 64 during route calculation and used to determine routing. This practice does not comply with the related protocol. In the actual application, external routes may be preferred over internal routes. If this happens during interworking with old versions of some vendors, you can modify the related setting (such as metric or metric-type) of each device to ensure that internal routes are preferred over external routes.

Redistributing the Level-1 Reachable Routing Information of the Specified IS-IS Instance to Level-2 of the Current Instance

Command	redistribute isis [<i>tag</i>] level-1 into level-2 [route-map <i>route-map-name</i> distribute-list <i>access-list-name</i>]
Parameter Description	<i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed. route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured. distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	You can use the route-map or distribute-list parameter to filter the specified instance's Level-1 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-2 of the current instance. The route-map and distribute-list parameters cannot be used at the same time. The no redistribute isis [<i>tag</i>] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution. For example, no redistribute isis <i>tag1</i> level-1 into level-2 cancels the redistribution of the routes of the IS-IS instance name <i>tag1</i>. no redistribute isis <i>tag1</i> level-1 into level-2 route-map <i>aa</i> cancels the use of the route map named <i>aa</i> to filter redistributed routes.

Redistributing the Level-2 Reachable Routing Information of the Specified IS-IS Instance to Level-1 of the Current Instance

Command	redistribute isis [<i>tag</i>] level-2 into level-1 [route-map <i>route-map-name</i> distribute-list <i>access-list-name</i> (prefix <i>ip-address net-mask</i> ipv6-prefix <i>ipv6-address/length</i>)]
Parameter Description	<i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed. route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured. Distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>. prefix <i>ip-address net-mask</i>: Determines the routes to be redistributed by address and prefix length. ipv6-prefix <i>ipv6-address/length</i>: Determines the IPv6 routes to be redistributed by address and prefix length.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode

Usage Guide	You can use the route-map, distribute-list, or prefix parameter to filter the specified instance's Level-2 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-1 of the current instance. The no redistribue isis [tag] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution. For example: no redistribue isis tag1 level-2 into level-1 cancels the redistribution of the routes of the IS-IS instance name tag1. no redistribue isis tag1 level-2 into level-1 route-map aa cancels the use of the route map named aa to filter redistributed routes.

Configuration Example

Configuring the Maximum Number of Equal-Cost Paths

Configuration Steps	- Configure IS-IS neighbors. (Omitted) - Configure the maximum number of equal-cost paths.
	<pre>A(config)# router isis A(config-router)# maximum-paths 5</pre>
Verification	Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
	<pre>A# show ip route isis</pre>

Configuring the Maximum Length Allowed for Received LSPs

Configuration	- Configure IS-IS neighbors. (Omitted) - Configure the maximum length allowed for received LSPs.
	<pre>A(config)# router isis A(config-router)# lsp-length receive 512</pre>
Verification	Capture packets to check the length of received LSPs.

Configuring the Maximum Length Allowed for Sent LSPs

Configurations	- Configure IS-IS neighbors. (Omitted) - Configure the maximum length allowed for sent LSPs.

	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# lsp-length originate 512 level-2</pre>
Verification	Capture packets to check the length of sent LSPs.

📌 Configuring a Passive Interface

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configure a passive interface.
	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# passive-interface GigabitEthernet 0/0</pre>
Verification	Capture packets to check whether the interface receives and sends IS-IS packets.

📌 Configuring the Metric of an IS-IS Interface

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configure metric of the IS-IS interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)#isis metric 1</pre>
Verification	Check the database details of IS-IS.
	<pre>A# show isis database detail</pre>

📌 Configuring an Interface as a Passive Interface

- Configuration Steps**
- Configure IS-IS neighbors. (Omitted)
 - Configure the interface as a passive interface.

```
A(config)# interface GigabitEthernet 0/1
A(config-if)# isis passive
```

Verification Check the interface status of IS-IS.

```
A# show isis interface GigabitEthernet 0/1
```

📌 Configuring the Priority of the DIS

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configure the priority of the DIS.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis priority 127 level-1</pre>
Verification	Check whether the device with the changed priority setting is elected as the DIS.
	<pre>A# show isis database detail</pre>

📌 Generating a Default Route

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Generate a default route.
	<pre>A(config)# router isis A(config-router)# default-information originate</pre>
Verification	Capture packets to check whether the sent LSP contains a default route.

📌 Configuring SPF Calculation Cycle

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configuring SPF calculation cycle.
	<pre>A(config)# router isis A(config-router)# spf-interval 5 100 200</pre>
Verification	Check whether the SPF calculation cycle works.

📌 Configuring an IS-IS Summary Route

Configuration Requirements	Router A and Router B are connected through the Ethernet and run IS-IS. Configure Router A to advertise only the 172.16.0.0/22 route instead of the 172.16.1.0/24 and 172.16.2.0/24 routes.

Figure 6-20
IS-IS Route
Summary
Topology

**Configuration
Steps**

- Configure IS-IS.
- Configure Ethernet interfaces.
- Configure the password for IS-IS authentication.

A

Configure IS-IS.

```
A(config)# router isis
A(config-router)# net 49.0001.0000.0000.0001.00
A(config-router)# summary-address 172.16.0.0/16 level-1-2
```

Configure Ethernet interfaces.

```
A(config)# interface GigabitEthernet 0/0
A(config-if)# ip address 192.168.20.1 255.255.255.0
A(config-if)# ip router isis
A(config)# interface GigabitEthernet 1/0
A(config-if)# ip address 172.16.1.1 255.255.255.0
A(config-if)# ip router isis
A(config)# interface GigabitEthernet 1/1
A(config-if)# ip address 172.16.2.1 255.255.255.0
A(config-if)# ip router isis
```

B

Configure IS-IS.

```
B(config)# router isis
B(config-router)# net 49.0001.0000.0000.0002.00
```

Configure an Ethernet interface.

```
B(config)# interface GigabitEthernet 0/0
B(config-if)# ip address 192.168.20.2 255.255.255.0
B(config-if)# ip router isis
```

Verification	Run the show ip route command on Router B to check whether only one summary route exists.
B	<pre> B(config)# show ip route i L1 172.16.0.0/16 [115/20] via 192.168.20.1, FastEthernet0/0 </pre>

Configuring an IS-ISv6 Summary Route

	Router A and Router B are connected through the Ethernet and run IS-ISv6. Configure Router A to advertise only the 2000::/96 route instead of the 2000::1111:0/112 and 2000::2222:0/112 routes.
Figure 6-21 IS-ISv6 Route Summary Topology	
Configuration Steps	● Configure IS-IS. ● Configure Ethernet interfaces. ● Configure the password for IS-IS authentication.
A	Configure IS-IS.
	<pre> A(config)# ipv6 unicast-routing A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config-router)# address-family ipv6 unicast A (config-router-af)# summary-prefix 2000::/96 level-1-2 A (config-router-af)# exit-address-family </pre>
	Configure Ethernet interfaces. <pre> A(config)# interface GigabitEthernet 0/0 A(config-if)# ipv6 address 5000::1/64 A(config-if)# ipv6 router isis A(config)# interface GigabitEthernet 1/0 A(config-if)# ipv6 address 2000::1111:0001/112 A(config-if)# ipv6 router isis </pre>

	<pre>A(config)# interface GigabitEthernet 1/1 A(config-if)# ipv6 address 2000::2222:0001/112 A(config-if)# ipv6 router isis</pre>
B	Configure IS-IS.
	<pre>B(config)# ipv6 unicast-routing B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00</pre>
	Configure an Ethernet interface.
	<pre>B(config)# interface GigabitEthernet 0/0 B(config-if)# ipv6 address 5000::2/64 B(config-if)# ipv6 router isis</pre>
Verification	Run the show ipv6 route command on Router B to check whether only one summary route exists.
B	<pre>B(config)# show ipv6 route I1 2000::/96 [115/20] via FE80::C800:1BFF:FEF8:1C, FastEthernet1/0</pre>

📌 Enabling Neighbor Relationship Event Output

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Enable neighbor relationship event output.
	<pre>A(config-router)# log-adjacency-changes</pre>
Verification	Change the neighbor state and verify that the change is recorded when debugging is disabled.

📌 Configuring Route Redistribution

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configure OSPF routes. (Omitted) ● Configure route redistribution
	<pre>A(config)# router isis A(config-router)# redistribute ospf 1 metric 10 level-1</pre>
Verification	Check whether routing entries with redistributed routes exist.

Configuration Steps	● Configure IS-IS neighbors. (Omitted) ● Configure OSPF routes. (Omitted) ● Configure route redistribution
	<pre>A(config)# router isis A(config-router)# redistribute ospf 1 metric 10 level-1</pre>
Verification	Check whether routing entries with redistributed routes exist.
	<pre>A# show ip route isis</pre>

6.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears all IS-IS neighbor relationship tables.	clear clns neighbors
Clears all IS-IS data structures.	clear isis *
Clears all IS-IS counters.	clear isis [tag] counter

Displaying

Description	Command
Displays all IS neighbors and inter-device neighbor relationships.	show clns [tag] is-neighbors [interface-type interface-number] [detail]
Displays all IS neighbors and provides device information and information about the neighbor relationship with ESs.	show clns [tag] neighbors [interface-type interface-number] [detail]
Displays all IS-IS counters.	show isis [tag] counter
Displays the LSDB information.	show isis [tag] database [FLAGS] [LEVEL] [LSPID]
Displays the state information related to IS-IS GR.	show isis [tag] graceful-restart
Displays the relationship between the device name and system ID.	show isis [tag] hostname
Displays the details of an IS-IS interface.	show isis [tag] interface [interface-type interface-number] [counter]

Displays the mesh group configuration of all interfaces.	show isis [tag] mesh-groups
Displays IS-IS neighbor information.	show isis [tag] neighbors [detail]
Displays IS-IS NSR information.	show isis [tag] nsr
Displays the neighbor information of virtual systems in IS-IS.	show isis [tag] virtual-neighbors
Displays IS-IS information.	show isis [tag] protocol
Displays the topology of IS-IS device connection.	show isis [tag] topology [fr { self-originate WORD all }] [l1 l2 level-1 level-2]
Displays information of an IS-IS IPv6 unicast topology.	show isis [tag] ipv6 topology [l1 l2 level-1 level-2]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables IS-IS debugging.	debug isis { all auth events fr gr ifsm lsp mtr nfsm nsm nsr pdu spf warn }

7 Configuring BGP

7.1 Overview

The Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) used for communication between routers in different autonomous systems (ASs). BGP is used to exchange network accessibility information between different ASs and eliminate routing loops by using its own mechanism.

BGP uses TCP as the transmission protocol. The reliable transmission mechanism of TCP is used to ensure the transmission reliability of BGP.

Routers running BGP are called BGP speakers. BGP speakers between which a BGP session is established are called BGP peers.

Two modes can be used to establish peers between BGP speakers: Internal BGP (IBGP) and External BGP (EBGP).

- IBGP refers to a BGP connection established within an AS and completes transition of routing information within the AS.
- EBGP refers to a BGP connection established between different ASs and completes exchange of routing information between different ASs.

Rules for BGP to select an optimum route:

1. Invalid routing table entries are not involved in optimum route selection.

 Invalid entries include entries of inaccessible next hops and flapping entries.

2. Otherwise, select a route with a large value of **LOCAL_PREF**.

3. Otherwise, select a route generated by a BGP speaker.

 Routes generated by a BGP speaker include routes generated by the **network**, **redistribute** and **aggregate** commands.

4. Otherwise, select a route with the shortest AS length.

5. Otherwise, select a route with a smaller value of **ORIGIN**.

6. Otherwise, select a route with the smallest value of **MED**.

7. Otherwise, EBGP routes have higher priorities than IBGP routes and routes in the AS alliance, and the IBGP routes have the same priorities as the routes in the AS alliance.

8. Otherwise, select a route with the smallest IGP metric value to the next hop.

9. Otherwise, select an EBGP route that is received first.

10. Otherwise, select a route advertised by a BGP speaker with a smaller router ID.

11. Otherwise, select a route with a large cluster length.

12. Otherwise, select a route with a large neighbor address.

- i** The preceding shows the route selection process under the default configurations. By using CLI commands, you can change the route selection process. For example, you can run the **bgp bestpath as-path ignore** command to make step 4 of the route selection process lose effect or run the **bgp bestpath compare-routerid** command to make step 9 lose effect.

Protocols and Standards

- RFC4271: A Border Gateway Protocol 4 (BGP-4)
- RFC4273: Definitions of Managed Objects for BGP-4
- RFC4360: Proposed Standard: BGP Extended Communities Attribute
- RFC4486: Proposed Standard: Subcodes for BGP Cease Notification Message
- RFC4724: Proposed Standard: Graceful Restart Mechanism for BGP
- RFC4760: Draft Standard: Multiprotocol Extensions for BGP-4
- RFC5492: Draft Standard: Capabilities Advertisement with BGP-4
- RFC7313: Enhanced Route Refresh Capability for BGP-4
-

7.2 Applications

Application	Description
Inter-AS Route Advertisement	Implement inter-AS route advertisement by using BGP.
Intra-AS Route Reflection	Set up a route reflection topology within an AS to reduce BGP connections.

7.2.1 Inter-AS Route Advertisement

Scenario

BGP implements route advertisement and maintenance across different ASs.

As shown in Figure 7-1, BGP transfers the route of AS 65536 to AS 65538 through AS 65537.

Figure 7-1

Remarks	R1 is a device at the network edge of AS 65536. R2 and R3 are devices at the network edge of AS 65537. R4 is a device at the network edge of AS 65538.

Deployment

- Establish the EBGP neighborship between R1 and R2 to implement inter-AS route advertisement.
- Establish the IBGP neighborship between R2 and R3 to implement intra-AS route advertisement.
- The Internet runs OSPF to ensure network accessibility between R2 and R3.
- Establish the EBGP neighborship between R3 and R4 to implement inter-AS route advertisement.

7.2.2 Intra-AS Route Reflection

Scenario

According to the BGP route advertisement principles, routes learned by an IBGP neighbor will not be advertised to the next IBGP neighbor by default. Therefore within an AS, a device running BGP must implement full-mesh. When there are many BGP devices within the AS, implementing full-mesh may cause large difficulties for network deployment. In this case, route reflection can be used to solve this problem.

As shown in Figure 7-2, route reflection is deployed to implement BGP full-mesh among R1 to R4 and RR.

Figure 7-2

Remarks	RR is a route reflector. R1 to R4 are route reflection clients.

Deployment

- Establish IBGP neighborships between R1 to R4 and RR respectively.
- Configure R1 to R4 as the route reflection clients of RR.

7.3 Features

Basic Concept

➤ BGP Speaker and AS Number

A router enabled with BGP is called a BGP speaker.

After a route is enabled with BGP, a local AS number must be specified for the router. An AS number is a globally unique number allocated by IANA, ranging from 1 to 4294967295.

➤ BGP Neighbor and Peer

Before a route is advertised between BGP speakers, a neighborhood must be established in advance. You need to manually configure BGP neighbors on both BGP speakers. That is, configure the peer as a neighbor on the two BGP speakers respectively. Therefore, BGP neighbors are also called BGP peers.

➤ Neighbor Type and Route Type

BGP neighborhoods are classified into the following types:

- **IBGP neighborhood:** The neighborhood between BGP speakers within an AS is called IBGP neighborhood. Routes learned from IBGP neighbors are called IBGP routes.
- **EBGP neighborhood:** The neighborhood between BGP speakers in different ASs is called EBGP neighborhood. Routes learned from EBGP neighbors are called EBGP routes.

➤ BGP route attribute

When a BGP speaker advertises routes to its neighbors, the BGP speaker also advertises the attributes carried by the routes. Common BGP attributes are as follows:

- **ORIGIN:** Specifies the origin of a BGP route and can be set to **IGP**, **EGP**, or **INCOMPLETE**.
- **AS-PATH:** Lists the ASs passed by a route in a reverse order. The last AS is placed at the beginning of the list.
- **NEXT-HOP:** Specifies the IP address of the next hop to be reached by a BGP route.
- **MULTI-EXIT-DISC:** Distinguishes multiple output/input interfaces for reaching the same neighbor AS. A smaller value means a higher priority.
- **LOCAL-PREF:** Distinguishes the priorities of IBGP routes in an AS. A larger value means a higher priority.

Overview

Feature	Description
Creating a BGP Neighbor	Create a BGP neighbor.
Configuring a BGP Route Reflector	Set up a BGP route reflection topology to simplify network deployment for BGP neighbor full-mesh.
Configuring a BGP Alliance	Configure a BGP alliance to simplify network deployment for BGP neighbor full-mesh.
Re-distributing Local AS Network Information to BGP	Re-distribute routing information to BGP and advertise local routes through BGP.

Feature	Description
Controlling Route Exchange Between BGP Peers	Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.
Obtaining Accessible Networks of Other ASs from BGP	Re-distribute routing information in BGP into a core routing table or IGP.
Configuring Synchronization Between BGP and IGP	Configure BGP to check whether BGP routes are synchronized with IGP routes.
Configuring BGP Soft Reset	After a routing policy changes, use soft reset to apply a new policy.
Configuring the Route Attributes of BGP	Configure the route selection algorithms and routing policy control of BGP.
Configuring BGP Route Aggregation	Reduce routes by means of route aggregation.
Configuring BGP Route Dampening	Reduce the impacts of route flapping on a network topology.
Configuring the Management Distance of BGP	Change the priorities of BGP routes.
Configuring Multi-path Load Balancing of BGP	Configure multi-path load balancing for BGP to enhance the network reliability and increase the network bandwidth.
Configuring BGP FRR	Configure fast rerouting for BGP to enhance the network reliability.
Configuring BGP Timers	Modify the internal timer time of BGP.
Configuring BGP Route Update Mechanisms	Disable/Enable regular scanning for BGP routes and configure the route scanning interval.
Configuring the Next-Hop Triggering Update Function of BGP	Configure the next hop triggering update function of BGP.
Configuring BGP LOCAL AS	Configure the LOCAL AS for a BGP neighbor.
Configuring BGP Capacity Protection	Avoid non-predictable running status caused by consumption of device capacity.
Configuring BGP GR	Configure the BGP GR function to enhance the network reliability.
Configuring 4-Byte AS Numbers of BGP	Configure the display mode of a 4-byte AS number.
Configuring a Regular Expression	Use a regular expression to filter routing information.

Feature	Description
Configuring BGP Session Retention	Configure BGP to ensure that after an address family with incorrect routing attributes is detected for a neighbor, other address family routes advertised by the neighbor will not be affected.
Configuring BGP Delayed Advertisement upon System Restart	Configure BGP to delay route advertisement to a neighbor within a period after the system is restarted.
Configuring BGP NSR	Enable the NSR function for BGP neighbor.
Configuring BGP Routes to Be Recursive Only to Host Routes	Enable IBGP or EBGp routes to be recursive only to host routes.
Configuring Outbound Loop Detection for a BGP Neighbor	Enable outbound loop detection for a BGP neighbor.
Shutting Down BGP Connection Gracefully	Shut down BGP connection gracefully. Make sure that the service traffic is not interrupted or is interrupted for a very short period of time.
EVPN Route Attribute	Indicate EVPN route attribute.
Configuring BGP EVPN	Configure the BGP EVPN function.
Other Related Configurations	Configure extended BGP functions.

7.3.1 Creating a BGP Neighbor

A BGP neighbor is manually configured by a user. Two connection modes are supported: IBGP and EBGp. You can identify the connection mode between BGP speakers based on the AS where the BGP peer resides and the AS where the BGP speaker resides.

 Generally, BGP speakers between which an EBGp connection is established are directly connected whereas BGP speakers between which an IBGP connection is established can be at any location within an AS.

Working Principle

A BGP speaker can initiate a TCP connection request to a BGP peer specified by a user. After the TCP connection is successfully created, the peers will exchange BGP packets to negotiate about connection parameters. The BGP neighborhood is successfully established after the negotiation succeeds.

📌 Creating a TCP Connection

A BGP speaker initiates a TCP connection request to a neighbor. The destination IP address is the peer IP address specified by the user and the port number is fixed to 179.

The BGP speaker also listens on the port number 179 of the local TCP connection to receive connection requests from its peer.

📌 Negotiating about Protocol Parameters

After the TCP connection is successfully created, the BGP speakers exchange OPEN packets to negotiate about BGP connection parameters. The parameters for negotiation include:

- Version: Indicates the BGP version number. At present, only version 4 is supported.
- Neighbor AS number: Determines whether the AS number of the neighbor is consistent with the local AS number. If not, the connection request will be denied.
- Hold Time: Negotiates about the timeout duration for the BGP connection. The default value is 180 seconds.
- Neighbor capability: Negotiates about various extended capabilities supported by the neighbor, including the address family, dynamic route update, and GR functions.

📌 Maintaining Neighborhood

The Keepalive message is periodically sent between BGP speakers. If a new Keepalive packet is not received from the BGP neighbor after the Hold Time expires, the BGP speaker considers that the neighbor is not accessible, disconnects the TCP connection from the neighbor, and attempts to reconnect to it. The interval for a BGP speaker to send the Keepalive message is one third of the Hold Time determined through negotiation and is 60 seconds by default.

Related Configuration

📌 Creating a BGP Neighbor

By default, a BGP speaker does not specify any neighbor. You can manually configure a BGP neighbor.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **remote-as** { *as-number* | **route-map** *map-tag* } command to manually create a BGP neighbor and specify the AS number of the neighbor.

📌 Setting the Neighbor TTL

By default, The TTL field in a TCP packet sent by an IBGP neighbor is set to the maximum value (255). It is set to 1 by an EBGP neighbor.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **ebgp-multihop** [*tth*] command to set the TTL field of a TCP packet sent by a BGP neighbor.

A larger value of TTL means a longer distance between BGP neighbors. When TTL is 1, the BGP neighbor devices must be directly connected.

📌 Setting the Source Address of TCP

By default, BGP automatically selects the source IP address of a TCP connection based on the IP address of the neighbor. Generally, the IP address of a local packet output interface is used.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *address* } command to adjust the source IP address of the neighbor's TCP connection.

📌 Setting the TCP Connection Mode

By default, BGP neighbors can actively and passively establish TCP connections.

Run the `neighbor { neighbor-address | peer-group-name } transport connection-mode { active-only | both | passive-only } command` to set the TCP connection mode of a BGP neighbor.

📌 Setting MD5 Encryption

By default, a BGP connection is not encrypted through MD5.

You can run the `neighbor { neighbor-address | peer-group-name } password [ 0 | 7 ] string` command to set encryption for a BGP neighbor's TCP connection.

📌 Activating the Address Family Capability of a Neighbor

You can run the `address-family` command to enter a corresponding address family mode, and then run the `neighbor { neighbor-address | peer-group-name } activate` command to activate the address family capability for the BGP neighbor.

7.3.2 Configuring a BGP Route Reflector

According to the principle of BGP route advertisement, full mesh must be established for all BGP speakers within an AS (neighborships need to be established between each two BGP speakers). Too many BGP speakers within an AS will increase the resource overhead of the BGP speakers, increase the network administrator's workload and complexity of configuration and decrease the network expansion capability.

Using a route reflector is a method for reducing IBGP peer connections within an AS.

-
- 📘 The methods for reducing the IBGP peer connections within an AS include using a route reflector and using an AS alliance.
-

Working Principle

Configure a BGP speaker as a route reflector which classifies IBGP peers in an AS into two types: clients and non-clients.

The rules for implementing a route reflector within an AS are as follows:

- Configure a route reflector and specify clients for the route reflector. The route reflector and its clients form a cluster. The route reflector will connect to its clients.
- The clients of a route reflector in a cluster cannot connect to other BGP speakers out of the cluster.
- Within an AS, full mesh is established among IBGP peers of non-clients. The IBGP peers of non-clients include the following situations: Multiple route reflectors in a cluster; a route reflector in a cluster and BGP speakers (generally not supporting the route reflector function) not involved in the route reflector function out of the cluster; a route reflector in a cluster and route reflectors in other clusters.

The rules for processing a route received by a route reflector are as follows:

- A route update message received by an EBGP speaker will be sent to all clients and non-clients.
- A route update message received by a client will be sent to other clients and all non-clients.
- A route update message received by an IBGP speaker will be sent to all the other clients.

-
- 📘 Generally, only one route reflector is configured in a cluster. In this case, the Router ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set multiple route reflectors in a cluster. In this case, you
-

must configure the cluster ID so that a route reflector can identify the route update messages from other route reflectors in the cluster.

-  If multiple route reflectors are configured for a cluster, you must configure a cluster ID for the cluster.
-  Generally, it is unnecessary to create connections between the clients of a route reflector in a cluster because the route reflector will reflect the routes between the clients. However, if full mesh has been established among all clients, you can cancel the client route reflection function of the route reflector.

Related Configuration

↘ Configuring a BGP Route Reflector and Reflected Clients

By default, BGP is not configured with route reflection.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **route-reflector-client** command to configure a device as a route reflector and its neighbor devices as reflected clients.

↘ Configuring BGP Client-Client Reflection

By default, BGP client-client route reflection is enabled, which means that routes received from a reflected client can be advertised to other clients.

You can run the **bgp client-to-client reflection** command to enable or disable (using the **no** form of this command) client-client reflection.

↘ Configuring a BGP Reflection Cluster ID

By default, a BGP reflection cluster ID is the Router-ID of BGP. If multiple reflection clusters are deployed within an AS, different reflection cluster IDs must be configured for these reflection clusters.

You can run the **bgp cluster-id** *cluster-id* command to manually configure the cluster ID of a route reflector.

7.3.3 Configuring a BGP Alliance

An alliance is another method for reducing the IBGP peer connections within an AS.

Working Principle

Divide an AS into multiple sub ASs and configure a unified alliance ID (namely, the alliance AS NUMBER) for these sub ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, full mesh of IBGP peers can be established for BGP speakers within a sub AS, and EBGP connections can be established for BGP speakers in different sub ASs. Though EBGP connections are established between BGP speakers within a sub AS, when information is exchanged, NEXT_HOP, MED, LOCAL_PREF and other path attributes keep unchanged.

Related Configuration

↘ Configuring a BGP Alliance ID

By default, no alliance ID is configured for a BGP speaker.

You can run the **bgp confederation identifier** *as-number* command to configure a BGP alliance ID. After the configuration is successful, the local AS (specified by the **router bgp** *as-number* command) of BGP becomes the private AS inside the alliance and is invisible to other ASs.

📌 Configuring a BGP Alliance Neighbor

By default, no alliance neighbor is configured for BGP.

You can run the **bgp confederation peers** *as-number* [...] *as-number* command to configure a BGP alliance neighbor. After the configuration succeeds, the AS specified by this command and the local AS belong to the same alliance.

7.3.4 Re-distributing Local AS Network Information to BGP

BGP cannot automatically discover or learn accessible networks. The accessible network information of a local AS must be re-distributed to BGP. Then, BGP can advertise the information to neighbors.

Working Principle

Two methods can be used to re-distribute local AS network information to BGP:

- Manual static configuration: re-distribute the accessible network information within a specified range to BGP.
- Configuring route re-distribution: re-distribute accessible IGP network information to BGP.

 In addition, you can also re-distribute local AS network information to BGP routes by configuring route aggregation.

Related Configuration

📌 Configuring a BGP Network

By default, no network is configured for BGP.

You can run the **network** { *network-number* [**mask** *mask*] | *prefix* } [**route-map** *map-tag*] [**backdoor**] command to configure a BGP network to re-distribute specified accessible network information to BGP. The prerequisite for successfully re-distributing routing information to BGP is that a route is available in the core routing table and this route can be an IGP, directly-connected or static route.

📌 Configuring BGP Route Re-distribution

By default, BGP is not configured with route re-distribution.

Run the **redistribute** *protocol-type* command to import routes of other protocols to BGP, including OSPF, RIP, ISIS, static, and direct routes, host routes converted by ARP, and routes converted by ND.

📌 Importing Routes with Multiple Paths or Next Hops to BGP

By default, routes imported to BGP have only one next hop.

Run the **bgp sourced-paths** *protocol-type* **all** command to import routes with multiple next hops of other protocols to BGP.

7.3.5 Controlling Route Exchange Between BGP Peers

BGP provides powerful route management functions. You can actively control the route exchange between BGP peers.

Working Principle

Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.

Related Configuration

✚ Configuring the Default Route to Be Advertised to a Peer

By default, BGP does not advertise the default route.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*] command to advertise the default route to a peer (or a peer group).

✚ Configuring Next-Hop-Self for a Peer

By default, BGP does not change the next hop of a route when it advertises the route to an IBGP neighbor and sets the next hop to the local BGP speaker when it advertises the route to an EBGP neighbor.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **next-hop-self** command to configure the next hop of a route to the local BGP speaker when distributing the route to a specified BGP peer (group).

✚ Configuring Remove-Private-AS for a Peer

By default, BGP does not delete the private AS in the AS-PATH attribute when it advertises routing information to a peer.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **remove-private-as** [**force** [**ignore-remote-as**]] [**replace-as**] command to require that the private AS number recorded in the AS path attribute should be deleted when routing information is distributed to an EBGP peer (group). This command does not apply to an IBGP neighbor.

✚ Configuring Send-Community for a Peer

By default, BGP does not send the community attribute when it advertises routing information to a peer.

You can run the **neighbor** { *neighbor-address* | *peer-group-name* } **send-community** command to specify that the community attribute can be sent to a specified BGP peer (group).

✚ Configuring Maximum-Prefix for a Peer

By default, BGP does not restrict the records of routing information that can be received by a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **maximum-prefix** *maximum* [**warning-only**] command to specify the records of routing information received from a specified peer (group).

✚ Configuring Route Filtering for a BGP Neighbor

By default, a BGP neighbor is not enabled with any filtering policy and receives all legal routing information advertised by a neighbor.

BGP supports multiple methods of configuring the route filtering policies for a neighbor, including:

- **neighbor** { *neighbor-address* | *peer-group-name* } **distribute-list** { *access-list-number* | *access-list-name* } { **in** | **out** }
Use an ACL to filter routes in the input and output directions of the neighbor.
- **neighbor** { *neighbor-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }
Use an AS-PATH list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *neighbor-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }
Use a prefix-list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *neighbor-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }
Use a route map to filter routes in the input and output directions of the neighbor.
- **neighbor** { *neighbor-address* | *peer-group-name* } **unsuppress-map** *map-tag*
Allow for advertising certain routing information previously suppressed by the **aggregate-address** command when distributing routing information to a specified peer.
- **bgp advertise-map** *map-tag*
Use command **bgp advertise-map** *map-tag* to advertise route policy to all neighbors

7.3.6 Obtaining Accessible Networks of Other ASs from BGP

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Working Principle

📌 BGP Sends Routing Information to a Core Routing Table

BGP controls routing information sent to the core routing table by using **table-map**. **table-map** can modify the attributes of routing information sent to the core routing table. If the route is matched, BGP modifies the attribute of the routing information and sends the route. If the route is not matched or route matching is denied, BGP does not modify the attribute of the routing information but sends the route.

Changes of **table-map** are not reflected in the core routing table immediately, but reflected a moment later. To update the application of **table-map** immediately, you can run the **clear ip bgp [vrf *vrf-name*] table-map** command to update the routing information in the core routing table immediately. This command does not clear the existing routes in the core routing table, but directly applies **table-map** to send the updated routing information, thereby not causing forwarding flapping.

📌 Re-distributing BGP Routes to IGP

Re-distribute BGP routes on a BGP speaker to IGP to ensure that routers within an AS can obtain routes to other ASs.

Related Configuration

📌 Configuring table-map

By default, BGP is not configured with a table-map and allows for sending all routes without modifying the attributes of the routes.

You can run the **table-map** *route-map-name* command to set a table-map and control the routing information to be sent to the core routing table. *route-map-name* specifies a route-map to be associated.

 Run the **table-map** command in the BGP configuration mode or in the IPv4 address family mode.

The Match and Set statements supported in the table-map are as follows:

Match statements: as-path, community, ip address, ip next-hop, metric, origin and route-type

Set statements: metric, tag and next-hop

 You can run the **no table-map** command to delete the table-map configurations.

Configuring BGP Route Re-distribution by IGP

By default, IGP does not re-distribute BGP routes.

You can run the **redistribute bgp** [**route-map** *map-tag*] [**metric** *metric-value*] command to re-distribute BGP routes to IGP (RIP\OSPF\ISIS).

The **bgp redistribute-internal** command controls only whether to re-distribute routes learned from IBGP to IGP. By default, routes learned from IBGP can be re-distributed to IGP.

 You can run the **bgp redistribute-internal** command in the BGP configuration mode, IPv4/IPv6 address family mode or the IPv4 VRF address family mode.

 You can run the **no bgp redistribute-internal** command to delete the configuration.

7.3.7 Configuring Synchronization Between BGP and IGP

Generally, BGP speakers working as mutual IBGP neighbors are not directly connected. IGP devices between the BGP speakers may fail to learn routing information same as that learned by the BGP speakers. When a BGP speaker at the border of an AS forwards packets received from other domains to the next-hop IBGP neighbor, the packets pass an IGP device in the middle. In this case, the packets may be lost due to no routing information on the IGP device.

Working Principle

To keep synchronization between BGP and IGP, you must ensure that all routers within an AS can learn routing information to be sent to another AS before the routing information is advertised to this AS.

Synchronization between BGP and IGP is not required only in the following cases:

- Routing information passing through an AS is not available. For example, the AS is an end AS.
- All routers within an AS run BGP. Full mesh is established among all BGP speakers (neighborship is established between each two BGP speakers).

Related Configuration

Configuring BGP Route Synchronization

By default, synchronization between BGP and IBGP routes is disabled.

You can run the **synchronization** command to enable synchronization between BGP and IGP.

You can run the **no synchronization** command to disable synchronization between BGP and IGP.

7.3.8 Configuring BGP Soft Reset

If routing policies (including **neighbor distribute-list**, **neighbor route-map**, **neighbor prefix-list** and **neighbor filter-list**) change, an effective method must be provided to implement new routing policies. A traditional method is to terminate a BGP connection and then create a new BGP connection. By configuring BGP Soft Reset, you can execute a new routing policy without terminating a BGP session connection.

Working Principle

Routing policies that affect inbound routing information are called inbound routing policies (such as In-route-map and In-dist-list) and routing policies that affect outbound routing information are called outbound routing policies (such as Out-route-map and Out-dist-list).

When outbound routing policies change, BGP soft reset will re-advertise all routing information of a BGP speaker to its neighbors.

If inbound routing policies change, the operation is more complex than that when outbound routing policies change. This is because outbound routing policies are executed in the routing table of the local BGP speaker whereas inbound routing policies are executed for routing information received from the BGP peer. To reduce cost, the local BGP speaker does not store the original routing information received from the BGP peer.

If inbound routing policies change and a neighbor device supports route update, you can configure soft reset to send a route update request to the neighbor device. After receiving the request, the neighbor device re-advertises all routing information. You can also perform configuration to ensure that each BGP peer stores original routing information on the local BGP speaker and provides original routing information basis for modifying inbound routing policies subsequently.

The "route update capability" allows for modifying and executing routing policies without storing original routing information. This product supports the route update capability. You can run the **show ip bgp neighbors** command to check whether a BGP peer supports route update. If yes, you do not need to run the **neighbor soft-reconfiguration inbound** command when inbound routing policies change.

Related Configuration

Configuring BGP Soft Reset

Run the **clear ip bgp { * | neighbor-address | peer-group peer-group-name | external } soft out** command to soft reset a BGP connection. You can activate execution of a routing policy without restarting the BGP session.

Saving Original Routing Information of Neighbors

By default, BGP does not save original routing information of neighbors.

Run the **neighbor { neighbor-address | peer-group-name } soft-reconfiguration inbound** command to save unmodified routing information sent by a BGP peer (group).

7.3.9 Configuring the Route Attributes of BGP

BGP provides various control policies for route attributes. You can apply the policies based on actual conditions.

Working Principle

AS_PATH Attribute

BGP can control distribution of routing information in three modes:

- IP address. You can run the **neighbor distribute-list** and **neighbor prefix-list** commands for implementation.
- AS_PATH attribute. See the description in this section.
- COMMUNITY attribute. See the related configuration of the COMMUNITY attribute.

You can use an AS path-based access control list (ACL) to control the distribution of routing information. Where, the AS path-based ACL uses a regular expression to parse the AS path.

Based on the standard (RFC1771), BGP does not consider the AS path length when selecting the optimum path. Generally, a shorter AS path length means a higher path priority; therefore, Ruijie considers the AS path length when selecting the optimum path. You can determine whether to consider the AS path length when selecting the optimum path based on the actual conditions.

-
-  Within an AS, whether to consider the AS path should be consistent for all BGP speakers when the optimum path is selected; otherwise, the optimum paths selected by the BGP speakers may be different.
-

MULTI_EXIT_DISC Attribute

BGP uses the MED value as the basis for comparing priorities of paths learned from EBGp peers. A smaller MED value means a higher path priority.

- By default, the MED value is compared only for paths of peers from the same AS when the optimum path is selected.
- By default, the MED value is not compared for paths of peers from other sub ASs within an AS alliance.
- By default, if a path not configured with the MED attribute is received, it is considered that the MED value of this path is 0. Since a smaller MED value means a higher path priority, this path has the highest priority.
- By default, the MED value is not compared with paths from different ASs; instead, the sequence of receiving the paths is compared.

LOCAL_PREF Attribute

When sending routes received from EBGp peers to IBGP peers, a BGP speaker adds the LOCAL_PREF attribute. BGP uses the LOCAL_PREF attribute as the basis for comparing priorities of paths learned from IBGP peers. A larger value of LOCAL_PREF means a higher path priority.

You can also run the **set local-preference** command of a route map to modify the LOCAL_PREF attribute of the specified path.

COMMUNITY Attribute

The COMMUNITY attribute is another mode for controlling distribution of routing information.

A community is a set of destination addresses. The COMMUNITY attribute is intended to facilitate execution of a routing policy based on a community and thereby simplify the configuration of routing information distribution control on BGP speakers. Each destination address may belong to multiple communities. An AS administrator can define the communities to which a destination address belongs.

By default, all destination addresses belong to the Internet community and are carried in the community attribute of the path.

At present, four common community attribute values are pre-defined:

- Internet: Indicates the Internet community. All paths belong to this community.
- no-export: Indicates that the path is not advertised to EBGp peers.
- no-advertise: Indicates that the path is not advertised to any BGP peer.
- local-as: Indicates that a path is not advertised to other ASs. When an AS alliance is configured, the path is not advertised to other ASs or sub ASs.

By using the community attribute, you can control the receiving, prioritization and distribution of routing information. BGP speakers can set, add or modify the community attribute when learning, advertising or re-distributing routes. An aggregation path will contain the community attribute values of all aggregated paths.

BGP supports up to 32 COMMUNITY attributes for each route and allows for up to 32 COMMUNITY attributes when match and set COMMUNITY of a route map are configured.

Others

During selection of the optimum path, if two paths with the same path attributes are received from different EBGp peers, the optimum path is selected based on the receiving sequence by default. You can disable comparison of the receiving sequence but use the path with a smaller router ID as the optimum path.

Related Configuration

Configuring AS_PATH Attribute

- **ip as-path access-list** *path-list-name* { **permit** | **deny** } *as-regular-expression*
Defines an AS path list.
- **neighbor** { *neighbor-address* | *peer-group-name* } **filter-list** *path-list-name* { **in** | **out** }

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on the AS path list to advertise or receive only routes that match the policies.

- **neighbor** { *neighbor-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

By default, no filtering policy is configured for BGP peers.

The configuration is the same as when receiving and sending routing information for a specified BGP peer (group). Routing policies are executed based on a route map or the set rules in the route map are used to modify routing attributes.

-
-  In the route-map configuration mode, you can run the **match as-path** command to modify AS path attributes by using an AS path list or directly run the **set as-path** command to modify AS attribute values.
-

- **bgp bestpath as-path ignore**

Allows BGP not to consider the AS path length when selecting the optimum path. The AS path length is compared by default.

By default, a smaller AS path length means a higher path priority.

Configuring MULTI_EXIT_DISC Attribute

- **bgp always-compare-med**

Allows for comparing the MED values of paths from different ASs, which is disabled by default.

- **bgp bestpath med confed**

Allows for comparing the MED values of paths of peers from other sub ASs in the same AS alliance, which is disabled by default.

- **bgp bestpath med missing-as-worst**

Sets a path not configured with the MED attribute to the lowest priority, which is disabled by default.

- **bgp deterministic-med**

Allows for comparing the paths of peers within the same AS, which is disabled by default.

Configuring LOCAL_PREF Attribute

- **bgp default local-preference** *value*

Changes the default local preference value, ranging from 0 to 4,294,967,295. A larger value means a higher priority. The default value is 100.

Configuring COMMUNITY Attribute

- **ip community-list standard** *community-list-name* { **permit** | **deny** } *community-number*

Creates a community list. **community-list-name** indicates the name of the community list.

-
-  *community-number*: Indicates a value (0 to 4,294,967,295) specified by a user or a known community attribute (internet, local-AS, no-advertise or no-export).
-

- **neighbor** { *neighbor-address* | *peer-group-name* } **send-community**

Allows for sending the community attribute to a specified BGP peer (group), which is not configured by default.

- **neighbor** { *neighbor-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on a route map. No filtering policy is configured for peers by default.

-
-  In the route-map configuration mode, you can run the **match community-list [exact]** and **set community-list delete** commands to modify the community attribute by using a community list or directly run the **set community** command to modify the community value.
-

Others

- **bgp bestpath compare-routerid**

Allows BGP to compare the router ID when selecting the optimum path, which is disabled by default.

- **bgp bestpath igp-metric ignore**

Enable BGP not to compare the IGP metric value of the next hop when selecting the optimum path. By default, a next hop with a smaller IGP metric value has a higher priority.

7.3.10 Configuring BGP Route Aggregation

BGP-4 supports CIDR and therefore allows for creating aggregation entries to reduce the size of a BGP routing table. BGP aggregation entries can be added to a BGP routing table only when valid paths are available within the aggregation range.

Working Principle

Aggregate one or more detailed BGP routes into a BGP route with a shorter network mask.

-
-  By default, BGP advertises all path information before and after aggregation. If you hope that only aggregated path information is advertised, you can run the **aggregate-address summary-only** command.
-  When the **aggregate-address** command is used to configure an aggregated route, the aggregated route takes effect immediately as long as there are routes in the configured address range.
-

Related Configuration

Configuring BGP Route Aggregation

By default, BGP does not aggregate any route entries.

Run the **aggregate-address { ip-address mask | prefix } [as-set] [summary-only] [suppress-map map-tag1] [advertise-map map-tag2] [attribute-map map-tag3]** command to configure BGP route aggregation.

7.3.11 Configuring BGP Route Dampening

If a route changes between being valid and invalid, route flapping occurs.

Route flapping often causes transmission of unstable routes in a network, and thereby causes network instability. BGP route dampening is a method for reducing route flapping. It reduces possible route flapping by monitoring routing information from EBGP peers.

Working Principle

Terms used in BGP route dampening are as follows:

- Route Flap: A route changes between being valid and invalid.
- Penalty: Once route flapping occurs, a BGP speaker enabled with route dampening adds a value to the penalty for this route. The penalty is accumulated until the Suppress Limit is reached.
- Suppress Limit: When the penalty of a route is greater than this value, the route will be suppressed.
- Half-life-time: The time used for the penalty to be halved.
- Reuse Limit: When the penalty value of a route is smaller than this value, route suppression will be canceled.
- Max-suppress-time: The longest time that a route can be suppressed.

A brief description of route dampening processing: BGP speaker punishes a route once (adds to the penalty) route flapping occurs. When the penalty reaches the Suppress Limit, the route will be suppressed. When the Half-life-time reaches, the penalty is halved. When the penalty is reduced to the Reuse Limit, the route is activated again. The Max-suppress-time indicates the longest time that the route can be suppressed.

By default, the penalty value increases by 1000 when a route is canceled and increases by 500 when a route is updated.

Related Configuration

📌 Configuring BGP Route Dampening

Run the **bgp dampening** [*half-life* [*reusing suppressing* max-suppress-time] [**withdrawal-ignore**] | **route-map** *name*] command to enable BGP route dampening.

half-life-time (1~45minutes): The default value is 15 minutes. A larger value means a longer flapping suppression and dampening period.

reuse (1~20000): The default value is 750. A smaller value means longer time for continuous stabilization before a flapping route is enabled again.

suppress (1~20000): The default value is 2,000. A smaller value means more flapping times allowed before suppression.

max-suppress-time (1~255minutes): The default value is 4*half-life-time. A larger value means longer maximum suppression time.

Run the **withdrawal-ignore** command to ensure that the penalty value is not increased for route cancellation.

Run the **route-map** *name* command to set the routing policy to apply route dampening to some routes.

📌 Setting Route Dampening Policy

Run the **set dampening** *half-life reusing suppressing* max-suppress-time [**withdrawal-ignore**] command to apply the route dampening function in the routing policy.

📌 Displaying BGP Route Dampening

- **show ip bgp dampening flap-statistics**
Displays the flapping statistics about all routes.
- **show ip bgp dampening dampened-paths**

Displays the statistics about suppressed routes.

↘ Resetting BGP Route Dampening

- **clear ip bgp flap-statistics**

Clears the flapping statistics about all routes that are not suppressed.

- **clear ip bgp flap-statistics** *address mask*

Clears the flapping statistics about specified routes (excluding suppressed routes).

- **clear ip bgp dampening** [*address* [*mask*]]

Clears the flapping statistics about all routes, including routes whose suppression is cancelled.

7.3.12 Configuring the Management Distance of BGP

The management distance is used to evaluate the reliability of various route sources. A smaller management distance means a better route.

Working Principle

↘ Management Distance of BGP

The management distance indicates the reliability of a route source, ranging from 1 to 255. A larger value means lower reliability. BGP sets different management distances for routing information learned from different sources, including External-distance, Internal-distance and Local-distance.

- External-distance: Indicates the management distance of routes learned from EBGp peers.
- Internal-distance: Indicates the management distance of routes learned from IBGP peers.
- Local-distance: Indicates the management distance for routes learned from peers but it is considered that better routes can be learned from IGP. Generally, these routes can be indicated by the **Network Backdoor** command.

You are not advised to change the management distance of BGP. If you really need to change the management distance of BGP, please remember:

The external-distance should be shorter than the management distances of other IGP routing protocols (OSPF and RIP).

The internal-distance and local-distance should be longer than the management distances of other IGP routing protocols.

↘ Backdoor Route

If you prefer an IGP route but do not use an EBGp route, you can set the EBGp route as the backdoor route. By default, the management distance for routes learned from a BGP speaker for which an EBGp connection is established is 20. You can run the **network backdoor** command to set the management distance of the network information to 200 so that the same network information learned from IGP has the highest priority. The networks learned from IGP are considered backdoor networks and are not advertised.

Related Configuration

Configuring the Management Distance of BGP

You can run the **distance bgp** *external-distance internal-distance local-distance* command to configure the management distance of BGP. The value ranges from 1 to 255.

The default value of *external-distance* is 20; the default value of *internal-distance* is 200; the default value of *local-distance* is 200.

A longer management distance means a lower route priority.

Configuring a Backdoor Route

Run the **network** *network-number* **mask** *network-mask* **backdoor** command to configure a backdoor route. By default, no backdoor route is configured.

7.3.13 Configuring Multi-path Load Balancing of BGP

Multi-path load balancing means that there are multiple paths to the same network and data packets are evenly forwarded by these paths. In a routing table, one route has multiple next hops.

According to the types of equivalent routes, multi-path load balancing of BGP is classified into the following types:

- EBGp load balancing: implement load balancing for routes learned from EBGp neighbors.
- IBGP load balancing: implement load balancing for routes learned from IBGP neighbors.

 Both the IPv4 and IPv6 protocol stacks support multi-path load balancing.

 Load balancing cannot be implemented between IBGP and EBGp routes (including EBGp routes in an alliance).

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. If there are optimum multiple routes with the same priorities, BGP still selects a unique route by using comparison rules, notifies the route to the forwarding plane and controls the forwarding of data streams. After multi-path load balancing is enabled, BGP calculates a unique optimum route and also lists paths with the same priorities as equivalent routes. Then, BGP notifies the optimum route and the equivalent routes to the forwarding plane to implement load balancing.

Equivalent routes have the same basic attributes and priorities. That is, according to the optimum path selection rules of BGP, the paths have the same priorities before router-IDs are compared.

AS_PATH Loose Comparison

By default, equivalent routes must have the same AS-PATH attributes. Under such strict conditions, load balancing cannot be implemented in certain environments. In this case, you are advertised to enable the AS-PATH loose comparison mode. In the AS-PATH loose comparison mode, when other conditions for equivalent routes are met, as long as the AS-PATH lengths of routes and the AS-PATH lengths of routes from an alliance are the same respectively, it is considered that the conditions for equivalent routes are met.

When the next hops of multiple BGP equivalent paths recur to the same IGP output interface, load balancing cannot be implemented.

Router ID Multi-path Comparison

By default, equivalent routes do not need to come from the same device (Router ID of the source route does not need to be the same). Enable this function so that only the routes from the same Router ID can be equivalent.

Related Configuration

Configuring Multi-path Load Balancing of BGP

- **maximum-paths { ebgp | ibgp } number**

Enables the multi-path load balancing function of BGP.

number indicates the number of equivalent next hops, ranging from 1 to device capacity. The default value is 1. A larger value means more equivalent next hops allowed.

Configuring AS_PATH Loose Comparison

- **bgp bestpath as-path multipath-relax**

Enables the BGP AS-PATH loose comparison mode.

Configuring Router ID Multi-path Comparison

- **bgp bestpath multipath-compare-routerid**

7.3.14 Enables the router ID multi-path comparison mode. Configuring BGP FRR

With high-speed development of IP technologies and application of various complex services, the requirements for network security and stability become increasingly higher. Especially, certain real-time services (audios and videos) are sensitive to network running status and may be largely affected by unstable networks. Therefore, more and more focus and importance are attached to network reliability. With these requirements, the IP FRR function comes into being. It is intended to use a backup link to maintain data forwarding during route platform convergence after a faulty link is detected, in order to achieve the ideal targets of "zero delay" and "zero loss" in packet forwarding.

BGP FRR is shorted for Fast Reroute.

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. After the BGP FRR function is used, BGP selects a backup route for each optimum route. After BFD FRR detects that the master link is faulty, it switches the data to the originally calculated backup link for forwarding. After route convergence is completed, data is switched to the optimum route re-calculated for forwarding. In this way, BGP FRR can avoid route disconnection due to a link fault before BGP route convergence is completed.

Only one backup route can be generated and the next hop of the backup route cannot be the same as that of the preferred route.

-  A backup next hop cannot be generated for an Equal-Cost Multi-Path Routing (ECMP) route.
-  BGP FRR has a lower priority than VPN FRR. That is, if VPN FRR is enabled in the VRF mode, BGP FRR takes effect only when VPN FRR fails to calculate a backup route.

Related Configuration

Configuring BGP FRR

Run the **bgp fast-reroute** command to enable the BGP FRR function, which is disabled by default.

Configuring a BFD Session to a BGP Neighbor

Run the **neighbor { neighbor-address | peer-group-name } fall-over bfd** command to configure a BFD session to a BGP neighbor, which is not configured by default.

Manually Configuring a BGP BFD Session

If the BFD session to a BGP neighbor cannot be used to fast detect the failure of the master link, you can run the **bfd bind bgp peer-ip ip-address interface interface-type interface-index source-ip ip-address** command to configure a BGP BFD session, which is not configured by default.

7.3.15 Configuring Fast Withdrawal of Specified BGP Routes

With the rapid development of IP technologies and the application of various complex services, increasingly higher requirements are imposed on the network. Customers may need to implement fast convergence on specific routes. Fast route withdrawal can meet customers' requirements for preferentially withdrawal of specific routes.

Working Principle

By default, routes are withdrawn based on preferential calculation according to the sequence in the routing table. Fast route withdrawal adds the routes meeting conditions to a high-priority queue to implement preferential processing of specified routes, so that the specified routes can be withdrawn quickly.

-  The L2VPN address family supports the route map mode only.
-  Only one of the access list and prefix list takes effect.

Related Configuration

Activating the Address Family Capability

By default, only the IPv4 unicast address family capability is activated for the neighbors created in BGP configuration mode.

Run the **address-family** command to enter the corresponding address family mode.

Configuring Fast Withdrawal of Specified BGP Routes

Run the **bgp fast-withdraw { access-list { access-list-number | access-list-name } | prefix-list prefix-list-name | route-map map-tag }** command to enable fast withdrawal of specified BGP routes in the address family. This function is disabled by default.

7.3.16 Configuring BGP Multi-path Bypass Protection

The original BGP FRR supports only 1:1 protection. After the ECMP function is enabled, the FRR becomes unavailable. The multi-path bypass protection enables BGP to support 1:N protection. Users can configure BGP multi-path bypass protection to enable the system to select a backup bypass path even if ECMP is configured. When all ECMP routes fail, the bypass route becomes the primary route for forwarding.

Working Principle

By default, when there are multiple paths reachable to the same network in the BGP routing table, BGP calculates one route with the highest priority. After the BGP multi-path bypass protection function is enabled, BGP preferentially selects a backup route when ECMP routes exist. When BFD detects a fault occurring on the master path, the system switches to the selected backup path for data forwarding. After route convergence is completed, the system switches to the optimum path that is re-calculated based on routes to forward data.

-  Only one bypass route is generated and the next hop of the bypass route cannot be the same as next hops of ECMP routes.
-  The BGP FRR function conflicts with the BGP multi-path bypass protection function. If either of them is configured when the other function is already available, a conflict prompt will be displayed.

Related Configuration

Configuring BGP Multi-path Bypass Protection

Run the **bgp install standby-path** command to enable BGP multi-path bypass protection, which is disabled by default.

Configuring a BFD Session to a BGP Neighbor

Run the **neighbor { neighbor-address | peer-group-name } fall-over bfd** command to configure a BFD session to a BGP neighbor, which is not configured by default.

7.3.17 Allowing the BGP Route Reflector to Modify Route Attributes

According to RFC4456, the BGP route reflector cannot modify route attributes when reflecting routes (the purpose is to prevent route loops). However, relevant route attributes need to be modified when network traffic paths need to be re-planned. This command is configured to allow the route reflector to modify route attributes (including **Route-map** or **nexthop-self**).

Working Principle

The route reflector is not allowed to modify route attributes by default. After this command is configured, the route reflector is allowed to modify route attributes.

Related Configuration

Configuring a BGP Route Reflector and Reflection Client

No BGP route reflector is configured by default.

Run the **neighbor** *neighbor-address* **route-reflector-client** command to configure the local device as the route reflector and the neighbor as the route reflection client.

↘ Configuring BGP Client-Client Reflection

By default, client-client route reflection is automatically enabled on the BGP route reflector, and routes received from the reflection client are allowed to be advertised to other clients.

Run the **bgp client-to-client reflection** command to enable client-client reflection. Run the **no** form of this command to disable client-client reflection.

↘ Configuring a BGP Reflection Cluster Identifier

By default, the BGP reflection cluster identifier directly uses the BGP Route-ID. When multiple reflection clusters are deployed in one AS domain, different reflection cluster identifiers need to be configured for them.

Run the **bgp cluster-id** *cluster-id* command to manually configure a cluster identifier for the route reflector.

↘ Allowing the BGP Route Reflector to Modify Route Attributes

By default, BGP does not allow the route reflector to modify route attributes.

Run the **bgp route-reflector attribute-change** command to allow the route reflector to modify route attributes.

7.3.18 Configuring the BGP Device to Advertise Routes with the Lowest Priority upon Restart

By default, after the device is restarted and a neighborship is established, a BGP peer can advertise routes to its neighbors. However, in some cases, for example, there are a large number of neighbors or routes when the device is started but is slow in writing entries to hardware. The neighbors have learnt routes and start forwarding traffic, but the local device has not completed entry writing to the hardware, resulting in a traffic forwarding failure. Therefore, BGP needs to advertise routes with the lowest priority after device restart. In this way, other available routes instead of routes that pass through the local device are preferentially selected.

Working Principle

Configure the BGP device to advertise routes with the lowest priority upon restart. In this way, after the BGP device is restarted and neighborships are established, the BGP device advertises routes with the lowest priority to its neighbors. Adjust the **MED** value of routes to **4,294,967,295** for EBGP neighbors and adjust the value of **local-pref** to **0** for IBGP neighbors. After all ARP entries are delivered and all forwarding entries are written into hardware, run the **clear bgp advertise lowest-priority on-startup** command to restore the priority of advertised routes. If a user does not configure to restore the priority of advertised routes, the device automatically restores the priority of advertised routes after a period of time.

Related Configuration

↘ Configuring the BGP Device to Advertise Routes with the Lowest Priority upon Restart

- **bgp advertise lowest-priority on-startup** [*recover-time*]

Configure BGP to adjust the priority of advertised routes to the lowest upon device restart. The priority is not adjusted by default. **recover-time** indicates the time (in seconds) of the timer for restoring the priority of advertised routes. The value range is from **1** to **65,535** and the default value is **600**.

7.3.19 Configuring BGP Timers

You can manually configure various timers within BGP to meet the neighbor keepalive and route management requirements in different network environments.

Working Principle

📌 BGP Neighbor Keepalive Timer

BGP uses the Keepalive timer to maintain a valid connection with a peer and uses the Holdtime timer to identify whether a peer is valid. By default, the value of the Keepalive timer is 60 seconds and the value of the Holdtime timer is 180 seconds. When a BGP connection is established between two BGP speakers, the two BGP speakers negotiate about the Holdtime timer value and select a smaller value. 1/3 of the negotiated Holdtime timer value and the configured Keepalive timer value are compared and the smaller value is used as the Keepalive timer value.

📌 Neighbor Reconnection Timer

To reduce the impacts of frequent BGP reconnection to a neighbor on the network bandwidth, after a BGP speaker detects failure of a neighbor connection, the BGP speaker attempts to reconnect the neighbor after the connect-retry timer expires. By default, the value of the connect-retry timer is 15s.

📌 Route Advertisement Timer

To reduce the impacts of route update packets on the network bandwidth, after a BGP speaker detects a network topology change, the BGP speaker does not advertise the route update to its neighbors immediately. Instead, the BGP speaker uses a regular update mechanism to advertise all changed routing information to its neighbors.

Related Configuration

📌 Configuring the BGP Neighbor Keepalive Timer

- **timers bgp** *keepalive holdtime*

Adjusts the BGP *keepalive* and *holdtime* values for all peers.

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

- **neighbor** { *neighbor-address* | *peer-group-name* } **timers** *keepalive holdtime*

Configures the *keepalive* and *holdtime* values used for connecting to a specified BGP peer (group).

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

📌 Configuring the Neighbor Re-connection Timer

- **neighbor** { *neighbor-address* | *peer-group-name* } **timers connect connect-retry**

Configures the *connect-retry* value used for reconnecting to a specified BGP peer (group).

The value of *connect-retry* ranges from 1 to 65,535. The default value is 15 seconds.

📌 Configuring the Route Advertisement Timer

- **neighbor** { *neighbor-address* | *peer-group-name* } **advertisemet-interval seconds**

Configures the minimum interval for sending route updates to a specified BGP peer (group). The value of *advertisemet-interval* ranges from 0 to 600 seconds. The default value for IBGP peers is 0 seconds and the default value for EBGP peers is 30 seconds.

- **neighbor** { *neighbor-address* | *peer-group-name* } **as-origination-interval seconds**

Configures the minimum interval for sending local initial route updates to a specified BGP peer (group). The value of *As-origination-interval* ranges from 1 to 65,535. The default value is 1 second.

7.3.20 Configuring BGP Route Update Mechanisms

Working Principle

BGP provides two route update mechanisms: regular-scanning update and event-triggering update. Regular-scanning update indicates that BGP uses an internal timer to start scanning regularly and update the routing table. Event-triggering update indicates that BGP starts scanning and updates the routing table when the BGP configuration commands are changed due to user configuration or the next hop of a BGP route changes.

- ❗ This function is configured based on address families and can be configured in the IPv4, IPv6, IPv4 vrf and IPv6 VRF address family modes.
- ❗ If you set the BGP route update mechanism to event-triggering update (by running the **bgp scan-rib disable** command), you must disable synchronization (by running the **no synchronization** command) and enable the BGP next-hop triggering update function (by running the **bgp nexthop trigger enable** command). On the other hand, if you enable synchronization or disable the BGP next-hop triggering update function, the BGP routing table must be updated in the regular scanning mode.

Related Configuration

📌 Configuring Route Update Mechanisms

- **bgp scan-rib disable**

Sets the BGP route update mechanism to event-triggering update. Regular-scanning update is used by default.

- **bgp scan-time scan-time**

Configures the regular update interval of BGP. The value of *scan-time* ranges from 5 to 60 seconds. The default value is 60 seconds.

7.3.21 Configuring the Next-Hop Triggering Update Function of BGP

The next-hop triggering update function of BGP is a method for reducing the BGP convergence time. This function is used to optimize the method for monitoring the next hop of a route to ensure that BGP can increase the BGP route convergence speed when the network topology is stable.

Working Principle

When BGP connects to a neighbor, BGP automatically monitors the next hop of the BGP route learned from the neighbor. When the next hop changes in the core routing table, BGP receives an advertisement about the next hop change and updates the BGP routing table. This optimization measure improves the BGP route convergence performance by reducing the time for detecting next-hop changes.

If this function is disabled, BGP next hop update will be discovered through regular scanning specified by scan-timer.

-
-  This function is configured based on address families and can be configured in the IPv4, IPv6, and IPv4 vrf address family modes.
 -  **bgp nexthop trigger delay** and **bgp scan-time** control the same timer. When bgp scan is enabled (it is enabled by default and can be disabled by the **bgp scan-rib disable** command), if the value of **bgp nexthop trigger delay** is larger than 60s, bgp scan does not take effect because the scan timer is always triggered before the delay.
 -  If the network environment is unstable (with frequent next-hop changes), especially with many routes, this function performs unnecessary route calculations, which consumes more CPU resources. Therefore, you are advised to disable this function in this environment.
-

Related Configuration

📌 Configuring the Next-Hop Triggering Update Function of BGP

- **bgp nexthop trigger enable**
Enables the BGP next-hop triggering function, which is enabled by default.
- **bgp nexthop trigger delay** *delay-time*
Configures the delay of BGP next-hop triggering update. The value of *delay-time* ranges from 0 to 100 seconds. The default value is 5 seconds.

7.3.22 Configuring BGP LOCAL AS

The Local AS function of BGP is used to configure a local AS different from a router BGP AS for a specific peer. This is similar to deploying a new virtual AS between the peer devices. When the local router BGP AS changes, you can establish a BGP connection without changing the BGP configurations on the peer device. This function is mainly used for AS migration and merging of large networks and ensures that the device configurations in other interconnected ASs are not affected.

Working Principle

In BGP, when a local device connects to a peer, the local device advertises the local AS number to the peer by using an Open message. The peer checks whether the BGP AS number advertised is the same as the local AS number. If the AS

numbers are different, the peer will deny the BGP connection. By default, the local AS in the BGP connection is a route BGP AS. However, if a local AS is configured for the peer, the configured local AS will replace the route BGP AS when a BGP connection is established between the local device and the peer.

-  The **neighbor** { *neighbor-address* | *peer-group-name* } **local-as** *as-num* command for configuring the BGP Local AS function can be followed by more options. For details, see the Command Reference.
-  The BGP Local AS function is applied only to EBGP peers, but is not applied to IBGP peers and alliance EBGP peers. In addition, the BGP Local AS function has the following restrictions:
 - 1) The configured local AS cannot be the same as the remote AS of a peer.
 - 2) The local AS cannot be configured independently for a member of a peer group.
 - 3) The configured local AS cannot be the same as the route BGP AS.
 - 4) If a device is a member of an AS alliance, the local AS cannot be the same as the AS alliance number.

Related Configuration

Configuring BGP LOCAL AS

- **neighbor** { *neighbor-address* | *peer-group-name* } **local-as** *as-number*
Configures a local AS for a peer. By default, no local AS is configured for any peer. The local AS of a peer is the route BGP AS.

7.3.23 Configuring BGP Capacity Protection

There are often a large number of BGP routes, which may cause overload of a device, especially for a device with small memory. Protecting BGP capacity helps avoid non-predictable running status caused by consumption of device capacity.

Working Principle

Restricting the Number of BGP Routes

Restrict the number of BGP routes by setting the maximum number of routes in a BGP address family and the maximum number of routes that can be learned by a BGP neighbor.

Entering the OVERFLOW State in case of Insufficient Memory

If the memory is insufficient, BGP can enter the OVERFLOW state. In the OVERFLOW state, BGP generates a default route pointing to a NULL interface. If a newly learned route is not a refined route other than the default route in the current routing table, the route is discarded. In other words, general newly learned routes are discarded to ensure that the system memory is stable. The purpose of not discarding all routes is to avoid route loops in the entire network. Therefore, it is safe for BGP to enter the OVERFLOW state. BGP is allowed to enter the OVERFLOW state by default.

-  By default, BGP enters the OVERFLOW state in case of insufficient memory. If you do not want BGP to enter the OVERFLOW state, you can run the **no overflow memory-lack** command to disable this function.
-  In the OVERFLOW state, BGP supports only the **clear bgp** { *addressfamily* | **all** } * command at present. You can also exit from the OVERFLOW state by disabling and enabling BGP again. When the memory becomes sufficient again, BGP can also automatically exit from the OVERFLOW state.

Related Configuration

Restricting the Number of BGP Routes

- **neighbor** { *neighbor-address* | *peer-group-name* } **maximum-prefix** *maximum* [**threshold**] [**warning-only**]
Restricts the maximum number of routes that can be learned from a BGP neighbor, which is not restricted by default.
- **maximum-prefix** *maximum*
Restricts the maximum number of routes in a BGP address family, which is not restricted by default..
- Run the **bgp maximum-prefix** *maximum* [**vrf** *vrf-name*] command to restrict the maximum number of routes in the BGP global or specified VRF. When a route advertisement in an address family causes the current number of BGP routes to exceed the maximum number, a prompt indicating route overflow in the global or specified VRF is displayed, and the BGP global or specified VRF is set to the overflow state. This function is disabled by default.

Configuring BGP Overflow

- **overflow memory-lack**
Enable BGP to enter the OVERFLOW state in case of insufficient memory, which is enabled by default.

7.3.24 Configuring BGP GR

Graceful Restart (GR) is intended to implement uninterrupted data forwarding during restart of BGP. During active/standby switching of the management boards, the GR function keeps the network topology stable, maintains the forwarding table and ensures that key services are not interrupted.

Working Principle

-  Comply with RFC4724: Graceful Restart Mechanism for BGP. [BGP GR] is used in the following description to indicate the RFC.

BGP GR is not an independent process, but is jointly completed by the Restarter and Helper.

- The Restarter performs restart and maintains the working capability of the route forwarding plane when the route control plane is faulty.
- The Helper is the BGP neighbor of the Restarter and helps the Restarter to complete GR.

A capability indicating GR is added to the OPEN message of BGP, which is called "Graceful Restart Capability". This capability is used by BGP to tell its neighbor it supports the graceful restart capability. During initialization of a BGP connection, two neighbors negotiate about the GR capability.

The route update end flag (End-of-RIB, shorted as EOR) is added to the Update packet of BGP, which indicates that the routing information update to the neighbor is completed.

Figure 7-3 BGP GR Interaction Process

5. ① When BGP establishes neighborhood at the beginning, BGP uses the GR capability field in the OPEN message to negotiate about the GR capabilities of the two neighbors.
6. ② At a moment, the Restarter starts restart, and the BGP session is disconnected. The Helper detects the disconnection, keeps the route of the Restarter valid but adds the "Stale (aged but not updated)" flag to the route.
7. ③ and ④ The Restarter completes restart and connects to the Helper again.
8. ⑤ The Restarter waits for the route update message and EOR flag from the Helper.
9. ⑥ After receiving the EOR flag from all neighbors, the Restarter performs route calculation, update routing entries and then sends updated routes to the Helper.
10. ⑦ After receiving the updated routes, the Helper cancels the "Stale" flag of the routes. After receiving the EOR flag from the Restarter, the Helper deletes routes with the "Stale" flag (these routes are not updated), performs route calculation, and updates the routing entries. The entire GR process is completed.

BGP GR defines several extended and important timers:

- **Restart-Timer:** The GR Restarter advertises the time value to the GR Helper, which indicates the maximum waiting time that the GR Restarter hopes the Helper to wait before a new connection is established between them. You can run the **bgp graceful-restart restart-time** command to modify the time value.
- **Wait-For-EOR Timer:** Indicates the maximum time that the GR Restarter waits for the EOR flag from all GR Helpers. After receiving the EOR flag from all GR Helpers or after the Wait-For-EOR timer expires, the GR Restarter calculates the preferred route and updates the routing entries. You can run the **bgp update-delay** command to modify the time value.
- **StalePath Timer:** Indicates the maximum time that the GR-Helper waits for the EOR flag from the GR Restarter after a new connection is established between them. Within this period, the Helper keeps the original route of the Restarter valid. After receiving the EOR flag or after the StalePath timer expires, the Helper clears the routing entries still with the "Stale" tag. You can run the **bgp graceful-restart stalepath-time** command to modify the time value.

Related Configuration

📄 Configuring BGP GR

- **bgp graceful-restart**
Enables the Restarter capability, which is enabled by default.
- **bgp graceful-restart restart-time *time***
Sets the Restart Timer. The default value is 120 seconds.
- **bgp update-delay *delay***
Sets the Wait-For-EOR Timer. The default value is 120 seconds.
- **bgp graceful-restart stalepath-time *time***
Sets the StalePath Timer. The default value is 360 seconds.
- **bgp graceful-restart disable**
Disables the address family GR capability. The address family GR capability is enabled by default. After the global BGP GR is enabled, the GR capability is automatically enabled for all address families.

i When BGP GR is implemented, all BGP peers must enable the BGP GR capability. If certain peers do not support or enable GR, BGP GR may fail to be implemented. GR failure may cause a short route black-hole or route loop, which may affect the network. Therefore, you are advised to verify that all neighbors are enabled with the BGP GR capability. You can run the **show ip bgp neighbors** command to display the capabilities successfully negotiated between BGP peers and verify that the GR capability negotiation is successful. In the BGP route configuration mode, run the **bgp graceful-restart** command to enable the BGP GR capability.

i The **bgp graceful-restart** command will not be applied to a successfully established BGP connection immediately. That is, when the BGP connection is in the Established state, the BGP peers will not re-negotiate about the GR capability immediately. To enable the BGP peers of the BGP connection to negotiate about the GR capability immediately, you need to forcibly restart the BGP peers to re-negotiate about the GR capability by running the **clear ip bgp**

192.168.195.64 command (for example). To make GR enabling or disabling take effect immediately, you must restart the neighborhood for capability negotiation, which may cause network flapping and affect normal use of users. Therefore, you can explicitly control whether to restart the neighborhood.

-  Supporting BGP GR does not mean that a device can be used as the Restarter to implement BGP GR. Whether to implement BGP GR also depends on the hardware capabilities of the device. Ruijie devices must support the dual-engine hot backup when being used as the GR Restarter.
-  The restart period configured by the **bgp graceful-restart restart-time** command should not be longer than the Hold Time of the BGP peers; otherwise, the Hold Time will be used as the restart time to be advertised to the BGP peers during GR capability negotiation.
-  The **bgp graceful-restart disable** command is used to disable the GR capability in an address family in the address family configuration mode, which is not configured by default.

7.3.25 Configuring 4-Byte AS Numbers of BGP

A traditional AS number consists of 2 bytes, ranging from 1 to 65,535. A newly defined AS number consists of 4 bytes, ranging from 1 to 4,294,967,295. Newly defined AS numbers are used to cope with exhaustion of AS number resources.

Working Principle

4-byte AS numbers support two expression modes: the decimal mode and dot mode. The decimal mode is the same as the original expression mode, that is, expressing the 4 bytes of an AS number as decimal digits. The dot mode is expressed as ([higher 2 bytes.]lower 2 bytes). If the higher 2 bytes are 0, they will not be displayed.

For example, an AS number is 65534 in the decimal mode and is 65,534 in the dot mode (the 0 at the beginning is not displayed).

For example, an AS number is 65,536 in the decimal mode, and is 1.0 in the dot mode.

For example, an AS number is 65,538 in the decimal mode, and is 1.2 in the dot mode.

-  Related protocols are as follows: RFC 4893 and RFC 5396.

Configuring the Display Mode of a 4-Byte AS Number

A 4-byte AS number is displayed in the decimal mode by default. You can manually set the display mode to the dot mode. After the setting, a regular expression will use the dot mode for matching 4-byte AS numbers.

Compatibility with Devices Supporting Only 2-Byte AS Numbers

With introduction of 4-byte AS numbers, BGP connections may be established between old BGP speakers supporting only 2-byte AS numbers and new BGP speakers supporting 4-byte AS numbers. If the AS where a new BGP speaker resides has a 4-byte AS number, when an old BGP speaker creates neighborhood with the new BGP speaker, the old BGP speaker uses the reserved AS number 23,456 to replace the 4-byte AS number of the new BGP speaker. In the OPEN packets sent by the new BGP speaker to the old BGP speaker, the 4-byte AS number in the **My Autonomous System** field will be replaced by 23,456. In addition, in UPDATE packets sent to the old BGP speaker, the 4-byte AS number in the AS-PATH and AGGREGATOR attributes will also be replaced by 23,456. In addition, new optional transfer attributes AS4-PATH and AS4-

AGGREGATOR will be used to record the real 4-byte AS number so that the real AS-PATH and AGGREGATOR attributes can be restored when the route reaches a next new BGP speaker.

In other cases, the real AS number of the remote end is used to create neighborhood.

Related Configuration

Configuring the Display Mode of a 4-Byte AS Number

- **bgp asnotation dot**

Displays a 4-byte AS number in the dot mode. The decimal mode is used by default.

7.3.26 Configuring a Regular Expression

A regular expression is a formula that matches strings based on a template.

The formula is used to assess text data and return True or False to indicate whether the expression can correctly describe the data.

Working Principle

Regular expressions are used in BGP path attributes. The following table describes the usages of special characters in a regular expression.

Character	Symbol	Special Meaning
Period	.	Matches any single character.
Asterisk	*	Matches zero or any sequence in a string.
Plus sign	+	Matches one or any sequence in a string.
Question mark	?	Matches zero or one symbol in a string.
Caret	^	Matches the start of a string.
Dollar sign	\$	Matches the end of a string.
Underline	_	Matches the start, end and space of commas, brackets and strings.
Square brackets	[]	Matches a single character within a range.

Related Configuration

Using a Regular Expression in a show Command

- **show ip bgp regexp *regexp***

Displays the BGP routing information in a specified regular expression matched by the AS-PATH attribute.

- **show ip bgp quote-regexp *regexp***

Displays the BGP routing information in a regular expression within the specified double quotation marks matched by the AS-PATH attribute.

7.3.27 Configuring BGP Session Retention

By default, when an UPDATE packet is received from a neighbor, a BGP session will be disconnected if an error is detected on the multi-protocol routing attribute. This will cause flapping of the routes in all address families of this neighbor. That is, the routing error in an address family will affect the route stability in other address families.

Working Principle

After the BGP session retention function is enabled, if an error occurs in the routing attribute of an address family, only the routing information in this address family related to the neighbor is deleted. In addition, the BGP session and other address families are not affected, which enhances the stability of BGP.

recovery-time is used to configure the time for waiting for automatic route recovery, which requires that a neighbor should support the route-refresh capability. After the recovery-time, BGP sends the route-refresh message of the address family to the neighbor and re-advertises all routing information in the address family to this neighbor.

In the session retention state, you can manually reset the neighbor to exit from the session retention state.

Related Configuration

Configuring BGP Session Retention

- **bgp mp-error-handle session-retain [recovery-time time]**

Enables the BGP session retention function, which is disabled by default.

recovery-time time configures the time for waiting for automatic route recovery, ranging from 10 to 65535 seconds. The default value is 120.

7.3.28 Configuring BGP Delayed Advertisement upon System Restart

By default, after the neighborhood is established after system restart, a BGP peer can advertise route information to its neighbors. This is normal in most cases. However, in certain cases, for example, there are many neighbors or routes during startup but writing entries into the hardware is slow. In this case, the neighbors have learned the routes and started forwarding traffic, but the hardware has not completed writing of entries at the local end, which causes failure of traffic forwarding.

Working Principle

The BGP delayed advertisement upon system restart ensures that routes are not advertised to neighbors immediately after the neighborhood is established upon system restart and that the routes are advertised after a period. This function has no effect on other behaviors such as route receiving performed by the neighbors. If part of the routes is not affected by the delay, configure prefix-list policy to match this part of routes so that route advertisement can be more flexible.

delay-time is used to configure the waiting time before routes are advertised to the neighbors. **startup-time** is used to configure the startup time. Within the startup-time, BGP sends routing information to the neighbors at the interval specified by **delay-time**.

-
-  After the startup-time ends, the default route advertisement behavior recovers.
-

Related Configuration

📄 Configuring BGP Delayed Advertisement upon System Restart

- **bgp initial-advertise-delay delay-time [startup-time] [wait-for-controller]**

Enables BGP delayed advertisement upon system restart, which is disabled by default.

delay-time configures the delay time for advertising routes after the BGP neighborhood is established upon system restart, ranging from 1 to 600 seconds. The default value is 1s.

startup-time configures the time range for system restart, ranging from 5 to 58,400 seconds. The delayed route advertisement mechanism is used within this range. The default value is 600s.

7.3.29 Configuring BGP Delayed Advertisement for First Routes

By default, after the neighborhood is established, a BGP peer can advertise route information to its neighbors. However, neighbors with the neighborhood newly established will send out the route information after a delayed period of time.

Working Principle

After BGP starts, BGP peers negotiate to establish the neighborhood before sending route information (update packets). After **update-delay** is configured on the local end, a specific neighbor sends route information to the local end, the local end will send to other neighbors after the delay time.

-
-  If BGP delayed advertisement upon system restart and BGP delayed advertisement for first routes are enabled at the same time, BGP delayed advertisement upon system restart takes precedence over BGP delayed advertisement for first routes.
-  BGP GR is not affected by either BGP delayed advertisement upon system restart or BGP delayed advertisement for first routes, that is, the BGP GR route advertisement is not affected by the delay time.
-

Related Configuration

📄 Creating a BGP Neighbor

By default, no neighbor is specified on a BGP speaker. You need to manually configure a BGP neighbor.

Run the **neighbor { neighbor-address | peer-group-name } remote-as as-number** command to manually create a BGP neighbor and specify the AS number of the neighbor.

📄 Configuring BGP Delayed Advertisement for First Routes

By default, BGP delayed advertisement for first routes is disabled for neighbors.

Run the **neighbor { neighbor-address | peer-group-name } update-delay delay-time** command to enable BGP delayed advertisement for first routes.

7.3.30 Configuring BGP NSR

None-Stop-Routing (NSR) is used to ensure uninterrupted routes during protocol restart upon a switchover between the active and standby management boards. During a switchover between the active and standby management boards, the NSR function ensures stable network topology, maintains neighbor status and forwarding tables, and guarantees uninterrupted key services.

Working Principle

Different from BGP GR, BGP NSR is a function implemented individually by a BGP speaker and does not rely on neighbors.

- During a switchover between the active and standby management boards, connections between BGP neighbors are not interrupted.
- Neighbors do not perceive the restart behavior on the local end. The GR technology is used for restart restoration.

Neighbors with the BGP NSR function enabled do not need to negotiate the GR capability. In addition, neighbor assistance is not required and interworking problems do not exist as NSR is a reliability technology not perceived by neighbors.

Related Configuration

📄 Creating a BGP Neighbor

By default, no neighbor is specified on a BGP speaker. You need to manually configure a BGP neighbor.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify the AS number of the neighbor.

📄 Enabling the NSR Function for BGP Neighbors

By default, the NSR function is disabled for BGP neighbors.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **ha-mode nsr** command to enable the NSR function for BGP neighbors.

📄 Enabling the NSR Function for BGP Neighbors Globally

By default, the NSR function is disabled.

Run the **bgp nsr** command to enable the NSR function for BGP neighbors globally.

-
- 📘 When the BGP NSR function is enabled for a neighbor, the connection to the neighbor will be reset, the tcp nss (none-stop-service) of the neighbor will be enabled, and the related neighbor and route information are backed up to the standby management board. In this case, if the NSR function is enabled after the neighborship is established, the neighborship will be re-established, causing neighbor down. It is recommended that the NSR function be enabled before the neighborship is established.
 - 📘 The NSR function does not take effect on a neighbor that fails to establish the BGP connection, that is, if the BGP connection is not in the **Established** state, the neighbor will not execute NSR related backup operations. Only if the BGP connection is in the **Established** state, the neighbor performs NSR related backup operations.
-

-  Not all devices that support the BGP NSR function can perform switchovers between the active and standby management boards. To perform switchovers between the active and standby management boards, the device hardware must meet specific requirements. NSR devices on Ruijie networks must support the dual engine redundancy hot backup function.
-  Currently, only the IPv4/IPv6 unicast address family supports the NSR function. If a neighbor activates other address families except the unicast address family, NSR switchovers cannot be performed.
-  If the BGP or TCP backup is not complete, the BGP NSR switchover may fail. When this status occurs, the BGP GR will reconnect the route. It is recommended to enable the BGP NSR and BGP GR at the same time.

7.3.31 Configuring BGP Routes to Be Recursive Only to Host Routes

BGP routes use optimal matching for route recursion by default. Therefore, BGP routes may be recursive to default routes or incorrect network segment routes, resulting in an egress or next hop error. After the function of making BGP routes recursive only to host routes is enabled, BGP routes are recursive only to 32-bit IPv4 host routes or 128-bit IPv6 host routes. This function is applied to routes learnt by neighbors of IBGP or multi-hop EBGP neighborships established using the Loopback interface.

Working Principle

After the function of making BGP routes recursive only to host routes is enabled, the function checks the validity of the next-hop addresses of IBGP or multi-hop EBGP routes via exact matching, and conducts route recursion on the IBGP or multi-hop EBGP routes via exact matching after they are written into the FIB. For example, the next-hop address of the IBGP route 192.168.2.0/24 is 1.1.1.1. The next-hop address of the IBGP route 192.168.2.0/24 is valid only when the route 1.1.1.1/32 exists, and the egress of the route written into the FIB is the egress of the route 1.1.1.1/32.

Related Configuration

📄 Creating a BGP Neighbor

By default, no neighbor is specified for a BGP speaker. You need to manually configure a BGP neighbor.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify an AS number for the neighbor.

📄 Enabling BGP Routes to Be Recursive Only to Host Routes

By default, recursion is performed on BGP routes via exact matching.

Run the **bgp recursion host** command to enable BGP routes to be recursive only to host routes.

7.3.32 Configuring Outbound Loop Detection for a BGP Neighbor

By default, BGP conducts loop detection on BGP routes when receiving the BGP routes from a neighbor. When the **AS Path** attribute carried in a BGP route contains the local AS number, BGP filters out the BGP route. The outbound loop detection function of a neighbor is to conduct loop detection on routes in advance when the routes are transmitted to a neighbor, so as to filter out loop routes.

Working Principle

When sending a route to an EBGp neighbor, the device judges whether the **AS Path** attribute carried in the BGP route contains the AS number of the neighbor. If yes, the route is looped and the device does not send the route to the EBGp neighbor.

Related Configuration

📌 Creating a BGP Neighbor

By default, no neighbor is specified for a BGP speaker. You need to manually configure a BGP neighbor.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify an AS number for the neighbor.

📌 Enabling Outbound Loop Detection for a Neighbor

The outbound loop detection is disabled for a neighbor by default.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **as-loop-check out** command to enable the outbound loop detection for the BGP neighbor.

7.3.33 Shutting Down BGP Connections Gracefully

The RFC 6198 *Requirements for the Graceful Shutdown of BGP Sessions* defines a requirement for shutting down BGP connections gracefully, and requests that a BGP neighbor shut down connections under the precondition that service traffic is not interrupted or is interrupted for a very short period of time.

Working Principle

This feature adopts the "Make-Before-Break" mode to shut down BGP connections, to ensure that service traffic is not interrupted or is interrupted for a very short period of time in the process from the feature configuration to actual BGP connection shutdown. The steps are as follows:

- The feature enables the device to advertise a route with the lowest priority (the value of **local-preference** is 0 or the value of **med** is 4,294,967,295) to a neighbor and carry the **gshut community** attribute in the route so that the neighbor updates routes and switch traffic to a backup link or other equivalent links in advance.
- The device shuts down the BGP connection with the neighbor after a period of time.

The delay period of time for BGP connection shutdown can be manually specified or automatically calculated. The automatically calculated delay time is 1 second for 1000 routes.

- 📘 If the **local-preference** or **med** attribute of the route with the lowest priority cannot enable the neighbor to switch traffic to backup links or other equivalent links in advance, configure an inbound policy on the neighbor to change the priority of routes carrying the **gshut community** or specified **community** attribute or to filter such routes.

Related Configuration

📌 Shutting Down All Connections of a BGP Instance Gracefully

By default, all connections of BGP instances are not shut down.

Run the **bgp shutdown graceful [community value] [delay time]** command to shut down all connections of a BGP instance.

✚ Shutting Down Connections of the BGP Neighbor Gracefully

By default, the connections of BGP neighbors are not shut down.

Run the **neighbor { neighbor-address | peer-group-name } shutdown graceful [community value] [delay time]** command to disable connections of a BGP neighbor.

7.3.34 Configuring Enhanced VPN Route Import

Working Principle

During inter-VRF route import, import of L3VPN remote routes to VRF, or import of EVPN routes to the IP route table, only routes with preferred next hops are imported by default.

The enhanced VPN route import function is an extension of the inter-import of the preceding routes. It enables all routes with next hops or equivalent next hops to be imported.

Related Configuration

✚ Configuring the Route Import Policy

By default, only routes with preferred next hops are imported.

Run the **import path selection { all | bestpath | multipath }** command to import all routes with next hops, routes with preferred next hops, or routes with equivalent next hops.

7.3.35 BGP Route Update Group

The BGP route update group function is used to enhance the performance for advertising routes to neighbors.

Working Principle

The BGP route update group function automatically classifies neighbors with the same outbound policy to the same update group. When routes are sent to neighbors, the update packet is encapsulated based on the update group and sent to all neighbors in the update group. In this case, the update packet is encapsulated for once and sent multiple times, improving the performance of route advertisement to neighbors.

7.3.36 Configuring BGP EVPN

As a layer-2 VPN technology, the Ethernet Virtual Private Network (EVPN) uses the MB-BGP on the control plane to distribute layer-2 and layer-3 routing information and uses the Virtual eXtensible Local Area Network (VXLAN) on the data plane to encapsulate service traffic.

Working Principle

The EVPN is a layer-2 VPN technology extended based on the MP-BGP. The MP-BGP expands the EVPN address family to transfer the required layer-2 and layer-3 routing information, and support multiple types of data planes. At present, only the VXLAN can serve as the data plane of the EVPN.

The MP-BGP adds not only the EVPN address family, but also the EVPN network layer reachability information, which includes the following:

1. Ethernet Auto-discovery Route: Automatically discovers Ethernet Segment (ES) information in a multi-homed network.
2. MAC/IP Advertisement Route: Advertises the MAC address and host ARP information.
3. Inclusive Multicast Ethernet Tag (IMET) Route: Automatically discovers VXLAN tunnel end points (VTEPs) and creates VXLAN tunnels.
4. Ethernet Segment Route: Advertises ES information and information about connected VTEPs.
5. IP Prefix Route: Advertises routing information of IP network segments.

At present, Ethernet Auto-discovery Route and Ethernet Segment Route are not supported.

The preceding EVPN routing information includes the RD (for EVPN routes of different VNIs) and route target (for importing EVPN routes between different devices).

Related Configuration

Configuring EVPN

By default, the EVPN mode is not activated.

Run the **evpn** command to enter the EVPN mode.

Creating an EVI Instance

By default, no EVI instance is configured.

Run the **vni vni-id** command to create an EVI instance and enter the EVI instance configuration mode.

Run the **vni range vni-id-list** command to create EVI instances in batches and enter the EVI instance batch configuration mode.

Configuring RD

By default, no RD is configured in evpn-vni mode.

Run the **rd { auto | rd_value }** command to add RD.

Configuring Route Target

By default, no route target is configured in evpn-vni mode.

Run the **route-target { import | export | both }** command to configure route target.

Configuring a Route Map for EVI Instances

By default, no route map is configured for EVI instances.

Run the **export map** *route-map-name* command to configure the route map for exporting the extended community attribute of EVPN routes from the local device to the remote device.

Run **import map** *route-map-name* command to configure the route map for importing the remote EVPN routes to the local VNI instance.

↘ Configuring an EVPN Address Family

By default, no EVPN address family is activated.

Run the **address-family l2vpn evpn** command to activate an EVPN address family.

↘ Configuring MAC Mobility Parameters

By default, if five MAC address moves are detected within 180s, it is considered that a MAC address conflict occurs.

Run the **bgp mac-mobility timer count** command to adjust the MAC mobility detection parameters.

7.3.37 Configuring BMP

BGP Monitor Protocol (BMP) monitors BGP running on a device, focusing on the status, entry sending and receiving, and all kinds of statistics of BGP peers.

Working Principle

A BGP speaker proactively sends a TCP connection request carrying a destination IP address and a port number (the destination IP address is the BMP server address, and both of the address and port number are specified by the client) to the specified BMP server. After the TCP connection is successfully established, the BGP speaker advertises BMP packets to the BMP server.

Related Configuration

↘ Creating a BMP Server Instance

By default, no BMP server instance is configured.

Run the **bmp server server-number** command to create a BMP server instance and enter the BMP instance configuration mode.

↘ Configuring the Address and Port Number of the BMP Server

By default, the BMP server address and port number are not configured in BMP configuration mode.

Run the **address bmp-server-address port port-number** command to configure the address and port number of the BMP server.

↘ Configuring the Source IP Address of a TCP Connection to the BMP Server

By default, the outbound interface of a TCP connection is automatically selected based on the IP address of the BMP server. In normal cases, the outbound interface of the local packet is used.

Run the **update-source** *interface-type interface-number* command to set the outbound interface of the TCP connection to the BMP server.

↘ Configuring VRF

By default, a TCP connection is established to the BMP server under the default VRF instance.

Run the **vrf** *vrf-name* command to establish a TCP connection to the BMP server under a specific VRF instance.

↘ Configuring failure-retry-delay

By default, the interval to reconnect to the BMP server increases from 30s.

Run the **failure-retry-delay** *second* command to set the interval to establish a TCP connection to the BMP server

↘ Configuring description

By default, no description is configured.

Run the **description** *text* command to add the description to BMP instance.

↘ Configuring the BMP Server to Monitor BGP Peers

By default, BGP peers are not monitored by the BMP server.

Run the **neighbor** { *neighbor-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number* [*server-number* [*server-number*]] } command to enable the BMP server to monitor BGP peers.

↘ Configuring All BMP Servers to Monitor BGP Peers

By default, BGP peers are not monitored by all BMP servers.

Run the **bgp bmp-active** command to enable all BMP servers to monitor BGP peers.

↘ Configuring the BMP Server to Monitor BGP Peer Packets

By default, the BMP server does not enable route mirroring packet sending.

Run the **route mirroring** command to enable route mirroring packet sending to send real-time mirroring BGP packets to the BMP server.

↘ Configuring the Interval for Sending Status Statistics to the BMP Server

By default, when status statistics of a monitored peer are changed, the BMP module sends the status statistics to the BMP server.

Run the **stats-reporting-period** *time* command to specify the interval for sending status statistics to the BMP server.

↘ Configuring the BMP Server to Monitor Unchanged Routing Information Received from a BGP Peer

By default, the BMP server does not monitor unchanged routing information received from a BGP peer.

Run the **adj-rib-in pre-policy** command to enable the BMP server to monitor unchanged routing information received from a BGP peer.

↘ [Configuring the BMP Server to Monitor Routing Information Received from a BGP Peer After the Routing Policy Is Applied](#)

By default, the BMP server does not monitor routing information received from a BGP peer after the routing policy is applied.

Run the **adj-rib-in post-policy** command to enable the BMP server to monitor routing information received from a BGP peer after the routing policy is applied.

↘ [Configuring the BMP Server to Monitor Routing Information Sent to a BGP Peer After the Routing Policy Is Applied](#)

By default, the BMP server does not monitor routing information sent to a BGP peer after the routing policy is applied.

Run the **adj-rib-out post-policy** command to enable the BMP server to monitor routing information sent to a BGP peer after the routing policy is applied.

7.3.38 Other Related Configurations

-  For configuration and application of BGP MCE, see section "VRF Configuration Guide".
-  For configuration and application of the BGP MDT address family, see section "Multicast VPN (MD Configuration Guide)".

7.4 Configuration

Configuration	Description and Command	
Configuring a BGP Peer (Group)	 (Mandatory) It is used to create a BGP neighbor.	
	router bgp	Enables BGP.
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.
Configuring MD5 Authentication	 (Optional) It is used to perform encrypted authentication for the BGP neighbor.	
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>	Configures the password for encryption.
Configuring a Route Reflector	 (Optional) It is used to reduce the number of BGP neighbor connections.	
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } route-reflector-client	Specifies a peer (group) as a reflector client.
Configuring an AS Alliance	 (Optional) It is used to reduce the number of BGP neighbor connections.	
	bgp confederation identifier <i>as-number</i>	Configures the BGP alliance ID.
	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]	Configures a BGP alliance neighbor.

Configuration	Description and Command	
Configuring Multi-path Load Balancing of BGP	 (Optional) It is used to implement multi-path load balancing.	
	maximum-paths ibgp <i>number</i>	Configures IBGP load balancing.
	maximum-paths ebgp <i>number</i>	Configures EBGp load balancing.
	bgp bestpath as-path multipath-relax	Enables the BGP AS-PATH loose comparison mode.
Configuring EBGp FRR	 (Optional) It is used to increase the convergence speed when a network fault occurs.	
	bgp fast-reroute	Configures BGP FRR.
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } fall-over bfd	Configures a BFD session to a BGP neighbor.
Configuring Fast Withdrawal of Specified BGP Routes	 (Optional) It is used to fast withdraw the specified BGP routes.	
	bgp fast-withdraw { access-list { <i>access-list-number</i> <i>access-list-name</i> } prefix-list <i>prefix-list-name</i> route-map <i>map-tag</i> }	Configures fast withdrawal of specified BGP routes.
Configuring Local ASs	 (Optional) It is used for transitional deployment during network migration.	
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [<i>dual-as</i>]]]	Configures the local AS for a BGP neighbor.
Configuring BGP GR	 (Recommended) It is used to improve the network reliability.	
	bgp graceful-restart	Enables the BGP GR capability.
	bgp graceful-restart restart-time <i>restart-time</i>	Configures the maximum time for BGP GR.
	bgp graceful-restart stalepath-time <i>time</i>	Configures the maximum retention time for BGP stable route.
Configuring a BGP IPv6 Address Family	 (Optional) It is used to deploy an IPv6 network by using BGP.	
	address-family ipv6 unicast	Enters the BGP IPv6 unicast configuration mode.
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } activate	Activates the address family capability of a BGP neighbor in the current configuration mode.
Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers	 Optional. It is used for interconnecting with an old device that supports only 2-byte AS numbers.	
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.

Configuration	Description and Command	
Configuring BMP Monitoring	 (Optional) It is used to configure BMP monitoring.	
	bmp server <i>server-number</i>	Creates a BMP server instance.
	address <i>bmp-server-address</i> port <i>port-number</i>	Configures the address and port number of the BMP server.
	update-source <i>interface-type</i> <i>interface-number</i>	Configures the outbound interface of the BMP server.
	vrf <i>vrf-name</i>	Configures the VRF instance to which a TCP connection to the BMP server belongs.
	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } bmp-active { all server <i>server-number</i> [<i>server-number</i>] }	Configures BGP peers to be monitored by the specified BMP server.
	bgp bmp-active	Configures BGP peers to be monitored by all BMP servers.
	route mirroring	Enables a device to send route mirroring packets to the BMP server.
	failure-retry-delay <i>time</i>	Configures the interval to establish a TCP connection to the BMP server.
	description <i>time</i>	Sets the description for BMP instance.
	stats-reporting-period <i>time</i>	Sets the interval for sending status statistics to the BMP server.
	adj-rib-in pre-policy	Configures the BMP server to monitor unchanged routing information received from a BGP peer.
	adj-rib-in post-policy	Configures the BMP server to monitor routing information received from a BGP peer after the routing policy is applied.
	adj-rib-out post-policy	Configures the BMP server to monitor routing information sent to a BGP peer after the routing policy is applied.
Configuring BGP EVPN	 Optional. It is used to configure the EVPN VXLAN network.	
	address-family l2vpn evpn	address-family l2vpn evpn
	vni <i>vni-id</i>	Create EVI instance
	rd { auto <i>rd_value</i> }	Configure RD
	route-target { import export both } { auto <i>rt_value</i> }	
	export map <i>routemap-name</i>	Configure the extended group attribute policy of the local end to EVPN route

Configuration	Description and Command	
	import map <i>routemap-name</i>	Configure the policy of the EVPN route to the local VNI instance
	bgp mac-mobility <i>timer count</i>	Configure MAC mobility parameter

7.4.1 Configuring a BGP Peer (Group)

Configuration Effect

- Configure BGP and create IBGP and EBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **ebgp-multihop** parameter for the neighbor.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Configuring a Source Interface for a BGP Neighbor

- (Optional) Perform this configuration in the BGP configuration mode. By default, BGP automatically selects a local interface that reaches the destination IP address of a peer as the source interface.

 For an IBGP neighbor, you are advised to use a Loopback interface as the source interface.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

📌 Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

📌 Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor -address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

📌 Creating a Source Interface for a BGP Neighbor

Command	neighbor { <i>neighbor -address</i> <i>peer-group-name</i> } update-source { <i>interface-type interface-number</i> <i>address</i> }
Parameter Description	<i>neighbor -address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>interface-type interface-number</i> : Indicates an interface name. <i>address</i> : Directly specifies the network interface address used for creating a BGP connection.
Command Mode	BGP configuration mode
Usage Guide	The source interface of a neighbor must be a local valid interface or address.

📌 Configuring the BGP Connection Mode

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } transport connection-mode { active-only both passive-only }
Parameter Description	<i>neighbor-address</i> : Specifies the IPv4 or IPv6 address of a peer. <i>peer-group-name</i> : Specifies a peer group name. active-only : Specifies that a neighbor can only actively establishes a connection. Both : Specifies that a neighbor can actively or passively establish a connection. passive-only : Specifies that a neighbor can only passively establishes a connection.
Command Mode	BGP configuration mode
Usage Guide	The source interface of a neighbor must be a valid local interface or address.

Configuration Example

📌 Configuring a BGP Peer (Group)

Scenario
Figure 7-4

Configuration Steps

- Enable BGP on all devices and set the AS numbers as shown in Figure 7-4.
- Configure a loopback interface on A, B, and C and create an IBGP neighbor based on the loopback interface.
- Create an EBGP neighborship by using the directly connected interfaces on C and D.
- Create an IBGP peer group on C.

A

```
A# configure terminal
A(config)# interface loopback 0
A(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255

Common Errors

- IGP is not enabled and the interconnection between the local loopback address and the loopback address on the IBGP neighbor fails, which causes that the neighbor fails to be created.
- `ebgp-multihop` is not configured when an EBGP is not directly connected, which causes that a TCP connection fails to be created.

7.4.2 Configuring MD5 Authentication

Configuration Effect

- Configure MD5 for encrypted authentication between EBGP and IBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **`ebgp-multihop`** parameter for the neighbor.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring an MD5 Password for a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. 0 : Displays a password not encrypted. 7 : Displays a password encrypted. <i>string</i> : Indicates a password for TCP MD5 authentication, consisting of a maximum of 80 characters.
Command Mode	BGP configuration mode
Usage Guide	The same passwords must be configured on the two ends of a BGP neighborhood.

Configuration Example

↘ Configuring BGP MD5 Authentication

Scenario Figure 7-5	
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 7-5. ● Configure a loopback interface on B and C and create an IBGP neighbor based on the loopback interface. ● Create an EBGP neighborhood by using the directly connected interfaces on A and B. ● Configure the passwords on A, B and C for their neighbors.

Common Errors

- The passwords for MD5 encrypted authentication at the two ends of a BGP neighborhood are different.

7.4.3 Configuring a Route Reflector

Configuration Effect

- Configure a route reflector in the IBGP environment to reduce the number of BGP neighbor connections.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Creating a BGP Reflector

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Creating a BGP Reflector

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } route-reflector-client
Parameter	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6

Description	address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

Configuring a BGP Route Reflector

Scenario Figure 7-6	
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 7-6. ● Configure a loopback interface on all devices and create an IBGP neighborship by using the loopback interface according to the connection lines as shown in Figure 7-6. ● Configure route reflection on the device RR and specify A, B, C and D as reflector clients.
A	<pre> A# configure terminal A(config)# interface loopback 0 A(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255 A(config-if-Loopback 0)# exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# router bgp 65536 A(config-router)# neighbor 10.1.1.5 remote-as 65536 A(config-router)# neighbor 10.1.1.5 update-source loopback 0 A(config-router)# network 192.168.1.0 mask 255.255.255.0 </pre>

B	<pre>B# configure terminal B(config)# interface loopback 0 B(config-if-Loopback 0)# ip address 10.1.1.2 255.255.255.255 B(config-if-Loopback 0)# exit B(config)# interface GigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)# ip address 192.168.2.2 255.255.255.0 B(config-if-GigabitEthernet 0/1)# exit B(config)# router bgp 65536 B(config-router)# neighbor 10.1.1.5 remote-as 65536 B(config-router)# neighbor 10.1.1.5 update-source loopback 0</pre>
C	<pre>C# configure terminal C(config)# interface loopback 0 C(config-if-Loopback 0)# ip address 10.1.1.3 255.255.255.255 C(config-if-Loopback 0)# exit C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ip address 192.168.3.3 255.255.255.0 C(config-if-GigabitEthernet 0/1)# exit C(config)# router bgp 65536 C(config-router)# neighbor 10.1.1.5 remote-as 65536 C(config-router)# neighbor 10.1.1.5 update-source loopback 0</pre>
D	<pre>C# configure terminal C(config)# interface loopback 0 C(config-if-Loopback 0)# ip address 10.1.1.4 255.255.255.255 C(config-if-Loopback 0)# exit C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ip address 192.168.4.4 255.255.255.0 C(config-if-GigabitEthernet 0/1)# exit C(config)# router bgp 65536 C(config-router)# neighbor 10.1.1.5 remote-as 65536 C(config-router)# neighbor 10.1.1.5 update-source loopback 0</pre>
RR	<pre>RR# configure terminal</pre>

	<pre> RR(config)# interface loopback 0 RR(config-if-Loopback 0)# ip address 10.1.1.5 255.255.255.255 RR(config-if-Loopback 0)# exit RR(config)# interface GigabitEthernet 0/1 RR(config-if-GigabitEthernet 0/1)# ip address 192.168.1.5 255.255.255.0 RR(config-if-GigabitEthernet 0/1)# exit RR(config)# interface GigabitEthernet 0/2 RR(config-if-GigabitEthernet 0/2)# ip address 192.168.2.5 255.255.255.0 RR(config-if-GigabitEthernet 0/2)# exit RR(config)# interface GigabitEthernet 0/3 RR(config-if-GigabitEthernet 0/3)# ip address 192.168.3.5 255.255.255.0 RR(config-if-GigabitEthernet 0/3)# exit RR(config)# interface GigabitEthernet 0/4 RR(config-if-GigabitEthernet 0/4)# ip address 192.168.4.5 255.255.255.0 RR(config-if-GigabitEthernet 0/4)# exit RR(config)# router bgp 65536 RR(config-router)# neighbor 10.1.1.1 remote-as 65536 RR(config-router)# neighbor 10.1.1.1 update-source loopback 0 RR(config-router)# neighbor 10.1.1.1 route-reflector-client RR(config-router)# neighbor 10.1.1.2 remote-as 65536 RR(config-router)# neighbor 10.1.1.2 update-source loopback 0 RR(config-router)# neighbor 10.1.1.2 route-reflector-client RR(config-router)# neighbor 10.1.1.3 remote-as 65536 RR(config-router)# neighbor 10.1.1.3 update-source loopback 0 RR(config-router)# neighbor 10.1.1.3 route-reflector-client RR(config-router)# neighbor 10.1.1.4 remote-as 65536 RR(config-router)# neighbor 10.1.1.4 update-source loopback 0 RR(config-router)# neighbor 10.1.1.4 route-reflector-client </pre>
Verification	Run the show command to display the BGP neighbor status.
RR	<pre> RR# show ip bgp summary BGP router identifier 10.1.1.5, local AS number 65536 </pre>

7.4.4 Configuring an AS Alliance

Configuration Effect

- Configure a BGP alliance to reduce the number of BGP neighbor connections.

Notes

- It is advised to use private AS numbers for sub ASs (also called member ASs) within an alliance. Private AS numbers range from 64,512 to 65,535.
- Within a sub AS of an alliance, full mesh must be established for all BGP speakers (route reflectors can be further configured within the sub AS).
- An EBGP neighborhood must be established between sub ASs of an alliance.
- All BGP speakers within an alliance must belong to a sub AS within the alliance.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

📌 Configuring a BGP Alliance ID

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Configuring a BGP Alliance Member

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring Multiple Hops for an EBGp Neighbor

- Perform this configuration in the BGP configuration mode. It is mandatory when an EBGp neighbor is not directly connected.

↘ Configuring BGP Route Re-distribution to a Network

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when a local route needs to be advertised. You can also configure an alternative network by means of re-distribution.

Verification

- Run the **show** command to display the BGP neighbor status.
- Run the **show** command to display the BGP routing table information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Enabling a BGP Alliance ID

Command	bgp confederation identifier <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring a BGP Alliance Member

Command	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	All member ASs of a local EBGp alliance must be identified.

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>

Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring Multiple Hops for an EBGp Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } ebgp-multihop [<i>ttl</i>]
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>ttl</i> : Indicates the maximum number of hops that are allowed, ranging from 1 to 255.
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring BGP Route Re-distribution to a Network

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network address. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP configuration mode
Usage Guide	The core routing table must contain same IGP (or static and directly connected) routes.

Configuration Example

↘ Configuring a BGP Alliance

Scenario
Figure 7-7

Configuration Steps

- Configure BGP on A and B, set the AS number to 65,536 and configure an IBGP neighborship.
- Configure BGP on C and D, set the AS number to 65,537 and configure an IBGP neighborship.
- Configure BGP on ASBR1 and E, set the AS number to 65,538 and configure an IBGP neighborship.
- Configure an alliance ID 100 on A, B, C, D, E and ASBR1.
- Configure the alliance member 65,537 on A, configure C as an EBGP neighbor, and set the peer AS number to 65,537.
- Configure the alliance members 65,536 and 65,538 on C, configure A as an EBGP neighbor and set the peer AS number to 65,536, configure ASBR1 as an EBGP neighbor and set the peer AS number to 65,538.
- Configure the alliance members 65,537 on ASBR1, configure C as an EBGP neighbor and set the peer AS number to 65,537, configure ASBR2 as an EBGP neighbor and set the peer AS number to 200.
- Configure BGP on ASBR2 and set the AS number to 200; configure ASBR1 as an EBGP neighbor and set the peer AS number to 100.

Common Errors

- No BGP alliance neighbor is configured.
- Full mesh is not established within sub ASs of an alliance.

7.4.5 Configuring Multi-path Load Balancing of BGP

Configuration Effect

- Implement multi-path load balancing for IBGP routes.
- Support AS-PATH loose comparison.

Notes

- Routes learned from an IBGP neighbor must have the same priority (the router-ID does not need to be compared).

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Configuring BGP Load Balancing

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Configuring AS-PATH Loose Comparison

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when load balancing needs to be implemented for routes learned from different ASs.

Verification

- Run the **show** command to display BGP routing information.
- Run the **show** command to display the core routing table information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring BGP Load Balancing

Command	maximum-paths { ebgp ibgp } <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of equivalent paths, ranging from 1 to device capacity. If the value is 1 , multi-path load balancing of IBGP will be disabled.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring AS-PATH Loose Comparison

Command	bgp bestpath as-path multipath-relax
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

↘ Configuring Multi-path Load Balancing of IBGP

Scenario
Figure 7-8

Configuration Steps

- Enable BGP on all devices and set the AS numbers as shown in Figure 7-8.
- Establish IBGP neighborships between A and B and between A and C by using directly connected interfaces.
- Establish EBGP neighborships between B and D and between C and E by using directly connected interfaces.
- Re-distribute the same routes to D and E.
- Configure IBGP load balancing on A and enable the AS-PATH loose comparison mode.

    [200/0] via 10.4.1.1, 00:27:56

```

Common Errors

- The priorities of multi-hop BGP routes are different, which causes load balancing failure.

7.4.6 Configuring EBGp FRR

Configuration Effect

- Implement EBGp FRR.

Notes

- (Optional) Configure a neighbor BFD session to implement fast link fault detection.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

➤ Configuring BGP FRR

- (Mandatory) Perform this configuration in the BGP configuration mode.

➤ Configuring a Neighbor BFD Session

- (Optional) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display routing information.

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Creating a BFD Session to a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } fall-over bfd
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

↘ Configuring EBGp FRR

Scenario
Figure 7-9

Configuration Steps

- Enable BGP on all devices.
- Configure the addresses of the directly connected interfaces on A, B and C to establish EBGP neighborships.
- Configure a BFD session for the EBGP neighborship between B and C.
- Configure FRR on C.

Common Errors

- No BFD session is configured for BGP neighbors.

7.4.7 Configuring Fast Withdrawal of Specified BGP Routes

Configuration Effect

- Implement fast withdrawal of specified BGP routes.

Notes

- Configure fast withdrawal of specified routes to preferentially advertise the withdrawal of specified routes.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

📌 Configuring Fast Withdrawal of Specified BGP Routes

- (Mandatory) Perform this configuration in BGP configuration mode.

Verification

- Run the **show** command to display the configurations.

Related Commands

📌 Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number. The value ranges from 1 to 4,294,967,295 , which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	N/A

📌 Configuring Fast Withdrawal of Specified BGP Routes

Command	bgp fast-withdraw { access-list { <i>access-list-number</i> <i>access-list-name</i> } prefix-list <i>prefix-list-name</i> route-map <i>map-tag</i> }
Parameter Description	<i>access-list-number</i> : Indicates the ACL number. The value ranges from 1 to 199 and 1300 to 2699 . <i>access-list-name</i> : Indicates an ACL name. <i>prefix-list-name</i> : Indicates the name of a prefix list. <i>map-tag</i> : Indicates the name of a route map.
Command Mode	BGP configuration mode
Usage Guide	N/A

📌 Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group). The value ranges from 1 to 4,294,967,295 .
Command Mode	BGP configuration mode
Usage Guide	The AS number specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

Configuration Example

➤ **Configuring Fast Withdrawal of Specified BGP Routes**

Scenario Figure 7-10	
Configuration Steps	● Enable BGP on all devices. ● Establish a BGP neighbor relationship between Routers A and B. ● Configure ACLs on Router A. ● Configure fast withdrawal of specified routes on Router A.
A	A# conf terminal
Verification	Run the show command to display the configurations.
A	A#show run router bgp

7.4.8 Configuring Local ASs

Configuration Effect

- Smoothly migrate the network configurations of router A from AS 23 to AS 3600.

Notes

N/A

Configuration Steps

➤ **Enabling BGP**

- (Mandatory) Perform this configuration in the global configuration mode.

➤ **Creating a BGP Neighbor**

- (Mandatory) Perform this configuration in the BGP configuration mode.

➤ **Configuring the Local AS for a BGP Neighbor**

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the information.

Related Commands

➤ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

➤ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ Configuring the Local AS for a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [dual-as]]]
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates a local AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode. no-prepend : Does not add the local AS to the AS-PATH in the routing information received by a peer. This option is not available by default. replace-as : For the AS-PATH in the routing information sent by a peer, the local AS is used to replace the BGP AS. This option is not available by default. dual-as : Enables a peer to use the BGP AS or Local AS to establish a BGP connection with a device. This option is not available by default.
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

➤ Configuring BGP Local-AS

Scenario	

Figure 7-11

- Configuration Steps**
- Create an EBGP neighborhood with B on A and specify the Local-AS for the EBGP neighborhood.
 - Create an EBGP neighborhood for connecting to A on B.

A

```
A# configure terminal
A(config)# router bgp 3600
A(config-router)# neighbor 57.50.1.1 remote-as 5750
A(config-router)# neighbor 57.50.1.1 update-source loopback 0
A(config-router)# neighbor 57.50.1.1 ebgp-multihop 255
A(config-router)# neighbor 57.50.1.1 local-as 23 no-prepend replace-as dual-as
```

B

```
B# configure terminal
B(config)# router bgp 5750
B(config-router)# neighbor 36.0.1.1 remote-as 23
B(config-router)# neighbor 36.0.1.1 update-source loopback 0

```

7.4.9 Configuring BGP GR

Configuration Effect

- Configure BGP GR to implement network deployment with high reliability.

Notes

- To successfully deploy the BGP GR function, you need to use a neighbor device as the GR Helper.
- In an BGP environment, you also need to configure IGP GR.
- After BGP GR is enabled, you need to reset a BGP neighbor connection to make it take effect.

Configuration Steps

▾ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

▾ Configuring BGP GR

- Perform this configuration in the BGP configuration mode, which is configured by default.

▾ Configuring a BGP GR Timer

- (Optional) Perform this configuration in the BGP configuration mode.

▾ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

▾ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode

Usage Guide	-

📌 Configuring BGP GR

Command	bgp graceful-restart
Parameter	-
Description	
Command Mode	BGP configuration mode
Usage Guide	-

📌 Configuring the BGP GR Restart Timer

Command	bgp graceful-restart restart-time <i>restart-time</i>
Parameter Description	<i>restart-time</i> : Indicates the maximum waiting time that the GR Restarter hopes the GR Helper to wait before a new connection is created, ranging from 1 to 3600 seconds.
Command Mode	BGP configuration mode
Usage Guide	-

📌 Configuring the BGP GR Route Stale Timer

Command	bgp graceful-restart stalepath-time <i>time</i>
Parameter Description	<i>time</i> : Indicates the maximum time that a stale route keeps valid after the connection with a neighbor GR device is recovered, ranging from 1 to 3600 seconds.
Command Mode	BGP configuration mode
Usage Guide	-

📌 Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

Configuration Example

📌 Configuring BGP GR

Scenario
Figure 7-12

Configuration Steps

- Enable BGP on all devices and set the AS numbers as shown in Figure 7-12.
- Configure a loopback interface on R2, R3, and R4 and create an IBGP neighborship based on the loopback interface.
- Create an EBGP neighborship by using the directly connected interfaces on R1 and R2.
- Enable BGP GR on R1, R2, R3, and R4.

R1

```
R1# configure terminal
R1(config-router)# exit
R1(config)# router bgp 100
R1(config-router)# bgp graceful-restart
```

R2

```
R2# configure terminal
R2(config)# router ospf 1
R2(config-router)# graceful-restart
R2(config-router)# exit
R2(config)# router bgp 100
R2(config-router)# bgp graceful-restart
```

R3

```
R3# configure terminal
R3(config)# router ospf 1
R3(config-router)# graceful-restart
R3(config-router)# exit
R3(config)# router bgp 100
```

	R3(config-router)# bgp graceful-restart
R4	<pre> R4# configure terminal R4(config)# router ospf 1 R4(config-router)# graceful-restart R4(config-router)# exit R4(config)# router bgp 100 R4(config-router)# bgp graceful-restart </pre>
Verification	Run the show command to display the BGP neighbor status.
R2	<pre> R2# show ip ospf Routing Process "ospf 1" with ID 10.0.0.2 Process uptime is 4 minutes Process bound to VRF default Conforms to RFC2328, and RFC1583Compatibility flag is enabled Supports only single TOS(TOS0) routes Supports opaque LSA This router is an ASBR (injecting external routing information) SPF schedule delay 5 secs, Hold time between two SPFs 10 secs LsaGroupPacing: 240 secs Number of incoming current DD exchange neighbors 0/5 Number of outgoing current DD exchange neighbors 0/5 Number of external LSA 4.     None

.....
```

Common Errors

- GR is not enabled for IGP.
- GR is not enabled for a BGP neighbor device.

7.4.10 Configuring a BGP IPv6 Address Family

Configuration Effect

- Configure BGP IPv6 routes to implement IPv6 network access in different ASs.

Notes

- Generally, BGP uses IPv6 addresses to create neighborships and implement exchange of IPv6 routes.
- Configurations related to BGP IPv6 services must be configured in the BGP IPv6 address family mode.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring the BGP IPv6 Address Family Mode

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the IPv6 Address Family Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring IPv6 Route Advertisement in BGP

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Indicates the address of a peer, which is usually an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

Command	no neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } activate
Parameter	<i>neighbor-address</i> : Indicates the address of a peer, which is usually an IPv6 address.

Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP IPv4 address family mode
Usage Guide	Neighbors with IPv6 addresses are used to exchange IPv6 routes.

📌 Configuring the BGP IPv6 Address Family Mode

Command	address-family ipv6 unicast
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

📌 Configuring the IPv6 Address Family Capability for a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } activate
Parameter Description	<i>neighbor-address</i> : Indicates the address of a peer, which is usually an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

📌 Configuring IPv6 Route Advertisement in BGP

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network number. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

Configuration Example

📌 Configuring BGP to Implement IPv6 Route Exchange in Different ASs

Scenario Figure 7-13	 The diagram illustrates a BGP configuration scenario for IPv6 route exchange between two Autonomous Systems (ASs). Router A, representing AS 65530, and Router B, representing AS 65531, are connected via a physical link. Both routers are also connected to the Internet, represented by clouds.

Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 7-13. ● Configure a BGP neighbor, disable the IPv4 address family capability for the neighbor and activate the IPv6 address family capability. ● Configure IPv6 route advertisement in BGP.
A	<pre> A# configure terminal A(config)# int loopback 0 A(config-if-Loopback)# ipv6 address 30::1/128 A(config-if-Loopback)# exit A(config)# router bgp 65530 A(config-router)# neighbor 100::1 remote-as 65531 A(config-router)# address-family ipv4 A(config-router-af)# no neighbor 100::1 activate A(config-router-af)# exit-address-family A(config-router)# address-family ipv6 A(config-router-af)# neighbor 100::1 activate A(config-router-af)# network 30::1/128 </pre>
B	<pre> B# configure terminal B(config)# router bgp 65531 B(config-router)# neighbor 100::2 remote-as 65530 B(config-router)# address-family ipv4 B(config-router-af)# no neighbor 100::2 activate B(config-router-af)# exit-address-family B(config-router)# address-family ipv6 B(config-router-af)# neighbor 100::2 activate </pre>
Verification	Run the show command to display the BGP neighbor status.
A	<pre> A# show bgp ipv6 unicast summary BGP router identifier 1.1.1.1, local AS number 65530 BGP table version is 1 1 BGP AS-PATH entries 0 BGP Community entries 1 BGP Prefix entries (Maximum-prefix:4294967295) </pre>

	<pre> Neighbor V AS MsgRcvd MsgSent TblVer InQ OutQ Up/Down State/PfxRcd 100::1 4 65531 4 6 1 0 0 00:01:49 0 Total number of neighbors 1 </pre>
B	Run the show command to display BGP routing information. <pre> B# show bgp ipv6 unicast BGP table version is 4, local router ID is 2.2.2.2 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 30::1/128 100::2 0 0 65530 i Total number of prefixes 1 </pre>

Common Errors

- The IPv6 address family capability is not activated for BGP neighbors.
- In non-6PE scenarios, IPv4 addresses are used to establish IPv6 routes for exchange between neighbors.

7.4.11 Configuring a BGP EVPN

Configuration Effect

- Configure BGP protocol to use RR in the VXLAN scenario for L2VPN EVPN deployment.

Notes

- By default, the BGP routing mode is located in the IPv4 unicast address family and a BGP EVPN must be configured in L2VPN EVPN address family mode.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

✚ Activating the EVPN Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in BGP L2VPN EVPN address family mode.

✚ Creating an EVI Instance

- (Mandatory) Perform this configuration in EVPN configuration mode.

✚ Creating EVI Instances in Batch

- (Optional) Perform this configuration in EVPN configuration mode.

✚ Creating RD

- (Mandatory) Perform this configuration in EVPN-VNI configuration mode.

✚ Creating Route Target

- (Mandatory) Perform this configuration in EVPN-VNI configuration mode.

✚ Configuring Route Map for EVI Instance

- (Optional) Perform this configuration in EVPN-VNI address family mode.

✚ Configuring MAC Mobility Parameters

- (Optional) Perform this configuration in BGP L2VPN EVPN configuration mode.

Verification

- Run the **show** command to display the information.

Related Commands

✚ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	-

✚ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.

	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

📌 Entering the L2VPN EVPN Address Family

Command	address-family l2vpn evpn
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

📌 Activating the EVPN Capability for a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } activate
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address must be an IPv4 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP L2VPN EVPN address family mode
Usage Guide	-

📌 Creating an EVI Instance

Command	vni <i>vni-id</i>
Parameter Description	<i>vni-id</i> : indicates the VNI ID. Ranges from 1 to 16777215.
Command Mode	EVPN configuration mode
Usage Guide	After VNI configuration is completed, related RD/RT needs to be configured.

📌 Creating EVI Instances in Batches

Command	vni range <i>vni-id-list</i>
Parameter Description	<i>vni-id-list</i> : Specifies the name of a VNI ID list.
Command	EVPN configuration mode

Mode	
Usage Guide	The configuration fails if the number of configured VNI instances exceeds the capacity or a VNI instance is being deleted. The RD values of different VNI instances must be different. Therefore, only the automatic RD configuration mode is available for configuring VNI instances in batches, and VNI instances cannot be configured manually.

📌 Configuring an RD

Command	rd { auto rd_value }
Parameter Description	auto: Generates an RD value automatically. rd_value: Specifies the value of an RD. The parameter <i>rd_value</i> has three forms: (1) <i>rd_value</i> = as_num:nn as_num indicates the 2-byte public AS number. nn is user-defined and ranges from 0 to 4294967295. (2) <i>rd_value</i> = ip_addr:nn ip_addr refers to the global IP address. nn is user-defined and ranges from 0 to 65535. (3) <i>rd_value</i> = as4_num:nn as4_num indicates the 4-byte public AS number. nn is user-defined and ranges from 1 to 65535. The 4-byte AS number ranges from 1 to 4294967295, which is 1 to 65535.65535 in dot mode.
Command Mode	EVPN VNI configuration mode
Usage Guide	If an EVI is defined and has an RD value configured, the RD value cannot be modified. To modify it, you need to delete the EVI first, and then define the EVI again and configure a new RD value for it. One EVI has only one RD value.  The RD value of the 4-byte AS is in the format of AS4:NN. AS4 can be expressed in decimal or dot mode. AS4 ranges from 1 to 4294967295, which is 1 to 65535.65535 in dot mode. NN ranges from 1 to 65535.  The AS number in the range of 1 to 65535 is displayed the same in both decimal mode and dot mode. Therefore, save the AS number in the range of 1 to 65535 as a 2-byte AS number.  The automatically generated RD value is in the format of ip_addr:nn. ip_addr indicates the BGP router ID, and nn indicates the VNI ID. Because the VNI ID occupies a maximum of three bytes but there is only two bytes available for nn, when the VNI ID occupies more than 2 bytes, the VNI ID is split before being filled in the position for nn. Once generated, the RD value remains unchanged.

📌 Configuring a Route Target

Command	route-target { import export both } { auto rt_value }
Parameter Description	import: Specifies the import RT value. export: Specifies the export RT value. both: Specifies the import and export RT values.

	auto: Generates an RT value automatically. <i>rt_value</i>: Specifies the value of an RT. The parameter <i>rt_value</i> has three forms: (1) <i>rt_value</i> = <i>as_num</i>:<i>nn</i> as_num indicates the 2-byte public AS number. nn is user-defined and ranges from 0 to 4294967295. (2) <i>rt_value</i> = <i>ip_addr</i>:<i>nn</i> ip_addr refers to the global IP address. nn is user-defined and ranges from 0 to 65535. (3) <i>rt_value</i> = <i>as4_num</i>:<i>nn</i> as4_num indicates the 4-byte public AS number. nn is user-defined and ranges from 1 to 65535. The 4-byte AS number ranges from 1 to 4294967295, which is 1 to 65535.65535 in dot mode.
Command Mode	EVPN VNI configuration mode
Usage Guide	One EVI supports multiple import and export RT values.  The automatically generated RT value is in the format of AS2:nn. AS2 indicates the 2-byte AS number. If a 4-byte AS number is used, it is split, and a two 2-byte part is filled in the position for nn while the other 2-byte part is filled in the position for the RT value. nn indicates the VNI ID. There are four bytes of space provided for accommodating the 3-byte VNI ID.  If the BGP AS number changes, the automatically-generated RT value will also be changed.  If the manually configured RT value is consistent with the automatically generated one, both of them are displayed. If the automatically generated RT value is 100:1, it is directly deleted. Deleting this value does not cancel the auto configuration mode. To cancel the auto configuration mode, run the no form of the route-target auto command.

Configuring a Route Map for EVI Instances

Command	export map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Specifies the name of a route map.
Command Mode	EVPN VNI configuration mode
Usage Guide	This command is used to modify the extended community attribute advertised by a type 5 route converted from a local EVPN route or IP route. This command supports only one route map, and the old configuration is overwritten by the new configuration.

Command	import map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Specifies the name of a route map.
Command Mode	EVPN VNI configuration mode

Usage Guide	This command is used to filter the remote EVPN routes to be imported to the local VNI instance, or modify the attribute of the remote EVPN routes imported to the local VNI instance. This command supports only one route map, and the old configuration is overwritten by the new configuration.

Configuring MAC Mobility Parameters

Command	bgp mac-mobility timer count
Parameter Description	<i>timer</i>: Specifies the timer duration (in seconds) for MAC mobility detection. If a number of <i>count</i> MAC address moves are detected within the duration, it is considered that a MAC conflict occurs and syslogs are displayed to warn users. The value is 180 by default and ranges from 1 to 3600. <i>count</i>: Specifies the detection times. The value is 5 by default and ranges from 1 to 360.
Command Mode	BGP L2VPN EVPN address family mode
Usage Guide	One MAC address may move for many times. When a MAC address move is detected by a PE through local learning, a timer of <i>timer</i> seconds (default value = 180s) will be enabled. If a number of <i>count</i> (default value = 5) MAC address moves are detected before the timer times out, it is considered that a MAC conflict occurs.

Configuration Example

Configuring a BGP EVPN Address Family

Scenario Figure 7-14	The diagram illustrates a network topology for BGP EVPN configuration. It consists of two PCs, PC1 and PC2, and two routers, R1 and R2. PC1, with IP address 1111::1/64, is connected to R1 via its Gi0/0 interface. R1's Gi0/1 interface is connected to R2's Gi0/1 interface. R2's Gi0/0 interface is connected to PC2, which has IP address 1111::2/64.
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 1-14. ● Configure BGP neighborhoods as shown in Figure 1-14. ● Activate the L2VPN EVPN address family capability for BGP neighbors.

A	<pre>A# config terminal A(config)# interface gigabitEthernet 0/1 A(config-GigabitEthernet 0/1)# no shutdown A(config-GigabitEthernet 0/1)# ip address 172.18.2.1 255.255.255.0 A(config-GigabitEthernet 0/1)# exit A(config)# interface gigabitEthernet 0/2 A(config-GigabitEthernet 0/1)# no shutdown A(config-GigabitEthernet 0/1)# ip address 172.18.1.1 255.255.255.0 A(config-GigabitEthernet 0/1)# exit A(config)# router bgp 100 A(config-router)# neighbor 172.18.2.3 remote-as 100 A(config-router)# neighbor 172.18.1.2 remote-as 100 A(config-router)# address-family l2vpn evpn A(config-router-af)# neighbor 172.18.2.3 activate A(config-router-af)# neighbor 172.18.1.2 activate A(config-router-af)# neighbor 172.18.2.3 route-reflector-client A(config-router-af)# neighbor 172.18.1.2 route-reflector-client A(config-router-af)# exit-address-family</pre>

Common Errors

- No L2VPN EVPN address family neighbor is configured.
- The EVPN address family capability is not activated for BGP neighbors.

7.4.12 Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers

Configuration Effect

- Successfully interconnect devices supporting 4-byte AS numbers with devices supporting only 2-byte AS numbers.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

📌 Configuring the Display Mode of a 4-Byte AS Number

- (Optional) Perform this configuration in the BGP configuration mode. By default, a 4-byte AS number is displayed as decimal digits.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring the Display Mode of a BGP 4-Byte AS Number

Command	bgp asnotation dot
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

↘ Configuring Compatibility Between BGP Devices Supporting 4-Byte AS Numbers and 2-Byte AS Numbers

Scenario
Figure 7-15

Configuration Steps

- Enable BGP on all devices and set the AS numbers as shown in Figure 7-15.
- Configure BGP neighborships.

A

```
A# configure terminal
A(config)# router bgp 64496
A(config-router)# neighbor 172.18.1.2 remote-as 64497
A(config-router)# neighbor 172.18.2.3 remote-as 23456
```

B

```
B# configure terminal
B(config)# router bgp 64497
B(config-router)# neighbor 172.18.1.1 remote-as 64496
B(config-router)# neighbor 172.18.3.3 remote-as 1.2
B(config-router)# bgp asnotation dot
B(config-router)# end
```

C

```
C# configure terminal
C(config)# router bgp 1.2
C(config-router)# neighbor 172.18.2.1 remote-as 64496
C(config-router)# neighbor 172.18.3.2 remote-as 64497
```

Verification

Run the **show** command to display the BGP neighbor status.

A

```
A# show ip bgp summary

BGP router identifier 172.18.1.1, local AS number 64496
```

	BGP table version is 1, main routing table version 1

7.4.13 Using Local IPv6 Link Addresses to Establish BGP Neighborships

Configuration Effect

- Use local IPv6 link addresses to establish BGP neighborships.

Notes

- Local IPv6 link addresses can be used for establishing only single-hop BGP neighborships.
- When local IPv6 link addresses are used for establishing neighborships, local IPv6 link addresses must be configured in address%interface name format, for example, neighbor fe80::1%Te0/1 remote-as 100.
- When local IPv6 link addresses are used for establishing neighborships, using local IPv6 link addresses as information sources must be specified on the peer end.
- When local IPv6 link addresses are used for establishing neighborships, local IPv6 link addresses must be configured on both ends.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.
- **Disabling the IPv4 Address Family Capability for a BGP Neighbor**
- (Optional) Perform this configuration in the BGP IPv6 configuration mode.
- **Configuring the IPv6 Address Family Capability for a BGP Neighbor**
- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.
- **Configuring IPv6 Route Advertisement in BGP**
- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

➤ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

➤ Creating a BGP Neighbor

Command	neighbor <i>neighbor-address</i> remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Indicates the peer address, which must be in Linklocal address%interface name format. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ Disabling the IPv4 Address Family Capability for a BGP Neighbor

Command	no neighbor <i>neighbor-address</i> activate

Parameter Description	<i>neighbor-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Command Mode	BGP IPv4 address family mode
Usage Guide	Neighbors with IPv6 addresses are used to exchange IPv6 routes.

📌 Configuring the IPv6 Address Family Capability for a BGP Neighbor

Command	neighbor <i>neighbor-address</i> activate
Parameter Description	<i>neighbor-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

📌 Configuring IPv6 Route Advertisement in BGP

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network number. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

Configuration Example

📌 Using a Local IPv6 Link Address for Configuring a BGP Neighborhood to Implement IPv6 Route Exchange in Different ASs

Scenario Figure 7-16	
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 7-16. ● Configure a BGP neighbor, specify the update-source, disable the IPv4 address family capability for the neighbor and activate the IPv6 address family capability. ● Configure IPv6 route advertisement in BGP.
A	<pre> A# configure terminal A(config)# int loopback 0 A(config-if-Loopback)# ipv6 address 30::1/128 A(config-if-Loopback)# exit A(config)# int GigabitEthernet 0/1 A(config-if-Loopback)# ipv6 address fe80:100::2/64 A(config-if-Loopback)# exit A(config)# router bgp 65530 A(config-router)# neighbor fe80:100::1%Gi0/1 remote-as 65531 A(config-router)# address-family ipv4 A(config-router-af)# no neighbor fe80:100::1%Gi0/1 activate A(config-router-af)# exit-address-family A(config-router)# address-family ipv6 A(config-router-af)# neighbor fe80:100::1%Gi0/1 activate A(config-router-af)# network 30::1/128 </pre>
B	<pre> B# configure terminal B(config)# int GigabitEthernet 0/1 B(config-if-Loopback)# ipv6 address fe80:100::1/64 B(config-if-Loopback)# exit B(config)# router bgp 65531 B(config-router)# neighbor fe80:100::2%Gi0/1 remote-as 65530 B(config-router)# address-family ipv4 B(config-router-af)# no neighbor fe80:100::2%Gi0/1 activate B(config-router-af)# exit-address-family B(config-router)# address-family ipv6 </pre>

	B(config-router-af)# neighbor fe80:100::2%Gi0/1 activate
Verification	Run the show command to display the BGP neighbor status.
A	<pre> A# show bgp ipv6 unicast summary BGP router identifier 1.1.1.1, local AS number 65530 BGP table version is 1 1 BGP AS-PATH entries 0 BGP Community entries 1 BGP Prefix entries (Maximum-prefix:4294967295) Neighbor V AS MsgRcvd MsgSent TblVer InQ OutQ Up/Down State/PfxRcd fe80:100::1%Gi0/1 4 65531 4 6 1 0 0 00:01:49 0 Total number of neighbors 1 </pre>
B	Run the show command to display BGP routing information. <pre> B# show bgp ipv6 unicast BGP table version is 4, local router ID is 2.2.2.2 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 30::1/128 fe80:100::2 0 0 65530 i Total number of prefixes 1 </pre>

Common Errors

- When a neighborhood is configured, a local IPv6 link address is used to specify the neighborhood; however, no update source is specified as the interface for this local IPv6 link address during local configuration.
- Only one end uses a local IPv6 link address for establishing a neighborhood.

7.4.14 Configuring BGP NSR

Configuration Effect

- Configure the BGP NSR function to ensure highly reliable network deployment.

Notes

- To deploy the BGP NSR function successfully, the device must support the dual engine redundancy hot backup function.

- After the BGP NSR function is enabled, connections to the BGP neighbors will be reset for the function to take effect.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

➤ Configuring the NSR Function for BGP Neighbors

- (Mandatory) Perform this configuration in BGP configuration mode.

Verification

- Run the **show** command to query the BGP neighbor status.

Related Commands

➤ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	-

➤ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ Configuring the NSR Function for BGP Neighbors

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } ha-mode nsr

Parameter Description	<i>neighbor-address</i>: Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i>: Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

Configuring BGP NSR

Scenario Figure 7-17	
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in Figure 7-17. ● Establish the EBGP neighborship between routers A and B via the directly connected port. ● Enable the BGP NSR function on A.
A	<pre>A# configure terminal A(config-router)# exit A(config)# router bgp 65530 A(config-router)# neighbor 192.168.195.182 ha-mode nsr</pre>
Verification	Run the show command to query the BGP neighbor status.
A	<pre>A# show ip bgp neighbors BGP neighbor is 192.168.195.183, remote AS 65530, local AS 65531, external link Using BFD to detect fast fallover - BFD session state up BGP version 4, remote router ID 10.0.0.1 BGP state = Established, up for 00:06:37 Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds Neighbor capabilities: Route refresh: advertised and received (old and new) Address family IPv4 Unicast: advertised and received Graceful restart: advertised and received</pre>

	<pre> Remote Restart timer is 120 seconds Address families preserved by peer: None </pre>
B	<pre> B# show ip bgp neighbors BGP neighbor is 192.168.195.183, remote AS 65530, local AS 65531, external link Using BFD to detect fast fallover - BFD session state up BGP version 4, remote router ID 10.0.0.1 BGP state = Established, up for 00:06:37 Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds Neighbor capabilities: Route refresh: advertised and received (old and new) Address family IPv4 Unicast: advertised and received Graceful restart: advertised and received Remote Restart timer is 120 seconds Address families preserved by peer: None </pre>

Common Errors

- IGP is not configured.
- The NSR function is not enabled for BGP neighbors.

7.4.15 Configuring BGP Routes to Be Recursive Only to Host Routes

Configuration Effect

- Configure BGP routes to be recursive only to host routes, to enable IBGP or multi-EBGP routes to be recursive only to host routes.

Notes

- This feature is effective only to IBGP or multi-hop EBGP routes. It is unavailable to direct EBGP routes or routes whose next-hop addresses are direct connection addresses.
- IBGP or multi-hop EBGP neighborships of the device need to be established using the address of the Loopback interface. Otherwise, this feature is unavailable.

Configuration Steps

Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

Configuring BGP Routes to Be Recursive Only to Host Routes

- (Mandatory) Perform this configuration in BGP address family mode.

Verification

- Run the **show running-config** command to display the configuration.

Related Commands

Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number. The value range is from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring BGP Routes to Be Recursive Only to Host Routes

Command	Bgp recursion host
Parameter Description	N/A
Command Mode	BGP address family mode
Usage Guide	N/A

Configuration Example

Configuring BGP Routes to Be Recursive Only to Host Routes

Scenario Figure 7-18	

Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in the preceding figure. ● Establish the multi-hop EBGP neighborships on Router A and Router B through the Loopback interface. ● Enable the function of making BGP routes recursive only to host routes on Router A and Router B.
Verification	Run the show command to display the BGP neighbor status.

Common Errors

- If the feature is enabled on a device but IBGP or multi-hop EBGP neighborships are not established using the address of the Loopback interface, the device cannot find a host route that matches the next-hop address of a BGP route. As a result, the next hop of the BGP route is invalid and routes cannot be preferentially selected.

7.4.16 Configuring Outbound Loop Detection for a BGP Neighbor

Configuration Effect

- Configure outbound loop detection for a BGP neighbor

Notes

- This feature is available only to EBGP neighbors.

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

📌 Configuring Outbound Loop Detection for a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

📌 Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number. The value range is from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS number specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

Configuring Outbound Loop Detection for a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } as-loop-check out
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters.
Command Mode	BGP configuration mode
Usage Guide	N/A

Configuration Example

Configuring Outbound Loop Detection for a BGP Neighbor

Scenario Figure 7-19	

Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in the preceding figure. ● Establish the EBGP neighborship between Device A and Device C, and between Device B and Device C. ● On Device C, enable outbound loop detection for its neighbors: Device A and Device B.
A	<pre>A# configure terminal A(config)# router bgp 65536 A(config-router)# neighbor 10.1.1.1 remote-as 65537</pre>

Verification	Run the show command to display the BGP neighbor status.
C	<pre>C# show ip bgp neighbors 10.1.1.2 BGP neighbor is 10.1.1.2, remote AS 65536, local AS 65537, external link Using as path loop detection in announcing route BGP version 4, remote router ID 10.0.0.1 BGP state = Established, up for 00:06:37 Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds Neighbor capabilities: Route refresh: advertised and received (old and new) Address family IPv4 Unicast: advertised and received Graceful restart: advertised and received Remote Restart timer is 120 seconds Address families preserved by peer: None ...</pre>

7.4.17 Shutting Down BGP Connections Gracefully

Configuration Effect

- Shut down BGP connections gracefully. Service traffic is not interrupted or is interrupted for a very short period of time in the process from feature configuration to actual BGP connection shutdown.

Notes

N/A

Configuration Steps

📌 Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

📌 Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

📌 Shutting Down Connections of the BGP Neighbor Gracefully

- (Optional) Perform this configuration in BGP configuration mode.

📌 Shutting Down All Connections of a BGP Instance Gracefully

- (Optional) Perform this configuration in BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

📌 Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number. The value range is from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	N/A

📌 Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.

	<i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS number specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

📌 Shutting Down Connections of the BGP Neighbor Gracefully

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } shutdown graceful [community value] [delay time]
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters. community value : Indicates the community value carried in the route sent to the neighbor. delay time : Indicates the delay time (in seconds) for shutting down BGP connections. The value range is from 1 to 65,535.
Command Mode	BGP configuration mode
Usage Guide	N/A

📌 Shutting Down All Connections of a BGP Instance Gracefully

Command	bgp shutdown graceful [community value] [delay time]
Parameter Description	community value : Indicates the community value carried in the route sent to the neighbor. delay time : Indicates the delay time (in seconds) for shutting down BGP connections. The value range is from 1 to 65,535.
Command Mode	BGP configuration mode
Usage Guide	N/A

Configuration Example

📌 Shutting Down BGP Connections Gracefully

Scenario Figure 7-20	
Configuration Steps	● Enable BGP on all devices and set the AS numbers as shown in the preceding figure. ● Establish the EBGP neighborship between Device A and Device C and between Device B and Device C. ● On Device A, shut down all connections of a BGP instance gracefully.
A	<pre> A# configure terminal A(config)# router bgp 65536 A(config-router)# neighbor 10.1.1.1 remote-as 65537 A(config-router)# bgp shutdown graceful med 4294967295 </pre>

7.4.18 Configuring EBGp Multi-path Bypass Protection

Configuration Effect

- Implement EBGp multi-path bypass protection.

Notes

- BFD sessions can be configured for neighbors to implement fast link fault detection.

Configuration Steps

➤ Enabling BGP

- (Mandatory) Perform this configuration in global configuration mode.

➤ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in BGP configuration mode.

➤ Configuring BGP ECMP

- (Mandatory) Perform this configuration in BGP configuration mode.

➤ Configuring BGP Multi-path Bypass Protection

- (Mandatory) Perform this configuration in BGP configuration mode.

➤ Configuring a BFD Session to a BGP Neighbor

- (Optional) Perform this configuration in BGP configuration mode.

Verification

- Run the **show** command to display route information.

Related Commands

➤ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number. The value range is from 1 to 4,294,967,295, which is 1 to 65535.65535 in dot mode.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring BGP Multi-path Bypass Protection

Command	bgp install standby-path
Parameter Description	N/A
Command Mode	BGP configuration mode
Usage Guide	N/A

➤ Creating a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS number specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Creating a BFD Session to a BGP Neighbor

Command	neighbor { <i>neighbor-address</i> <i>peer-group-name</i> } fall-over bfd
Parameter Description	<i>neighbor-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, containing no more than 32 characters.
Command Mode	BGP configuration mode
Usage Guide	N/A

Configuration Example

 The following configuration example describes only the configuration relevant to BGP multi-path bypass protection.

↘ Configuring BGP Multi-path Bypass Protection

Scenario
Figure 7-21

- Configuration Steps
- Enable BGP on all devices.
 - Configure addresses for directly-connected ports on Device A, Device B, and Device C, and mutually establish the EBGP neighborhood between every two of them.
 - Configure a BFD session for the EBGP neighborhood between Device A and Device C.
 - Configure BGP multi-path bypass protection on Device C.
 - Configure ECMP on Device C.

A

```
A# conf terminal
A(config)# interface GigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
A(config-if-GigabitEthernet 0/1)# exit
A(config)# interface GigabitEthernet 0/2
A(config-if-GigabitEthernet 0/2)# ip address 192.168.2.1 255.255.255.0
A(config-if-GigabitEthernet 0/2)# exit
A(config)# interface GigabitEthernet 0/3
A(config-if-GigabitEthernet 0/3)# ip address 192.168.4.1 255.255.255.0

7.4.19 Configuring Inter-VRF Multi-Path Route Import

Configuration Effect

- Ensure inter-VRF route import and ECMP multi-path for inter-imported routes.

Notes

- N/A

Configuration Steps

📌 Configuring a BGP VRF Address Family

- (Mandatory) Perform this configuration in BGP configuration mode.

📌 Importing Static Routes to BGP

- (Mandatory) Perform this configuration in BGP address family mode.

↘ Importing Multi-Path Static Routes to BGP

- (Mandatory) Perform this configuration in BGP address family mode.

↘ Configuring BGP ECMP

- (Mandatory) Perform this configuration in BGP address family mode.

↘ Configuring Inter-VRF Import for All Path Routes

- (Mandatory) Perform this configuration in BGP address family mode.

Verification

- Run the **show** command to display route information.

Related Commands

↘ Configuring a BGP VRF Address Family

Command	address-family ipv4 vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the VRF instance name.
Command Mode	BGP configuration mode
Usage Guide	N/A

↘ Importing Static Routes to BGP

Command	redistribute <i>protocol-type</i> [route-map <i>map-tag</i>] [metric <i>metric-value</i>]
Parameter Description	<i>protocol-type</i> : Indicates the source protocol type of a redistributed route. route-map <i>map-tag</i> : Indicates the name of an associated route map. metric <i>metric-value</i> : Indicates the default metric value of a redistributed route. The value range is from 0 to 4,294,967,295 .
Command Mode	BGP address family mode
Usage Guide	N/A

↘ Importing Multi-Path Static Routes to BGP

Command	bgp sourced-paths <i>protocol-type</i> all
Parameter Description	<i>protocol-type</i> : Indicates the source protocol type of a redistributed route.
Command Mode	BGP address family mode
Usage Guide	This command needs to be used together with the redistribution command to import routes with multiple

next hops from other protocols to BGP.

Configuring BGP ECMP

Command	maximum-paths { ebgp ibgp } number
Parameter Description	ebgp : Specifies the number of equivalent paths of the EBGp multipath load balancing function. ibgp : Specifies the number of equivalent paths of the IBGP multipath load balancing function. number : Indicates the maximum number of equivalent paths. The minimum value is 1 , and the maximum value depends on the device capability. If the value is 1 , the EBGp multipath load balancing function is disabled.
Command Mode	BGP address family mode
Usage Guide	The maximum-paths ebgp command is also used to configure equivalence of confederation EBGp multiple paths and local inter-VRF import routes. IBGP and EBGp routes cannot form equivalent routes.

Configuring Inter-VRF Import for All Path Routes

Command	import path selection { all bestpath multipath }
Parameter Description	all : Imports all routes with next hops. bestpath : Imports routes with preferred next hops. By default, only routes with preferred next hops are imported. multipath : Imports routes with preferred and equivalent next hops.
Command Mode	BGP address family mode
Usage Guide	This command can be used to control inter-VRF route import, L3VPN remote routes import to VRF, and EVPN routes import to the IP route table.

Configuration Example

Configuring BGP Multi-Path Bypass Protection

Scenario
Figure 7-22

Device A connects to two networks through VRF vpn1 and vpn2, and cross-VRF access is implemented

	through device A.
Configuration Steps	Configure VRF. Configure VRF static routes. Configure a VRF address family. Import VRF static routes to BGP. Enable multi-path static route import to BGP. Configure BGP ECMP. Configure inter-VRF import for all path routes.
A	<pre> A# conf terminal A(config)# ip vrf vpn1 A(config-vrf)# rd 200:1 A(config-vrf)# route-target both 100:100 A(config-vrf)# exit A(config)# ip vrf vpn2 A(config-vrf)# rd 300:1 A(config-vrf)# route-target both 100:100 A(config-vrf)# exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# A(config-if-GigabitEthernet 0/1)# ip vrf forwarding vpn1 A(config-if-GigabitEthernet 0/1)# ip address 44.1.1.2 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)# ip vrf forwarding vpn1 A(config-if-GigabitEthernet 0/2)# ip address 45.1.1.2 255.255.255.0 A(config-if-GigabitEthernet 0/2)# exit A(config)# interface GigabitEthernet 0/3 A(config-if-GigabitEthernet 0/3)# ip vrf forwarding vpn2 A(config-if-GigabitEthernet 0/3)# ip address 46.1.1.2 255.255.255.0 A(config-if-GigabitEthernet 0/3)# exit A(config)# interface GigabitEthernet 0/4 A(config-if-GigabitEthernet 0/4)# ip vrf forwarding vpn2 </pre>

7.4.20 Configuring BMP Monitoring

Configuration Effect

- Enable BGP to be monitored by the BMP server.

Notes

None

Configuration Steps

↳ Creating a BMP Server Instance

- (Mandatory) Perform this configuration in global configuration mode.

↳ Configuring the Address and Port Number of the BMP Server

- (Mandatory) Perform this configuration in BMP configuration mode.

↳ Configuring the Source Address of a TCP Connection to the BMP Server

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the VRF Instance to Which a TCP Connection to the BMP Server Belongs

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the Interval to Establish a TCP Connection to the BMP Server

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the Description for BMP Instance

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the BMP Server to Monitor Routing Information Received from a BGP Peer After the Routing Policy Is Applied

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the BMP Server to Monitor Unchanged Routing Information Received from a BGP Peer

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the BMP Server to Monitor Routing Information Sent to a BGP Peer After the Routing Policy Is Applied

- (Optional) Perform this configuration in BMP configuration mode.

↳ Configuring the BMP Server to Monitor BGP Peers

- (Mandatory) Perform this configuration in BGP configuration mode.

↳ Configuring All BMP Servers to Monitor BGP Peers

- (Optional) Perform this configuration in BGP configuration mode.

↳ Configuring the BMP Server to Monitor BGP Packets

- (Optional) Perform this configuration in BGP configuration mode.

↳ Configuring the Interval for Sending Status Statistics to the BMP Server

- (Optional) Perform this configuration in BGP configuration mode.

Verification

- Run the **show running-config** command to display the configurations.

7.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears BGP IPv4 unicast routes.	clear ip bgp [<i>vrf vrf-name</i>] update-group [<i>update-group-index</i> <i>neighbor-address</i>] [<i>soft</i>] [<i>in</i> <i>out</i>]
Restores the priority of advertised routes.	clear bgp advertise lowest-priority on-startup

Displaying

Description	Command
Displays the update-group information of BGP IPv4 unicast address family.	show ip bgp [<i>vrf vrf-name</i>] update-group [<i>neighbor-address</i> <i>update-group-index</i>] [<i>summary</i>]
Displays information about a BMP server instance.	show bgp bmp server [<i>server-number</i> [<i>detail</i>] <i>detail</i>] }
Displays neighbors monitored by the BMP server.	show bgp bmp neighbor
Display abstract information of a connection to the BMP server.	show bgp bmp summary

Displays BGP statistics.	show bgp statistics [vrf <i>vrf-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables all BGP debugging.	debug ip bgp all
Enables BGP BMP debugging.	debug ip bgp bmp
Debugs BGP route flapping.	debug ip bgp dampening
Debugs BGP event processing.	debug ip bgp event
Debugs BGP route filtering.	debug ip bgp filter
Debugs BGP status machine.	debug ip bgp fsm
Debugs BGP neighbor keepalive.	debug ip bgp keepalives
Debugs BGP core route processing.	debug ip bgp nsm
Debugs BGP UPDATE packets.	debug ip bgp update
Debugs BGP EVPN.	debug ip bgp evpn
Debugs BGP UPDATE-GROUP.	debug ip bgp update-group

8 Configuring RIPng

8.1 Overview

RIP next generation (RIPng) is a unicast routing protocol that applies to IPv6 networks. RIPng-enabled routers exchange routing information to obtain routes to remote networks.

As an Interior Gateway Protocol (IGP), RIPng can run only within the autonomous system (AS) and is applicable to small-sized networks with routes no more than 16 hops.

Protocols and Standards

- RFC2080: Defines the RIPng.

8.2 Application

RIPng is generally used on some small-sized networks, such as office networks of small companies.

As shown in the following figure, the company builds an IPv6 network, on which all routers support IPv6. The network is small in size, but the workload is still heavy if the network is maintained manually. In this case, RIPng can be configured to adapt to topological changes of the small-sized network, which reduces the workload.

Figure 8-1

8.3 Features

Basic Concepts

↘ IGP and EGP

IGP runs within an AS. For example, RIPng is a type of IGP.

Exterior Gateway Protocol (EGP) runs between ASs. For example, BGP is a type of EGP.

Feature

Feature	Description
RIPng and RIP	RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.
Exchanging Routing Information	By exchanging routing information, RIPng-enabled devices can automatically obtain routes to a remote network and update routes in real time.
Routing Algorithm	RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.
Avoiding Route Loops	RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

8.3.1 RIPng and RIP

RIP applies to IPv4 networks. Two RIP versions are available, including RIPv1 and RIPv2.

RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.

Working Principle

➤ RIPv2

RIPv2 packets are multicast. The multicast address is 224.0.0.9, and the UDP port ID is 520. RIPv2 can identify the subnet mask.

➤ RIPng

RIPng packets are multicast. The multicast address is FF02::9, the source address is FE80::/10, and the UDP port ID is 521. RIPng can identify the subnet mask.

 This chapter describes functions and configurations of RIPng. For details about RIPv2, see "Configuring RIP".

Related Configuration

➤ Enabling the RIPng Process

By default, the RIPng process is disabled.

Run the **ipv6 router rip** command to enable the RIPng process.

You must enable the RIPng process on a device; otherwise, all functions related to RIPng cannot take effect.

➤ Running RIPng on an Interface

By default, RIPng does not run on an interface.

Run the **ipv6 rip enable** command to run RIPng on an interface.

After RIPng runs on an interface, RIPng packets can be exchanged on the interface and RIPng can learn routes to the network segments directly connected to the device.

📌 Prohibiting an Interface from Sending or Receiving Packets

By default, a RIPng-enabled interface is allowed to send and receive RIPng packets.

Run the **passive-interface** command to prohibit an interface from sending RIPng packets.

8.3.2 Exchanging Routing Information

Compared with static routing, the dynamic routing protocol has a significant advantage, that is, by exchanging routing information, devices can automatically obtain routes to a remote network and update the routes in real time.

Working Principle

📌 Initialization

After RIPng is enabled on a router, the router sends a request packet to its neighbor router, requesting for all routing information, that is, the routing table. After receiving the request message, the neighbor router returns a response packet containing the local routing table. After receiving the response packet, the router updates the local routing table, and sends an update packet to the neighbor router, informing the neighbor router of the route update information. After receiving the update packet, the neighbor router updates the local routing table, and sends the update packet to other adjacent routers. After a series of updates, all routers can obtain and retain the latest routing information.

📌 Periodical Update

By default, periodical update is enabled for RIPng. Adjacent routers exchange complete routing information with each other every 30s (update timer), that is, the entire routing table is sent to neighbor routers.

i For every non-local route, if the route is not updated within 180s (invalid timer), the metric of the route is changed to 16 (unreachable). If the route is still not updated in the next 120s (flush timer), the route is deleted from the routing table.

📌 Default Route

In the routing table, a route to the destination network `::0` is called default route.

The default route can be learned from a neighbor router, or sent to a neighbor router.

📌 Route Redistribution

For RIPng, other types of routes (such as direct routes, static routes, and routes of other routing protocols) are called external routes.

External routes (excluding the default route) can be redistributed to RIPng and advertised to neighbors.

📌 Route Filtering

Filtering conditions can be configured to limit the routing information exchanged between adjacent routers. Only the routing information that meets filtering conditions can be sent or received.

Related Configuration

📌 RIPng Timers

By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Run the **timers basic** command to modify durations of RIPng timers.

Increasing the duration of the flush timer can reduce the route flapping. Decreasing the duration of the flush timer helps accelerate route convergence.

The durations of RIPng timers must be consistent on adjacent routers. Unless otherwise required, you are advised not to modify the RIPng timers.

📌 Default Route

Run the **ipv6 rip default-information** command to advertise the default route to neighbors on an interface.

📌 Route Redistribution

Run the **redistribute** command to redistribute external routes (excluding the default route) to RIPng and advertise them to neighbors.

📌 Route Filtering

Run the **distribute-list out** command to set filtering rules to limit the routing information sent by the device.

Run the **distribute-list in** command to set filtering rules to limit the routing information received by the device.

8.3.3 Routing Algorithm

RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.

Working Principle

📌 Distance-Vector Algorithm

RIPng is a protocol based on the distance-vector algorithm. The distance-vector algorithm treats a route as a vector that consists of the destination network and distance (metric). The router obtains a route from its neighbor and adds the distance vector from itself to the neighbor to the route to form its own route.

RIPng uses the hop count to evaluate the distance (metric) to the destination network. By default, the hop count from a router to its directly connected network is 0, the hop count from a router to a network that can be reached through a router is 1, and so on. That is, the metric is equal to the number of routers from the local network to the destination network. To restrict the convergence time, RIPng stipulates that the metric must be an integer between 0 and 15. If the metric is equal to or greater than 16, the destination network or host is unreachable. For this reason, RIPng cannot be applied to a large-scale network. As shown in the following figure 8-2, Router A is connected to the network 2::/64. Router B obtains the route (2::/64, 0) from Router A and adds the metric 1 to the route to obtain its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-2

Selecting the Optimum Route

RIPng selects an optimum route based on the following principle: If multiple routes to the same destination network is available, a router preferentially selects the route with the smallest metric.

As shown in the following figure 8-3, Router A is connected to the network 2::/64. Router C obtains the route (2::/64, 0) from Router A and the route (2::/64, 1) from Router B. Router C will select the route that is obtained from Router A and add metric 1 to this route to form its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-3

i When routes coming from different sources exist on a router, the route with the smaller distance is preferentially selected.

Route Source	Default Distance
Directly-connected network	0
Static route	1
OSPF route	110
IS-IS route	115
RIPng route	120
Unreachable route	255

Related Configuration

Modifying the Distance

By default, the distance of a RIPng route is 120.

Run the **distance** command to modify the distance of a RIPng route.

✚ Modifying the Metric

For a RIPng route that is proactively discovered by a device, the default metric is equal to the number of hops from the local network to the destination network. The metric offset of the interface is 1.

For a RIPng router that is manually configured (default route or redistributed route), the default metric is 1.

Run the **ipv6 rip metric-offset** command to modify the metric offset of the interface.

Run the **default-metric** command to modify the default metric of an external route (redistributed route).

Run the **redistribute** command to modify the metric of an external route (redistributed route) when advertising this route.

Run the **ipv6 rip default-information** command to modify the metric of a default route when advertising the default route.

8.3.4 Avoiding Route Loops

RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

Working Principle

✚ Route Loop

A RIPng route loop occurs due to inherent defects of the distance-vector algorithm.

As shown in the following figure 8-4, Router A is connected to the network 2::/64, and sends an update packet every 30s. Router B receives the route to 2::/64 from Router A every 30s. If Router A is disconnected from 2::/64, the route to 2::/64 will be deleted from the routing table on Router A. Next time, the update packet sent by Router A no longer contains this route. As Router B does not receive an update packet related to 2::/64, Router B determines that the route to 2::/64 is valid within 180s and uses the update packet to send this route to Router A. As the route to 2::/64 does not exist on Router A, the route learned from Router B is added to the routing table. Router B determines that data can reach 2::/64 through Router A, and Router A determines that data can reach 2::/64 through Router B. In this way, a route loop is formed.

Figure 8-4

✚ Split Horizon

Split horizon can prevent route loops. After split horizon is enabled, a route received on this interface will not be sent out from this interface.

As shown in the following figure 8-5, after split horizon is enabled on Router B, Router B will not send the route to 2::/64 back to Router A. Router B will learn 180s later that 2::/64 is not reachable.

Figure 8-5

➤ Poison Reverse

Poison reverse can also prevent route loops. Compared with split horizon, poison reverse is more reliable, but brings more protocol packets, which makes network congestion more severe.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric of this router will be changed to 16 (unreachable).

As shown in the following figure, after poison reverse is enabled on Router A, if Router A detects a disconnection from 2::/64, Router A will not delete the route to 2::/64. Instead, Router A changes the number of hops to 16, and advertises the route through the update packet. On receiving the update packet, Router B learns that 2::/64 is not reachable.

Figure 8-6

Related Configuration

➤ Split Horizon

By default, split horizon is enabled.

Run the **no split-horizon** command to disable split horizon.

➤ Poison Reverse

By default, poison reverse is disabled.

Run the **split-horizon poisoned-reverse** command to enable poison reverse. (After poison reverse is enabled, split horizon is automatically disabled.)

8.4 Configuration

Configuration	Related Commands	
Configuring RIPng Basic Functions	 (Mandatory) It is used to build a RIPng routing domain.	
	ipv6 router rip	Enables a RIPng routing process and enters routing process configuration mode.
	ipv6 rip enable	Runs RIPng on an interface.
	split-horizon	Enables split horizon or poison reverse.
	passive-interface	Configures a passive interface.
Advertising the Default Route or External Routes	 Optional.	
	ipv6 rip default-information	Advertise the default route to neighbors on an interface.
	redistribute	Redistributes routes and advertising external routes to neighbors.
Setting Route Filtering Rules	 Optional.	
	distribute-list in	Filters the received RIPng routing information.
	distribute-list out	Filters the sent RIPng routing information.
Modifying Route Selection Parameters	 Optional.	
	distance	Modifies the administrative distance of a RIPng route.
	ipv6 rip metric-offset	Modifies the metric offset on an interface.
	default-metric	Configure the default metric for route redistribution.
Modifying Timers	 Optional.	
	timers	Modifies the update timer, invalid timer, and flush timer of RIPng.

8.4.1 Configuring RIPng Basic Functions

Configuration Effect

- Build a RIPng routing domain on the network.
- Routers in the domain obtain routes to a remote network through RIPng.

Notes

- IPv6 addresses must be configured.
- IPv6 unicast routes must be enabled.

Configuration Steps

▾ Enabling a RIPng Routing Process

- Mandatory.
- Unless otherwise required, perform this configuration on every router in the RIPng routing domain.

▾ Running RIPng on an Interface

- Mandatory.
- Unless otherwise required, perform this configuration on every interconnected interface of routers in the RIPng routing domain.

▾ Enabling Split Horizon or Poison Reverse

- By default, split horizon is enabled and poison reverse is disabled.
- Unless otherwise required, enable split horizon on every interface connected to the broadcast network, such as the Ethernet. (Retain the default setting.)
- Unless otherwise required, enable split horizon on every interface connected to the point-to-point (P2P) network, such as the PPP and HDLC. (Retain the default setting.)
- It is recommended that split horizon and poison reverse be disabled on an interface connected to a non-broadcast multi-access network, such as FR and X.25; otherwise, some devices cannot learn the complete routing information.
- If the secondary IP address is configured for an interface connected to a non-broadcast, it is recommended that split horizon and poison reverse be disabled.

▾ Configuring a Passive Interface

- This configuration is recommended.
- Use the passive interface to set the boundary of the RIPng routing domain. The network segment of the passive interface belongs to the RIPng routing domain, but RIPng packets cannot be sent over the passive interface.
- If RIPng routes need to be exchanged on an interface (such as the router interconnect interface) in the RIPng routing domain, this interface cannot be configured as a passive interface.

Verification

- Check the routing table on a router to verify that the route to a remote network can be obtained through RIPng.

Related Commands

▾ Enabling a RIPng Routing Process

Command	ipv6 router rip
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to create a RIPng routing process and enter routing process configuration mode.

▾ Running RIPng on an Interface

Command	ipv6 rip enable
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	The configuration for running the RIPng on an interface is different from that of RIPv2. In RIPv2, the network command is configured in routing process configuration mode to define an IP address range. If the IP address of an interface belongs to this IP address range, RIP automatically runs on this interface.

▾ Enabling Split Horizon

Command	split-horizon [poisoned-reverse]
Parameter	poisoned-reverse: Indicates that the split horizon function contains the poison reverse function.
Description	
Command Mode	Routing process configuration mode
Usage Guide	Run the show ipv6 rip command to check whether split horizon is enabled. The configuration is different from that of RIPv2. In RIPv2, the split horizon function is configured in interface configuration mode.

▾ Configuring a Passive Interface

Command	passive-interface { default <i>interface-type interface-num</i> }
Parameter	default: Indicates all interfaces.
Description	<i>interface-type interface-num</i>: Specifies an interface.
Command Mode	Routing process configuration mode
Usage Guide	First, run the passive-interface default command to configure all interfaces as passive interfaces. Then, run the no passive-interface <i>interface-type interface-num</i> command so that the interfaces used for interconnection between routers in the domain are not passive interface.

▾ Displaying the IP Routing Table

Command	show ipv6 route
Parameter	N/A
Description	
Command Mode	Privileged EXEC mode or global configuration mode
Usage Guide	Check whether the routing table contains any route to a remote network that is learned through RIPng.

Configuration Example

▾ Building a RIPng Routing Domain

Scenario
Figure 8-7

- Configuration Steps**
- Configure IPv6 addresses on all routers.
 - Enable RIPng on all routers.

A

```
A# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
A(config)# ipv6 router rip
A(config-router)# exit
A(config)# interface GigabitEthernet 0/0
A(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::1/32
A(config-if-GigabitEthernet 0/0)# ipv6 rip enable
```

B

```
B# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
B(config)# ipv6 router rip
B(config-router)# exit
B(config)# interface GigabitEthernet 0/0
B(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::2/32
B(config-if-GigabitEthernet 0/0)# ipv6 rip enable
```

C

```
C# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
C(config)# ipv6 router rip
C(config-router)# exit
C(config)# interface GigabitEthernet 0/0
C(config-if-GigabitEthernet 0/0)#
```

	<pre> C(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::3/32 C(config-if-GigabitEthernet 0/0)# ipv6 rip enable C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ipv6 address 2::1/64 C(config-if-GigabitEthernet 0/1)# ipv6 rip enable </pre>
Verification	Check the routing tables on Router A, Router B, and Router C. The routing tables should contain routes to a remote network that are learned through RIPng.
A	<pre> A# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::1/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:E7CE/128 via GigabitEthernet 0/0, local host </pre>
B	<pre> B# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 </pre>

	<pre> IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::2/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C9BA/128 via GigabitEthernet 0/0, local host </pre>
C	<pre> Ruijie# show ipv6 route IPv6 routing table name - Default - 9 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 2::/64 via GigabitEthernet 0/1, directly connected L 2::2/128 via GigabitEthernet 0/1, local host C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::3/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/1, local host </pre>

Common Errors

- The IPv6 address is not configured on an interface.
- The interface used for interconnection between devices is configured as a passive interface.

8.4.2 Advertising the Default Route or External Routes

Configuration Effect

- In the RIPng domain, introduce a unicast route of another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.
- In the RIPng domain, inject a default route to another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

📄 Configuring External Route Redistribution

- Optional.
- Perform this configuration if external routes of the RIPng domain should be introduced to the AS border router (ASBR).

📄 Generating a Default Route

- Optional.
- Perform this configuration if the default route should be introduced to an ASBR so that other routers in the RIPng domain access other AS domains through this ASBR by default.

Verification

- Run the **show ipv6 route rip** command on a non-ASBR to check whether the external routes of the domain and default route have been loaded.

Related Commands

📄 Advertising the Default Route to Neighbors on an Interface

Command	ipv6 rip default-information { only originate } [metric <i>metric-value</i>]
Parameter Description	only: Advertises only IPv6 default route. originate: Advertises the IPv6 default route and other routes. metric <i>metric-value</i>: Indicates the metric of the default route. The value ranges from 1 to 15. The default value is 1.
Command Mode	Interface configuration mode
Usage Guide	After this command is configured on the interface, an IPv6 default route is advertised to the external devices through this interface, but the route itself is not added to the route forwarding table or the device and the RIPng route database. To prevent occurrence of a route loop, once this command is configured on an interface, RIPng refuses to receive the default route updates advertised by neighbors.

Redistributing Routes and Advertising External Routes to Neighbors

Command	redistribute { bgp connected isis [<i>area-tag</i>] ospf <i>process-id</i> static } [metric <i>metric-value</i> route-map <i>route-map-name</i>]
Parameter Description	bgp : Indicates redistribution from BGP. Connected : Indicates redistribution from direct routes. isis [<i>area-tag</i>] : Indicates redistribution from IS-IS. <i>area-tag</i> indicates the IS-IS process ID. ospf <i>process-id</i> : Indicates redistribution from OSPF. <i>process-id</i> indicates the OSPF process ID. The value ranges from 1 to 65535. static : Indicates redistribution from static routes. metric <i>metric-value</i> : Sets the metric of the route redistributed to the RIPng domain. route-map <i>route-map-name</i> : Sets the redistribution filtering rules.
Command Mode	Routing process configuration mode
Usage Guide	During route redistribution, it is not necessary to convert the metric of one routing protocol to the metric of another routing protocol because different routing protocols use completely different metric measurement methods. RIP measures the metric based on the hop count, and OSPF measures the metric based on the bandwidth. Therefore, the computed metrics cannot be compared with each other.

Configuration Example

Scenario Figure 8-8	
Configuration Steps	- Configure the interface IPv6 addresses on all routers. (Omitted) - Configure the RIPng basic functions on all routers. (Omitted) - On Router B, configure redistribution of static routes. - On the GE0/1 interface of Router A, configure advertisement of the default route.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ipv6 rip default-information originate</pre>
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# redistribute static</pre>
Verification	Check the routing tables on Router A and Router B, and confirm that Router A can learn the route 3001:10:10::/64, and Router B can learn the default route ::/0.

A	<pre>A# show ipv6 route rip</pre> IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area <pre>R 3001:10:10::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>
B	<pre>B# show ipv6 route rip</pre> IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area <pre>R ::/0 [120/2] via FE80::21A:A9FF:FE41:5B06, GigabitEthernet 0/1</pre>

8.4.3 Setting Route Filtering Rules

Configuration Effect

- Routes that do not meet filtering criteria cannot be loaded to the routing table, or advertised to neighbors. In this way, users within the network can be prevented from accessing specified destination networks.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

Filtering the Received RIP Routing Information

- To refuse receiving some specified routes, you can configure the route distribution control list to process all the received route update packets. If no interface is specified, route update packets received on all interfaces will be processed.

Filtering the Sent RIPvng Routing Information

- If this command does not contain any optional parameter, route update advertisement control takes effect on all interfaces. If the command contains the interface parameter, route update advertisement control takes effect only on the specified interface. If the command contains other routing process parameters, route update advertisement control takes effect only on the specified routing process.

Verification

- Run the **show ipv6 route rip** command to check that the routes that have been filtered out are not loaded to the routing table.

Related Commands

Command	distribute-list prefix-list <i>prefix-list-name</i> { in out } [<i>interface-type interface-name</i>]
Parameter	prefix-list <i>prefix-list-name</i> : Indicates the name of the prefix list, which is used to filter routes.
Description	in out : Specifies update routes (received or sent routes) that are filtered. <i>interface-type interface-name</i> : Indicates that the distribution list is applied to the specified interface.
Command Mode	Routing process configuration mode
Usage Guide	N/A

Configuration Example

Scenario Figure 8-9	
Configuration Steps	● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPvng basic functions on all routers. (Omitted) ● On router A, configure route filtering.
A	<pre>A# configure terminal A(config)# ipv6 prefix-list hello permit 4001::/64 A(config)# ipv6 router rip A(config-router)# distribute-list prefix-list hello in</pre>
Verification	● Check that Router A can learn only the route to 4001::/64.

A

```
A# show ipv6 route rip

IPv6 routing table name - Default - 17 entries

Codes: C - Connected, L - Local, S - Static

        R - RIP, O - OSPF, B - BGP, I - IS-IS

        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

        E1 - OSPF external type 1, E2 - OSPF external type 2

        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

        IA - Inter area

R      4001::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1
```

8.4.4 Modifying Route Selection Parameters

Configuration Effect

- Change the RIPng routes to enable the traffic pass through specified nodes or avoid passing through specified nodes.
- Change the sequence that a router selects various types of routes so as to change the priorities of RIPng routes.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

✚ Modifying the Administrative Distance of a RIPng Route

- Optional.
- Perform this configuration if you wish to change the priorities of RIPng routes on a router that runs multiple unicast routing protocols.

✚ Modifying the Metric Offset on an Interface

- Optional.
- Unless otherwise required, perform this configuration on a router where the metrics of routes need to be adjusted.

✚ Configuring the Default Metric of an External Route Redistributed to RIPng

- Optional.
- Unless otherwise required, perform this configuration on an ASBR to which external routes are introduced.

Verification

- Run the **show ipv6 rip** command to display the administrative distance of RIPng routes.
- Run the **show ipv6 rip data** command to display the metrics of external routes redistributed to RIPng.

Related Commands

✚ Modifying the Administrative Distance of a RIPng Route

Command	distance <i>distance</i>
Parameter Description	<i>distance</i> : Sets the administrative distance of a RIPng route. The value is an integer ranging from 1 to 254.
Command Mode	Routing process configuration mode
Usage Guide	Run this command to set the administrative distance of a RIPng route.

✚ Modifying the Metric Offset on an Interface

Command	ipv6 rip metric-offset <i>value</i>
Parameter Description	<i>value</i> : Indicates the interface metric offset. The value ranges from 1 to 16.
Command Mode	Routing process configuration mode
Usage Guide	Before a route is added to the routing table, the metric of the route must be added with the metric offset set on the interface. You can control the use of a route by setting the interface metric offset.

✚ Configuring the Default Metric of an External Route Redistributed to RIPng

Command	default-metric <i>metric</i>
Parameter Description	<i>metric</i> : Indicates the default metric. The valid value ranges from 1 to 16. If the value is equal to or greater than 16, the RGOS determines that this route is unreachable.
Command Mode	Global configuration mode
Usage Guide	If the metric is not specified during redistribution of a routing protocol process, RIPng uses the metric defined by the default-metric command. If the metric is specified, the metric defined by the default-metric command is overwritten by the specified metric. If this command is not configured, the value of default-metric is 1.

Configuration Example

✚ Modifying the Administrative Distance of a RIPng Route

Scenario
Figure 8-10

Configuration Steps	- Configure the interface IPv6 addresses on all routers. (Omitted) - Configure the RIPng basic functions on all routers. (Omitted) - On Router A, set the administrative distance of a RIPng route to 160.
	<pre>A# configure terminal A(config)# ipv6 router rip A(config-router)# distance 160</pre>
Verification	On Router A, check whether the administrative distance of a RIPng route is 160.
	<pre>A# show ipv6 route rip in 3001::/64 R 3001::/64 [160/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>

8.4.5 Modifying Timers

Configuration Effect

- Change the duration of RIPng timers to accelerate or slow down the change of the protocol state or occurrence of an event.

Notes

- The RIPng basic functions must be configured.
- Modifying the protocol control parameters may result in protocol running failures. Therefore, you are advised not to modify the timers.

Configuration Steps

✎ Modifying the Update Timer, Invalid Timer, and Flush Timer

- Mandatory.
- Unless otherwise required, perform this configuration on a router where RIPng timers need to be modified.

Verification

- Run the **show ipv6 rip** command to display settings of timers.

Related Commands

Command	timers update invalid flush
Parameter Description	<i>Update</i>: Indicates the route update time in second. It defines the interval at which the device sends the route update packet. Each time an update packet is received, the invalid timer and flush timer are reset. By default, a route update packet is sent every 30s. <i>Invalid</i>: Indicates the route invalid time in second, counted from the last time when a valid update packet is received. It defines the time after which the route in the routing list becomes invalid because the route is not updated. The duration of the invalid timer must be at least three times the duration of the update timer. If no

	update packet is received before the invalid timer expires, the corresponding route enters the invalid state. If the update packet is received before the invalid timer expires, the timer is reset. The default duration of the invalid timer is 180s. <i>Flush</i>: Indicates the route flushing time in second, counted from the time when the RIPng route enters the invalid state. When the flush timer expires, the route in the invalid state will be deleted from the routing table. The default duration of the flush timer is 120s.
Command Mode	Routing process configuration mode
Usage Guide	By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Configuration Example

Scenario Figure 8-11	
Configuration Steps	● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On Router A, configure the update timer, invalid timer, and flush timer.
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# timers 10 30 90</pre>
Verification	● On Router B, check the settings of RIPng timers.

B

```

B# show ipv6 rip

Routing Protocol is "RIPng"

  Sending updates every 10 seconds with +/-50%, next due in 12 seconds
  Timeout after 30 seconds, garbage collect after 90 seconds

  Outgoing update filter list for all interface is: not set
  Incoming update filter list for all interface is: not set

  Default redistribution metric is 1

  Default distance is 120

  Redistribution:

    Redistributing protocol connected

  Default version control:  send version 1, receive version 1

  Interface                Send    Recv

    GigabitEthernet 0/1    1      1

  Routing Information Sources:

    Gateway: fe80::2d0:f8ff:fe22:334a  Distance: 120

  Last Update: 00:00:02   Bad Packets: 0   Bad Routes: 0

```

Common Errors

- Settings of RIPng timers on devices connected to the same network are inconsistent. Consequently, routes cannot be learned properly.

8.5 Monitoring

Displaying

Description	Command
Displays information about the RIPng process.	show ipv6 rip
Displays the RIPng routing table.	show ipv6 rip database

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs RIPng.	debug ipv6 rip [interface <i>interface-type interface-num</i> nsm restart]

9 Configuring PBR

9.1 Overview

Policy-based routing (PBR) is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured and cannot automatically update with network changes. In addition, PBR is effective only for packets sent from local interfaces and devices. As compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on source and destination addresses, packet length and input interface.

9.2 Applications

Application	Description
Selecting an ISP by Using PBR	Specify preferential output interfaces for packets from different subnets.
Implementing Traffic Classification by Using PBR	Specify QoS values for packets from different subnets.

9.2.1 Selecting an ISP by Using PBR

An existing user network often uses resources of multiple internet server providers (ISPs). PBR needs to be used since different bandwidths may be requested from different ISPs or the network resources for key users need to be protected. By controlling forwarding of certain data packets, you can make full use ISP resources as well as meet the requirements of flexible and diversified applications.

Scenario

Figure 9-1

A LAN has two output interfaces for connecting the Internet. PBR is configured on the layer-3 device DEV1 to enable the two output interfaces to implement load sharing and mutual backup.

The specific requirements are as follows:

- Data streams from subnet 1 are sent from GE 0/1.
- Data streams from subnet 2 are sent from GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Deployment

- Configure two different ACLs on the layer-3 device DEV1:
ACL1: source addresses belong to subnet 1.
ACL2: source addresses belong to subnet 2.
- Configure two policies in the route map on the layer-3 device DEV1:
Policy 1: sets the next hops for packets matching ACL1 to GE0/1 and GE0/2 (Based on the configuration sequence, GE0/1 takes effect first and GE0/2 works in the backup mode).
Policy 2: sets the next hops for packets matching ACL2 to GE0/2 and GE0/1 (Based on the configuration sequence, GE0/2 takes effect first and GE0/1 works in the backup mode).
- Configure PBR on GE0/3 (by using a route map). Then, packets received on this interface are forwarded based on the policies.

9.2.2 Implementing Traffic Classification by Using PBR

Scenario

Networks of medium- and small-sized enterprises have simple structures. Different branch nodes are interconnected to the central nodes through carrier dedicated lines or the Internet VPN mode. Enterprise networks often need to implement

three-in-one integration (of audio, video and data) to maximize the utilization of existing IP networks and save costs. Since all traffic is output from a single output interface, it is necessary to adjust the QoS policies for the output interface, in order to provide preferential communication quality for bandwidth- and delay-sensitive applications.

Figure 9-2

A LAN has an output interface for connecting the Internet. PBR is configured on the layer-3 device DEV1 to change the QoS values for packets from different networks.

The specific requirements are as follows:

- For data streams from subnet 1, representing audio streams, set the DSCP value to 56.
- For data streams from subnet 2, representing video streams, set the DSCP value to 40.
- For data streams from subnet 3, representing data streams, set the DSCP value to 24.

Deployment

- Configure three different ACLs on the layer-3 device DEV1:
 - ACL1: source addresses belong to subnet 1.
 - ACL2: source addresses belong to subnet 2.
 - ACL3: source addresses belong to subnet 3.
- Configure three policies in the route map on the layer-3 device DEV1:
 - Policy 1: sets the DSCP value for packets matching ACL1 to 56.
 - Policy 2: sets the DSCP value for packets matching ACL2 to 40.
 - Policy 3: sets the DSCP value for packets matching ACL3 to 24.
- Configure PBR on GE0/3 (by using a route map). Then, the DSCP values for packets received on this interface are changed based on the policies.

9.3 Features

Feature	Description
Configuring a Policy	Before configuring PBR, configure policies in a route map.
Configuring PBR	Apply a route map including policies to interfaces and devices to implement PBR.

9.3.1 Configuring a Policy

A policy is a "match ..., set..." statement, which indicates that "if certain conditions are matched, perform certain processing actions".

 For detailed introduction to the policies, see the section "Route Map".

Executing Policies

In the global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a policy in a route map.

A route map may contain multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be executed and the route map exits. If no matching condition of any policy is met, no processing action will be performed.

Policies have two working modes:

- **permit**: When the matching condition of a policy is met, perform the processing action for this policy and exit the route map.
- **deny**: When the matching condition of a policy is met, do not perform the processing action for this policy and exit the route map.

Matching conditions of policies

The matching conditions of a policy may contain 0, 1 or more matching rules.

- If 0 matching rule is contained, no packet will be matched.
- If one or more match rules are contained, all match rules must be matched at the same time to meet the matching conditions of the policy.

In the route map mode, run the **match** command to configure match rules. One **match** command is mapped to one match rule.

PBR supports the following **match** commands:

	Command	Description
	match ip address	The source IPv4 address (and the destination IPv4 address) is used as the matching condition.  Multiple match ip address commands can be configured in a policy.

IPv6 PBR	match ipv6 address	The source IPv6 address (and the destination IPv6 address) is used as the matching condition.  Only one match ipv6 policy command can be configured in a policy.

-  IPv4 PBR defines the source IP address (and destination IP address) ranges of packets by using the IP standard or extended ACLs. IPv6 PBR defines the source IPv6 address (and destination IPv6 address) ranges of packets by using the IPv6 extended ACLs.
-  Packet forwarding based on policies of IPv4 PBR interfaces supports expert-level and MAC name ACLs. Packet forwarding based on local policies does not support expert-level and MAC name ACLs.
-  When PBR uses an ACL that is unavailable, the route sub-map will not be matched and the next route sub-map will be matched instead. If no route sub-map is matched, a common route will be selected for forwarding. If only ACLs are configured but no ACE is configured, the PBR forwarding behavior is the same as that in a scenario where an ACL is unavailable
-  On a switch, if a route sub-map uses multiple ACLs in PBR, only the first ACL is matched.

Processing action for a policy

The processing action of a policy may contain 0, 1 or more set rules.

- If 0 set rule is contained, no processing action will be performed and the route map will directly exit.
- If one or more set rules are contained, all processing actions will be performed and the route map will exit.

 If set rules have different priorities, the set rule with the highest priority will take effect.

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

PBR supports the following **set** commands:

	Command	Description
IPv4 PBR	set ip tos	Modifies the tos field of an IPv4 packet.
		 Command set ip and dscp cannot work with each other.
	set ip precedence	Modifies the precedence field of an IPv4 packet.
		 Command set ip and dscp cannot work with each other.
	set ip dscp	Modifies the dscp field of an IPv4 packet.
		 Command set ip tos and precedence cannot work with each other.

	Command	Description
	set ip next-hop	Configures the next hop of IPv4 packet forwarding. The next hop must be directly connected; otherwise, this command is invalid. A packet matching the match rules will be forwarded to the next hop specified by set ip next-hop first, no matter whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR.  On a switch, the output interfaces for next hops supported by PBR include the SVI, routing and layer-3 AP interfaces.
	set ip next-hop recursive	Configures the recursive next hop of IPv4 packet forwarding. The next hop can be directly connected or not directly connected. A non-directly-connected next hop will recur to a static or dynamic route in the routing table. This command supports recursion to multiple ECMP next hops of a static or dynamic route. A maximum of 32 next hops are supported. If a recursive route is a static route, only one next hop is supported for the static recursive route. The redundant backup or load balancing mode of multiple recursive next hops is also determined by the ip policy { redundance load-balance } command. A packet matching the match rules will be forwarded to the recursive next hop specified by set ip next-hop recursive first, no matter whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR.  Only when a static or dynamic route has an output interface and a next-hop IP address, the policy-based recursive next hop can take effect.
	set ip default next-hop	Configures the default next hop of IPv4 packet forwarding. A packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table.
IPv6 PBR	set ipv6 precedence	Modifies the precedence field of an IPv6 packet.  IPv6 PBR does not support set ipv6 tos or set ipv6 dscp.
	set ipv6 next-hop	Configures the next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the next hop specified by set ipv6 next-hop first, no matter whether the route selected for the IPv6 packet in the routing table is consistent with the next hop specified by PBR. The next hop must be directly connected; otherwise, this command is invalid.

	Command	Description
	set ipv6 next-hop recursive	Configures the recursive next hop for IPv6 packet forwarding. The next hop can be directly or indirectly connected. An indirectly connected next hop will be recursed to a static or dynamic route in the routing table. This command supports recursion to multiple ECMP next hops of a static or dynamic route, and a maximum of 32 next hops are supported. The redundancy or load balancing mode of multiple recursive next hops is determined by the ipv6 policy { redundancy load-balance } command. A packet matching the match rules will be first forwarded to the next hop specified by the set ipv6 next-hop recursive command, regardless of whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR. The recursive next hop takes effect only upon recursion to a static or dynamic route that has an egress and next-hop IPv6 address.
	set ipv6 default next-hop	Configures the default next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table. The next hop must be directly connected; otherwise, this command is invalid.

-  The priority sequence is as follows: **set vrf > set ip next-hop > set ip next-hop > set ip next-hop recursive > common route > set ip default next-hop > default route**. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
-  The priority sequence is as follows: **set ipv6 next-hop > set ipv6 next-hop recursive > common route > set ipv6 default next-hop > default route**. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
-  For switches, the **set ipv6 default next-hop** command does not take effect for IPv6 addresses whose mask length exceeds 64.

9.3.2 Configuring PBR

PBR

Apply a route map including policies to interfaces or devices to implement PBR.

- Apply a route map to an interface so that packets received by the interface are routed based on the policy.
The PBR is often used to control user packets received by a device. This command is effective only for forwarded packets, but not for locally initiated packets.
- Apply a route map to a device so that packets locally initiated are routed based on the policy.
The PBR is often used to control protocol packets exchanged between devices (such as ping packets sent locally). This command is effective only for locally initiated packets, but not for forwarded packets.

-  By default, PBR is not unavailable on a device and packets are forwarded based on a routing table.

i On a switch, the interfaces which support PBR are L3 Ethernet interface, SVI interface and L3 AP interface.

Redundant backup or load balancing

You can set multiple next hops in a policy. Either redundant backup or load balancing can be implemented among multiple next hops. Redundant backup is implemented by default.

i Redundant backup or load balancing is only effective for next hops configured in the **set ip next-hop**, **set ip next-hop recursive**, **set ip default next-hop**, **set ipv6 next-hop**, **set ipv6 next-hop recursive** and **set ipv6 default next-hop** commands, and only effective among multiple next hops in the same set rule.

- **Redundant backup**

Based on the configuration sequence, the first accessible next hop takes effect. When the currently effective next hop (R1) is faulty, the traffic automatically switches to the next accessible next hop (R2). When R1 becomes accessible again, the traffic automatically switches back to R1.

A newly added next hop is arranged at the last of the sequence. Assume that the original sequence of multiple next hops is R1 > R2 > R3. After R1 is deleted and added again, the sequence changes to R2 > R3 > R1.

If no next hop is accessible, packets will be discarded.

Correlation with BFD

Correlation between PBR and BFD is effective only for next hops configured by the **set ip next-hop** or **set ipv6 next-hop** command.

The **set ip next-hop** and **set ipv6 next-hop** commands carry the **verify-availability** and **bfd [vrf vrf-name] interface-type interface-number gateway** parameters, which can establish correlation between PBR and a BFD session and monitor the accessibility of next hops.

Correlation between PBR and BFD helps enhance the PBR's perception about network environment changes. When BFD detects that the current next hop is not accessible, the BFD will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i For the configuration and related commands for correlation between PBR and BFD, see the "BFD" section.

Correlation with Track

Correlation between PBR and Track is effective only for next hops configured by the **set ip next-hop** command.

The **set ip next-hop** command carries the **verify-availability** and **track track-obj-number** parameters, which can establish correlation between PBR and a Track session and monitor the accessibility of next hops.

Correlation between PBR and Track helps enhance the PBR's perception about network environment changes. When Track detects that the current next hop is not accessible, the Track will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i Only IPv4 PBR supports correlation with Track.

i For the configuration and related commands for correlation between PBR and Track, see the "RNS" section.

Source-addressed-based PBR

Run the global configuration commands **ip policy-source in-interface** and **ipv6 policy-source in-interface** to directly generate source-address-based PBR. You do not need to configure a route map.

- If only source IPv4 or Ipv6 addresses need to be matched for packets forwarded by an interface, you can apply the command for source-address-based PBR. The procedure for configuring this command is simpler than that for interface-based PBR.
- If source-address-based PBR is applied to a specified interface, packets received on this interface will be routed based on policies according to the source addresses.
The PBR is often used to control user packets received by a device. This command is effective only for forwarded packets, but not for locally initiated packets.

 Source-address-based PBR has a higher priority than interface-based PBR. If source-address-based PBR and interface-based PBR are applied to the same interface, only interface-based PBR takes effect.

 By default, source-address-based routing is not available on devices and packets are forwarded based on the routing table.

9.4 Limitations

- If PBR refers ACL which does not exist, the route submap is not matched but match the next route submap. When all route submaps do not match, it is forwarded through common route. It is the same if only ACL is configured but the ACE is not.
- On a switch, if a route submap of PBR refers to multiple ACLs, it matches only the first ACL and does not match the subsequent ACL.

9.5 Configuration

Configuration	Description and Command	
Configuring Basic Functions of PBR	 (Mandatory) It is used to apply PBR to forward packets.	
	ip policy route-map	Applies PBR for IPv4 packets received by an interface.
	ipv6 policy route-map	Applies PBR for IPv6 packets received by an interface.
	ip local policy route-map	Applies PBR for IPv4 packets locally initiated.
	ipv6 local policy route-map	Applies PBR for IPv6 packets locally initiated.
Setting Redundant Backup or Load Balancing	 (Optional) It is used to set whether PBR implements redundant backup or load balancing among multiple next hops.	

Configuration	Description and Command	
	ip policy { redundance load-balance }	Sets whether IPv4 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
	ipv6 policy { redundance load-balance }	Sets whether IPv6 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
Configuring Source-Address-Based PBR	 (Optional) It is used to apply source-address-based PBR to forward packets.	
	ip policy-source in-interface	Applies source-address-based PBR for IPv4 packets received by an interface.
	ipv6 policy-source in-interface	Applies source-address-based PBR for IPv6 packets received by an interface.

9.5.1 Configuring Basic Functions of PBR

Configuration Effect

Perform personalized routing management for user data streams by preparing flexible policies.

Perform personalized management for protocol interaction and network topologies by preparing flexible policies.

Notes

- A route map must be used when PBR is configured; therefore, you must configure a route map on a device.
- If an ACL is used when the route map is configured, you must configure the ACL on the device.

Configuration Steps

📌 Applying PBR for IPv4 packets received by an interface

- To perform personalized routing management for IPv4 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.
- Run the **ip policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv4 packets received on this interface.

Command	ip policy route-map <i>route-map-name</i>
Parameter	<i>route-map-name</i> : Indicates the name of a route map.
Description	
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command	Interface configuration mode

Mode	
Usage Guide	Only one ip policy route-map command can be configured for an interface. If multiple ip policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect. It will not take effect, if the PBR is configured on DAILER, loopback or tunnel interface.

📌 Applying PBR for IPv6 packets received by an interface

- To perform personalized routing management for IPv6 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.
- Run the **ipv6 policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv6 packets received on this interface.

Command	ipv6 policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one ipv6 policy route-map command can be configured for an interface. If multiple ipv6 policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect. It will not take effect, if the PBR is configured on DAILER, loopback or tunnel interface.

📌 Applying PBR for IPv4 packets locally initiated

- To perform personalized management for IPv4 protocol interaction and IPv4 network topologies, you should perform this configuration.
- Run the **ip local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv4 packets locally initiated.

Command	ip local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ip local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

📌 Applying PBR for IPv6 packets locally initiated

- To perform personalized management for IPv6 protocol interaction and IPv6 network topologies, you should perform this configuration.
- Run the **ipv6 local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv6 packets locally initiated.

Command	ipv6 local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ipv6 local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

Verification

- Check the configurations of PBR.
- Check the configurations of the route map used by PBR.
- If an ACL is used when the route map is configured, you should check the configurations of the ACL.

📌 Checking the configurations of IPv4 PBR

Command	show ip policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Check the interfaces configured with IPv4 PBR according to the output information and the name of the used route map. <pre>Ruijie# show ip policy Banlance mode: redundance Interface Route map local RM_for_PBR_1 GigabitEthernet 0/1 RM_for_PBR_2</pre> Local indicates applying policy-based routing for IPv4 packets locally initiated.

📌 Checking the configurations of IPv6 PBR

Command	show ipv6 policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command	Privilege, global and interface configuration modes

Mode							
Usage Guide	Check the interfaces configured with IPv6 PBR according to the output information and the name of the used route map. <pre>Ruijie#show ipv6 policy</pre> <pre>Banlance mode: redundance</pre> <table> <tr> <td>Interface</td><td>Route map</td></tr> <tr> <td>local</td><td>RM_for_PBR_1</td></tr> <tr> <td>VLAN 1</td><td>RM_for_PBR_2</td></tr> </table> Local indicates applying policy-based routing for IPv6 packets locally initiated.	Interface	Route map	local	RM_for_PBR_1	VLAN 1	RM_for_PBR_2
Interface	Route map						
local	RM_for_PBR_1						
VLAN 1	RM_for_PBR_2						

📌 Checking the configurations of a route map

Command	show route-map [route-map-name]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Multiple route maps may be available on a device. Focus on the route map used in PBR and check its policy settings. <pre>Ruijie# show route-map</pre> <pre>route-map RM_FOR_PBR, permit, sequence 10</pre> <pre> Match clauses:</pre> <pre> ip address acl1</pre> <pre> Set clauses:</pre> <pre>ip next-hop 200.24.18.1</pre> <pre>route-map RM_FOR_PBR, permit, sequence 20</pre> <pre> Match clauses:</pre> <pre> ip address acl2</pre> <pre> Set clauses:</pre> <pre>ip next-hop 200.24.19.1</pre>

📌 Checking the configurations of an ACL

Command	show access-lists [acl-id acl-name]
Parameter Description	<i>acl-id</i>: Indicates the ACL ID. <i>acl-name</i>: Indicates the ACL name.
Command	Privilege, global and interface configuration modes

Mode	
Usage Guide	Multiple ACLs may be available on a device. Focus on the ACL used by a route map and check its configurations. <pre> Ruijie# show access-lists 1 ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255 </pre>

📌 Checking the routing information of IPv4 PBR

Command	show ip pbr route [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a local interface or device and check the routing information of IPv4 PBR. <pre> Ruijie# show ip pbr route PBR IPv4 Route Summay : 1 Interface : GigabitEthernet 0/1 Sequence : 10 Min Length : None Max Length : None VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Tos_Dscp : None Precedence : None Tos_Dscp : 0 Precedence : 0 Mode : redundance Nexthop Count : 1 </pre>

	Nexthop[0] : 192.168.8.100 Weight[0] : 1 Ifindex[0] : 2

📌 Checking the routing information of IPv6 PBR

Command	show ipv6 pbr route [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a local interface or device and check the routing information of IPv6 PBR. <pre> Ruijie# show ipv6 pbr route PBR IPv6 Route Summary : 1 Interface : GigabitEthernet 0/1 Sequence : 10 ACL[0] : 2900 ACL_CLS[0] : 5 Min Length : None Max Length : None VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Tos_Dscp : None Precedence : None Tos_Dscp : 0 Precedence : 0 Mode : redundance Nexthop Count : 1 Nexthop[0] : 10::2 Weight[0] : 1 Ifindex[0] : 2 </pre>

📌 Checking a route map used by IPv4 PBR

Command	show ip pbr route-map <i>rmap-name</i>
Parameter Description	<i>rmap-name</i> : Indicates the route map name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a route map and check the route map used by IPv4 PBR. <pre> Ruijie# show ip pbr route-map rm PBR VRF: GLOBAL, ID: 0 Forward Mode: redundance Forwarding: On Route-map rm Route-map index: Sequence 10, permit Match rule: ACL ID : 2900, CLS: 1, Name: acl1 Set rule: IPv4 nexthop: 192.168.8.100, (VRF name: , ID: 0), Weight: 0 PBR state info ifx: 2, Connected: True, Track state: Up </pre>

📌 Checking a route map used by IPv6 PBR

Command	show ipv6 pbr route-map <i>rmap-name</i>
Parameter Description	<i>rmap-name</i> : Indicates the route map name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a route map and check the route map used by IPv6 PBR. <pre> Ruijie# show ipv6 pbr route-map rm6 PBR VRF: GLOBAL, ID: 0 Forward Mode: redundance Forwarding: On Route-map rm6 Route-map index: Sequence 10, permit </pre>

	<pre>Match rule: ACL ID : 2901, CLS: 5, Name: ac16 Set rule: IPv6 nexthop: 10::2, (VRF name: , ID: 0), Weight: 0 PBR state info ifx: 2, Connected: True, Track state: Up</pre>

📌 Checking the statistics about packets forwarded by IPv4 PBR

Command	show ip pbr statistics [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<pre>Ruijie# show ip pbr statistics IPv4 Policy-based route statistic gigabitEthernet 0/1 statistics : 10</pre>

📌 Checking the statistics about packets forwarded by IPv6 PBR

Command	show ipv6 pbr statistics [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<pre>Ruijie# show ipv6 pbr statistics IPv6 Policy-based route statistic gigabitEthernet 0/1 statistics : 20</pre>

Configuration Example

Configuring IPv4 PBR and selecting an output link based on source addresses of packets

Scenario Figure 9-3	
	The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24. DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.
	This LAN has two output interfaces for connecting the Internet. The requirements are as follows: ● Data streams from subnet 1 for accessing the Internet should pass GE 0/1. ● Data streams from subnet 2 for accessing the Internet should pass GE 0/2. ● If the GE 0/1 link is disconnected, the data streams on the GE 0/1 interface are switched to the GE 0/2 interface. Vice versa.
Configuration Steps	● Configure two ACLs to match packets from subnets 1 and 2 respectively. ● Set a policy to set the next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.) ● Set a policy to set the next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.) ● Apply the policy to GE 0/3. ● Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.)  During redundant backup, based on the configuration sequence, the first next hop takes effect first.
	<pre>DEV1(config)# access-list 1 permit 200.24.16.0 0.0.0.255 DEV1(config)# access-list 2 permit 200.24.17.0 0.0.0.255</pre>

	<pre> DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 2 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundancy </pre>
Verification	● Check the configurations of IPv4 PBR. ● Check the configurations of the route map. ● Check the configurations of an ACL.
	<pre> DEV1# show ip policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR </pre>
	<pre> DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop 200.24.18.1 200.24.19.1 route-map RM_FOR_PBR, permit, sequence 20 Match clauses: ip address 2 Set clauses: </pre>

	<pre>ip next-hop 200.24.19.1 200.24.18.1</pre>
	<pre>DEV1# show access-lists ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255</pre>

Configuring IPv6 PBR and selecting an output link based on source addresses of packets

Scenario Figure 9-4	
	DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64 whereas the network segment where subnet 2 resides is 2004::/64. DEV1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 2001::1/64 and 2002::1/64.
	This LAN has two output interfaces for connecting the Internet. The requirements are as follows: • Data streams from subnet 1 for accessing the Internet should pass GE 0/1. • Data streams from subnet 2 for accessing the Internet should pass GE 0/2. • If the GE 0/1 link is disconnected, the data streams on the GE 0/1 interface are switched to the GE 0/2 interface. Vice versa.
Configuration Steps	• Configure two ACLs to match packets from subnets 1 and 2 respectively. • Set a policy to set the next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.) • Set a policy to set the next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.) • Apply the policy to GE 0/3.

	Set PBR to implement redundant backup among multiple next hops.  During redundant backup, based on the configuration sequence, the first next hop takes effect first.
	<pre> DEV1(config)# ipv6 access-list net1 DEV1(config-ipv6-acl)# permit ipv6 2003::/64 any DEV1(config-ipv6-acl)# exit DEV1(config)# ipv6 access-list net2 DEV1(config-ipv6-acl)# permit ipv6 2004::/64 any DEV1(config-ipv6-acl)# exit DEV1(config)# route-map RM_FOR_PBR 30 DEV1(config-route-map)# match ipv6 address net1 DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 40 DEV1(config-route-map)# match ipv6 address net2 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ipv6 policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ipv6 policy redundance </pre>
Verification	- Check the configurations of IPv6 PBR. - Check the configurations of the route map. - Check the configurations of an ACL.
	<pre> DEV1# show ipv6 policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR </pre>
	<pre> DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 11 </pre>

	<pre>Match clauses: ipv6 address net1 Set clauses: ipv6 next-hop 2001::1 2002::1 route-map RM_FOR_PBR, permit, sequence 21 Match clauses: ipv6 address net2 Set clauses: ipv6 next-hop 2002::1 2001::1</pre>
	<pre>DEV1# show access-lists ipv6 access-list net1 10 permit ipv6 2003::/64 any (0 packets matched) ipv6 access-list net2 10 permit ipv6 2004::/64 any (0 packets matched)</pre>

📌 **Configuring correlation between IPv4 PBR and Track**

Scenario Figure 9-5	
	The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24. DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and

	200.24.19.1.
	● DEV1 can fast detect a faulty output link and switch to a backup link.
Configuration Steps	When configuring IPv4 PBR and selecting an output link based on source addresses of the packets, add or modify the following configurations (red fields): ● Set two Track objects and track the accessibility of the next hops of the two output interfaces. ● When configuring a policy, set the correlation between the next hops and the Track objects.
DEV1	<pre> DEV1(config)# ip access-list extended 101 DEV1(config-ip-acl)# permit ip 200.24.16.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)# ip access-list extended 102 DEV1(config-ip-acl)# permit ip 200.24.17.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)#ip rns 1 DEV1(config-ip-rns)#icmp-echo 200.24.18.1 DEV1(config)#ip rns schedule 1 start-time now life forever DEV1(config)#track 1 rns 1 DEV1(config)#ip rns 2 DEV1(config-ip-rns)#icmp-echo 200.24.19.1 DEV1(config)#ip rns schedule 2 start-time now life forever DEV1(config)#track 2 rns 2 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 101 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1 track 2 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 102 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1 track 2 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR </pre>

	<pre>DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundancy</pre>
Verification	● Check whether the Track objects are up.
DEV1	<pre>Ruijie#show track Track 1 Reliable Network Service 1 The state is Up 1 change, current state last: 120 secs Delay up 30 secs, down 50 secs Track 2 Reliable Network Service 2 The state is Up 1 change, current state last: 130 secs Delay up 30 secs, down 50 secs</pre>

Configuring IPv4 recursive PBR, selecting an output link based on source addresses of the packets, and recurring to the output link of a dynamic route

Scenario Figure 9-6	
	The layer-3 device DEV 1 is connected to subnet 1 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24. DEV 1 is connected to subnet 2 through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.
	Subnet 1 is connected to subnet 2 through two output interfaces of DEV1. The requirements are as follows: ● Configure static or dynamic routes in advance to ensure that static or dynamic routes in the network segment 200.24.20.0 are available in the routing table of DEV1.

	● Data streams from subnet 1 for accessing the Internet can recur to a dynamic route whose IP address is 200.24.20.1. ● If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.
Configuration Steps	● Configure an ACL to match packets from subnet 1. ● Set a policy to set the recursive next hop for packets from subnet 1 to 200.24.20.1. ● Apply the policy to GE 0/3. ● Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.)  During redundant backup, the sequence for the next hops to take effect is related to the sequence for the static or dynamic routes to take effect.
	<pre> DEV1(config)# access-list 1 permit 200.24.16.0 0.0.0.255 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 1 DEV1(config-route-map)# set ip next-hop recursive 200.24.20.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundancy </pre>
Verification	● Check the configurations of IPv4 PBR. ● Check the configurations of the route map. ● Check the configurations of the ACLs.
	<pre> DEV1# show ip policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR </pre>
	<pre> DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop recursive 200.24.20.1 </pre>

```
DEV1# show access-lists

ip access-list standard 1

10 permit 200.24.16.0 0.0.0.255
```

Common Errors

- A route map is used when PBR is configured but the route map does not exist.
- An ACL is used when a route map is configured but the ACL does not exist.

9.5.2 Setting Redundant Backup or Load Balancing

Configuration Effect

- Using multiple next hops in the mutual backup mode can enhance the network reliability.
- Implementing load balancing among multiple next hops can expand the network bandwidth.

Notes

- The basic functions of PBR must be configured.
- Redundant backup and load balancing are effective only for the next hops set by the following **set** commands.

Command	Description
set ip next-hop	Configures the next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ip default next-hop	Configures the default next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 next-hop	Configures the next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 default next-hop	Configures the default next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ip next-hop recursive	Configures the recursive next hop of IPv4 packets. Only one command can be configured for a route map and packets can recur to multiple next hops (up to 32 next hops) of a static or dynamic ECMP route. The redundant backup or load balancing mode for recurring to multiple next hops is also determined by the ip policy { redundancy load-balance } command.
set ip next-hop recursive	Configures the recursive next hop of IPv4 packets. Only one command can be configured for a route map and packets can recur to multiple next hops (up to 32 next hops) of a static or dynamic ECMP route. The redundant backup or load balancing mode for recurring to multiple next hops is also determined by the ip policy { redundancy load-balance } command.

 Up to eight next hops can be set for WCMP whereas up to 32 next hops can be set for ECMP.

Configuration Steps

- 1  Setting whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ip policy { redundance load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

📌 Setting whether Ipv6 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ipv6 policy { redundance load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

Verification

- Check whether redundant backup or load balancing is implemented among multiple next hops.

📌 Checking whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

Command	show ip policy [route-map-name]
Parameter Description	route-map-name: Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre>ruijie# show ip policy Banlance mode: redundance Interface Route map</pre>

	local	test
	GigabitEthernet 0/3	test

📌 Checking whether IPv6 PBR implements redundant backup or load balancing among multiple next hops

Command	show ipv6 policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre> PE#show ipv6 policy Banlance mode: redundance Interface Route map VLAN 1 RM_for_Vlan_1 VLAN 2 RM_for_Vlan_2 </pre>

Configuration Example

📌 Configuring IPv4 PBR to implement redundant backup among multiple next hops

See the preceding example: [Configuring IPv4 PBR and selecting an output link based on source addresses of packets](#)

📌 Configuring IPv6 PBR to implement redundant backup among multiple next hops

See the preceding example: [Configuring IPv6 PBR and selecting an output link based on source addresses of packets](#)

📌 Configuring IPv4 PBR to implement load balancing among multiple next hops

Scenario Figure 9-7	
	The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24. DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.
	This LAN has two output interfaces for connecting the Internet. The requirements are as follows: The traffic is equally shared by GE0/1 and GE0/2.
Configuration Steps	● Configure basic functions of PBR. Specify multiple next hops. ● Set the load balancing mode.
	<pre> DEV1(config)# route-map RM_LOAD_PBR 10 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_LOAD_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy load-balance </pre>
Verification	● Check the configurations of IPv4 PBR. ● Check the configurations of the route map.
	<pre> DEV1# show ip policy Balance mode: load-balance </pre>

	Interface	Route map
	GigabitEthernet 0/3	RM_LOAD_PBR
<pre> DEV1# show route-map route-map PBR-VRF-Selection, permit, sequence 10 Match clauses: Set clauses: ip next-hop 200.24.18.1 8 ip next-hop 200.24.19.1 8 </pre>		

Configuring IPv6 PBR to implement load balancing among multiple next hops

Scenario
Figure 9-8

DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64 whereas the network segment where subnet 2 resides is 2004::/64.

DEV1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 2001::1/64 and 2002::1/64.

This LAN has two output interfaces for connecting the Internet. The requirements are as follows: The traffic is equally shared by GE0/1 and GE0/2.

- Configuration Steps**
- Configure basic functions of PBR. Specify multiple next hops.
 - Set the load balancing mode.

```

DEV1(config)# route-map RM_LOAD_PBR 20

DEV1(config-route-map)# set ipv6 next-hop 2001::1

DEV1(config-route-map)# set ipv6 next-hop 2002::1

DEV1(config-route-map)# exit

```

	<pre> DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ipv6 policy route-map RM_LOAD_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ipv6 policy load-balance </pre>
Verification	● Check the configurations of IPv6 PBR. ● Check the configurations of the route map.
	<pre> DEV1# show ipv6 policy Balance mode: load-balance Interface Route map GigabitEthernet 0/3 RM_LOAD_PBR DEV1# show route-map route-map PBR-VRF-Selection, permit, sequence 10 Match clauses: Set clauses: ipv6 next-hop 2001::1 ipv6 next-hop 2002::1 </pre>

9.5.3 Configuring Source-Address-Based PBR

Configuration Effect

Perform personalized routing management for IPv4 or IPv6 addresses of user data streams by preparing flexible policies.

Notes

- Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.

Configuration Steps

📌 Applying source-address-based PBR for IPv4 packets received by an interface

- To perform personalized routing management based on source IPv4 addresses for IPv4 user data streams passing a device, you should perform this configuration.
- The global configuration takes effect on the input interface of specified user data streams.
- Run the **ip policy-source in-interface** command to perform source-address-based PBR for IPv4 packets received by a specified interface.

Command	ip policy-source in-interface <i>interface-type</i> <i>sequence</i> { <i>source-address mask</i> <i>source-address/mask</i> } { [default] next-hop <i>ip-address</i> [<i>weight</i>] [default] interface <i>out-interface-type</i> vrf <i>vrf-name</i> }
Parameter Description	<i>interface-type</i> : Specifies the type of an interface to which source-address PBR is applied. <i>sequence</i> : Indicates the sequence number of a policy. A smaller sequence number means a higher priority. <i>source-address</i> : Indicates the source IPv4 address. <i>mask</i> : Indicates the mask of the source IPv4 address. <i>ip-address</i> : Indicates the next-hop IPv4 address. <i>weight</i> : Indicates the weight of a next hop. <i>out-interface-type</i> : Indicates the type of the next hop output interface. <i>vrf-name</i> : Indicates the name of a VRF instance.
Defaults	By default, source-address-based PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Configure multiple ip policy-source in-interface commands for the same interface. The sequence numbers of different source addresses are different. A smaller sequence number means a higher priority of the source-address-based PBR. When the sequence number is the same, the priorities of next hops are as follows: vrf <i>vrf-name</i> > next-hop <i>ip-address</i> > interface <i>out-interface-type</i> > default next-hop <i>ip-address</i> > default interface <i>out-interface-type</i> . Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.

📌 Applying source-address-based PBR for IPv6 packets received by an interface

- To perform personalized routing management based on source IPv6 addresses for IPv6 user data streams passing a device, you should perform this configuration.
- The global configuration takes effect on the input interface of specified user data streams.
- Run the **ipv6 policy-source in-interface** command to perform source-address-based PBR for IPv6 packets received by a specified interface.

Command	ipv6 policy-source in-interface <i>interface-type</i> <i>sequence</i> { <i>source-address/prefix-length</i> } { [default] next-hop <i>ipv6-address</i> [<i>weight</i>] [default] interface <i>out-interface-type</i> vrf <i>vrf-name</i> }
Parameter Description	<i>interface-type</i> : Specifies the type of an interface to which source-address PBR is applied. <i>sequence</i> : Indicates the sequence number of a policy. A smaller sequence number means a higher priority. <i>source-address</i> : Indicates the source IPv6 address. <i>prefix-length</i> : Indicates the prefix length of a source IPv6 address. <i>ipv6-address</i> : Indicates the next-hop IPv6 address. <i>weight</i> : Indicates the weight of a next hop. <i>out-interface-type</i> : Indicates the type of the next hop output interface. <i>vrf-name</i> : Indicates the name of a VRF instance.

Defaults	By default, source-address-based PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Configure multiple ipv6 policy-source in-interface commands for the same interface. The sequence numbers of different source addresses are different. A smaller sequence number means a higher priority of the source-address-based PBR. When the sequence number is the same, the priorities of next hops are as follows: vrf vrf-name > next-hop ipv6-address > interface out-interface-type > default next-hop ipv6-address > default interface out-interface-type. Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.

Verification

📄 Checking the routing information of source-address-based IPv4 PBR

Command	show ip pbr source-route [interface <i>if-name</i>]
Parameter Description	<i>if-name</i> : Indicates an interface name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify an interface and check the routing information of IPv4 source-address-based PBR. <pre> Ruijie# show ip pbr source-route PBR IPv4 Source Route Interface : GigabitEthernet 0/1 Sequence : 10 Source address : 10.1.1.1/24 VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Match_ipaddr : Exist Mode : redundance Nexthop Count : 1 Nexthop[0] : 192.168.8.100 </pre>

```

Weight[0]      : 1
Ifindex[0]     : 2

```

📌 Checking the routing information of IPv6 PBR

Command	show ipv6 pbr source-route [interface <i>if-name</i>]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify an interface and check the routing information of IPv6 PBR. <pre> Ruijie# show ipv6 pbr source-route PBR IPv6 Source Route Interface : GigabitEthernet 0/1 Sequence : 10 Source address : 1000::1/64 VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Match_ipaddr : Exist Mode : redundance Nexthop Count : 1 Nexthop[0] : 1001::2 Weight[0] : 1 Ifindex[0] : 3 </pre>

Configuration Example

📌 Configuring IPv4 source-address-based PBR and selecting an output link based on source addresses of packets

Scenario
Figure 9-9

The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24.

DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.

This LAN has two output interfaces for connecting the Internet. The requirements are as follows:

- Data streams from subnet 1 for accessing the Internet should pass GE 0/1.
- Data streams from subnet 2 for accessing the Internet should pass GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Configuration Steps

- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.)
- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.)
- Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.)

i During redundant backup, based on the configuration sequence, the first next hop takes effect first.

```

DEV1(config)# ip policy-source in-interface gigabitEthernet 0/3 1 200.24.16.0/24 next-hop
200.24.18.1 200.24.19.1

DEV1(config)# ip policy-source in-interface gigabitEthernet 0/3 2 200.24.17.0/24 next-hop
200.24.19.1 200.24.18.1

DEV1(config)# ip policy redundancy
  
```

Verification

- Check the routing information of source-address-based IPv4 PBR.

```
DEV1# show ip pbr source-route
```

```
PBR IPv4 Source Route

Configuring IPv6 source-address-based PBR and selecting an output link based on source addresses of packets

Scenario Figure 9-10

DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64 whereas the network segment where subnet 2 resides is 2004::/64.

DEV1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 2001::1/64 and 2002::1/64.

This LAN has two output interfaces for connecting the Internet. The requirements are as follows:

- Data streams from subnet 1 for accessing the Internet should pass GE 0/1.
- Data streams from subnet 2 for accessing the Internet should pass GE 0/2.
- If the GE 0/1 link is faulty, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Configuration Steps

- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.)
- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.)
- Set PBR to implement redundant backup among multiple next hops.

	 During redundant backup, based on the configuration sequence, the first next hop takes effect first.
	<pre> DEV1(config)# ipv6 policy-source in-interface gigabitEthernet 0/3 1 2003::/64 next-hop 2001::1 2002::1 DEV1(config)# ip policy-source in-interface gigabitEthernet 0/3 2 2004::/64 next-hop 2002::1 2001::1 DEV1(config)# ipv6 policy redundancy </pre>
Verification	Check the configuration of IPv6 source-address-based PBR.
	<pre> DEV1# show ipv6 pbr source-route PBR IPv6 Source Route Interface : GigabitEthernet 0/3 Sequence : 1 Source address : 2003::/64 VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Match_ipaddr : Exist Mode : redundancy Nexthop Count : 2 Nexthop[0] : 2001::1 Weight[0] : 1 Ifindex[0] : 1 Nexthop[1] : 2002::1 Weight[1] : 1 Ifindex[1] : 2 Interface : GigabitEthernet 0/3 Sequence : 2 Source address : 2004::/64 VRF ID : 0 </pre>

9.6 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics about packets forwarded by IPv4 PBR.	clear ip pbr statistics [interface <i>if-name</i> local]
Clears the statistics about packets forwarded by IPv6 PBR.	clear ipv6 pbr statistics [interface <i>if-name</i> local]

Displaying

Description	Command
Displays the configurations of IPv4 PBR.	show ip policy
Displays the configurations of IPv6 PBR.	show ipv6 policy
Displays the configurations of a route map.	show route-map [<i>name</i>]
Displays the configurations of an ACL.	show access-list
Displays the correlation between IPv4 PBR and BFD.	show ip pbr bfd
Displays the correlation between IPv6 PBR and BFD.	show ipv6 pbr bfd
Displays the routing information of IPv4 PBR.	show ip pbr route [interface <i>if-name</i> local]

Description	Command
Displays the routing information of IPv6 PBR.	show ipv6 pbr route [interface <i>if-name</i> local]
Displays a route map used by IPv4 PBR.	show ip pbr route-map <i>rmap-name</i>
Displays a route map used by IPv6 PBR.	show ipv6 pbr route-map <i>rmap-name</i>
Displays the routing information of IPv4 source-address-based PBR.	show ip pbr source-route [interface <i>if-name</i>]
Displays the routing information of IPv6 source-address-based PBR.	show ipv6 pbr source-route [interface <i>if-name</i>]
Displays the statistics about IPv4 PBR.	show ip pbr statistics [interface <i>if-name</i> local]
Displays the statistics about IPv6 PBR.	show ipv6 pbr statistics [interface <i>if-name</i> local]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs PBR errors.	debug pbr error
Debugs PBR events.	debug pbr events
Debugs multiple service cards supported by PBR.	debug pbr ms
Debugs PBR message communication.	debug pbr msg
Debugs interaction between PBR and NSM.	debug pbr nsm
Debugs packet forwarding of PBR.	debug pbr packet
Debugs PBR GR.	debug pbr restart

10 Managing Routes

10.1 Overview

The network service module (NSM) manages the routing table, consolidates routes sent by various routing protocols, and selects and sends preferred routes to the routing table. Routes discovered by various routing protocols are stored in the routing table. These routes are generally classified by source into three types:

- Direct route: It is the route discovered by a link-layer protocol and is also called interface route.
- Static route: It is manually configured by the network administrator. A static route is easy to configure and less demanding on the system, and therefore applicable to a small-sized network that is stable and has a simple topology. However, when the network topology changes, the static route must be manually reconfigured and cannot automatically adapt to the topological changes.
- Dynamic route: It is the route discovered by a dynamic routing protocol.

10.2 Applications

Application	Description
Basic Functions of the Static Route	Manually configure a route.
Floating Static Route	Configure a standby route in the multipath scenario.
Load Balancing Static Route	Configure load balancing static routes in the multipath scenario.
Correlation of Static Routes with BFD	Use the Bidirectional Forwarding Detection (BFD) function to test whether the next hop of a static route is reachable.
Fast Reroute of Static Routes	Use the fast reroute function to improve the switching performance in the multipath scenario.
ARP-to-host Conversion	Use the ARP-to-host conversion to not transmit ARP packets sent by hosts across the whole network.
ND-to-route Conversion	Use the ND-to-route conversion to not transmit ND across the whole network
ND-to-route Delayed Release	Specify the time of delayed release to not immediately release the ND-to-route route

10.2.1 Basic Functions of the Static Route

Scenario

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

As shown in Figure 10-1, to implement interworking between PC 1, PC 2, and PC 3, you can configure static routes on R 1, R 2, and R 3.

- On R 1, configure a route to the network segment of PC 2 through R 2, and a route to the network segment of PC 3 through R 3.
- On R 2, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 3 through R 3.
- On R 3, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 2 through R 2.

Figure 10-1

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

10.2.2 Floating Static Route

Scenario

If no dynamic routing protocol is configured, you can configure floating static routes to implement dynamic switching of routes to prevent communication interruption caused by the network connection failures.

As shown in Figure 10-2, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3. Normally, packets are forwarded on a path with a small administrative distance. If a link on this path is down, the route is automatically switched to the path with a large administrative distance.

- On R1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2).
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2).

Figure 10-2

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

10.2.3 Load Balancing Static Route

Scenario

If there are multiple paths to the same destination, you can configure load balancing routes. Unlike floating routes, the administrative distances of load balancing routes are the same. Packets are distributed among these routes based on the balanced forwarding policy.

As shown in Figure 10-3, load balancing routes are configured respectively on R 1 and R 3 so that packets sent to the network segment of PC 3 or PC 1 are balanced between two routes, including a route through R 2 and a route through R 4.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 2 and a route through R 4.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 2 and a route through R 4.

Figure 10-3

Remarks	On the switch, the load is balanced based on the destination IP address by default.

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, R 3, and R 4.
- Configure the load balancing policy on R 1 and R 3.

10.2.4 Correlation of Static Routes with Track, BFD or ARP

Scenario

When the floating static routes or load balancing static routes are configured, the static routes may fail to sense the route failures if the line is faulty but the interface status is normal. To resolve this problem, the device needs to check whether the next hop of a static route is reachable. If the next hop is not reachable, the device can switch the traffic to the standby route.

You can use the Track, BFD or ARP function to check whether the next hop of a static route is reachable. The following scenario takes BFD as an example.

- ⚠ Three modes can all check whether the next hop of a static route is reachable. If more than one mode is configured, when one mode checks the next hop of a static route is unreachable, then the static route is invalid. Therefore, it is recommend to take only one mode.

As shown in Figure 10-4, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3, and correlate static routes with BFD.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.3 is reachable, and on the second route to check whether the next hop 1.1.12.2 is reachable.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.1 is reachable, and on the second route to check whether the next hop 1.1.23.2 is reachable.

Figure 100-4

Deployment

- Configure the address and subnet mask of each interface.
- Configure the BFD parameters on each interface.
- Configure static routes and correlate these static routes with BFD on R 1, R 2, and R 3.

10.2.5 Fast Reroute of Static Routes

Scenario

To accelerate route switching and shorten the communication interruption time when no dynamic routing protocol is configured, you can either correlate static routes with Track, BFD or ARP to check whether the next hop is reachable. In addition, you can or configure fast reroute to further improve the convergence performance.

As shown in Figure 10-5, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure static fast reroute respectively on R 1 and R 3. Normally, packets are forwarded on the path between R 1 and R 3. When the link on this route is down, packets are automatically rerouted to R 2.

- On R 1, configure a route with the exit interface set to Gi0/3 and the next hop set to 1.1.13.3, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.12.2.
- On R 3, configure a route with the exit interface set to Gi0/1 and the next hop set to 1.1.13.1, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.23.2.

Figure 10-5

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.
- Configure static fast reroute on R 1, R 2, and R 3.

10.2.6 ARP-to-host Conversion

Scenario

In special requirement scenarios, communication is required between hosts, but ARP packets sent by hosts are not desired to transmit across the whole network. In this case, you can run the arp-to-host command on the devices connected to hosts to convert ARP entries to host routes, so that the remote devices learn the host routes through BGP redistribution to meet the scenario requirement.

As shown in the following figure, PC1 and PC2 are two hosts in the same network segment. PC1 and PC2 are required to communicate with each other, but ARP packets are not desired to transmit across the whole network. Run the arp-to-host command on R1 and R2 to generate ARP host routes, establish a BGP neighbor relationship between R1 and R2, and enable ARP host route redistribution. In this case, both R1 and R2 can obtain routes to PC1 and PC2 to implement network interconnection.

Figure 10-6

Deployment

- Configure IP addresses and masks for interfaces.
- Enable ARP-to-host conversion on interfaces of R1 and R2.
- Establish a BGP neighbor relationship between R1 and R2, and redistribute ARP host routes.

10.2.7 nd-to-route Conversion

Scenario

In special requirement scenarios, interconnection is required among hosts, but ND packets sent by hosts are not desired to transmit across the whole network. In this case, you can run the `nd-to-route` command on the devices connected to hosts to convert ND entries to routes, so that the remote devices learn the nd-route route through BGP redistribution to meet the scenario requirement.

As shown in the following figure, PC1 and PC2 are two hosts in the same network segment. PC1 and PC2 are required to communicate with each other, but ND packets are not desired to transmit across the whole network. Run the `nd-to-route` command on R1 and R2 to generate nd-route routes, establish a BGP neighbor relationship between R1 and R2, and enable nd-route route redistribution. In this case, both R1 and R2 can obtain routes to PC1 and PC2 to implement network interconnection.

The hardware delivery performance of remote route is better than that of local device, so the time to release nd-route route should be controlled to avoid premature traffic diversion to the local device. By configuring the nd-route delayed redistribution function, you can configure the time to redistribute the nd-route route based on the actual scenario.

By default, the route converted by ND is a static route with a mask of 128 bits. If there are too many ND entries, a large number of nd-route routes are generated, which greatly increases the memory overhead and reduces the computational performance of the route, so you need to aggregate nd-route on the same network segment. You can convert nd-route routes to routes with fixed-length masks to aggregate nd-route routes on the same network segment.

Figure 100-7

Deployment

- Configure IP addresses and masks for interfaces.
- Enable nd-to-route conversion on interfaces of R1 and R2.
- Establish a BGP neighbor relationship between R1 and R2, and redistribute nd-route routes.

10.3 Features

Feature	Description
Route Computation	Generate a valid route on a device.
Optimal Route Selection	Select an optimal route to forward packets.
Default Route	Forward all packets and help reduce the size of a routing table.
Route Reliability	Quickly detect a route failure and recover communication.

10.3.1 Route Computation

[Routing Function](#)

Routing functions are classified into IPv4 and IPv6 routing functions. If the routing functions are disabled, a device is equivalent to a host and cannot forward routes.

[Dynamic Route](#)

A dynamic routing protocol learns remote routes and dynamically updates routes by exchanging routes with neighbors. If a neighbor is the next hop of a route and this neighbor fails, the route fails as well.

[Static Route](#)

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

Whether a static route is active is computed based on the status of the local interface. When the exit interface of a static route is located at layer 3 (L3) and is in Up status (the link status is Up and the IP address is configured), this route is active and can be used for packet forwarding.

A static route can go across VPN routing & forwarding (VRF) instances. The next hop or exit interface of a static route of VRF 1 can be configured on VRF 2.

[ARP-to-host Conversion](#)

Enable ARP-to-host conversion on a specified interface. If the interface is a Layer-3 interface in up status, ARP entries will be converted into 32-bit host routes on the interface.

[ND-to-route Conversion](#)

Enable nd-to-route conversion on a specified interface. If the interface is a Layer-3 interface in up status, ND entries will be converted into routes with fixed-length masks on the interface. By configuring the delayed redistribution of nd-to-route, the nd-to-route is redistributed according to the configured time.

10.3.2 Optimal Route Selection

Administrative Distance

When multiple routing protocols generate routes to the same destination, the priorities of these routes can be determined based on the administrative distance. A smaller administrative distance indicates a higher priority.

Equal-Cost Route

If multiple routes to the same destination have different next hops but the same administrative distance, these routes are mutually equal-cost routes. Packets are distributed among these routes to implement load balancing based on the balanced forwarding policy.

On a specific device, the total number of equal-cost routes is limited. Routes beyond the limit do not participate in packet forwarding.

Floating Route

If multiple routes to the same destination have different next hops and different administrative distances, these routes are mutually floating routes. The route with the smallest administrative distance will be first selected for packet forwarding. If this route fails, a route with a larger administrative distance is further selected for forwarding, thus preventing communication interruption caused by a network line failure.

10.3.3 Default Route

In the forwarding routing table, the route with the destination network segment 0.0.0.0 and the subnet mask 0.0.0.0 is the default route. Packets that cannot be forwarded by other routes will be forwarded by the default route. The default route can be statically configured or generated by a dynamic routing protocol.

Static Default Route

On a L3 switch, a static route with the network segment 0.0.0.0 and the subnet mask 0.0.0.0 is configured to generate the default route.

Default Network

The default network is configured to generate a default route. If the **ip default-network** command is configured to specify a network (a classful network, such as a Class A, B, or C network), and this network exists in the routing table, the router will use this network as the default network and the next hop of this network is the default gateway. As the network specified by the **ip default-network** command is a classful one, if this command is used to identify a subnet in a classful network, the router automatically generates a static route of the classful network instead of any default route.

10.3.4 Route Reliability

When a device on a network is faulty, some routes become unreachable, resulting in traffic interruption. If connectivity of the next hop can be detected in real time, the route can be re-computed when a fault occurs, or traffic can be switched over to the standby route.

Correlation with Track

A track object is an abstract concept. It can be used to trace whether an IP address is reachable or whether an interface is up. If a dynamic routing protocol or a static route is correlated with the Track function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

Correlation with BFD

The BFD protocol provides a light-load and fast method for detecting the connectivity of the forwarding path between two adjacent routers. If a dynamic routing protocol or a static route is correlated with the BFD function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

 The detection performance of BFD is better than that of Track.

Correlation with ARP

If a static route is correlated with the ARP function, when the ARP does not exist, the static route can quickly learn that the next hop is unreachable so as to respond quickly.

Fast Reroute

Fast reroute provides a standby route. When a dynamic routing protocol or a static route detects that the next hop is unreachable, it immediately switches traffic over to the standby route to recovery communication.

10.4 Limitations

Support 64 groups of ECMP, and each group supports a maximum of 32 entries. A group refers to multiple equivalent next hops of a prefix.

10.5 Configuration

Configuration Item	Description and Command	
Configuring a Static Route	 (Mandatory) It is used to configure a static route entry.	
	ip route	Configures an IPv4 static route.
	ipv6 route	Configures an IPv6 static route.
Configuring a Default Route	 (Optional) It is used to configure the default gateway.	
	ip route 0.0.0.0 0.0.0.0 gateway	Configures an IPv4 default gateway on a L3 device.
	ipv6 route ::/0 ipv6-gateway	Configures an IPv6 default gateway on a L3 device.
	ip default network	Configures an IPv4 default network on a L3 device.

Configuration Item	Description and Command	
Configuring Route Limitations	 (Optional) It is used to limit the number of equal-cost routes and number of static routes, or disable routing.	
	maximum-paths	Configures the maximum number of equal-cost routes.
	ip static route-limit	Configures the maximum number of IPv4 static routes.
	ipv6 static route-limit	Configures the maximum number of IPv6 static routes.
	no ip routing	Disables IPv4 routing.
	noipv6 unicast-routing	Disables IPv6 routing.
	no ip route static inter-vrf	Prohibits static routing across VRFs.
Correlating a Static Route with BFD	 (Optional) It is used to correlate a static route with BFD.	
	ip route static bfd	Correlates an IPv4 static route with BFD.
	ipv6 route static bfd	Correlates an IPv6 static route with BFD.
Configure Static Fast Reroute	 (Optional) It is used to configure static fast reroute.	
	route-map	Configures a route map.
	set fast-reroute backup-nexthop	Configures the standby interface and standby next hop for fast reroute.
	ip fast-reroute	Configures static fast reroute.
Configure ARP-to-host Conversion	ip route arp-to-host interface <i>interface-name</i>	Configures ARP-to-host conversion on a specified interface.
	ip route arp-to-host tag <i>tag-number</i>	Configures the tag of ARP-to-host
	ip route arp-to-host delay-time <i>time-number</i>	Configures the delayed redistribution of ARP-to-host route
	redistribute arp-host [route-map <i>map-tag</i>] [metric <i>metric-value</i>]	Configures BGP redistribution of ARP host route.
Configure nd-to-route Conversion	ipv6 route nd-to-route delay-time <i>time-number</i>	Configures the delayed redistribution of nd-to-route
	ipv6 route nd-to-route interface <i>interface-name</i> [ipv6-prefix <i>X:X:X:X/0-128</i>] [prefix-len <i>masklen</i>]	Enables nd-to-route on a specific interface
	ipv6 route nd-to-route tag <i>tag-number</i>	Configures the tag of nd-to-route

Configuration Item	Description and Command	
	ipv6 route nd-to-route warning-ignore	Ignores the alarm log of nd-to-route conversion
	redistribute nd-route[route-map map-tag] [metric-metric-value]	Configures BGP redistribution of nd-route route

10.5.1 Configuring a Static Route

Configuration Effect

- Generate a static route in the routing table. Use the static route to forward packets to a remote network.

Notes

- If the **no ip routing** command is configured on a L3 switch, you cannot configure IPv4 static routes on this switch, and existing IPv4 static routes will also be deleted. Before the device is restarted, reconfiguring the **ip routing** command can recover the deleted IPv4 static routes. After the device is restarted, deleted IPv4 static routes cannot be recovered.
- If the **no ipv6 unicast-routing** command is configured on a L3 switch, you cannot configure IPv6 static routes on this switch, and existing IPv6 static routes will also be deleted. Before the device is restarted, reconfiguring the **ipv6 unicast-routing** command can recover the deleted IPv6 static routes. After the device is restarted, deleted IPv6 static routes cannot be recovered.
- To correlate a static route with the Track function, you must run the **track** command to configure a track object.

Configuration Steps

📌 Configuring a Static IPv4 Route

Configure the following command on an IPv4-enabled router.

Command	ip route [vrf vrf_name] networknet-mask {ip-address interface [ip-address]} [distance] [tag tag] [permanent track object-number] arp] [weight number] [descriptiondescription-text] [disabled enabled] [global]	
Parameter Description	vrfvrf_name	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by default.
	network	Indicates the address of the destination network.
	net-mask	Indicates the mask of the destination network.
	ip-address	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static direct route is configured.
	interface	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop

		in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	<i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	track <i>object-number</i>	(Optional) Indicates correlation with Track. <i>object-number</i> indicates the ID of the track object. By default, the static route is not correlated with the Track function.
	weight number	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
	disabled/enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.
	global	(Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .
	arp	(Optional) Correlate the static route with ARP function. By default, it is not correlated.
Defaults	By default, no static route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ip route networknet-maskip-address. If the static route is correlated with Track and the down status of the trace object is detected, the static route is not active and does not participate in packet forwarding. If the static route is correlated with ARP, but no ARP information is detected, the static route is not active and does not participate in packet forwarding.	

📌 Configuring an IPv6 Static Route

Configure the following command on an IPv6-enabled router.

Command	ipv6 route [vrfvrf-name] ipv6-prefix/prefix-length { ipv6-address [nexthop-vrf {vrf-name1 default}] interface [ipv6-address [nexthop-vrf {vrf-name1 default}]] } [distance] [weightnumber] [descriptiondescription-text]	
Parameter Description	vrfvrf-name	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	<i>ipv6-prefix</i>	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	<i>prefix-length</i>	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a

		recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	nexthop-vrf <i>vrf-name1</i>	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by the VRF name. nexthop-vrf default indicates that the VRF of the next shop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	weight <i>number</i>	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
Defaults	By default, no static route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ipv6 route <i>ipv6-prefix / prefix-length</i> <i>ipv6-address</i> .	

Verification

- Run the **show ip route** command to display the IPv4 routing table and check whether the configured IPv4 static route takes effect.
- Run the **show ipv6 route** command to display the IPv6 routing table and check whether the configured IPv6 static route takes effect.

Configuration Example

📌 Configuring Static Routes to Implement Interworking of the IPv4 Network

Scenario
Figure 10-7

Configuration Steps

- Configure interface addresses on each device.

R1

```
R1#configure terminal
R1(config)#interface gigabitEthernet 0/0
R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0
R1(config-if-GigabitEthernet 0/0)# exit
R1(config)#interface gigabitEthernet 0/2
R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0
R1(config-if-GigabitEthernet 0/0)# exit
R1(config)#interface gigabitEthernet 0/3
R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0
```

R2

```
R2#configure terminal
R2(config)#interface gigabitEthernet 0/0
R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0
R2(config-if-GigabitEthernet 0/0)# exit
R2(config)#interface gigabitEthernet 0/1
R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0
R2(config-if-GigabitEthernet 0/0)# exit
R2(config)#interface gigabitEthernet 0/3
R2(config-if-GigabitEthernet 0/3)# ip address 1.1.23.2 255.255.255.0
```

R3

```
R3#configure terminal
R3(config)#interface gigabitEthernet 0/0
```

	<pre> R3(config-if-GigabitEthernet 0/0)# ip address 1.1.3.1 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/1 R3(config-if-GigabitEthernet 0/1)# ip address 1.1.13.3 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/2 R3(config-if-GigabitEthernet 0/2)# ip address 1.1.23.3 255.255.255.0 </pre>
	● Configure static routes on each device.
R1	<pre> R1#configure terminal R1(config)#ip route 1.1.2.0 255.255.255.0 GigabitEthernet 0/2 1.1.12.2 R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3 </pre>
R2	<pre> R2#configure terminal R2(config)#ip route 1.1.1.0 255.255.255.0 GigabitEthernet 0/1 1.1.12.1 R2(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.23.3 </pre>
R3	<pre> R3#configure terminal R3(config)#ip route 1.1.2.0 255.255.255.0 GigabitEthernet 0/2 1.1.23.2 R3(config)# ip route 1.1.1.0 255.255.255.0 GigabitEthernet 0/1 1.1.13.1 </pre>
Verification	● Display the routing table.
R1	<pre> R1# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. C    1.1.23.0/24 is directly connected, GigabitEthernet 0/2
C    1.1.23.3/32 is local host.

```

Correlating IPv4 Static Routes with Track

Scenario Figure 10-8	
Configuration Steps	- Configure static routes on R 1 and R 2, and specify the exit interface or next hop as the interworking interface. - Correlate static routes with Track on R 1 and R 2, and check the connectivity of the next hops of static routes.
R1	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.2.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.2 track 2 </pre>
R2	<pre> R2#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.1.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.1 track 2 </pre>
Verification	- Display the Track status. - Display the static routes correlated with Track.

```

R1# show track 2

Track 2

Interface gigabitEthernet 0/1

The state is Up, delayed Down (5 secs remaining)

1 change, current state last: 300 secs

Delay up 0 secs, down 0 secs

R1#show ip route track-table

ip route 1.1.2.0 255.0.0.0 GigabitEthernet 0/1 1.1.12.2 track 2 up

```

Configuring Static Routes to Implement Interworking of the IPv6 Network

Scenario Figure 10-9	
Configuration Steps	Configure interface addresses on each device.
R1	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ipv6 address 1111:1111::1/64 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::1/64 </pre>
R2	<pre> R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ipv6 address 1111:2323::1/64 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::2/64 </pre>
	Configure static routes on each device.

R1	<pre>R1#configure terminal R1(config)# ipv6 route 1111:2323::0/64 gigabitEthernet 0/1</pre>
R2	<pre>R2#configure terminal R2(config)#ipv6 route 1111:1111::0/64 gigabitEthernet 0/1</pre>
Verification	● Display the routing table.
R1	<pre>R1# show ipv6 route</pre> IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area <pre>C 1111:1111::/64 via GigabitEthernet 0/0, directly connected L 1111:1111::1/128 via GigabitEthernet 0/0, local host C 1111:1212::/64 via GigabitEthernet 0/1, directly connected L 1111:1212::1/128 via GigabitEthernet 0/1, local host S 1111:2323::/64 [1/0] via GigabitEthernet 0/1, directly connected C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host</pre>
R2	<pre>R2# show ipv6 route</pre> IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS

```

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2

SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

IA - Inter area

C    1111:2323::/64 via GigabitEthernet 0/0, directly connected
L    1111:2323::1/128 via GigabitEthernet 0/0, local host
C    1111:1212::/64 via GigabitEthernet 0/1, directly connected
L    1111:1212::1/128 via GigabitEthernet 0/1, local host
S    1111:1111::/64 [1/0] via GigabitEthernet 0/1, directly connected
C    FE80::/10 via ::1, Null0
C    FE80::/64 via GigabitEthernet 0/0, directly connected
L    FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host
C    FE80::/64 via GigabitEthernet 0/1, directly connected
L    FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host

```

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.
- The static route is correlated with Track, but the track object is not configured.

10.5.2 Configuring a Default Route

Configuration Effect

- Generate a default route in the routing table. The default route is used to forward packets that cannot be forwarded by other routes.

Notes

- On a L3 switch, run the **ip route 0.0.0.0 0.0.0.0 gateway** or **ipv6 route ::/0 ipv6-gateway** command to configure the default gateway.
- If the **no ip routing** or **no ipv6 unicast-routing** command is configured on a L3 switch, you can run the **ip default gateway** or **ipv6 default gateway** command to configure the default gateway.

Configuration Steps

📌 Configuring the IPv4 Gateway on a L2 Switch

Command	ip default-gateway <i>gateway</i>	
Parameter	<i>gateway</i>	indicates the IPv4 gateway address.
Description		
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

📌 Configuring the IPv6 Gateway on a L2 Switch

Command	ipv6 default-gateway <i>gateway</i>	
Parameter	<i>gateway</i>	indicates the IPv6 gateway address.
Description		
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

📌 Configuring the IPv4 Default Gateway on a L3 Switch

Command	ip route [vrf <i>vrf_name</i>] 0.0.0.0.0.0.0.0 { <i>ip-address</i> <i>interface</i> [<i>ip-address</i>]} [<i>distance</i>] [tag <i>tag</i>] [permanent] [weight <i>number</i>] [description <i>description-text</i>] [disabled enabled] [global]	
Parameter Description	vrf <i>vrf_name</i>	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by default.
	0.0.0.0	Indicates the address of the destination network.
	0.0.0.0	Indicates the mask of the destination network.
	<i>ip-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	<i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	weight <i>number</i>	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
	disabled / enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.

	global	(Optional) Indicates that the next hop belongs to a global VRF. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> .
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ip route 0.0.0.0 0.0.0.0 <i>ip-address</i> .	

📌 Configuring the IPv6 Default Gateway on a L3 Switch

Command	ipv6 route [vrf <i>vrf-name</i>] ::/0 { <i>ipv6-address</i> [nexthop-vrf {<i>vrf-name1</i> default}] interface [<i>ipv6-address</i> [nexthop-vrf {<i>vrf-name1</i> default}]] } [distance] [weight <i>number</i>] [description <i>description-text</i>]	
Parameter Description	vrf <i>vrf-name</i>	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	::	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	0	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	nexthop-vrf <i>vrf-name1</i>	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> . nexthop-vrf default indicates that the VRF of the next shop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	weight <i>number</i>	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ipv6 route ::/0 <i>ipv6-gateway</i> .	

➤ **Configuring the IPv4 Default Network on a L3 Switch**

Command	ip default-network network	
Parameter	<i>network</i>	Indicates the address of the network. (The network must be a Class A, B, or C network.)
Description		
Defaults	By default, no default network is configured.	
Command Mode	Global configuration mode	
Usage Guide	If the network specified by the ip default-network command exists, a default route is generated and the next hop to this network is the default gateway. If the network specified by the ip default-network command does not exist, the default route is not generated.	

Verification

- On a L2 switch (or a L3 switch where routing is disabled), run the **show ip redirects** or **show ipv6 redirects** command to display the default gateway.
- On a L3 switch where routing is enabled, run the **show ip route** or **show ipv6 route** command to display the default route.

Configuration Example

➤ **Configuring IPv4 Default Routes on L3 Switches to Implement Network Interworking**

Scenario Figure 10-10	
Configuration Steps	● Configure IP addresses on L3 devices.
R1	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit</pre>
R2	<pre>R2#configure terminal</pre>

	<pre> R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit </pre>
R1	● Configure an IPv6 default gateway on R 1. <pre> R1#configure terminal R1(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.2 </pre>
R2	<pre> R2#configure terminal R2(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.1 </pre>
Verification	● Display the routing table.
R1	<pre> R1# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is 1.1.12.2 S* 0.0.0.0/0 [1/0] via 1.1.12.2, GigabitEthernet 0/1 C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. C 1.1.12.0/24 is directly connected, GigabitEthernet 0/1 C 1.1.12.1/32 is local host. </pre>

10.5.3 Configuring Route Limitations

Configuration Effect

- Limit the number of equal-cost routes and number of static routes, or disable routing.

Notes

Route limitations cannot be configured on a L2 switch.

Configuration Steps

📌 Configuring the Maximum Number of Equal-Cost Routes

Command	maximum-paths <i>number</i>	
Parameter Description	<i>number</i>	Indicates the maximum number of equal-cost routes. The value ranges from 1 to 64.
Defaults	The default value varies from products.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to configure the maximum number of next hops in the equal-cost route. In load balancing mode, the number of routes on which traffic is balanced does not exceed the configured number of equal-cost routes.	

📌 Configuring the Maximum Number of IPv4 Static Routes

Command	ip static route-limit <i>number</i>	
Parameter Description	<i>number</i>	Indicates the upper limit of routes. The value ranges from 1 to 10,000.
Defaults	By default, a maximum of 1,024 IP static routes can be configured.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to configure the maximum number of IPv4 static routes. If the maximum number of IPv4 static routes is reached, no more IPv4 static route can be configured.	

📌 Configuring the Maximum Number of IPv6 Static Routes

Command	ipv6 static route-limit <i>number</i>	
Parameter Description	<i>number</i>	Indicates the upper limit of routes. The value ranges from 1 to 10,000.
Defaults	By default, a maximum of 1,000 IPv6 static routes can be configured.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to configure the maximum number of IPv6 static routes. If the maximum number of IPv6 static routes is reached, no more IPv6 static route can be configured.	

📌 Disabling IPv4 Routing

Command	no ip routing	
Parameter Description	N/A	

Defaults	By default, IPv4 routing is enabled.
Command Mode	Global configuration mode
Usage Guide	Run this command to disable IPv4 routing. If the device functions only as a bridge or a voice over IP (VoIP) gateway, the device does not need to use the IPv4 routing function of the RGOS software. In this case, you can disable the IPv4 routing function of the RGOS software.

📌 Disabling IPv6 Routing

Command	no ipv6 unicast-routing
Parameter Description	N/A
Defaults	By default, IPv6 routing is enabled.
Command Mode	Global configuration mode
Usage Guide	Run this command to disable IPv6 routing. If the device functions only as a bridge or a VoIP gateway, the device does not need to use the IPv6 routing function of the RGOS software. In this case, you can disable the IPv6 routing function of the RGOS software.

📌 Prohibiting Static Routing Across VRFs

Command	no ip route static inter-vrf
Parameter Description	N/A
Defaults	By default, static IP or IPv6 routing across VRFs is allowed.
Command Mode	Global configuration mode
Usage Guide	Run this command to prohibit static IP routing across VRFs. After this command is configured, the static IP route across VRFs is not active and cannot participate in packet forwarding.

Verification

Run the **show run** command to display the configuration file and verify that the preceding configuration commands exist.

Configuration Example

📌 Configuring at Most Two Static Routing Limitations

Scenario Figure 10-6	
Configuration Steps	On R 1, configure the IP addresses, static routes, and maximum number of static routes.
	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)#ip route 1.1.3.0 255.255.255.0 1.1.13.3 R1(config)#ip route 1.1.4.0 255.255.255.0 1.1.12.2 R1(config)#ip route 1.1.5.0 255.255.255.0 1.1.12.2 R1(config)#ip static route-limit 2 % Exceeding maximum static routes limit. </pre>
Verification	Check the static routes that really take effect in the routing table.
	<pre> R1(config)# show ip route </pre>

```

Codes:  C - Connected, L - Local, S - Static

        R - RIP, O - OSPF, B - BGP, I - IS-IS

        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

        E1 - OSPF external type 1, E2 - OSPF external type 2

        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

        IA - Inter area, * - candidate default

Gateway of last resort is no set

C      1.1.1.0/24 is directly connected, GigabitEthernet 0/0
C      1.1.1.1/32 is local host.
S      1.1.3.0/24 [1/0] via 1.1.13.3
S      1.1.4.0/24 [1/0] via 1.1.12.2
C      1.1.12.0/24 is directly connected, GigabitEthernet 0/2
C      1.1.12.1/32 is local host.
C      1.1.13.0/24 is directly connected, GigabitEthernet 0/3
C      1.1.13.1/32 is local host.

```

10.5.4 Correlating a Static Route with BFD

Configuration Effect

- A static route can quickly detect a route failure with the help of BFD.

Notes

- BFD correlation cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure the BFD session parameters by running the **bfd interval xmin_rx xmultiplier x** command.

Configuration Steps

📌 Correlating an IPv4 Static Route with BFD

Command	ip route static bfd [vrf vrf-name] interface-type interface-number gateway[sourceip-address]	
Parameter Description	vrf vrf-name	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is a global VRF by default.
	interface-type	Indicates the interface type.
	interface-number	Indicates the interface number.
	gateway	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the

		next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	source ip-address	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the source IP address is not specified.
Defaults	By default, a static route is not correlated with BFD.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to correlate an IPv4 static route with BFD. If the down status of the BFD session is detected, the IPv4 static route is not active and does not participate in packet forwarding.	

✚ Correlating an IPv6 Static Route with BFD

Command	ipv6 route static bfd [vrfvrf-name] <i>interface-type interface-number gateway</i> [source ipv6-address]	
Parameter Description	vrfvrf-name	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is a global VRF by default.
	<i>interface-type</i>	Indicates the interface type.
	<i>interface-number</i>	Indicates the interface number.
	<i>gateway</i>	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	sourceip-address	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the neighbor IP address of the BFD session is a single hop, and the source IP address is not used.
Defaults	By default, a static route is not correlated with BFD.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to correlate an IPv6 static route with BFD. If the down status of the BFD session is detected, the IPv6 static route is not active and does not participate in packet forwarding.	

Verification

- Run the **show bfd neighbors** command to display information about BFD neighbors.
- Run the **show ip route static bfd** or **show ipv6 route static bfd** command to display information about correlation of static routes with BFD.

Configuration Example

✚ Correlating an IPv4 Static Route with BFD

Scenario Figure 10-7															
Configuration Steps	● Configure a BFD session on the interconnect interface between R 1 and R 2. ● Configure static routes on R 1 and R 2, and specify the exit interface or next hop as the interworking interface. ● Correlate static routes with BFD on R 1 and R 2, and check the connectivity of the next hops of static routes.														
R1	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# no switchport R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R1(config-if-GigabitEthernet 0/1)# exit R1(config)# ip route 1.1.2.0 255.0.0.0 FastEthernet 0/1 1.1.12.2 R1(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.2</pre>														
R2	<pre>R2#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# no switchport R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R1(config-if-GigabitEthernet 0/1)# exit R1(config)# ip route 1.1.1.0 255.0.0.0 FastEthernet 0/1 1.1.12.1 R1(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.1</pre>														
Verification	● Display the status of BFD neighbors. ● Display the static routes correlated with BFD.														
R1	<pre>R1#show bfd neighbors</pre> <table><tr><th>OurAddr</th><th>NeighAddr</th><th>LD/RD</th><th>RH/RS</th><th>Holdown(mult)</th><th>State</th><th>Int</th></tr><tr><td>1.1.12.1</td><td>1.1.12.2</td><td>8192/0</td><td>Up</td><td>0(3)</td><td>Up</td><td>GigabitEthernet 0/1</td></tr></table>	OurAddr	NeighAddr	LD/RD	RH/RS	Holdown(mult)	State	Int	1.1.12.1	1.1.12.2	8192/0	Up	0(3)	Up	GigabitEthernet 0/1
OurAddr	NeighAddr	LD/RD	RH/RS	Holdown(mult)	State	Int									
1.1.12.1	1.1.12.2	8192/0	Up	0(3)	Up	GigabitEthernet 0/1									

```
R1#show ip route static bfd
S    1.1.2.0/24 via 1.1.12.2, GigabitEthernet 0/1, BFD state is Up
```

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.
- No BFD session parameters are configured.
- No static route is configured.

10.5.5 Configure Static Fast Reroute

Configuration Effect

- Configure and enable static fast reroute.

Notes

- Static fast reroute cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure a route map.

Configuration Steps

📌 Defining a Standby Route in the Route Map

Command	set fast-reroute backup-nexthop <i>interface ip-address</i>	
Parameter	<i>interface</i>	Indicates the standby exit interface.
Description	<i>ip-address</i>	Indicates the standby next hop.
Defaults	N/A	
Command Mode	Global configuration mode	
Usage Guide	Run the route-map <i>name</i> [permit deny] <i>sequence</i> command to create a road map. Run the match command to define matching conditions. Run the set fast-reroute backup-nexthop <i>interface ip-address</i> command to define the standby exit interface and standby next hop. If a route meets matching conditions, a standby route is generated for this route. If the match command is not configured, standby routes are generated for any static route with the exit interface and next hop.	

📌 Enabling Fast Reroute and Referencing the Route Map

Command	ip fast-reroute [vrf <i>vrf-name</i>] static route-map <i>route-map-name</i>

Parameter Description	<i>vrf-name</i>	(Optional) Specifies a VRF. If the VRF is not specified, the command is executed on all VRFs.
	<i>route-map-name</i>	Indicates the name of the road map for the standby route.
Defaults	By default, static fast reroute is not configured.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to enable fast reroute and reference the route map.	

Verification

Run the **show ip route fast-reroute** command to display the active and standby routes that take effect.

Configuration Example

Configuring Fast Re-Routing

Scenario Figure 10-8	
Configuration Steps	On R 1, configure a static route to the network segment of PC 3, and the next hop of the exit interface is R 3. On R 1, configure static fast reroute. The next hop of the exit interface of the standby route is R2. <pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit </pre>

	<pre> R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3 R1(config)#route-map fast-reroute R1(config-route-map)# set fast-reroute backup-interface GigabitEthernet 0/2 backup-nexthop 1.1.12.2 R1(config-route-map)# exit R1(config)#ip fast-reroute static route-map fast-reroute </pre>
Verification	Display the active and standby routes on R 1. <pre> R1#show ip route fast-reroute Codes: C - connected, S - static, R - RIP, B - BGP O - OSPF, IA - OSPF inter area N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 ia - IS-IS inter area, * - candidate default Status codes: m - main entry, b - backup entry, a - active entry Gateway of last resort is no set S 1.1.3.0 /24 [ma] via 1.1.13.3, GigabitEthernet 0/3 [b] via 1.1.12.2, GigabitEthernet 0/2 </pre>

Common Errors

- The link on the interface is not up.
- No static route is configured.
- The matching conditions are not configured or are not properly configured in the road map.

10.5.6 Configuring ARP-to-host Conversion

Configuration Effect

- Enable ARP-to-host conversion on a specified interface.

Notes

- This configuration cannot be performed on a Layer-2 switch.
- The interface must be a Layer-3 interface in up status.

Configuration Steps

▾ Enabling ARP-to-host Conversion on a Specified Interface

Command	ip route arp-to-host interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates an interface name.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	This command is used to convert ARP entries into 32-bit host routes on a specified interface.

▾ Enabling ARP Proxy

Command	local-proxy-arp
Parameter Description	N/A
Defaults	N/A
Command Mode	Interface configuration mode
Usage Guide	After receiving an ARP request, the device uses a proxy to send an ARP response with its own Ethernet MAC address. In this case, hosts communicate with each other through Layer-3 routes.

▾ Configuring BGP Redistribution of ARP Host Routes

Command	redistribute arp-host [route-map <i>map-tag</i>] [metric <i>metric-value</i>]
Parameter Description	route-map <i>map-tag</i> : Indicates the name of an associated route map. No route map is associated by default. metric <i>metric-value</i> : Indicates the default metric value for redistributing routes, in the range from 0 to 4,294,967,295 . The value is not set by default.
Defaults	N/A
Command Mode	BGP configuration mode
Usage Guide	This command is used to configure BGP redistribution of ARP host routes.

Verification

Run the **show ip route arphost** command to display the generated host routes.

Configuration Example

Configuring ARP-to-host Conversion

Scenario Figure 10-9	
Configuration Steps	Configure interface addresses on R1 and R2. Enable ARP-to-host conversion on specified interfaces of R1 and R2, configure a BGP neighbor relationship, and redistribute ARP host routes.
R1	<pre> R1#configure terminal R1(config)#interface vlan 40 R1(config-if-VLAN 40)#ip address 1.1.1.3 24 R1(config-if-VLAN 40)#local-proxy-arp R1(config-if-VLAN 40)#exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)#switchport R1(config-if-GigabitEthernet 0/1)#switchport mode trunk R1(config-if-GigabitEthernet 0/1)#switchport trunk allowed vlan only 40 R1(config-if-GigabitEthernet 0/1)#exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 10.10.10.1 255.255.255.0 R1(config-if-GigabitEthernet 0/2)# exit R1(config)#router bgp 1 R1(config-router)#neighbor 10.10.10.2 remote-as 1 R1(config-router)#redistribute arp-host R1(config-router)#address-family ipv4 R1(onfig-router-af)#neighbor 10.10.10.2 next-hop-self R1(onfig-router-af)#exit R1(config-router)#exit R1(config)#ip route arp-to-host vlan 40 R1(config)#ip route arp-to-host delay-time 1 </pre>
R2	<pre> R2#configure terminal R2(config)#interface vlan 40 R2(config-if-VLAN 40)#ip address 1.1.1.4 24 R2(config-if-VLAN 40)#local-proxy-arp R2(config-if-VLAN 40)#exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# switchport </pre>

	<pre> R2(config-if-GigabitEthernet 0/1)#switchport mode trunk R2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan only 40 R2(config-if-GigabitEthernet 0/1)#exit R2(config)#interface gigabitEthernet 0/2 R2(config-if-GigabitEthernet 0/2)# ip address 10.10.10.2 255.255.255.0 R2(config-if-GigabitEthernet 0/2)# exit R2(config)#router bgp 1 R2(config-router)#neighbor 10.10.10.1 remote-as 1 R2(config-router)#redistribute arp-host R2(config-router)#address-family ipv4 R2(onfig-router-af)#neighbor 10.10.10.1 next-hop-self R2(onfig-router-af)#exit R2(config-router)#exit R2(config)#ip route arp-to-host vlan 40 R2(config)#ip route arp-to-host delay-time 1 </pre>
Verification	Display the ARP host routes of R1 to check that PC1 can ping PC2. <pre> R1(config)#show ip route arphost A 1.1.1.1/32 [1/0] via 1.1.1.1, gigabitEthernet 0/1 R1#show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, EV - BGP EVPN, A - Arp to host * - candidate default Gateway of last resort is 0.0.0.0 to network 0.0.0.0 S* 0.0.0.0/0 is directly connected, Null 0 C 10.10.10.0/24 is directly connected, GigabitEthernet 0/2 C 10.10.10.1/32 is local host. C 1.1.1.0/24 is directly connected, VLAN 40 A 1.1.1.1/32 [1/0] via 1.1.1.1, VLAN 40 C 1.1.1.3/32 is local host. B 1.1.1.2/32 [200/0] via 10.10.10.2, 00:57:12 </pre>

Common Errors

- The ARP proxy function is not enabled on specified interfaces.

10.5.7 Configuring nd-to-route Conversion

Configuration Effect

- Enable nd-to-route on a specified interface

Notes

- This configuration cannot be performed on a Layer-2 switch.
- The interface must be a Layer-3 interface in up status.

Configuration Steps

📌 Enabling nd-to-route on a Specified Interface

Command	ipv6 route nd-to-route interface <i>interface-name</i> [ipv6-prefix <i>X:X:X:X::X/<0-128></i>] [prefix-len <i>masklen</i>]
Parameter	<i>interface-name</i> : the interface name.
Description	<i>X:X:X:X::X/<0-128></i>: Ipv6 network segment. If the nd entries match this network segment, the route is converted according to the mask specified by this network segment. If the network segment does not specify a mask, the default mask is 128. <i>masklen</i>: the mask length of the nd-to-route. The range is 0 to 128, and the default value is 128. If an IPv6 network segment is specified, it is longer than the mask length of configured network segment. If no IPv6 network segment is specified, it is longer than the mask length of IPv6 address on the interface. Otherwise, the configuration fails.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	If the IPv6 network segment and prefix-len are not specified, the ND learned on the default interface generates a 128-bit route. If no IPv6 network segment is specified but prefix-len is specified, ND on the interface generate the specified prefix- len. If IPv6 network segment is specified but prefix-len is not specified, the network segment generates a 128-bit route by default. If the network segment and the prefix-len are specified, the network segment is verified to match with the prefix when the ND is learned, and then the prefix-len is generated. If the network segment and prefix-len are specified, and the prefix-len of an unspecified network segment is configured, the specified interface generates the route according to its prefix-len, while the unspecified interface generates the route according to the unspecified prefix-len. If you configure the IPv6 address of an interface before configuring the prefix-len of the interface address to generate a route with fixed-length mask, a configuration error occurs when the prefix-len is shorter than or equal to the mask of the IPv6 address. The prefix-len command fails. For example, first configure IPv6 address 10::1/64 on the interface of vlan 40, and then configure ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60 in the global configuration mode, the configuration fails. If you configure the IPv6 address of an interface before configuring the prefix-len of an unspecified network segment, a configuration error occurs when the prefix-len is shorter than or equal to the mask of any of the IPv6 addresses on the interface. The prefix-len configuration command for the unspecified network segment

fails. For example, first configure IPv6 address 10::1/64 on the interface of vlan 40, and then configure ipv6 route nd-to-route interface vlan 40 prefix-len 60 in the global configuration mode, the configuration fails.

If you configure the prefix-len of an unspecified network segment before configuring the IPv6 address of this interface, syslog is displayed and the prefix-len configuration of unspecified network segment is canceled when one of the IPv6 addresses is longer than or equal to the prefix-len of the unspecified network segment. For example, first configure ipv6 route nd-to-route interface vlan 40 prefix-len 60 in the global configuration mode, and then configure address 10::1/64 on the interface of vlan 40, syslog alarm is displayed and the configuration ipv6 route nd -to-route interface vlan 40 prefix-len 60 is deleted.

If you configure the prefix-len of the specified network segment and then configure the IPv6 address of the corresponding network segment, syslog is displayed and the prefix-len configuration of the specified network segment is canceled when the IPv6 address mask of the corresponding network segment is longer than or equal to the prefix-len of the specified network segment. For example, first configure ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60 in the global configuration mode, and then configure the address 10::1/64 on the interface of vlan 40, the syslog alarm is displayed and the configuration ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60 is deleted.

If you configure the prefix-len of unspecified network segment and the prefix-len of the specified network segment, and then configure the IPv6 address of the interface, please check whether the mask of each IPv6 address is longer than or equal to the prefix-len of the specified/unspecified network segment. Syslog is displayed and the prefix-len configuration of specified network segment is canceled when the mask of each IPv6 address is longer than or equal to the prefix-len of the corresponding network segment. Syslog is displayed and the prefix-len configuration of unspecified network segment is canceled when the mask of each IPv6 address is longer than or equal to the prefix-len of unspecified network segment. For example, first configure ipv6 route nd-to-route interface vlan 40 prefix-len 62 and ipv6 route nd-to-route interface vlan 40 ipv6-prefix 10::1/58 prefix-len 60, and then configure address 10::1/64 on the interface of vlan 40, the syslog alarm is displayed and two configurations are deleted.

📌 Configuring Delayed Redistribution of nd-to-route

Command	ipv6 route nd-to-route delay-time <i>time-number</i>
Parameter	<i>time-number</i> : time of the delayed redistribution of nd-to-route. The unit is second, the range is 1-1000, and
Description	the default value is 0
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	This command is used to delay the redistribution of nd-to-route

📌 Configuring Tag of nd-to-route

Command **ipv6 route nd-to-route tag** *tag-number*

Parameter *time-number*: tag attribute value of nd-to-route. The range is 1-4294967295, and the default value is 0.

Description

Defaults N/A

Command Mode Global configuration mode

Usage Guide

📌 **Ignoring Warning Log of nd-to-route**

Command **ipv6 route nd-to-route warning-ignore**

Parameter -

Description

Defaults N/A

Command Mode Global configuration mode

Usage Guide After you configure to ignore the warning of nd-to-route, the alarm that the same PORT ND generates the same network segment route is ignored. If this command is not configured, the warning log that the same PORT ND generates the same network segment route is printed (only once). The alarm that different ports generate the same network segment route is not controlled by this command.

📌 **Enabling nd Proxy**

Command **local-proxy-nd enable**

Parameter -

Description

Defaults N/A

Command Mode SVI interface mode

Usage Guide When the device receives an ND request, it will send an ND response. The MAC address of the response is the local Ethernet MAC address, so that the interconnection among different hosts is implemented by Layer 3 routing.

📌 **Configuring BGP Redistributed nd-route Route**

Command	redistribute nd-route [route-map <i>map-tag</i>] [metric <i>metric-value</i>]
Parameter	route-map <i>map-tag</i> : name of the associated route-map. There is no associated route-map by default.
Description	metric <i>metric-value</i> : configured the metric value of redistributed route by default, the range is 0-4294967295. There is no default value.
Defaults	N/A
Command Mode	BGP mode
Usage Guide	Configure BGP to redistribute nd-route route

Verification

Run the **show ipv6 route ndroute** command to display the generated host routes.

Configuration Example

Configuring nd-to-route

Scenario

Figure 10-16

Configuration Configure interface addresses on R1 and R2.

Steps

Enable nd-to-route conversion on the specified interface of R1 and R2, configure BGP and redistribute nd-route routes.

R1

```

R1#configure terminal

R1(config)#interface vlan 40

R1(config-if-VLAN 40)#ipv6 address 10::1/64

R1(config-if-VLAN 40)# local-proxy-nd enable

R1(config-if-VLAN 40)#exit

R1(config)#interface gigabitEthernet 0/1

R1(config-if-GigabitEthernet 0/1)#switchport

```

```
R1(config-if-GigabitEthernet 0/1)#switchport mode trunk

R1(config-if-GigabitEthernet 0/1)#switchport trunk allowed vlan only 40

R1(config-if-GigabitEthernet 0/1)#exit

R1(config)#interface gigabitEthernet 0/2

R1(config-if-GigabitEthernet 0/2)# ipv6 address 11::1/64

R1(config-if-GigabitEthernet 0/2)# exit

R1(config)#router bgp 1

R1(config-router)#neighbor 11::2 remote-as 1

R1(config-router)#address-family ipv6

R1(onfig-router-af)#neighbor11::2 next-hop-self

R1(config-router-af)#redistribute nd-route

R1(config-router-af)#exit

R1(config-router)#exit

R1(config)#ipv6 route nd-to-route vlan 40

R1(config)#ipv6 route nd-to-route delay-time 1
```

R2

```
R2#configure terminal

R2(config)#interface vlan 40

R2(config-if-VLAN 40)# ipv6 address 10::2/64

R2(config-if-VLAN 40)# local-proxy-nd enable

R2(config-if-VLAN 40)#exit

R2(config)#interface gigabitEthernet 0/1

R2(config-if-GigabitEthernet 0/1)# switchport

R2(config-if-GigabitEthernet 0/1)#switchport mode trunk

R2(config-if-GigabitEthernet 0/1)# switchport trunk allowed vlan only 40

R2(config-if-GigabitEthernet 0/1)#exit

R2(config)#interface gigabitEthernet 0/2

R2(config-if-GigabitEthernet 0/2)# ipv6 address 11::2/64
```

```
R2(config-if-GigabitEthernet 0/2)# exit

R2(config)#router bgp 1

R2(config-router)#neighbor 11::1 remote-as 1

R2(config-router)#address-family ipv6

R2(config-router-af)#neighbor 11::1 next-hop-self

R2(onfig-router-a)#redistributend-route

R2(onfig-router-af)#exit

R2(config-router)#exit

R2(config)# ipv6 route nd-to-route vlan 40

R2(config)# ipv6 route nd-to-route delay-time 1
```

Verification Display the nd-route routes of R1 to check that PC1 can ping PC2.

```
R1(config)#show ipv6 route ndroute

N      1111::1/128 [1/0] via 1111::1, VLAN 40

R1#show ipv6 route

IPv6 routing table name - Default - 18 entries

Codes: C - Connected, L - Local, S - Static

        R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route

        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

        E1 - OSPF external type 1, E2 - OSPF external type 2

        SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

        IA - Inter area, N - Nd to host

C      10::/64 via VLAN 1, directly connected

L      10::1/128 via VLAN 1, local host

C      101::/64 via VLAN 101, directly connected

L      101::2/128 via VLAN 101, local host

C      102::/64 via VLAN 102, directly connected
```

```

L    102::2/128 via VLAN 102, local host
C    103::/64 via VLAN 103, directly connected
L    103::2/128 via VLAN 103, local host
N    1111::1/128 [1/0] via 1111::1, VLAN 40
B    1111::2/128 [200/0] via 11::2, 00:57:12

```

Common Error

- The nd proxy function is not enabled on the specified interface.

10.6 Monitoring

Displaying

Description	Command
Displays the IPv4 routing table.	show ip route
Displays the IPv6 routing table.	show ipv6route

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs IPv4 route management.	debug nsm kernel ucast- v4
Debugs IPv6 route management.	debug nsm kernel ucast-v6
Debugs fast reroute management.	debug nsm kernel frr
Debugs default network management.	debug nsm kernel default-network
Debugs internal events of route management.	debug nsm events
Debugs sending of route management and routing protocol messages.	debug nsm packet send
Debugs receiving of route management and routing protocol messages.	debug nsm packet recv

11 Configuring VRF

11.1 Overview

A Virtual Private Network (VPN) Routing and Forwarding (VRF) table is used for the forwarding of VPN packets. Each VPN corresponds to a VRF table.

A device that provides the VPN service has multiple routing tables, including a public network routing table and one or multiple VRF tables. The public-network routing table is used for the forwarding of public network packets, and the VRF tables are used for the forwarding of VPN packets. These routing tables are created to separate routes in the public network from those in VPNs and separate routes in different VPNs.

 A VPN is a private dedicated network built in the public network. "Virtual" means that the VPN is logically exclusive, instead of physically exclusive.

11.2 Applications

Application	Description
Local Inter-VPN Access	Provide the VPN service on a routing device and enable VPNs to access each other.
VRF only on Provider Edges (PEs)	Provide the VPN service in an IP network and connect one Customer Edge (CE) to one VPN.
VRF on CEs and PEs	Provide the VPN service in an IP network and connect one CE to multiple VPNs.

 CE: An edge device in a customer network

 PE: An edge device in a Service Provider (SP) network

11.2.1 Local Inter-VPN Access

Scenario

Provide the VPN service on a routing device and enable VPNs to access each other.

In Figure 11-1, Sub a runs the Routing Information Protocol (RIP), Sub b runs the Open Shortest Path First (OSPF) protocol, and Servers is a network segment directly connected to C. Provide the VPN service on C to Sub a, Sub b, and Servers, and enable Sub a and Sub b to access Servers.

Figure 11-1

Related Configuration

- On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP.
- On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF.
- On C, create a VRF table for Servers and bind the interface directly connected to Servers.
- On C, configure the route targets (RTs) of the VRF tables for Suba, Subb, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b.
- Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b, and introduce the direct routes to the VRF table for Servers.

11.2.2 VRF only on PEs

Scenario

An Internet Service Provider (ISP) provides the VPN service in an IP backbone network.

In Figure 11-2, VPN1 runs RIP, and VPN2 runs OSPF.

- One CE is connected to one VPN, and all routes on the CE are exclusively used by the connected VPN. Therefore, no VRF table needs to be created to separate the routes.
- On each PE, VRF tables must be created to separate the routes in VPN1, those in VPN2, and those in the public network from each other.

Figure 11-2

Deployment

- On PE1, create a VRF table for VPN1 and bind the interface directly connected to CE1. On PE2, create a VRF table for VPN1 and bind the interface directly connected to CE3.
- On PE1, create a VRF table for VPN2 and bind the interface directly connected to CE2. On PE2, create a VRF table for VPN2 and bind the interface directly connected to CE4.
- On PE1, associate the VRF table for VPN1 with CE1 by using RIP. On PE2, associate the VRF table for VPN1 with CE3 by using RIP.
- On PE1, associate the VRF table for VPN2 with CE2 by using OSPF. On PE2, associate the VRF table for VPN2 with CE4 by using OSPF.
- In the VRF instance for VPN1 on PE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on PE2 is similar.
- In the VRF instance for VPN2 on PE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on PE2 is similar.

11.2.3 VRF on CEs and PEs (MCE Application)

Scenario

An ISP provides the VPN service in an IP backbone network.

In Figure 11-3, VPN a runs RIP, VPN b runs OSPF, and PE1 and PE2 are connected to BGP.

- One Multi-VPN-Instance CE (MCE) is connected to multiple VPNs. VRF tables must be created to separate the routes in VPN a from those in VPN b.
- On each PE, VRF tables must be created to separate the routes in VPN a, those in VPN b, and those in the public network from each other.

Figure 11-3

Deployment

- On MCE1, create VRF tables for VPN a and VPN b respectively, bind the interfaces directly connected to VPN a and VPN b, and bind the VLAN interface connected to PE1. The configuration on MCE2 is similar.
- On PE1, create VRF tables for VPN a and VPN b respectively, and bind the VLAN interface connected to MCE1. The configuration on PE2 is similar.
- On MCE1, associate the VRF table for VPN a with VPN a by using RIP. The configuration on MCE2 is similar.

- On MCE1, associate the VRF table for VPN b with VPN b by using OSPF. The configuration on MCE2 is similar.
- In the VRF instance for VPN a on MCE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on MCE2 is similar.
- In the VRF instance for VPN b on MCE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on MCE2 is similar.

11.3 Features

Overview

Feature	Description
VPN Instance	A VPN instance is used to provide the VPN service. It is typically represented by a VRF table.
VPN Route	A VPN route is used to forward VPN packets.
VPN Route Attribute	Route distinguisher (RD): Identifies the VPN to which a route belongs. RT: Indicates the route trade-off mode of VRF.
Global VRF	Global default VPN instance

11.3.1 VPN Instance

A VPN instance is used to provide the VPN service. On a device that provides the VPN service, a VPN instance consists of the VRF table, interfaces, routing protocol processes, and configuration that belong to the same VPN. A VPN instance is typically represented by a VRF table.

Working Principle

A PE exchanges routes with a CE by using the related routing protocol in the corresponding VPN instance. A VRF table is bound to a specific interface to generate its interface set. Packets received on these interfaces will be associated with the VRF table and forwarded along corresponding routes.

Related Configuration

 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. Single-protocol VRF tables only support IPv4, whereas multiprotocol VRF tables support IPv4 and IPv6.

📄 Configuring a Single-Protocol VRF Table

By default, a device has no VRF table.

Run the **ip vrf** command to create a single-protocol VRF table.

Run the **ip vrf forwarding** command to bind an interface.

Currently, single-protocol VRF tables only support IPv4.

📄 Configuring a Multiprotocol VRF Table

By default, a device has no VRF table.

Run the **vrf definition** command to create a multiprotocol VRF table.

Run the **address-family ipv4** command to enable the IPv4 address family.

Run the **address-family ipv6** command to enable the IPv6 address family.

Run the **vrf forwarding** command to bind an interface.

Multiprotocol VRF tables support IPv4 and IPv6.

11.3.2 VPN Route

A VPN route is only used to forward VPN packets. It comes from:

- Direct route and host route on the bound interface
- Direct route and host route on the configured import interface (not bound)
- Static and dynamic routes (RIP, RIPv6, OSPFv2, OSPFv3, ISIS, and BGP) in the configured VPN instance

 For details about the static routes in a VPN instance, see "Configuration Guide > IP Route".

 For details about RIP in a VPN instance, see "Configuration Guide > IP Route > RIP".

 For details about RIPv6 in a VPN instance, see "Configuration Guide > IP Route > RIPv6".

 For details about OSPFv2 in a VPN instance, see "Configuration Guide > IP Route > OSPFv2".

 For details about OSPFv3 in a VPN instance, see "Configuration Guide > IP Route > OSPFv3".

 For details about ISIS in a VPN instance, see "Configuration Guide > IP Route > ISIS".

 For details about BGP in a VPN instance, see "Configuration Guide > IP Route > BGP".

11.3.3 VPN Route Attribute

The BGP extended attributes include two attributes specific to VPN routes: RD and RT.

Working Principle

RD

Two routes with the same address but different RDs in two VRF tables can be advertised separately between PEs, because the routes are sent together with their RDs through multiprotocol BGP (MP-BGP).

RT

RT in essence indicates each VRF table's route trade-off and preferences. It is mainly used to control the advertising and installation policies for VPN routes. RT is divided into the import attribute and export attribute. The import attribute indicates the route of interest, and the export attribute indicates the advertised route. A PE advertises a route to other PEs based on the RT export rule in the corresponding VRF table. The peer PE checks all received routes against the RT import rule in each VRF table. If a route matches an RT export rule (the export rule contains the import rule), it will be added to the corresponding VRF table.

Related Configuration

RD

By default, no RD is configured in VRF mode.

Run the **rd** command to configure an RD.

RT

By default, no RT is configured in VRF mode or address family mode.

Run the **route-target** { **import** | **export** | **both** } command to configure an RT.

11.3.4 Global VRF

Default VPN instance.

Working Principle

Global VRF

Configure VPN routing and attributes in the default VPN configuration mode,

Related Configuration

Enter Global VRF Mode

By default, global VRF exists.

Run the **vrf global-vrf** command to enter the global VRF mode.

11.4 Configuration

Configuration	Description and Command	
Configuring a Single-Protocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table; otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 network. IPv6 is not supported.	
	ip vrf <i>vrf-name</i>	Creates a VRF table.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.
	ip vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
	ip vrf receive <i>vrf_name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.

Configuration	Description and Command	
Configuring a Multiprotocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table. otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 or IPv6 network.	
	vrf definition <i>vrf-name</i>	Creates a VRF table.
	description <i>string</i>	Configures a VRF descriptor.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.
	address-family ipv4	Enables the IPv4 address family.
	address-family ipv6	Enables the IPv6 address family.
	vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
	vrf receive <i>vrf-name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.

11.4.1 Configuring a Single-Protocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP backbone network.
- Only IPv4 is supported.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.
- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

➤ Creating a VRF Table

- Mandatory.
- Create a VRF table for each VPN.

➤ Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.
- Run the **rd** command in single-protocol VRF mode.

✚ Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in single-protocol VRF mode.

✚ Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).
- If you bind an interface to the corresponding single-protocol VRF table and enable IPv6 on the interface, the device cannot forward the IPv6 packets received on the interface.

✚ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If policy-based routing (PBR) is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether VRF tables are created correctly on the router.

Related Commands

✚ Creating a VRF Table

Command	ip vrf <i>vrf-name</i>

Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

↘ Configuring an RD

Command	rd <i>rd_value</i>
Parameter Description	<i>rd_value</i> has the following three different parameter forms: (1) <i>rd_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public autonomous system (AS). nn is configurable in the range 0..4294967295. (2) <i>rd_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535. (3) <i>rd_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.
Command Mode	VRF configuration mode
Usage Guide	You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD. A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.

↘ Configuring an RT

Command	route-target { import export both } <i>rt_value</i>
Parameter Description	<i>rt_value</i> has the following three different parameter forms: (1) <i>rt_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295. (2) <i>rt_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535. (3) <i>rt_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.
Command Mode	VRF configuration mode
Usage Guide	A VRF table can be configured with multiple import and export RT attributes.

↘ Binding an Interface

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command	Interface configuration mode

Mode	
Usage Guide	By default, an interface does not belong to any VRF table. After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table. You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).

✚ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	ip vrf receive <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the ip vrf forwarding command, the ip vrf receive command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table. The ip vrf forwarding and ip vrf receive commands are mutually exclusive on the same interface.

✚ Displaying the VRF Information on a Device

Command	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Parameter Description	brief: Displays brief information. detail: Displays detailed information. interfaces: Displays the interface binding information. <i>vrf-name</i>: Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.

✚ Displaying the Routes in a VRF Table

Command	show ip route vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

✚ Local Inter-VPN Access

Scenario Figure 11-4																									
	Sub a, Sub b, and Servers are three VPNs that have separate address spaces. Sub a runs RIP, Sub b runs OSPF, and Servers is a network segment directly connected to C.																								
Configuration Requirements	Routes in Sub a are separated from those in Sub b, but both Sub a and Sub b can access Servers.																								
Configuration Steps	- On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP. - On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF. - On C, create a VRF table for Servers and bind the interface directly connected to Servers. - On C, configure the RTs of the VRF tables for Sub a, Sub b, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b. - Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b (enabled with an address family), and introduce the direct routes to the VRF table for Servers (enabled with an address family). <i>i</i> Planning of interfaces and addresses: <table><tr><th>Interface Description</th><th>Interface Name</th><th>IP Address/Mask</th><th>VRF Table</th></tr><tr><td>Interface on C connected to A</td><td>GE0/1</td><td>10.10.1.1/24</td><td>VRF table for Sub a</td></tr><tr><td>Interface on C connected to B</td><td>GE0/2</td><td>10.10.2.1/24</td><td>VRF table for Sub b</td></tr><tr><td>Interface on C connected to Servers</td><td>GE0/3</td><td>10.10.3.1/24</td><td>VRF table for Servers</td></tr><tr><td>Interface on A connected to C</td><td>GE0/1</td><td>10.10.1.2/24</td><td>-</td></tr><tr><td>Interface on B connected to C</td><td>GE0/2</td><td>10.10.2.2/24</td><td>-</td></tr></table>	Interface Description	Interface Name	IP Address/Mask	VRF Table	Interface on C connected to A	GE0/1	10.10.1.1/24	VRF table for Sub a	Interface on C connected to B	GE0/2	10.10.2.1/24	VRF table for Sub b	Interface on C connected to Servers	GE0/3	10.10.3.1/24	VRF table for Servers	Interface on A connected to C	GE0/1	10.10.1.2/24	-	Interface on B connected to C	GE0/2	10.10.2.2/24	-
Interface Description	Interface Name	IP Address/Mask	VRF Table																						
Interface on C connected to A	GE0/1	10.10.1.1/24	VRF table for Sub a

C# show ip route vrf Subb

Routing Table: Subb

Codes: C - connected, S - static, R - RIP, B - BGP
        O - OSPF, IA - OSPF inter area
        N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
        E1 - OSPF external type 1, E2 - OSPF external type 2
        i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2
        ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set

O    10.2.0.0/16 [20/0] via 0.0.0.0, 00:10:46, GigabitEthernet 0/2
O    10.10.2.0/24 [20/0] via 0.0.0.0, 00:10:46, GigabitEthernet 0/2
C    10.10.2.1/32 is local host.
C    10.10.3.0/24 is directly connected, GigabitEthernet 0/3
C    10.10.3.1/32 is local host.

```

Common Errors

- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

11.4.2 Configuring a Multiprotocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP backbone network.
- Support IPv4 and IPv6 through address family configuration.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.

- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

📄 Creating a VRF Table

- Mandatory.
- Create a VRF table for each VPN.

📄 Configuring an Address Family

- Mandatory.
- Enable the corresponding address family for each created VRF table.

📄 Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.

📄 Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in multiprotocol VRF mode or multiprotocol VRF address family mode.

📄 Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface.

- You must bind an interface to the corresponding multiprotocol VRF table before you configure the IPv4 or IPv6 address of the interface. If you bind the interface after its IPv4 or IPv6 address is configured, the address will be invalid.

✚ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If PBR is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether multiprotocol VRF tables are created correctly on the router and corresponding address families are enabled.

Related Commands

✚ Creating a VRF Table

Command	vrf definition <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

✚ Enabling the IPv4 Address Family

Command	address-family ipv4
Parameter Description	N/A
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv4 address family submode.

✚ Enabling the IPv6 Address Family

Command	address-family ipv6
Parameter Description	N/A
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv6 address family submode.

✚ Configuring an RD

Command	rd <i>rd_value</i>
Parameter	<i>rd_value</i> has the following three different parameter forms:

Description	(1) rd_value = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295. (2) rd_value = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535. (3) rd_value = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.
Command Mode	VRF configuration mode
Usage Guide	You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD. A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.

↘ Configuring an RT

Command	route-target { import export both } rt_value
Parameter Description	rt_value has the following three different parameter forms: (1) rt_value = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295. (2) rt_value = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535. (3) rt_value = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.
Command Mode	VRF configuration mode or VRF address family submode
Usage Guide	One VRF table can be configured with multiple import and export RT attributes.

↘ Binding an Interface

Command	vrf forwarding vrf-name
Parameter Description	vrf-name : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	By default, an interface does not belong to any VRF table. After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table. Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface. You must bind an interface to a multiprotocol VRF table before you configure the IPv4, IPv6, VRRP IPv4,

	and VRRP IPv6 addresses of the interface; otherwise, these addresses will be invalid and the IPv6 protocol on the interface will be disabled. If the IPv4 address family is deleted from the multiprotocol VRF table, the IPv4 and VRRP IPv4 addresses of all interfaces bound to the VRF table will be deleted, and the IPv4 static routes in the VRF table or next-hop routes are also deleted. If the IPv6 address family is deleted from the multiprotocol VRF table, the IPv6 and VRRP IPv6 addresses of all interfaces bound to the VRF table will be deleted, the IPv6 protocol on the interfaces will be disabled, and the IPv6 static routes in the VRF table or next-hop routes are also deleted.

✚ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	vrf receive <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the vrf forwarding command, the vrf receive command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table. The vrf forwarding and vrf receive commands are mutually exclusive on the same interface.

✚ Displaying the VRF Information on a Device

Command	show vrf [brief detail ipv4 ipv6] [<i>vrf-name</i>]
Parameter Description	brief: Displays brief information. detail: Displays detailed information. ipv4: Displays the brief information of an IPv4 VRF table. ipv6: Displays the brief information of an IPv6 VRF table. <i>vrf-name</i>: Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.

✚ Displaying the Routes in a VRF Table

Command	show ip route vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

- i** The following example only describes VRF-related configuration on A1, B1, MCE1, and PE1. The configuration on A2, B2, MCE2, and PE2 is similar.

📌 VRF on CEs and PEs (MCE Application)

Scenario Figure 11-5																									
	VPN a and VPN b have independent address spaces. VPN a runs RIP and VPN b runs OSPF.																								
Configuration Requirements	The routes in VPN a are separated from those in VPN b. A1 and A2 can access each other, and B1 and B2 can access each other.																								
Configuration Steps	● Connect MCE1 and A1 through RIP. Extend RIP routes on A1. On MCE1, create a VRF table for VPN a, bind the directly connected interface, and configure RIP routes. ● Connect MCE1 and B1 through OSPF. Extend OSPF routes on B1. On MCE1, create a VRF table for VPN b, bind the directly connected interface, and configure OSPF routes. ● Connect MCE1 and PE1 through BGP. On MCE1 and PE1, create a VRF table for each VPN, bind the VLAN interface, and configure BGP routes. ● Configure the physical link between MCE1 and PE1 in Trunk mode. ● In the VRF instance for VPN a on MCE1, redistribute the RIP routes to BGP, and redistribute the BGP routes to RIP. ● In the VRF instance for VPN b on MCE1, redistribute the OSPF routes to BGP, and redistribute the BGP routes to OSPF.

Verification	● On A1, run the show ip route command to display the routes in VPN a. ● On B2, run the show ip route command to display the routes in VPN b. ● On MCE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b. ● On PE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b.
	—

Common Errors

- A multiprotocol VRF table is configured, but no address family is enabled.
- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

11.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the routes in a specified VRF table.	clear ip route vrf <i>vrf-name</i>

Displaying

Description	Command
Displays the information of a single-protocol VRF table.	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Displays the information of a multiprotocol VRF table.	show vrf [ipv4 ipv6 brief detail] [<i>vrf-name</i>]
Displays the global VRF information.	show global-vrf [ipv4 ipv6 brief detail]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Displays the debugging information during the processes where a VRF table is created, an address family is enabled, and an interface is bound to the VRF table.	debug vrf
Prints the information of interface-related VRF operation debugging.	debug vrf interface

12 Configuring L3MAC

12.1 Overview

A layer-3 MAC address for forwarding can be configured for a device so that packets whose destination MAC addresses match the configured layer-3 MAC address are forwarded at layer 3. In data center scenarios, this MAC address can be configured in static ARP entries of neighbors so that routing can be triggered on any neighbor device.

12.2 Applications

Application	Description
Data Center Scenario	Layer-3 routing can be triggered on any neighbor without perceiving the layer-3 MAC address of the device.

12.2.1 Data Center Scenario

Scenario

A data center adopting the topology shown in the figure below is used as an example:

- A global layer-3 MAC address is configured on SW2 and SW3.
- A static ARP entry is configured on SW1.
- The MAC address in the static ARP entry configured on SW1 is the global layer-3 MAC address of its neighbors, that is, SW2 and SW3.

Figure 1-1

Deployment

- Packets from SW1 can be routed at layer 3 through its neighbors: SW2 and SW3.

12.3 Configuration

Configuration	Description and Command	
Adding a Layer-3 MAC Address	 Mandatory.	
	l3intf-mac-add	Adds a layer-3 MAC address.

12.3.1 Adding a Layer-3 MAC Address

Configuration Effect

- Add a global layer-3 MAC address so that layer-3 routing can be triggered when packets matching this layer-3 MAC address are received.

Notes

- Up to two layer-3 MAC addresses can be added.

Configuration Steps

➤ Adding a Layer-3 MAC Address

Command	l3intf-mac-add mac
Parameter Description	<i>mac</i> : Indicates the layer-3 MAC address.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Deleting a Layer-3 MAC Address

Command	no l3intf-mac-add mac
Parameter Description	<i>mac</i> : Indicates the layer-3 MAC address.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

1. Run the **show run** command to check whether the current configuration is correct.
2. Run the **show l3intf-mac-add** command to check whether the current configuration is correct.

Configuration Example

➤ Adding a Layer-3 MAC Address

Scenario Figure 1-2	
Configuration Steps	Configure a static ARP entry on SW1, and a global layer-3 MAC address on SW2 and SW3. Other configurations are omitted.
SW2	SW2# configure terminal SW2#(config)#l3intf-mac-add 0000.0001.2233
SW3	SW3# configure terminal SW3#(config)#l3intf-mac-add 0000.0001.2233
SW1	SW1# configure terminal SW1(config)# arp 192.168.22.20 0000.0001.2233 arpa
Verification	1. Run the show command to display the global MAC address configured on SW2 and SW3. 2. Pump traffic and verify that packets from SW1 are routed at layer 3 regardless of whether the next hop of SW1 is SW2 or SW3.
SW2	SW2(config)#show l3intf-mac-add l3intf mac address: 0000.0001.2235
SW3	SW3(config)#show l3intf-mac-add l3intf mac address: 0000.0001.2235

12.4 Monitoring

Displaying

Description	Command
Displays the configured global layer-3 MAC address of the device.	show l3intf-mac-add

13 Configuring Hardware Capacity Query

13.1 Overview

Hardware capacity query provides the function of querying the capacity and usage condition of the Forwarding Information Base (FIB) hardware.

Protocols and Standards

N/A

13.2 Features

Basic Concepts

Route hardware resources are classified into IPv4 route resources and IPv6 route resources by protocol, and host route resources and network route resources by route prefix.

The allocation of route resources varies with the chip hardware type.

- RG-S6500 series

Host route resources and network route resources are managed separately and their capacities are fixed. IPv4 and IPv6 host routes share the host route resources while IPv4 and IPv6 network routes share network route resources. One IPv6 route occupies twice resources of one IPv4 route. For example, if the total host route capacity is 200K, then 200K IPv4 host routes, 100K IPv6 host routes, or 100K IPv4 host routes and 50K IPv6 host routes are supported.

IPv6 network routes include network routes with the prefix length of 0-64 and network routes with the prefix length of 65-127. The two types of network route resources are managed separately and their capacities are fixed.

 When a hash conflict occurs during the configuration of host routes, network route resources are occupied and the actually used network route capacity may be greater than the displayed used capacity.

13.3 Monitoring

Displaying

Description	Command
Displays the capacity and usage condition of the FIB hardware of the switch.	show route-res usage

Debugging

N/A

 The monitoring command above is also applicable to chassis-type and box-type devices, standalone devices, and VSUs.

1 Configuring IP Multicasting

1.1 Overview

IP multicasting is abstracted hardware multicasting and an extended multicast routing protocol on the standard IP network layer.

In traditional IP transmission, only one host can send packets to a single host (unicast communication) or all hosts (broadcast communication). However, the multicast technology provides the third choice: a host can send packets to certain specified hosts.

IP multicasting is applicable to one-to-many multimedia applications.

1.2 Applications

Application	Description
PIM-DM Applications	The PIM-DM multicast service is provided on the same network.
PIM-SM Applications	The PIM-SM multicast service is provided on the same network.

1.2.1 PIM-DM Applications

Scenario

The PIM-DM multicast service is provided on the same network.

As shown in Figure 1-1:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-1

Remarks	A and B are layer-3 devices and C is a layer-2 access device. Source is connected to the Gi 0/1 interface of A, and receiver A and receiver B are connected to the Gi 0/2 and Gi 0/3 interfaces of C.

Deployment

- Run the Open Shortest Path First (OSPF) protocol on the same network to implement unicast routing.
- Run PIM-DM on the same network to implement multicast routing.
- Run the Internet Group Membership Protocol (IGMP) in a user host network segment to implement group member management.

1.2.2 PIM-SM Applications

Scenario

The PIM-SM multicast service is provided on the same network.

As shown in Figure 1-2:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-2

Remarks	A, B, and C are layer-3 routers. The multicast source is connected to the Gi 0/1 interface of A, receiver B is connected to the Gi 0/1 interface of B, and receiver B is connected to the Gi 0/1 interface of C.

Deployment

- Run OSPF on the same network to implement unicast routing.
- Run PIM-SM on the same network to implement multicast routing.
- Run IGMP in a user host network segment to implement group member management.

1.3 Features

Basic Concepts

📌 PIM Routers and PIM Interfaces

Routers enabled with PIM are called PIM routers. Interfaces enabled with PIM protocol are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for sending multicast packets are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments. The network segments where downstream interfaces are located are called downstream network segments.

📌 PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On certain PIM interfaces, borders are configured to divide a large PIM network into multiple PIM domains. Borders may reject specified multicast packets or limit transmission of PIM messages.

📌 Multicast Distribution Tree, DR and RP

Multicast packets are transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called a multicast distribution tree (MDT) and has the following types:

- Rendezvous Point Tree (RPT): The RP is regarded as the root and the designated router (DR) that connects group members is regarded as a leaf.
- Shortest Path Tree (SPT): The DR that connects multicast sources is regarded as the root, and RP or DR that connects group members is regarded as a leaf.

The DR and RP are functional roles for a PIM router.

- The RP collects multicast sources and group member information on the network.
- The DR that connects multicast sources reports multicast source information to the RP. The DR that connects group members reports group member information to the RP.

📌 (*,G) and (S,G)

- (*,G): Packets sent from any source to group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Packets sent from source S to group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

📌 ASM and SSM

PIM-SM supports the following multicast models that are applicable to different multicast address segments:

- Any-Source Multicast (ASM): In the ASM model, user hosts cannot select multicast sources. User hosts join a group and receive packets sent from all sources to the group.

- Source-Specific Multicast (SSM): In the SSM model, user hosts can select multicast sources. User hosts specify source addresses when joining a group and receive only packets sent from specified sources to the group.

i SSM model requirements: User hosts must know the multicast source address in advance using other network services so that the hosts can select multicast sources.

Overview

Feature	Description
Configuring Basic Functions of IP Multicasting	Creates a PIM network and provides data sources and user terminals on the network with the IPv4 multicast service.
Configuring a TTL Threshold	Configures a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	Allows the multicast forwarding path to be different from the unicast path.
Configuring Layer-2 Direction Control for Multicast Streams	Allows a specified multicast stream to be configured with multiple commands, that is, to be configured with multiple ports that can forward the stream. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.
Configuring RPF Route Selection Based on the Longest Match Rule	Selects an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among these three routes, the one with the longest match mask is selected as the RPF route.
Configuring Multicast Non-Stop Forwarding Parameters	During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of the multicast protocol.

Feature	Description
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	Deletes the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

1.3.1 Configuring Basic Functions of IP Multicasting

Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Working Principle

A device maintains the routing table for forwarding multicast packets through multicast routing protocols (such as PIM-DM or PIM-SM) and learns the states of group members in the directly connected network segment through IGMP. A host sends IGMP Report messages to join a specified IGMP group.

Related Configuration

➤ Enabling IPv4 Multicast Routing

By default, IPv4 multicast routing is disabled.

Run **ip multicast-routing** to enable IPv4 multicast routing.

➤ Configuring IP Multicasting on an Interface

By default, IP multicasting is disabled on an interface.

Run **ip pim sparse-mode** or **ip pim dense-mode** to enable IP multicasting on an interface.

1.3.2 Configuring a TTL Threshold

Configure a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.

Working Principle

Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Related Configuration

➤ Configuring a TTL Threshold

By default, the TTL threshold of an interface is 0.

Run **ip multicast ttl-threshold *ttl-value*** to change the TTL threshold of an interface. The value ranges from 0 to 255.

A larger value of *ttl-value* means a larger TTL value of multicast packets to be forwarded.

1.3.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Working Principle

The number of entries in the IP multicasting routing table is limited based on the actual network and service performance requirements to ensure device performance.

Related Configuration

📌 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

By default, a maximum of 1024 entries can be added to an IP multicast routing table.

Run **ip multicast route-limit** *limit* [*threshold*] to change the number of entries that can be added to the IP multicasting routing table. The value ranges from 1 to 65536.

A larger value of *limit* means a larger number of entries that can be added to the IP multicasting routing table.

1.3.4 Configuring an IP Multicasting Border

Configure an IP multicasting border to specify the transmission range of multicast packets.

Working Principle

An IP multicasting border is configured to specify the transmission range of multicast packets. When an IP multicasting border is configured on an interface, this interface cannot forward or receive multicast packets, including those sent from the local host.

Related Configuration

📌 Configuring an IP Multicasting Border

By default, no IP multicasting border is configured.

Run **ip multicast boundary** *access-list* [*in* | *out*] to configure an IP multicasting border.

1.3.5 Configuring an IP Multicasting Static Route

Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Working Principle

An RPF check is performed once multicast packets are forwarded. An IP multicasting static route can be configured to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Related Configuration

Configuring an IP Multicasting Static Route

By default, no IP multicasting static route is configured.

Run **ip mroute source-address mask** { [**bgp** | **isis** | **ospf** | **rip** | **static**] { *v4rpf-address* | *interface-type interface-number* } } [*distance*] to configure an IP multicasting static route.

1.3.6 Configuring Layer-2 Direction Control for Multicast Streams

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Working Principle

Configure layer-2 direction control for multicast streams and a forwarding interface so that multicast streams can be forwarded only through configured interfaces. In this case, layer-2 forwarding of multicast streams can be controlled.

Related Configuration

Configuring Layer-2 Direction Control for Multicast Streams

By default, layer-2 direction control for multicast streams is disabled.

Run **ip multicast static source-address group-address interface-type interface-number** to configure layer-2 direction control for multicast streams.

1.3.7 Configuring RPF Route Selection Based on the Longest Match Rule

Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Working Principle

A multicast static route, an MBGP route, and a unicast route that can be used for RPF check are selected respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules.

- If the longest match rule is used, the route with the longest match mask is selected as the RPF route. If the three routes have the same mask, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.
- Otherwise, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

Configuring RPF Route Selection Based on the Longest Match Rule

By default, the route with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Run **ip multicast rpf longest-match** to configure RPF route selection based on the longest match rule.

1.3.8 Configuring Multicast Non-Stop Forwarding Parameters

The non-stop forwarding function ensures continuous forwarding of multicast data streams during the re-convergence of multicast protocols.

Working Principle

During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

After the configured protocol convergence period times out, all multicast forwarding table entries that are not updated during the convergence period are deleted.

Related Configuration

✚ Configuring the Maximum Period for Multicast Protocol Convergence

By default, the maximum period for multicast protocol convergence is 20s.

Run **msf nsf convergence-time** *time* to configure the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s.

A larger value of *time* means a longer maximum period for multicast protocol convergence.

✚ Configuring the Multicast Packet Leakage Period

By default, the multicast packet leakage period is 30s.

Run **msf nsf leak** *interval* to configure the multicast packet leakage period. The value ranges from 0 to 3600s.

A larger value of *interval* means a longer leakage period.

1.3.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Working Principle

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries .

Related Configuration

✚ Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

By default, the overwriting mechanism upon the overflow of multicast hardware forwarding entries is disabled.

Run **msf ipmc-overflow override** to configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of IP Multicasting	 (Mandatory) It is used to configure the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.
Configuring a TTL Threshold	 Optional.	
	ip multicast ttl-threshold <i>ttl-value</i>	Configures a TTL threshold for an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	ip multicast route-limit <i>limit</i> [<i>threshold</i>]	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	ip multicast boundary <i>access-list</i> [<i>in</i> <i>out</i>]	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	ip mroute <i>source-address mask</i> { [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } } [<i>distance</i>]	Configures an IP multicasting static route.
Configuring Layer-2 Direction Control for Multicast Streams	ip multicast static <i>source-address group-address interface-type interface-number</i>	Controls the direction of data streams on layer-2 interfaces.
Configuring RPF Route Selection Based on the Longest Match Rule	ip multicast rpf longest-match	Configures RPF route selection based on the longest match rule.
Configuring Multicast Non-Stop Forwarding Parameters	msf nsf convergence-time <i>time</i>	Configures the maximum period for multicast protocol convergence.
	msf nsf leak <i>time</i>	Configures the multicast packet leakage period.
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	msf ipmc-overflow override	Configures the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4.1 Configuring Basic Functions of IP Multicasting

Configuration Effect

- Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Notes

- A PIM network needs to use existing unicast routes on the network. Therefore, IPv4 routes must be configured on the network.

Configuration Steps

↘ Enabling IPv4 Multicast Routing

- Mandatory.
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

↘ Enabling IP Multicasting for an Interface

- Mandatory.
- IP multicasting protocol should be enabled on interfaces unless otherwise specified:

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Check whether the user hosts can successfully receive packets from each group.

Related Commands

↘ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring IP Multicasting

-  For IGMP configuration, see the IGMP section.
-  For PIM-DM configuration, see the PIM-DM section.
-  For PIM-SM configuration, see the PIM-SM section.
-  After layer-3 multicasting is enabled in the private VLAN and super VLAN and a multicast source exists in the sub-VLAN, an extra entry whose ingress is the sub-VLAN into which the multicast stream enters needs to be copied due to the validity check during multicast forwarding. This results in occupation of one more multicast hardware entry and one less in the multicast capacity.

↘ Displaying Information About the Multicast Forwarding Table

Command	<code>show ip mroute [group-or-source-address [group-or-source-address]] [dense sparse] [summary count]</code>
Parameter Description	<i>group-or-source-address</i>: Specifies a group address or source address. <i>group-or-source-address</i>: Specifies a group address or source address. dense: Displays the core entry of PIM-DM multicast. sparse: Displays the core entry of PIM-SM multicast. summary: Displays summary information about multicast routing entries. count: Displays counting information about multicast routing entries.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	The three parameters are optional, and the source address and group address must be specified simultaneously. When no source address or group address is specified, all MFC entries are displayed. When only the source address and group address are specified, MFC entries of the source address and group address are displayed.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

Scenario Figure 1-3	 The diagram illustrates a network topology for IP multicast. A 'Multicast Source' (represented by a server icon) is connected to Router A at interface Gi0/1. Router A is connected to Router B at interface Gi0/2. Router B is connected to 'Receiver A' (represented by a laptop icon) at interface Gi0/1.
Configuration Steps	● Configure an IPv4 unicast routing protocol (such as OSPF) on a router. ● Enable IPv4 multicast routing on all routers. ● Enable PIM-DM on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>

	<pre> A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit </pre>
B	<pre> B# configure terminal B(config)# ip multicast-routing B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit </pre>
Verification	Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G. ● Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from G. ● Check multicast forwarding tables on A and B.
A	<pre> A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:01:55, stat expires 00:02:19 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) </pre>
B	<pre> B# show ip mroute IP Multicast Routing Table </pre>

```

Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed,
      R - RPT, S - SPT, s - SSM Group

Timers: Uptime/Stat Expiry

Interface State: Interface (TTL)

(192.168.1.100, 233.3.3.3), uptime 00:00:35, stat expires 00:02:55

Owner PIMDM, Flags: TFS

  Incoming interface: GigabitEthernet 0/2

  Outgoing interface list:

    GigabitEthernet 0/1 (1)

```

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.
- IP multicasting is not enabled on an interface.

1.4.2 Configuring a TTL Threshold

Configuration Effect

- Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Set a TTL threshold on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Set a TTL threshold to a value that is larger than the TTL value of the multicast packet on the PIM router interface directly connected to the user host and check whether the user can receive the multicast packet.

Related Commands

📄 Configuring a TTL Threshold

Command	ip multicast ttl-threshold <i>ttl-value</i>
Parameter Description	<i>ttl-value</i> : Specifies a TTL threshold for an interface. The value ranges from 0 to 255. The default value is 0.
Command Mode	Interface configuration mode
Usage Guide	A multicast-enabled device can retain a TTL threshold for each interface. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded. A TTL threshold takes effect only for multicast frames and must be configured on layer-3 interfaces.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring a TTL Threshold

Scenario Figure 1-4	 <pre> graph LR MS[Multicast Source] --- Gi0/1 A((A)) A --- Gi0/2 B((B)) B --- Gi0/1 RA[Receiver A] </pre>
Configuration Steps	- Configure the basic functions of IP multicasting. (Omitted) - Configure the TTL threshold as 100 on the Gi 0/2 interface of device A.
A	<pre> A# configure terminal A(config)#int gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ip multicast ttl-threshold 100 A(config-if-GigabitEthernet 0/2)# exit </pre>
Verification	Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G. - Configure the TTL threshold as 100 on the Gi 0/2 interface of device A, which is larger than the TTL value of the multicast packet. - Check the difference between the route forwarding entries before and after the TTL threshold is configured.
Before Configuring the TTL Threshold	<pre> A# show ip mroute </pre> IP Multicast Routing Table

	Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:08, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1)
After Configuring the TTL Threshold	<pre>A# show ip mroute</pre> IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:01, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (100)

1.4.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Configuration Effect

- Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Verification

Send N groups of multicast packets from the multicast source on the network, configure user hosts to join the groups, configure the number of entries that can be added to the IP multicast routing table as N-1, and check whether the multicast packet received by the user host is that of the N-1 group.

Related Commands

Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Command	<code>ip multicast route-limit limit [threshold]</code>
Parameter	
Description	<i>limit</i> : Specifies the number of entries in the multicast routing table. The value ranges from 1 to 65536. The default value is 1024. <i>threshold</i> : Specifies the number of entries in the multicast routing table that triggers the warning message. The default value is 65536.
Command Mode	Global configuration mode
Usage Guide	Due to limitations on hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, deteriorating the performance.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Scenario Figure 1-5	
Configuration Steps	● Configure basic the functions of IP multicasting. (Omitted) ● Configure the number of entries that can be added to the multicast routing table on device B as 2.
B	<pre>B# configure terminal</pre>

	B(config)# ip multicast route-limit 2
Verification	Enable the multicast source (192.168.1.100) to send packets to G1 (233.3.3.1), G2 (233.3.3.2), and G3 (233.3.3.3). Enable receiver A to join G1, G2, and G3. ● Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from two groups among G1, G2, and G3. ● Check multicast routing entries on A and B. ● When the number of entries in the IP multicasting routing table reaches the upper threshold, a prompt message is displayed.
A	<pre> A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.1), uptime 00:00:06, stat expires 00:03:24 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.2), uptime 00:00:05, stat expires 00:03:25 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.3), uptime 00:00:00, stat expires 00:03:30 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: </pre>

	GigabitEthernet 0/2 (1)
B	<pre> B# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.1), uptime 00:01:13, stat expires 00:03:23 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1) (192.168.1.100, 233.3.3.3), uptime 00:06:08, stat expires 00:03:23 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1) </pre>
	When the number of entries in the IP multicasting routing table reaches the upper threshold, a prompt message is displayed. <pre> B# Dec 26 10:43:07: %MROUTE-4-ROUTELIMIT: IPv4 Multicast route limit 2 exceeded - VRF default. </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.4 Configuring an IP Multicasting Border

Configuration Effect

- Configure an IP multicasting border to specify the transmission range of multicast packets.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Configure an IP multicasting border on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups. Configure an IP multicasting border on the PIM router interface connected to the user host and check whether the user can receive the multicast packet.

Related Commands

Enabling IPv4 Multicast Routing

Command	<code>ip multicast boundary access-list [in out]</code>
Parameter	<i>access-list</i> : Indicates the group address range defined by ACL.
Description	<i>in</i> : Indicates that the IP multicasting border takes effect in the incoming direction of the multicast stream. <i>out</i> : Indicates that the IP multicasting border takes effect in the outgoing direction of the multicast stream.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, IGMP and PIM-SM packets in the group range are filtered on this interface and multicast data streams are not going in and out through this interface. The ACL associated with this command can be a standard ACL or an extended ACL. For extended ACLs, only the destination address is matched and the source address is matched.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring an IP Multicasting Border

Scenario Figure 1-6	
Configuration Steps	● Configure the basic functions of IP multicasting. (Omitted) ● Configure an ACL on device A. ● Configure an IP multicasting border on the Gi 0/1 interface of device A.
A	<pre>A# configure terminal A(config)#ip access-list standard ip_multicast A(config-std-nacl)#deny any</pre>

	<pre> A(config-std-nacl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit </pre>
Verification	Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G. Run debug ip pim sparse-mode events.
A	<pre> A# debug ip pim sparse-mode events Jan 1 20:58:34: %7: VRF(0): No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 *Jan 1 20:58:34: %7: VRF(0): Ignore No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 in PIM_BOUNDARY_FLT_BOTH range </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.5 Configuring an IP Multicasting Static Route

Configuration Effect

- Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- An IP multicasting static route can be configured on each device unless otherwise specified.

Verification

Run **show ip rpf source-address** to check the RPF information of a specified source.

Related Commands

Configuring Basic Functions of IP Multicasting

Command	ip mroute <i>source-address mask</i> { [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } } [<i>distance</i>]
Parameter Description	<i>source-address</i>: Specifies the multicast source address. <i>mask</i>: Specifies the mask of the multicast source address.

	<i>protocol</i>: Indicates the unicast routing protocol currently used. <i>rpf-address</i>: Specifies the address of the RPF neighbor (next hop of the multicast source). <i>interface-type interface-number</i>: Indicates the RPF interface (outgoing interface of the multicast source). <i>distance</i>: Specifies the route management distance. The value ranges from 0 to 255. The default value is 0.
Command Mode	Global configuration mode
Usage Guide	Multicast static routes are applicable only to RPF check. If the IP address of the outgoing interface, but not the next hop, of the static multicast route needs to be specified, the outgoing interface must be a point-to-point type.

📌 Displaying the RPF Information of a Specified Source Address

Command	show ip rpf source-address
Parameter Description	<i>source-address</i> : Specifies the source IP address.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	The three parameters are optional, and the source address and group address must be specified simultaneously. When no source address or group address is specified, all MFC entries are displayed. When only the source address and group address are specified, MFC entries of the source address and group address are displayed.

Configuration Example

📌 Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

Scenario Figure 1-7	
Configuration Steps	- Configure the basic functions of IP multicasting. (Omitted) - Configure a static route to the receiver on device B.
A	<pre>B# configure terminal B(config)# ip mroute 10.10.10.10 255.255.255.255 ospf 192.168.1.1 1</pre>
Verification	Run show ip rpf to view the RPF information to the receiver before and after the configuration.

Before Configuration	<pre> B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1 </pre>
After Configuration	<pre> B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0 RPF neighbor: 192.168.1.1 RPF route: 10.10.10.10/32 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 1 Metric: 0 </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a device.

1.4.6 Configuring Layer-2 Direction Control for Multicast Streams

Configuration Effect

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Layer-2 direction control for multicast streams can be configured on layer-2 devices unless otherwise specified.

Verification

Send multicast packets on the network containing layer-2 device A, connect multiple user hosts to VLAN 1 of layer-2 device A to receive the group, configure layer-2 direction control for multicast streams on device A, and check whether multicast packets are sent to the configured layer-2 interface.

Related Commands

Configuring Layer-2 Direction Control for Multicast Streams

Command	ip multicast static <i>source-address group-address interface-type interface-number</i>
Parameter Description	<i>source -address</i> : Specifies the multicast source address. <i>group-address</i> : Specifies the multicast group address. <i>interface-type interface-number</i> : Specifies a layer-2 interface that is allowed to forward the multicast flow.
Command Mode	Global configuration mode
Usage Guide	Allow a specified multicast flow to be configured with multiple commands, that is, to be configured with multiple interfaces. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream. This command controls only the forwarding of multicast streams on the interface, but does not directly affect the processing of multicast protocols on the protocol packets. However, since certain features of the multicast protocol are driven by multicast data streams, behaviors of the multicast routing protocols may also be affected.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring Layer-2 Direction Control for Multicast Streams

Scenario Figure 1-8	<pre> graph LR Source[Source] --- Gi0/1 A[A] A --- Gi0/2 B[B] B --- Gi0/2 RA[Receiver A] B --- Gi0/3 RB[Receiver B] </pre>
Configuration Steps	● Configure the basic functions of IP multicasting. (Omitted) ● Configure layer-2 direction control for multicast streams on device B so that the streams are sent only

	to the Gi 0/2 interface.
B	<pre>A# configure terminal A(config)# ip multicast static 192.168.1.100 233.3.3.3 gigabitEthernet0/2</pre>
Verification	Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.1). Enable receivers A and B to join G. Check multicast packets received by receiver A. Receiver B should not be able to receive multicast packets from G.

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.7 Configuring RPF Route Selection Based on the Longest Match Rule

Configuration Effect

- Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Configure RPF route selection based on the longest match rule on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route to have the same priority and configure the unicast static route to have a longer mask length.

- Run **show ip rpf source-address** to check the RPF information of a specified source.

Related Commands

Configuring RPF Route Selection Based on the Longest Match Rule

Command	ip multicast rpf longest-match
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	The steps for selecting RFP routes are as follows: Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table for RPF check.

- 2, Select one from the three routes as the RPF route.

If the longest match rule is used, the route with the longest match mask is selected. If the three routes have the same mask, the one with the highest priority is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

If the longest match rule is not used, the route with the longest match mask is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring RPF Route Selection Based on the Longest Match Rule

Scenario Figure 1-9	
Configuration Steps	- Configure the basic functions of IP multicasting. (Omitted) - On device B, configure an IP multicast static route whose mask length is smaller than that of the unicast static route. - Configure RPF route selection based on the longest match rule on device B.
B	<pre> B# configure terminal B(config)# ip multicast-routing B(config)# ip mroute 10.10.10.10 255.255.0.0 ospf 192.168.1.1 B(config)# ip multicast rpf longest-match </pre>
Verification	Run show ip rpf to check the RFP information of the multicast source before and after configuring RPF route selection based on the longest match rule.
Before configuration	<pre> B#show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0 RPF neighbor: 192.168.1.1 RPF route: 10.10.0.0/16 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables </pre>

	Distance: 0 Metric: 0
After configuration	<pre> B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing prefix-length-preferred lookups across tables Distance: 110 Metric: 1 </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.

1.4.8 Configuring Multicast Non-Stop Forwarding Parameters

Configuration Effect

- The non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

📌 Configuring the Maximum Period for Multicast Protocol Convergence

- The maximum period for multicast protocol convergence can be specified on each device unless otherwise specified.

📌 Configuring the Multicast Packet Leakage Period

- The multicast leakage period can be configured on each device unless otherwise specified.

Verification

Run **show msf nsf** to check the configured multicast non-stop forwarding parameters.

Related Commands

✚ Configuring the Maximum Period for Multicast Protocol Convergence

Command	msf nsf convergence-time <i>time</i>
Parameter Description	convergence-time <i>time</i> : Specifies the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s. The default value is 20s.
Command Mode	Global configuration mode
Usage Guide	-

✚ Configuring the Multicast Packet Leakage Period

Command	msf nsf leak <i>interval</i>
Parameter Description	leak <i>interval</i> : Specifies the multicast packet leakage period. The value ranges from 0 to 3600s. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	-

✚ Displaying Multicast Non-Stop Forwarding Configurations

Command	show msf nsf
Parameter Description	-
Command Mode	Privilege, global and interface configuration modes
Usage Guide	-

Configuration Example

✚ Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

Scenario	Basic environment of the IP multicasting service (Omitted)
Configuration Steps	● Configure the basic functions of IP multicasting. (Omitted) ● Configure the maximum period for multicast protocol convergence. ● Configure the multicast packet leakage period.
A	<pre>A# configure terminal A(config)# msf nsf convergence-time 200 A(config)# msf nsf leak 300</pre>
Verification	Run show msf nsf to display multicast non-stop forwarding configurations.
A	<pre>A# show msf nsf</pre>

Multicast HA Parameters	
-----+-----+	
protocol convergence timeout	200 secs
flow leak interval	300 secs

1.4.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Configuration Effect

- Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- The overwriting mechanism upon overflow of multicast hardware forwarding entries can be configured on each device unless otherwise specified.

Verification

Run **show running-config** to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.

Related Commands

📌 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Command	msf ipmc-overflow override
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

📌 Creating the IP Multicast Service on the IPv4 Network and Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Scenario	Basic environment of the IP multicasting service (Omitted)
Configuration	● Configure the basic functions of IP multicasting. (Omitted)

Steps	Configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.
A	<pre>A# configure terminal A(config)#msf ipmc-overflow override</pre>
Verification	Run show running-config to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.
A	<pre>A# show running-config ... msf ipmc-overflow override ...</pre>

1.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and interrupt services.

Description	Command
Clears the IPv4 multicast forwarding table.	clear ip mroute { * <i>v4group-address</i> [<i>v4source-address</i>] }
Resets statistics in the IPv4 multicast forwarding table.	clear ip mroute statistics { * <i>v4group-address</i> [<i>v4source-address</i>] }

Displaying

Description	Command
Displays help guidance information of each multicast module.	multicast help
Displays status of the IPv4 multicast modules.	view multicast
Displays the IPv4 multicast forwarding table.	show ip mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [dense sparse] [summary count]
Displays IPv4 static multicast route information.	show ip mroute static
Displays the RFP Information of a specified IPv4 source address.	show ip rpf { <i>source-address</i> [<i>group-address</i>] [rd route-distinguisher] } [metric]
Displays information about IPv4 multicast interfaces.	show ip mvif [<i>interface-type interface-number</i>]
Displays the IPv4 layer-3 multicast forwarding table.	show ip mrf mfc

Description	Command
Displays the IPv4 multi-layer multicast forwarding table.	show msf msc
Displays IPv4 multicast non-stop forwarding configurations.	show msf nsf

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs running of the multicast core.	debug nsm mcast all
Debugs communication between the IPv4 multicast core and the protocol module.	debug nsm mcast fib-msg
Debugs the interface running of the IPv4 multicast core.	debug nsm mcast vif
Debugs the interface and entry statistics processing of the IPv4 multicast core.	debug nsm mcast stats
Debugs the processing of IPv4 layer-3 multicast packet forwarding.	debug ip mrf forwarding
Debugs the operation on layer-3 multicast forwarding entries on an IPv4 network.	debug ip mrf mfc
Debugs the processing of layer-3 multicast forwarding events on an IPv4 network.	debug ip mrf event
Debugs the processing of IPv4 multi-layer multicast packet forwarding.	debug msf forwarding
Debugs the operation on multi-layer multicast forwarding entries on an IPv4 network.	debug msf mfc
Debugs the bottom-layer hardware processing of IPv4 multi-layer multicast packet forwarding.	debug msf ssp
Debugs the invocation of API interfaces provided by IPv4 multi-layer multicast forwarding.	debug msf api
Debugs the processing of multi-layer multicast forwarding events on an	debug msf events

Description	Command
IPv4 network.	

2 Configuring IPv6 Multicast

2.1 Overview

IPv6 multicast is enrichment and enhancement of IPv4 multicast. In comparison with IPv4 multicast, the IPv6 multicast address mechanism is greatly enriched.

In traditional IP transmission, a host is allowed to send packets only to a single host (unicast communication) or all hosts (broadcast communication). The multicast technology provides a third choice: A host is allowed to send packets to certain hosts.

The IP multicast technology is applicable to one-to-many multimedia applications.

Protocols and Standards

IPv6 multicast covers the following protocols:

- Multicast Listener Discovery (MLD): Runs between a multicast device and a host, and tracks and learns relationships of group members.
- Protocol Independent Multicast – Sparse Mode for IPv6 (PIM-SMv6): Runs between devices and implements multicast packet forwarding by establishing a multicast routing table.

2.2 Applications

Application	Description
Typical Application of PIM-SMv6	The PIM-SMv6 multicast service is provided in the same network.

2.2.1 Typical Application of PIM-SMv6

Scenario

The PIM-SMv6 multicast service is provided in the same network.

As shown in the following figure:

- R1 and the multicast source are in the same network, R2 is configured as a rendezvous point (RP), R3 is in the same network as Receiver A, and R4 is in the same network as Receiver B. Assume that devices and hosts are correctly connected, IPv6 is enabled on each interface, and IPv6 unicast is enabled on each device.

Figure 2-1

Remarks	R1, R2, R3, and R4 are Layer-3 devices and R2 functions as an RP. The multicast source is directly connected to R1, Receiver A is directly connected to R3, and Receiver B is directly connected to R4.

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the same network to implement unicast routing.
- Run the PIM-SMv6 protocol in the same network to implement multicast routing.

2.3 Features

Basic Concepts

📌 PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

📌 PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

📌 Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

✚ (*,G), (S,G)

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

✚ ASM, SSM

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.
- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.

i SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Configuring IPv6 Multicast Basic Functions	Creates a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	Restricts the number of entries that can be added to the multicast routing table.

Feature	Description
Configuring the IPv6 Multicast Border	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	Configures multicast static routing to adopt multicast forwarding paths different from unicast forwarding paths.
Configuring Layer-2 Flow Direction Control for Multicast Streams	Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast stream.
Configuring RPF Route Selection According to the Longest Matching Principle	One optimal route is selected from each of the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among the three optimal routes, the route with the longest subnet mask matching is selected as the RPF route.

2.3.1 Configuring IPv6 Multicast Basic Functions

Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

Working Principle

A device maintains the routing table used for multicast packet forwarding over an IPv6 multicast routing protocol (such as PIM-SMv6), and learns information about the status of group members in the directly-connected network segments over the MLDv1/v2 protocol. A host joins a specific IPv6 multicast group by transmitting the MLD REPORT message.

Related Configuration

▾ Enabling the IPv6 Multicast Routing Function

The IPv6 multicast routing function is disabled by default.

Run the **ipv6 multicast-routing** command to enable the IPv6 multicast routing function.

▾ Configuring an IP Multicast Protocol on an Interface

The IPv6 multicast protocol is disabled on an interface by default.

Run the **ipv6 pim dense-mode** command to enable the IPv6 multicast protocol on an interface.

2.3.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Working Principle

Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements, so as to sustain the device performance.

Related Configuration

📌 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

By default, 1,024 entries can be added to the IP multicast routing table.

Run the **ipv6 multicast route-limit** *limit* [*threshold*] command to adjust the number of entries that can be added to the IPv6 multicast routing table. The value ranges from 1 to 65,536.

A larger value of *limit* means that more entries can be added to the IPv6 multicast routing table, and a smaller value of *limit* means that fewer entries can be added to the IPv6 multicast routing table.

2.3.3 Configuring the IPv6 Multicast Border

Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Working Principle

Configure the multicast border to specify the transmission scope of multicast packets. When the multicast forwarding border is configured on an interface, multicast packets including multicast packets sent by the local device cannot be forwarded or received by this interface.

Related Configuration

📌 Configuring the IPv6 Multicast Border

No multicast border is configured by default.

Run the **ipv6 multicast boundary** *access-list-name* [*in* | *out*] command to configure the multicast border.

2.3.4 Configuring IPv6 Multicast Static Routing

Configure IPv6 multicast static routing to specify a reverse path forwarding (RPF) interface or RPF neighbor for multicast packets from a specific multicast source.

Working Principle

The RPF check is conducted during forwarding of multicast packets. IPv6 multicast static routing can be configured to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Related Configuration

📌 Configuring IPv6 Multicast Static Routing

No multicast static routing is configured by default.

Run the **ipv6 mroute** *ipv6-prefix/prefix-length* [**bgp** | **isis** | **ospfv3** | **ripng** | **static**] { *ipv6-prefix* | *interface-type interface-number* } [*distance*] command to configure IPv6 multicast static routing.

2.3.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Working Principle

Configure Layer-2 flow direction control for multicast streams to configure the ports that are allowed to forward multicast streams. Then, multicast streams are forwarded only by the configured ports, thereby controlling Layer-2 forwarding of multicast streams.

Related Configuration

▾ Configuring Layer-2 Flow Direction Control for Multicast Streams

Layer-2 flow direction control is disabled for multicast streams by default.

Run the **ipv6 multicast static** *source-address group-address interface-type interface-number* command to configure the Layer-2 flow direction control for multicast streams.

2.3.6 Configuring RPF Route Selection According to the Longest Matching Principle

Among the three optimal routes selected from the multicast static routing table, Multiprotocol Border Gateway Protocol (MBGP) routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Working Principle

According to RPF rules, select a multicast static route, MBGP route, and unicast route used for the RPF check respectively from the multicast static routing table, MBGP routing table, and unicast routing table.

- If route selection according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.
- If route selection according to the longest matching principle is not configured, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

▾ Configuring RPF Route Selection According to the Longest Matching Principle

A route with the highest priority is selected as the RPF route by default. If the routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Run the **ipv6 multicast rpf longest-match** command to configure RPF route selection according to the longest matching principle.

2.4 Configuration

Configuration	Description and Command	
Configuring IPv6 Multicast Basic Functions	 (Mandatory) It is used to create a multicast service.	
	ipv6 multicast-routing	Enables the IPv6 multicast routing function.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	 Optional.	
	ipv6 multicast route-limit limit [threshold]	Restricts the number of entries that can be added to the multicast routing table.
Configuring the IPv6 Multicast Border	ipv6 multicast boundary access-list-name [in out]	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	ipv6 mroute ipv6-prefix/prefix-length [protocol] { v6rpf-address interface-type interface-number } [distance]	Configures IPv6 multicast static routing.
Configuring Layer-2 Flow Direction Control for Multicast Streams	ipv6 multicast static source-address group-address interface-type interface-number	Controls the flow direction of data streams on Layer-2 ports.
Configuring RPF Route Selection According to the Longest Matching Principle	ipv6 multicast rpf longest-match	Configures RPF route selection according to the longest matching principle.

2.4.1 Configuring IPv6 Multicast Basic Functions

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

Notes

- The PIM network needs to use existing unicast routing in the network. Therefore, IPv6 unicast routing must be configured in the network.

Configuration Steps

📌 Enabling the IPv6 Multicast Routing Function

- Mandatory.
- Enable the IPv6 multicast routing function on each router unless otherwise specified.

📌 Enabling an IP Multicast Protocol on Interfaces

- Mandatory.
- Enable the IPv6 multicast protocol function on interfaces unless otherwise specified.

Verification

Make multicast sources in the network send multicast packets and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.

Related Commands

▾ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The IPv6 multicast routing function must be enabled before various IPv6 multicast protocols are enabled. The IPv6 multicast routing function and the MLD snooping function are mutually exclusive.

▾ Configuring IPv6 Multicast Protocols

- i** For details about the MLD configuration method, see the *Configuring MLD*.
- i** For details about the PIM-SMv6 configuration method, see the *Configuring PIM-SMv6*.
- i** After the Layer-3 multicast function is enabled on a private VLAN and Super VLAN, if there is a multicast source in the sub-VLAN, an entry needs to be additionally copied, with the inlet of the sub-VLAN where multicast streams enter because the validity check needs to be conducted at the inlet during multicast packet forwarding. As a result, one more multicast hardware entry is occupied, and the multicast capacity needs to be decreased by one.

▾ Displaying Multicast Forwarding Table Information

Command	show ipv6 mroute [group-or-source-address [group-or-source-address]] [sparse] [summary count]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. <i>group-or-source-address</i> : Indicates the group address or source address. sparse : Displays the core entry of the PIM-SMv6 multicast routing table. summary : Displays the summary of IPv6 multicast routing entries. count : Displays the count information about IPv6 multicast routing entries.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

▾ Creating the IPv6 Multicast Service on an IPv6 Network to Support PIMv6-SM

Scenario Figure 2-2	
Configuration Steps	● Configure an IPv6 unicast routing protocol (for example, OSPFv3) on routers. ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIMv6-SM function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source.
A	<pre> A# configure terminal A(config)# ipv6 multicast-routing A(config)# interface gigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode A(config-if)# exit A(config)# interface gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode A(config-if)# exit </pre>
B	<pre> B# configure terminal B(config)# ipv6 multicast-routing B(config)# interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode B(config-if)# exit </pre>
Verification	Make Multicast Source (2001::1) send packets to G(ff16::16) and make Receiver A join G. ● Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from G. ● Check the multicast forwarding table on Receiver A and Device B.

A	<pre> A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:03:12, stat expires 00:02:03 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 </pre>
B	<pre> B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:23, stat expires 00:03:07 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 </pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- No IPv6 multicast protocol is enabled on an interface.

2.4.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Configuration Effect

- Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Verification

Make multicast sources in the network send multicast packets to N different multicast groups and make a user host join these groups. Set the number of entries that can be added to the IPv6 multicast routing table to N-1 on the device and check that multicast packets received by the user host are from N-1 groups.

Related Commands

✎ Configuring the Number of Entries That Can Be Added to the IP Multicast Routing Table

Command	ipv6 multicast route-limit <i>limit</i> [<i>threshold</i>]
Parameter Description	<i>limit</i>: Indicates the number of multicast routing entries. The value ranges from 1 to 65,536 and the default value is 1,024. <i>threshold</i>: Indicates the multicast routing entry quantity for triggering an alarm. The default value is 65,536.
Command Mode	Global configuration mode
Usage Guide	Routing entries that are beyond the allowable range of hardware can be forwarded only by software due to hardware resource restrictions, making the performance deteriorate.

Configuration Example

✎ Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Scenario Figure 2-3	<pre> graph LR Source[Source] --- Gi0/1 A((A)) A --- Gi0/2 B((B)) B --- Gi0/1 RA[Receiver A] </pre>
Configuration Steps	- Configure IP multicast basic functions (omitted). - Set the number of entries that can be added to the IP multicast routing table to 2 on Device B.
B	<pre> B# configure terminal B(config)# ipv6 multicast route-limit 2 </pre>
Verification	Make Multicast Source (2001: : 1) send packets to G1(ff16::16), G2(ff16::17), and G3(ff16::18) and make Receiver A join G1, G2, and G3. - Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from two groups of G1, G2, and G3. - Check multicast routing entries on Receiver A and Device B. - A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.
A	<pre> A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:01:01, stat expires 00:02:29 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 </pre>

	<pre> (2001::1, ff16::17), uptime 00:01:01, stat expires 00:02:29 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (2001::1, ff16::18), uptime 00:00:57, stat expires 00:02:33 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 </pre>
B	<pre> B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:29, stat expires 00:03:01 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (2001::1, ff16::17), uptime 00:00:29, stat expires 00:03:01 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 </pre>

A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.

```
B##* Jan 3 21:40:07: %MROUTE-4-ROUTELIMIT: IPv6 Multicast route limit 2 exceeded..
```

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.3 Configuring the IPv6 Multicast Border

Configuration Effect

- Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure the IPv6 multicast border on each PIM router interface unless otherwise specified.

Verification

Make multicast sources send multicast packets to multicast groups and make a user host join these multicast groups. Configure the IPv6 multicast border on the PIM router interface connected to the user host and check whether the user host can receive multicast packets.

Related Commands

📌 Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast boundary <i>access-list-name</i> [in out]
Parameter Description	<i>access-list-name</i> : Uses the group address range defined by an access control list (ACL). in : Indicates that the multicast border takes effect in the incoming direction of multicast streams. out : Indicates that the multicast border takes effect in the outgoing direction of multicast streams.
Command Mode	Interface configuration mode
Usage Guide	The ACL referenced in this command can be a standard ACL or an extended ACL. If an extended ACL is used, only destination addresses need to be matched. This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not transmitted or received by multicast border interfaces.

Configuration Example

📌 Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the IPv6 Multicast Border

Scenario Figure 2-4	
Configuration Steps	- Configure IP multicast basic functions (omitted). - Configure an ACL on Device A. - Configure the IP multicast border on Interface Gi0/1 of Device A.
A	<pre> A# configure terminal A(config)# ipv6 access-list ip_multicast A(config-ipv6-acl)#deny udp any any A(config-ipv6-acl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit </pre>
Verification	Make Multicast Source (192.168.1.100) send packets to G (233.3.3.3) and make Receiver A join G. Run the debug ipv6 pim sparse-mode events command to debug multicast events in SM mode.
A	<pre> A# debug ipv6 pim sparse-mode events Dec 28 11:54:07: %7: No cache message: src 2001::1 for ff16::16 vif 1 *Dec 28 11:54:07: %7: Ignore No cache message: src 2001::1 for ff16::16 vif 1 in PIM6_BOUNDARY_FLT_BOTH range </pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.4 Configuring IPv6 Multicast Static Routing

Configuration Effect

- Configure IPv6 multicast static routing to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure IPv6 multicast static routing on each device unless otherwise specified.

Verification

Configure IPv6 multicast static routing and then run the **show ipv6 rpf v6source-address** command to check RPF information about a specific multicast source.

Related Commands

Configuring IPv6 Multicast Static Routing

Command	ipv6 mroute <i>ipv6-prefix/prefix-length</i> [<i>protocol</i>] { <i>v6rpf-address</i> <i>interface-type interface-number</i> } [<i>distance</i>]
Parameter Description	<i>ipv6-prefix</i>: Indicates the IPv6 address of a multicast source. <i>prefix-length</i>: Indicates the subnet mask of the IPv6 address of the multicast source. <i>protocol</i>: Indicates the unicast routing protocol that is being used currently. <i>v6rpf-address</i>: Indicates the IPv6 address of the RPF neighbor (next hop to the multicast source). <i>interface-type interface-number</i>: Indicates the RPF interface (outbound interface to the multicast source). <i>distance</i>: Indicates the route management distance. The value ranges from 0 to 255 and the default value is 0.
Command Mode	Global configuration mode
Usage Guide	IPv6 multicast static routing is used only for the RPF check. To specify the outbound interface rather than the next-hop IP address of IPv6 static multicast routing, the outbound interface must be of the point-to-point type.

Displaying RPF Information About a Specific Source Address

Command	show ipv6 rpf v6source-address
Parameter Description	<i>v6source-address</i> : Indicates the IPv6 source address.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring IPv6 Multicast Static Routing

Scenario Figure 2-5	
Configuration Steps	● Configure IPv6 multicast basic functions (omitted). ● Configure a static route to the receiver on Device B.
A	<pre>B# configure terminal B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2</pre>
Verification	Run the show ipv6 rpf command to display the RPF information received by the receiver before and after configuration.
Before Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1 RPF neighbor: fe80::2d0:f8ff:fe22:341b RPF route: 2005::1/128 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
After Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2 RPF neighbor: 2002::2 RPF route: 2005::/64 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.

2.4.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configuration Effect

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure Layer-2 flow direction control for multicast streams on devices unless otherwise specified.

Verification

Make Device A send multicast packets to multicast groups in the network. Multiple user hosts connected to VLAN 1 of Device A receive multicast packets from these multicast groups. Configure Layer-2 flow direction control for multicast streams on Device A so that multicast packets are sent to configured ports.

Related Commands

📌 Configuring Layer-2 Flow Direction Control for Multicast Streams

Command	ipv6 multicast static <i>source-address group-address interface-type interface-number</i>
Parameter Description	<i>source -address</i> : Indicates the multicast source address. <i>group-address</i> : Indicates the multicast group address. <i>interface-type interface-number</i> : Indicates a Layer-2 port that is allowed to forward multicast streams.
Command Mode	Global configuration mode
Usage Guide	Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast stream. This command controls only the forwarding behavior of multicast streams on ports. It does not directly affect processing of protocol packets by multicast protocols. Some features of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.

Configuration Example

📌 Creating the IPv6 Multicast Service on an IPv6 Network and Configuring Layer-2 Flow Direction Control for Multicast Streams

Scenario Figure 2-6	
Configuration Steps	- Configure IP multicast basic functions (omitted). - Configure Layer-2 flow direction control for multicast streams on Device B so that multicast streams are transmitted only to Interface Gi0/2.
B	<pre>A# configure terminal A(config)# ipv6 multicast static 2001::1 ff16::16 gigabitEthernet 0/2</pre>
Verification	Make Multicast Source (2001: : 1) send packets to G (ff16::16) and make Receiver A and Receiver B join G. Receiver A should be able to receive multicast packets from G but Receiver B cannot receive multicast packets from G.

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.6 Configuring RPF Route Selection According to the Longest Matching Principle

Configuration Effect

Among the three optimal routes selected from the multicast static routing table, MBGP routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Notes

- The IP multicast basic functions must be configured.

Configuration Steps

- Configure RPF route selection according to the longest matching principle on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route with the same priority and configure the unicast static route to have the longest subnet mask matching.

- Run the **show ipv6 rpf v6source-address** command to check RPF information about a specific source.

Related Commands

Configuring RPF Route Selection According to the Longest Matching Principle

Command	ipv6 multicast rpf longest-match
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The steps of selecting an RPF route are as follows: Select one optimal route used for the RPF check from each of the IPv6 multicast static routing table, IPv6 MBGP routing table, and IPv6 unicast routing table. Select one route out of the three optimal routes as the RPF route. If the command for selecting the RPF route according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three optimal routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route. If the command for selecting the RPF route according to the longest matching principle is not configured, the route with the highest priority is selected out of the three optimal routes as the RPF route. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route.

Configuration Example

Creating the IPv6 Multicast Service on the IPv6 Network and Configuring the RPF Route Selection According to the Longest Matching Principle

Scenario Figure 2-7	 The diagram illustrates a network topology for IPv6 multicast. A Source is connected to Device A through interface Gi0/2. Device A is connected to Device B through interfaces Gi0/1 and Gi0/2. Device B is connected back to Device A through interfaces Gi0/1 and Gi0/2.
Configuration Steps	- Configure IP multicast basic functions (omitted). - Configure an IPv6 multicast static route with the subnet mask length smaller than that of the unicast route on Device B. - Configure the RPF route selection according to the longest matching principle on Device B.
B	<pre> B# configure terminal B(config)# ipv6 multicast-routing B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2 </pre>

	B(config)# ipv6 multicast rpf longest-match
Verification	Run the show ipv6 rpf command to display the RPF information about the multicast source before and after RPF route selection according to the longest matching principle is configured.
Before Configuration	<pre> B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2 RPF neighbor: 2002::2 RPF route: 2005::/64 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1 </pre>
After Configuration	<pre> B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1 RPF neighbor: fe80::2d0:f8ff:fe22:341b RPF route: 2005::1/128 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1 </pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.

2.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the IPv6 multicast forwarding table.	clear ipv6 mroute { * <i>v6group-address</i> [<i>v6source-address</i>] }
Clears the statistics in the IPv6 multicast forwarding table.	clear ipv6 mroute statistics { * <i>v6group-address</i> [<i>v6source-address</i>] }

Displaying

Description	Command
Displays the IPv6 multicast forwarding table information.	show ipv6 mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [sparse] [summary count]
Displays RPF information about a specific IPv6 source address.	show ipv6 rpf <i>v6source-address</i>
Displays information the IPv6 static multicast route.	show ipv6 mroute static
Displays information about the configured IPv6 multicast interface that takes effect.	show ipv6 mvif [<i>interface-type interface-number</i>]
Displays the IPv6 Layer-3 multicast forwarding table.	show ipv6 mrf mfc
Displays the IPv6 multi-layer multicast forwarding table.	show msf6 msc

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all running processes of the IPv6 multicast.	debug nsm mcast6 all
Debugs the communication between the IPv6 multicast and the protocol module.	debug nsm mcast6 fib-msg
Debugs the interface running of the IPv6 multicast.	debug nsm mcast6 mif
Debugs the processing of interfaces and behavior statistics of the IPv6 multicast.	debug nsm mcast6 stats
Debugs the Layer-3 multicast forwarding of IPv6.	debug ipv6 mrf forwarding
Debugs the operation process of IPv6 Layer-3 multicast forwarding	debug ipv6 mrf mfc

Description	Command
entries.	
Debugs the processing of IPv6 Layer-3 multicast forwarding events.	debug ipv6 mrf event
Debugs the forwarding of IPv6 multi-layer multicast packets.	debug msf6 forwarding
Debugs the operation process of IPv6 multi-layer multicast forwarding entries.	debug msf6 mfc
Debugs the underlying hardware for IPv6 multi-layer multicast forwarding.	debug msf6 ssp
Debugs the APIs for IPv6 multi-layer multicast forwarding.	debug msf6 api
Debugs the processing of IPv6 multi-layer multicast forwarding events.	debug msf6 event

3 Configuring IGMP

3.1 Overview

The Internet Group Management Protocol (IGMP) is a member of TCP/IP protocol family. It manages IP multicast members and is used to establish and maintain multicast group membership between hosts and directly neighboring multicast routers. IGMP behaviors are classified into host behaviors and device behaviors.

- At present, three IGMP versions are available, which are IGMPv1, IGMPv2 and IGMPv3.
- All IGMP versions support the Any-Source Multicast (ASM) model.
- IGMPv3 can be directly used for the Source-Specific Multicast (SSM) model.
- IGMPv1 and IGMPv2 can be used for the SSM model only when the IGMP SSM Mapping technology is supported.

Protocols and Standards

- RFC 1112: Host Extensions for IP Multicasting
- RFC 2236: Internet Group Management Protocol, Version 2
- RFC 3376: Internet Group Management Protocol, Version 3
- RFC 4605: Internet Group Management Protocol (IGMP) / Multicast Listener Discovery (MLD)-Based Multicast Forwarding ("IGMP/MLD Proxying")

3.2 Applications

Application	Description
Local IGMP Service	Implements the IGMP service in a local network.
IGMP Proxy Service	In a simple tree network topology, use the IGMP proxy service instead of the PIM service.

3.2.1 Local IGMP Service

Scenario

As shown in Figure 3-1, receivers 1 and 2 and routers A and B form a local network.

Query packets sent by router A or B are valid in the LAN, whereas Report packets sent by receivers 1 and 2 are also valid locally.

Figure 3-1

Remarks	C is the egress gateway (EG) device. A and B are core routers.

Deployment

- Routers A, B and C run OSPF.
- The interfaces of A, B and C run multicast protocols (PIM-SM or PIM-DM).

3.2.2 IGMP Proxy Service

Scenario

As shown in Figure 3-2, router A implements the proxy function working as a host and forms a local network group with router B. Router A forwards Report packets sent by receivers 1 and 2.

Figure 3-2

Remarks	Router A implements the proxy function. Router B provides the PIM service.

Deployment

- Routers A and B run OSPF.
- The interfaces of A and B run multicast protocols (PIM-SM or PIM-DM).
- The multicast proxy function is implemented on the interfaces Gi0/0 and Gi0/1 of router A.

3.3 Features

Basic Concepts

Host Behavior and Device Behavior

- Layer-3 multicast devices that run multicast management protocols are called devices and their behaviors are called device behaviors.
- PCs or simulated PCs that run multicast management protocols are called hosts and their behaviors are called host behaviors.

Querier

- Devices compete against each other by comparing IP addresses. Devices with lower IP addresses become queriers and send Query packets regularly.

IGMP Proxy-Service Interface

- This interface performs host behaviors, receives Query packets sent by upstream devices (hence also called uplink interface), and sends Report information collected by the router proxy.

IGMP Mroute-Proxy Interface

- This interface implements the router functions, sends packets received by the IGMP PROXY-SERVICE interface (hence also called downlink interface), and collects host information and sends the host information to the IGMP PROXY-SERVICE interface.

IGMP SSM Mapping

- Mapping of the SSM model. IGMPv1 and IGMPv2 do not support the SSM model, but can enable the SSM-MAP function to support the SSM model.

Overview

Feature	Description
IGMP Router	Sends Query packets and obtains local member information.
IGMP Querier	Selects a unique querier from a network segment.
IGMP Group Filtering	Filters group members and limit the number of group members.
Static IGMP Group	Static group information is available on a router; therefore, it is unnecessary for the host to send a Report packet to obtain the static group information.
Simulating Hosts to Join IGMP Groups	Simulate the host behavior to directly join a multicast group on an interface.
IGMP Proxy	Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed.

Feature	Description
IGMP SSM Mapping	Provide the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.
Router Alert Option	Checks whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option. Sends IGMP packets with the Router Alert option.

3.3.1 IGMP Router

- This function is used to send Query packets and obtain local member information.

Working Principle

- In a multicast network running the IGMP, a multicast device periodically sends IGMP Query packets and confirms information about local members based on responses.
- Only one multicast device sends IGMP Query packets in one network segment and this device is called querier. The querier is determined by means of selection. Initially, all multicast devices are in the Querier state. When a device receives a membership query from a device with a lower IP address, the device changes from the Querier state to the Non-querier state. Therefore, only one device is in the Querier state finally. This device has the lowest IP address among all multicast devices in the network.
- The querier sends IGMP packets of different versions based on the IGMP version settings. In addition, the following querier parameters can be modified: frequency for the querier to send IGMP Query packets, query times and query interval for the last member, maximum response time of IGMP Query packets, and keepalive time of the existing querier.

Related Configuration

📌 Enabling IGMP

IGMP is disabled on an interface by default.

You can run the **ip pim { sparse-mode | dense-mode }** command to enable or disable IGMP for an interface.

IGMP can be enabled only when Sparse Mode (SM) or Dense Mode (DM) is configured on the interface.

📌 Specifying the IGMP Version

IGMPv2 is enabled by default.

You can run the **ip igmp version { 1 | 2 | 3 }** command to set or reset the IGMP version.

📌 Configuring the Last-Member Query Interval

The interval for sending the last-member Query packets is 1s by default.

You can run the **ip igmp last-member-query-interval** *interval* command to set or reset the interval for an interface to send Query packets.

A larger value means a larger interval; a smaller value means a smaller interval.

✚ Configuring the Last-Member Query Times

The number of the last-member query times is 2 by default.

You can run the **ip igmp last-member-query-count** *count* command to set or reset the number of the last-member query times.

A larger value means more last-member query times; a smaller value means fewer last-member query times.

✚ Configuring the Common Member Query Interval

The common member query interval is 125s by default.

You can run the **ip igmp query-interval** *seconds* command to set or reset the common member query interval.

A larger value means a larger common query interval; a smaller value means a smaller common query interval.

✚ Configuring the Maximum Response Time

The maximum response time is 10s by default.

You can run the **ip igmp query-max-response-time** *seconds* command to set or reset the maximum response time.

A larger value means longer response time; a smaller value means shorter response time.

3.3.2 IGMP Querier

Select a unique querier from a network segment. The querier sends Query packets to obtain group information of the local network.

Working Principle

In a multicast network running IGMP, a multicast device is specified for sending IGMP Query packets. This device is determined through selection. At the beginning, all devices are in the Querier state. When the devices receive membership queries from a device with a lower IP address, the devices change from the Querier state to the Non-querier state. Therefore, only one device is in the Querier state finally. This device has the lowest IP address among all multicast devices in the network. When the selected querier fails, IGMPv2 also works. Non-querier devices maintain the interval timer for survival of querier. This timer is reset each time a device receives a membership Query packet. If the timer expires, a new round of querier selection starts.

Related Configuration

✚ Configuring the Querier Timeout

The querier timeout is 255s by default.

You can run the **ip igmp query-timeout** *seconds* command to set the querier timeout.

A larger value means longer survival time; a smaller value means shorter survival time.

3.3.3 IGMP Group Filtering

Filter group members and limit the number of group members.

Working Principle

To prevent hosts in a network segment where an interface resides from joining a multicast group, you can configure an ACL on this interface as a filter. The interface will filter the received IGMP membership Report packets based on this ACL, maintain group membership only for multicast groups allowed by this ACL and set the maximum number of router members.

Related Configuration

📌 Configuring the IGMP Group ACL

By default, no ACL is used and any group is allowed to join.

You can run the **ip igmp access-group** *access-list-name* command to set or reset the multicast group ACL.

After the ACL is configured, a router receives only packets set in the ACL.

📌 Configuring the Maximum Number of IGMP Group Members

The maximum number of IGMP group members is 1,024 by default.

You can run the **ip igmp limit** *number* command to set or reset the maximum number of multicast group members.

A larger value means more members; a smaller value means fewer members.

3.3.4 Static IGMP Group

When static IGMP groups are available on a router, it is unnecessary for the host to send a Report packet to obtain the static group information. The router can directly exchange group information with a PIM router.

Working Principle

You need to set static group information manually.

Related Configuration

📌 Configuring a Static Group

No static group is configured by default.

You can run the **ip igmp static-group** *group-address* command to configure a static group.

3.3.5 Simulating Hosts to Join IGMP Groups

Simulate the host behavior to directly join a multicast group on an interface.

Related Configuration

✚ Configuring the Join-Group function

No join-group information is set by default.

You can run the **ip igmp join-group group-address** command to configure the address of the multicast group to be joined by the simulated host.

3.3.6 IGMP Proxy

Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed. In this way, a downstream proxy host can send IGMP packets and maintain the membership.

Working Principle

When an upstream router is configured as an IGMP proxy-service interface, it is equal to a host that can receive Query packets sent by upstream routers or forward group information sent by downstream hosts. When a downstream router is configured as an IGMP multicast proxy interface, it is equal to a router that can forward Query packets sent by upstream routers or receive Report packets sent by downstream routers.

Related Configuration

✚ Configuring the IGMP Proxy Service

The IGMP proxy service function is disabled by default.

You can run the **ip igmp proxy-service** command to enable the IGMP proxy service.

This function is mandatory when a proxy is to be used.

✚ Configuring the IGMP Mroute Proxy

The IGMP mroute proxy function is disabled by default.

You can run the **ip igmp mroute-proxy interface-name** command to enable the IGMP mroute proxy.

This function is mandatory when a proxy is to be used.

3.3.7 IGMP SSM Mapping

Provide the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.

Working Principle

Based on IGMP v1/v2, IGMPv3 provides an extra function, namely, the multicast source filter function. In IGMPv1/v2, a host determines to join a group only based on the group address and then receive multicast streams sent to this group address from any source. A host using IGMPv3 advertises the multicast group that the host wants to join and the addresses of multicast sources from which this host wants to receive packets. IGMPv1 and IGMPv2 also implement "source address filtering" in some sense; however, they implement this function on the multicast receivers by enabling the SSM mapping function and configuring the static SSM mapping group.

Related Configuration

➤ Enabling IGMP SSM Mapping

The SSM mapping function is disabled by default.

You can run the **ip igmp ssm-map enable** command to enable the function.

Mandatory.

➤ Configuring Static IGMP SSM Mapping

No static SSM mapping is set by default.

You can run the **ip igmp ssm-map static access-list-num A.B.C.D** command to configure static SSM mapping.

3.3.8 Router Alert Option

Check whether IGMP packets contain the Router Alert option and discard packets without the Router Alert option.

Support sending IGMP packets containing the Router Alert option.

Working Principle

If a packet contains the Router Alert option, the device needs to check the packet in depth and updates the control data accordingly. If the packet does not contain the option, the device does not check the packet.

After Router Alert option check is enabled, the IGMP packets not containing the Router Alert option are discarded.

After enabled with the function of sending packets with Router Alert option, the device sends IGMP packets with Router Alert option encapsulated.

Related Configuration

➤ Checking Router Alert Option

Router Alert option check is disabled by default.

You can run the **ip igmp enforce-router-alert** command to enable the function.

➤ Sending IGMP Packets with Router Alert Option Encapsulated

Packets are sent without the Router Alert option by default.

You can run the **ip igmp send-router-alert** command to enable the function.

3.4 Configuration

Configuration	Description and Command	
Configuring IGMP Basic Functions	 (Mandatory) It is used to set up the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.

	ip pim { sparse-mode dense-mode }	Enables the PIM-SM or PIM-DM function.
Configuring IGMP Routers	ip igmp version { 1 2 3 }	Specifies the IGMP version.
	ip igmp last-member-query-interval interval	Configures the last-member query interval.
	ip igmp last-member-query-count count	Configures the last-member query times.
	ip igmp query-interval seconds	Configures the membership query interval.
	ip igmp query-max-response-time seconds	Configures the maximum response time.
Configuring IGMP Querier	ip igmp query-timeout seconds	Configures the querier timeout.
Configuring IGMP Group Filtering	ip igmp access-group access-list	Configures the IGMP group ACL.
	ip igmp limit number [except access-list]	Configures the maximum number of IGMP group members.
Configuring IGMP Proxy	ip igmp proxy-service	Configures the IGMP proxy service.
	ip igmp mroute-proxy interface-type interface-number	Configures the IGMP mroute proxy.
Configuring IGMP SSM Mapping	ip igmp ssm-map enable	Enables IGMP SSM mapping.
	ip igmp ssm-map static access-list source-address	Configures static IGMP SSM mapping.
Configuring Alert Option	ip igmp enforce-router-alert	Checks the Router Alert option.
	ip igmp send-router-alert	Sends IGMP packets containing the Router Alert option.

3.4.1 Configuring IGMP Basic Functions

Configuration Effect

- Enable the multicast routing function of a local network and collect group information of the local network.

Notes

- An interface must be enabled with the PIM-SM or PIM-DM function.

Configuration Steps

📌 Enabling the IPv4 Multicast Routing Function

- Mandatory.
- If there is no special requirement, the IPv4 multicast routing function should be enabled on each router in the local network.

📌 Enabling the PIM-SM or PIM-DM Function

- Mandatory.

- If there is no special requirement, the PIM-SM or PIM-DM function should be directly enabled on an interface of the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to check whether IGMP is enabled on the interface.

Related Commands

▾ Enabling the IPv4 Multicast Routing Function

Command	ip multicast-routing
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling the PIM-SM or PIM-DM Function

Command	ip pim { sparse-mode dense-mode }
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including routing interfaces, L3AP, SVI and loopback interfaces. All PIM interfaces should be accessible to IPv4 unicast routes.

Configuration Example

▾ Enabling IGMP for a Local Network

Scenario	● Configure an IPv4 unicast routing protocol (such as OSPF) on a router and ensure that the loopback interface is accessible to a unicast route. ● Enable the IPv4 multicast route function on all routers. ● Enable the PIM-SM or PIM-DM function on interfaces interconnecting devices and interfaces connecting user hosts and multicast sources.
	<pre>VSU(config)#ip multicast-routing VSU(config)#int gi 0/5 VSU(config-if-GigabitEthernet 0/5)#ip add 192.168.1.90 255.255.255.0 VSU(config-if-GigabitEthernet 0/5)#ip pim sparse-mode</pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check whether IGMP is enabled on the interface.

```
VSU#show ip igmp interface gigabitEthernet 0/5

Interface GigabitEthernet 0/5 (Index 5)

IGMP Active, Querier, Version 2 (default)

Internet address is 192.168.1.90

IGMP interface limit is 1024

IGMP interface has 1 group-record states

IGMP interface has 0 static-group records

IGMP activity: 3 joins, 0 leaves

IGMP query interval is 125 seconds

IGMP querier timeout is 255 seconds

IGMP max query response time is 10 seconds

Last member query response interval is 10

Last member query count is 2

Group Membership interval is 260 seconds

Robustness Variable is 2
```

Common Errors

- Routers in the network are not enabled with the multicast routing function.
- No multicast interface is available in the network.

3.4.2 Configuring IGMP Routers

Configuration Effect

- Modify the IGMP router parameters will affect the type of packets to be sent and the sending method.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

➤ Specifying the IGMP Version

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

➤ Configuring the Last-Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

✚ Configuring the Last-Member Query Times

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

✚ Configuring the Common Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

✚ Configuring the Maximum Response Time

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to display the interface configurations.

Related Commands

✚ Specifying the IGMP Version

Command	ip igmp version { 1 2 3 }
Parameter Description	1: Indicates IGMPv 1. 2: Indicates IGMPv 2. 3: Indicates IGMPv 3.
Command Mode	Interface configuration mode
Usage Guide	After this command is configured, IGMP will automatically restart.

✚ Configuring the Last-Member Query Interval

Command	ip igmp last-member-query-interval <i>interval</i>
Parameter Description	<i>Interval</i> : Indicates the interval for sending the Query packets of a specific group. The value ranges from 1 to 255 in the unit of 0.1s, and the default value is 10 (namely, 1s).
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3.

	When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

✚ Configuring the Last-Member Query Times

Command	ip igmp last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Indicates the times for sending the Query packets of a specific group, ranging from 2 to 7. The default value is 2.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3. When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

✚ Configuring the Common Member Query Interval

Command	ip igmp query-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the common member query interval, ranging from 1 to 18,000s. The default value is 125.
Command Mode	Interface configuration mode
Usage Guide	N/A

✚ Configuring the Maximum Response Time

Command	ip igmp query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the maximum response time, ranging from 1 to 25s. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, the interface waits for a response. If timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the group information.

Configuration Example

✚ Configuring Basic Router Parameters

Scenario	● Configure basic functions of IGMP. ● Specify the IGMPv3. ● Configure the last-member query interval to 15 (1.5s). ● Configure the number of the last-member queries to 3. ● Configure the common member query interval to 130s. ● Configure the maximum response time to 15s.
	<pre> VSU(config-if-GigabitEthernet 0/5)#ip igmp version 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-count 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-interval 130 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-max-response-time 15 </pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check the IGMP functions of the interface.
	<pre> VSU#show ip igmp interface gigabitEthernet 0/5 Interface GigabitEthernet 0/5 (Index 5) IGMP Enabled, Active, Querier, Version 3 Internet address is 192.168.1.90 IGMP interface limit is 1024 IGMP interface has 1 group-record states IGMP interface has 0 static-group records IGMP activity: 3 joins, 0 leaves IGMP query interval is 130 seconds IGMP querier timeout is 267 seconds IGMP max query response time is 15 seconds Last member query response interval is 15 Last member query count is 3 Group Membership interval is 275 seconds Robustness Variable is 2 VSU# </pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.3 Configuring IGMP Querier

Configuration Effect

- Select a unique querier in a local network.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

- If necessary, the querier timeout can be configured.
- If there is no special requirement, you can perform the configuration on all interfaces enabled with IGMP in the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to display the interface configurations.

Related Commands

📌 Configuring the Querier Timeout

Command	ip igmp query-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keepalive time of the querier, ranging from 60 to 300s. The default value is 255s.
Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, an interface waits for Query packets sent by other devices. If timeout occurs, the IGMP router assumes that the querier is unique in the directly connected network segment.

Configuration Example

📌 Configuring the Querier Timeout

Scenario	● Configure basic functions of IGMP. ● Set the querier timeout to 280S.
	VSU(config-if-GigabitEthernet 0/5)#ip igmp query-timeout 280
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check the IGMP functions of the interface.

```
VSU#show ip igmp interface gigabitEthernet 0/5

Interface GigabitEthernet 0/5 (Index 5)

  IGMP Enabled, Active, Querier, Version 3

  Internet address is 192.168.1.90

  IGMP interface limit is 1024

  IGMP interface has 1 group-record states

  IGMP interface has 0 static-group records

  IGMP activity: 11 joins, 0 leaves

  IGMP query interval is 130 seconds

  IGMP querier timeout is 280 seconds

  IGMP max query response time is 15 seconds

  Last member query response interval is 15

  Last member query count is 3

  Group Membership interval is 275 seconds

  Robustness Variable is 2

VSU#
```

Common Errors

- The basic functions of IGMP are not enabled.

3.4.4 Configuring IGMP Group Filtering

Configuration Effect

- A router filters IGMP group members.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

📌 Configuring the IGMP Group ACL

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

✚ Configuring the Maximum Number of IGMP Group Members

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

✚ IGMP Group ACL

- Configure an interface to allow only groups in ACL 1 to join. The access addresses of ACL 1 are 225.0.0.1~225.0.0.255.
- Configure the interface to join a group whose address is 225.0.0.5.
- Configure the interface to join a group whose address is 236.0.0.5.
- View the group information of the current interface.

✚ Maximum Number of IGMP Group Members

- Set the maximum member quantity to 5 on an interface.
- Configure the interface to join a group whose address is from 225.0.0.5 to 225.0.0.10.
- View the group information of the interface.

Related Commands

✚ Configuring the IGMP Group ACL

Command	ip igmp access-group <i>access-list</i>
Parameter Description	<i>access-list</i> : Defines a group address range by using a standard IP ACL or an extended ACL. The value ranges from 1 to 199, 1300 to 2699 and characters.
Command Mode	Interface configuration mode
Usage Guide	Configure this command on an interface to control the groups that hosts in a directly connected network segment can join. Use an ACL to limit the group address range. If Report packets denied by the ACL are received, the packets will be discarded. When IGMPv3 is enabled, this command supports an extended ACL. If the received IGMP Report information is (S1,S2,S3...Sn,G), this command will apply the corresponding ACL to the (0,G) information for matching. Therefore, you must configure a (0,G) record explicitly for the extended ACL in order to normally filter (S1,S2,S3...Sn,G).

✚ Configuring the Maximum Number of IGMP Group Members

Command	ip igmp limit <i>number</i> [except <i>access-list</i>]
Parameter Description	<i>number</i> : Indicates the maximum number of IGMP group members, whose value range varies with devices. The default value is 1,024 for an interface and 65,536 globally.

	except access-list: Indicates that the groups in the ACL are not counted. access-list indicates a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words.
Command Mode	Interface configuration mode
Usage Guide	Global configuration mode: Limits the maximum quantity of the IGMP group members in a system. Interface configuration mode: limits the maximum quantity of IGMP group members on an interface. If the quantity of group members exceeds the interface or global limit, the Report packets received subsequently will be ignored. If an Except ACL is configured, Report packets within a specified range can be normally processed; therefore, the generated group members are not counted. The interface and global configurations can be performed independently. If the global quantity limit is smaller than that for an interface, the global configuration shall be used.

Configuration Example

Configuring IGMP Group Filtering

Scenario	- Configure the basic functions of IGMP. - Configure the access address range of ACL 1 from 225.0.0.1 to 225.0.0.255. - Set the address of the group to be joined to 225.0.0.5. - Set the address of the group to be joined to 236.0.0.5.
	<pre>VSU(config)#access-list 1 permit 225.0.0.1 225.0.0.255 VSU(config-if-GigabitEthernet 0/5)#ip igmp access-group 1 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 236.0.0.5</pre>
Verification	Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.
	<pre>VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.5 GigabitEthernet 0/5 00:14:00 00:02:45 192.168.1.90</pre>

Configuring the Maximum Number of IGMP Group Members

Scenario	- Configure the basic functions of IGMP. - Configure the maximum number of IGMP group members for the interface to 5. - Add group information (225.0.0.5~225.0.0.12). - View group information.
	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp limit 5</pre>

	<pre>VSU(config-if-GigabitEthernet 0/5)# VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.6 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.7 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.8 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.9 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.10 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.11 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.12</pre>																														
Verification	Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.																														
	<pre>VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups</pre> IGMP Connected Group Membership <table><tr><th>Group Address</th><th>Interface</th><th>Uptime</th><th>Expires</th><th>Last Reporter</th></tr><tr><td>225.0.0.5</td><td>GigabitEthernet 0/5</td><td>00:20:15</td><td>00:03:09</td><td>192.168.1.90</td></tr><tr><td>225.0.0.6</td><td>GigabitEthernet 0/5</td><td>00:20:24</td><td>00:02:58</td><td>192.168.1.90</td></tr><tr><td>225.0.0.7</td><td>GigabitEthernet 0/5</td><td>00:00:15</td><td>00:04:29</td><td>192.168.1.90</td></tr><tr><td>225.0.0.8</td><td>GigabitEthernet 0/5</td><td>00:00:13</td><td>00:04:34</td><td>192.168.1.90</td></tr><tr><td>225.0.0.9</td><td>GigabitEthernet 0/5</td><td>00:00:11</td><td>00:04:33</td><td>192.168.1.90</td></tr></table>	Group Address	Interface	Uptime	Expires	Last Reporter	225.0.0.5	GigabitEthernet 0/5	00:20:15	00:03:09	192.168.1.90	225.0.0.6	GigabitEthernet 0/5	00:20:24	00:02:58	192.168.1.90	225.0.0.7	GigabitEthernet 0/5	00:00:15	00:04:29	192.168.1.90	225.0.0.8	GigabitEthernet 0/5	00:00:13	00:04:34	192.168.1.90	225.0.0.9	GigabitEthernet 0/5	00:00:11	00:04:33	192.168.1.90

Common Errors

- The basic functions of IGMP are not enabled.

3.4.5 Configuring IGMP Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

📌 Configuring the IGMP Proxy Service

- Optional.
- If there is no special requirement, you can perform this configuration on directly connected upstream router interfaces.

✚ Configuring the IGMP Mroute Proxy

- Optional.
- If there is no special requirement, you can perform this configuration on directly connected downstream host interfaces.

Verification

- Set interface 7 for directly connecting to an upstream router as a multicast proxy server.
- Set interface 1 for directly connecting to a downstream host as a multicast proxy.
- Set interface 1 to be joined by groups whose addresses are 225.0.0.6 and 225.5.5.5.
- View the current group information.

Related Commands

✚ Configuring the IGMP Proxy Service

Command	ip igmp proxy-service
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run the ip igmp proxy-service command to set the uplink interface as a Proxy-Service interface. Run the ip igmp mroute-proxy command to set the downlink interface as a Mroute-Proxy interface. Forward IGMP Query packets from the Proxy-Service interface to the Mroute-Proxy interface. Forward IGMP Report packets from the Mroute-Proxy interface to the Proxy-Service interface. A device allows a maximum of 32 Proxy-Service interfaces. After a Proxy-Service interface receives an IGMP Query packet, the interface sends a response based on the IGMP group member records. If the switchport command is executed on the Proxy-Service interface, the ip igmp mroute-proxy command configured on the Mroute-Proxy interface will be deleted automatically.

✚ Configuring the IGMP Mroute Proxy

Command	ip igmp mroute-proxy <i>interface-type interface-number</i>
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run the ip igmp proxy-service command to set the uplink interface as a Proxy-Service interface. Run the ip igmp mroute-proxy command to set the downlink interface as a Mroute-Proxy interface. Forward IGMP Query packets from the Proxy-Service interface to the Mroute-Proxy interface. Forward IGMP Report packets from the Mroute-Proxy interface to the Proxy-Service interface.

Configuration Example

Scenario	● Configure basic functions of IGMP.

	● Configure interface 7 as a proxy server. ● Configure interface 1 as a multicast proxy. ● Set interface 1 to be joined by groups whose addresses are 225.0.0.6 and 225.5.5.5.
	<pre> VSU(config-if-GigabitEthernet 0/7)#ip igmp proxy-service VSU(config-if-GigabitEthernet 0/7)#exit VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)#ip igmp mroute-proxy gigabitEthernet 0/7 VSU(config-if-GigabitEthernet 0/1)#ip igmp join-group 225.0.0.6 VSU(config-if-GigabitEthernet 0/1)#ip igmp join-group 225.5.5.5 </pre>
Verification	Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.
	<pre> VSU(config-if-GigabitEthernet 0/1)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.6 GigabitEthernet 0/1 00:23:05 00:02:40 192.168.36.90 225.5.5.5 GigabitEthernet 0/1 00:22:06 00:02:41 192.168.36.90 IGMP Proxy-server Connected Group Membership Group Address Interface Uptime 225.0.0.6 GigabitEthernet 0/7 00:23:05 225.5.5.5 GigabitEthernet 0/7 00:22:06 VSU(config-if-GigabitEthernet 0/1)# </pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.6 Configuring IGMP SSM Mapping

Configuration Effect

- IGMPv3 supports source filtering; however, IGMPv1 and IGMPv2 do not support source filtering, but provides the SSM mapping function to filter sources.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

✚ Enabling SSM Mapping

(Mandatory) Enable the SSM mapping function.

Enable the SSM mapping function on a router.

✚ Configuring Static SSM Mapping

Optional.

Configure this function on routers enabled with SSM mapping.

Verification

Run the **show ip igmp ssm-mapping** [*group-address*] command to display SSM mapping information.

Related Commands

✚ Enabling SSM Mapping

Command	ip igmp ssm-map enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp ssm-map enable command to enable the SSM mapping function. Run the ip igmp ssm-map static command to set static mapping entries. Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.

✚ Configuring Static SSM Mapping

Command	ip igmp ssm-map static <i>access-list source-address</i>
Parameter Description	N/A <i>access-list</i> : Indicates the group address range set by a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words. <i>source-address</i> : Indicates the source address.
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp ssm-map enable command to enable the SSM mapping function. Run the ip igmp ssm-map static command to set static mapping entries. Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.

Configuration Example

Scenario	Configure the basic functions of IGMP.

	● Enable SSM mapping. ● Configure static SSM mapping ACL 1.
	<pre>VSU(config)#ip igmp ssm-map enable VSU(config)#ip igmp ssm-map static 1 192.168.5.9</pre>
Verification	Run the show ip igmp ssm-mapping [group-address] command to display SSM mapping information.
	<pre>VSU#show ip igmp ssm-mapping SSM Mapping : Enabled Database : Static mappings configured</pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.7 Configuring Alert Option

Configuration Effect

Check whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option.

Support sending IGMP packets with the Router Alert option.

Notes

The basic functions of IGMP must be configured.

Configuration Steps

Checking Router Alert Option

Optional.

Sending IGMP Packets with Router Alert Option Encapsulated

Optional,

Verification

📌 Checking Router Alert Option

Check whether the IGMP-enabled interface discards the IGMP packets without the Router Alert option.

📌 Sending IGMP Packets with Router Alert Option Encapsulated

Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

Related Commands

📌 Checking Router Alert Option

Command	ip igmp [vrf <i>vrf-name</i>] enforce-router-alert
Parameter Description	vrf <i>vrf-name</i> : Specifies a VRF.
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp enforce-router-alert command to enable Router Alert option check. Run the no ip igmp enforce-router-alert command to disable Router Alert option check.

✚ Sending IGMP Packets with Router Alert Option Encapsulated

Command	ip igmp [vrf <i>vrf-name</i>] send-router-alert
Parameter Description	vrf <i>vrf-name</i> : Specifies a VRF.
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp send-router-alert command to enable the function of sending IGMP packets containing Router Alert option. Run the no ip igmp send-router-alert command to disable the function.

Configuration Example

✚ Checking Router Alert Option

Scenario	Configure the basic functions of IGMP. Configure Router Alert option check.
	<pre>VSU(config)#ip igmp enforce-router-alert</pre>
Verification	IGMP packets containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are processed. Run the show ip igmp groups command and you will see 225.1.1.1. IGMP packets not containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are discarded. Run the show ip igmp groups command and you will not see 225.1.1.1

✚ Sending IGMP Packets with Router Alert Option Encapsulated

Scenario	Configure the basic functions of IGMP. Configure the function of sending IGMP packets containing router alert option.

	VSU(config)#ip igmp send-router-alert
Verification	Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

3.5 Monitoring

Clearing

Description	Command
Clears dynamic group membership from the IGMP buffer.	clear ip igmp group
Clears interface information from the IGMP buffer.	clear ip igmp interface <i>interface-type interface-number</i>

Displaying

Description	Command
Displays all groups in a directly connected subnet.	show ip igmp groups
Displays details about all groups in a directly connected subnet.	show ip igmp groups detail
Displays specified groups in a directly connected subnet.	show ip igmp groups <i>A.B.C.D</i>
Displays details about specified groups in a directly connected subnet.	show ip igmp groups <i>A.B.C.D detail</i>
Displays IGMP configurations of a specified interface in a directly connected subnet.	show ip igmp interface <i>interface-type interface-number</i>
Displays details about all groups of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number detail</i>
Displays information about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number A.B.C.D</i>
Displays details about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number A.B.C.D detail</i>
Displays configurations of an IGMP interface.	show ip igmp interface [<i>interface-type interface-number</i>]

Displays configurations of all IGMP interfaces.	show ip igmp interface
Displays configurations of IGMP SSM mapping.	show ip igmp ssm-mapping
Displays the information of IGMP SSM mapping to <i>A.B.C.D</i> .	show ip igmp ssm-mapping <i>A.B.C.D</i>

Debugging

Description	Command
Displays whether IGMP debugging is enabled.	show debugging
Debugs all IGMP information.	debug ip igmp all
Debugs IGMP packet decoding.	debug ip igmp decode
Debugs IGMP packet encoding.	debug ip igmp encode
Debugs IGMP events.	debug ip igmp events
Debugs IGMP FSM.	debug ip igmp fsm
Debugs IGMP state machine.	debug ip igmp tib
Debugs IGMP warning.	debug ip igmp warning

4 Configuring MLD

4.1 Overview

Multicast Listener Discovery (MLD) is a protocol used in the multicast technology.

This protocol receives the multicast member relationship between hosts and routers to determine multicast flow forwarding. Using information obtained from MLD, a device maintains an interface-based multicast listener status table. The multicast listener status table is activated only when at least one host in the link of the interface is a group member.

Currently, MLD has two versions: MLDv1 and MLDv2.

- MLD of both versions supports the Any-Source Multicast (ASM) model.
- MLDv2 can be directly applied to the Source-Specific Multicast (SSM) model.
- MLDv1 can be applied to the SSM model only when MLD SSM mapping is configured.

Protocols and Standards

- RFC2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

4.2 Applications

Application	Description
Configuring the MLD Service on the Local Network	Implements the MLD service on the local network.
Configuring the MLD Proxy Service	In the simple tree topology, the MLD proxy service, instead of the PIM service, is used.

4.2.1 Configuring the MLD Service on the Local Network

Scenario

As shown in Figure 4-1, the local network consists of receiver 1, receiver 2, router A, and router B.

Query messages sent by router A or router B are valid on the local network, and Report messages sent by receiver A and receiver B are also valid on the local network.

Figure 4-1

Remarks	Router C is the egress gateway. Routers A and B are local routers.

Deployment

- Routers A, B, and C run the OSPFv6 protocol.
- Interfaces on routers A, B, and C run the multicast protocol (PIM SMv6).

4.2.2 Configuring the MLD Proxy Service

Scenario

As shown Figure 4-2, the proxy function is enabled on router A. Router A functions as a host and forms a local management group with router B. Router A forwards Report messages from receivers 1 and 2.

Figure 4-2

Remarks	Router A functions as the proxy. Router B provides the PIM service.

Deployment

- Routers A and B run the OSPFv6 protocol.

- Interfaces on routers A and B run the multicast protocol (PIM SMv6).
- The multicast proxy service is enabled on Gi 0/0 and Gi 0/1 of router A.

4.3 Features

Basic Concepts

Host Behaviors and Device Behaviors

Layer-3 multicast devices running multicast management protocols are referred to as devices and their behaviors are device behaviors.

PCs or simulated PCs running multicast management protocols are referred to as hosts and their behaviors are host behaviors.

Querier

Devices interact and compete with each other. After IP address comparison, the device with a lower IP address becomes the querier and periodically sends Query messages.

MLD PROXY-SERVICE Interface

This interface, also called uplink interface, implements host behaviors. It receives Query messages sent by upstream devices and sends Report messages collected by the router proxy.

MLD MROUTE-PROXY Interface

This interface, also called downlink interface, implements router functions. It sends messages received by the proxy service interface and collects and sends host information to the proxy service interface.

MLD SSM-MAP

SSM mapping refers to mapping of source-specific multicast. MLDv1 does not support the SSM model until the SSM-MAP function is enabled.

Overview

Feature	Description
Setting MLD Router Parameters	Sends Query messages to obtain local member information.
Querier Selection Process or Timeout Mechanism	Selects the unique querier in the current network segment.
Filtering MLD Groups	Filters group members and limits the number of group members.
Supporting Static MLD Groups	Stores static group information on the local router instead of obtaining group information by sending Report messages.

Feature	Description
Configuring Simulated Host Group Information	Simulates host behaviors to directly configure group joining information.
Supporting MLD Proxy	Uses this function in the simple tree topology instead of complex multicast routing protocols, such as the PIM.
Supporting SSM-MAP	Provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

4.3.1 Setting MLD Router Parameters

Sends Query messages to obtain local member information.

Working Principle

A device periodically sends Query messages to ensure that a group has at least one host. If no host is available in a group, the group will be deleted.

Related Configuration

▾ Enabling MLD

By default, MLD is disabled on an interface.

Run the **ipv6 pim { sparse-mode }** command to enable or disable MLD on an interface.

MLD can be enabled only after PIM SM is enabled on the interface.

▾ Configuring MLD Version

By default, the MLD version is 2.

Run the **ipv6 mld version { 1 | 2 }** command to configure or restore the MLD version of an interface.

▾ Configuring the Query Interval of the Last Member

By default, the interval for sending Query messages is 1s.

Run the **ipv6 mld last-member-query-interval *interval*** command to configure or restore the interval for sending Query messages.

A larger value means a longer interval for sending Query messages.

▾ Configuring the Number of Times for Querying the Last Member

By default, the number of times for querying the last member is 2.

Run the **ipv6 mld last-member-query-count *count*** command to configure or restore the number of times for querying the last member.

A larger value means a larger number of times for querying the last member.

✎ Configuring the Interval for Querying a Common Member

By default, the interval for querying a common member is 125s.

Run the **ipv6 mld query-interval** *seconds* command to configure or restore the interval for querying a common member.

A larger value means a longer interval for querying a common member.

✎ Configuring the Maximum Response Time

By default, the maximum response time is 10s.

Run the **ipv6 mld query-max-response-time** *seconds* command to configure or restore the maximum response time.

A larger value means a longer maximum response time.

4.3.2 Querier Selection Process or Timeout Mechanism

Selects the unique querier in the current network segment. The querier sends a Query message to obtain group information on the local network.

Working Principle

On a multicast network running MLD, a multicast device dedicated to query sends MLD Query messages. The device is determined by election. Initially, all devices are in the querier state. When receiving member relationship Query messages from devices with lower IP addresses, the devices switch from the receiver state to non-querier state. Therefore, there is only one device in the query state in the end. This device has the lowest IP address among all multicast devices on the network. When the querier device does not work, MLD also works. Non-querier devices maintain the keepalive interval timer for other queriers. The timer is reset once the device receives a member relationship query message. If the timer times out, the device starts to send Query messages and a new querier election starts.

Related Configuration

✎ Configuring the Keepalive Interval of the Querier

By default, the keepalive interval of the querier is 255s.

Run the **ipv6 mld querier-timeout** *seconds* command to configure or restore the keepalive interval of the querier.

A larger value means a longer keepalive interval of the querier.

4.3.3 Filtering MLD Groups

Filters group members and limits the number of group members.

Working Principle

If you do not want hosts in the network segment where an interface resides to be added to certain multicast groups, you can configure ACL rules on the interface as a filter. The interface will filter received MLD member relationship Report messages

based on the ACL rules and maintain member relationships only for multicast groups permitted by the rules. The largest number of router members can also be set.

Related Configuration

📌 **Configuring Access Control for Multicast Groups**

By default, no access control is configured and hosts can be added to any groups.

Run the **ipv6 mld access-group** *access-list-name* command to configure or restore access control for multicast groups.

After the configuration, the router can receive messages only from hosts in groups specified in the access list.

📌 **Configuring the Maximum Number of MLD Group Members**

By default, an MLD group has a maximum of 1024 members.

Run the **ipv6 mld limit** *number* command to configure or restore the maximum number of MLD group members.

A larger value means a larger number of group members.

4.3.4 Supporting Static MLD Groups

Stores static group information on a local router instead of obtaining group information by sending Report messages. The local router can directly exchange group information with the PIM router.

Working Principle

Manually configure static group information.

Related Configuration

📌 **Configuring Static-Group**

By default, no static group information is configured.

Run the **ipv6 mld static-group** *group-address* command to configure or cancel static group information.

4.3.5 Configuring Simulated Host Group Information

Simulates host behaviors to directly configure group joining information.

Related Configuration

📌 **Configuring Join-Group**

By default, no join-group information is configured.

Run the **ipv6 mld join-group** *group-address* command to configure or cancel join-group information.

4.3.6 Supporting MLD Proxy

In the simply tree topology, it is not necessary to run complex multicast routing protocols (such as PIM). In this case, MLD proxy can be used to send MLD messages for downstream hosts and maintain member relationships.

Working Principle

When an upstream router is configured as an MLD proxy service interface, it functions as a host and can receive Query messages from upstream routers as well as forward group information of downstream hosts. When a downstream router is configured as an MLD multicast proxy interface, it functions as a router and can forward Query messages of upstream routers as well as receive Report messages from downstream routers.

Related Configuration

✚ Configuring MLD PROXY-SERVICE

By default, the MLD proxy service is disabled on an interface.

Run the **ipv6 mld proxy-service** command to configure or cancel the MLD proxy function on an interface.

This function must be configured when proxy is used.

✚ Configuring MLD MROUTE-PROXY

By default, the multicast proxy service is disabled on an interface.

Run the **ipv6 mld mroute-proxy** interfacename command to configure or cancel the multicast proxy function on an interface.

This function must be configured when proxy is used.

4.3.7 Supporting SSM-MAP

This function provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

Working Principle

Based on MLDv1, MLDv2 provides an extra function, that is, source filtering multicast. In MLDv1, a host determines to join a group only based on the group address and receives multicast streams sent to the group address from any source. However, an MLDv2 host advertises the multicast group that the host wants to join and the address of the multicast source that it wants to receive. In MLDv1, source address filtering can be implemented to some extent, but filtering is implemented by enabling SSM-MAP and configuring SSM-MAP static groups on multicast flow receivers.

Related Configuration

✚ Enabling MLD SSM-MAP

By default, SSM-MAP is disabled.

Run the **ipv6 mld ssm-map enable** command to enable or disable the SSM-MAP function.

This function must be enabled when SSM-MAP is used.

✎ Configuring MLD SSM-MAP STATIC

By default, no SSM-MAP static link table is configured.

Run the **ipv6 mld ssm-map static** *access-list-num A.B.C.D* command to enable or disable the SSM-MAP static link table.

4.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD	 (Mandatory) It is used to configure the multicast service.	
	ipv6 multicast-routing	Enables the IPv6 multicast routing function.
	ipv6 pim sparse-mode	Enables the PIM-SM function.
Configuring MLD Router Parameters	ipv6 mld version { 1 2 }	Configures the MLD version.
	ipv6 mld last-member-query-interval <i>interval</i>	Configures the interval for querying the last member.
	ipv6 mld last-member-query-count <i>count</i>	Configures the number of times for querying the last member.
	ipv6 mld query-interval <i>seconds</i>	Configures the interval for querying a common member.
	ipv6 mld query-max-response-time <i>seconds</i>	Configures the maximum response interval.
Querier Selection Process or Timeout Mechanism	ipv6 mld querier-timeout <i>seconds</i>	Configures the keepalive interval of the querier.
Filtering MLD Groups	ipv6 mld access-group <i>access-list</i>	Filters MLD group members.
MLD Proxy	ipv6 mld proxy-service	Configures the MLD PROXY-SERVICE.
	ipv6 mld mroute-proxy <i>interface-type interface-number</i>	Configures the MLD MROUTE-PROXY.
Supporting SSM-MAP	ipv6 mld ssm-map enable	Enables the SSM-MAP function.
	ipv6 mld ssm-map static <i>access-list source-address</i>	Configures the SSM-MAP static link table.

4.4.1 Configuring Basic Functions of MLD

Configuration Effect

- Enable the multicast routing function and collect group information on the local network.

Notes

- The PIM SM function must be enabled on an interface.

Configuration Steps

✚ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on all routers on the local network unless otherwise specified.

✚ Enabling the PIM SM Function

- Mandatory.
- The PIM SM function should be directly enabled on an interface on the local network unless otherwise specified.

Verification

Run the **show ipv6 mld interface *interface-type* *interface-number*** command to check whether MLD is enabled on the interface.

Related Commands

✚ Enabling the IPv6 Multicast Routing Function

Command	Ipv6 multicast-routing
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	-

✚ Enabling the PIM SM Function

Command	Ipv6 pim { sparse-mode }
Parameter	-
Description	
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including: routing, L3AP, SVI, and loopback interfaces. IPv6 unicast routes should be accessible to all PIM interfaces.

Configuration Example

✚ Enabling MLD on the Local Network

Configuration Steps	● Configure an IPv6 unicast routing protocol (such as OSPF) on a router and ensure that unicast routes are accessible to the loopback interface. (Omitted) ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIM SM function on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.

	<pre> VSU(config)#ipv6 multicast-routing VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)# ipv6 address 2001::1/64 VSU(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode </pre>
Verification	Run the show ipv6 mld interface <i>interface-type</i> <i>interface-number</i> command to check whether MLD is enabled on the interface.
	<pre> VSU#show ipv6 mld interface gigabitEthernet 0/1 Interface GigabitEthernet 0/1 (Index 1) MLD Active, Querier, Version 2 (default) Internet address is fe80::2d0:f8ff:fe22:33b1 MLD interface limit is 1024 MLD interface has 0 group-record states MLD interface has 0 join-group records MLD interface has 0 static-group records MLD activity: 0 joins, 0 leaves MLD query interval is 125 seconds MLD querier timeout is 255 seconds MLD max query response time is 10 seconds Last member query response interval is 10 (1/10s) Last member query count is 2 Group Membership interval is 260 Robustness Variable is 2 </pre>

Common Errors

- Multicast routing is disabled on routers on the network.
- No multicast interface is available on the network.

4.4.2 Configuring MLD Router Parameters

Configuration Effect

- Modify MLD router parameters to change the message type or sending mode.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

Configuring MLD Version

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Configuring the Interval for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Configuring the Number of Times for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Configuring the Interval for Querying a Common Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Configuring the Maximum Response Interval

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

Run the **show ipv6 mld interface** *interface-type interface-number* command to view the configuration information.

Related Commands

Configuring the MLD Version

Command	ipv6 mld version { 1 2 }
Parameter Description	1: Indicates version 1. 2: Indicates version 2.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, MLD will automatically restart.

Configuring the Interval for Querying the Last Member

Command	ipv6 mld last-member-query-interval <i>interval</i>
Parameter	<i>Interval</i> : Specifies the interval for sending Query messages of a specified group. The unit is 0.1s, the value

Description	ranges from 1 to 255, and the default value is 10 (1s).
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows: Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2.

✎ Configuring the Number of Times for Querying the Last Member

Command	ipv6 mld last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Specifies the number of times for sending Query messages of a specified group. The value ranges from 2 to 7. The default value is 2 .
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows: Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2

✎ Configuring the Interval for Querying a Common Member

Command	ipv6 mld query-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Specifies the interval for querying a common member. The unit is s, the value ranges from 1 to 18000, and the default value is 125.
Command Mode	Interface configuration mode
Usage Guide	-

✎ Configuring the Maximum Response Interval

Command	ipv6 mld query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Specifies the maximum response time. The unit is s, the value ranges from 1 to 25, and the default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for responses. After timeout, it is considered that no group member exists in the directly-connected network segment and group information is deleted.

Configuration Example

✎ Configuring Basic Router Parameters

Configuration Steps	● Configure basic functions of MLD. (Omitted) ● Configure MLD version 2. ● Configure the interval for querying the last member as 15 (1.5s). ● Configure the number of times for querying the last member as 3. ● Configure the interval for querying the common member as 130s. ● Configure the maximum response time as 15s.
	<pre> VSU(config-if-GigabitEthernet 0/1)#ipv6 mld version 2 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-count 3 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-interval 130 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-max-response-time 15 </pre>
Verification	Run the show ipv6 mld interface <i>interface-type interface-number</i> command to check whether MLD is enabled on the interface.
	<pre> VSU(config-if-GigabitEthernet 0/1)# show ipv6 mld interface gi 0/1 Interface GigabitEthernet 0/1 (Index 1) MLD Enabled, Active, Querier, Version 2 (default) Internet address is fe80::2d0:f8ff:fe22:33b1 MLD interface limit is 1024 MLD interface has 0 group-record states MLD interface has 0 join-group records MLD interface has 0 static-group records MLD activity: 0 joins, 0 leaves MLD query interval is 130 seconds MLD querier timeout is 267 seconds MLD max query response time is 15 seconds Last member query response interval is 15 (1/10s) Last member query count is 3 Group Membership interval is 275 Robustness Variable is 2 </pre>

Common Errors

- Basic functions of MLD are not enabled.

4.4.3 Querier Selection Process or Timeout Mechanism

Configuration Effect

- Select the unique querier on the local network.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

- This function must be configured if the querier keepalive interval needs to be configured.
- This function can be configured on all MLD-enabled interfaces on the local network.

Verification

Run the **show ipv6 mld interface** *interface-type interface-number* command to view the configuration information of the interface.

Related Commands

📌 Configuring the Keepalive Interval of Other Queriers

Command	ipv6 mld querier-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Specifies the keepalive interval for other queriers. The unit is s, the value ranges from 60 to 300, and the default value is 255.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for Query messages from other devices. After timeout, it is considered that it is the unique querier in the directly-connected network segment.

Configuration Example

📌 Configuring the Keepalive Interval of Other Queriers

Configuration Steps	● Configure the basic functions of MLD. (Omitted) ● Configure the keepalive interval of a querier as 280s.
	<pre>VSU(config-if-GigabitEthernet 0/1)#ipv6 mld querier-timeout 280</pre>
Verification	Run the show ipv6 mld interface <i>interface-type interface-number</i> command to check whether MLD is enabled on the interface.

```
VSU#show ipv6 mld interface gigabitEthernet 0/1

Interface GigabitEthernet 0/1 (Index 1)

  MLD Enabled, Active, Querier, Version 2 (default)

  Internet address is fe80::2d0:f8ff:fe22:33b1

  MLD interface limit is 1024

  MLD interface has 0 group-record states

  MLD interface has 0 join-group records

  MLD interface has 0 static-group records

  MLD activity: 0 joins, 0 leaves

  MLD query interval is 130 seconds

  MLD querier timeout is 280 seconds

  MLD max query response time is 15 seconds

  Last member query response interval is 15 (1/10s)

  Last member query count is 3

  Group Membership interval is 275

  Robustness Variable is 2
```

Common Errors

- The basic functions of MLD are not enabled.

4.4.4 Filtering MLD Groups

Configuration Effect

- A router filters MLD group information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

📌 Configuring Access Control for Multicast Groups

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

📌 Configuring the Maximum Number of MLD Group Members

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

Filtering MLD Groups

Configure the interface to allow for only groups in link table 1. The access address of link table 1 is (FF66::100/64).

Configure the interface to add a group FF66::05.

Configure the interface to add a group FF65::05.

Check group information on the interface.

Configuring the Maximum Number of MLD Group Members

Configure the number of group members as 5 on the interface.

Configure the interface to add a group (FF66::05 ~ FF65::0B).

Check group information on the interface.

Related Commands

Configuring Access Control for Multicast Groups

Command	ipv6 mld access-group <i>access-list</i>
Parameter Description	<i>access-list</i> : Specifies the group address range by using IP standard ACLs or IP extended ACLs. The value ranges from 1 to 199, 1300 to 2699, and WORD.
Command Mode	Interface configuration mode
Usage Guide	After running this command on the interface, you can control the groups that hosts in the directly-connected network segment can join. Use ACLs to limit the group address range. Report messages denied by the ACLs will be discarded. When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 messages. When the received MLD Report message is (S1,S2,S3...Sn,G), this command will match (0,G) using the corresponding ACLs. Therefore, to normally use this command, you must explicitly configure a (0, G) in the extended ACLs to filter (S1,S2,S3...Sn,G).

Configuring the Maximum Number of MLD Group Members

Command	ipv6 mld limit <i>number</i> [except <i>access-list</i>]
Parameter Description	<i>number</i>: Specifies the maximum number of MLD group members. The value range depends on the specific device. The interface default value is 1024 and the global one is 65536. except <i>access-list</i>: Groups in the access list are not counted. The access list is an IP standard ACL. The value ranges from 1 to 99, 1300 to 1999, and WORD.
Command Mode	Interface configuration mode
Usage Guide	Global configuration mode: Limits the number of MLD group members on the whole device.

	Interface configuration mode: Limits the number of MLD group members of the interface. If the number of group members exceeds the interface limit or global limit, subsequent Report messages will be ignored. If an except list is configured, Report messages in a specified range can be normally processed. Therefore, the group members are not counted. Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, use the global limit.

Configuration Example

Configuring Group Filtering

Configuration Steps	- Configure the basic functions of MLD. (Omitted) - Configure the access address of link table 1 as (FF66::100/64). - Configure the group to join as FF66::05. - Configure the group to join as FF65::05.
	<pre>VSU(config)#ipv6 access-list acl VSU(config-ipv6-acl)#permit ipv6 ::/64 ff66::100/64 VSU(config-ipv6-acl)#permit ipv6 2222::3333/64 ff66::100/64 VSU(config-ipv6-acl)#exit VSU(config)# VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld access-group acl VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff65::5</pre>
Verification	Run the show ipv6 mld groups [interface-type interface-number] [group-address] [detail] command to view the group information on the interface.
	<pre>VSU#show ipv6 mld groups MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ff66::5 GigabitEthernet 0/1 00:05:07 00:03:46 fe80::2d0:f8ff:fe22:33b1</pre>

Configuring the Maximum Number of MLD Group Members

Configuration Steps	- Configure the basic functions of MLD. (Omitted) - Configure the maximum number of group members on the interface as 5. - Add group information (FF66::5 ~ FF66::0B).

	View the group information.
	<pre> VSU(config-if-GigabitEthernet 0/1)#ipv6 mld limit 5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::5 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::6 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::7 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::8 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::9 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::A VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::B </pre>
Verification	Run the show ipv6 mld groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to view group information on the interface.
	<pre> MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ff66::5 GigabitEthernet 0/1 00:00:36 00:04:00 fe80::2d0:f8ff:fe22:33b1 ff66::6 GigabitEthernet 0/1 00:00:34 00:04:01 fe80::2d0:f8ff:fe22:33b1 ff66::7 GigabitEthernet 0/1 00:00:22 00:04:13 fe80::2d0:f8ff:fe22:33b1 ff66::8 GigabitEthernet 0/1 00:00:18 00:04:19 fe80::2d0:f8ff:fe22:33b1 ff66::9 GigabitEthernet 0/1 00:00:14 00:04:21 fe80::2d0:f8ff:fe22:33b1 </pre>

Common Errors

- The basic functions of MLD are not enabled.

4.4.5 MLD Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

✚ Configuring MLD PROXY-SERVICE

Optional.

This function can be configured on the interface of routers directly connected to the upstream devices unless otherwise specified.

✚ Configuring MLD MROUTE-PROXY

Optional

This function can be configured on the interface of hosts directly connected to the downstream devices unless otherwise specified.

Verification

- Configure the interface that directly connects interface 7 and upstream router as the multicast proxy service.
- Configure the interface that directly connects interface 1 and downstream host as the multicast proxy.
- Configure groups FF66::05 and FF66::06 to be added to interface 1.
- Check information of the current group.

Related Commands

✚ Configuring MLD PROXY-SERVICE

Command	ipv6 mld proxy-service
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Run the ipv6 mld proxy-service command to configure the upstream interface as the proxy-service interface. Run the ipv6 mld mroute-proxy command to configure the downstream interface as the mroute-proxy interface. Configure the proxy-service interface to forward MLD Query messages to the mroute-proxy interface. Configure the mroute-proxy interface to forward MLD Reports messages to the proxy-service interface. A maximum of 32 proxy-service interfaces can be configured on a device. After receiving MLD Query messages, the proxy-service interface sends a response based on the MLD group member records. If you run switchport command on the proxy-service interface, the ipv6 mld mroute-proxy command configured on the mroute-proxy interface will be automatically deleted.

✚ Configuring MLD MROUTE-PROXY

Command	ipv6 mld mroute-proxy <i>interface-type interface-number</i>
Parameter Description	-
Command	Interface configuration mode

Mode	
Usage Guide	Run the ipv6 mld proxy-service command to configure the upstream interface as the proxy-service interface. Run the ipv6 mld mroute-proxy command to configure the downstream interface as the mroute-proxy interface. Configure the proxy-service interface to forward MLD Query messages to the mroute-proxy interface. Configure the mroute-proxy interface to forward MLD Reports messages to the proxy-service interface.

Configuration Example

Configuration Steps	● Configure MLD basic functions. (Omitted) ● Configure interface 7 as the proxy server. ● Configure interface 1 as the multicast proxy. ● Configure groups FF66::05 and FF66::06 to be added to interface 1.
	<pre>VSU(config-if-GigabitEthernet 0/7)#ipv6 mld proxy-service VSU(config-if-GigabitEthernet 0/7)#exit VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld mroute-proxy gigabitEthernet 0/7 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::05 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld join-group ff66::06</pre>
Verification	Run the show ipv6 mld groups [interface-type interface-number] [group-address] [detail] command to view the group information on the interface.
	<pre>VSU(config-if-GigabitEthernet 0/1)#show ipv6 mld groups MLD Connected Group Membership Group Address Interface Uptime Expires Last Reporter ----- ff66::5 GigabitEthernet 0/1 00:00:11 00:04:31 fe80::2d0:f8ff:fe22:33b1 ff66::6 GigabitEthernet 0/1 00:00:11 00:04:33 fe80::2d0:f8ff:fe22:33b1 MLD Proxy-server Connected Group Membership Group Address Interface Uptime ----- ff66::5 GigabitEthernet 0/7 00:00:11 ff66::6 GigabitEthernet 0/7 00:00:11</pre>

Common Errors

- The basic functions of MLD are not enabled.

4.4.6 Supporting SSM-MAP

Configuration Effect

- MLDv2 supports source filtering while MLDv1 does not. However, MLDv1 provides the SSM-MAP function to implement source filtering.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

▾ Enabling SSM-MAP

This function must be configured if SSM-MAP.

This function must be enabled on a router where SSM-MAP is enabled.

▾ Configuring an SSM-MAP Static Link Table

Optional.

This function must be enabled on a router where SSM-MAP is enabled.

Verification

Run the **show ipv6 mld ssm-mapping** [*group-address*] command to display SSM-MAP information.

Related Commands

▾ Enabling SSM-MAP

Command	ipv6 mld ssm-map enable
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	Run the ipv6 mld ssm-map enable command to enable the SSM-MAP function. Run the ipv6 mld ssm-map static command to configure static mapping table items. The interface runs MLDv2. When receiving Report messages from MLDv1, the interface adds the static mapping source address.

▾ Configuring an SSM-MAP Static Link Table

Command	ipv6 mld ssm-map static access-list source-address
Parameter Description	access-list: Specifies the group address range configured by the ACL. source-address: Source address
Command Mode	Global configuration mode

Usage Guide	Run the ipv6 mld ssm-map enable command to enable the SSM-MAP function. Run the ipv6 mld ssm-map static command to configure static mapping table items. The interface runs MLDv2. When receiving Report messages from MLDv1, the interface adds the static mapping source address.

Configuration Example

Configuration Steps	● Configure the basic functions of MLD. (Omitted) ● Enable SSM-MAP. ● Configure SSM-MAP static link table 3.
	<pre>VSU(config)#ipv6 mld ssm-map enable VSU(config)#ipv6 mld ssm-map static 3 1500::5</pre>
Verification	Run the show ipv6 mld ssm-mapping [group-address] command to view SSM mapping information.
	<pre>VSU(config)#show ipv6 mld ssm-mapping SSM Mapping : Enabled Database : Static mappings configured</pre>

Common Errors

- The basic functions of MLD are not enabled.

4.5 Monitoring

Clearing

Description	Command
Clears dynamic group member records in the MLD cache.	clear ipv6 mld group [<i>group-address</i>] [<i>interface-type interface-number</i>]
Clears all MLD statistics and group member records on the interface.	clear ipv6 mld interface <i>interface-type interface-number</i>

Displaying

Description	Command
Displays groups directly connected to the device and group information learned from MLD.	show ipv6 mld groups [<i>group-address</i> <i>interface-type interface-number</i>] [detail]
Displays configurations of the interface.	show ipv6 mld interface [<i>interface-type interface-number</i>]
Displays SSM-MAP information.	show ipv6 mld ssm-mapping [<i>group-address</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Displays the MLD debugging switch status.	show debugging
Debugs all MLD information.	debug ipv6 mld all
Debugs MLD packet resolution.	debug ipv6 mld decode
Debugs MLD packet encoding.	debug ipv6 mld encode
Debugs MLD event information.	debug ipv6 mld events
Debugs MLD Finite State Machine (FSM).	debug ipv6 mld fsm
Debugs MLD state machine information.	debug ipv6 mld tib
Debugs MLD warning.	debug ipv6 mld warning

5 Configuring PIM-DM

5.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC3973: Protocol Independent Multicast - Dense Mode (PIM-DM)
- RFC2715: Interoperability Rules for Multicast Routing Protocols

5.2 Applications

Application	Description
Providing the Multicast Service in the Same Network	The multicast service is provided in the same network.

5.2.1 Providing the Multicast Service in the Same Network

Scenario

The multicast service is provided in the same network.

The following figure is taken as an example:

- A multicast source sends a multicast packet, and Receiver A and Receiver B in the same network receive the multicast packet.

Figure 5-1

Remarks	A, B, and C are Layer-3 routers. The multicast source is connected to the Gi0/1 interface of A, Receiver A is connected to the Gi0/1 interface of B, and Receiver B is connected to Gi0/1 of C.

Deployment

- Run the Open Shortest Path First (OSPF) protocol in the same network to implement unicast routing.
- Run the PIM-DM protocol in the same network to implement multicast routing.
- Run the Internet Group Management Protocol (IGMP) in a user host network segment to implement group member management.

5.2.2 PIM-DM Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-DM. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 5-2

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-DM on R1 and R2 to implement multicast routing.
- Make R2 run in a hot backup environment.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.

5.3 Features

Basic Concepts

📌 PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM Routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called Upstream Interfaces, and the PIM interfaces where multicast packets are sent are called Downstream Interfaces.

The network segments where upstream interfaces are located are called Upstream Network Segments. The network segments where downstream interfaces are located are called Downstream Network Segments.

📌 PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders are able to reject specified multicast packets or limit the transmission of PIM messages.

📌 Multicast Distribution Tree

Multicast packets are packets transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called the Multicast Distribution Tree (MDT).

✚ (*,G), (S,G)

- (*,G): Packets sent from any source to Group G, the corresponding routing entries, and the forwarding path called Rendezvous Point Tree (RPT).
- (S,G): Packets sent from Source S to Group G, the corresponding routing entries, and the forwarding path called Shortest Path Tree (SPT).

Overview

Feature	Description
PIM-DM Neighbor	Neighbor relationships are established between PIM routers to form a PIM network.
PIM-DM MDT	PIM-DM creates the MDT by using flooding, pruning, and grafting.
PIM-DM SRM	PIM-DM uses a State Refresh Message (SRM) to update the network state.
MIB	The Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

5.3.1 PIM-DM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control messages can be exchanged or multicast packets can be forwarded.

Working Principle

A Hello message is sent from a PIM interface. For the IPv4 multicast packet with the Hello message encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet with the Hello message encapsulated, the destination address is ff02::d.

Function of a Hello message: It is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

✚ Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13 or ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello packets.

✚ Coordinating Protocol Parameters

A Hello message includes multiple protocol parameters, which are described as follows:

- DR_Priority: Router interfaces contend for the designated router (DR) based on their DR priorities. A higher priority means a higher chance of winning.

- Holdtime: Time in which a neighbor is held in the reachable state
- LAN_Delay: LAN delay for transmitting a Prune message in a shared network segment
- Override-Interval: Prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override message to the upstream interface within the Override-Interval.

$\text{LAN\_Delay} + \text{Override-Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune message from an downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection message from the downstream interface, the PIM router cancels pruning.

✚ Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

✚ Enabling PIM-DM on an Interface

By default, PIM-DM is disabled on an interface.

Use the **ip pim dense-mode** command to enable or disable PIM-DM on an interface.

PIM-DM must be enabled on an interface to involve the interface in the PIM protocol.

✚ Setting the Interval of Hello Messages on an Interface

By default, a Hello message is sent at an interval of 30 seconds.

The **ip pim query-interval** *interval-seconds* command is used to adjust the interval of Hello messages. The value of the interval ranges from 1 to 65,535.

A Hello message is transmitted less frequently when the value of *interval-seconds* is larger.

5.3.2 PIM-DM MDT

PIM-DM creates the MDT by using flooding, pruning, and grafting.

Working Principle

When a multicast source sends multicast packets, the system may forward them to the outgoing interfaces of multicast neighbors and local members, depending on the results of the Reverse Path Forwarding (RPF) check. The packets not passing the RPF check are discarded. If an outgoing interface exists, the packets that have passed the RPF check are accepted for forwarding; if no outgoing interface exist, a prune packet is sent to upstream devices. After the upstream interface receives the prune packet, the upstream interface transmits the source interface of the prune packet as the Pruned state and sets the Prune Timer (PT). In this way, the MDT based on the multicast source is created.

When the system receives a Join message from a local member, if a downstream device in the Pruned state sends a Graft message to an upstream device, the upstream device returns a Graft Ack message and resume multicast forwarding to the interfaces of the downstream device after receiving the Graft message.

-  In network deployment, when multiple PIM-DM neighbors are created through multiple links between devices and downstream devices have no or less need in receiving, the CPU usage may be high. In this scenario, PIM-SM is recommended to deploy the environment.

Related Configuration

📌 Configuring the Prune Override Interval on an Interface

By default, the prune override interval is 500 ms.

The **ip pim override-interval** *interval-milliseconds* command is used to modify the prune override interval.

5.3.3 PIM-DM SRM

PIM-DM uses an SRM to refresh the network state.

Working Principle

Devices connected to a multicast source periodically send SRMs to downstream devices to notify changes of the network topology. After receiving the SRMs, the adjacent devices receiving the SRMs add the local topology state information to the messages by modifying some fields in SRMs, and send the messages to downstream devices. When the messages reach leaf devices, the state information of the entire network is updated.

Related Configuration

📌 Disabling the Processing and Forwarding of SRMs

By default, the processing and forwarding of SRMs are enabled.

The **ip pim state-refresh disable** command is used to disable the processing and forwarding of SRMs.

-  Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable SRM in general conditions.

📌 Setting the Interval of SRMs

By default, an SRM is sent at an interval of 60 seconds.

The **ip pim state-refresh origination-interval** *interval-seconds* command is used to adjust the interval of SRMs. The value of the interval ranges from 1 to 100.

SRMs are transmitted less frequently when the value of *interval-seconds* is larger.

-  Only devices that are directly connected to a multicast source will periodically send a PIM SRM to downstream interfaces. For a device not directly connected to the multicast source, the interval of SRMs on its downstream interfaces is invalid.

5.3.4 MIB

Connected to other agents, the Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

Working Principle

The MIB specifies variables (namely information that can be queried and set by the management process) maintained by network elements and directly manages the PIM-DM function.

Related Configuration

📌 Enabling PIM-DM MIB

By default, the PIM-DM MIB function is enabled.

The **ip pim mib dense-mode** command is used to enable the PIM-DM MIB function.

5.4 Configuration

Configuration	Description and Command	
Configuring PIM-DM Basic Functions	 (Mandatory) It is used to create the multicast service.	
	ip multicast-routing	Enables IPv4 multicast routing.
	ip pim dense-mode	Enables PIM-DM.
Configuring PIM-DM Neighbors	 (Optional) It is used to limit the (S,G) pairs of legitimate multicast packets in Any Source Multicast (ASM) model.	
	ip pim query-interval <i>interval-seconds</i>	Sets the Interval of Hello messages on an interface.
	ip pim propagation-delay <i>interval-milliseconds</i>	Sets the prune propagation delay on an interface.
	ip pim override-interval <i>interval-milliseconds</i>	Sets the prune override interval on an Interface.
	ip pim neighbor-filter <i>access-list</i>	Configures neighbor filtering on an interface.
Configuring PIM-DM SRMs	ip pim state-refresh disable	Disables the processing and forwarding of SRMs.
	ip pim state-refresh origination-interval <i>interval-seconds</i>	Sets the Interval of SRMs on an interface.
Configuring PIM-DM MIB	ip pim mib dense-mode	Enables PIM-DM MIB.

5.4.1 Configuring PIM-DM Basic Functions

Configuration Effect

- Create a PIM-DM network and provide data sources and user terminals in the network with the IPv4 multicast service.

Notes

- PIM-DM needs to use the unicast routes existing in the network. Therefore, IPv4 unicast routing must be configured in the network.

Configuration Steps

▾ Enabling IPv4 Multicast Routing

- Mandatory
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

▾ Enabling PIM-DM

- Mandatory
- PIM-DM should be enabled on the following interfaces unless otherwise specified: interconnected interfaces on routers and interfaces connecting multicast sources and user hosts.

Verification

Make multicast sources send multicast packets and make user hosts join the groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether correct PIM-DM routing entries are created on routers.

Related Commands

▾ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling PIM-DM

Command	ip pim dense-mode
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces.

	For all PIM interfaces, IPv4 unicast routes should be reachable.

▾ Displaying the PIM-SM Routing Table

Command	show ip pim dense-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [summary]
Parameter	<i>group-or-source-address</i> : Indicates a group address or source address.
Description	<i>group-or-source-address</i> : Indicates a group address or source address (The two addresses cannot be group addresses or source addresses at the same time). summary : Displays the routing table summary.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Check whether sufficient routing entries are provided. Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.

Configuration Example

▾ Enabling IPv4 Multicast Routing on the IPv4 Network

Scenario Figure 5-3	
Configuration Steps	● Configure IPv4 unicast routing protocols (for example, OSPF) on all the routers. ● Enable the IPv4 multicast routing function on all the routers. ● Enable the PIM-DM function on all the interconnected interfaces of the routers, Source, and Receiver..
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>
B	<pre>B# configure terminal B(config)# ip multicast-routing</pre>

	<pre> B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit </pre>
Verification	Configure the multicast source (192.168.1.10) to send packets to G (229.1.1.1). Make Receiver A join G. ● Check whether the multicast packets from Source G are received by Receiver A.. ● Check PIM-DM routing tables on Router A and Router B.
A	<pre> A# show ip pim dense-mode mroute PIM-DM Multicast Routing Table (192.168.1.10, 229.1.1.1) MRT lifetime expires in 182 seconds Source directly connected on GigabitEthernet 0/1 State-Refresh Originator State: Originator SRT:57, SAT:147 Upstream IF: GigabitEthernet 0/1 Upstream State: Forwarding Assert State: NoInfo Downstream IF List: GigabitEthernet 0/2, in 'olist': Downstream State: NoInfo Assert State: NoInfo </pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.2 Configuring PIM-DM Neighbors

Configuration Effect

- Coordinate protocol parameters and adjust parameters in the Hello packet.
- Enable neighbor filtering to improve network security.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- Set parameters on PIM router interfaces unless otherwise specified.

Verification

- Set parameters in a Hello packet on an interface and run the **debug ip pim dense-mode encode** command to check parameters.
- Enable neighbor filtering and run the **show ip pim dense-mode decode** command to display neighbor filtering information.
- Run the **show running-config interface** [*interface-type interface-number*] command to display configurations on an interface.

Related Commands

📌 Setting the Interval of Hello Messages

Command	ip pim query-interval <i>interval-seconds</i>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 65,535 in the unit of seconds.
Command Mode	Interface configuration mode

Usage Guide	When the Hello interval is set, the holdtime value will be updated as its 3.5 times.
	Every time when the interval of Hello messages is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval of Hello messages multiplied by 3.5 is greater than 65,535, the holdtime value is updated as 65,535.

Setting the Prune Propagation Delay

Command	ip pim propagation-delay <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command Mode	Interface configuration mode
Usage Guide	Set propagation-delay of an interface, that is, configure the prune propagation delay of an interface.

Setting the Prune Override Interval

Command	ip pim override-interval <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command Mode	Interface configuration mode
Usage Guide	Set override-interval of an interface, that is, configure the prune override time of an interface.

Configuring PIM-DM Neighbor Filtering

Command	ip pim neighbor-filter <i>access-list</i>
Parameter Description	<i>access-list</i> : The supported ACL ranges from 1 to 99. Naming an ACL is also supported.
Command Mode	Interface configuration mode
Usage Guide	Only addresses that meet ACL filtering conditions can be used as PIM neighbors of the current interface. Otherwise, the addresses filtered out cannot be neighbors. Peering refers to exchange of protocol packets between PIM neighbors. If peering with a PIM device is suspended, the neighbor relationship with it cannot be formed so that PIM protocol packets will not be received from the device.

Configuration Example

Configuring PIM-DM Neighbors on the IPv4 Network

Scenario Figure 5-4	
Configuration Steps	- Configure basic functions of PIM-DM (omitted). - Set protocol parameters in a Hello packet on the Gi0/1 interface of device A.
A	<pre> A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim query-interval 60 A(config-if)# ip pim propagation-delay 800 A(config-if)# ip pim override-interval 1000 A(config-if)# exit </pre>
Verification	- Run the show running-config interface [interface-type interface-number] command to display configurations on an interface. - Run the debug ip pim dense-mode encode command to debug parameters in a Hello packet.
A	<pre> A# (config)#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 245 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim query-interval 60 ip pim propagation-delay 800 ip pim override-interval 1000 </pre>
	<pre> A# debug ip pim dense-mode encode *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello Hold-Time 210 *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello Gen-ID 1362200073 *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello PD=800 ms, OI=1000 ms *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello SR-Interval 60 *Dec 22 15:00:58: %7: [ENCODE] Enc Msg Hdr: Hello Checksum=65396, MsgLen=34 Assert State: Loser, </pre>

AT:125

Configuring PIM-DM Neighbor Filtering on the IPv4 Network

Scenario Figure 5-5	
Configuration Steps	● Configure basic functions of PIM-DM (omitted). ● Configure an ACL on device A. ● Configure PIM neighbor filtering on the Gi0/1 interface of device A.
A	<pre> A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim query-interval 60 A(config-if)# ip pim propagation-delay 800 A(config-if)# ip pim override-interval 1000 A(config-if)# exit </pre>
Verification	● Run the show running-config interface [<i>interface-type interface-number</i>] command to display configurations on the interface. ● Run the debug ip pim dense-mode decode command to debug parameters in a Hello packet.
A	<pre> A#show running-config interface gigabitEthernet 0/2 Building configuration... Current configuration : 187 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim neighbor-filter pim-dm </pre>
	<pre> A# debug ip pim dense-mode decode Dec 22 15:15:47: %7: [DECODE] Dec Msg: PIM Hello message, version 2 Dec 22 15:09:47: %7: [DECODE] Dec Msg: Neighbor 192.168.2.2/32 on GigabitEthernet 0/1 denied by access-list pim-dm </pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.3 Configuring PIM-DM SRMs

Configuration Effect

- Enable or disable the PIM-DM SRM function.
- Adjust the interval of SRMs.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- The interval of SRMs is only applicable only to the PIM router interfaces that are directly connected to the multicast source.

Verification

- Configure the PIM-DM SRMs and run the **show running-config** command to display the SRM status.
- Run the **show ip pim dense-mode track** command to display the SRM number.
- Run the **show running-config interface [interface-type interface-number]** command to display interface configurations.

Related Commands

📌 Disabling the Processing and Forwarding of SRMs

Command	ip pim state-refresh disable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the processing and forwarding of SRMs are disabled, the State Refresh Capable option is not included in a Hello packet, and is not processed when the Hello packet is received. Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable this function in general conditions.

📌 Setting the Interval of SRMs

Command	<code>ip pim state-refresh origination-interval interval-seconds</code>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 100 in the unit of second.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Disabling the Processing and Forwarding of SRMs on an Interface on the IPv4 Network

Scenario Figure 5-6	
Configuration Steps	● Configure basic functions of PIM-DM (omitted). ● Disable processing and forwarding of a PIM-DM SRM on an Interface of device A.
A	<pre>A# configure terminal A(config)# ip pim state-refresh disable</pre>
Verification	● Run the show running-config command to check the configuration.
A	<pre>A# (config)# show running-config ... ! ip pim state-refresh disable ! ...</pre>

Setting the Interval of SRMs on the IPv4 Network

Scenario Figure 5-7	
Configuration Steps	- Configure basic functions of PIM-DM (omitted). - Set the interval of PIM-DM SRMs on the Gi0/1 interface of device A.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim state-refresh origination-interval 5 A(config-if)# exit</pre>
Verification	- Run the show running-config interface [interface-type interface-number] command to display interface configurations. - Run the show ip pim dense-mode track command to display the SRM number.
A	<pre>A#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 201 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim state-refresh origination-interval 5</pre>

6 Configuring PIM-SM

6.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On Layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

6.2 Applications

Application	Description
Enabling ASM for PIM-SM	The receiver receives any multicast source.
Enabling SSM for PIM-SM	The receiver receives only a specific multicast source.

6.2.1 Enabling ASM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives any multicast source.

Figure 6-1

Remarks	R 1 is connected directly to the multicast source. R 2 serves as the rendezvous point (RP). R 3 is connected directly to Receiver A. R 4 is connected directly to Receiver B.

Deployment

- Run the Open Shortest Path First (OSPF) protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the Internet Group Management Protocol (IGMP) in the network segment of the user host to manage group members.

6.2.2 Enabling SSM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives a specific multicast source.

Figure 6-2

Remarks	R 1 is connected directly to the multicast source. R 2 serves as the RP.

R 2 is connected directly to Receiver A. R 2 is connected directly to Receiver B.

Deployment

- Run the OSPF protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the source-specific multicast (SSM) of PIM-SM within the domain.
- Run IGMPv3 in the network segment of the user host to manage group members.

6.2.3 PIM-SM Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-SM. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 6-3

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-SM on R1 and R2 to implement multicast routing.
- Make R2 run in a hot backup environment.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello

packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.

6.3 Features

Basic Concepts

📌 PIM Router and PIM Interface

A router running PIM is called a PIM router. An interfaces running PIM is called a PIM interface.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called upstream interfaces, and the PIM interfaces where multicast packets are sent are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments, and the network segments where downstream interfaces are located are called downstream network segments.

📌 PIM Network and PIM Domain

PIM routers are connected through PIM interfaces to form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders can reject the passage of specific multicast packets or limit the transmission of PIM packets.

📌 Multicast Distribution Tree, DR, and RP

Multicast packets are transmitted from one point to multiple points, forming a tree-shaped forwarding path. Such forwarding path is called the multicast distribution tree (MDT), which includes the following two types:

- RP Tree (RPT): It is rooted at an RP, and uses the designated router (DR) of the member groups connected to it as its leaves.
- Shortest path tree (SPT): It is rooted at a DR that is connected to the multicast source, and uses the RP or the DR of the member groups connected to it as its leaves.

Both the DR and RP are the functions of a PIM router.

- An RP collects the information of a multicast source or multicast member on the network.

- The DR connected to the multicast source advertises the multicast source information to the RP; the DR connected to multicast group members advertises the information of multicast group members to the RP.

↘ (*, G), (S, G)

- (*, G): Indicates the packets sent from any source to a group (G), the corresponding route entries, and the RPT.
- (S, G): Indicates the packets sent from the source (S) to a group (G), the corresponding routing entries, and the SPT.

↘ ASM, SSM

PIM-SM supports both any-source multicast (ASM) and SSM, and it is applicable to different multicast group address segments.

- ASM: In this model, a user is not allowed to select a multicast source. The user host joins a group, and receives the packets sent from all sources.
- SSM: In this model, a user can select a multicast source. The user host joins a group and specifies the source address. Then only the packets sent from this source address is received.

Requirements for using an SSM model: Before selecting a multicast source, you need to learn the address of the multicast source using other network services.

Overview

Feature	Description
PIM-SM Neighbor	Establishes neighbor relationships between RIM routers to form a PIM network.
DR Election	In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members. In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.
BSR Mechanism	On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses.
RP Mechanism	On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router.
Register Information of the Multicast Source	When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.
Creating an RPT	When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.
Creating an SPT	When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT.
ASM and SSM	A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model.

6.3.1 PIM-SM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control packets can be exchanged or multicast packets can be forwarded.

Working Principle

A PIM interface sends a Hello packet. For the IPv4 multicast packet whose Hello packet is encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet whose Hello packet is encapsulated, the destination address is ff02::d.

A Hello packet is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

Coordinating Protocol Parameters

A Hello packet includes multiple protocol parameters, which are described as follows:

- DR_Priority: indicates the priority of a router interface for competing for the DR. A higher priority means a higher chance of winning.
- Holdtime: Indicates the time in which a neighbor is held in the reachable state
- LAN_Delay: Indicates the LAN delay for transmitting a Prune packet in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello packet.

When a PIM router receives a Prune packet from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override packet to the upstream interface within the override interval.

$\text{LAN\_Delay} + \text{Override Interval} = \text{PPT (Prune-Pending Timer)}$. After a PIM router receives a Prune packet from a downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection packet from the downstream interface, the PIM router cancels pruning.

Maintaining Neighbor Relationships

A Hello packet is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

✚ Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, candidate RP (C-RP), or candidate BSR (C-BSR), corresponding roles of the PIM protocol cannot be run.

✚ Setting the Interval of Hello Packets on an Interface

By default, a Hello packet is sent every 30s.

Run **ip pim query-interval** *interval-seconds* to adjust the interval of Hello packets. The value ranges from 1 to 65,535.

A Hello packet is transmitted less frequently when the value of *interval-seconds* is greater.

6.3.2 DR Election

In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members.

In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.

The DR sends Join/Prune packets toward the MDT, or sends the multicast source data to the MDT.

Working Principle

When creating a PIM neighbor, you can send a Hello packet to obtain the IP address and DR priority of the neighbor to elect a DR.

Two parameters play a key role in winning the DR election: the DR priority of an interface and the IP address of the interface.

✚ DR Priority of an Interface

During the DR election, the RIM router with the highest DR priority will be elected as the DR.

✚ Interface IP Address

During the DR election, if the priority of interfaces is the same, then interface IP addresses will be compared. The interface with the maximum IP address will be elected as the DR.

Related Configuration

✚ Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, C-RP, or C-BSR, corresponding protocols cannot be run.

Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run **ip pim dr-priority** *priority-value* to adjust the DR priority of the interface. The value ranges from 0 to 4,294,967,294.

The DR priority is used in the DR election in the network segment directly connected the interface. A greater value indicates a higher priority.

6.3.3 BSR Mechanism

On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain. All the routers on the entire network will receive these bootstrap packets, and record these candidate RPs and their corresponding group addresses.

Working Principle

One or multiple candidate BSRs are configured in a PIM-SM domain. You need to apply a certain algorithm to select the BSR from these candidate BSRs.

Related Configuration

Configuring Candidate BSRs

By default, candidate BSRs are not configured.

Run **ip pim bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]] to configure or cancel the configuration of candidate BSRs.

Through bootstrap packet (BSM) learning and competition of candidate BSRs, a unique BSR is generated for the PIM-SM domain.

Configuring BSR Borders

By default, BSR borders are not configured.

Run **ip pim bsr-border** to configure or cancel the configuration of BSR borders.

After this command is configured, BSMs received by the interface will be discarded and will not be forwarded by this interface, preventing BSM flooding.

Filtering BSMs

By default, BSMs from the BSR are not filtered.

Run **ip pim accept-bsr list** { <1-99> | <1300-1999> | *WORD* } to configure whether to filter BSMs.

If this function is enabled, only legible BSMs are received by the interface; if this function is disabled, all the external BSMs will be received by the device running PIM-SM.

Configuring Legible C-RP Addresses and the Multicast Groups They Serve for a Candidate BSR

By default, Candidate-RP-Advertisement (C-RP-Adv) packets are not filtered by a candidate BSR.

Run **ip pim accept-crp list { <100-199> | <2000-2699> | WORD }** to configure whether to filter C-RP-Adv packets.

If this function is enabled, C-RP addresses and corresponding multicast groups are filtered by a candidate BSR. If this function is disabled, all external C-RP-Adv packets are received by a candidate BSR.

✚ Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

By default, a candidate BSR cannot receive a C-RP-ADV packet whose prefix-count is 0.

Run **ip pim accept-crp-with-null-group** to configure whether to receive a C-RP-ADV packet whose prefix-count is 0.

If this function is enabled, a C-RP-ADV packet whose prefix-count is 0 can be received by a candidate BSR. If this function is disabled, a C-RP-ADV packet whose prefix-count is 0 cannot be received by a candidate BSR.

6.3.4 RP Mechanism

On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router. The RP as the root of the RPT, is the point where the RPT is rooted at and RPT data traffic is forwarded from.

Working Principle

All PIM routers in the same PIM domain must be mapped to the same RP as a specific multicast group address. On a PIM network, an RP can be configured as static or dynamic.

✚ Static RP

In static RP configuration, RP addresses are configured directly on PIM routers and these addresses are learnt by the entire PIM network.

✚ Dynamic RP

In a PIM-SM domain, there are candidate RPs that send unicast packets (including RP addresses and the multicast groups they serve) to the BSR, which generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain, and received and saved by PIM routers, which apply a hash function to map the group addresses to the candidate RP that can provide services. Then the RP corresponds to these multicast group addresses can be confirmed.

Related Configuration

✚ Configuring Static RP Addresses

By default, no RP address is configured.

Run **ip pim rp-address rp-address [access-list]** to configure a static RP address for a PIM router.

To use static RP addresses, the static RP address of all routers in the PIM-SM domain must be the same, so that the PIM SM multicast routing remains consistent.

✚ Configuring Candidate C-RP Addresses

By default, no C-RP address is configured.

Run **ip pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *access-list*] to configure or cancel a PIM router as a candidate C-RP.

After a candidate RP is configured, it can send periodic C-RP-Adv packets to the BSR, and the information carried by these C-RP-Adv packets will be advertized to all PIM-SMs in the domain, ensuring the uniqueness of RP mapping.

Ignoring the RP Priority in RP-Set

By default, C-RP of the highest priority is configured.

Run **ip pim ignore-rp-set-priority** to select or deselect the RP priority when selecting the corresponding RP of a multicast group.

If you want to select an RP from multiples RPs that serve the same multicast group address, you can run this command to ignore the RP priority. If this command is not configured, RP priority will be considered when two RPs are compared.

6.3.5 Register Information of the Multicast Source

When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.

Working Principle

When a source DR receives a multicast packet from the host directly connected to it, the source DR encapsulates the multicast packet into the register packet, and sends the unicast packet to RP to form an (S, G) entry.

If the RP has an outgoing interface for the forwarding entry, it encapsulates the data packet and forwards the packet to the outgoing interface.

If the RP does not have the forwarding entry of the present group, it generates the (S, G) entry and enables the timer. If the timer times out, the RP sends a Register-Stop packet to the DR to delete the entry. The source DR sends an inspection packet before timeout after it receives the Register-Stop packet.

If no Register-Stop packet is received by the DR, the DR on the timeout data source will encapsulate the multicast data in the register packet and send the unicast packet to the RP.

If a Register-Stop packet is received by the DR, time-delay will be performed once again, and an inspection packet will be sent before time delay.

Related Configuration

Detecting the Reachability of a Register Packet

By default, the reachability of an RP is not detected.

Run **ip pim register-rp-reachability** to configure or cancel the detection of the reachability of an RP.

You can enable this function if you want to detect whether an RP is reachable for a register packet sent from a DR. After this function is enabled, the DR will detect the reachability of a register packet before it is sent to an RP, namely, the DR will

check whether a route to the RP exists in the unicast routing entry and static multicast routing entry. If the route does not exist, the register packet will not be sent.

✚ Configuring an RP to Filter the Addresses of Register Packets

By default, all register packets are received an RP.

Run **ip pim accept-register** { **list** *access-list* [**route-map** *map-name*] | **route-map** *map-name* [**list** *access-list*] } to configure an RP to filter or cancel the filtering of the source addresses of received register packets.

You can run this command if you want to filter the source addresses of received register packets. If this function is not enabled, all register packets will be received by the RP. If this function is disabled, only the register packets whose source addresses and multicast group addresses included in access control lists (ACLs) are processed; otherwise, the packets will be filtered.

✚ Limiting the Speed for Sending a Register Packet

By default, the speed for sending a register packet is not limited.

Run **ip pim register-rate-limit** *rate* to limit or cancel the limitation of the speed for sending a register packet.

If the **no** form of this command is configured, the speed is not limited. This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system.

✚ Calculating the Checksum of the Entire Register Packet Length

By default, the checksum of a register packet is calculated as stipulated by the protocol.

Run **ip pim register-checksum-wholepkt** [**group-list** *access-list*] to configure the checksum of the register packet length.

You can enable this function if you want to include the length of encapsulated multicast packets into the checksum of the register packet length. If this function is disabled, the checksum of a register packet is calculated as stipulated by the protocol.

✚ Configuring an RP to Forward Multicast Data Packets to Downstream Interfaces After Decapsulating Register Packets

By default, register packets are not decapsulated and multicast packet are not forwarded to interfaces.

Run **ip pim register-decapsulate-forward** to forward or cancel the forwarding of data packets to downstream interfaces.

You can run this command if you want to decapsulate a register packet and forward the multicast packet. If this function is disabled, the multicast packet will not be forwarded.

✚ Configuring the Source IP Address of a Register Packet

By default, the source IP address of a register packet is the same as the interface address of the DR connected to the multicast source.

Run **ip pim register-source** { *local_address* | *Interface-type interface-number* } to configure the source IP address.

You can run this command if you want to configure the source IP address of the register packet sent by a DR. If this function is disabled or the **no** form of this command is used, the source address of the register packet will be the same as the interface address of the DR connected to the multicast source. If you want to configure *local_address*, the configured address must be reachable for a unicast route. *Interface-type interface-number* can be a typical a loopback interface or an interface of other types. The interface address must have been advertised by a unicast route.

✚ Configuring the Suppression Time of a Register Packet

By default, the suppression time of a register packet is 60s.

Run **ip pim register-suppression** *seconds* to configure the suppression time.

If you run this command on a DR, you can change the suppression time of the register packets sent from the DR. If you run this command but does not run **ip pim rp-register-kat** on an RP, the keepalive period of the RP will be changed.

✚ Configuring the Inspection Time of a Null Register Packet

By default, the inspection time is 5s.

Run **ip pim probe-interval** *interval-seconds* to configure the inspection time.

In the time interval before the timeout of register packet suppression, the source DR can send a null register packet to an RP. This time interval is called the inspection time, which is 5s by default.

✚ Configuring the Time of a RP KAT

By default, the default value of a keepalive timer (KAT) is used. The default value is calculated as follows: Suppression time of a register packet x 3 + Inspection time of a null register packet.

Run **ip pim rp-register-kat** *seconds* to configure the KAT time.

You can run this command if you want to configure the keepalive time of (S, G) of a register packet sent from an RP.

6.3.6 Creating an RPT

When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.

Working Principle

To create an RPT, perform the following steps:

A receiver DR receives an IGMP (*, G) include report packet from the receiving end.

If the DR is not the RP of this group (G), the DR will send a (*, G) Join packet toward the RP. The router receiving this (*, G) Join packet will send the packet hop by hop until it is received by the RP, which means that the RP has joined the RPT.

When the data source host sends the multicast data to a group, the source data is encapsulated in the register packet, and sent from the source DR to the RP in unicast mode. Then the RP decapsulates the register packet, takes the data packets out, and forwards these packets to each group member along the RPT.

The RP sends the (S, G) Join packets along the data source to join the SPT of this source.

After the SPT between the RPs to the source DR is created, the data packets from the data source will be sent decapsulated to the RPs along the SPT.

When the first multicast data packet arrives at an RP along the SPT, the RP sends a Register-Stop packet to the source DR to stop sending a register packet. After the source DR receives the Register-Stop packet, it stops encapsulating a register packet and sends the packet along the SPT to the RP, which will forwards the packet to each group member.

Related Configuration

✚ Configuring the Interval for Sending a Join/Prune Packet

By default, the interval for sending a Join/Prune packet is 60s.

Run **ip pim jp-timer** *seconds* to configure the interval for sending a Join/Prune packet.

You can run this command to configure the interval for sending a Join/Prune packet. If not configured, the value will be a default 60s.

6.3.7 Creating an SPT

When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT. In this way, the burden on RP in the RPT is reduced, and the source DR will arrive at the receiver DR with less hops.

Working Principle

To create an SPT, perform the following steps:

The receiver DR sends (*, G) Join packets toward the source DR along the SPT, and (*, G) Join packets are then send hop by hop until they are received by the source DR, forming an SPT.

Related Configuration

By default, SPT switchover is not enabled.

Run **ip pim spt-threshold** [**group-list** *access-list*] to configure whether to switch to an SPT.

If this function is enabled, upon the reception of the first (S, G) packet, a PIM Join packet is triggered, and an SPT is created. If **group-list** is specified, all the specified groups will be switched to the SPT. If the **no** form of this command is used and **group-list** is not specified, an RPT will not be switched to an SPT, and the DR will remain in the RPT and send a Prune packet toward the source DR; if the **no** form of this command is used and **group-list** is specified, and that the ACLs have been configured, it means that the association between **group-list** and the ACLs is canceled, and all the groups are allowed to switch from an RPT to an SPT.

6.3.8 ASM and SSM

A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model. In an ASM model,

only the multicast group (G) is specified for a multicast receiver, and the multicast source (S) is not specified. In an SSM model, both the multicast source (S) and multicast group (G) can be specified for a multicast receiver.

Working Principle

! To realize SSM in an IPv4 router, IGMPv3 needs to be applied for managing membership between the host and devices, and PIM-SM needs to be applied to connect to devices.

In an SSM model, as a multicast receiver has learnt the (S, G) of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement), when a multicast receiver needs to request a multicast service, the multicast receiver can send the IGMP (S, G) Join packet toward the router of last hop. For example, as shown in Figure 6-3, the multicast receiver 1 sends the IGMP (S, G) Join packet to request the multicast service (S, G). After the router of last hop receives the IGMP (S, G) Join packet, it sends the PIM (S, G) Join packet to the multicast source hop by hop. As shown in Figure 6-4, when R 1 receives the IGMP (S, G) Join packet sent from multicast Receiver 1, R 1 sends the PIM (S, G) Join packet to R 3, which then sends the packet to R 4, thereby forming an SPT connecting the multicast receiver and multicast source.

Figure 6-4 SSM Model

To create an SSM model, the following requirements need to be met:

- A multicast receiver needs to learn the (S, G) of the multicast source in advance, and an IGMP (S, G) Join packet needs to be sent if the receiver needs to request a multicast service.
- IGMPv3 must be run on the interface of the last hop router connecting to the multicast receiver. IGMPv1 and IGMPv2 does not support SSM.
- PIM-SM and SSM must be run on the devices connecting the multicast receiver and multicast source.

! The default range of SSM groups is 232/8. You can run a command to change the value.

An SSM has the following features:

- A multicast receiver can learn the information of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement) in advance.

- An SSM model is a specific subnet of PIM-SM. It handles only the PIM (S, G) Join and PIM (S, G) Prune packets and discards the RPT-related packets, for example, PIM (*, G) Join/Prune packets, that are within the scope the SSM. If the SSM detects a register packet within the scope, it will respond immediately with a Register-Stop packet.
- If an RP is not required, the election and distribution of RP information are not performed. The MDTs in an SSM are all SPTs.

Related Configuration

ASM is enabled by default.

Run **ip pim ssm { default | range access-list }** to configure whether to switch to SSM.

In SSM, multicast packets can be received by the multicast source directly but not along the RP tree.

6.4 Configuration

Configuration	Description and Command	
Configuring Basic PIM-SM Functions	 (Mandatory) It is used to configure the multicast service.	
	ip multicast-routing	Enables IPv4 multicast routing.
	ip pim sparse-mode	Enables PIM-SM.
	ip pim rp-address	Configures a static RP.
	ip pim rp-candidate	Configures a C-RP.
	ip pim bsr-candidate	Configures a C-BSR.
	ip pim ssm	Enables SSM.
Configuring PIM-SM Neighbors	 (Optional) It is used to configure the parameters for sending and receiving the Hello packets between neighbors.	
	ip pim query-interval <i>interval-seconds</i>	Configures the interval for sending Hello packets.
	ip pim propagation-delay <i>milliseconds</i>	Configures the prune propagation delay.
	ip pim override-interval <i>milliseconds</i>	Configures the prune override interval.
	ip pim neighbor-tracking	Enables the suppression capability of an interface for sending Join packets.
	ip pim triggered-hello-delay <i>interval-seconds</i>	Configures the delay for sending Hello packets.
	ip pim dr-priority <i>priority-value</i>	Configures the DR priority of a Hello packet.
	ip pim neighbor-filter <i>access_list</i>	Configures neighbor filtering.
Configuring BSR Parameters	 (Optional) It is used to configure a BSR.	
	ip pim bsr-border	Configures BSR borders.
	ip pim accept-bsr list { <1-99> <1300-1999> WORD }	Configures BSM packets limit on a PIM router.

Configuration	Description and Command	
	ip pim accept-crp list <i>access-list</i>	Configures a C-BSR to inspect the address range of a C-PR.
Configuring RP and DR Parameters	 (Optional) It is used to configure the parameters of an RP or a DR.	
	ip pim ignore-rp-set-priority	Ignores the C-RP priority.
	ip pim register-rp-reachability	Enables the source DR to detect the RP reachability.
	ip pim accept-register list <i>access-list</i>	Configures the range of source register (S, G) addresses.
	ip pim register-rate-limit <i>rate</i>	Limits the speed for sending register packets.
	ip pim register-checksum-wholepkt [group-list <i>access-list</i>]	Calculates the checksum of the entire register packet.
	ip pim register-decapsulate-forward	Enables an RP to decapsulate a register packet and forwards the multicast packet to interfaces.
	ip pim register-source { <i>local_address</i> <i>Interface-type interface-number</i> }	Configures the source IP address of a register packet.
	ip pim register-suppression <i>seconds</i>	Configures the suppression time of a register packet.
	ip pim probe-interval <i>seconds</i>	Configures the inspection time of a null register packet.
	ip pim rp-register-kat <i>seconds</i>	Configures the interval of KATs on an RP.
Configuring the Interval for Sending a Join/Prune Packet	 (Optional) It is used to specify the interval for sending a Join/Prune packet.	
	ip pim jp-timer <i>seconds</i>	Configures the interval for sending a Join/Prune packet.
Configuring the Router of Last Hop to Switch from an RPT to SPT	 (Optional) It is used to switch from SPT to RPT.	
	ip pim spt-threshold [group-list <i>access-list</i>]	Enables SPT switchover.

6.4.1 Configuring Basic PIM-SM Functions

Configuration Effect

- Create a PIM-SM network and provide data sources and user terminals on the network with the IPv4 multicast service.
- Any of ASM or SSM or both models can be configured.

Notes

- PIM-SM needs to use existing unicast routes on the network. Therefore, IPv4 unicast routes must be configured on the network.
- If the PIM network needs to support SSM multicast services, IGMPv3 or SSM mapping must be configured.

Configuration Steps

➤ Enabling IPv4 Multicast Routing

- Mandatory.
- If not specified, IPv4 multicast routing must be enabled on each router.

➤ Enabling PIM-SM

- Mandatory.
- If not specified, PIM-SM must be enabled on the following interfaces: interconnecting router interfaces, interfaces of static RPs, C-RPs, and C-BSRs, and the interfaces connecting to the multicast source and user hosts.

➤ Configuring an RP

- An RP must be configured if ASM multicast services need to be provided on a PIM network.
- An RP can be configured in three models: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and dynamic RP. If both a static RP and dynamic RP are configured, the dynamic RP takes precedence over the static RP.
- Configuring a static RP: If not specified, a static RP should be configured on each router.
- Configuring a dynamic RP: If not specified, a C-RP and C-BSR should be configured on one or multiple routers.

➤ Enabling SSM

- SSM must be enabled if SSM multicast services need to be provided on a PIM network.
- If not specified, SSM must be enabled on every router.

Verification

Send multicast packets from the multicast source to the groups within the address range of ASM and SSM, and join user hosts to these groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether PIM-SM routing entries are created on routers correctly.

Related Commands

➤ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter	N/A
Description	

Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling PIM-SM

Command	ip pim sparse-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces. For all PIM interfaces, IPv4 unicast routes should be reachable.

↘ Configuring a Static RP

Command	ip pim rp-address <i>rp-address</i> [<i>access_list</i>]
Parameter Description	<i>rp-address</i>: Indicates the address of an RP. <i>access_list</i>: Specifies the range of multicast group addresses served by a static RP using an ACL. By default, an RP services all groups.
Command Mode	Global configuration mode
Usage Guide	This command is used to locate a static RP. A static RP should be one with good routing performance. It is recommended that the address of the loopback interface be used as the static RP address. The static RP of all routers must be the same (including the RP address and the range of multicast group addresses it serves). It is recommended that the address of the loopback interface be used as the static RP address. The load can be shared if you configure multiple static RPs to serve different multicast group addresses. It is recommended that the address of the loopback interface be used as the static RP address.

↘ Configuring a C-RP

Command	ip pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>seconds</i>] [group-list <i>access_list</i>]
Parameter Description	<i>interface-type interface-number</i>: Uses the address of this interface as the address of the C-RP. priority <i>priority-value</i>: Competes for the RP priority. A greater value indicates a higher priority. The value ranges from 0 to 255 (192 by default). interval <i>seconds</i>: Indicates the interval for sending a C-RP packet to a BSR. The value ranges from 1 to 16,383 (60 by default). group-list <i>access_list</i>: Specifies the range of multicast group addresses served by a C-RP using an ACL. By default, a C-RP services all multicast groups.

Command Mode	Global configuration mode
Usage Guide	This command is used to configure a router as a C-RP. A C-RP should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers. It is recommended that the address of the loopback interface be used as the C-RP address. If multiple C-RPs serve the same group, redundancy can be realized. If multiple C-RPs serve the different groups, load can be shared.

📌 Configuring a C-BSR

Command	ip pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<i>interface-type interface-number</i>: Uses the address of this interface as the address of the C-BSR. <i>hash-mask-length</i>: Indicates the length of hash mask used to competing for the RP. The value ranges from 0 to 32 (10 by default). <i>priority-value</i>: Indicates the priority for competing for the BSR. A greater value indicates a higher priority. The value ranges from 0 to 255 (64 by default).
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a router as a C-BSR. A C-BSR should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers. It is recommended that the address of the loopback interface be used as the C-BSR address. Configuring multiple C-BSRs can realize redundancy.

📌 Enabling SSM

Command	ip pim ssm { default range access_list }
Parameter Description	default: Indicates the default range of SSM group addresses, which is 232.0.0.0/8. range access_list: Specifies the range of SSM group addresses using an ACL.
Command Mode	Global configuration mode
Usage Guide	The SSM group addresses configured on all routers must be the same.

📌 Displaying the PIM-SM Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [proxy]
Parameter Description	<i>group-or-source-address</i>: Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time). proxy: Indicates the RPF vector carried by an entry.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Check whether sufficient routing entries are provided. Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.

Configuration Example

Enabling IPv4 Multicast Routing to Support ASM and SSM

Scenario
Figure 6-5

Configuration
Steps

- Configure a IPv4 unicast routing protocol (such as OSPF) on a router, and the router is reachable for the unicast route of a loopback interface. (Omitted)
- Enable IPv4 multicast routing on all the routers.
- Enable PIM-SM on all the interconnected interfaces of the routers, Source, and Receiver.
- Configure C-RP and C-BSR on the loopback interfaces of Router A and Router B, and enable PIM-SM on the loopback interfaces.
- Enable SSM on all routers.
- Enable IGMPv3 on the router interfaces connecting to user terminals. (Omitted)

A

```
A# configure terminal
A(config)# ip multicast-routing
A(config)# ip pim ssm default
A(config)# interface GigabitEthernet 0/1
A(config-if)# ip pim sparse-mode
A(config-if)# exit
A(config)# interface GigabitEthernet 0/2
A(config-if)# ip pim sparse-mode
A(config-if)# exit
A(config)# interface loopback 0
A(config-if)# ip pim sparse-mode
A(config-if)# exit
A(config)# ip pim rp-candidate loopback 0
```

B

```
B# configure terminal
```

	<pre> B(config)# ip multicast-routing B(config)# ip pim ssm default B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# interface loopback 0 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# ip pim bsr-candidate loopback 0 </pre>
Verification	Send packets from S (192.168.1.10) to G 1 (229.1.1.1) and G2 (232.1.1.1). Add the user to G 1 and G 2, and specify the source when the user joins G 2. ● Check that multicast packets from S (192.168.1.10) to G 1 and G 2 are received by the user. ● Check the PIM-SM routing entries on Router A and Router B. Entries (*, 229.1.1.1), (192.168.1.10, 229.1.1.1), and (192.168.1.10, 232.1.1.1) should be displayed.

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- SSM is not enabled on a router or the SSM group address is different from that of the others'.
- PIM-SM is not enabled on an interface (for example, the interface is configured as a C-RP or C-BSR interface, or is used to connecting to the user host or used as an interface of the multicast source).
- IGMPv3 is not enabled on an interface connecting to the used host.
- RP is not configured on the network.
- A static RP is not configured on a router, or the configured static RP is different from that on other routers.
- C-RPs are configured on the network, but C-BSRs are not.
- Static RPs, C-RPs or C-BSRs are unreachable for unicast routes.

6.4.2 Configuring PIM-SM Neighbors

Configuration Effect

- Coordinate protocol parameters and adjust parameters in the Hello packet.
- A RIM router is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.
- Maintain neighbor relationships and filter the neighbors.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure parameters on PIM router interfaces If not specified.

Verification

Configure the parameters of a Hello packet sent from an interface and run **debug ip pim sparse-mode packet** to display the parameters.

Enable neighbor filtering and run **show ip pim sparse-mode neighbor** to display neighbor information.

Related Commands

✚ Configuring the Interval for Sending Hello Packets

Command	ip pim query-interval <i>interval-seconds</i>
Parameter Description	Indicates the interval for sending Hello packets, Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (30 by default).
Command Mode	Interface configuration mode
Usage Guide	Every time when the interval for sending Hello packets is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval for sending Hello packets multiplied by 3.5 is greater than 65,535, the holdtime value is forcibly updated as 18,725.

✚ Configuring the Prune Propagation Delay

Command	ip pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 32,767 (500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed. As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.

✚ Configuring the Prune Override Interval

Command	ip pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 65,535 (2,500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed. As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.

▾ Enabling Suppression Capability of an Interface for Sending Join Packets

Command	ip pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Once Join packets suppression of an interface is enabled, when the present router is to send a Join packet to the upstream neighbor, which has sent a Join packet to its own upstream neighbor, the present router will not send the Join packet; if Join packets suppression is disabled, the Join packet will be sent. When Join packets suppression from downstream receivers are disabled, upstream neighbors will learn how many downstream neighbors are there by counting the Join packets it received, which is called neighbor tracking.

▾ Configuring the Delay for Sending Hello Packets

Command	ip pim triggered-hello-delay <i>interval-seconds</i>
Parameter Description	<i>Seconds</i> : The unit is second. The value ranges from 1 to 5 (5 by default).
Command Mode	Interface configuration mode
Usage Guide	When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

▾ Configuring the DR Priority of a Hello Packet

Command	ip pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A greater value indicates a higher priority. The value ranges from 0 to 4,294,967,294 (1 by default).
Command Mode	Interface configuration mode
Usage Guide	A DR may be selected based on the following principles: If all the Hello packets sent from the routers on a local area network (LAN) are configured with priorities, when selecting a DR, the priorities will be compared, and the router with the highest priority will be selected as the DR. If the priority of all routers is the same, their IP addresses will be compared, and the router with the maximum IP address will be selected as the DR. If the priority of the Hello packets sent from a certain router is not configured, the IP addresses of the routers will be compared, and the router with the maximum IP address will be selected as the DR.

▾ Configuring Neighbor Filtering

Command	ip pim neighbor-filter <i>access_list</i>
Parameter Description	<i>access_list</i> : Configures the range of neighbor addresses using a standard IP ACL. The value can be set from 1 to 99 or a string.
Command	Interface configuration mode

Mode	
Usage Guide	Enabling neighbor filtering can enhance the security of the PIM network and limit the range of legible neighbor addresses. Once a neighbor is filtered out, PIM-SM will not establish peering with it or stop the peering with it.

▾ Displaying the Neighbor Information of an Interface

Command	show ip pim sparse-mode neighbor [detail]
Parameter	
Description	detail: Displays detailed information.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure the interval for sending Hello packets as 50s. ● Configure the prune propagation delay as 400 ms. ● Configure the prune override interval as 3,000 ms. ● Enable suppression capability of an interface for sending Join packets. ● Configure the delay for sending Hello packets as 3s. ● Configure the DR priority of a hello packet as 5.
	<pre> Ruijie# configure terminal Ruijie (config)#int gi 0/1 Ruijie (config-if-GigabitEthernet 0/1)#ip pim query-interval 50 Ruijie (config-if-GigabitEthernet 0/1)#ip pim propagation-delay 400 Ruijie (config-if-GigabitEthernet 0/1)#ip pim override-interval 3000 Ruijie (config-if-GigabitEthernet 0/1)#ip pim triggered-hello-delay 3 Ruijie (config-if-GigabitEthernet 0/1)#ip pim neighbor-tracking </pre>
Verification	Run debug ip pim sparse-mode packet to display the parameters of a Hello packet.
	<pre> Ruijie# debug ip pim sparse-mode packet 00:01:49:43: %7: VRF(0): Hello send to GigabitEthernet 0/1 00:01:49:43: %7: Send Hello packet 00:01:49:43: %7: Holdtime: 175 00:01:49:43: %7: T-bit: on 00:01:49:43: %7: Propagation delay: 400 </pre>

	Ruijie# show ip pim sparse-mode neighbor															

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.

6.4.3 Configuring BSR Parameters

Configuration Effect

- Configure the address range of BSM packets.

Notes

- Basic PIM-SM functions must be configured.
- C-RPs and C-BSRs must be configured.
- Borders must be configured on the interfaces between domains.

Configuration Steps

✚ Configuring Boarders

- Boarders must be configured if there are multiple domains.
- Boarders are configured on the interfaces separating two domains.

✚ Configuring BSM Packets Limit on a PIM Router

- Optional.
- If not specified, BSM packets limit can be configured on all PIM routers.

✚ Configuring a C-BSR to Inspect the Address Range of a C-PR

- Optional.
- If not specified, C-PR range inspection can be configured on all C-BSRs.

✚ Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

- Optional.
- If not specified, this function can be configured on all C-BSRs.

Verification

✚ Border Inspection

Enable basic PIM-SM functions. Configure two routers to be in different domains, configure Router B as the C-BSR, and Router A to receive BSM packets.

Configure the junction of Router A and Router B as the border so that Router A does not receive BSM packets.

✚ Configuring to Inspect BSM Packets Limit on a PIM Router

When basic PIM-SM functions are enabled, and Router B is set as the C-BSR, Router A can receive BSM packets. When the address range of C-BSRs are limited on Router A, BSM packets will not be received by Router A.

✚ Configuring a C-BSR to Inspect the Address Range of a C-PR

When basic PIM-SM functions are enabled, Router B is set as the C-BSR, and Router A as the C-RP, if the address range of the C-RPs is limited on C-BSR, Router B will not receive the packets sent from the C-RPs.

Related Commands

✚ Configuring BSR Boarders

Command	ip pim bsr-border
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To prevent BSM flooding, you can configure a BSR boarder on an interface, so that the BSM packets arriving at this interface will be discarded but not forwarded.

Configuring BSM Packets Limit on a PIM Router

Command	ip pim accept-bsr list { <1-99> <1300-1999> WORD }
Parameter Description	list access-list: Configures the range of BSR addresses using a standard IP ACL. The value can be 1 to 99, 1,300 to 1,999, or a string.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, PIM-SM routers receive only the BSM packets sent from legible BSRs.

Configuring a C-BSR to Inspect the Address Range of a C-PR

Command	ip pim accept-crp list access-list
Parameter Description	list access-list: Specifies the range of C-RP addresses and the multicast group addresses they serve using an extended IP ACL. The value can be 100 to 199, 2,000 to 2,699, or a string.
Command Mode	Global configuration mode
Usage Guide	This command should be configured on a C-BSR. When the C-BSR becomes a BSR, it can set the range of legible C-RP addresses and the range of multicast group addresses they serves.

Displaying BSM Packets Information

Command	show ip pim sparse-mode bsr-router
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Displaying the Packets of All RPs and the Multicast Group Addresses They Serve

Command	show ip pim sparse-mode rp mapping
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring BSR Borders

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as

	192.168.6.6. Configure a BSR boarder on the junction of Router A and Router B.
	<pre>Ruijie# configure terminal Ruijie(config)# int GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip pim bsr-border Ruijie(config)# end</pre>
Verification	Before configuring the boarder, display the BSM information on Router A.
	<pre>Ruijie# show ip pim sparse-mode bsr-router PIMv2 Bootstrap information This system is the Bootstrap Router (BSR) BSR address: 192.168.6.6 Uptime: 01:14:25, BSR Priority: 64, Hash mask length: 10 Next bootstrap packet in 00:00:52 Role: Candidate BSR Priority: 64, Hash mask length: 10 State: Elected BSR Candidate RP: 192.168.8.8(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:06</pre>
	 Candidate RP: Indicates all the C-RPs configured on the existing router. It does not include the C-RPs configured on other routers.
	After the boarder is configured, display the BSM information on Router A.
	<pre>Ruijie# show ip pim sparse-mode bsr-router</pre>

Configuring BSM Packets Limit on a PIM Router, Filtering BSM Source Addresses, and Configuring the Range of BSM Source Addresses to 192.168.1.1 to 192.168.1.255

Configuration Steps	- Configure basic PIM-SM functions. (Omitted) - On Router A, configure the address of the C-RP as 192.168.8.8. - On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. - On Router A, configure the range of allowed BSM source addresses to 192.168.1.1 to 192.168.1.255.
	<pre>Ruijie# configure terminal Ruijie(config)# ip pim accept-bsr list 1</pre>

	<pre>% access-list 1 not exist Ruijie(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Ruijie(config)#</pre>
Verification	Before configuring BSM packets limit, display the BSM information on Router A.
	<pre>Ruijie#show ip pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 192.168.6.6 Uptime: 00:00:11, BSR Priority: 64, Hash mask length: 10 Expires: 00:01:59 Role: Non-candidate BSR Priority: 0, Hash mask length: 10 State: Accept Preferred Candidate RP: 192.168.8.8(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:06</pre>
	After BSM packets limit is configured, display the BSM information on Router A.
	<pre>Ruijie# show ip pim sparse-mode bsr-router Candidate RP: 192.168.8.8(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:06</pre>

➤ **Configuring a C-BSR to Inspect the Address Range of a C-PR, Filtering C-RP Addresses, and Configuring the Range of C-RP Addresses to 192.168.1.1 to 192.168.1.255**

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. ● On Router B, configure the range of allowed C-RP source addresses to 192.168.1.1 to 192.168.1.255.
	<pre>Ruijie# configure terminal Ruijie(config)# ip pim accept-crp list 100 % access-list 1 not exist Ruijie(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Ruijie(config)#</pre>
Verification	Before configuring C-RP filtering, display the information of all RP groups on Router B.

	<pre> Ruijie#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.8.8(Not self) Info source: 192.168.8.8, via bootstrap, priority 192 Uptime: 00:15:16, expires: 00:02:18 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 18:52:30, expires: 00:02:00 </pre>
	After C-RP filtering is configured, display the information of all RP groups on Router B.
	<pre> Ruijie#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 21:38:20, expires: 00:02:10 </pre>
	 After C-RP filtering is configured on a router, only the C-RP packets sent from other routers are filtered, and those sent from the present router are not filtered.

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- C-BSRs are not configured.
- The BSR border is not configured on the interfaces of different domains.

6.4.4 Configuring RP and DR Parameters

Configuration Effect

- Ignore the C-RP priority and reselect an RP.
- Detect the reachability of an RP for the source DR.
- Configure the range of (S, G) addresses of source register packets, and allow the ASM to serve only the multicast packets within the range.

- Limit the speed of the source DR for sending register packets.
- Configure the checksum of the register packet length.
- Configure an RP to decapsulate register packets and forward the multicast packets to downstream interfaces.
- Configure the source IP address of a register packet.
- Configure the suppression time of a register packet.
- Configure the inspection time of a null register packet.
- Configure the (S, G) lifetime based on the register packet received by an RP.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

✚ Ignoring the C-RP Priority and Reselecting an RP

- Optional.
- If not specified, the C-RP priority can be disabled on every router.

✚ Detecting the Reachability of an RP for the Source DR

- Optional.
- If not specified, this function can be enabled on the DR connected directly to the data source.

✚ Configuring the Range of Source Register (S, G) Addresses

- Optional.
- If not specified, source register address filtering can be enabled on all C-RPs or static RPs.

✚ Limiting the Speed of the Source DR for Sending Register Packets

- Optional.
- If not specified, this function can be enabled on the source DR.

✚ Configuring the Checksum of the Register Packet Length

- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.

✚ Configuring Whether to Forward the Multicast Packet After Decapsulating a Register Packet

- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.

✚ Configuring the Source IP Address of a Register Packet

- Optional.
- If not specified, the source IP address of a register packet can be configured on the DR connected directly to the data source.

✚ Configuring the Suppression Time of a Register Packet

- Optional.
- If not specified, the suppression time of a register packet can be configured on the DR connected directly to the data source.

✚ Configuring the Inspection Time of a Null Register Packet

- Optional.
- If not specified, the inspection time of a null register packet can be configured on the DR connected directly to the data source.

✚ Configuring the (S, G) Lifetime Based on the Register Packet Received by an RP

- Optional.
- If not specified, the (S, G) lifetime can be configured on all C-RPs or static RPs.

Verification

✚ Ignoring the C-RP priority

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 200, and C-BSR address as 192.168.6.6.

- Run **show ip pim sparse-mode rp** 233.3.3.3 to display the RPs of the present group.

✚ Enabling the Source DR to Detect RP Reachability

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 192, and C-BSR address as 192.168.6.6. Enable Router B to detect RP reachability.

- Run **show running-config** to check whether the preceding configurations take effect.

✚ Configuring the Range of Source Register (S, G) Addresses

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the address of the C-BSR as 192.168.6.6. Configure the source address as 192.168.1.100 and the multicast group address as 233.3.3.3. On Router A, configure the range of allowed source multicast group addresses to 192.168.2.0 to 192.168.2.255.

- Run **show ip pim sparse-mode mroute** to display the (S, G) entry.

✚ Limiting the Speed of the Source DR for Sending Register Packets

Configure the speed of Router B for sending register packets, and run **show ip pim sparse-mode track** to display the number of packets that has been sent.

✚ Configuring the Checksum of the Register Packet Length

On Router A, configure to calculate the checksum of the entire register packet length but not just the packet header. Run **show running-config** to check the configuration.

✚ Forwarding an RP Register Packet After It Is Decapsulated

On Router A, configure to forward a register packet after it is decapsulated. Run **show running-config** to display the configuration.

✚ Configuring the Source IP Address of a Register Packet

Configure the source address of a register packet on Router B, and run **show running-config** to display the configuration.

✚ Configuring the Suppression Time of a Register Packet and the Inspection Time of a Null Register Packet

On Router B, configure the suppression time and inspection time of a register packet, and run **show ip pim sparse-mode track** to display the configuration.

✚ Configuring an RP to Receive Register Packets and the (S, G) Lifetime

On Router A, configuring an RP to receive register packets and the (S, G) lifetime, and run **show ip pim sparse-mode mroute** to display the maximum (S, G) lifetime.

Related Commands

✚ Ignoring the C-RP priority

Command	ip pim ignore-rp-set-priority
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Displaying the RP Corresponding to a Group

Command	show ip pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed multicast group address.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

✚ Enabling the Source DR to Detect RP Reachability

Command	ip pim register-rp-reachability
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	After this function is enabled, the source DR will detect the RP reachability before sending a register packet. If the RP is unreachable, the packet will not be sent.

✚ Configuring the Range of Source Register (S, G) Addresses

Command	ip pim accept-register { list <i>access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>access-list</i>] }
Parameter Description	list <i>access-list</i> : Configures the range of (S, G) addresses using an extended IP ACL. The value can be 100 to 199, 2,000 to 2699, or a string. route-map <i>map-name</i> : Configures the range of (S, G) addresses using a route map.
Command Mode	Global configuration mode
Usage Guide	This command is run on a static RP or a C-RP to specify the source address and multicast group address of a register packet.

✚ Displaying a Multicast Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [proxy]
Parameter Description	<i>group-or-source-address</i> : Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time). Proxy : Indicates the RPF vector carried by an entry.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	You can specify either a multicast group address or source address, or both a multicast group address and source address; or you can specify neither a multicast group address nor source address. The two addresses cannot be multicast group addresses or source addresses at the same time.

✚ Limiting the Speed of the Source DR for Sending Register Packets

Command	ip pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the maximum number of register packets that can be sent each second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system. Enabling this command can reduce the burden on the source DR and RPs. Only the packets within the speed limit can be sent.

✚ Displaying the Counters of PIM-SM Packets

Command	show ip pim sparse-mode track
Parameter	N/A

Description	
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	The start time for counting PIM-SM packets is automatically enabled upon system startup. Run clear ip pim sparse-mode track to reset the start time and clear the PIM-SM packet counters.

✚ Calculating the Checksum of the Entire Register Packet Length

Command	ip pim register-checksum-wholepkt [group-list access-list]
Parameter Description	group-list access-list: Configures the multicast group addresses applicable to this configuration using an ACL. access-list: The value can be set to 1 to 99, and 1300 to 1999. It also supports the naming of the ACL.
Command Mode	Global configuration mode
Usage Guide	You can enable this function if you want to calculate the length of the entire PIM-SM packet, including that of the multicast packet encapsulated in the register packet, but not just the length of the PIM-SM packet header. If group-list access-list is specified, this configuration takes effect for all multicast group addresses.

✚ Enabling an RP to Decapsulate a Register Packet and Forward the Multicast Packet to Interfaces

Command	ip pim register-decapsulate-forward
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is configured on a static RP or a C-RP. It is used to decapsulate a register packet with multicast packet and forward the multicast packet to interfaces. If there are too many register packets to be decapsulated, the CPU will be greatly burdened. In this case, this function is recommended to be disabled.

✚ Configuring the Source IP Address of a Register Packet

Command	ip pim register-source { local_address Interface-type interface-number }
Parameter Description	local_address: Specifies the source IP address of a register packet. interface-type interface-number: Specifies the IP address of this interface as the source IP address of the register packet.
Command Mode	Global configuration mode
Usage Guide	The specified address must be reachable. When an RP sends a Register-Stop packet, the PIM router corresponds to this address need to respond. Therefore, it is recommended that a loopback address (or other physical addresses) be used. This configuration does not require the enabling of PIM.

✚ Configuring the Suppression Time of a Register Packet

Command	ip pim register-suppression seconds
Parameter Description	<i>Seconds</i> : Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (60 by default).
Command Mode	Global configuration mode
Usage Guide	If you configure this parameter on a DR, the suppression time of a register packet sent from the DR will be changed. If ip pim rp-register-kat is not configured and if you configure this parameter on an RP, the RP keepalive will be changed.

✚ Configuring the Inspection Time of a Null Register Packet

Command	ip pim probe-interval seconds
Parameter Description	<i>Seconds</i> : Indicates the inspection time of a null register packet in the unit of seconds. The value ranges from 1 to 65,535 (5 by default).
Command Mode	Global configuration mode
Usage Guide	The inspection time of a null register packet indicates the period of time for sending a null register packet to an RP before the timeout of suppression time. The inspection time cannot exceed half of the suppression time; otherwise, the configuration will not take effect, and a warning message will be displayed. Meanwhile, the result of suppression time multiplied by 3 plus the inspection time cannot exceed 65,535, otherwise, a warning will be displayed.

✚ Configuring the Interval of KATs on an RP

Command	ip pim rp-register-kat seconds
Parameter Description	<i>Seconds</i> : Indicates the interval of a KAT in the unit of second. The value ranges from 1 to 65,535 (210 by default).
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ Configuring the RPs of Corresponding Multicast Group Addresses When the C-RP Priority is Considered or Not Considered

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, priority as 200, and the address of the C-BSR as 192.168.6.6. ● Display the group corresponding to 233.3.3.3. ● Configure to ignore the C-RP priority on Router B.

	<pre>Ruijie# configure terminal Ruijie(config)# ip pim ignore-rp-set-priority</pre>
Verification	Display the information before you configure to ignore the C-RP priority.
	<pre>Ruijie# show ip pim sparse-mode rp-hash 233.3.3.3 RP: 192.168.8.8 Info source: 192.168.8.8, via bootstrap PIMv2 Hash Value 10(mask 255.192.0.0) RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102 RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709</pre>
	Display the information after you configure to ignore the C-RP priority.
	<pre>Ruijie# show ip pim sparse-mode rp-hash 233.3.3.3 RP: 192.168.5.5 Info source: 192.168.6.6, via bootstrap PIMv2 Hash Value 10(mask 255.192.0.0) RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102 RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709</pre>

📌 Configuring to Inspect the Reachability of a Source RP

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure to inspect the reachability of a source RP.
	<pre>Ruijie(config)# ip pim register-rp-reachability</pre>
Verification	Run show running-config to check whether the following information is displayed.
	<pre>Ruijie(config)#show running-config ip pim register-rp-reachability</pre>

📌 Configuring the Range of Source Register (S, G) Addresses

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure source address filtering on Router A. The allowed address range is from 192.168.2.0 to 192.168.2.255.
	<pre>Ruijie#show ip pim sparse-mode mroute</pre>

	<pre>Ruijie(config)#ip pim accept-register list 101 % access-list 101 not exist Ruijie(config)#access-list 101 permit ip 192.168.2.0 0.0.0.255 any Ruijie#show ip pim sparse-mode mroute</pre>
Verification	Before enabling source address filtering, run show ip pim sparse-mode mroute to display the multicast entry, and check whether the (S, G) entry and (S, G, RPT) entry exist.
	<pre>Ruijie#show ip pim sparse-mode mroute IP Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0 (192.168.1.100, 233.3.3.3) RPF nbr: 192.168.36.90 RPF idx: VLAN 1 SPT bit: 0 Upstream State: NOT JOINED kat expires in 187 seconds 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local 0 Joined 0 Asserted 0</pre>

📌 **Configuring the Checksum of the Register Packet Length**

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Calculate the checksum of the entire register packet length. ● Run show running-config to check whether the preceding configurations take effect.
	<pre>Ruijie(config)#ip pim register-checksum-wholepkt</pre>
Verification	Display the configurations on Router A, which should be as follows:
	<pre>Ruijie#show running-config ! ip pim register-checksum-wholepkt ip pim rp-candidate Loopback 0</pre>

	<pre>!</pre>

▾ Enabling an RP to Decapsulate a Register Packet and Forward the Multicast Packet to Interfaces

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Enable Router A to forward a register packet. ● Run show running-config to check whether the preceding configurations take effect.
	<pre>Ruijie(config)#ip pim register-decapsulate-forward</pre>
Verification	Display the configurations on Router A, which should be as follows:
	<pre>Ruijie#show running-config ! ! ip pim register-decapsulate-forward ip pim register-checksum-wholepkt ip pim rp-candidate Loopback 0 ! ! !</pre>

▾ Configuring the Source IP Address of a Register Packet

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure the source address of Loop 2 as 192.168.2.2. ● Configure source address interface for the register packet of Router B as Loop 2. ● Run show running-config to check whether the preceding configurations take effect.
Verification	Display the configurations on Router B, which should be as follows:
	<pre>Ruijie#show running-config ! ! ! ip pim register-source Loopback 1 ip pim bsr-candidate Loopback 0</pre>

	<pre>! ! ! !</pre>

 Configuring the Suppression Time of a Register Packet and the Inspection Time of a Null Register Packet

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure the suppression time of a register packet on Router B to 20s. ● Configure the inspection time of a null register packet on Router B to 2s. ● Run show ip pim sparse-mode track to display number of register packets.
	<pre>Ruijie(config)#ip pim register-suppression 20 Ruijie(config)#ip pim probe-interval 2</pre>
Verification	Display the number of register packets on Router B. The information should be displayed as follows: <pre>Ruijie#show ip pim sparse-mode track PIM packet counters track Elapsed time since counters cleared: 04d23h15m received sent Valid PIM packets: 23788 43249 Hello: 13817 23178 Join-Prune: 0 4568 Register: 0 8684 Register-Stop: 4223 0 Assert: 0 0 BSM: 0 6819 C-RP-ADV: 5748 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0</pre>

	<pre> Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 0 Packets received with unknown PIM version: 0 Ruijie# Ruijie# </pre>
	In 18s, display the number of register packets on Router B. The information should be displayed as follows:

Configuring an RP to Receive Register Packets and the (S, G) Lifetime

[illegible]

	. Outgoing 0 (192.168.1.100, 233.3.3.3, rpt) RP: 192.168.8.8 RPF nbr: 0.0.0.0 RPF idx: None Upstream State: RPT NOT JOINED 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local 0 Pruned 0 Outgoing 0 (*, 239.255.255.250) RP: 192.168.8.8 RPF nbr: 0.0.0.0 RPF idx: None Upstream State: JOINED 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local 0 Joined 0 j

	Asserted
	0
	.
	FCR:
	Ruijie(config)#
	Ruijie(config)#show ip pi

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- The (S, G) of register packets is not configured on a C-RP or static RP, or the configuration is not successful.
- The ACL for limiting the (S, G) of register packets is not configured or the range of (S, G) in this ACL is not correctly configured.
- The range of (S, G) of register packets on each C-RP or static RP is not the same.

6.4.5 Configuring the Interval for Sending a Join/Prune Packet

Configuration Effect

- Change the interval for sending a Join/Prune packet to form an RPT or SPT.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the interval for sending a Join/Prune packet.

Verification

On Router B, configure the interval for sending a Join/Prune packet as 120s. Run **show ip pim sparse-mode mroute** to display the lifetime of the entry.

Related Commands

📌 Configuring the Interval for Sending a Join/Prune Packet

Command	ip pim jp-timer <i>seconds</i>
Parameter	<i>Seconds</i> : Indicates the interval for sending a Join/Prune packet.

6.4.6 Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Effect

- Switch from an RPT to SPT

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the router of last hop to switch from an RPT to SPT.

Verification

Configure basic PIM-SM functions first. Configure the source DR to send the data traffic (*, 233.3.3.3), and the receiving end to join group 233.3.3.3 forcibly to form an RPT. Configure the receiver DR to switch from the RPT to SPT forcibly. Run **show running-config** to display the result.

Related Commands

📌 Enabling SPT switchover

Command	ip pim spt-threshold [group-list access-list]
Parameter Description	group-list access-list: Specifies the range of multicast group addresses allowed for SPT switchover using an ACL. access-list: The supported value ranges from 1 to 99 or 1,300 to 1,999. Naming an ACL is also supported.
Command Mode	Global configuration mode
Usage Guide	If group-list access-list is not specified, all groups are allowed to perform SPT switchover.

Configuration Example

📌 Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Steps	● Configure basic PIM-SM functions. (Omitted) ● Configure the source DR to send the data traffic of group 233.3.3.3. ● Configure the receiver DR to receive the data traffic of group 233.3.3.3. ● Configure the receiver DR of last hop to switch from an RPT to SPT.
	<pre>Ruijie(config)#ip pim spt-threshold</pre>
Verification	Run show running-config to display the configuration.
	<pre>! ! ip pim jp-timer 120 ip pim spt-threshold ip pim rp-candidate Loopback 0 !</pre>

	!
	!

6.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears multicast routing entries.	clear ip mroute { * <i>group-address</i> [<i>source-address</i>] }
Clears the counters of multicast routes.	clear ip mroute statistics { * <i>group-address</i> [<i>source-address</i>] }
Clears the information about dynamic RPs.	clear ip pim sparse-mode bsr rp-set *
Clears the counters of PIM-SM packets.	clear ip pim sparse-mode track

Displaying

Description	Command
Displays the details of BSR information.	show ip pim sparse-mode bsr-router
Displays the PIM-SM information of an interface.	show ip pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local IGMP information about a PIM-SM interface.	show ip pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the information about a PIM-SM multicast routing entry, and displays the RPF vector of a PIM-SM entry using proxy .	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [proxy]
Displays the information about PIM-SM neighbors.	show ip pim sparse-mode neighbor [detail]
Displays the information about the next hop of PIM-SM obtained from the NSM.	show ip pim sparse-mode nexthop
Displays the information about the RP corresponding the multicast group address <i>group-address</i> .	show ip pim sparse-mode rp-hash <i>group-address</i>
Displays the information about all the RPs and the groups they serve.	show ip pim sparse-mode rp mapping

Description	Command
Displays the number of PIM-SM packets sent and received since the statistic start time.	show ip pim sparse-mode track

7 Configuring PIM-SMv6

7.1 Overview

Protocol Independent Multicast (PIM) is a multicast routing protocol.

PIM does not rely on a specific unicast routing protocol. It uses the unicast routing table established by any unicast routing protocol to complete the reverse path forwarding (RPF) check and establish multicast routes. PIM does not need to transmit and receive multicast route updates. Therefore, the overhead of PIM is much lower than that of other multicast routing protocols.

PIM defines two modes: dense mode and sparse mode. Protocol Independent Multicast Sparse Mode (PIM-SM) is applicable to various network environments.

 PIM-SM running on IPv6 is called PIM-SMv6.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

7.2 Applications

Application	Description
ASM Implementation by Using PIM-SMv6	A receiver receives packets from any multicast source.
SSM Implementation by Using PIM-SMv6	A receiver selects a multicast source.
Application Example of an Embedded RP	An embedded RP address is configured within the IPv6 multicast group address.
PIM-SMv6 Application in a Hot Backup Environment	The multicast PIM-SMv6 protocol runs in a hot backup environment.

7.2.1 ASM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from any multicast source.

Figure 7-1

Remarks	R1 is directly connected to the multicast source. R2 is configured as a rendezvous point (RP). R3 is directly connected to Receiver A. R4 is directly connected to Receiver B.

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Run the Internet Group Management Protocol version 6 (IGMPv6) protocol in a user host network segment to implement group member management.

7.2.2 SSM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from a specific multicast source.

Figure 7-2

Remarks	R1 is directly connected to the multicast source. R2 is configured as an RP.

R2 is directly connected to Receiver A. R2 is directly connected to Receiver B.

Deployment

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the source-specific multicast (SSM) function of the PIM-SMv6 protocol to implement the SSM function.
- Run the Internet Group Management Protocol version 3 (IGMPv3) in a user host network segment to implement group member management.

7.2.3 Application Example of an Embedded RP

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, an RP address is configured for R2 to make the router become an embedded RP.

Figure 7-3

Remarks	R1 is directly connected to the multicast source. R2 is configured as an RP. R2 is directly connected to Receiver A. R2 is directly connected to Receiver B. R2 is configured as an embedded RP.

Deployment

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the SSM function of the PIM-SMv6 protocol to implement the SSM function.
- Run the IGMPv3 protocol in a user host network segment to implement group member management.
- Configure the RP address and embedded RP on R2.

7.2.4 PIM-SMv6 Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-SMv6. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 7-4

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-SMv6 on R1 and R2 to implement multicast routing.
- Make R2 run in two-node cluster hot backup mode.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In addition, if the convergence time of the unicast function is long, the transmission interval of PIM Join/Prune packets also need to be adjusted, because the keepalive time of PIM

Join/Prune packets is 3.5 times the transmission interval of PIM Join/Prune packets. The default keepalive time of PIM Join/Prune packets is 210 seconds. If R2 is configured as a dynamic RP, the interval for a candidate RP (C-RP) to transmit C-RP notifications also needs to be adjusted. The default transmission interval is 60 seconds and the keepalive time is 2.5 times the transmission interval of C-RP notifications. For example, if the convergence time of the unicast function is longer than 150 seconds, the transmission interval of C-RP notifications needs to be adjusted. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.

7.3 Features

Basic Concepts

📌 PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

📌 PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

📌 Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

📌 (*,G), (S,G)

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

ASM, SSM

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.
- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.

 SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Establishment of PIM Neighbor Relationships	Neighbor relationships are established between PIM routers to form a PIM network.
DR Election	In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to group members. In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.
RP Mechanism	In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP.
Registration Information About a Multicast Source	When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.
RPT Establishment	When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.
SPT Establishment	When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT.
ASM and SSM Models	PIM routers provide multicast services of the ASM model and SSM model. The SSM model is used for groups within the SSM address range, and the ASM model is used for other groups.

7.3.1 Establishment of PIM Neighbor Relationships

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before other PIM control messages are exchanged or multicast packets are forwarded.

Working Principle

A Hello message is sent by a PIM interface. For the multicast packet for encapsulating the Hello message, the destination address is ff02::d (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1.

Hello messages are used to discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.

📌 Discovering PIM Neighbors

PIM routers in the same network segment receive multicast packets with the destination address of ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

📌 Negotiating About Protocol Parameters

A Hello message contains multiple protocol parameters, which are described as follows:

- DR_Priority: Indicates the priority of each router interface for DR election. A higher priority means a higher possibility of being elected as the DR.
- Holdtime: Indicates the timeout time in which a neighbor is held in the reachable state.
- LAN_Delay: Indicates the delay for transmitting a Prune message in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that other downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, it must send a Prune Override message to the upstream interface within the time of **Override-Interval**.

$\text{LAN\_Delay} + \text{Override-Interval} = \text{PPT (Prune-Pending Timer)}$. After a PIM router receives a Prune message from a downstream interface, it does not immediately perform pruning but waits for PPT timeout. After the PPT times out, the PIM router performs pruning. Within the time of PPT, if the PIM router receives a Prune Override message from the downstream interface, it cancels pruning.

📌 Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any changes in PIM neighbors will cause multicast topology changes in the network. If an upstream neighbor or a downstream neighbor in an MDT is unreachable, multicast routing re-convergence is performed again and the MDT is migrated.

Related Configuration

✚ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, candidate - rendezvous point (C-RP), or candidate – bootstrap router (C-BSR), the corresponding protocol role does not take effect.

✚ Adjusting the Transmission Interval of Hello Messages on an Interface

By default, Hello messages are transmitted at an interval of 30 seconds.

Run the **ipv6 pim query-interval** *seconds* command to adjust the transmission interval of Hello messages on an interface. The value ranges from 1 to 65,535.

A larger value of *interval-seconds* means a larger transmission interval of Hello messages and a smaller value of *interval-seconds* means a smaller transmission interval of Hello messages.

7.3.2 DR Election

In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to the group members.

In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.

The DR transmits the Join/Prune message in the MDT root node direction for the directly connected group members, or transmits data of the directly connected multicast source to the MDT.

Working Principle

The neighbor IP address and DR priority are obtained from Hello packets of neighbors during establishment of PIM neighbor relationships, so as to elect the DR.

The key of DR election is the DR priorities and IP addresses of interfaces.

✚ Interface DR Priority

A higher interface DR priority means a higher probability that a PIM router is successfully elected as the DR during the DR election.

✚ Interface IP Address

If interfaces of PIM routers share the same DR priority during DR election, IP addresses of neighbors are compared. A larger IP address means a higher probability that a PIM router is successfully elected as the DR.

Related Configuration

✚ Setting IP Addresses of Interfaces

By default, no IP addresses are configured for interfaces.

Run the **ipv6 address** command to set an IP address for an interface.

When PIM routers share the same DR priority, the PIM router with a larger IP address is elected as the DR.

✚ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, C-RP, or C-BSR, the corresponding protocol role does not take effect.

✚ Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run the **ipv6 pim dr-priority** *priority-value* command to adjust the DR priority of an interface. The priority value ranges from 0 to 4,294,967,294.

The DR priority of an interface is used to elect the DR in the directly connected network segment of the interface. A larger priority value means a higher probability that a PIM router is elected as the DR.

7.3.3 BSR Mechanism

In a PIM network, the bootstrap router (BSR) periodically generates bootstrap messages (BSMs) including information about a series of C-RPs and relevant group addresses. BSMs are transmitted hop by hop in the entire domain. PIM routers throughout the network receive BSMs and record information about C-RPs and the relevant group addresses.

Working Principle

One or more C-BSRs are configured in the PIM-SMv6 domain and the BSR is elected from the candidate BSRs according to certain rules.

Related Configuration

✚ Configuring a C-BSR

By default, no C-BSR is configured.

Run the **ipv6 pim bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]] command to configure or cancel a C-BSR.

C-BSRs elect the globally unique BSR in the PIM-SM domain by means of BSM learning and election. The BSR transmits BSMs.

✚ Configuring the BSR Border

By default, no BSR border is configured.

Run the **ipv6 pim bsr-border** command to configure or cancel the BSR border.

After this command is configured for an interface, the interface immediately discards the received BSMs and does not forward BSMs, thereby preventing BSM flooding. No BSR border is configured if this command is not configured.

➤ Defining the Valid BSR Range

By default, the BSMs of BSRs are not filtered.

Run the **ipv6 pim accept-bsr list** *ipv6_access-list* command to define or cancel the BSR range.

After this command is configured, the valid BSR range is defined. If this command is not configured, the device with the PIM-SMv6 function enabled will receive all BSMs.

➤ Configuring a C-BSR to Restrict the Address Range of Valid C-RPs and the Range of Multicast Groups Served by the C-RPs

A C-BSR receives notifications from all C-RPs.

Run the **ipv6 pim accept-crp list** *ipv6_access-list* command to configure whether to filter notifications from C-RPs.

After this command is configured, the C-BSR restricts the address range of valid C-RPs and the range of multicast groups served by the C-RPs. If this command is not configured, the C-BSR receives notifications from all C-RPs.

➤ Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

By default, a C-BSR does not receive C-RP-ADV packets with prefix-count of 0.

Run the **ipv6 pim accept-crp-with-null-group** command to configure whether to receive C-RP-ADV packets with prefix-count of 0.

After this command is configured, the C-BSR can receive C-RP-ADV packets with prefix-count of 0. If this command is not configured, the C-BSR does not process C-RP-ADV packets with prefix-count of 0.

7.3.4 RP Mechanism

In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP. The RP serves as the root of the RPT. The RPT establishment and the forwarding of RPT data streams must use the RP as the forwarding point.

Working Principle

All PIM routers in a PIM domain must be able to be mapped to the same RP through a specific multicast group address. RPs are classified into static RPs and dynamic RPs in a PIM network.

➤ Static RP

In static RP configuration, the RP address is directly configured on each PIM router so that all PIM routers in the PIM network know the RP address.

➤ Dynamic RP

C-RPs are also configured in the PIM-SMv6 domain. These C-RPs transmit data packets that contain their addresses and information about multicast groups served by them to the BSR in unicast mode. The BSR periodically generates BSMs that contain information about a series of C-RPs and their group addresses. BSMs are transmitted hop by hop in the entire domain. Devices receive and store these BSMs. The DR at the receive end uses a hash algorithm to map a group address to the C-RP that can serve the group. Then, the RP corresponding to the group address can be determined.

Related Configuration

✚ Setting a Static RP Address

By default, no RP address is configured.

Run the **ipv6 pim rp-address** *ipv6_rp-address* [*ipv6_access-list*] command to configure or cancel a static RP address for a PIM router.

An RP must be configured so as to implement ASM in a PIM-SMv6 network. You can configure a static RP or dynamic RP.

If a static RP is configured in a PIM-SMv6 network, the static RP configuration on all devices in the PIM-SMv6 domain must be consistent to prevent multicast route ambiguity in the PIM-SMv6 domain.

✚ Configuring a C-RP Address

By default, no C-RP address is configured.

Run the **ipv6 pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *ipv6_access-list*] command to configure or cancel a PIM router as a C-RP.

C-RPs periodically transmit C-RP notifications to the BSR. Information contained in these C-RP notifications is dispersed to all PIM-SMv6 devices in the domain, thereby ensuring the uniqueness of RP mapping.

✚ Ignoring the RP Priority in RP Setting

By default, a C-RP with a higher priority is selected preferentially.

Run the **ipv6 pim ignore-rp-set-priority** command to specify or ignore the RP priority when selecting the RP for a group.

When one RP needs to be selected for a multicast address and multiple RPs can serve this multicast address, use this command if the RP priority needs to be ignored during the RP comparison. If this command is not configured, the RP priority will be considered during the RP comparison.

✚ Configuring the Static RP First

By default, a dynamic C-RP is adopted preferentially.

Run the **ipv6 pim static-rp-preferred** command to select the static RP first during RP selection.

After this command is configured, the static RP is adopted first. If this command is not configured, a C-RP is adopted first.

✚ Configuring the Embedded RP Function

By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

Run the **ipv6 pim rp embedded** [**group-list** *ipv6_acl_name*] command to enable the embedded RP function.

The embedded RP function is the peculiar RP discovery mechanism of IPv6 PIM. This mechanism uses the IPv6 multicast address where the RP address is embedded, to enable a multicast device to directly extract the RP address from the multicast address. By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

7.3.5 Registration Information About a Multicast Source

When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.

Working Principle

The DR at the data source end receives a multicast data packet from the directly connected host, and encapsulates the multicast data into a Register message. Then, it transmits the Register message to the RP in unicast mode. The RP generates the (S,G) entry.

If the forwarding entry contains an outgoing interface on the RP, the RP forwards the encapsulated data packet to the outgoing interface.

If the RP does not have the forwarding entry of the current group, it starts the (S,G) entry start timer. After the timer expires, the RP transmits the Register-Stop message to the DR and deletes the entry. After the DR at the data source end receives the Register-Stop message, the DR transmits the probing packet before the Register-Stop message timer expires.

If the DR does not receive the Register-Stop message, after the timer expires, the DR at the data source end encapsulates the multicast data into the Register message and transmits it to the RP in unicast mode.

If the DR receives the Register-Stop message, it re-starts the delay and re-transmits the probing packet before the delay expires.

Related Configuration

📌 Configuring Reachability Detection of RP Register Packets

By default, the RP reachability is not detected.

Run the **ipv6 pim register-rp-reachability** command to set or cancel the RP reachability detection.

If the RP reachability needs to be detected for the Register packet transmitted from the DR to the RP, you can configure this command. After this command is configured, the RP reachability is detected before the DR transmits the Register packet to the RP. That is, the DR queries the unicast routing table and static multicast routing table to check whether a route reachable to the RP exists. If no, the DR does not transmit the Register packet.

📌 Configuring the RP to Filter Register Packets

By default, the RP allows every received Register packet.

Run the **ipv6 pim accept-register { list ipv6_access-list [route-map map-name] | route-map map-name [list ipv6_access-list] }** command to enable or disable the RP to filter received Register packets.

To filter received Register packets on the RP, configure this command. If this command is not configured, the RP allows every received Register packet. If this command is configured, only Register packets whose source addresses and group addresses are allowed by the ACL are processed. Otherwise, the Register packets are filtered out.

✚ Configuring the Transmission Rate Limit for Register Packets

By default, the transmission rate of Register packets is not limited.

Run the **ipv6 pim register-rate-limit** *rate* command to configure whether to limit the transmission rate of Register packets.

If **no** is set in this command, the transmission rate is not limited. This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the transmission rate of Register packets of the entire system.

✚ Configuring the Checksum Calculation of a Register Packet Based on the Entire Register Packet

By default, the checksum in a Register packet is calculated in default mode specified in the protocol.

Run the **ipv6 pim register-checksum-wholepkt** [**group-list** *ipv6_access-list*] command to set the packet length for checksum calculation.

If the entire PIM protocol packet including the encapsulated multicast data packet is used for checksum calculation of a Register packet, use this command. If this command is not configured, the checksum in a Register packet is calculated in default mode specified in the protocol.

✚ Configuring the Source Address of Register Packets

By default, the source address of Register packets uses the address of the DR interface connected to a multicast source.

Run the **ipv6 pim register-source** { *ipv6_local_address* | *interface-type interface-number* } command to configure the source address of Register packets.

To configure the source address of Register packets transmitted from the DR, use this command. If this command is not configured or **no** is set in this command, the source address of Register packets uses the address of the DR interface connected to a multicast source. If the address parameter of this command is used, the configured address must be a reachable unicast route. If the interface parameter of this command is used, this interface may be a loopback interface or an interface of other types and the interface address must be an advertised unicast route.

✚ Configuring the Suppression Time of Register Packets

The default suppression time of Register packets is 60 seconds.

Run the **ipv6 pim register-suppression** *seconds* command to configure the suppression time.

If this command is used to configure the suppression time of Register packets, configuring the value on the DR will change the suppression time of Register packets on the DR. If the **ipv6 pim rp-register-kat** *seconds* command is not configured, defining the value on the RP will change the keepalive time on the RP.

✚ Configuring the Probing Time of NULL Register Packets

The default probing time is 5 seconds.

Run the **ipv6 pim probe-interval** *interval-seconds* command to set the probing time.

The source DR transmits the NULL-Register packet to the RP within a certain interval prior to the timeout of the suppression time of the Register packet. This interval is the probing time. The default probing time is 5 seconds.

Configuring the Time Value of the RP KAT Timer

By default, the KAT default value is used. KAT default value = Registration suppression time x 3 + Registration detection time.

Run the **ipv6 pim rp-register-kat seconds** command to set time of the KAT timer.

To configure the keepalive time of Register packets from the (S,G) multicast group address on the RP, use this command.

7.3.6 RPT Establishment

When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.

Working Principle

The RPT establishment process is as follows:

1. The DR at the receive end receives an MLD (*,G)Include report packet from a receiver.
2. If the DR at the receive end is not the RP of Group G, the DR at the receive end transmits one (*,G)join packet in the RP direction. The upstream device that receives the (*,G)join packet transmits the (*,G)join packet in the RP direction. The (*,G)join packet is transmitted hop by hop till the RP of Group G receives the (*,G)join packet, indicating that the DR at the receive end joins the RPT.
3. When the data source host transmits multicast data to a group, the source data is encapsulated into the Register message and is transmitted to the RP in unicast mode by the DR at the data source end. The RP decapsulates the Register message, retrieves the data packet, and then forwards it to each group member along the RPT.
4. The RP transmits the (S,G)join packet to the DR at the data source end to join the SPT of this data source.
5. After the SPT from the RP to the DR at the data source end is established, data packets from the data source are transmitted to the RP along the SPT without encapsulation.
6. When the first multicast data packet reaches the RP along the SPT, the RP transmits the Register-Stop message to the DR at the data source end to enable the DR to stop the encapsulation of Register packets. After the DR at the data source end receives the Register-Stop message, it does not encapsulate the Register packets but transmits the Register packets to the RP along the SPT of the data source. The RP forwards the Register packets to each group member along the RPT.

Related Configuration

Configuring the Transmission Interval of Join/Prune Packets

The default transmission interval of Join/Prune packets is 60 seconds.

Run the **ipv6 pim jp-timer seconds** command to set the transmission interval of Join/Prune packets.

To change the default transmission interval of Join/Prune packets, configure this command. If this command is not configured, the default transmission interval of Join/Prune packets is 60 seconds.

7.3.7 SPT Establishment

When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT, thereby relieving the load of the RP in the RPT and reducing the number of hops from the DR at the data source end to the receive end.

Working Principle

The SPT establishment process is as follows:

The DR at the receive end transmits the (*,G)join packet to the DR at the source end along the SPT. The (*,G)join packet is transmitted hop by hop till the DR at the source end receives the (*,G)join packet, forming an SPT.

Related Configuration

By default, SPT switching is disabled.

Run the **ipv6 pim spt-threshold [group-list ipv6_access-list]** command to configure whether to start SPT switching.

After this command is configured, when the DR receives the (S,G) packet from the first group member, one PIM Join message is generated and forwarded to the RP to establish a SPT tree. If **group-list** is defined, the defined group is switched from the RPT to the SPT. If **no** is set in this command and **group-list** is not defined, the switching from the RPT to the SPT is disabled and the device redirects to the RPT and transmits one Prune packet to the source. If **no** is set in this command, **group-list** is defined, and the defined ACL is a configured ACL, the ACL associated with **group-list** is cancelled and all groups are allowed to switch from the RPT to the SPT.

7.3.8 ASM and SSM Models

PIM-SM supports two multicast models: ASM and SSM. In the ASM model, a multicast data receiver specifies only to join a multicast group G but does not specify the multicast source S. In the SSM model, a multicast data receiver can specify both the multicast source S and multicast group G.

 When the SSM model is implemented over IPv6, MLDv2 needs to be used to manage the member relationship between hosts and devices and PIM-SMv6 needs to be used to connect devices.

In the SSM model, a multicast receiver learns about the multicast source (S,G) information by means of some channels (such as accessing the server or receiving advertisements) in advance. When the multicast receiver needs to order a multicast service, it directly transmits the MLD(S,G) Join packet to the last-hop device, for example, as shown in the following figure, Multicast Receiver 1 transmits the MLD(S,G) Join packet to order the multicast service (S,G). After receiving the MLD(S,G) Join packet from the multicast receiver, the last-hop device transmits the PIM(S,G) Join packet to the multicast source hop by hop, for example, as shown in the following figure, after receiving the MLD(S,G) Join packet from Multicast Receiver 1, R1 transmits the PIM(S,G) Join packet to R3, which transmits the PIM (S,G) Join packet to R4. As a result, the SPT from the multicast receiver to the multicast source is established.

Figure 7-5

The following conditions need to be met for the implementation of the SSM model:

- A multicast receiver learns about the multicast source (S,G) information beforehand by means of some channels. The multicast receiver initiates the MLD(S,G) Join packet to the desired multicast service.
- MLDv2 must be enabled on the interface of the last-hop device connected to the multicast receiver. MLDv1 does not support SSM.
- PIM-SM and SSM must be enabled on the intermediate devices between the multicast receiver and the multicast source.

i After the SSM function is enabled, the default group range of SSM is FF3x::/32. You can run a command to change the group range of SSM.

The SSM model has the following features:

- In the SSM model, a multicast receiver can learn about the multicast source information in advance by means of some channels (for example, receiving advertisements or accessing a specified server).
- The SSM model is a specific subset of PIM-SM and processes only PIM(S,G) Join and PIM(S,G) Prune messages. It discards RPT-relevant messages within the SSM range, for example, PIM(*,G) Join/Prune messages. For Register packets within the SSM range, it immediately responds with the Register-Stop packet.
- In the SSM model, no RP is required and the election and distribution of RP messages are not required. The established MDT is the SPT in SSM.

7.4 Configuration

7.4.1 Configuring Basic Functions of PIM-SMv6

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.
- Both or either of the two multicast service models (ASM and SSM) can be supported.

Notes

- PIM-SMv6 needs to use the IPv6 unicast routing function.
- If the PIM network needs to support the multicast service of the SSM model, MLDv3 or SSM Mapping needs to be configured.

Configuration Steps

▾ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on each router unless otherwise specified.

▾ Enabling the PIM-SMv6 Function

- Mandatory.
- The PIM-SMv6 function should be enabled on the following interfaces unless otherwise specified: router interconnection interfaces, interface that function as a static RP, C-RP, or C-BSR, interface for connecting to a multicast source, and interface for connecting to a user host.

▾ Enabling the PIM-SMv6 PASSIVE Mode

- In a PIM network, if an interface needs to receive only multicast data packets and does not need to participate in the establishment of the PIM network topology, the interface can be configured to work in PIM-SMv6 PASSIVE mode.
- The PIM-SMv6 PASSIVE function should be enabled on the following interfaces unless otherwise specified: interface for connecting the stub network device to a user host. After the PIM-SMv6 PASSIVE mode is configured, this interface neither transmits nor receives PIM packets.

▾ Configuring an RP

- If a PIM network needs to support the multicast service of the ASM model, an RP must be configured.
- There are three methods of configuring an RP: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and a dynamic RP. If both a static RP and a dynamic RP are configured, the dynamic RP is preferred.
- Configuring a static RP: A static RP should be configured on each router unless otherwise specified.
- Configuring a dynamic RP: A C-RP or C-BSR should be configured on one or more routers unless otherwise specified.

▾ Enabling the SSM

- If a PIM network needs to support the multicast service of the SSM model, the SSM must be enabled.
- The SSM should be enabled on each router unless otherwise specified.

Verification

Make a multicast source in the network send packets to groups within the range of ASM and SSM and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.
- Check whether correct PIM-SMv6 routing entries are created on routers.

Related Commands

✚ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Enabling the PIM-SMv6 Function

Command	ipv6 pim sparse-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Before enabling the PIM-SMv6 function, enable the multicast routing forwarding function in global configuration mode. Otherwise, multicast data packets cannot be forwarded even if the PIM-SMv6 function is enabled. When the PIM-SMv6 function is enabled, MLD is automatically enabled on each interface without manual configuration. If the message "Failed to enable PIM-SMv6 on <interface name>, resource temporarily unavailable, please try again" is displayed during the configuration of this command, try to configure this command again. If the message "PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!" is displayed during the configuration of this command, the configured number of multicast interfaces reaches the upper limit of multicast interfaces that can be configured on the device. If the PIM-SMv6 function still needs to be enabled on an interface, delete some unnecessary PIM-SMv6 or PIM-DMv6 interfaces. If an interface is of the tunnel type, only the 6Over4 configuration tunnel, 6Over4 GRE tunnel, 6Over6 configuration tunnel, and 6Over6 GRE tunnel support the IPv6 multicast function. The multicast function can also be enabled on tunnel interfaces that do not support the multicast function but no prompts are displayed and multicast packets are neither received nor transmitted. Multicast tunnels can be established only on Ethernet ports. Embedded tunnels and QoS/ACL of multicast data are not supported.

✚ Enabling the PIM-SMv6 PASSIVE Function

Command	ipv6 pim sparse-mode passive
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	Before enabling the PIM-SMv6 function, enable the multicast routing forwarding function in global configuration mode. Otherwise, multicast data packets cannot be forwarded even if the PIM-SMv6 PASSIVE function is enabled. When the PIM-SMv6 function is enabled, MLD is automatically enabled on each interface without manual configuration. Interfaces with the PIM-SMv6 PASSIVE function enabled neither receive nor transmit PIM packets but can forward multicast packets. Therefore, the PIM-SMv6 PASSIVE mode is generally configured on the interface of the stub network device connected to a user host, so as to prevent Layer-2 flooding of PIM Hello packets.

📌 Configuring a Static RP

Command	ipv6 pim rp-address <i>ipv6_rp-address</i> [<i>ipv6_access-list</i>]
Parameter	<i>ipv6_rp-address</i> : Indicates the IPv6 address of an RP.
Description	<i>ipv6_access-list</i> : References an IPv6 ACL to restrict the group address range served by the static RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	Multicast static RPs can be configured. A static RP and a C-RP can coexist. Notes: 1. If both the BSR mechanism and RP static configuration are effective, the dynamic configuration is preferred. 2. A control list can be used to statically configure the address of an RP for multiple multicast groups (using the ACL) or all multicast groups (without using the ACL), but one static RP address cannot be used multiple times. 3. If multiple static RPs serve the same group, the static RP with a larger IPv6 address is used preferentially. 4. Only multicast groups with the addresses allowed by the ACL are effective. By default, all multicast groups are allowed. 5. After the configuration is complete, the static RP source address will be inserted into the group range-based static RP group tree structure. The multicast static group in each group range maintains the linked list structure of one static RP group. This linked list is arranged in descending order by IPv6 address. When an RP is selected for a group range, the RP with the largest IPv6 address will be selected. 6. When a static RP address is deleted, this address is deleted from all existing groups and an address is selected from the existing static RP tree structure as the RP address.

📌 Configuring a C-RP

Command	ipv6 pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>interval-seconds</i>]

	[group-list <i>ipv6_access-list</i>]
Parameter Description	<i>interface-type interface-number</i>: Indicates an interface name. This interface address is used as the C-RP address. priority <i>priority-value</i>: Specifies the priority of the C-RP. The value ranges from 0 to 255 and the default value is 192. interval <i>seconds</i>: Indicates the interval for transmitting C-RP messages to the BSR, with the unit of seconds. The value ranges from 1 to 16,383 and the default value is 60. group-list <i>ipv6_access-list</i>: References an IPv6 ACL to restrict the group address range served by the C-RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	In the PIM-SMv6 protocol, the RPT created by the multicast routing uses an RP as the root node. After the BSR is elected, all C-RPs periodically transmit C-RP messages to the BSR in unicast mode and then the BSR disperses the messages in the entire PIM domain. To specify an interface as the C-RP of a specific group range, contain the ACL option in this command. Note that the calculation of the group range is based only on the permitted access control entries (ACEs) and denied ACEs are not involved in the calculation. If group-list <i>ipv6_access-list</i> is not carried in the command, all groups are served.

📌 Configuring a C-BSR

Command	ipv6 pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<i>interface-type interface-number</i>: Indicates an interface name. This interface address is used as the C-BSR address. <i>hash-mask-length</i>: Indicates the hash mask length. The value ranges from 0 to 128 and the default value is 126. <i>priority-value</i>: Indicates the priority. The value ranges from 0 to 255 and the default value is 64.
Command Mode	Global configuration mode
Usage Guide	A unique BSR must exist in a PIM-SMv6 domain. The BSR collects and advertises RP information. The unique well-known BSR is elected from multiple C-BSRs by means of BSMs. All C-BSRs consider that they are the BSR before knowing the BSR information. They periodically transmit BSMs that contain the BSR address and priority in the PIM-SMv6 domain. This command can be used to enable a device to transmit one BSM to all PIM neighbors by using the allocated BSR address. Each neighbor compares the original BSR address with the address in the received BSM. If the IPv6 address in the received BSM is equal to or larger than its BSR address, the neighbor stores this address as the BSR address and forwards the BSM. Otherwise, the neighbor discards the BSM. The current device deems that it is the BSR till it receives a BSM from another C-BSR and learns that the C-BSR has a higher priority (or the same priority but a larger IPv6 address).

📌 Enabling the SSM

Command	ipv6 pim ssm { default range <i>ipv6_access-list</i> }

Parameter Description	default: The default group address range of SSM is FF3x::/32. range <i>ipv6_access-list</i>: References an IPv6 ACL to restrict the SSM group address range. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	To apply SSM in a PIM-SMv6 network, you must configure this command.

📌 Displaying the PIM-SM Routing Table

Command	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both group address and source address can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

Configuration Example

📌 Creating the IPv6 Multicast Service on an IPv6 Network to Support ASM and SSM

Scenario Figure 7-6	
Configuration Steps	● Configure an IPv6 unicast routing protocol (such as OSPFv6) on the routers and ensure that the unicast routes of the loopback interfaces are reachable. (Omitted) ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIM-SMv6 function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source. ● Configure a C-RP and a C-BSR on the loopback interfaces of Router A and Router B. Enable the PIM-SMv6 function on the loopback interfaces. ● Enable SSM on all routers.

	● Enable MLDv3 on the router interface for connecting to the user host. (Omitted)
A	<pre> switch(config)#ipv6 multicast-routing switch(config)#ipv6 pim ssm default switch(config)#int gi 0/2 switch(config-if-GigabitEthernet 0/2)#ipv6 add 2000::2/64 switch(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode switch(config-if-GigabitEthernet 0/2)#exit switch(config)#int gi 0/1 switch(config-if-GigabitEthernet 0/1)#ipv6 add 1000::1/64 switch(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode switch(config-if-GigabitEthernet 0/1)#exit switch(config)#int Loopback 0 switch(config-if-Loopback 0)#ipv6 add 3000::5/64 switch(config-if-Loopback 0)#ipv6 pim sparse-mode switch(config-if-Loopback 0)#exit switch(config)#ipv6 pim rp-candidate Loopback 0 </pre>
B	<pre> ruijie(config)#ipv6 multicast-routing ruijie(config)#ipv6 pim ssm default ruijie(config)#int gi 0/2 ruijie(config-if-GigabitEthernet 0/2)#ipv6 add 2000::1/64 ruijie(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode ruijie(config-if-GigabitEthernet 0/2)#exit ruijie(config)#int gi 0/1 ruijie(config-if-GigabitEthernet 0/1)#ipv6 add 1100::1/64 ruijie(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode ruijie(config-if-GigabitEthernet 0/1)#exit ruijie(config)#int Loopback 0 ruijie(config-if-Loopback 0)#ipv6 add 5000::5/64 ruijie(config-if-Loopback 0)#ipv6 pim sparse-mode ruijie(config-if-Loopback 0)#exit ruijie(config)#ipv6 pim bsr-candidate Loopback 0 </pre>

Verification	Make Source(2000::2/64) send packets to G1(ff16::1) and make User join G1. ● Check the multicast packets received by the User. The User should be able to receive multicast packets from G1. ● Check PIM-SMv6 routing tables on Router A and Router B. Entries should exist on the PIM-SMv6 routing tables.

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- SSM is not enabled on a router or the SSM group address range of the router is different from that of other routers.
- PIM-SMv6 is not enabled on an interface (for example, interface that is specified as a C-RP or C-BSR, or interface that functions as the gateway of a user host or multicast source).
- MLDv3 is not enabled on an interface connected to a user host.
- No RP is configured in the network.
- No static RP is configured on a router or the configured static RP is different from that on other routers.
- A C-RP is configured but no C-BSR is configured in the network.
- The unicast route to the static RP, C-RP, or C-BSR is unreachable.

7.4.2 Configuring PIM Neighbor Parameters

Configuration Effect

- Negotiate about protocol parameters and adjust parameters in a Hello packet.
- PIM routers discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.
- Protect neighbor relationships to restrict neighbors.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Set parameters on each PIM router interface unless otherwise specified.

Verification

Set parameters in a Hello packet on an interface and run the **debug ipv6 pim sparse-mode packet** command to check parameters in the Hello packet.

Set neighbor filtering and run the **show ipv6 pim sparse-mode neighbor** command to check the neighbor relationship.

Related Commands

📌 Configuring the Transmission Interval of Hello Messages

Command	ipv6 pim query-interval <i>seconds</i>
Parameter	Indicates the transmission interval of Hello packets.
Description	The unit is seconds. The value ranges from 1 to 65,535 and the default value is 30 .
Command Mode	Interface configuration mode
Usage Guide	Each time the transmission interval of Hello messages is updated, the Holdtime of Hello messages is accordingly updated according to the following rule: The Holdtime of Hello messages is updated to 3.5 times transmission interval of Hello messages. If the transmission interval of Hello messages multiplied by 3.5 is larger than 65,535, the transmission interval of Hello messages is forcibly updated to 18,725.

📌 Configuring the Propagation Delay for Hello Messages

Command	ipv6 pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 32,767 and the default value is 500 .
Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred. This must be maintained and guaranteed by network administrators.

📌 Configuring the Prune Override Interval for Hello Messages

Command	ipv6 pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 65,535 and the default value is 2500 .
Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred.

✚ Configuring the Interface Joining Suppression Capability for Hello Messages

Command	ipv6 pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	When the joining suppression capability of an interface is enabled and the local router needs to transmit a Join packet to an upstream neighbor, the Join packet of the local router is suppressed and is not transmitted if the local router receives a Join packet from a neighbor to the upstream router. If the joining suppression capability of the interface is disabled, the local router transmits the Join packet. When the joining suppression capability of a downstream receiver is disabled, the upstream neighbor can accurately know the number of receivers connected to the downstream neighbor through the received Join packet, thereby implementing neighbor tracking.

✚ Configuring the Delay of Sending Out Hello Messages

Command	ipv6 pim triggered-hello-delay <i>seconds</i>
Parameter Description	<i>Seconds</i> : The unit is seconds. The value ranges from 1 to 5 and the default value is 5 .
Command Mode	Interface configuration mode
Usage Guide	When an interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

✚ Configuring the DR Priority for Hello Messages

Command	ipv6 pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A larger value means a higher priority. The value ranges from 0 to 4,294,967,294 and the default value is 1 .
Command Mode	Interface configuration mode
Usage Guide	The process of selecting a DR is as follows: The priority parameter is set for Hello packets of devices in the same LAN. The priority is compared for the selection of a DR. The device with a higher priority is the DR. If multiple devices share the same priority, the device with a larger IP address is the DR. When the priority parameter is not set for Hello packets of a device in a LAN, the device with a larger IP address is elected as the DR in the LAN.

✚ Configuring Neighbor filtering

Command	ipv6 pim neighbor-filter <i>ipv6_access-list</i>
Parameter Description	<i>ipv6_access-list</i> : References an IPv6 ACL to restrict the neighbor address range.

Command Mode	Interface configuration mode
Usage Guide	This command can be used to filter neighbors to strengthen the security of the PIM network and restrict the address range of legitimate neighbors. If a neighbor is rejected by an ACL, PIM-SMv6 will not establish a peering relationship with this neighbor or suspend the peering relationship with this neighbor.

Displaying Neighbor Information About an Interface

Command	show ipv6 pim sparse-mode neighbor [detail]
Parameter Description	detail: Displays details.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the transmission interval of Hello packets of PIM-SMv6 to 50 seconds. ● Set the propagation delay of Hello packets of PIM-SMv6 to 400 milliseconds. ● Set the prune override interval of Hello packets of PIM-SMv6 to 3,000 milliseconds. ● Configure the interface joining suppression capability for Hello messages of PIM-SMv6. ● Set the delay of sending out Hello messages of PIM-SMv6 to 3 seconds. ● Set the DR priority of Hello messages of PIM-SMv6 to 5.
	<pre> switch # configure terminal switch (config)#int gi 0/1 switch (config-if-GigabitEthernet 0/1)#ipv6 pim query-interval 50 switch (config-if-GigabitEthernet 0/1)#ipv6 pim propagation-delay 400 switch (config-if-GigabitEthernet 0/1)#ipv6 pim override-interval 3000 switch (config-if-GigabitEthernet 0/1)#ipv6 pim triggered-hello-delay 3 switch (config-if-GigabitEthernet 0/1)# ipv6 pim dr-priority 5 </pre>
Verification	Run the debug ipv6 pim sparse-mode packet command to check parameters in a Hello packet.

	<pre>switch # debug ipv6 pim sparse-mode packet *Jan 2 02:37:55: %7: Hello send to GigabitEthernet 0/2 *Jan 2 02:37:55: %7: Send Hello message *Jan 2 02:37:55: %7: Holdtime: 175 *Jan 2 02:37:55: %7: T-bit: off *Jan 2 02:37:55: %7: Propagation delay: 400 *Jan 2 02:37:55: %7: Override interval: 3000 *Jan 2 02:37:55: %7: DR priority: 5 *Jan 2 02:37:55: %7: Gen ID: 99572792 *Jan 2 02:37:55: %7: Secondary Addresses: *Jan 2 02:37:55: %7: 2000::2</pre>								
Configuration Steps	Configure neighbor filtering on an interface to receive neighbor packets with the address of (8000::1/64).								
	<pre>switch(config-if-GigabitEthernet 0/2)#ipv6 pim neighbor-filter acl % access-list acl not exist switch(config-if-GigabitEthernet 0/2)#exit switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::1/64 any</pre>								
Verification	Before neighbor filtering is configured, display the neighbor information.								
	<pre>switch#show ipv6 pim sparse-mode neighbor</pre> <table><tr><th>Neighbor Address</th><th>Interface</th><th>Uptime/Expires</th><th>DR Pri/Mode</th></tr><tr><td>fe80::21a:a9ff:fe3a:6355</td><td>GigabitEthernet 0/2</td><td>00:32:29/00:01:16</td><td>1 /</td></tr></table>	Neighbor Address	Interface	Uptime/Expires	DR Pri/Mode	fe80::21a:a9ff:fe3a:6355	GigabitEthernet 0/2	00:32:29/00:01:16	1 /
Neighbor Address	Interface	Uptime/Expires	DR Pri/Mode						
fe80::21a:a9ff:fe3a:6355	GigabitEthernet 0/2	00:32:29/00:01:16	1 /						
Verification	After neighbor filtering is configured, the neighbor information is blank.								
	<pre>switch#show ipv6 pim sparse-mode neighbor</pre>								

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.

7.4.3 Configuring BSR Parameters

Configuration Effect

- Restrict the range of BSMs.

Notes

- The basic functions of PIM-SMv6 must be configured.
- A C-RP and a C-BSR must be configured.
- The border must be configured on the interface between domains.

Configuration Steps

📄 Configuring the Border

- The border must be configured if there are multiple domains.
- Configure the border the interface between two domains.

📄 Configuring a PIM Router to Restrict BSMs

- Optional.
- This configuration can be performed on a PIM router unless otherwise specified.

📄 Configuring a C-BSR to Restrict the C-PR Range

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

📄 Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

Verification

📄 Verifying the Border

Enable the basic functions of PIM-SMv6, set two routers in different domains, and set Router B as a C-BSR. Router A can normally receive BSMs.

Set the common border between Router A and Router B as a border interface. Router A cannot receive BSMs.

📄 Verifying a PIM Router to Restrict BSMs

Enable the basic functions of PIM-SMv6 and set Router B as a C-BSR. Router A can normally receive BSMs. Restrict the C-BSR range on Router A. Router A cannot receive BSMs.

📄 Verifying a C-BSR to Restrict the C-PR Range

Enable the basic functions of PIM-SMv6, set Router B as a C-BSR, set Router A as a C-RP, and restrict the C-RP range on the C-BSR. Router B cannot receive packets from the C-RP.

Related Commands

➤ Configuring the BSR Border

Command	ipv6 pim bsr-border
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The BSR border can be configured on an interface to restrict flooding of BSMs. When this interface receives BSMs, it immediately discards them and BSMs are not forwarded by this interface.

➤ Configuring a PIM Router to Restrict BSMs

Command	ipv6 pim accept-bsr list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the BSR address range. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring a C-BSR to Restrict the C-PR Range

Command	ipv6 pim accept-crp list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the address range of the C-RP and the group address range served by the C-RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	Configure this command on a C-BSR. When this C-BSR is elected as the BSR, it can restrict the address range of the valid C-RP and the multicast group range served by the C-RP.

➤ Displaying BSMs

Command	show ipv6 pim sparse-mode bsr-router
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

➤ Displaying All RPs Configured on the Local Device and the Multicast Groups Served by the RPs

Command	show ipv6 pim sparse-mode rp mapping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode

Usage Guide	N/A

Configuration Example

📌 Configuring the BSR Border

Configuration Steps	- Configure basic functions of PIM-SMv6. (Omitted) - Configure the BSR border on the juncture interface between Router B and Router A.
	<pre>Ruijie(config-if-GigabitEthernet 0/2)#ipv6 pim bsr-border</pre>
Verification	Before the BSR border is configured, the BSM information of Router A is displayed as follows:
	<pre>switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch#</pre>
	 Candidate RP: Indicates all C-RPs configured on the local router, excluding other routers.
	After the BSR border is configured, the BSM information of Router A is displayed as follows:
	<pre>switch#show ipv6 pim sparse-mode bsr-router Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:53</pre>

📌 Configuring a PIM Router to Restrict the Source Address Range of BSMs to (8000::5/64)

Configuration Steps	- Configure basic functions of PIM-SMv6. (Omitted) - Configure PIM Router A to restrict BSMs. The restricted source address range is (8000::5/64).

	<pre> switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::5/64 any switch(config-ipv6-acl)#exit switch(config)#ipv6 pim accept-crp list acl </pre>
Verification	Before the BSM restriction is configured, the BSM information of Router A is displayed as follows: <pre> switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch# </pre>
	After the BSM restriction is configured, the BSM information of Router A is displayed as follows: <pre> switch#show ipv6 pim sparse-mode bsr-router Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:34 </pre>

Configuring a C-BSR to Restrict the Source Address Range of C-PR Packets to (9000::5/64)

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Configure Router B to restrict C-RP packets. The restricted source address range is (9000::5/64).
	<pre> Ruijie(config)#ipv6 access-list acl Ruijie(config-ipv6-acl)#permit ipv6 9000::5/64 any Ruijie(config-ipv6-acl)#exit Ruijie(config)#ipv6 pim accept-crp list acl </pre>

Verification	Before C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:
	<pre> Ruijie#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): ff00::/8 RP: 3000::5(Not self) Info source: 3000::5, via bootstrap, priority 192 Uptime: 00:02:26, expires: 00:02:08 Ruijie# </pre>
	After C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:
	<pre> Ruijie#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) </pre>

📌 Configuring the Static RP First

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address of Interface Loopback0 of Router A to 3000::5. (Omitted) ● Set the address of Interface Loopback1 of Router A to 4000::5. (Omitted) ● Set the static address of Router A to 3300::5. (Omitted) ● Set the static address of Router B to 3300::5. ● Configure the static RP first on Router A.
	<pre> switch(config)#ipv6 pim rp-address 3300::5 switch(config)#ipv6 pim static-rp-preferred </pre>
Verification	Before static RP first is configured, display information about the RP corresponding to FF16::1.

	<pre> switch#show ipv6 pim sparse-mode rp ff16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765 RP 3300::5, static (hash value 204800453 not used) </pre>
Verification	After static RP first is configured, display information about the RP corresponding to FF16::1.
	<pre> switch(config)#show ipv6 pim sparse-mode rp ff16::1 RP: 3300::5 (Static) PIMv2 STATIC RP PREFERRED PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765 RP 3300::5, static (hash value 204800453 not used) switch(config)# </pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- No C-BSR is configured.
- The BSR border is not configured on an interface between different domains.

7.4.4 Configuring RP and DR Parameters

Configuration Effect

- Configure the ignorance of the C-RP priority for the RP reselection.
- Configure the DR at the data source end to detect the RP reachability.
- Restrict the (S,G) multicast group address of the data source so that the ASM model provides the multicast service only for multicast packets within the allowable range.
- Configure the rate limit for the DR at the data source end to transmit Register packets.

- Configure the checksum length of Register packets.
- Configure the source address of Register packets.
- Configure the suppression time of Register packets.
- Configure the probing time of NULL packets.
- Configure the TTL of Register packets received by the RP from the (S,G) multicast group address.
- Configure the static RP first.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

↘ Configuring the Ignorance of the C-RP Priority for the RP Reselection

- Optional.
- The ignorance of the C-RP priority can be enabled on each router unless otherwise specified.

↘ Configuring the DR at the Data Source End to Detect the RP Reachability

- Optional.
- The reachability detection can be enabled on the DR that is directly connected to the data source unless otherwise specified.

↘ Restricting the (S,G) Address Range of Register Packets at the Data Source End

- Optional.
- The (S,G) address range of Register packets at the data source end can be restricted on all routers that function as C-RPs or static RPs unless otherwise specified.

↘ Restricting the Rate for the DR at the Data Source End to Transmit Register Packets

- Optional.
- The transmission rate limit of Register packets can be enabled on the DR that is directly connected to the data source unless otherwise specified.

↘ Configuring the Checksum Length of Register Packets

- Optional.
- The checksum length of Register packets can be configured on all C-RPs or static RPs unless otherwise specified.

↘ Configuring the Source Address of Register Packets

- Optional.

- The source address of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

✚ Configuring the Suppression Time of Register Packets

- Optional.
- The suppression time of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

✚ Configuring the Probing Time of NULL Packets

- Optional.
- The probing time of NULL packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

✚ Configuring the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

- Optional.
- The TTL of Register packets from the (S,G) multicast group address can be configured on all routers that function as C-RPs or static RPs unless otherwise specified.

✚ Configuring the Static RP First

- Optional.
- The static RP first can be configured on all routers unless otherwise specified.

Verification

✚ Verifying the Ignorance of the C-RP Priority

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000::5 on Router B.

- Run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the RP that serves the current group.

✚ Verifying the DR at the Data Source End to Detect the RP Reachability

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000::5 on Router B. Configure the RP reachability detection on Router B.

- Run the **show running-config** command to check whether the RP reachability detection is configured.

✚ Verifying the Restriction of the (S,G) Address Range of Register Packets at the Data Source End

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000::5 on Router B. The address of the multicast group is FF16::2. Set Router A to receive packets only from the multicast source with the source address of (1300::1/64).

- Run the **show ip pim sparse-mode mroute** command to display the (S,G) entries.

✚ Verifying the Rate Limit for the DR at the Data Source End to Transmit Register Packets

- Set the rate of transmitting Register packets for Router B and then run the **show ip pim sparse-mode track** command to check the number of transmitted Register packets for confirmation.

✚ Verifying the Checksum Length of Register Packets

- Set Router A to check a Register packet based on the entire packet rather than based only on the packet header and Register packet header. Run the **show running-config** command to check the configuration.

✚ Verifying the Source Address of Register Packets

- Configure the source address of Register packets on Router B and run the **show running-config** command to check the configuration on Router A.

✚ Verifying the Suppression Time and Probing Time of Register Packets

- Configure the suppression time and probing time of Register packets on Router B and run the **show running-config** command to check the configuration.

✚ Verifying the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

- Configure the TTL of Register packets from the (S,G) multicast group address on Router A and run the **show ip pim sparse-mode mroute** command to display the maximum (S,G) TTL.

✚ Verifying the Static RP First

- Configure a static RP and a C-RP on Router A, configure the static RP first, and then run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the current RP.

Related Commands

✚ Ignoring the C-RP Priority

Command	ipv6 pim ignore-rp-set-priority
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Displaying Information About the RP That Serves a Group

Command	show ipv6 pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed group address.
Command	Privileged EXEC mode, global configuration mode, and interface configuration mode

Mode	
Usage Guide	N/A

✚ Configuring the DR Directly Connected to the Data Source to Detect RP Reachability

Command	ipv6 pim register-rp-reachability
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the RP reachability is detected before Register packets are transmitted. If the RP is reachable, Register packets are transmitted. If the RP is unreachable, Register packets are not transmitted.

✚ Restricting the (S,G) Address Range of Register Packets at the Data Source End

Command	ipv6 pim accept-register { list <i>ipv6_access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>ipv6_access-list</i>] }
Parameter Description	list <i>ipv6_access-list</i> : References an IP extended ACL to restrict the (S,G) address range. The value range is 100-199, 2000-2699, and Word. route-map <i>map-name</i> : Uses a route map to restrict the (S,G) address range.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, when receiving a Register packet from an unauthorized source, the RP immediately returns the Register-Stop packet.

✚ Displaying Multicast Routing Entries

Command	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both addresses can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

✚ Configuring the Rate Limit for the DR to Transmit Register Packets

Command	ipv6 pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the number of Register packets that are allowed to be transmitted per second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode

Usage Guide	This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the Register packets of the entire system. After this command is configured, the load of the source DR and RP will be relieved and Register packets whose rate does not exceed the limit will be transmitted.

▾ Displaying the Statistics on PIM Packets

Command	show ipv6 pim sparse-mode track
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	When the system is started, the statistics start time point is first set. Each time clear ip pim sparse-mode track is called, the statistics start time point is set again and the PIM packet counter is cleared.

▾ Configuring the Checksum Calculation of a Register Packet Based on the Entire Packet

Command	ipv6 pim register-checksum-wholepkt [group-list <i>ipv6_access-list</i>]
Parameter Description	group-list <i>access-list</i> : Uses an ACL to restrict the group addresses that use this configuration. access-list : Supports digits <1,99> and <1300,1999>. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	The device calculates the checksum of a Register packet based on the entire PIM protocol packet including the encapsulated multicast data packet, rather than the PIM header of the Register packet. If group-list <i>ipv6_access-list</i> is not carried in this command, all group addresses apply this configuration.

▾ Configuring the Source Address of Register Packets

Command	ipv6 pim register-source { <i>ipv6_local_address</i> <i>interface-type interface-number</i> }
Parameter Description	<i>local_address</i> : Specifies an IPv6 address as the source address of Register packets. <i>interface-type interface-number</i> : Specifies the IPv6 address of an interface as the source address of Register packets.
Command Mode	Global configuration mode
Usage Guide	The configured address must be reachable. When the RP receives a Register packet, it transmits the Register-Stop packet with the source IPv6 address of the Register packet as the destination address. PIM-SMv6 does not need to be enabled on associated interfaces.

▾ Configuring the Suppression Time of Register Packets

Command	ipv6 pim register-suppression <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the suppression time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command Mode	Global configuration mode

Usage Guide	Configuring this value on the DR will change the suppression time of Register packets defined on the DR. If the ipv6 pim rp-register-kat command is not configured, configuring this value on the RP will change the keepalive time of the RP.

✚ Configuring the Probing Time of Register Packets

Command	ipv6 pim probe-interval <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the probing time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 5 .
Command Mode	Global configuration mode
Usage Guide	Probing time of Register packets is the interval for the source DR to transmit the NULL-Register packet to the RP prior to the timeout of the suppression time of Register packets. The probing time of Register packets cannot be larger than half of the suppression time of Register packets. Otherwise, the configuration fails and a warning is displayed. In addition, the suppression time of Register packets multiplied by three plus the probing time of Register packets cannot be larger than 65,535. Otherwise, a warning will be displayed.

✚ Configuring the KAT Interval on the RP

Command	lrv6 pim rp-register-kat <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the time of the KAT timer. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 210 .
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring the Static RP First

Command	ipv6 pim static-rp-preferred
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the priority of the static RP is higher than that of the RP elected by using the BSR mechanism.

Configuration Example

✚ Configuring Whether the C-RP Priority Is Considered for the Group-to-RP Mapping

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. (Omitted) ● Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. (Omitted) ● Set the C-BSR address to 5000::5 on Router B. (Omitted)

	● Display the group corresponding to FF16::1. ● Configure the ignorance of C-RP priority on Router B.
	<pre>switch#configure terminal Ruijie(config)# ipv6 pim ignore-rp-set-priority</pre>
Verification	Before the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765</pre>
	After the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 3000::5 Info source: 5000::5, via bootstrap</pre>

📌 Configuring the Reachability Detection of the RP Directly Connected to the Data Source

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the reachability detection of the RP directly connected to the data source.
	<pre>Ruijie(config)#ipv6 pim register-rp-reachability</pre>
Verification	Run the show running-config command to check the configuration. The following information is displayed:
	<pre>Ruijie(config)#show running-config ! ! ! ipv6 pim register-rp-reachability ipv6 pim bsr-candidate Loopback 0 ! !</pre>

📌 Restricting the (S,G) Address Range of Register Packets at the Data Source End

[illegible]

	<pre>0 1 Asserted 0 1 FCR: (1100::2, ff16::1) RPF nbr: fe80::21a:a9ff:fe3a:6355 RPF idx: GigabitEthernet 0/2 SPT bit: 1 Upstream State: JOINED jt_timer expires in 36 seconds kat expires in 191 seconds 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local</pre>
	After the (S,G) address range of Register packets at the data source end is restricted, run the show ipv6 pim sparse-mode mroute command to display multicast entries. The (S,G) entry and (S,G,RPT) entry exist.
	<pre>switch#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 0 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0</pre>

[illegible]

✎ Restricting the Rate for the DR at the Data Source End to Transmit Register Packets

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Check the number of PIM packets transmitted by Router B. ● Check the number of PIM packets transmitted by Router B one second later. ● Set the rate for Router B to transmit Register packets. ● Check the number of PIM packets transmitted by Router B one second later.
	<code>Ruijie(config)#ipv6 pim register-rate-limit 1</code>
Verification	Before the rate limit is configured, check the number of PIM packets transmitted by the DR. The following information is displayed:
	<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:54 received sent Valid PIMv6 packets: 5064 7727 Hello: 1329 4057 Join-Prune: 863 0 Register: 0 2636 Register-Stop: 975 0 Assert: 0 0 BSM: 0 1034 C-RP-ADV: 1897 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 5 </pre>

	Packets received with unknown PIM version: 0
	Before the rate limit is configured, check the number of PIM packets transmitted by the DR one second later. The following information is displayed:
	<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:55 received sent Valid PIMv6 packets: 5064 7727 Hello: 1335 4063 Join-Prune: 866 0 Register: 0 2639 Register-Stop: 978 0 Assert: 0 0 BSM: 0 1035 C-RP-ADV: 1897 0 PIMDM-Graft: 0 PIMDM-Graft-Ack: 0 PIMDM-State-Refresh: 0 Unknown PIM Type: 0 Errors: Malformed packets: 0 Bad checksums: 0 Send errors: 5 Packets received with unknown PIM version: 0 </pre>
	After the rate limit is configured, check the number of PIM packets transmitted by the DR. The following information is displayed:
	<pre> Ruijie#show ipv6 pim sparse-mode track PIMv6 packet counters track Elapsed time since counters cleared: 17:14:56 </pre>

	received	sent
Valid PIMv6 packets:	5064	7727

Unknown PIM Type:	0	
Errors:		
Malformed packets:		0
Bad checksums:		0
Send errors:		5
Packets received with unknown PIM version:	0	

📌 Configuring the Checksum Length of Register Packets

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the checksum calculation of a Register packet based on the entire packet on Router A. ● Run the show running-config command to check the configuration.
	<pre>switch(config)#ipv6 pim register-checksum-wholepkt switch(config)#show running-config</pre>
Verification	Check the configuration on Router A. The configuration is displayed as follows:
	<pre>! ! ipv6 pim register-checksum-wholepkt ipv6 pim rp-candidate Loopback 0 priority 200 ipv6 pim rp-candidate Loopback 1 priority 56</pre>

	<pre> ipv6 pim ssm default ! ! </pre>

✎ Configuring the Source Address of Register Packets

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the source address of Interface Loopback1 to 5500::5/64 on Router B. (Omitted) ● Set the source address of Register packets to the address of Interface Loopback2 on Router B. (Omitted) ● Run the show running-config command to check the configuration.
	<pre> Ruijie(config)#ipv6 pim register-source Loopback 1 </pre>
Verification	Check the configuration on Router B.
	<pre> ! ! ipv6 pim register-source Loopback 1 ipv6 pim register-rate-limit 1 ipv6 pim bsr-candidate Loopback 0 ! ! </pre>

✎ Configuring the Suppression Time and Probing Time of Register Packets

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the suppression time to 20 seconds on Router B. ● Set the probing time to 2 seconds on Router B. ● Run the show running-config command to check the configuration.
	<pre> Ruijie(config)#ipv6 pim register-suppression 20 Ruijie(config)#ipv6 pim probe-interval 2 Ruijie(config)# show ip pim sparse-mode track </pre>
Verification	Check the configuration on Router B.
	<pre> ! ipv6 pim register-source Loopback 1 ipv6 pim register-rate-limit 1 ipv6 pim register-suppression 20 </pre>

	<pre>ipv6 pim probe-interval 2 ipv6 pim bsr-candidate Loopback 0 ! !</pre>

📌 **Configuring the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address**

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Set the TTL of Register packets received by Router A from the (S,G) multicast group address to 60 seconds. ● Run the show ip pim sparse-mode mroute command to check the number of Register packets.
	<pre>Ruijie(config)#ip pim rp-register-kat 60</pre>
Verification	After the TTL is configured, check the TTL of Register packets from the (S,G) multicast group address on Router A. The TTL is not larger than 60 seconds.
	<pre>switch(config)#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 0 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0 (1100::2, ff16::1) RPF nbr: fe80::21a:a9ff:fe3a:6355 RPF idx: GigabitEthernet 0/2 SPT bit: 0 Upstream State: NOT JOINED kat expires in 60 seconds 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local 0 . .</pre>

	RPF nbr: ::
	RPF idx: None

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- The (S,G) address range of Register packets at the data source end is not restricted or fails to be configured on a C-RP or static RP.
- When the (S,G) address range of Register packets at the data source end is restricted, the referenced ACL is not configured or the source/group address range allowed by the ACL is configured incorrectly.
- The source/group address ranges allowed by C-RPs or static RPs are inconsistent.

7.4.5 Configuring the Transmission Interval of Join/Prune Packets

Configuration Effect

- Change the transmission interval of Join/Prune packets to form an RPT or SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the transmission interval of Join/Prune packets.

Verification

Set the transmission interval of Join/Prune packets to 120 seconds on Router B. Run the **show ipv6 pim sparse-mode mroute** command to check the entry TTL.

Related Commands

Configuring the Transmission Interval of Join/Prune Packets

Command	ipv6 pim jp-timer <i>seconds</i>
Parameter	<i>Seconds</i> : Indicates the transmission interval of Join/Prune packets.
Description	The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Transmission Interval of Join/Prune Packets on a Router

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the transmission interval of Join/Prune packets on a router.
	<pre>Ruijie(config)#ip pim jp-timer 120</pre>
Verification	Run the show ipv6 pim sparse-mode mroute command to check the entry. The transmission time of Join/Prune packets is not larger than 120.
	<pre>switch(config)#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.

7.4.6 Configuring the Last-Hop Device to Switch from the RPT to the SPT

Configuration Effect

- Switch the last-hop device from the RPT to the SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the last-hop device to switch from the RPT to the SPT.

Verification

Configure basic functions of PIM-SMv6, make the DR at the data source end transmit data streams to Group FF16::1, and make the receiver forcibly join the Group FF16::1 to form a RPT. The DR at the receive end forcibly performs the switching from the RPT to SPT. Check the configuration on the RP.

Related Commands

↘ Enabling the SPT Switching Function

Command	ipv6 pim spt-threshold [group-list ipv6_access-list]
Parameter Description	group-list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the group address range that allows SPT switching. <i>ipv6_access-list</i> : A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	If group-list <i>ipv6_access-list</i> parameter is not carried in this command, all multicast groups are allowed to conduct SPT switching.
	If no is set in this command, group-list is carried, and the carried ACL is a configured ACL, the restriction of the ACL associated with group-list is cancelled and all groups are allowed to switch from the RPT to the SPT.

Configuration Example

↘ Configuring the Last-Hop Device to Switch from the RPT to the SPT

Configuration Steps	● Configure basic functions of PIM-SMv6. (Omitted) ● Make the DR at the data source end transmit code streams to Group FF16::1. ● Make the DR at the receive end receive code streams from Group FF16::1. ● Configure the last-hop device to switch from the RPT to the SPT on the DR at the receive end.
	<pre>switch(config)#ipv6 pim spt-threshold</pre>
Verification	Run the show running-config command to check the configuration.
	<pre>switch(config)#show running-config ! ! ip pim jp-timer 120 ip pim spt-threshold ip pim rp-candidate Loopback 0 ! !</pre>

7.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears information about the dynamic RP.	clear ipv6 pim sparse-mode bsr rp-set *
Sets the packet statistics start time again and clears the PIMv6 packet counter.	clear ipv6 pim sparse-mode track

Displaying

Description	Command
Displays details about the BSR.	show ipv6 pim sparse-mode bsr-router
Displays the PIM-SM information about an interface.	show ipv6 pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local MLD information about a PIM-SMv6 interface.	show ipv6 pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the PIM-SMv6 routing information.	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i>] [<i>group-or-source-address</i>]

Displays the PIM-SMv6 neighbor information.	show ipv6 pim sparse-mode neighbor [detail]
Displays next hop-relevant information, including the next-hop interface ID, address, and metric.	show ipv6 pim sparse-mode nexthop
Displays all RPs configured on the local device and the groups served by the RPs.	show ipv6 pim sparse-mode rp mapping
Displays information about the RP that serves the group address.	show ipv6 pim sparse-mode rp-hash <i>ipv6-group-address</i>
Displays the number of PIM packets transmitted and received from the statistics start time to the current time.	show ipv6 pim sparse-mode track

8 Configuring MSDP

8.1 Overview

Multicast Source Discovery Protocol is used to connect multiple rendezvous points (RPs) on the network and share the multicast source information among these RPs.

- Use MSDP among multiple Protocol Independent Multicast - Sparse-Mode (PIM-SM) domains to share the multicast source information of these PIM-SM domains to implement cross-domain multicast.
- Use MSDP in a PIM-SM domain to share the multicast source information of multiple RPs to implement anycast-RP.

Protocols and Standards

- RFC3618: Multicast Source Discovery Protocol(MSDP)

8.2 Applications

Application	Description
Cross-Domain Multicast	Connect multiple ASs, share the multicast resources among autonomous systems (ASs), and provide the multicast service across ASs.
Anycast-RP	Share the multicast source information among multiple RPs in a single AS.

8.2.1 Cross-Domain Multicast

Scenario

Connect multiple ASs, run PIM-SM within the ASs, and establish an MSDP peer relationship between RPs of different ASs.

As shown in Figure 8-1, DR 1 connected to the multicast source registers with RP 1 in the local domain. DR 2 connected to the group member host triggers a join towards RP 2 in the local domain. RP 1 uses the SA message to notify RP 2 of the multicast source information. RP 2 continues to trigger a join towards the multicast source to build a multicast distribution tree (MDT).

Cross-domain multicast allows group member hosts to apply for the multicast streams across ASs.

Figure 8-1

Deployment

- Run Open Shortest Path First (OSPF) within each AS, and run Border Gateway Protocol (BGP) between ASs to implement cross-domain unicast.
- Run PIM-SM within each AS, and run MSDP between ASs to implement cross-domain multicast.

8.2.2 Anycast-RP

Scenario

PIM-SM runs within each AS. Multiple RPs exist, use the same RP address, and serve the same group. An MSDP peer relationship is established between these RPs.

As shown in Figure 8-2, DR 1 connected to the multicast source registers with the nearest RP 1 in the local domain. DR 2 connected to the group member host triggers a join towards the nearest RP 2. RP 1 uses the SA message to notify RP 2 of the multicast source information. RP 2 continues to trigger a join towards the multicast source to build an MDT.

Anycast-RP provides redundancy and load balancing for RPs, and helps accelerate convergence of multicast routes.

Figure 8-2

Deployment

- Run OSPF within each AS to implement intra-domain unicast.
- Run PIM-SM within each AS to implement intra-domain multicast.
- Run MSDP among RPs to share the multicast source information.

8.3 Features

Function	Description
Establishing an MSDP Peer Relationship	Connect multiple RPs to share the multicast source information.
Receiving and Forwarding SA Messages	Prevent SA flooding and suppress SA storms.

8.3.1 Establishing an MSDP Peer Relationship

Working Principle

Configure one or more pairs of MSDP peers on the network to connect RPs, thereby notifying other RPs of the multicast source information on an RP.

Use the TCP connection between MSDP peers through port 639. So far as the unicast route is reachable, the MSDP peer relationship can be established.

Figure 8-3

RP Connected to the Multicast Source

Configure the MSDP peer on the RP connected to the multicast source. Then, this RP can use SA messages to send the local multicast source information to other RPs.

As shown in Figure 8-3, DR 1 registers the multicast source information with RP 1. As a peer relationship is established between RP 1 and RP 2, RP 1 sends the multicast source information to X.

SA Message Forwarder

Non-RPs can also act as MSDP peers, but only forwards SA messages.

As shown in Figure 8-3, X forwards SA messages sent from RP 1 to RP 2. In this way, the multicast source information is transferred to RP 2.

RP Connected to the Multicast Receiver

Configure the MSDP peer on the RP connected to the multicast receiver. Then, this RP can trigger a join towards the multicast source based on the received SA message.

As shown in Figure 8-3, DR 2 triggers a join towards RP 2. As RP 2 already obtains the multicast source information, RP 2 continues to trigger a join towards the multicast source, thus establishing an MDT from DR 1 to DR 2.

8.3.2 Receiving and Forwarding SA Messages

Working Principle

An SA message contains the multicast source address, multicast group address, and RP address. The RP address is the IP address of the RP with which the multicast source is registered.

- The RP encapsulates the locally registered multicast source information in an SA message, sends the message to all its MSDP peers.
- On receiving the SA message, each MSDP peer performs the Peer-RPF check, compares the SA-Cache, and matches the SA message against the SA incoming and outgoing filtering rules. If the SA message passes the Peer-RPF check, does not exist in the SA SA-Cache, and meets the outgoing filtering rules, this SA message is forwarded to other MSDP peers.

 The SA request and SA response messages are also used between MSDP peers to transfer source information of a specific group.

Peer-RPF Check

Any SA message coming from an MSDP peer (address: N) will be checked as follows:

-  Judge whether the SA message passes the Peer-RPF check in the following sequence. Once the SA message passes the Peer-RPF check, accept the SA message; otherwise, drop the SA message.
1. If N is a member of the mesh group, the SA message passes the Peer-RPF check; otherwise, go to step 2.
 2. If N is the only active MSDP peer on the local device, the SA message passes the Peer-RPF check; otherwise, go to step 3.
 3. If N is the RP address in the SA message, the SA message passes the Peer-RPF check; otherwise, go to step 4.
 4. If an EBGp route to the RP address in the SA message exists on the local device, and the next hop of this route is N, the SA message passes the Peer-RPF check; otherwise, go to step 5.
 5. If an optimum route to the RP address in the SA message exists on the local device, check as follows:

If this optimum route is a distance vector route (such as the BGP/RIP route), and this router is advertised by N, the SA message passes the Peer-RPF check.

If this optimum route is a link status route (such as the OSPF/IS-IS route), and the next hop of this router is N, the SA message passes the Peer-RPF check.

Otherwise, go to step 6.
 6. If an optimum route to the RP address in the SA message exists on the local device, and this route is a MBGP/BGP route, extract the nearest AS of the AS-Path of this MBGP/BGP route. If the local device has multiple MSDP peers in this AS and N is the MSDP peer with the largest IP address, or N is the only MSDP peer in this AS, the SA message passes the Peer-RPF check; otherwise, go to step 7.
 7. If N is the default MSDP peer, the SA message passes the Peer-RPF check; otherwise, go to step 8.
 8. The SA message fails in the Peer-RPF check.

The Peer-RPF check helps prevent loops and SA flooding.

Mesh Group

In a mesh group, an MSDP peer relationship is established on every two members.

- For SA messages coming from entities outside the mesh group, after passing the Peer-RPF check and SA-Cache comparison, these SA messages are forwarded to other members in the group.
- Intra-group SA messages are no longer forwarded to other members in the group.

The mesh group helps reduce the number of SA messages.

Figure 8-4

SACache

The SA cache is used to buffer the SA message status. Expired SA messages will be deleted.

When an MSDP peer receives an SA message, if this message does not exist in the SA cache and passes the Peer-RPF check, the message is stored in the SA cache. If this message already exists in the SA cache, the message is ignored. This helps suppress the SA storms.

When an MSDP peer receives an SA message, if this message already exists in the SA cache, the message is immediately responded. This helps improve the protocol efficiency.

8.4 Configuration

Configuration Item	Description and Command	
Configuring Cross-Domain Multicast	This configuration is mandatory in the cross-domain multicast scenario.	
	<code>ip</code> <code>peer peer-address connect-source interface-type interface-number</code> <code>msdp</code>	Establishes an MSDP peer relationship.
Configuring an Anycast-RP	This configuration is mandatory in the Anycast-RP scenario.	

Configuration Item	Description and Command	
	ip msdp peer <i>peer-address</i> connect-source <i>interface-type interface-number</i>	Establishes an MSDP peer relationship.
	ip msdp originator-id <i>interface-type interface-number</i>	Modifies the RP address in the SA message.
Configuring the Peer-RPF Check Green Channel	 Optional. It is used to let SA message successfully pass the Peer-RPF check.	
	ip msdp default-peer <i>peer-address</i> [prefix-list <i>prefix-list-name</i>]	Configures the default MSDP peer.
	ip msdp mesh-group <i>mesh-name peer-address</i>	Configures an MSDP mesh group.
Enabling Security Measures	 Optional. It is used to prevent illegal TCP connections and suppress SA storms.	
	ip msdp password peer <i>peer-address</i> [<i>encryption-type</i>] <i>string</i>	Enables TCP MD5 encryption.
	ip msdp sa-limit <i>peer-address sa-limit</i>	Limits the number of SA messages in the SA cache.
Restricting Broadcasting of SA Messages	 Optional. It is used to restrict releasing, receiving, and forwarding of SA messages.	
	ip msdp redistribute [list <i>access-list</i>] [route-map <i>route-map</i>]	Filters the source information released locally.
	ip msdp filter-sa-request <i>peer-address</i> [list <i>access-list</i>]	Filters received SA requests.
	ip msdp sa-filter in <i>peer-address</i> [list <i>access-list</i>] [route-map <i>route-map</i>] [rp-list <i>rp-access-list</i>] [rp-route-map <i>rp-route-map</i>]	Filters received SA messages.
	ip msdp sa-filter out <i>peer-address</i> [list <i>access-list</i>] [route-map <i>route-map</i>] [rp-list <i>rp-access-list</i>] [rp-route-map <i>rp-route-map</i>]	Filters sent SA messages.
Managing MSDP Peers	 Optional. It is used to conveniently manage the MSDP peer relationship.	
	ip msdp description <i>peer-address text</i>	Adds a description to an MSDP peer.
	ip msdp shutdown <i>peer-address</i>	Shuts down an MSDP peer.
Modifying Protocol Parameters	 Optional. You are advised not to modify the default values of protocol parameters.	
	ip msdp timer <i>interval</i>	Modifies the TCP reconnection interval.

Configuration Item	Description and Command	
	ip msdp ttl-threshold <i>peer-address</i> <i>ttl-value</i>	Modify the TTL value of the multicast data packet carried in the SA message.

8.4.1 Configuring Cross-Domain Multicast

Configuration Effect

Establish the MSDP peer relationship between multiple ASs so that group member hosts can apply for the multicast streams across ASs.

Notes

- The inter-AC unicast route must be reachable.
- Run PIM-SM within each AS, and configure the BSR border.

Configuration Steps

✚ Establishing an MSDP Peer Relationship

- Mandatory.
- Establish a peer relationship between RPs of the corresponding multicast PIM domain.
- Establish an MSDP peer relationship between EBGPs devices of different ASs.
- Establish an MSDP peer relationship between the RP and the EBGPs device in each AS.

Command	ip msdp peer <i>peer-address</i> connect-source <i>interface-type interface-number</i>
Parameter Description	<i>peer-address</i> : Indicates the IP address of a remote peer. <i>interface-type interface-number</i> : Indicates the local interface, which is used to establish a TCP connection with the remote peer.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	The peer relationship is a bidirectional relationship. Therefore, this command must be configured on both sides. The IP address and local interface of the MSDP peer must be the same as those of the EBGPs peer. To ensure that SA messages can successfully pass the Peer-RPF check, you are advised to: ● Configure a mesh group. ● Configure the default MSDP peer.

Verification

Send a packet from a source (S) close to an RP to the group (G), and enable a host close to another RP to join G.

- Verify that the host can receive the (S, G) packet.

- Run the **show ip msdp summary** command on an RP in another AS to display the status of the MSDP peer.
- Run the **show ip msdp sa-cache** command on an RP in another AS to display the learned MSDP source information.

📌 Displaying the Learned MSDP Source Information

Command	show ip msdp sa-cache
Parameter Description	N/A
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	If no address is specified, all the (S, G) information is displayed by default. If an address is specified, the device checks whether this address is a unicast or multicast address. If the address is a unicast address, this address is treated as the multicast source (S), and all (S, G) information in which the multicast source is S will be displayed. If the address is a multicast address, this address is treated as the multicast group (G), and all (S, G) information in which the multicast group is G will be displayed. If this address is neither a unicast or multicast address, no information is displayed. If two addresses are specified, one address is treated as the multicast source (S), and the other as the multicast group (G). If one address is the unicast address, and the other address is the multicast group address, no information is displayed.
	<pre> uijie# show ip msdp sa-cache MSDP Source-Active Cache: 2 entries (200.200.200.200, 227.1.2.2), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05, Peer 200.200.200.2 Learned from peer 200.200.200.2, RPF peer 200.200.200.2, SAs received: 277, Encapsulated data received: 0 (200.200.200.200, 227.1.2.3), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05, Peer 200.200.200.2 Learned from peer 200.200.200.2, RPF peer 200.200.200.2, SAs received: 277, Encapsulated data received: 0 </pre>

📌 Displaying the Brief MSDP Peer Information

Command	show ip msdp summary
Parameter Description	N/A
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	N/A
	<pre> Ruijie# show ip msdp summary </pre>

Msdp Peer Status Summary							
Peer Address	As	State	Uptime/Downtime	Reset-Count	Sa-Count	Peer-description	
200.200.200.2	100	Up	04:22:11	10	6616	No description	
200.200.200.3	100	Down	19:17:13	4	0	peer-A	

Configuration Example

Configuring Cross-Domain Multicast

Scenario
Figure 8-5

The following table lists the interfaces and IP addresses of different devices:

Device	Interface	IP Address	Remark
A	G0/1	100.100.100.1/24	N/A
	Loopback0	10.10.10.10/32	RP address, which is used to establish an MSDP connection.
B	G0/1	100.100.100.2/24	N/A
	G0/2	1.1.1.1/24	BSR border
	Loopback0	20.20.20.20/32	Used to establish the EBGP and MSDP connections.
C	G0/1	1.1.1.2/24	BSR border
	G0/2	2.2.2.1/24	BSR border
	Loopback0	30.30.30.30/32	Used to establish the EBGP and MSDP connections.

	D	G0/2	2.2.2.2/24	BSR border
		G0/1	3.3.3.1/24	N/A
		Loopback0	40.40.40.40/32	Used to establish the EBGP and MSDP connections.
	E	G0/1	3.3.3.2/24	N/A
		Loopback0	50.50.50.50/32	RP address, which is used to establish an MSDP connection.
Configuration Steps	● Configure IP addresses of interfaces. ● Enable OSPF in each AS. Set up an EBGP peer relationship between AS 200 and AS 100 and between AS 200 and AS 300. Introduce BGP and OSPF to each other. ● Enable PIM-SM in each AS, configure C-BSR and C-RP, and configure the BSR border. ● Establish the MSDP peer relationship between EBGP peers and between the RP and EBGP peers.  The IP address and local interface of the MSDP peer must be the same as those of the EBGP peer.

Verification	Use the multicast source to send the packet (200.200.200.200, 225.1.1.1), and enable the host to join the group 225.1.1.1. ● Verify that the host receives this packet. ● On device C, check the status and SA message of the MSDP peer.
D	<pre> D# show ip msdp summary Msdp Peer Status Summary Peer Address As State Uptime/Downtime Reset-Count SA-Count Peer-Description 30.30.30.30 200 Up 00:01:420 1 1 No description D# show ip msdp sa-cache MSDP Source-Active Cache: 1 entries (200.200.200.200, 225.1.1.1), RP:10.10.10.10, (M)BGP/AS 100, 00:00:18/00:01:57, Peer 30.30.30.30 Learned from peer 30.30.30.30, RPF peer 30.30.30.30, SAs received: 1, Encapsulated data received: 1 </pre>

Common Errors

- The BSR border is not configured, or is not configured on a correct interface.

- PIM-SM is not enabled on the local interface used to establish the MSDP peer connection or on the interface of the peer IP address.
- SA messages cannot pass the Peer-RPF check.

8.4.2 Configuring an Anycast-RP

Configuration Effect

Establish the MSDP peer relationship within an AS to provide redundancy and load balancing for RPs.

Notes

- The inter-AC unicast route must be reachable.
- PIM-SM must run within the AS, and multiple RPs using the same IP addresses must be configured.
- The C-RP and C-BSR cannot be configured on the same interface.

Configuration Steps

✚ Establishing an MSDP Peer Relationship

- Mandatory.
- Configure the following command on each RP of the same AS to establish an MSDP peer relationship with each of other RPs:

Command	ip msdp peer <i>peer-addressconnect-sourceinterface-typeinterface-number</i>
Parameter	<i>peer-address</i> : Indicates the IP address of a remote peer.
Description	<i>interface-type interface-number</i> : Indicates the local interface, which is used to establish a TCP connection with the remote peer.
Defaults	The MSDP peer relationship is not established.
Command Mode	Global configuration mode
Usage Guide	The peer relationship is a bidirectional relationship. Therefore, this command must be configured on both sides. To ensure that SA messages can successfully pass the Peer-RPF check, you are advised to configure a mesh group.

✚ Modifying the RP Address in the SA Message

- Mandatory.
- Configure the following command on each RP of the same AS:

Command	ip msdp originator-id <i>interface-type interface-number</i>
Parameter	<i>interface-type interface-number</i> : Uses the IP address of this interface as the RP address in the SA message.
Description	
Defaults	By default, the RP address in the SA message is not modified.

Command Mode	Global configuration mode
Usage Guide	In the anycast-RP application scenario, the RP addresses on all RP devices are the same. If the RP address in an SA message is not modified, the RP device may determine that this SA message is sent by itself and therefore discards this message. Therefore, you need to configure different RP addresses for SA messages sent by different RP devices.

Verification

Send a packet from a source (S) close to an RP to the group (G), and enable a host close to another RP to join G.

- Verify that the host can receive the (S, G) packet.
- Run the **show ip msdp sa-cache** command on an RP in another AS to display the learned MSDP source information.

🔗 Displaying the Learned MSDP Source Information

Command	show ip msdp sa-cache
Parameter Description	N/A
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	If no address is specified, all the (S, G) information is displayed by default. If an address is specified, the device checks whether this address is a unicast or multicast address. If the address is a unicast address, this address is treated as the multicast source (S), and all (S, G) information in which the multicast source is S will be displayed. If the address is a multicast address, this address is treated as the multicast group (G), and all (S, G) information in which the multicast group is G will be displayed. If this address is neither a unicast nor multicast address, no information is displayed. If two addresses are specified, one address is treated as the multicast source (S), and the other as the multicast group (G). If one address is the unicast address, and the other address is the multicast group address, no information is displayed.
	<pre> Ruijie# show ip msdp sa-cache MSDP Source-Active Cache: 2 entries (200.200.200.200, 227.1.2.2), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05, Peer 200.200.200.2 Learned from peer 200.200.200.2, RPF peer 200.200.200.2, SAs received: 277, Encapsulated data received: 0 (200.200.200.200, 227.1.2.3), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05, Peer 200.200.200.2 Learned from peer 200.200.200.2, RPF peer 200.200.200.2, SAs received: 277, Encapsulated data received: 0 </pre>

Configuration Example

Sharing the Source information Among Anycast-RPs in the Same Multicast Domain

Scenario
Figure 8-6

The following table lists the interfaces and IP addresses of different devices:

Device	Interface	IP Address	Remark
A	G0/2	2.2.2.1/24	
	G0/1	1.1.1.1/24	
	Loopback0	100.100.100.100/32	The C-BSR is configured on this interface.
B	G0/2	2.2.2.2/24	
	G0/1	3.3.3.1/24	
	Loopback1	20.20.20.20/32	Used to establish an MSDP connection and modify the RP address in the SA message.
	Loopback0	10.10.10.10/32	The C-RP is configured on this interface.
C	G0/2	1.1.1.2/24	
	G0/1	4.4.4.1/24	
	Loopback1	30.30.30.30/32	Used to establish an MSDP connection and modify the RP address in the SA message.
	Loopback0	10.10.10.10/32	The C-RP is configured on this interface.
D	G0/1	4.4.4.2/24	
	G0/2	5.5.5.1/24	
E	G0/1	3.3.3.2/24	
	G0/2	6.6.6.1/24	

Configuration Steps

- Configure IP addresses of interfaces.
- Enable OSPF within the AS.
- Enable PIM-SM within the AS, and configure the C-BSR and C-RP.
- Establish the MSDP peer relationship between RPs, and modify the RP address in the SA message.

	● Configure a mesh group.
A	<pre> A#configure terminal A(config)#ip multicast-routing A(config)#interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)#interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ip pim sparse-mode A(config-if-GigabitEthernet 0/2)# exit A(config)#interface loopback 0 A(config-if-loopback 0)#ip pim sparse-mode A(config-if-loopback 0)# exit A(config)#ip pim bsr-candidate loopback0 </pre>
B	<pre> B#configure terminal B(config)#ip multicast-routing B(config)#interface GigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ip pim sparse-mode B(config-if-GigabitEthernet 0/1)# exit B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/2)#ip pim sparse-mode B(config-if-GigabitEthernet 0/2)# exit B(config)#interface loopback 0 B(config-if-loopback 0)#ip pim sparse-mode B(config-if-loopback 0)# exit B(config)#interface loopback 1 B(config-if-loopback 1)#ip pim sparse-mode B(config-if-loopback 1)# exit B(config)#ip pim rp-candidate loopback 0 B(config)#ip msdp peer 30.30.30.30 connect-source loopback 1 B(config)# ip msdp originator-id loopback 1 B(config)#ip msdp mesh-group mesh-name 30.30.30.30 </pre>

C	<pre> C#configure terminal C(config)#ip multicast-routing C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)#ip pim sparse-mode C(config-if-GigabitEthernet 0/1)# exit C(config)#interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)#ip pim sparse-mode C(config-if-GigabitEthernet 0/2)# exit C(config)#interface loopback 0 C(config-if-loopback 0)#ip pim sparse-mode C(config-if-loopback 0)# exit C(config)#interface loopback 1 C(config-if-loopback 1)#ip pim sparse-mode C(config-if-loopback 1)# exit C(config)#ip pim rp-candidate loopback 0 C(config)#ip msdp peer 20.20.20.20 connect-source loopback 1 C(config)# ip msdp originator-id loopback 1 C(config)#ip msdp mesh-group mesh-name 20.20.20.20 </pre>
D	<pre> D#configure terminal D(config)#ip multicast-routing D(config)#interface GigabitEthernet 0/1 D(config-if-GigabitEthernet 0/1)#ip pim sparse-mode D(config-if-GigabitEthernet 0/1)# exit D(config)#interface GigabitEthernet 0/2 D(config-if-GigabitEthernet 0/2)#ip pim sparse-mode D(config-if-GigabitEthernet 0/2)# exit </pre>
E	<pre> E#configure terminal E(config)#ip multicast-routing E(config)#interface GigabitEthernet 0/1 E(config-if-GigabitEthernet 0/1)#ip pim sparse-mode E(config-if-GigabitEthernet 0/1)# exit </pre>

	<pre>E(config)#interface GigabitEthernet 0/2 E(config-if-GigabitEthernet 0/2)#ip pim sparse-mode E(config-if-GigabitEthernet 0/2)# exit</pre>
Verification	Use the multicast source to send the packet (6.6.6.6,225.1.1.1), and enable the host to join the group 225.1.1.1. ● Verify that the host receives this packet. ● On device C, check the status and SA message of the MSDP peer.
C	<pre>C# show ip msdp summary Msdp Peer Status Summary Peer Address As State Uptime/Downtime Reset-Count SA-Count Peer-Description 20.20.20.20 Unknown Up 00:01:420 1 No description C# show ip msdp sa-cache MSDP Source-Active Cache: 1 entries (6.6.6.6, 225.1.1.1), RP:10.10.10.10, (M)BGP/AS unknown, 00:00:18/00:01:57, Peer 20.20.20.20 Learned from peer 20.20.20.20, RPF peer 20.20.20.20,</pre>

Common Errors

- The C-BSR and C-RP are configured on the same interface.
- The RP address in the SA message is not modified.
- SA messages cannot pass the Peer-RPF check.

8.4.3 Configuring the Peer-RPF Check Green Channel

Configuration Effect

Configure the Peer-RPF check green channel so that all SA messages sent from a specified MSDP peer can pass the Peer-RPF check.

Configure an MSDP mesh group so that all SA messages sent from members of the mesh group can pass the Peer-RPF check.

Notes

- The MSDP peer relationship must be established between devices.

Configuration Steps

📌 Configuring the Default MSDP Peer

- Optional.
- On an MSDP peer, if it is not necessary to perform the Peer-RPF check on SA messages sent from a specified peer, configure this peer as the default peer.

Command	ip msdp default-peer <i>peer-address</i> [prefix-list <i>prefix-list-name</i>]
Parameter	<i>peer-address</i> : Indicates the IP address of a remote peer.
Description	prefix-list <i>prefix-list-name</i> : Specifies the prefix list, which is used to limit the RPs initiating SA messages.
Defaults	By default, no default peer is configured.
Command Mode	Global configuration mode
Usage Guide	If the command does not contain prefix-list<i>prefix-list-name</i>, all SA messages are accepted. If the command contains prefix-list<i>prefix-list-name</i> but the specified prefix list does not exist, all SA messages are accepted. If the command contains prefix-list<i>prefix-list-name</i>, and the specified prefix list exists, only the SA messages initiated by RPs specified in this prefix list are accepted.

📌 Creating a Mesh Group

- Optional.
- Among multiple MSDP peers, if SA messages coming from any of these peers pass the Peer-RPF check by default, you can add these peers to a mesh group.

Command	ip msdp mesh-group <i>mesh-name</i> <i>peer-address</i>
Parameter	<i>mesh-name</i> : Indicates the name of the mesh group. The name is case sensitive.
Description	<i>peer-address</i> : Indicates the IP address of the MSDP peer to be added to the mesh group.
Defaults	By default, no mesh group is configured.
Command Mode	Global configuration mode
Usage Guide	An MSDP peer relationship must be established between every two MSDP peers added to the same mesh group. All SA messages sent by members of the mesh group can pass the Peer-RPF check.

Verification

- Check whether SA messages sent by the default peer can pass the Peer-RPF check.
- Check the configuration of the mesh group, and check whether all SA messages sent by members of the mesh group can pass the Peer-RPF check.

📌 Displaying Information about the Peer-RPF Check of a Specified MSDP Peer

Command	show ip msdp rpf-peer <i>ip-address</i>
Parameter	<i>peer-address</i> : Indicates the IP address of the SA message initiator.
Description	

Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	N/A
	<pre>Ruijie# show ip msdp rpf-peer 1.1.1.1 RPF peer information for 1.1.1.1 RPF peer: 200.200.200.2 RPF rule: Peer is only active peer RPF route/mask: Not-used RPF type: Not-used</pre>

📌 **Displaying the Mesh Group Configuration**

Command	show ip msdp mesh-group
Parameter Description	N/A
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	N/A
	<pre>Ruijie# show ip msdp mesh-group MSDP peers in each Mesh-group, <Mesh-group name>:<# peers> msdp-mesh: 1.1.1.2 1.1.1.3</pre>

Configuration Example

📌 **Configuring the Peer-RPF Check and a Mesh Group**

	The following table lists the interfaces and IP addresses of different devices:				
	Device	Interface	IP Address	Remark	
	A	G0/1	20.0.0.3/24		
		Loopback0	10.1.1.1/24		
	B	G0/1	20.0.0.4/24		
		Loopback0	40.0.0.1/24		
		G0/1	20.0.0.222/24		
		Loopback0	30.0.0.2/24		
	Configuration Steps	● Configure IP addresses of interfaces. ● Enable OSPF within the AS. ● Establish the MSDP peer relationship between A and B and between A and C. ● Enable PIM-SM on the G0/1 interface of device C. ● Before configuration, there are two active MSDP peers on device A, but it is not known which one should be selected as the RPF peer. Therefore, display the RPF peer information. "RPF peer does not exist" is displayed. ● Configure the default MSDP peer, and check whether the configuration is successful. ● Configure a mesh group.			
A	<pre>A#configure terminal A(config)#ip msdp peer 20.0.0.4 connect-source gi0/1 A(config)#ip msdp peer 30.0.0.2 connect-source loopback 0</pre>				
B	<pre>B#configure terminal B(config)#ip msdp peer 20.0.0.3 connect-source gi0/1</pre>				
C	<pre>C#configure terminal C(config)#ip msdp peer 10.0.0.1 connect-source loopback 0 C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)#ip pim sparse-mode C(config-if-GigabitEthernet 0/1)# exit</pre>				
	● Before configuration, there are two active MSDP peers on device A, but it is not known which one should be selected as the RPF peer. Therefore, display the RPF peer information. "RPF peer does not exist" is displayed. ● Configure the default MSDP peer. Then, display the RPF peer information. " Peer is best default peer" is displayed.				
A	<pre>A#configure terminal A(config)#ip msdp default-peer 30.0.0.2</pre> ● Cancel the default peer, and send the multicast source information to device C. Information is				

	displayed on device A, indicating that the SA message is received, but does not pass the Peer-RPF check. On device A, add 30.0.0.2 to the mesh group. Then, device A can receive the SA message normally.
A	<pre>A#configure terminal A(config)#no ip msdp default-peer 30.0.0.2</pre>
A	<pre>A#configure terminal A(config)#ip msdp mesh-group first 30.0.0.2</pre>
Verification	N/A

8.4.4 Enabling Security Measures

Configuration Effect

Enable MD5 encryption on TCP connections between MSDP peers to prevent illegal TCP connections.

Limit the number of SA messages in the SA cache of a specified MSDP peer to suppress SA storms.

Notes

- The MSDP peer relationship must be established between devices.

Configuration Steps

✎ Configuring MD5 Encryption on TCP Connections Between MSDP Peers

- Optional.
- Configure consistent MD5 encryption on MSDP peers that require encryption.

Command	ip msdp password peer <i>peer-address</i> [<i>encryption-type</i>] <i>string</i>
Parameter Description	<i>peer-address</i>: Indicates the IP address of a remote peer. <i>encryption-type</i>: Indicates the encryption level. Currently, only levels 0 to 7 are supported. 0 is the lowest level, and 7 is the highest level. The default value is 0. <i>string</i>: Indicates the cipher used for TCP MD5 authentication.
Defaults	By default, MD5 encryption is not configured.
Command Mode	Global configuration mode
Usage Guide	To authenticate the ID of an MSDP peer, enable MD5 encryption on the TCP connection established with this MSDP peer. The MSDP peer must have the consistent configuration, and the cipher must be the same; otherwise, the connection fails. If the configuration or cipher changes, the local device does not stop the current session, and will attempt to use a new cipher to retain the current session until timeout. If the encryption level is set to 7, the cipher text length must be an even number equaling to or greater than

4; otherwise, the configuration fails.

Limiting the Number of SA Messages in the SA Cache of a Specified MSDP Peer

- Optional.
- Perform this configuration if you need to limit the number of SA messages in the SA cache of a specified MSDP peer.

Command	ip msdp sa-limit <i>peer-address sa-limit</i>
Parameter	<i>peer-address</i> : Indicates the IP address of a remote peer.
Description	<i>sa-limit</i> : Indicates the maximum number of SA messages in the SA cache.
Defaults	The default value is 1,024.
Command Mode	Global configuration mode
Usage Guide	An MSDP peer relationship must be established between every two MSDP peers added to the same mesh group. Assume that the number of SA messages in the SA cache already exceeds the limit. After the configuration is completed, the number of SA messages in the SA cache does not exceed the limit.

Verification

- Check the connection between peers on which MD5 encryption is configured.
- Send a number of source information packets that exceeds the limit to the peer where the maximum number of SA messages in the SA cache is configured. Check whether all the source information can be learned.

Displaying the Number of SA Messages Learned from a Specified Peer

Command	show ip msdp count
Parameter	N/A
Description	
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	N/A
	<pre> Ruijie# show ip msdp count SA State per Peer Counters, <Peer>: <# SA learned> 1.1.1.2 : 0 100.100.100.14 : 0 100.100.100.15 : 0 100.100.100.200 : 0 200.200.200.2 : 2 200.200.200.3 : 0 200.200.200.6 : 0 </pre>

	<pre>200.200.200.13 : 0 200.200.200.66 : 0 SA State per ASN Counters, <asn>: <# sources>/<# groups> Total entries: 2 100: 1/2</pre>

Configuration Example

Configuring MD5 Encryption on an MSDP Peer and Limiting the Number of SA Messages Sent by This MSDP Peer in the SA Cache

Scenario Figure 8-8	
Configuration Steps	- Establish an MSDP peer relationship between A and B. - Configure MD5 encryption on device A. - After MSDP timeout, configure the MD5 cipher of the peer on device B, which is the same as the cipher on device A. Then, the session is reconnected. - On device A, set the maximum number of SA messages sent by the peer 20.0.0.4 in the SA cache to 10.
A	<pre>A#configure A(config)# ip msdp password peer 20.0.0.4 0 1234567 A(config)# ip msdp sa-limit 20.0.0.4 10</pre>
B	<pre>B#configure B(config)# ip msdp password peer 20.0.0.4 0 1234567</pre>
Verification	- After MD5 is configured on device A, but is not configured on device B, a message will be displayed, indicating the MD5 encryption failure. At this time, the MSDP peer is in DOWN state. - A period of time after MD5 is configured on device B, the MSDP peer is in DOWN state. - Send 20 multicast source packets to device B. A message will be displayed on device A, indicating that the number of SA messages exceeds the limit.
A	<pre>A# debug ip msdp sa-cache A# show ip msdp count</pre>

8.4.5 Restricting Broadcasting of SA Messages

Configuration Effect

Configure the SA message filtering rules to restricting broadcasting of SA messages.

Notes

- The MSDP peer relationship must be established between devices.

Configuration Steps

📌 Filtering the Source Information Released Locally

- Optional.
- Configure the SA release filtering rule on an MSDP device where releasing of the SA information needs to be limited.

Command	ip msdp redistribute [list access-list] [route-map route-map]
Parameter	list access-list: Indicates the access control list (ACL) used to control the ranges of S and G.
Description	route-map route-map: Indicates the route map used to control the ranges of S and G.
Defaults	By default, no rule is configured to filter locally released SA information.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, only the accepted (S, G) information (either coming from the local domain or other domains) can be injected to the MSDP. If the command contains list access-list, only the (S, G) information matching this ACL can be released. If the command contains route-map route-map, only the (S, G) information matching this route map can be released. If the command contains both parameters, only the (S, G) information matching the ACL and route map can be released. If the command does not contain any parameter, no (S, G) information is released.

📌 Filtering Received SA Requests

- Optional.
- Perform this configuration on the MSDP device where responding to the SA requests needs to be limited.

Command	ip msdp filter-sa-request peer-address[list access-list]
Parameter	peer-address: Indicates the IP address of a remote peer.
Description	list access-list: Indicates the ACL used to control the range of the group address.
Defaults	By default, no rule is configured to filter received SA requests.
Command Mode	Global configuration mode
Usage Guide	Use this command if you need to control the SA requests that can be accepted and responded.

	If the command does not contain list access-list, all SA requests will be ignored. If the command contains list access-list, but this AC does not exist, all SA requests will be ignored. If the command contains list access-list, and this AC exists, only the SA requests allowed by the ACL will be accepted, and others are ignored.

📌 Filtering Received SA Messages

- Optional.
- Perform this configuration on an MSDP device where the incoming SA information needs to be limited.

Command	ip msdp sa-filter in <i>peer-address</i> [list access-list] [route-map route-map] [rp-list rp-access-list] [rp-route-map rp-route-map]
Parameter Description	<i>peer-address</i>: Indicates the IP address of a remote peer. list access-list: Indicates the number or name of the extended IP ACL of a specified (S, G). It is used to control the multicast source information (S, G) that is allowed to pass. route-map route-map: Indicates the name of the route map of the specified (S, G). The multicast source information (S, G) is allowed to pass only when the AS path of the route on the S matches the AS path in the route map. rp-list rp-access-list: Indicates the number or name of the standard ACL of a specified RP. It is used to control the RPs, of which the multicast source information (S, G) that is allowed to pass. rp-route-map rp-route-map: Indicates the name of the route map of a specified RP. The multicast source information (S, G) is allowed to pass only when the AS path of the route on the RP matches the AS path in the route map.
Defaults	By default, no rule is configured to filter incoming SA messages.
Command Mode	Global configuration mode
Usage Guide	If this command is configured, but no ACL or route map is specified, all incoming SA messages will be filtered. If only one keyword (list or route-map) is specified, and every multicast source record (S, G) in the SA message meets the rule specified by the keyword, the multicast source record (S, G) will be received. If either rp-list or rp-route-map is specified, and the RP address contained in the SA message meets the rule specified by this keyword, this SA message will be received. If two or more of the keywords (including list, route-map, rp-list, and rp-route-map) are specified, only multicast source record (S, G) in the SA message that meets the rules specified by all the available keywords can be received.

📌 Filtering Sent SA Messages

- Optional.
- Perform this configuration on an MSDP device where the outgoing SA information needs to be limited.

Command	ip msdp sa-filter out <i>peer-address</i> [listaccess-list] [route-map route-map] [rp-list rp-access-list] [rp-route-map rp-route-map]
Parameter	<i>peer-address</i> : Indicates the IP address of a remote peer.

Description	list <i>access-list</i>: Indicates the number or name of the extended IP ACL of the specified (S, G). It is used to control the multicast source information (S, G) that is allowed to pass. route-map <i>route-map</i>: Indicates the name of the route map of the specified (S, G). The multicast source information (S, G) is allowed to pass only when the AS path of the route on the S matches the AS path in the route map. rp-list <i>rp-access-list</i>: Indicates the number or name of the standard ACL of a specified RP. It is used to control the RPs, of which the multicast source information (S, G) that is allowed to pass. rp-route-map <i>rp-route-map</i>: Indicates the name of the route map of a specified RP. The multicast source information (S, G) is allowed to pass only when the AS path of the route on the RP matches the AS path in the route map.
Defaults	By default, no rule is configured to filter outgoing SA messages.
Command Mode	Global configuration mode
Usage Guide	If this command is configured, but no ACL or route map is specified, no SA message will be sent to this MSDP peer. If only one of the keywords (including list, route-map, rp-list, and rp-route-map) is specified, any multicast source record (S, G) that meets the rule specified by the keyword will be forwarded to this MSDP peer. If two or more of the keywords (including list, route-map, rp-list, and rp-route-map) is specified, any multicast source record (S, G) that meets the rules specified by all the available keywords will be forwarded to this MSDP peer.

Verification

- Check whether SA messages initiated by the local device meet the filtering rules.
- Check whether SA messages learned by the local device meet the filtering rules.

🔗 Displaying SA Messages Initiated by the Local Device

Command	show ip msdp sa-originated
Parameter Description	N/A
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	If the local device is the RP of PIM-SM, multicast source (S, G) information is registered on the RP, and the MSDP peer is configured on the local device, you can run this command to display the (S, G) information initiated by the local device. The (S, G) information displayed by this command has met the criteria specified by the redistribution command ip msdp redistribute, but such (S, G) information can be sent to the MSDP peer only when the information meets the outgoing SA information filtering rules specified by the ip msdp sa-filter out command.
	Ruijie# show ip msdp sa-originated

MSDP Source-Active Originated: 5 entries

(192.168.23.78, 225.0.0.1), RP: 192.168.23.249

(192.168.23.79, 225.0.0.2), RP: 192.168.23.249

(192.168.23.80, 225.0.0.3), RP: 192.168.23.249

(192.168.23.81, 225.0.0.4), RP: 192.168.23.249

(192.168.23.82, 225.0.0.5), RP: 192.168.23.249

Configuration Example

Configuring Rules for Filtering Incoming or Outgoing SA Messages

Scenario
Figure 8-9

The following table lists the interfaces and IP addresses of different devices:

Device	Interface	IP Address	Remark
A	G0/1	20.0.0.3/24	
	Loopback0	10.1.1.1/24	
B	G0/1	20.0.0.4/24	
	Loopback0	40.0.0.1/24	
	G0/1	20.0.0.222/24	
	Loopback0	30.0.0.2/24	

- Configuration Steps
- Complete the basic configuration, as described in section 8.4.3 "Configuring the Peer-RPF Check Green Channel".
 - Configure rules for filtering incoming SA messages on device A.
 - Configure rules for filtering outgoing SA messages on device A.
 - Send the multicast source information to device C.

A

```
A#configure
A(config)# ip msdp sa-filter in 30.0.0.2
A(config)# ip msdp sa-filter in 30.0.0.2 list 100
```

	<pre> A(config)# ip access-list extended 100 A(config-ext-nacl)# permit ip host 20.0.0.100 host 225.0.0.1 A(config)# ip msdp sa-filter in 30.0.0.2 rp-list rp-acl-1 A(config)# ip access-list standard rp-acl-1 A(config-std-nacl) # permit host 20.0.0.221 A(config)# ip msdp sa-filter in 30.0.0.2 rp-route-map rp-rm-1 A(config)# route-map rp-rm-1 A(config-route-map)#match as-path 1 A(config)# ip as-path access-list 1 permit 2 A#configure A(config)# ip msdp sa-filter out 30.0.0.2 A(config)# ip msdp sa-filter out 30.0.0.2 list 101 A(config)# ip access-list extended 101 A(config-ext-nacl)# permit ip host 20.0.0.100 host 225.0.0.1 A(config)# ip msdp sa-filter out 30.0.0.2 rp-list rp-acl-2 A(config)# ip access-list standard rp-acl-2 A(config-std-nacl) # permit host 20.0.0.221 A(config)# ip msdp sa-filter out 30.0.0.2 rp-route-map rp-rm-2 A(config)# route-map rp-rm-1 A(config-route-map)#match as-path 1 A(config)# ip as-path access-list 1 permit 2 </pre>
Verification	● Send the multicast source information to device C in various scenarios. ● On device A, check whether the learned multicast source information meets the incoming requirements. ● On device B, check whether the learned multicast source information meets the outgoing requirements.
A	<pre>A#show ip msdp sa-cache</pre>
B	<pre>B#show ip msdp sa-cache</pre>
C	<pre>B#show ip msdp sa-originated</pre>

8.4.6 Managing MSDP Peers

Configuration Effect

Manage MSDP peers by adding descriptions to a specified MSDP or reset an MSDP peer.

Notes

- MSDP peers must be created in advance.

Configuration Steps

✚ Configuring the Description for an MSDP Peer

- Optional.
- Perform this configuration on an MSDP peer that should be managed.

Command	ip msdp description <i>peer-address text</i>
Parameter	<i>peer-address</i> : Indicates the IP address of a remote peer.
Description	<i>text</i> : Indicates the string that describes the MSDP peer.
Defaults	By default, no description information is configured of an MSDP peer.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Shutting Down an MSDP Peer

- Optional.
- Perform this configuration when it is required to temporarily shut down the connection with a specified peer.

Command	ip msdp shutdown <i>peer-address</i>
Parameter	<i>peer-address</i> : Indicates the IP address of an MSDP peer.
Description	
Defaults	By default, an MSDP peer is not shut down.
Command Mode	Global configuration mode
Usage Guide	This command shuts down only the TCP connection with an MSDP peer, but does not delete this MSDP peer or configuration of this MSDP peer.

Verification

- Display information about a specified MSDP peer, and check whether the description and peer status meet the requirements.

✚ Displaying Information about a Specified MSDP Peer

Command	show ip msdp peer [<i>peer-address</i>]
Parameter	N/A
Description	
Command Mode	Privileged mode, global configuration mode, or interface configuration mode

Usage Guide	N/A
	<pre> Ruijie#show ip msdp peer 20.0.0.1 MSDP PEER 20.0.0.1 (No description), AS unknown Connection status: State: Listen, Resets: 1, Connection source: GigabitEthernet 0/1 (20.0.0.2) Uptime(Downtime): 00:00:25, Message sent/received: 13/19 Input messages discarded: 0 Connection and counters cleared 00:13:25 ago Local Address of connection: 20.0.0.2 MD5 signature protection on MSDP TCP connection: enabled SA Filtering: Input (S,G) Access-list filter: None Input (S,G) route-map filter: None Input RP Access-list filter: None Input RP Route-map filter: None Output (S,G) Access-list filter: None Output (S,G) Route-map filter: None Output RP Access-list filter: None Output RP Route-map filter: None SA-Requests: Input filter: None Peer ttl threshold: 0 SAs learned from this peer: 2, SAs limit: No-limit Message counters: SA messages discarded: 0 SA messages in/out: 13/0 SA Requests discarded/in: 0/0 SA Responses out: 0 Data Packets in/out: 6/0 </pre>

Configuration Example

➤ **Configuring the Description of an MSDP Peer and Shutting Down the Connection with This Peer**

Scenario Figure 8-10	
Configuration Steps	● Establish the MSDP peer relationship between device A and device B. ● Configure the description "peer-router-B" for the peer 20.0.0.4 on device A. ● Wait 60, and shut down the connection with the MSDP peer 20.0.0.4 on device A.
A	<pre>A#configure A(config)# ip msdp peer 20.0.0.4 connect-source gi0/1 A(config)# ip msdp description 20.0.0.4 peer-router-B A(config)# end A# show ip msdp peer 20.0.0.4 A#configure A(config)# ip msdp shutdown 20.0.0.4 A(config)# show ip msdp peer 20.0.0.4</pre>
B	<pre>B# configure B(config)# ip msdp peer 20.0.0.3 connect-source gi0/1 B(config)# end</pre>
Verification	● Run the show ip msdp peer [peer-address] command to display the brief information of a specified peer, including the description and connection status of this MSDP peer.
A	<pre>A# show ip msdp peer 20.0.0.4</pre>

8.4.7 Modifying Protocol Parameters

Configuration Effect

Manage MSDP peers by adding descriptions to a specified MSDP or reset an MSDP peer.

Notes

- MSDP peers must be created in advance.

Configuration Steps

➤ **Configuring the TCP Reconnection Interval of an MSDP Peer**

- Optional.
- Perform this configuration on the device where the TCP reconnection interval of an MSDP peer needs to be modified.

Command	ip msdp timer <i>interval</i>
Parameter Description	<i>interval</i> : Indicates the TCP reconnection interval. The unit is second. The value ranges from 1 to 60. The default value is 30.
Defaults	By default, the reconnection interval is 30s.
Command Mode	Global configuration mode
Usage Guide	Within the TCP reconnection interval, the MSDP peer on the proactive connection side can initiate at most one TCP connection. In some application scenarios, you can shorten the TCP reconnection interval to accelerate convergence of the MSDP peer relationship.

📌 Configuring the TTL of the Multicast Packet Contained in the SA Message

- Optional.
- Perform this configuration on the MSDP device where inter-RP transfer of multicast packets should be restricted.

Command	ip msdp ttl-threshold <i>peer-address</i> <i>ttl-value</i>
Parameter Description	<i>peer-address</i> : Indicates the IP address of an MSDP peer. <i>peer-address</i> <i>ttl-value</i> : Indicates the TTL value. The value ranges from 0 to 255. The default value is 0.
Defaults	By default, the TTL value of the multicast packet contained in the SA message is not restricted.
Command Mode	Global configuration mode
Usage Guide	This command restricts the sending of multicast packet encapsulated in the SA message. A multicast packet is sent to the MSDP peer only when the TTL value in the IP header of the multicast packet is equal to or greater than the preset TTL threshold. If the the TTL value in the IP header of the multicast packet is smaller than the preset TTL threshold, the multicast packet will be removed from the SA message and discarded before the SA message is sent to the MSDP peer. This command affects the sending of multicast packet in the SA message, but does not affect the sending of the multicast source information (S, G) in the SA message.

📌 Configuring the MSDP Peer Capacity Supported by a Device

- Optional.
- If the default capacity (64 MSDP peers) is insufficient to support applications, you can modify the capacity on the device.

Command	ip msdp peer-limit <i>peer-limit</i>
Parameter Description	<i>peer-limit</i> : Indicates the maximum number of MSDP peers that can be configured. The value ranges from 1 to 128. The default value is 64.
Defaults	By default, at most 64 peers can be configured.
Command	Global configuration mode

Mode	
Usage Guide	This command is used to configure the maximum number of MSDP peers supported by a device. When configuring this command, if the number of MSDP peers on the device exceeds the value to be configured, a prompt will be displayed, and the configuration fails. The configuration can succeed only after the extra number peers are deleted.

✎ Configuring the SA Cache Capacity Supported by a Device

- Optional.
- Perform this configuration on a device where the SA cache capacity should be adjusted.

Command	ip msdp global-sa-limit <i>sa-limit</i>
Parameter Description	<i>sa-limit</i> : Indicates the maximum capacity of the SA cache supported by the device. The value ranges from 1 to 4,096. The default value is 1,024.
Defaults	By default, the SA cache supports 1,024 SA messages.
Command Mode	Global configuration mode
Usage Guide	This command is used to adjust the SA cache capacity of the device. You are advised to configure this command when the device is being started. If the capacity is increased when MSDP is in service, the adjustment does not affect the SA cache that is originally learned. If the capacity is increased when MSDP is in service, all SA caches that are originally learned from other devices or the SA caches initiated by the local devices must be deleted and re-learned.

Verification

- Shut down the connection with an MSDP peer. After the reconnection interval elapses, check whether the MSDP peer is in UP date again.

Configuration Example

✎ Setting the MSDP Peer Reconnection Interval to 20s

Scenario Figure 8-11	
Configuration Steps	● Establish the MSDP peer relationship between device A and device B. ● On device A, set the MSDP peer reconnection interval to 20s.
A	<pre>A#configure A(config)# ip msdp peer 20.0.0.4 connect-source gi0/1 A(config)# ip msdp description 20.0.0.4 peer-router-B</pre>

	<pre> A(config)# end A# show ip msdp peer 20.0.0.4 A#configure A(config)# ip msdp timer 20 A(config)# end </pre>
B	<pre> B# configure B(config)# ip msdp peer 20.0.0.3 connect-source gi0/1 B(config)# end </pre>
Verification	● On device B, shut down and then immediately reconnect the connection with the MSDP peer. ● Check whether the MSDP peer is in UP state within 20s.
A	<pre> A#debug ip msdp timer </pre>
B	<pre> B# configure B(config)# show ip msdp peer 20.0.0.3 </pre>

8.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Resets the TCP connection with a specified MSDP peer.	clear ip msdp peer <i>peer-address</i>
Clears the SA cache.	clear ip msdp sa-cache <i>[group-address]</i>
Clears the statistics of MSDP peers.	clear ip msdp statistics <i>[peer-address]</i>

Displaying

Description	Command
Displays the number of sources and number of groups generated by SA messages.	show ip msdp count <i>[as-number]</i>
Displays information about a mesh group.	show ip msdp mesh-group
Displays detailed information about MSDP peers.	show ip msdp peer <i>[peer-address]</i>

Description	Command
Displays information about the MSDP RPF peer corresponding to the specified initiator address.	show ip msdp rpf-peer <i>ip-address</i>
Displays the learned (S, G) information.	show ip msdpsa-cache [<i>group-address</i> <i>source-address</i>] [<i>group-address</i> <i>source-address</i>] [<i>as-number</i>]
Displays the (S, G) information initiated by the local device.	show ip msdpsa-originated
Displays brief information about all MSDP peers.	show ip msdp summary

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs MSDP peers.	debug ip msdp peer

9 Configuring IGMP Snooping

9.1 Overview

Internet Group Management Protocol (IGMP) snooping is a mechanism of listening to IP multicast. It is used to manage and control the forwarding of IP multicast traffic within VLANs, realizing Layer-2 multicasting.

As shown in the following figure, when a Layer-2 device is not running IGMP snooping, IP multicast packets are broadcasted within the VLAN; when the Layer-2 device is running IGMP snooping, IP multicast packets are transmitted only to profile members.

Figure 9-1 Networking Topology of IP Multicast Forwarding within the VLAN Before and After IGMP Snooping Is Run on the Layer-2 Device

Protocols and Standards

- RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

9.2 Applications

Application	Description
Layer-2 Multicast Control	Enables precise forwarding of Layer-2 multicast packets to avoid flooding at this layer.
Shared Multicast Services (Multicast VLAN)	Multiple users can share the multicast traffic of the same VLAN.
Premium Channels and Preview	Controls the range of multicast addresses that allow user demanding and allows preview for profiles who are inhibited from demanding.

9.2.1 Layer-2 Multicast Control

Scenario

As shown in the following figure, multicast packets are transmitted to users through a Layer-2 switch. When Layer-2 multicast control is not performed, namely, when IGMP snooping is not implemented, multicast packets are flooded to all the users including those who are not expected to receive these packets. After IGMP snooping is implemented, the multicast packets from an IP multicast profile will no longer be broadcast within the VLAN but transmitted to designated receivers.

Figure 9-2 Networking Topology of Implementing Layer-2 Multicast Control (Multicast VLAN)

Deployment

Configure basic IGMP snooping functions.

9.2.2 Shared Multicast Services (Multicast VLAN)

Scenario

In Shared VLAN Group Learning (SVGL) mode or IVGL-SVGL mode (IVGL: Independent VLAN Group Learning), a device running IGMP snooping can provide shared multicast services (or multicast VLAN services) to the VLAN users. Typically, this function is used to provide the same video-on-demand (VOD) services to multiple VLAN users.

The following figure shows the operation of a Layer-2 multicast device in SVGL mode of IGMP snooping. The multicast router sends a multicast packet to VLAN 1, and the Layer-2 multicast device automatically transfers the packet to VLAN 1, VLAN 2, and VLAN 3. In this way, the multicast services of VLAN 1 are shared by VLAN 2 and VLAN 3.

Figure 9-3 Networking Topology of Shared Multicast Services (Multicast VLAN)

- i** If the Layer-2 multicast device operates in IVGL mode, the router must send a packet to each VLAN, which wastes bandwidth and burdens the Layer-2 multicast device.

Deployment

- Configure basic IGMP snooping functions (in SVGL mode or IVGL-SVG mode).

9.2.3 Premium Channels and Preview

Scenario

In VOD application, by limiting the range of the multicast addresses that a user host can access, unpaid users will not be able to watch the premium channels. Thereafter, the preview service is offered to unpaid users before they decide whether to pay for it.

The users can preview a premium channel for a certain period of time (for example 1 minute) after demanding it.

Deployment

- Configure basic IGMP snooping functions (in any working mode).
- Configure the range of multicast addresses that a user can access.
- Enable the preview function for VOD profiles that are denied access.

9.3 Features

Basic Concepts

➤ Multicast Router Ports and Member Ports

i IGMP snooping is VLAN-based. The ports involved refer to the member ports within the VLAN.

The device running IGMP snooping identifies the ports within the VLAN as a multicast router port or member port so as to manage and control the forwarding of IP multicast traffic within the VLAN. As shown in the following figure, when IGMP snooping is run on a Layer-2 device, multicast traffic enters the multicast router port and exits from the member ports.

Figure 9-4 Networking Topology of Two IGMP Snooping Ports

- Multicast router port: The location of the multicast source is directed by the port on the Layer-2 multicast device which is connected to the multicast router (Layer-3 multicast device): By listening to IGMP packets, the Layer-2 multicast device can automatically detect the multicast router port and maintain the port dynamically. It also allows users to configure a static router port.
- Member port: The port is on a Layer-2 multicast device and is connected to member hosts. It directs the profile members. It is also called the Listener Port. By listening to IGMP packets, the Layer-2 multicast device can automatically detect the member port and maintain the port dynamically. It also allows users to configure a static member port.

➤ IGMP Snooping Forwarding Entry

The device running IGMP snooping forwards IP multicast packets in accordance with the IGMP snooping forwarding entry.

An IGMP snooping forwarding entry includes the following items: source address (S), profile address (G), VLAN ID (VLAN_ID), multicast router port, and member port. It indicates that packets of required features (including S, G, and

VLAN_ID) should enter the multicast router port and exit from a member port. An IGMP snooping forwarding entry is identified using a group of S, G, and VLAN_ID.

To display the IGMP snooping forwarding entry, run the **show ip igmp snooping gda-table** command.

```
Ruijie# show ip igmp snooping gda-table
Multicast Switching Cache Table

D: DYNAMIC    //Dynamic member port

S: STATIC     //Static member port

M: MROUTE     //Multicast router port (dynamic or static)

(*, 233.3.6.29, 1):  //(S: any; G: 233.3.6.29; VLAN_ID: VLAN 1)

VLAN(1) 3 OPORTS:

    GigabitEthernet 0/3(S)

    GigabitEthernet 0/2(M)

    GigabitEthernet 0/1(D)

(*, 233.3.6.30, 1):  //S: any; G: 233.3.6.30; VLAN_ID: VLAN 1)

VLAN(1) 2 OPORTS:

    GigabitEthernet 0/2(M)

    GigabitEthernet 0/1(D)
```

Overview

Feature	Description
Listening to IGMP Packets	Discovers and identifies the router port and member port to establish and maintain the IGMP snooping forwarding entries. :
IGMP Snooping Working Modes	Provides independent or shared multicast services to the user VLAN.
Multicast Security Control Profile	Controls the multicast service scope and load to prevent illegal multicast traffic.
Handling QinQ	Defines the range of multicast addresses that permit or deny user requests for reference of other functions.
IGMP Querier	Sets the forwarding mode of multicast packets on the QinQ interface.
	On a network without a Layer-3 multicast device, the Layer-2 multicast device acts as an IGMP querier.

9.3.1 Listening to IGMP Packets

A device running IGMP snooping analyzes IGMP packets received, and finds and identifies the router port and member port using these packets, thereby creating and maintaining an IGMP snooping entry.

Working Principle

A device running IGMP snooping can identify and handle the following types of IGMP packets:

Query Packets

-  An IGMP querier periodically sends General Query packets. When the IGMP querier receives Leave packets, it sends Group-Specific Query packets.

When the device running IGMP snooping receives the Query packets, it performs the following operations within the VLAN:

- Forward the IGMP Query packets to all the ports (except the receiving port of these packets).
- If the receiving port is a dynamic router port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- If the receiving port is not a dynamic router port, use it as a dynamic router port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- For general queries, reset the aging timer for all the dynamic member ports. If the timer expires, the port will no longer be used as the dynamic member port for the general group. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- For designated query packets, reset the aging timer for all the dynamic member ports of the designated profile. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- If dynamic router port learning is disabled, IGMP snooping will not learn the dynamic router port.

Report Packets

-  When a member host receives a query, it responds to the query with a Report packet. If a host requests to join a profile, it will also send a report.
-  . For IGMPv3 Report packets, Ruijie products only process group information contained in the packets .

When the device running IGMP snooping receives the Report packets, it performs the following operations within the VLAN:

- Forward the Report packets from all the router ports. After the **ip igmp snooping suppression enable** command is run in one IGMP query cycle, only the first report received by each profile will be forwarded.
- If the port on which Report packets are received is a dynamic member port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.
- If the port on which Report packets are received is not a dynamic member port, use it as a dynamic member port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.

↳ Leave Packets

 If a host requests to leave a profile, it will send a Leave packet.

When the device running IGMP snooping receives the Leave packets, it performs the following operations within the VLAN:

- Forward the leave packets from all the router ports.
- If the port on which leave packets are received is a dynamic member port and the Leave function is enabled, the port will be immediately deleted from the IGMP snooping forwarding entry of the designated profile and will no longer be used as the dynamic member port.
- If the port on which the leave packets are received is a dynamic member port and the Leave function is disabled, the port state should be maintained.

Related Configuration

↳ Configuring a Static Router Port

Run the **ip igmp snooping vlan mrouter interface** command to configure a static router port.

↳ Configuring a Static Member Port

Run the **ip igmp snooping vlan static interface** command to configure a static member port.

↳ Enabling Report Suppression

Report suppression is disabled by default.

Run the **ip igmp snooping suppression enable** command to enable report suppression.

After report suppression is enabled, in one IGMP query cycle, only the first Report packet received by each profile will be forwarded. The source media access control (MAC) address of the forwarded report will be changed to the MAC address of the device.

↳ Enabling Immediate Leave

Immediate leave is disabled by default.

Run the **ip igmp snooping fast-leave enable** command to enable immediate leave.

↳ Enabling Dynamic Router Port Learning

Dynamic router port learning is enabled by default.

Run the **no ip igmp snooping mrouter learn pim-dvmrp** command to disable dynamic router port learning.

Run the **no ip igmp snooping vlan vid mrouter learn pim-dvmrp** command to disable dynamic router port learning for designated VLANs.

✚ Configuring the Aging Time of a Dynamic Router Port

The default aging time is 300s.

When a dynamic router port receives a query packet, the aging timer of the port is enabled or reset; if the aging time is not configured, the maximum response time carried by the query packet is used as the aging time.

Run **ip igmp snooping dyn-mr-aging-time** to configure the aging time of the dynamic router port.

✚ Configuring the Aging Time of a Dynamic Member Port

The default aging time is 260s.

When a dynamic member port receives a query packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time carried by the query packet.

When a dynamic member port receives a Report packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time of the dynamic member port.

Run **ip igmp snooping host-aging-time** to configure the aging time of the dynamic member port.

✚ Configuring the Maximum Response Time of a Query Packet

The maximum response time of a query packet is not configured by default and the maximum response time carries by the query packet is used.

Run **ip igmp snooping query-max-response-time** to configure the maximum response time of a query packet.

9.3.2 IGMP Snooping Working Modes

A device running in the three modes (IVGL, SVGL, and IVGL-SVGL) of IGMP snooping can provide independent multicast services or shared multicast services to the user VLAN.

Working Principle

✚ IVGL

In IVGL mode, a device running IGMP snooping can provide independent multicast services to each user VLAN.

Independent multicast services indicate that multicast traffic can be forwarded only within the VLAN it belongs to, and a user host can subscribe to the multicast traffic within the VLAN that the host belongs to.

✚ SVGL

In SVGL mode, a device running IGMP snooping can provide shared multicast services to the user VLAN.

Shared multicast services can be provided only on shared VLANs and sub VLANs and SVGL multicast addresses are used. In a shared VLAN, the multicast traffic within the range of SVGL multicast addresses is forwarded to a sub VLAN, and the user hosts within the sub VLAN subscribe to such multicast traffic from the shared VLAN.

- In a shared VLAN and sub VLAN, shared multicast services will be provided to the multicast traffic within the range of SVGL multicast addresses. Other multicast traffic will be discarded.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

-
-  When the user VLAN is set to a shared VLAN or sub VLAN, shared multicast services are provided; when a user VLAN is set to other VLANs, independent multicast services are provided.
-

IVGL-SVGL

IVGL-SVGL mode is also called the hybrid mode. In this mode, a device running IGMP snooping can provide both shared and independent multicast services to the user VLAN.

- In a shared VLAN and sub VLAN, multicast services will be provided to the multicast traffic within an SVGL profile. For other multicast traffic, independent multicast services will be provided.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

-
-  When a user VLAN is configured as a shared VLAN or sub VLAN, both public multicast services and independent multicast services are available. When a user VLAN is configured as a VLAN other than shared VLAN and sub VLAN, only the independent multicast services are available.
-

Related Configuration

Enabling IGMP Snooping and Selecting a Working Mode

IGMP snooping is disabled by default.

Run the **ip igmp snooping ivgl** command to enable IGMP snooping in IVGL mode.

Run the **ip igmp snooping svgl** command to enable IGMP snooping in SVGL mode.

Run the **ip igmp snooping ivgl-svgl** command to enable IGMP snooping in IVGL-SVGL mode.

A working mode must be designated when enabling IGMP snooping, namely, one of the preceding working modes must be selected.

Configuring Shared VLAN

The shared VLAN is VLAN 1 by default.

Run the **ip igmp snooping svgl vlan** command to designate a VLAN as the shared VLAN.

In SVGL mode and IVGL-SVGL mode, only one VLAN can be configured as the shared VLAN.

Configuring Sub VLAN

By default, a sub VLAN is any VLAN except the shared VLAN.

Run the **ip igmp snooping svgl subvlan** command to designate a VLAN as the sub VLAN.

In SVGL mode and IVGL-SVGL mode, the number of sub VLANs is not limited.

Configuring an SVGL Profile

No default setting.

Run the **ip igmp snooping svgl profile *profile_num*** command to configure the address range of an SVGL profile.

-
-  In SVGL mode and IVGL-SVGL mode, the SVGL profile range must be configured; otherwise, shared multicast services cannot be provided.
-

9.3.3 IGMP Security Control

A device running IGMP snooping can control the multicast service scope and load, and effectively prevents illegal multicast traffic.

Working Principle

Configuring the Profile Filtering for User Demanding

By configuring the profile list that a user can access, you can customize the multicast service scope to guarantee the interest of operators and prevent illegal multicast traffic.

To enable this function, you should use a profile to define the range of multicast addresses that a user is allowed to access.

- When the profile is applied on a VLAN, you can define the multicast addresses that a user is allowed to access within the VLAN.
- When the profile is applied on an interface, you can define the multicast addresses that a user is allowed to access under the port.

Multicast Preview

If the service provider wants to allow the users to preview some multicast video traffic that denies the users' access, and stop the multicast video traffic after the preview duration is reached, the user-based multicast preview function should be provided. The multicast preview function is used together with multicast permission control. For example, in the application of videos, the administrator controls some premium channels by running the **ip igmp profile** command on a port or VLAN. In this way, unsubscribed users will not be able to watch these channels on demand. If users want to preview the channels before they decide whether to pay for watching or not, the multicast preview function can be enabled, allowing the premium channels to be previewed by unpaid users for a certain period of time (for example 1 minute).

Controlling the Maximum Number of Profiles Allowed for Concurrent Request

If there is too much multicast traffic requested at the same time, the device will be severely burdened. Configuring the maximum number of profiles allowed for concurrent request can guarantee the bandwidth.

- You can limit the number of profiles allowed for concurrent request globally.
- You can also limit the number of profiles allowed for concurrent request on a port.

Controlling the Entry of Multicast Traffic

By running the **ip igmp snooping source-check port** command to enable source port inspection, you can restrict the entry of multicast traffic to prevent illegal traffic.

- When source port inspection is enabled, only the multicast traffic entered from the router port is considered as legal; the traffic from other ports is considered as illegal and will be discarded.
- When source port inspection is disabled, the traffic entered from any port is considered as legal.

✚ Configuring the Source IP Inspection for Multicast Traffic

By enabling source IP inspection, you can restrict the IP address of multicast traffic to prevent illegal traffic.

Source IP inspection includes the inspection of the source IP addresses of specific profiles and of default profiles.

- Inspection of the source IP addresses of default profiles (also called source-check default-server): Specifies the source IP addresses for all the multicast profiles within all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- Inspection of the source IP addresses of specific profiles (also called limit-ipmc): Specifies the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Related Configuration

✚ Configuring the Profile Filtering

By default, profiles are not filtered and allow user access.

To filter multicast profiles, run the **ip igmp snooping filter** command in interface configuration mode or global configuration mode.

✚ Enabling Preview

Preview is not enabled by default.

Run the **ip igmp snooping preview** command to enable preview and restrict the range of the profiles permitted for multicast preview.

Run the **ip igmp snooping preview interval** to set the multicast preview duration.

✚ Configuring the Maximum Number of Profiles Allowed for Concurrent Request on a Port

By default, the number of profiles allowed for concurrent request is not limited.

Run the **ip igmp snooping max-groups** command to configure the maximum number of profiles allowed for concurrent request.

✚ Configuring the Maximum Number of Multicast Profiles Allowed Globally

By default, the maximum number of multicast profiles allowed globally is 65,536.

Run the **ip igmp snooping l2-entry-limit** command to configure the maximum number of multicast profiles allowed globally.

✚ Enabling Source Port Inspection

By default, source port inspection is not configured.

Run the **ip igmp snooping source-check port** command to enable source port inspection.

➤ Enabling Source IP Inspection

By default, source IP inspection is disabled.

- Run the **ip igmp snooping source-check default-server** *address* command to enable source IP inspection and specify the default source IP address (applicable to any profile of any VLAN).
- (Optional) Run the **ip igmp snooping limit-ipmc vlan** *vid* **address** *group-address* **server** *source-address* command to specify a specific source IP address for a specific profile of specific VLAN (applicable to a specific profile of specific VLAN).

First, you must enable source IP inspection to specify default source address, and then a specific source address can be specified for a specific profile of specific VLAN. If a source address is specified for a specific profile of specific VLAN, the multicast traffic of the specific profile will perform inspection for the source address specified by this command. Other multicast traffic will perform inspection for default source addresses.

9.3.4 IGMP Profile

A multicast profile is used to define the range of multicast addresses that permit or deny user demanding request for reference of other functions.

Working Principle

The profile is used to define the range of multicast addresses.

When SVGL mode is enabled, an SVGL profile is used to define the range of SVGL multicast addresses.

When the multicast filter is configured on an interface, a profile is used to define the range of multicast addresses that permit or deny user request under the interface.

When a VLAN filter is configured, a profile is used to define the range of multicast addresses that permit or deny user request under within the VLAN.

When the preview function is enabled, a profile is used to define the range of multicast address allowed for preview.

Related Configuration

➤ Configuring a Profile

Default configuration:

- Create a profile, which is **deny** by default.

Configuration steps:

- Run the **ip igmp profile** *profile-number* command to create a profile.
- Run the **range** *low-address* *high_address* command to define the range of multicast addresses. Multiple address ranges are configured for each profile.
- (Optional) Run the **permit** or **deny** command to permit or deny user request (**deny** by default). Only one **permit** or **deny** command can be configured for each profile.

9.3.5 IGMP QinQ

Working Principle

On a device with IGMP snooping enabled and dot1q-tunnel (QinQ) port configured, IGMP snooping will handle the IGMP packets received by the QinQ port using the following two approaches:

- Approach 1: Create a multicast entry on the VLAN where IGMP packets are located. The forwarding of IGMP packets on the VLAN where these packets are located is called transparent transmission. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 10 and forwards the multicast Query packet to the router port of VLAN 10.
- Approach 2: Create a multicast entry on the default VLAN of the QinQ port. Encapsulate the multicast packet with the VLAN tag of the default VLAN where the QinQ port is located and forward the packet within the default VLAN. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 1, encapsulates the multicast query packet with the tag of VLAN 1, and forward the packet to VLAN 1 router port.

Related Configuration

Configuring QinQ

By default, IGMP snooping works in the mode specified in Approach 2.

Run the **ip igmp snooping tunnel** command to implement Approach 1.

9.3.6 IGMP Querier

On a network with a Layer-3 multicast device, the Layer-3 multicast device acts as an IGMP querier. In this case, a Layer-2 device needs only to listen to IGMP packets to establish and maintain the forwarding entry, realizing Layer-2 multicast.

On a network without a Layer-3 multicast device, the Layer-2 multicast device must be configured with the IGMP querier function so that the device can listen to IGMP packets. In this case, a Layer-2 device needs to act as an IGMP querier as well as listen to IGMP packets to establish and maintain the forwarding entry to realize Layer-2 multicast.

Working Principle

A Layer-2 device acts as an IGMP querier to periodically send IGMP Query packets, listen to and maintain the IGMP Report packets replied by a user, and create a Layer-2 multicast forwarding entry. You can adjust relevant parameters of the Query packets sent by the IGMP querier through configuration.

When the device receives a Protocol-Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP) packet, it considers that a multicast router, which will act as an IGMP querier, exists on the network and disables the querier function. In this way, IGMP routing will not be affected.

When the device receives the IGMP Query packets from other devices, it will compete with other devices for the IGMP querier.

✎ Enabling the Querier Function

You can enable the querier for a specific VLAN or all VLANs.

Only when the global querier function is enabled can the queriers for specific VLANs take effect.

✎ Specifying the IGMP Version for a Querier

The version of IGMP used for sending Query packets can be configured as IGMPv1 or IGMPv2.

✎ Configuring the Source IP Address of a Querier

You can configure the source IP address of a query packet sent by the querier based on VLANs.

When the source IP address of the querier is not configured, the querier will not take effect.

✎ Configuring the Query Interval of a Querier

You can configure the intervals for sending global Query packets based on different queriers on different VLANs.

✎ Configuring the Maximum Response Time of a Query Packet

You can configure the maximum response time carried by a Query packet that is sent by a querier. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1. You can configure different maximum response time for queriers on different VLANs.

✎ Configuring the Aging Time of a Querier

When other IGMP queriers exist on a network, the existing device will compete with other queriers. If the existing device fails to be elected and is in the non-querier state, the aging timer of a querier will be enabled. After the timer expires, other queriers on the network are considered as expired and the existing device will be resumed as the querier.

Related Configuration

✎ Enabling the Querier Function

By default, the querier function of a device is disabled.

Run the **ip igmp snooping querier** command to enable the global querier function.

Run the **ip igmp snooping vlan num querier** command to enable the querier function for specific VLANs.

✎ Specifying the IGMP Version for a Querier

By default, a querier runs IGMPv2.

Run the **ip igmp snooping querier version** command to configure the global querier version.

Run the **ip igmp snooping vlan querier version** command to specify the querier version for specific VLANs.

✚ Configuring the Source IP Address of a Querier

By default, the source IP address of a querier is 0.

Run the **ip igmp snooping querier address** command to enable global source IP addresses of queriers.

Run the **ip igmp snooping vlan querier address** command to specify the source IP addresses of the queriers on specific VLANs.

✚ Configuring the Query Interval of a Querier

By default, the query interval of a querier is 60s.

Run the **ip igmp snooping querier query-interval** command to enable the global query interval of queriers.

Run **ip igmp snooping vlan querier query-interval** to specify the global query interval of the queriers on specific VLANs.

✚ Configuring the Maximum Response Time of a Query Packet

By default, the maximum response time of a query packet is 10s.

Run the **ip igmp snooping querier max-response-time** command to configure the maximum response time of the query packets sent by global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to specify the maximum response time of the query packets sent by the queriers on specific VLANs.

✚ Configuring the Aging Time of a Querier

By default, the aging time of a querier is 125s.

Run the **ip igmp snooping querier max-response-time** command to configure the aging time of global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to configure the aging time of queriers on specific VLANs.

9.4 Configuration

Configuration	Description and Command	
Configuring Basic IGMP Snooping Functions (IVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in IVGL mode.	
	ip igmp snooping ivgl	Enables global IGMP snooping in IVGL mode.
	no ip igmp snooping vlan <i>num</i>	Disables IGMP snooping for a VLAN.
Configuring Basic IGMP Snooping Functions (SVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in SVGL mode.	

Mode)	ip igmp snooping svgl	Enables global IGMP snooping in IVGL mode.
	no ip igmp snooping vlan <i>num</i>	Disables IGMP snooping for a VLAN.
	ip igmp snooping svgl profile <i>profile_num</i>	Configures the SVGL profile.
	ip igmp snooping svgl vlan	Specifies the SVGL shared VLAN.
	ip igmp snooping svgl subvlan	Specifies the SVGL sub VLAN.
Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in IVGL-SVGL mode.	
	ip igmp snooping ivgl-svgl	Enables global IGMP snooping in IVGL-SVGL mode.
	no ip igmp snooping vlan <i>num</i>	Disables IGMP snooping for a VLAN.
	ip igmp snooping svgl profile <i>profile_num</i>	Configures the SVGL profile.
	ip igmp snooping svgl vlan	Specifies the SVGL shared VLAN.
	ip igmp snooping svgl subvlan	Specifies the SVGL sub VLAN.
Configuring the Packet Processing	 (Optional) It is used to adjust relevant configurations for processing protocol packets.	
	ip igmp snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>	Configures a static router port.
	p igmp snooping vlan <i>vid</i> static group-address interface <i>interface-type</i> <i>interface-number</i>	Configures a static member port.
	ip igmp snooping vlan <i>vlan-id</i> mrouter learn pim-dvmrp	Enables dynamic router port learning.
	ip igmp snooping dyn-mr-aging-time <i>time</i>	Configures the aging time of a dynamic router port.
	ip igmp snooping host-aging-time <i>time</i>	Configures the aging time of a dynamic member port.
	ip igmp snooping fast-leave enable	Enables the immediate-leave function for a dynamic member port.
	ip igmp snooping query-max-response-time <i>time</i>	Configures the maximum response time of an IGMP query packet.
	ip igmp snooping suppression enable	Enables IGMP Report packet suppression.
Configuring IGMP Security Control	 (Optional) It used to guarantee the security when a user requests a multicast profile.	
	ip igmp snooping filter <i>profile-number</i>	Configures the profile filtering for user access.
	ip igmp snooping vlan <i>num</i> filter <i>profile-number</i>	Configures the per-VLAN profile filtering for user access.
	ip igmp snooping l2-entry-limit <i>number</i>	Configures the maximum number of profiles globally for user access.

	ip igmp snooping max-groups <i>number</i>	Configures the maximum number of dynamic profiles for user access.
	ip igmp snooping source-check port	Enables source IP inspection, which ensures the multicast traffic from the router port is legal.
	ip igmp snooping source-check default-server <i>address</i>	Enables source IP inspection. The multicast traffic whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping limit-ipmc vlan <i>vid address group-address server source-address</i>	Specifies a VLAN. In the multicast traffic of multicast addresses, the one whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping preview <i>profile-number</i>	Enables the preview function for a specified profile.
	ip igmp snooping preview interval <i>num</i>	Configures the preview duration.
Configuring an IGMP Profile	 (Optional) It is used to define the range of multicast addresses that permits or denies the access of a user host.	
	ip igmp profile <i>profile-number</i>	Creates a profile.
	range <i>low-address high_address</i>	Configures the profile range.
	permit	Permits the access of a user host.
	deny	Denies the access of a user host.
Configuring IGMP QinQ	 (Optional) It is used to configure QinQ interface to forward multicast packets using the VLAN identifier (VID) carried by packets.	
	ip igmp snooping tunnel	Configures QinQ to transmit IGMP packets transparently.
Configuring an IGMP Querier	 (Optional) It is used to enable IGMP querier function on a network without a Layer-3 multicast device.	
	ip igmp snooping querier	Enables global querier function.
	ip igmp snooping vlan <i>num querier</i>	Enables the querier for a VLAN.
	ip igmp snooping querier version <i>num</i>	Specifies the IGMP version for queriers globally.
	ip igmp snooping vlan <i>num querier version num</i>	Specifies the IGMP version for a querier of a VLAN.
	ip igmp snooping querier address <i>a.b.c.d</i>	Configures the source IP address of queriers globally.

	ip igmp snooping vlan <i>num</i> querier address a.b.c.d	Configures the source IP address for a querier of a VLAN.
	ip igmp snooping querier query-interval <i>num</i>	Configures the query interval of queriers globally.
	ip igmp snooping vlan <i>num</i> querier query-interval <i>num</i>	Configures the query interval for a querier of a VLAN.
	ip igmp snooping querier max-response-time <i>num</i>	Configures the maximum response time for query packets globally.
	ip igmp snooping vlan <i>num</i> querier max-response-time <i>num</i>	Configures the maximum response time of query packets for a VLAN.
	ip igmp snooping querier timer expiry <i>num</i>	Configures the aging timer for queriers globally.
	ip igmp snooping vlan <i>num</i> querier timer expiry <i>num</i>	Configures the aging timer for a querier of a VLAN.

9.4.1 Configuring Basic IGMP Snooping Functions (IVGL Mode)

Configuration Effect

- Enable IGMP snooping to realize Layer-2 multicast.
- Provide independent multicast services to each VLAN.

Notes

- IP multicast cannot be realized in SVGL mode. If IP multicast must be used, select the IVGL mode.

Configuration Steps

📌 Enabling Global IGMP Snooping in IVGL Mode

Mandatory.

After IGMP snooping is enabled globally, this function will be enabled for all VLANs.

If not specified, it is advised to run global IGMP snooping on all the devices connected user hosts.

📌 Disabling IGMP Snooping for a VLAN

(Optional) You can use this function if you wish to disable IGMP snooping on specified VLANs.

Only when global IGMP snooping is enabled can it be disabled on specified VLANs.

In IVGL mode, each VLAN can enjoy independent multicast services. Disabling any VLAN multicast services will not interfere in the services provided to the others.

Verification

- Run the **show ip igmp snooping gda-table** command to display the IGMP snooping forwarding table and verify that the member ports include only those connecting member hosts.
- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL mode.

Related Commands

▸ Enabling Global IGMP Snooping in IVGL Mode

Command	ip igmp snooping ivgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is executed, IGMP snooping will be run on all VLANs. By default, IGMP snooping is disabled.

▸ Disabling IGMP Snooping for a VLAN

Command	no ip igmp snooping vlan <i>num</i>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Only when global IGMP snooping is enabled can it be disabled on specified VLANs. In IVGL mode, you can disable IGMP snooping on any VLAN.

▸ Displaying the IGMP Snooping Entry

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	This command is used to verify that the ports include only those connecting member hosts.

▸ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in IVGL mode, the following information is displayed:

IGMP Snooping running mode: IVGL

Configuration Example

➤ Providing Layer-2 Multicast Services for the Subnet Hosts

Scenario
Figure 9-5

A is the multicast router and is connected directly to the multicast source.
B is the Layer-2 device and is connected directly to the user host.
Receiver 1, Receiver 2, and Receiver 3 belong to VLAN 1.

Configuration
Steps

- Configure the IP address and VLAN.
- Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1).
- Enable IGMP snooping on B and select IVGL mode.

A

```
A# configure terminal
A(config)# ip multicast-routing
A(config)# interface GigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode
A(config-if-GigabitEthernet 0/1)# exit
A(config)# interface vlan 1
A(config-if-VLAN 1)# ip pim sparse-mode
A(config-if-VLAN 1)# exit
```

B

```
B# configure terminal
B(config)# ip igmp snooping ivgl
```

Verification	Send packets from the source (10.1.1.1) to G (229.1.1.1) to add Receiver 1 to G. ● Confirm that the packets (10.1.1.1 and 229.1.1.1) are received by Receiver 1. ● Display the IGMP snooping forwarding entry on B and ensure that the port (10.1.1.1, 229.1.1.1, 1) includes only Fa0/2. ● Check whether the IGMP snooping working mode is IVGL.
B	<pre> B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*,224.1.1.1, 1): VLAN(1) 2 OPORTS: FastEthernet 0/1(M) FastEthernet 0/2(D) </pre> <pre> B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Global Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds) vlan 1 ----- IGMP Snooping state: Enable </pre>

	Multicast router learning mode: pim-dvmrp IGMP Fast-Leave: Disabled IGMP VLAN querier: Disable IGMP VLAN Mode: STATIC

Common Errors

- The working mode of IGMP snooping is improper.

9.4.2 Configuring Basic IGMP Snooping Functions (SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select SVGL mode to realize Layer-2 multicast.
- Share the VLAN multicast services.

Configuration Steps

➤ Enabling Global IGMP Snooping in SVGL Mode

Mandatory.

Enable global IGMP snooping in SVGL mode.

Configure the range of associated SVGL profiles.

➤ Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

➤ Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in SVGL mode.
- Run the **show ip igmp snooping gda-table** command to check whether inter-VLAN multicast entries are properly formed.

Related Commands

➤ Enabling Global IGMP Snooping in SVGL Mode

Command	ip igmp snooping svgl
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the SVGL mode is selected, the range of profiles within SVGL multicast addresses needs to be associated.

📌 Configuring the SVGL profile

Command	ip igmp snooping svgl profile <i>profile_num</i>
Parameter Description	<i>profile_num</i> : Configures SVGL to associate a profile.
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

📌 Specifying the SVGL Shared VLAN

Command	ip igmp snooping svgl vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates a VLAN.
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

📌 Specifying the SVGL Sub VLAN

Command	ip igmp snooping svgl subvlan <i>vid-range</i>
Parameter Description	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Command Mode	Interface configuration mode
Usage Guide	By default, all the VLANs except the shared VLAN are used as sub VLANs.

📌 Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in SVGL mode, the following information is displayed: IGMP Snooping running mode: SVGL

Configuration Example

Enabling SVGL on the Access Device

Scenario Figure 9-6	
	A is the multicast router and is connected directly to the multicast source. B is the Layer-2 device and is connected directly to the user host. Receiver 1 is connected to VLAN 2, Receiver 2 is connected to VLAN 3, and Receiver 3 is connected to VLAN 4.
Configuration Steps	● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select SVGL mode. ● Configure the range of associated SVGL multicast addresses on B.
A	A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit
B	B# configure terminal B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range 224.1.1.1 238.1.1.1

	<pre> B(config-profile)#exit B(config)#ip igmp snooping svgl B(config)#ip igmp snooping svgl profile 1 </pre>
Verification	Send packets from the source (10.1.1.1) to G (229.1.1.1) and add Receiver 1, Receiver 2 and Receiver 3 to G. ● Confirm that the packets (10.1.1.1 and 224.1.1.1) are received by Receiver 1, Receiver 2, and Receiver 3. ● Display the IGMP snooping forwarding entry on B and ensure that the ports (*, 224.1.1.1, 1) include Gi0/2, Gi0/3, and Gi0/4. ● Check whether the IGMP snooping working mode is SVGL.
B	<pre> B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*,224.1.1.1, 1): VLAN(2) 1 OPORTS: GigabitEthernet 0/2(D) VLAN(3) 1 OPORTS: GigabitEthernet 0/3(D) VLAN(4) 1 OPORTS: GigabitEthernet 0/4(D) B# show ip igmp snooping IGMP Snooping running mode: SVGL IGMP Snooping L2-entry-limit: 65536 SVGL vlan: 1 SVGL profile number: 1 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable </pre>

	IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.

9.4.3 Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select IVGL-SVGL mode to realize Layer-2 multicast.
- The SVGL profiles can share the multicast services.
- The non-SVGL profiles run in IVGL mode.

Configuration Steps

✚ Enabling Global IGMP Snooping in IVGL-SVGL Mode

Mandatory.

Enable global IGMP snooping in IVGL-SVGL mode.

Configure the range of associated SVGL profiles.

✚ Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

✚ Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL-SVGL mode.
- Run the **show ip igmp snooping gda-table** command to check whether inter-VLAN multicast entries are properly formed for the SVGL profiles.

- Run the **show ip igmp snooping gda-table** command to check whether intra-VLAN multicast entries are properly formed for the SVGL profiles.

Related Commands

↘ Enabling Global IGMP Snooping in IVGL-SVGL Mode

Command	ip igmp snooping ivgl-svgl
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the IVGL-SVGL mode is selected, the SVGL profiles needs to be associated.

↘ Configuring the SVGL Profile

Command	ip igmp snooping svgl profile <i>profile_num</i>
Parameter	<i>profile_num</i> : Configures SVGL to associate a profile.
Description	
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

↘ Specifying the SVGL Shared VLAN

Command	ip igmp snooping svgl vlan <i>vid</i>
Parameter	<i>vid</i> : Indicates a VLAN.
Description	
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

↘ Specifying the SVGL Sub VLAN

Command	ip igmp snooping svgl subvlan <i>vid-range</i>
Parameter	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Description	
Command Mode	Interface configuration mode

↘ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter	N/A

Description	
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in SVGL mode, the following information is displayed: IGMP Snooping running mode: SVGL

▶ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in IVGL-SVGL mode, the following information is displayed: IGMP Snooping running mode: IVGL-SVGL

Configuration Example

▶ Enabling IVGL-SVGL on the Access Device

Scenario Figure 9-7	
	A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1 is connected to VLAN 2, Receiver 2 is connected to VLAN 3, and Receiver 3 is connected to VLAN 4.
Configuration Steps	- Configure the IP address and VLAN. - Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and

	VLAN 1). ● Enable IGMP snooping on B and select IVGL-SVGL mode. ● Configure the range of associated SVGL multicast addresses on B.
A	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit </pre>
B	<pre> B# configure terminal B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range 224.1.1.1 238.1.1.1 B(config-profile)#exit B(config)#ip igmp snooping ivgl-svgl B(config)#ip igmp snooping svgl profile 1 </pre>
Verification	Send packets from Source 1 (10.1.1.1) to G (224.1.1.1) and add Receiver 1, Receiver 2 and Receiver 3 to G. Send packets from Source 2 (192.168.2.1) to the destination (239.1.1.1) and add Receiver 1 239.1.1.1. ● Confirm that the packets (10.1.1.1 and 224.1.1.1) are received by Receiver 1, Receiver 2, and Receiver 3. ● Check that packets (192.168.2.1 and 239.1.1.1) can be received by Receiver 1. ● Display the IGMP snooping forwarding entry on B and ensure that the ports (*, 224.1.1.1, 1) include Gi0/2, Gi0/3, and Gi0/4, and the port (*, 239.1.1.1, 1) is Gi0/2. ● Check whether the IGMP snooping working mode is IVGL-SVGL.

IGMP Snooping running mode: IVGL-SVGL

IGMP Snooping L2-entry-limit: 65536

SVGL vlan: 1

SVGL profile number: 0

Source port check: Disable

Source ip check: Disable

IGMP Fast-Leave: Disable

IGMP Report suppress: Disable

IGMP Globle Querier: Disable

IGMP Preview: Disable

IGMP Tunnel: Disable

IGMP Preview group aging time : 60(Seconds)

Dynamic Mroute Aging Time : 300(Seconds)

Dynamic Host Aging Time : 260(Seconds)

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.

- The IVGL multicast traffic cannot be forwarded within the SVGL profile.

9.4.4 Configuring the Packet Processing

Configuration Effect

- Configure specified ports as the static router ports to receive the multicast traffic from all profiles.
- Configure specified ports as the static member ports to receive the multicast traffic from specified profiles
- Enable Report packets suppression to forward only the first Report packet from a specified VLAN or profile to the router port within a query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.
- Configure the immediate-leave function to delete a port from the entry of member ports when a leave packet is received by the port.
- Disable dynamic router port learning to disable the learning of any router port.
- Based on network load and configuration of a multicast device, you can adjust the aging time of a router port and member port as well as the maximum response time of a query packet.

Notes

- Only when basic IGMP snooping is configured can relevant configurations take effect.

Configuration Steps

▾ Configuring a Static Router Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive all the multicast traffic within the VLAN.

▾ Configuring a Static Member Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive specific multicast traffic within the VLAN.

▾ Enabling Report Packet Suppression

- Optional.
- When there are numerous receivers to receive the packets from the same multicast profile, you can enable Report packets suppression to suppress the number of Report packets to be sent.

▾ Enabling the Immediate-Leave Function

- Optional.
- When there is only one receiver on a port, you can enable Leave to speed up the convergence of protocol upon leave.

▾ Disabling Dynamic Router Port Learning

- Optional.
- This function is used when multicast traffic needs to be forwarded only within the Layer-2 topology but not to a Layer-3 router.

▾ Configuring the Aging Time of a Dynamic Router Port

- Optional.
- You can configure the aging time based on network load.

▾ Configuring the Aging Time of a Dynamic Member Port

- Optional.
- You can configure the aging time based on the interval for sending IGMP query packets by the connected multicast router. Typically, the aging time is calculated as follows: Interval for sending IGMP query packets x 2 + Maximum response time of IGMP packets

▾ Configuring the Maximum Response Time of a Query Packet

- Optional.
- You can configure the aging time based on network load.

Verification

- Run the **show ip igmp snooping mrouter** command to check whether the configured static router port has an "S" in the displayed configuration information.
- Run the **show ip igmp snooping gda** command to check whether the configured static member port is marked with an S.
- Run the **show ip igmp snooping** command to check whether Report packets suppression, immediate leave, router port learning, router port aging time, member port aging time, and the maximum response time of the Query packet take effect.

Related Commands

▾ Configuring a Static Router Port

Command	ip igmp snooping vlan <i>vid</i> mrouter interface <i>interface-type</i> <i>interface-number</i>
Parameter	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094.
Description	<i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	In SVGL mode, if a sub VLAN is not configured, only the configurations for the static router port within the shared VLAN can take effect, and the others can be configured but cannot take effect. If a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL-SVGL mode, if a sub VLAN is not configured, the configurations for the static router ports within all

	the VLANs can take effect; if a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL mode, the configurations for the static router ports within all the VLANs can take effect.

✚ Configuring a Static Member Port

Command	ip igmp snooping vlan <i>vid</i> static <i>group-address</i> interface <i>interface-type</i> <i>interface-number</i>
Parameter Description	<i>vid</i>: Indicates a VLAN. The value ranges from 1 to 4,094. <i>group-address</i>: Indicates a profile address. <i>interface-type interface-number</i>: Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	By default, no static member port is configured.

✚ Enabling Report Packet Suppression

Command	ip igmp snooping suppression enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When Report packets suppression is enabled, only the first Report packet from a specified VLAN or profile is forwarded to the router port within a Query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network. Only the IGMPv1 and IGMPv2 Report packets can be suppressed, and the IGMPv3 Report packets cannot be suppressed.

✚ Enabling the Immediate-Leave Function

Command	ip igmp snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When this function is enabled, a port will be deleted from the entry of the member port when the port receives a leave packet. After that, the packets will no longer be forwarded to this port when it receives the query packets of specified profiles. Leave packets include the IGMPv2 Leave packets as well as the IGMPv3 Report packets that include types but carry no source address. The immediate-leave function applies only to the scenario where only one host is connected to a device port. It is used to conserve bandwidth and resources.

✚ Enabling Dynamic Router Port Learning

Command	ip igmp snooping [vlan <i>vid</i>] mrouter learn pim-dvmrp

Parameter Description	vlan vid: Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A router port is the port that is connected directly to a multicast device running IGMP snooping and a multicast neighbor device running multicast routing protocol. By default, dynamic router port learning is enabled and the device automatically listens to IGMP Query packets, DVMRP packets, and PIM Hello packets.

✚ Configuring the Aging Time of a Dynamic Router Port

Command	ip igmp snooping dyn-mr-aging-time <i>seconds</i>
Parameter Description	<i>seconds:</i> Indicates the aging time of a dynamic router port in the unit of seconds. The value ranges from 1 to 3,600.
Command Mode	Global configuration mode
Usage Guide	If a dynamic router port does not receive an IGMP general query packet or a PIM Hello packet before the aging timer expires, the device will delete this port from the router port entry. When dynamic router port learning is enabled, you can run this command to adjust the aging time of the dynamic router port. If the aging time is too short, the multicast device may frequently add or delete a router port.

✚ Configuring the Aging Time of a Dynamic Member Port

Command	ip igmp snooping host-aging-time <i>seconds</i>
Parameter Description	<i>seconds:</i> Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	The aging time of a dynamic member port indicates the time when a device port receives the IGMP join packet sent from host for subscribing to an IP multicast profile. When the IGMP join packet is received, the aging time of the dynamic member port will be reset. The value of the timer time is host-aging-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. After the aging time is configured, the aging time of following received IGMP join packets will be host-aging-time. This configuration takes effect after the next IGMP join packet is received, and the timer of the port in use will not be refreshed.

✚ Configuring the Maximum Response Time of a Query Packet

Command	ip igmp snooping query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds:</i> Indicates the maximum response time.
Command Mode	Global configuration mode

Mode	
Usage Guide	When an IGMP general Query packet is received, the multicast device will reset the aging time of all the dynamic member ports, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. When an IGMP profile-specific Query packet is received, the multicast device will reset the aging time of all the dynamic member ports of the specific profile, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. This configuration takes effect after the next Query packet is received, and the timer in use will not be refreshed. The timer of an IGMPv3 profile-specific Query packet is not refreshed.

Displaying Router Ports

Command	show ip igmp snooping mroute
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the router port is successfully configured, an "S" will be displayed in the port information. <pre> Ruijie(config)#show ip igmp snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S) </pre>

Displaying the Information of Dynamic Router Port Learning

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Run the show ip igmp snooping command to display the aging time and learning status of the dynamic router port. <pre> Dynamic Mroute Aging Time : 300(Seconds) </pre>

	Multicast router learning mode: pim-dvmrp

▾ Displaying the Information of a Member Port

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the member port is successfully configured, an "S" will be displayed in the port information. <pre> Ruijie(config)#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/1(S </pre>

▾ Displaying Other Parameters

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Run the show ip igmp snooping command to display the aging time of the router port, aging time of the dynamic member port, response time of the query packet, and Report packets suppression, and immediate leave. <pre> IGMP Fast-Leave: Enable IGMP Report suppress: Enable Query Max Response Time: 20(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds) </pre>

Configuration Example

▾ Configuring a Static Router Port and Static Member Port

Configuration Steps	● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.
	<pre> Ruijie# configure terminal Ruijie(config)# ip igmp snooping vlan 1 mrouter interface GigabitEthernet 0/0 Ruijie(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface GigabitEthernet 0/0 Ruijie(config)# end </pre>
Verification	Run the show ip igmp snooping mrouter and show ip igmp snooping gda-table commands to check whether the configuration takes effect.
	<pre> Ruijie#show ip igmp snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/0(S) Ruijie#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/0(SM) </pre>

[Enabling Report Packet Suppression](#)

Scenario Figure 9-8	
	A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.
Configuration Steps	● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable Report packets suppression on B.
A	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit </pre>
B	<pre> B# configure terminal B(config)# ip igmp snooping ivgl B(config)# ip igmp snooping suppression enable </pre>
Verification	Check whether Receiver 1 and Receiver 2 are added to profile 239.1.1.1, and only the IGMP Report packets

	of profile 239.1.1.1 are forwarded from interface Gi0/1 of B.
B	<pre> B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Enable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds) </pre>

Configuring Other Parameters

Configuration Steps	● Configure basic IGMP snooping functions. ● Enable Immediate-leave function. ● Disable router port learning. ● Configure the aging time of a router port. ● Configuring the aging time of a member port. ● Configure the response time of a Query packet.
	<pre> Ruijie# configure terminal Ruijie(config)# ip igmp snooping fast-leave enable Ruijie(config)# no ip igmp snooping mrouters learn pim-dvmrp Ruijie(config)# ip igmp snooping dyn-mr-aging-time 200 Ruijie(config)# ip igmp snooping host-aging-time 100 Ruijie(config)# ip igmp snooping query-max-response-time 60 Ruijie(config)# end </pre>
Verification	Run the show ip igmp snooping command to check whether the configuration is successful.
	<pre> Ruijie#show ip igmp snooping </pre>

```

IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 65536
Source port check: Disable
Source ip check: Disable
IGMP Fast-Leave: Enable
IGMP Report suppress: Enable
IGMP Globle Querier: Disable
IGMP Preview: Disable
IGMP Tunnel: Disable
Query Max Response Time: 60(Seconds)
IGMP Preview group aging time : 60(Seconds)
Dynamic Mroute Aging Time : 200(Seconds)
Dynamic Host Aging Time : 100(Seconds)

```

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

9.4.5 Configuring IGMP Security Control

Configuration Effect

- Configure the range of multicast addresses that a user can access.
- Configure to allow a user from an unauthorized profile to preview a multicast channel.
- Configure the number of multicast addresses that a user can access.
- Configure to limit a user to receive only the multicast traffic from a router port to prevent illegal multicast traffic sent by the end user.
- Configure to limit a user to receive only the multicast traffic from designated source IP addresses to prevent illegal multicast traffic.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

📄 Configuring the Profile Filtering

- Optional.
- If you want to limit the profile packets to be received by a port, you can configure the profile filtering on the port.

- If you want to limit the multicast packets to be received by a VLAN, you can configure the per-VLAN profile filtering.

▾ Enabling Multicast Preview

- Optional.
- You can enable multicast preview for a user from an unauthorized profile.

▾ Configuring the Maximum Number of Profiles

- Optional.
- If you want to limit the number of multicast profiles that a port is allowed to receive, you can configure the maximum number of multicast profiles allowed for this port.
- If you want to limit the number of multicast profiles that global ports are allowed to receive, you can configure the maximum number of multicast profiles allowed for these ports.

▾ Configuring Source Port Inspection

- Optional.
- You can perform this configuration if you want to allow a port to receive only the multicast traffic from the router port.

▾ Configuring Source IP Inspection

- Optional.
- You can perform this configuration to specify the source IP address for all the multicast profiles of all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- You can also specify the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Verification

- Run the **show ip igmp snooping interfaces** command to display the profile filtering and the maximum number of multicast profiles for a port.
- Run the **show ip igmp snooping vlan** command to display the per-VLAN profile filtering.
- Run the **show ip igmp snooping** command to check whether the maximum number of global multicast profiles, preview function, source port inspection, and source IP address inspection take effect.

Related Commands

▾ Configuring the Profile Filtering

Command	ip igmp snooping filter <i>profile-number</i>
Parameter Description	<i>profile-number</i> : Indicates a profile number.
Command Mode	Interface configuration mode

Usage Guide	N/A

✚ Configuring the Per-VLAN Profile Filtering

Command	ip igmp snooping vlan <i>vid</i> filter <i>profile-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>profile-number</i> : Indicates a profile number.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring the Maximum Number of Profiles on a Port

Command	ip igmp snooping max-groups <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Interface configuration mode
Usage Guide	This value indicates only the number of dynamic multicast profiles, and the number of static profiles is not included. The counter of multicast profiles is based on the VLAN that the port belongs to. For example, if a port belongs to three VLANs, and all three of them receive a request packet from multicast profile 224.1.1.1 simultaneously, then the counter of multicast profiles will be 3 but not 1.

✚ Configuring the Maximum Number of Global Profiles

Command	ip igmp snooping l2-entry-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Global configuration mode
Usage Guide	This value includes the number of both dynamic profiles as well as static profiles.

✚ Configuring Source Port Inspection

Command	ip igmp snooping source-check port
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After source port inspection is enabled, the multicast traffic received by a device will be discarded if no router port is detected in the network environment.

✚ Configuring Source IP Inspection

Command	ip igmp snooping source-check default-server <i>source-address</i>

Parameter Description	<i>source-address</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling Source IP Inspection for a Specific Profile

Command	ip igmp snooping limit-ipmc vlan <i>vid</i> address <i>group-address</i> server <i>source-address</i>
Parameter Description	<i>vid</i> vlan id <i>group-address</i> : Indicates a profile address. <i>source-address</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling Preview

Command	ip igmp snooping preview <i>profile-number</i>
Parameter Description	<i>profile number</i> : Indicates the range of multicast addresses allowed for preview. The value ranges from 1 to 1,024.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Preview Duration

Command	ip igmp snooping preview interval <i>num</i>
Parameter Description	<i>num</i> : Specifies the preview duration which ranges from 1s to 300s (60s by default).
Command Mode	Global configuration mode
Usage Guide	This configuration allows unauthorized users to receive multicast traffic within the preview duration. After the duration is met, the preview will be stopped; the preview can be resumed in 300s.

▾ Displaying the Per-Port Profile Filtering

Command	show ip igmp snooping interface
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the function is configured, the profile will be displayed, for example: <pre>Ruijie#show ip igmp snooping interfaces gigabitEthernet 0/1</pre>

Interface	Filter profile number	max-group
-----	-----	-----
GigabitEthernet 0/1	1	

▾ Displaying the Per-VLAN Profile Filtering

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the function is configured, the profile will be displayed, for example: IGMP VLAN filter: 1

▾ Displaying the Maximum Number of Interface Profiles

Command	show ip igmp snooping interface									
Parameter Description	N/A									
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode									
Usage Guide	If the maximum number of multicast addresses for a port is configures, the value will be displayed, for example: <pre>Ruijie#show ip igmp snooping interfaces gigabitEthernet 0/1</pre> <table><thead><tr><th>Interface</th><th>Filter profile number</th><th>max-group</th></tr></thead><tbody><tr><td>-----</td><td>-----</td><td>-----</td></tr><tr><td>GigabitEthernet 0/1</td><td>1</td><td>200</td></tr></tbody></table>	Interface	Filter profile number	max-group	-----	-----	-----	GigabitEthernet 0/1	1	200
Interface	Filter profile number	max-group								
-----	-----	-----								
GigabitEthernet 0/1	1	200								

▾ Displaying the Maximum Number of Global Profiles

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the function is configured, the profile will be displayed, for example: IGMP Snooping L2-entry-limit: 65536

▾ Displaying the Information of Source Port Inspection

Command	show ip igmp snooping vlan

Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If source port inspection is enabled, the following information will be displayed: <pre>Source port check: Enable</pre>

▾ Displaying the Information of Source IP Inspection

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If source IP address inspection is enabled, the following information will be displayed: <pre>Source ip check: Enable</pre>

▾ Displaying the Information of the Preview Function

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the range of multicast addresses for a port is configured, preview will be enabled, for example: <pre>IGMP Preview: Enable IGMP Preview group aging time : 60(Seconds)</pre>

Configuration Example

▾ Configuring the Profile Filtering and the Maximum Number of Demanded Profiles

Scenario
Figure 9-9

A is the multicast router and is connected directly to multicast Source 1.
 B is a Layer-2 device and is connected directly to the user host and multicast Source 2.
 Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.
 By configuring VLAN 1, you can configure to allow the users within VLAN 1 to receive only the profiles whose addresses range from 225.1.1.1 to 225.1.255.255.
 You can configure Receiver 1 to receive only the profiles whose addresses range from 225.1.1.1 to 225.1.1.255, Receiver 2 to receive only the profiles whose addresses range from 225.1.2.1 to 255.1.2.255, and Receiver 3 to receive only the profiles whose addresses range from 225.1.3.1 to 225.1.3.255.
 At most 10 profiles can be added to a port and at most 100 profiles can be added globally.

Configuration Steps	● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Configure the range and maximum number of multicast addresses on B.

A	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit </pre>

B	<pre> B# configure terminal </pre>

	<pre> B(config)#ip igmp snooping ivgl B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#rang B(config-profile)#range 225.1.1.1 225.1.255.255 B(config-profile)#exit B(config)#ip igmp profile 2 B(config-profile)#permit B(config-profile)#range 225.1.1.1 225.1.1.255 B(config-profile)#exit B(config)#ip igmp profile 3 B(config-profile)#permit B(config-profile)#range 225.1.2.1 225.1.2.255 B(config-profile)#exit B(config)#ip igmp profile 4 B(config-profile)#permit B(config-profile)#range B(config-profile)#range 225.1.3.1 225.1.3.255 B(config-profile)#exit B(config)#ip igmp snooping l2-entry-limit 100 B(config)#ip igmp snooping vlan 1 filter 1 B(config)#int gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping filter 2 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping max-groups 10 B(config)#int gigabitEthernet 0/3 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping filter 3 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping max-groups 10 B(config)#int gigabitEthernet 0/4 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping filter 4 Ruijie(config-if-GigabitEthernet 0/0)#ip igmp snooping max-groups 10 </pre>
Verification	Run the show ip igmp snooping interfaces command to display the profile filtering and the maximum

	number of multicast profiles for a port. ● Run the show ip igmp snooping command to display the maximum number of global multicast groups.															
B	B#show ip igmp snooping interfaces <table><thead><tr><th>Interface</th><th>Filter profile number</th><th>max-group</th></tr><tr><th>-----</th><th>-----</th><th>-----</th></tr></thead><tbody><tr><td>GigabitEthernet 0/2</td><td>2</td><td>10</td></tr><tr><td>GigabitEthernet 0/3</td><td>3</td><td>10</td></tr><tr><td>GigabitEthernet 0/4</td><td>4</td><td>10</td></tr></tbody></table> B#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 100 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)	Interface	Filter profile number	max-group	-----	-----	-----	GigabitEthernet 0/2	2	10	GigabitEthernet 0/3	3	10	GigabitEthernet 0/4	4	10

GigabitEthernet 0/4	4	10														

➤ **Configuring Source Port Inspection**

Scenario
Figure 9-10

A is the multicast router and is connected directly to multicast Source 1.
B is a Layer-2 device and is connected directly to the user host and multicast Source 2.
Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.
Source 1 sends the multicast address traffic from profile 224.1.1.1, and Source 2 sends the multicast address traffic from profile 225.1.1.1.
Receiver 1 can request profiles 224.1.1.1 and 225.1.1.1 respectively.
Source port inspection is enabled.

Configuration Steps	● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.

A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>

B	<pre>B# configure terminal</pre>

	B(config)#ip igmp snooping ivgl B(config)#ip igmp snooping source-check port
Verification	- Run the show ip igmp snooping mroute command to check whether Gi0/1 is learned as a router port. - Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and cannot request that of profile 225.1.1.1.

Configuring Source IP Inspection

Scenario Figure 9-11	The diagram illustrates a network topology for IGMP Snooping configuration. Device A, acting as a multicast router, is connected to Source 1 (IP 10.1.1.2/24) through its Gi 0/1 interface. Device A's Gi 0/2 interface is connected to Device B, a Layer-2 switch, and is labeled with the IP address 192.168.1.1 for VLAN 1. Device B's Gi 0/5 interface is connected to Source 2 (IP 10.1.1.1/24). Device B has three other interfaces (Gi 0/2, Gi 0/3, and Gi 0/4) that are all connected to a common VLAN 1. This VLAN 1 contains three receivers: Receiver 1, Receiver 2, and Receiver 3.
	A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.

	Source 1 sends the multicast address traffic from profiles 10.1.1.1 and 224.1.1.1, Source 2 sends the multicast address traffic from profiles 192.168.1.3 and 225.1.1.1, and Source 3 sends the multicast address traffic from profiles 192.168.1.3 and 226.1.1.1. Receiver 1 can request profiles 224.1.1.1, 225.1.1.1, and 226.1.1.1 respectively. The default IP address for source IP inspection is 10.1.1.1. Configure limit-ipmc and the multicast traffic of profile 225.1.1.1, and set the legal source address as 192.168.1.3.
Configuration Steps	● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.
A	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit </pre>
B	<pre> B# configure terminal B(config)# ip igmp snooping ivgl B(config)# ip igmp snooping source-check default-server 10.1.1.1 B(config)# ip igmp snooping limit-ipmc vlan 1 address 225.1.1.1 server 192.168.1.3 </pre>
Verification	● Run the show ip igmp snooping command to check whether source IP inspection is enabled. ● Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and 225.1.1.1 and cannot request that of profile 226.1.1.1.
B	<pre> B#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Enable IGMP Fast-Leave: Disable </pre>

	IGMP Report suppress: Disable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.
- The multicast router port is not learned, leading to failure to receive the multicast traffic.
- The IP address for source IP inspection is inconsistent with the multicast IP address, leading to failure to receive the multicast traffic.

9.4.6 Configuring an IGMP Profile

Configuration Effect

- Create an IGMP filtering profile.

Configuration Steps

➤ Creating a Profile

- (Optional) Create an IGMP filtering profile.

➤ Configuring the Profile Range

- (Optional) Configure the range of multicast profile addresses.

➤ Configuring the Profile Filtering

- (Optional) Configure the filtering mode of profile to **permit** or **deny**.

Verification

- Run the **show running-config** command to check whether the preceding configurations take effect.

Related Commands

➤ Creating a Profile

Command	ip igmp profile <i>profile-number</i>
Parameter	<i>profile-number</i> : Indicates the number of a profile.
Description	

Command Mode	Global configuration mode
Usage Guide	

↘ Configuring the Profile Range

Command	range <i>low-ip-address</i> [<i>high-ip-address</i>]
Parameter Description	<i>low-ip-address</i> : Specifies the start address. <i>low-ip-address</i> : Specifies the end address. Only one address is configured by default.
Command Mode	Profile configuration mode
Usage Guide	You can configure multiple addresses. If the IP addresses of different ranges are consecutive, the addresses will be combined.

↘ Configuring the Profile Filtering

Command	deny
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to deny while the range of multicast profiles is not specified, no profile is to be denied, which means to permit all profiles.

↘ Configuring the Profile Filtering

Command	permit
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to permit while the range of multicast profiles is not specified, no profile is to be permitted, which means to deny all profiles.

Configuration Example

↘ Creating a Filtering Profile

Configuration Steps	● Create a filtering profile.

	<pre> B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range B(config-profile)#range 224.1.1.1 235.1.1.1 B(config-profile)# </pre>
Verification	Run the show running-config command to check whether the configuration is successful.
	<pre> ip igmp profile 1 permit range 224.1.1.1 235.1.1.1 ! </pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.
- The mode of profile is set to **permit** while the range of multicast profiles is not specified, leading to the denial of all profiles.

9.4.7 Configuring IGMP QinQ

Configuration Effect

- Create a multicast entry on the VLAN where IGMP packets are located. Forward IGMP packets on the VLAN where these packets are located, realizing transparent transmission.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

📌 Configuring QinQ Transparent Transmission

- If the QinQ interface needs to forward multicast packets on the VLANs where the VIDs of the packets specify, enable QinQ to realize transparent transmission.

Verification

- Run the **show ip igmp snooping** command to check whether the configuration takes effect.

Related Commands

📌 Configuring QinQ Transparent Transmission

Command	ip igmp snooping tunnel
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Enable QinQ to realize transparent transmission of IGMP packets.

▾ Displaying QinQ Configuration

Command	show ip igmp snooping
Parameter	N/A
Description	
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. IGMP Tunnel: Enable

Configuration Example

▾ Configuring QinQ Transparent Transmission

Configuration Steps	● Configure basic IGMP snooping functions. ● Configure QinQ transparent transmission.
	<pre>Ruijie# configure terminal Ruijie(config)# ip igmp snooping tunnel Ruijie(config)# Ruijie(config)# end</pre>
Verification	Run the show ip igmp snooping command to check whether the configuration is successful. IGMP Tunnel: Enable

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

9.4.8 Configuring an IGMP Querier

Configuration Effect

- Configure the device as an IGMP querier, which will send IGMP Query packets periodically and collect user demanding information.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

✚ Enabling the Querier Function

- (Optional) Enable IGMP querier function globally or for a specified VLAN.
- (Optional) Disable the IGMP querier function for a specified VLAN.

✚ Configuring the Source IP Address of a Querier

- (Optional) You can configure the source IP address of a Query packet sent by the querier based on VLANs.
- After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect.

✚ Configuring the Maximum Response Time of a Query Packet

- (Optional) Adjust the maximum response time carried by an IGMP Query packet. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1.

✚ Configuring the Query Interval of a Querier

- (Optional) Adjust the interval of the IGMP querier for sending query packets.

✚ Configuring the Aging Timer of a Querier

- (Optional) Configure the aging timer of other IGMP queriers on the network.

✚ Specifying the IGMP Version for a Querier

- (Optional) Specify the IGMP version for a querier (IGMPv2 by default).

Verification

- Run the **show ip igmp snooping querier detail** command to check whether the configuration takes effect.

Related Commands

✚ Enabling the IGMP Querier Function

Command	ip igmp snooping [vlan vid] querier
Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	IGMP querier for a specified VLAN will take effect only after global IGMP querier is enabled. If global IGMP querier is disabled, IGMP querier for all the VLANs will be disabled.

✚ Configuring the Source IP Address of a Querier

Command	ip igmp snooping [vlan vid] querier address a.b.c.d

Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default. a.b.c.d : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect. If the source IP address is specified by a VLAN, the address will be used preferentially.

✚ Configuring the Maximum Response Time of a Querier

Command	ip igmp snooping [vlan vid] querier max-response-time seconds
Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default. seconds : Indicates the maximum response time. in the unit of seconds. The value ranges from 1 to 25.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

✚ Configuring the Query Interval of a Querier

Command	ip igmp snooping [vlan vid] querier address a.b.c.d
Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default. seconds : Indicates the query interval in the unit of seconds. The value ranges from 1 to 18,000.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

✚ Configuring the Aging Timer of a Querier

Command	ip igmp snooping [vlan vid] querier timer expiry seconds
Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default. seconds : Indicates the timeout time in the unit of seconds. The value ranges from 60 to 300.
Command Mode	Global configuration mode
Usage Guide	A device may fail to be elected as the querier even when its querier function is enabled. If a device that fails to be elected does not receive the Query packet sent by the querier in the aging time, the querier in use is considered as expired, and a new round of election will be raised. If the aging time is specified by a VLAN, the value will be used preferentially.

✚ Specifying the IGMP Version for a Querier

Command	ip igmp snooping [vlan vid] querier version 1
Parameter Description	vlan vid : Specifies a VLAN. This configuration applies to all VLANs by default.
Command	Global configuration mode

Mode	
Usage Guide	A querier can be run in IGMPv1 and IGMPv2 (IGMPv2 by default). You can also run a command to configure the version to IGMPv1. If the IGMP version for a querier is specified by a VLAN, the version will be used preferentially.

▾ Displaying the IGMP Querier Configuration

Command	show ip igmp snooping querier detail
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. <pre> Ruijie(config)#show ip igmp snooping querier detail Vlan IP Address IGMP Version Port ----- Global IGMP switch querier status ----- admin state : Enable admin version : 2 source IP address : 1.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 Vlan 1: IGMP switch querier status ----- admin state : Disable admin version : 2 source IP address : 1.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 operational state : Disable </pre>

	operational version	: 2

Configuration Example

Enabling the IGMP Querier Function

Scenario Figure 9-12	
	In the scenario without Layer-3 multicast equipment, the multicast traffic can be forwarded only on the Layer-2 network. A acts as a Layer-2 device to connect to the multicast source and receiver.
Configuration Steps	● Enable global IGMP snooping on A in IVGL mode. ● Enable IGMP querier for VLAN 1 on A.
A	<pre>A(config)#ip igmp snooping ivgl A(config)#ip igmp snooping querier A(config)#ip igmp snooping querier address 10.1.1.1 A(config)#ip igmp snooping vlan 1 querier</pre>
Verification	Run the show ip igmp snooping querier command to check whether the querier of VLAN 1 takes effect.
A	<pre>A(config)#show ip igmp snooping querier Vlan IP Address IGMP Version Port ----- 1 10.1.1.1 2 switch A(config)#show ip igmp snooping querier vlan 1</pre>

Vlan 1: IGMP switch querier status	

elected querier is 10.1.1.1 (this switch querier)	

admin state	: Enable
admin version	: 2
source IP address	: 10.1.1.1
query-interval (sec)	: 60
max-response-time (sec)	: 10

operational state	: Querier
operational version	: 2

Common Errors

- The source IP address is not configured for the querier and the querier does not take effect.

9.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics on IGMP snooping.	clear ip igmp snooping statistics
Clears the dynamic router ports and member ports.	clear ip igmp snooping gda-table

Displaying

Description	Command
Displays basic IGMP snooping configurations.	show ip igmp snooping [vlan <i>vlan-id</i>]
Displays the statistics on IGMP snooping.	show ip igmp snooping statistics [vlan <i>vlan-id</i>]
Displays the router ports.	show ip igmp snooping mrouter
Displays the IGMP snooping entries.	show ip igmp snooping gda-table
Displays the profile.	show ip igmp profile [<i>profile-number</i>]
Displays the IGMP snooping configurations on an interface.	show ip igmp snooping interface <i>interface-name</i>
Displays the IGMP querier.	show ip igmp snooping querier [detail]
Displays user information.	show ip igmp snooping user-info

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all IGMP Snooping functions.	debug igmp-snp
Debugs the IGMP snooping events.	debug igmp-snp event
Debugs the IGMP snooping packets.	debug igmp-snp packet
Debugs the communications between IGMP snooping and MSF.	debug igmp-snp msf
Debugs the IGMP snooping alarms.	debug igmp-snp warning

10 Configuring MLD Snooping

10.1 Overview

Multicast Listener Discovery (MLD) Snooping is used to control and manage the forwarding behaviors of IPv6 multicast packets at Layer 2.

The device running MLD Snooping analyzes MLD packets received by a port to create a mapping between the port and the MAC multicast address and forwards IPv6 multicast data at Layer 2 based on the mapping. When MLD Snooping is disabled, IPv6 multicast data packets are broadcasted at Layer 2. When MLD Snooping is enabled, multicast data packets of a known IPv6 multicast group are forwarded to a specified receiver at Layer 2 instead of being broadcasted at Layer 2.

Protocols and Standards

RFC4541: Considerations for Internet Group Management Protocol (IGMP)and Multicast Listener Discovery (MLD) Snooping Switches

10.1.1 Two Types of MLD Snooping Ports

As shown in Figure 10-1, the Layer-3 multicast device is connected to the multicast source. MLD Snooping is enabled on the access device. Host A and Host B are receivers (that is, members of the IPv6 multicast group).

Figure 10-1 Two Types of MLD Snooping Ports

- Multicast router port: Indicates the port on the access device for connecting to the Layer-3 multicast device, for example, Port Eth0/1 of the access device.
- Member port: Is short for IPv6 multicast group member port, also called listener port, and indicates the port on the access device for connecting to an IPv6 multicast group member, for example, Port Eth0/2 and Port Eth0/3 on the access device.

10.1.2 Work Mode of MLD Snooping

- **DISABLE mode:** MLD Snooping does not take effect in this mode. That is, the Layer-2 multicast device does not "snoop" MLD packets between the host and the router, and multicast streams are broadcasted within VLANs.
- **Independent VLAN Group Learn (IVGL) mode:** In this mode, multicast streams between VLANs are mutually independent. A host can request only the multicast router port in the same VLAN as the host to receive multicast packets, and can forward the received multicast data packets of any VLAN only to the member port and multicast router port in the same VLAN as the host.
- **Shared VLAN Group Learn (SVGL) mode:** In this mode, hosts of VLANs share the same multicast stream. A host in one VLAN can request multicast streams of another VLAN. When a shared VLAN is specified, only the multicast data streams of this VLAN can be forwarded to hosts of other VLANs. Multicast data streams of a shared VLAN, can be forwarded to the member ports of this multicast address, even though some member ports do not belong to the shared VLAN. In SVGL mode, MLD profiles must be used to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. By default, all the group ranges are not within the SVGL application ranges, and all the multicast packets are discarded.
- **IVGL-SVGL mode:** In this mode, IVGL and SVGL coexist. You can use MLD profiles to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. Member ports in the multicast forward entries corresponding to other multicast address ranges must belong to the same VLAN.

10.1.3 Working Principle of MLD Snooping

The device running MLD Snooping processes different MLD packets as follows:

MLD QUERY

The Layer-3 multicast device regularly sends an MLD General Query packet to all hosts and routers (with the address of FF02::1) in the local network segment, to query the IPv6 multicast group members in this network segment. When receiving the MLD General Query packet, the device running MLD Snooping forwards the packet all ports in the VLAN except the one receiving the packet, and processes the port receiving the packet as follows:

- If the port is already in the router multicast port list, its aging timer is reset.
- If the port is not contained in the router multicast port list, the port is added to the router multicast port list and its aging timer is started.
- Each time the Layer-2 multicast device receives an MLD General Query packet, it starts the aging timer for each member port, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.
- Each time the Layer 2 multicast device receives a MLD Group-Specific Query packet, it starts the aging timer for each member port in the specific group, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.

- When the Layer-2 multicast device receives a MLD Group-Specific Query packet, it no longer updates the preceding two types of timers.

MLD REPORT

In either of the following cases, the host sends an MLD Membership Report packet to the MLD querier.

- After receiving an MLD query (General Query or Group-Specific Query) packet, an IPv6 multicast group member host responds with an MLD Membership Report packet.
- If a host needs to join an IPv6 multicast group, it actively sends an MLD Membership Report packet to MLD querier to request to join this IPv6 multicast group.

When receiving an MLD Membership Report packet, the device running MLD Snooping forwards it to all multicast router ports in the VLAN, retrieves, from the packet, the address of the IPv6 multicast group that the host needs to join, and processes the port receiving the packet as follows:

- If there is no forwarding entry corresponding to the IPv6 multicast group, the forwarding entry is created, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group but the port is not contained in the egress port list, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group and dynamic member port is contained in the egress port list, its aging timer is reset.

MLD LEAVE

When a host leaves an IPv6 multicast group, it sends an MLD Leave packet (with the address of FF02::2) to notify the multicast router that it has left the IPv6 multicast group. When receiving an MLD Leave packet from a member port, the device running MLD Snooping directly forwards it to the multicast router port. If the fast leave function is enabled, the device directly deletes the port from the forwarding port list of the relevant multicast group.

10.1.4 Source Port Check

The source port check function of MLD Snooping improves the network security.

This function strictly limits the ingress ports of MLD multicast streams. When this function is disabled, multicast streams from any port are valid and the Layer-2 multicast device forwards them to registered member ports according to the forwarding list of MLD Snooping. When this function is enabled, multicast streams only from the multicast router ports are valid and the Layer-2 multicast device forwards them to registered ports. Multicast data streams from non-multicast router ports are invalid and discarded.

10.2 Applications

Application	Description
MLD Snooping SVGL Trans-VLAN Multicast On demand	MLD Snooping works in SVGL mode

Application	Description
Source Port Filtering	Multicast streams only from multicast router ports are received.

10.2.1 MLD Snooping SVGL Trans-VLAN Multicast On demand

Scenario

As shown in Figure 10-2, Host A of VLAN 3 and Host B of VLAN 4 order a video. The video streams are in VLAN 2.

- Enable the SVGL mode on the access device and set a shared VLAN 2.

Figure 10-2

Remarks	VLAN 2 is a shared VLAN. VLAN 3 and VLAN 4 are the VLANs through which the video on-demand service is output.

Deployment

- Enable the Layer-3 multicast protocol on the Layer-3 multicast device.
- Enable the SVGL mode on the Layer-2 device.

10.2.2 Source Port Filtering

Scenario

As shown in Figure 10-3, when the source port check function is configured, video streams can be received only from the source multicast router port. Multicast video streams from other ports are invalid and discarded. Note that when the source port check function is configured, there shall be at least one multicast router port. Otherwise, packet filtering is not performed on the multicast router port even though the source port filtering is enabled. When the source port check function is not configured, multicast video streams from all ports are received by default.

- Enable the IVGL mode on the access device.

Figure 10-3

Remarks	Port Eth0/1 is a multicast router port and Port Eth0/2 is a non-multicast router port. Video servers send same multicast video streams. Hosts A and B can receive multicast streams only from Video Server A.

Deployment

- Enable the source port check function and configure a static multicast router port.
- Enable the IVGL mode on the Layer-2 device.

10.3 Features

Basic Concepts

➤ Multicast Router Port and Member Port

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. If MLD Snooping is enabled, when the dynamic multicast router port learning function is enabled on a port, after receiving an MLD Query or PIMv6-Hello packet, the port learns the dynamic multicast router port and starts the aging timer of the dynamic multicast router port. A static multicast router port can be added by configuring the **ipv6 mld snooping vlan mrouter** command.

Member ports are classified into dynamic member ports and static member ports. If MLD Snooping is enabled, after receiving an MLD Report packet, a port learns the dynamic member router port and starts the aging timer of the dynamic member port. A static member port can be added by configuring the **ipv6 mld snooping vlan static interface** command.

➤ Fast Leave and Packet Suppression

When the fast leave function is enabled, a port is directly deleted after receiving an MLD Leave packet. The fast leave function is applicable only to scenarios in which only one user is connected to a port, and helps save the bandwidth. When

multiple users are connected to a port, if the fast leave function is enabled, other users wanting to receive packets fail to receive any packets.

When the packet suppression function is enabled, only the first MLD Report packet is forwarded within one query period.

Overview

Feature	Description
Globally Enabling MLD Snooping	Globally enables MLD Snooping and configures the work mode.
VLAN-based MLD Snooping	Enables or disables MLD Snooping for a single VLAN when MLD Snooping is globally enabled.
Aging Time of Multicast Router Ports	Adjusts the aging time of dynamic multicast router ports. The default aging time is 300s.
Dynamic Multicast Router Port Learning	After receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.
Fast Leave of Multicast Group Member Ports	A member port can be quickly deleted, instead of being aged and deleted after the query interval of a Group-Specific Query expires.
MLD Report Packet Suppression	Only the first Report packet is processed within one query period, reducing the work load of the module.
Source Port Check	Multicast streams received only from a multicast router port can be forwarded. Packets received from non-multicast router ports cannot be forwarded.
Port-based Specific Multicast Group Filtering	Only multicast group packets that meet the filter conditions can be received.
Maximum Number of Multicast Groups Supported by a Port	Limits the maximum number of multicast groups that a port can join.

10.3.1 Globally Enabling MLD Snooping

Globally enable MLD Snooping and configure the work mode. Multicast forwarding entries can be learnt and multicast streams are forwarded to a specified port.

Working Principle

Enable MLD Snooping. When an MLD Report packet with the time to live (TTL) of 1 is received, a multicast forwarding entry is created and the forwarding egress is this port.

↳ Learning a Dynamic Member Port

After a valid MLD Report packet is received, a dynamic member port is learnt and a forwarding entry is generated. The forwarding egress of this entry is the member port.

Coordinating Parameters

Configure the MLD Report packet suppression function.

Related Configuration

Configure the MLD Report packet suppression function so that only the first Report is processed within one query period, thereby reducing the number of packets in the network.

10.3.2 VLAN-based MLD Snooping

Enable or disable MLD Snooping for a single VLAN. By default, if MLD Snooping is globally enabled, the MLD Snooping function of each VLAN is enabled.

Related Configuration

Globally configure MLD Snooping. Then configure MLD Snooping for a single VLAN.

10.3.3 Aging Time of Multicast Router Ports

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. By default, the aging time of a dynamic multicast router port is 300s. Static multicast router ports are not aged.

Related Configuration

Ability of learning from dynamic multicast router port learning function

10.3.4 Dynamic Multicast Router Port Learning

By default, all ports support the dynamic multicast router port learning function.

Working Principle

When a port supports the dynamic multicast router port learning function, after receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.

Related Configuration

Configure a port as a static multicast router port.

10.3.5 Aging Time of Dynamic Member Ports

Member ports are classified into dynamic member ports and static member ports. By default, the aging time of a dynamic member port is 260s. Static member ports are not aged.

10.3.6 Fast Leave of Multicast Group Member Ports

By default, the fast leave function of multicast group member ports are disabled. If the fast leave function is enabled, the port is directly deleted after receiving a done packet.

10.3.7 MLD Report Packet Suppression

By default, the MLD report packet suppression function is disabled. If the function is enabled, only the first Report packet is processed within one query interval, thereby reducing the number of packets in the network.

10.3.8 Source Port Check

The source port check function is disabled by default.

Working Principle

When the source port check function is enabled, packets only from multicast router ports are valid and packets from non-multicast router ports are invalid.

Related Configuration

Configure a port as a static multicast router port.

10.3.9 Port-based Specific Multicast Group Filtering

Under certain circumstances, you may use the port filtering function to control a port to forward multicast packets only of a certain range.

10.3.10 Maximum Number of Multicast Groups Supported by a Port

The maximum number of multicast groups that a port is allowed to join can control the maximum number of multicast groups supported by the port.

10.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD Snooping	ipv6 mld snooping	Enables MLD Snooping and specifies the work mode.
	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>	Configures the static multicast router port.
	ipv6 mld snooping vlan <i>vlan-id</i> static ip-addr interface <i>interface-id</i>	Configures a static member port.
	ipv6 mld profile <i>profile-num</i>	Configures a profile.
	ipv6 mld snooping source-check port	Configures source port check.
	ipv6 mld snooping filter <i>profile-num</i>	Configures multicast group filtering for a port.
	ipv6 mld snooping max-groups <i>num</i>	Configures the maximum number of multicast groups that a port can join.

10.4.1 Configuring Basic Functions of MLD Snooping

Configuration Effect

- Enable MLD Snooping and configure the work mode.

Notes

- Enable MLD Snooping and set the work mode to SVGL. The MLD Snooping SVGL mode cannot coexist with IPv4 or IPv6 Layer-3 multicasting.
- When the work mode is SVGL or IVGL-SVGL, a profile must be associated to specify the multicast group range in which the SVGL mode applies.

Configuration Steps

▾ Enabling IPv6 MLD Snooping

- Mandatory.

Verification

Run the **show ipv6 mld snooping** command to check whether MLD Snooping is enabled.

- Check whether the device can create correct multicast forwarding entries.

Related Commands

▾ Enabling IPv6 MLD Snooping

Command	ipv6 mld snooping <i>mode</i>
Parameter	mode: Specifies the work mode.
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring a Profile

Command	ipv6 mld profile <i>profile-num</i>
Parameter	<i>profile-num:</i> Indicates the profile number.
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a profile and enter the profile configuration mode.

▾ Configuring a Static Multicast Router Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>
Parameter	vlan-id: Indicates the VLAN ID.

Description	<i>interface-id</i> : Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring a Static Member Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> static <i>ip-addr</i> interface <i>interface-id</i>
Parameter Description	<i>vlan-id</i> : Indicates the VLAN ID. <i>ip-addr</i> : Indicates the group address. <i>interface-id</i> : Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring Source Port Check

Command	ipv6 mld snooping source-check port
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	-

✚ Configuring Port-based Multicast Group Filtering

Command	ipv6 mld snooping filter <i>profile-num</i>
Parameter Description	<i>profile-num</i> : Indicates the profile number.
Command Mode	Interface configuration port
Usage Guide	N/A

✚ Configuring the Maximum Number of Multicast Groups Supported by a Port

Command	ipv6 mld snooping max-groups <i>num</i>
Parameter Description	<i>num</i> : Indicates the number of groups.
Command Mode	Interface configuration port
Usage Guide	N/A

✚ Configuring Report Packet Suppression

Command	ipv6 mld snooping suppression enable
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	When the Report packet suppression function is enabled, only the first Report packet of a specific VLAN and group is forwarded to a multicast router port within one query interval. The subsequent Report packets are forwarded to the multicast router port, so as to reduce the number of packets in the network. This function can only suppress the Report packets of MLDv1. It is invalid on the Report packets of MLDv2.

✚ Configuring Port Fast Leave

Command	ipv6 mld snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the port fast leave function is enabled, after receiving a Leave packet, the port is directly deleted from the member ports in the corresponding forwarding entries. Later, when receiving a relevant Group-Specific Query packet, the device does not forward the packet to this port. The Leaver packet includes the Leave packet of MLDv1, include type of MLDv2, and Report packet containing no source address. This function is applicable only to scenarios in which only one user is connected to a port, and helps save bandwidth and resources.

✚ Configuring Dynamic Multicast Router Port Learning

Command	ipv6 mld snooping [vlan vid] mrouter learn
Parameter Description	vlan-id: Specifies a VLAN ID. This function is applicable to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A multicast router port is a port that directly connects an MLD Snooping-enabled multicast device to a neighbor multicast device in which a multicast routing protocol is enabled. By default, when the dynamic multicast router port learning function is enabled, the device automatically listens to the MLD Query/PIM Hello packet and dynamically identifies a multicast router port.

✚ Configuring Aging Time of Dynamic Multicast Router Ports

Command	ipv6 mld snooping dyn-mr-aging-time seconds
Parameter Description	seconds: Indicates the aging time of dynamic multicast router ports. The unit is second and the value ranges from 1 to 3,600.
Command Mode	Global configuration mode
Usage Guide	If a dynamic multicast router port does not receive an MLD General Query packet or a PIM Hello packet before the timeout of its aging time, the device deletes the port from the multicast router port list. When the dynamic multicast router learning function is enabled, you can use this command to adjust the

	aging time of dynamic multicast router ports. If the aging time is too short, a multicast router port may be added and deleted frequently.

✚ Configuring Aging Time of Dynamic Member Ports

Command	ipv6 mld snooping host-aging-time <i>seconds</i>
Parameter Description	seconds: Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	The aging time of a dynamic member port refers to the aging time set when a dynamic member port of a device receives from the host an MLD packet of joining a certain IPv6 multicast group. After receiving an MLD Join packet from a dynamic member port, the device resets the aging timer of the dynamic member port and sets the timer time to host-aging-time. If the timer times out, it is deemed that no user host receives multicast packets through this port, and then the multicast device deletes the port from the MLD Snooping member port list. After this command is configured, the aging timer value of dynamic member ports when MLD Join packets are received subsequently is host-aging-time. The aging time takes effect immediately after configuration and the timers of started member ports are updated.

✚ Configuring Response Time of Query Packets

Command	ipv6 mld snooping query-max-response-time <i>seconds</i>
Parameter Description	seconds: Indicates the response time.
Command Mode	Global configuration mode
Usage Guide	After receiving an MLD General Query packet from a port, the multicast device resets the aging timers of all dynamic member ports and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list. After receiving an MLD Group-Specific Query packet from a port, the multicast device resets the aging timers of all dynamic member ports in the specific group and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list. The configuration takes effect when the a query packet is received next time, and the configuration of currently started timers are not updated. For Group-Specific Query packets of MLDv2, timers are not updated.

✚ Checking Multicast Router Ports

Command	show ipv6 mld snooping mroute
Parameter Description	N/A
Command	Privileged EXEC mode, global configuration mode, interface configuration mode

Mode	
Usage Guide	If a multicast router port is successfully configured, the mark "S" is shown in the interface information displayed. For example: <pre>Ruijie(config)#show ipv6 mld snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S)</pre>

📌 Checking Dynamic Multicast Router Port Learning

Command	show ipv6 mld snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	Run the show ip igmp snooping command to check the aging time and learning status of dynamic multicast router ports. <pre>Dynamic Mroute Aging Time : 300(Seconds) Multicast router learning mode: Enable</pre>

📌 Checking Member Ports

Command	show ipv6 mld snooping gda-table
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	If a member port is successfully configured, the mark "S" is shown in the interface information displayed. For example: <pre>Ruijie(config)#show ipv6 mld snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, FF15::100, 1):</pre>

	VLAN(1) 2 OPORTS: GigabitEthernet 3/7(S)

🔗 Checking Other Parameters

Command	show ipv6 mld snooping
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	Run the show ipv6 mld snooping command to check the aging time of multicast router ports, aging time of dynamic member ports, response time of query packet, and Report packet suppression, and fast leave parameters. <pre> MLD-snooping mode: IVGL Source port check: Disable MLD Fast-Leave: Disable MLD Report suppress: Disable Query Max Response Time: 10 (Seconds) Dynamic Mroute Aging Time: 300(Seconds) Dynamic Host Aging Time: 260(Seconds) </pre>

10.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears MLD Snooping multicast forwarding entries.	clear ipv6 mld snooping gda-table
Clears MLD Snooping statistics.	clear ipv6 mld snooping statistics

Displaying

Description	Command
Displays the current MLD Snooping mode.	show ipv6 mld snooping
Displays MLD Snooping forwarding entries.	show ipv6 mld snooping gda-table
Displays MLD Snooping statistics.	show ipv6 mld snooping statistics

Displays MLD Snooping multicast router ports.	show ipv6 mld snooping mrouter
Displays MLD Snooping interface information, interface filtering profiles and maximum number of groups that a port can join.	show ipv6 mld snooping interfaces <i>interface-type interface-name</i>
Displays multicast information about a single VLAN, on which MLD Snooping is configured.	show ipv6 mld snooping vlan <i>vid</i>
Displays an MLD Profile.	show ipv6 mld profile <i>profile-number</i>

1 Configuring AAA

1.1 Overview

Authentication, authorization, and accounting (AAA) provides a unified framework for configuring the authentication, authorization, and accounting services. Ruijie Networks devices support the AAA application.

AAA provides the following services in a modular way:

Authentication: Refers to the verification of user identities for network access and network services. Authentication is classified into local authentication and authentication through Remote Authentication Dial In User Service (RADIUS) and Terminal Access Controller Access Control System+ (TACACS+).

Authorization: Refers to the granting of specific network services to users according to a series of defined attribute-value (AV) pairs. The pairs describe what operations users are authorized to perform. AV pairs are stored on network access servers (NASs) or remote authentication servers.

Accounting: Refers to the tracking of the resource consumption of users. When accounting is enabled, NASs collect statistics on the network resource usage of users and send them in AV pairs to authentication servers. The records will be stored on authentication servers, and can be read and analyzed by dedicated software to realize the accounting, statistics, and tracking of network resource usage.

AAA is the most fundamental method of access control. Ruijie Networks also provides other simple access control functions, such as local username authentication and online password authentication. Compared to them, AAA offers higher level of network security.

AAA has the following advantages:

- Robust flexibility and controllability
- Scalability
- Standards-compliant authentication
- Multiple standby systems

1.2 Applications

Application	Description
Configuring AAA in a Single-Domain Environment	AAA is performed for all the users in one domain.
Configuring AAA in a Multi-Domain Environment	AAA is performed for the users in different domains by using different methods.

1.2.1 Configuring AAA in a Single-Domain Environment

Scenario

In the network scenario shown in Figure 1-1, the following application requirements must be satisfied to improve the security management on the NAS:

1. To facilitate account management and avoid information disclosure, each administrator has an individual account with different username and password.
2. Users must pass identity authentication before accessing the NAS. The authentication can be in local or centralized mode. It is recommended to combine the two modes, with centralized mode as active and local mode as standby. As a result, users must undergo authentication by the RADIUS server first. If the RADIUS server does not respond, it turns to local authentication.
3. During the authentication process, users can be classified and limited to access different NASs.
4. Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
5. The AAA records of users are stored on servers and can be viewed and referenced for auditing. (The TACACS+ server in this example performs the accounting.)

Figure 1-1

Remarks	User A, User B, and User C are connected to the NAS in wired or wireless way. The NAS is an access or convergence switch. The RADIUS server can be the Windows 2000/2003 Server (IAS), UNIX system component, and dedicated server software provided by a vendor. The TACACS+ server can be the dedicated server software provided by a vendor.

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Configure the authentication service on the NAS.

- Configure the authorization service on the NAS.
- Configure the accounting service on the NAS.

1.2.2 Configuring AAA in a Multi-Domain Environment

Scenario

Configure the domain-based AAA service on the NAS.

- A user can log in by entering the username PC1@ruijie.net or PC2@ruijie.com.cn and correct password on an 802.1X client.
- Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
- The AAA records of users are stored on servers and can be viewed and referenced for auditing.

Figure 1-2

Remarks	The clients with the usernames PC1@ruijie.net and PC2@ruijie.com.cn are connected to the NAS in wired or wireless way. The NAS is an access or convergence switch. The Security Accounts Manager (SAM) server is a universal RADIUS server provided by Ruijie Networks.

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Define an AAA method list on the NAS.
- Enable domain-based AAA on the NAS.
- Create domains and AV sets on the NAS.

1.3 Features

Basic Concepts

Local Authentication and Remote Server Authentication

Local authentication is the process where the entered passwords are verified by the database on the NAS.

Remote server authentication is the process where the entered passwords are checked by the database on a remote server. It is mainly implemented by the RADIUS server and TACACS+ server.

Method List

AAA is implemented using different security methods. A method list defines a method implementation sequence. The method list can contain one or more security protocols so that a standby method can take over the AAA service when the first method fails. On Ruijie devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a security method responds or all the security methods in the list are tried out. Authentication fails if no method in the list responds.

A method list contains a series of security methods that will be queried in sequence to verify user identities. It allows you to define one or more security protocols used for authentication, so that the standby authentication method takes over services when the active security method fails. On Ruijie devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a method responds or all the methods in the method list are tried out. Authentication fails if no method in the list responds.

 The next authentication method proceeds on Ruijie devices only when the current method does not respond. When a method denies user access, the authentication process ends without trying other methods.

Figure 1-3

Figure 1-3 shows a typical AAA network topology, where two RADIUS servers (R1 and R2) and one NAS are deployed. The NAS can be the client for the RADIUS servers.

Assume that the system administrator defines a method list, where the NAS selects R1 and R2 in sequence to obtain user identity information and then accesses the local username database on the server. For example, when a remote PC user initiates dial-up access, the NAS first queries the user's identity on R1. When the authentication on R1 is completed, R1 returns an Accept response to the NAS. Then the user is permitted to access the Internet. If R1 returns a Reject response, the user is denied Internet access and the connection is terminated. If R1 does not respond, the NAS considers that the R1 method times out and continues to query the user's identity on R2. This process continues as the NAS keeps trying the remaining authentication methods, until the user request is authenticated, rejected, or terminated. If all the authentication methods are responded with Timeout, authentication fails and the connection will be terminated.

 The Reject response is different from the Timeout response. The Reject response indicates that the user does not meet the criteria of the available authentication database and therefore fails in authentication, and the Internet access request is denied. The Timeout response indicates that the authentication server fails to respond to the identity query.

When detecting a timeout event, the AAA service proceeds to the next method in the list to continue the authentication process.

-  This document describes how to configure AAA on the RADIUS server. For details about the configuration on the TACACS+ server, see the *Configuring TACACS+*.

AAA Server Group

You can define an AAA server group to include one or more servers of the same type. If the server group is referenced by a method list, the NAS preferentially sends requests to the servers in the referenced server group when the method list is used to implement AAA.

VRF-Enabled AAA Group

Virtual private networks (VPNs) enable users to share bandwidths securely on the backbone networks of Internet service providers (ISPs). A VPN is a site set consisting of shared routes. An STA site connects to the network of an ISP through one or multiple interfaces. AAA supports assigning a VPN routing forwarding (VRF) table to each user-defined server group.

When AAA is implemented by the server in a group assigned with a VRF table, the NAS sends request packets to the remote servers in the server group. The source IP address of request packets is an address selected from the VRF table according to the IP addresses of the remote servers.

If you run the **ip radius/tacacs+ source-interface** command to specify the source interface for the request packets, the IP address obtained from the source interface takes precedence over the source IP address selected from the VRF table.

Overview

Feature	Description
AAA Authentication	Verifies whether users can access the Internet.
AAA Authorization	Determines what services or permissions users can enjoy.
AAA Accounting	Records the network resource usage of users.
Multi-Domain AAA	Creates domain-specific AAA schemes for 802.1X stations (STAs) in different domains.
Login Switch for the AAA Slave Device	Provides a login switch to control login of the AAA slave device.
Authorization Result Caching	Caches authorization results returned from the server.

1.3.1 AAA Authentication

Authentication, authorization, and accounting are three independent services. The authentication service verifies whether users can access the Internet. During authentication, the username, password, and other user information are exchanged between devices to complete users' access or service requests. You can use only the authentication service of AAA.

-  To configure AAA authentication, you need to first configure an authentication method list. Applications perform authentication according to the method list. The method list defines the types of authentication and the sequence in which they are performed. Authentication methods are implemented by specified applications. The only exception is the default method list. All applications use the default method list if no method list is configured.

AAA Authentication Scheme

- No authentication (**none**)

The identity of trusted users is not checked. Normally, the no-authentication (None) method is not used.

- Local authentication (**local**)

Authentication is performed on the NAS, which is configured with user information (including usernames, passwords, and AV pairs). Before local authentication is enabled, run the **username password/secret** command to create a local user database.

- Remote server group authentication (**group**)

Authentication is performed jointly by the NAS and a remote server group through RADIUS or TACACS+. A server group consists of one or more servers of the same type. User information is managed centrally on a remote server, thus realizing multi-device centralized and unified authentication with high capacity and reliability. You can configure local authentication as standby to avoid authentication failures when all the servers in the server group fail.

AAA Authentication Types

Ruijie products support the following authentication types:

- Login authentication

Users log in to the command line interface (CLI) of the NAS for authentication through Secure Shell (SSH), Telnet, and File Transfer Protocol (FTP).

- Enable authentication

After users log in to the CLI of the NAS, the users must be authenticated before CLI permission update. This process is called Enable authentication (in Privileged EXEC mode).

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authentication Scheme

By default, no AAA authentication scheme is configured.

Before you configure an AAA authentication scheme, determine whether to use local authentication or remote server authentication. If the latter is to be implemented, configure a RADIUS or TACACS+ server in advance. If local authentication is selected, configure the local user database information on the NAS.

Configuring an AAA Authentication Method List

By default, no AAA authentication method list is configured.

Determine the access mode to be configured in advance. Then configure authentication methods according to the access mode.

1.3.2 AAA Authorization

AAA authorization allows administrators to control the services or permissions of users. After AAA authorization is enabled, the NAS configures the sessions of users according to the user configuration files stored on the NAS or servers. After authorization, users can use only the services or have only the permissions permitted by the configuration files.

AAA Authorization Scheme

- Direct authorization (**none**)

Direct authorization is intended for highly trusted users, who are assigned with the default permissions specified by the NAS.

- Local authorization (**local**)

Local authorization is performed on the NAS, which authorizes users according to the AV pairs configured for local users.

- Remote server-group authorization (**group**)

Authorization is performed jointly by the NAS and a remote server group. You can configure local or direct authorization as standby to avoid authorization failures when all the servers in the server group fail.

AAA Authorization Types

- EXEC authorization

After users log in to the CLI of the NAS, the users are assigned with permission levels (0 to 15).

- Config-commands authorization

Users are assigned with the permissions to run specific commands in configuration modes (including the global configuration mode and sub-modes).

- Console authorization

After users log in through consoles, the users are authorized to run commands.

- Command authorization

Authorize users with commands after login to the CLI of the NAS.

- Network authorization

After users access the Internet, the users are authorized to use the specific session services. For example, after users access the Internet through PPP and Serial Line Internet Protocol (SLIP), the users are authorized to use the data service, bandwidth, and timeout service.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authorization Scheme

By default, no AAA authorization scheme is configured.

Before you configure an AAA authorization scheme, determine whether to use local authorization or remote server-group authorization. If remote server-group authorization needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local authorization needs to be implemented, configure the local user database information on the NAS.

✚ Configuring an AAA Authorization Method List

By default, no AAA authorization method list is configured.

Determine the access mode to be configured in advance. Then configure authorization methods according to the access mode.

1.3.3 AAA Accounting

In AAA, accounting is an independent process of the same level as authentication and authorization. During the accounting process, start-accounting, update-accounting, and end-accounting requests are sent to the configured accounting server, which records the network resource usage of users and performs accounting, audit, and tracking of users' activities.

In AAA configuration, accounting scheme configuration is optional.

✚ AAA Accounting Schemes

- No accounting (**none**)

Accounting is not performed on users.

- Local accounting (**local**)

Accounting is completed on the NAS, which collects statistics on and limits the number of local user connections. Billing is not performed.

- Remote server-group accounting (**group**)

Accounting is performed jointly by the NAS and a remote server group. You can configure local accounting as standby to avoid accounting failures when all the servers in the server group fail.

✚ AAA Accounting Types

- EXEC accounting

Accounting is performed when users log in to and out of the CLI of the NAS.

- Command accounting

Records are kept on the commands that users run on the CLI of the NAS.

- Network accounting

Records are kept on the sessions that users set up to access the Internet.

Related Configuration

✚ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

➤ Configuring an AAA Accounting Scheme

By default, no AAA accounting method is configured.

Before you configure an AAA accounting scheme, determine whether to use local accounting or remote server-group accounting. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local accounting needs to be implemented, configure the local user database information on the NAS.

➤ Configuring an AAA Accounting Method List

By default, no AAA accounting method list is configured.

Determine the access mode to be configured in advance. Then configure accounting methods according to the access mode.

1.3.4 Multi-Domain AAA

In a multi-domain environment, the NAS can provide the AAA services to users in different domains. The user AVs (such as usernames and passwords, service types, and permissions) may vary with different domains. It is necessary to configure domains to differentiate the user AVs in different domains and configure an AV set (including an AAA service method list, for example, RADIUS) for each domain.

Our products support the following username formats:

1. userid@domain-name
2. domain-name\userid
3. userid.domain-name
4. userid

The fourth format (userid) does not contain a domain name, and it is considered to use the **default** domain name.

The NAS provides the domain-based AAA service based on the following principles:

- Resolves the domain name carried by a user.
- Searches for the user domain according to the domain name.
- Searches for the corresponding AAA method list name according to the domain configuration information on the NAS.
- Searches for the corresponding method list according to the method list name.
- Provides the AAA services based on the method list.

 If any of the preceding procedures fails, the AAA services cannot be provided.

Figure 1-4 shows the typical multi-domain topology.

Figure 1-4

Related Configuration

➤ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

➤ Configuring an AAA Method List

By default, no AAA method list is configured.

For details, see section 5.2.1, section 5.2.2, and section 5.2.3.

➤ Enabling the Domain-Based AAA Service

By default, the domain-based AAA service is disabled.

To enable the domain-based AAA service, run the **aaa domain enable** command.

➤ Creating a Domain

By default, no domain is configured.

To configure a domain, run the **aaa domain domain-name** command.

➤ Configuring an AV Set for a Domain

By default, no domain AV set is configured.

A domain AV set contains the following elements: AAA method lists, the maximum number of online users, whether to remove the domain name from the username, and whether the domain name takes effect.

➤ Displaying Domain Configuration

To display domain configuration, run the **show aaa domain** command.

i The system supports a maximum of 32 domains.

1.3.5 Login Switch for the AAA Slave Device

A login switch is provided to control login of the AAA slave device. By default, the switch is off, so the slave device is not allowed to login. When the switch is turned on, the slave device can login.

Related Configuration

[Enabling AAA](#)

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

[Configuring a Login Switch for the AAA Slave Device](#)

By default, the slave device is not allowed to login.

Run the **aaa slave-login allow** command to permit login of the slave device.

1.3.6 Authorization Result Caching

The AAA module caches authorization results returned from the server. Therefore, later authorizations at the same level can be operated based on the cached resources.

Related Configuration

[Configuring Authorization Result Caching](#)

By default, authorization results are not cached.

To enable authorization result caching, run the **aaa command-author cache** command.

1.4 Configuration

Configuration	Description and Command	
Configuring AAA Authentication	 Mandatory if user identities need to be verified.	
	aaa new-model	Enables AAA.
	aaa authentication login	Defines a method list of login authentication.
	aaa authentication enable	Defines a method list of Enable authentication.
	aaa authentication ppp	Defines a method list of PPP authentication.
	aaa authentication sslvpn	Defines a method list of SSL VPN authentication.
	login authentication	Applies login authentication to a specific terminated line.
	dot1x authentication	Indicates 802.1x authentication.
	aaa local authentication attempts	Sets the maximum number of login attempts.
Configuring AAA Authorization	aaa local authentication lockout-time	Sets the lockout time for a login user.
	 Mandatory if different permissions and services need to be assigned to users.	
	aaa new-model	Enables AAA.

Configuration	Description and Command	
	aaa authorization exec	Defines a method list of EXEC authorization.
	aaa authorization commands	Defines a method list of command authorization.
	aaa authorization network	Configures a method list of network authorization.
	authorization exec	Applies EXEC authorization methods to a specified VTY line.
	authorization commands	Applies command authorization methods to a specified VTY line.
Configuring AAA Accounting	 Mandatory if accounting, statistics, and tracking need to be performed on the network resource usage of users.	
	aaa new-model	Enables AAA.
	aaa accounting exec	Defines a method list of EXEC accounting.
	aaa accounting commands	Defines a method list of command accounting.
	aaa accounting network	Defines a method list of network accounting.
	accounting exec	Applies EXEC accounting methods to a specified VTY line.
	accounting commands	Applies command accounting methods to a specified VTY line.
	aaa accounting update	Enables accounting update.
	aaa accounting update periodic	Configures the accounting update interval.
Configuring an AAA Server Group	 Recommended if a server group needs to be configured to handle AAA through different servers in the group.	
	aaa group server	Creates a user-defined AAA server group.
	server	Adds an AAA server group member.
	ip vrf forwarding	Configures the VRF attribute of an AAA server group.
Configuring the Domain-Based AAA Service	 Mandatory if AAA management of 802.1X access STAs needs to be performed according to domains.	
	aaa new-model	Enables AAA.
	aaa domain enable	Enables the domain-based AAA service.
	aaa domain	Creates a domain and enters domain configuration mode.
	accounting network	Associates the domain with a network accounting method list.

Configuration	Description and Command	
	authorization network	Associates the domain with a network authorization method list.
	state	Configures the domain status.
	username-format	Configures whether to contain the domain name in usernames.
Configuring a Login Switch for the AAA Slave Device	 Mandatory if a login switch needs to be configured for the AAA slave device.	
	aaa slave-login allow	Allows login of the slave device.
Configuring Authorization Result Caching	 Mandatory if later authorizations at the same level need to be operated based on the former results.	
	aaa command-author cache	Caches authorization results.

1.4.1 Configuring AAA Authentication

Configuration Effect

Verify whether users are able to obtain access permission.

Notes

- If an authentication scheme contains multiple authentication methods, these methods are executed according to the configured sequence.
 - The next authentication method is executed only when the current method does not respond. If the current method fails, the next method will be not tried.
 - When the **none** method is used, users can get access even when no authentication method gets response. Therefore, the **none** method is used only as standby.
-
-  Normally, do not use None authentication. You can use the **none** method as the last optional authentication method in special cases. For example, all the users who may request access are trusted users and the users' work must not be delayed by system faults. Then you can use the **none** method to assign access permissions to these users when the authentication server does not respond. It is recommended that the local authentication method be added before the **none** method.
-
- If AAA authentication is enabled but no authentication method is configured and the default authentication method does not exist, users can directly log in to the Console without being authenticated. If users log in by other means, the users must pass local authentication.
 - When a user enters the CLI after passing login authentication (the **none** method is not used), the username is recorded. When the user performs Enable authentication, the user is not prompted to enter the username again, because the username that the user entered during login authentication is automatically filled in. However, the user must enter the password previously used for login authentication.

- The username is not recorded if the user does not perform login authentication when entering the CLI or the **none** method is used during login authentication. Then, a user is required to enter the username each time when performing Enable authentication.

Configuration Steps

↘ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↘ Defining a Method List of Login Authentication

- Run the **aaa authentication login** command to configure a method list of login authentication.
- This configuration is mandatory if you need to configure a login authentication method list (including the configuration of the default method list).
- By default, no method list of login authentication is configured.

↘ Defining a Method List of Enable Authentication

- Run the **aaa authentication enable** command to configure a method list of Enable authentication.
- This configuration is mandatory if you need to configure an Enable authentication method list. (You can configure only the default method list.)
- By default, no method list of Enable authentication is configured.

↘ Defining a Method List of PPP Authentication

- Run the **aaa authentication ppp** command to configure a method list of PPP authentication.
- This configuration is mandatory if you need to configure an authentication method list for PPP dial-up access.
- By default, no method list of PPP authentication is configured.

↘ Defining a Method List of SSL VPN Authentication

- Run the **aaa authentication sslvpn** command to configure a method list of SSL VPN authentication.
- This configuration is mandatory if you need to configure an SSL VPN authentication method list (including the configuration of the default method list).
- By default, no method list of SSL VPN authentication is configured.

↘ Applying Login Authentication to a Specific Terminated Line

- In the Line mode, run the **login authentication** command to apply login authentication to a specific terminated line.
- This configuration is mandatory, if you need to apply login authentication to a specific terminated line.
- By default, the default method list is applied to all terminated lines.

✚ Setting the Maximum Number of Login Attempts

- Optional.
- By default, a user is allowed to enter passwords up to three times during login.

✚ Setting the Maximum Lockout Time After a Login Failure

- Optional.
- By default, a user is locked for 15 minutes after entering wrong passwords three times.

Verification

- Run the **show aaa method-list** command to display the configured method lists.
- Run the **show aaa lockout** command to display the settings of the maximum number of login attempts and the maximum lockout time after a login failure.
- Run the **show running-config** command to display the authentication method lists associated with login authentication authentication.

Related Commands

✚ Enabling AAA

Command	aaa new-model
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

✚ Defining a Method List of Login Authentication

Command	aaa authentication login { default list-name } method1 [method2...]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of a login authentication method list in characters. <i>method:</i> Indicates authentication methods from local, none, and group. A method list contains up to four methods. local: Indicates that the local user database is used for authentication. none: Indicates that authentication is not performed. group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	If the AAA login authentication service is enabled on the NAS, users must perform login authentication

	negotiation through AAA. Run the aaa authentication login command to configure the default or optional method lists for login authentication. In a method list, the next method is executed only when the current method does not receive response. After you configure login authentication methods, apply the methods to the VTY lines that require login authentication; otherwise, the methods will not take effect.

📌 Defining a Method List of Enable Authentication

Command	aaa authentication enable default <i>method1</i> [<i>method2...</i>]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of an Enable authentication method list in characters. <i>method:</i> Indicates authentication methods from enable, local, none, and group. A method list contains up to four methods. enable: Indicates that the password that is configured using the enable command is used for authentication. local: Indicates that the local user database is used for authentication. none: Indicates that authentication is not performed. group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	If the AAA login authentication service is enabled on the NAS, users must perform Enable authentication negotiation through AAA. Run the aaa authentication enable command to configure the default or optional method lists for Enable authentication. In a method list, the next method is executed only when the current method does not receive response.

📌 Defining a Method List of PPP or SSL VPN Authentication

Command	aaa authentication { ppp sslvpn } { default list-name } <i>method1</i> [<i>method2...</i>]
Parameter Description	ppp: Configures a method list of PPP authentication. sslvpn: Configures a method list of SSL VPN authentication. default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of an PPP authentication method list in characters. <i>method:</i> Indicates authentication methods from local, none, group, and subs. A method list contains up to four methods. local: Indicates that the local user database is used for authentication. none: Indicates that authentication is not performed. group: Indicates that a server group is used for authentication. Currently, the RADIUS and the TACACS+ server group is supported. subs: Specifies the SUBS authentication method using the SUBS database.
Command Mode	Global configuration mode
Usage Guide	If the AAA PPP authentication service is enabled on the NAS, users must perform PPP authentication negotiation through AAA. Run the aaa authentication ppp command to configure the default or optional

	method lists for PPP authentication. In a method list, the next method is executed only when the current method does not receive response.

Setting the Maximum Number of Login Attempts

Command	aaa local authentication attempts <i>max-attempts</i>
Parameter Description	<i>max-attempts</i> : Indicates the maximum number of login attempts. The value ranges from 1 to 2,147,483,647.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum number of times a user can attempt to login.

Setting the Maximum Lockout Time After a Login Failure

Command	aaa local authentication lockout-time <i>lockout-time</i>
Parameter Description	<i>lockout-time</i> : Indicates the time during which a user is locked after entering wrong passwords up to the specified times. The value ranges from 1 to 2,147,483,647, in the unit of minutes.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum time during which a user is locked after entering wrong passwords up to the specified times.

Configuration Example

Configuring AAA Login Authentication

Configure a login authentication method list on the NAS containing **group radius** and **local** methods in order.

Scenario Figure 1-5	 The diagram illustrates the network topology for AAA login authentication. A User (represented by a laptop) is connected to a Network Access Server (NAS, represented by a Ruijie switch) through interface Gi 0/1. The NAS is then connected to a Server (represented by a Ruijie switch) through interface Gi 0/2. The Server has the IP address 10.1.1.1.
Configuration Steps	Step 1: Enable AAA. Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.) Step 3: Configure an AAA authentication method list for login authentication users. (This example uses group radius and local in order.) Step 4: Apply the configured method list to an interface or line. Skip this step if the default authentication method is used.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#aaa new-model</pre>

	<pre>Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key ruijie Ruijie(config)#aaa authentication login list1 group radius local Ruijie(config)#line vty 0 20 Ruijie(config-line)#login authentication list1 Ruijie(config-line)#exit</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication login list1 group radius local Accounting method-list: Authorization method-list:</pre>
	Assume that a user remotely logs in to the NAS through Telnet. The user is prompted to enter the username and password on the CLI. The user must enter the correct username and password to access the NAS.
User	<pre>User Access Verification Username:user Password:pass</pre>

➤ **Configuring AAA Enable Authentication**

Configure an Enable authentication method list on the NAS containing **group radius**, **local**, and then **enable** methods in order.

Scenario Figure 1-6	 <pre>graph LR User[User] --- Gi 0/1 NAS[NAS] NAS --- Gi 0/2 Server[Server] Server --- IP[10.1.1.1]</pre>
Configuration Steps	Step 1: Enable AAA. Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be

	implemented. Configure Enable authentication passwords on the NAS if you use Enable password authentication. Step 3: Configure an AAA authentication method list for Enable authentication users.  You can define only one Enable authentication method list globally. You do not need to define the list name but just default it. After that, it will be applied automatically.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user privilege 15 password pass Ruijie(config)#enable secret w Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key ruijie Ruijie(config)#aaa authentication enable default group radius local enable</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: aaa authentication enable default group radius local enable Accounting method-list: Authorization method-list:</pre>
	The CLI displays an authentication prompt when the user level is updated to level 15. The user must enter the correct username and password to access the NAS.
NAS	<pre>Ruijie>enable Username:user Password:pass Ruijie#</pre>

Common Errors

- No RADIUS server or TACACS+ server is configured.
- Usernames and passwords are not configured in the local database.

1.4.2 Configuring AAA Authorization

Configuration Effect

- Determine what services or permissions authenticated users can enjoy.

Notes

- EXEC authorization is often used with login authentication, which can be implemented on the same line. Authorization and authentication can be performed using different methods and servers. Therefore, the results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot enter the CLI.
- The authorization methods in an authorization scheme are executed in accordance with the method configuration sequence. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried.
- Command authorization is supported only by TACACS+.
- Console authorization: The RGOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.

Configuration Steps

▾ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

▾ Defining a Method List of EXEC Authorization

- Run the **aaa authorization exec** command to configure a method list of EXEC authorization.
- This configuration is mandatory if you need to configure an EXEC authorization method list (including the configuration of the default method list).
- By default, no EXEC authorization method list is configured.

The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)

▾ Defining a Method List of Command Authorization

- Run the **aaa authorization commands** command to configure a method list of command authorization.
- This configuration is mandatory if you need to configure a command authorization method list (including the configuration of the default method list).
- By default, no command authorization method list is configured.

↘ Configuring a Method List of Network Authorization

- Run the **aaa authorization network** command to configure a method list of network authorization.
- This configuration is mandatory if you need to configure a network authorization method list (including the configuration of the default method list).
- By default, no authorization method is configured.

↘ Applying EXEC Authorization Methods to a Specified VTY Line

- Run the **authorization exec** command in line configuration mode to apply EXEC authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

↘ Applying Command Authorization Methods to a Specified VTY Line

- Run the **authorization commands** command in line configuration mode to apply command authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

↘ Enabling Authorization for Commands in Configuration Modes

- Run the **aaa authorization config-commands** command to enable authorization for commands in configuration modes.
- By default, authorization is disabled for commands in configuration modes.

↘ Enabling Authorization for the Console to Run Commands

- Run the **aaa authorization console** command to enable authorization for console users to run commands.
- By default, authorization is disabled for the Console to run commands.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode

Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

▾ Defining a Method List of EXEC Authorization

Command	aaa authorization exec { default <i>list-name</i> } <i>method1</i> [<i>method2</i>...]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of an EXEC authorization method list in characters. <i>method:</i> Specifies authentication methods from local, none, and group. A method list contains up to four methods. local: Indicates that the local user database is used for EXEC authorization. none: Indicates that EXEC authorization is not performed. group: Indicates that a server group is used for EXEC authorization. Currently, the RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	The RGOS supports authorization of the users who log in to the CLI of the NAS to assign the users CLI operation permission levels (0 to 15). Currently, EXEC authorization is performed only on the users who have passed login authentication. If a user fails in EXEC authorization, the user cannot enter the CLI. After you configure EXEC authorization methods, apply the methods to the VTY lines that require EXEC authorization; otherwise, the methods will not take effect.

▾ Defining a Method List of Command Authorization

Command	aaa authorization commands <i>level</i> { default <i>list-name</i> } <i>method1</i> [<i>method2</i>...]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of a command authorization method list in characters. <i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods. none: Indicates that command authorization is not performed. group: Indicates that a server group is used for command authorization. Currently, the TACACS+ server group is supported.
Command Mode	Global configuration mode
Usage Guide	The RGOS supports authorization of the commands executable by users. When a user enters a command, AAA sends the command to the authentication server. If the authentication server permits the execution, the command is executed. If the authentication server forbids the execution, the command is not executed and a message is displayed showing that the execution is rejected. When you configure command authorization, specify the command level, which is used as the default level. (For example, if a command above Level 14 is visible to users, the default level of the command is 14.) After you configure command authorization methods, apply the methods to the VTY lines that require command authorization; otherwise, the methods will not take effect.

▾ Configuring a Method List of Network Authorization

Command	aaa authorization network { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of a network authorization method list in characters. <i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods. none: Indicates that authentication is not performed. group: Indicates that a server group is used for network authorization. Currently, the RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	The RGOS supports authorization of network-related service requests such as PPP and SLIP requests. After authorization is configured, all authenticated users or interfaces are authorized automatically. You can configure three different authorization methods. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried. RADIUS or TACACS+ servers return a series of AV pairs to authorize authenticated users. Network authorization is based on authentication. Only authenticated users can perform network authorization.

Enabling Authorization for Commands in Configuration Modes (Including the Global Configuration Mode and Sub-Modes)

Command	aaa authorization config-commands
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If you need to enable authorization for commands only in non-configuration modes (for example, privileged EXEC mode), disable authorization in configuration modes by using the no form of this command. Then users can run commands in configuration mode and sub-modes without authorization.

Enabling Authorization for the Console to Run Commands

Command	aaa authorization console
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The RGOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.

Configuration Example

Configuring AAA EXEC Authorization

Configure login authentication and EXEC authorization for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC authorization is performed on a RADIUS server. If the RADIUS server does not respond, users are redirected to the local authorization.

Scenario Figure 1-7	
Configuration Steps	Step 1: Enable AAA. Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used. EXEC authorization is often used with login authentication, which can be implemented on the same line.
NAS	<pre> Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#username user privilege 6 Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa authentication login list1 group local Ruijie(config)#aaa authorization exec list2 group radius local Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication list1 Ruijie(config-line)# authorization exec list2 Ruijie(config-line)#exit </pre>
Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre> Ruijie#show aaa method-list Authentication method-list: aaa authentication login list1 group local </pre>

	Accounting method-list: Authorization method-list: aaa authorization exec list2 group radius local
	Ruijie# show running-config aaa new-model ! aaa authorization exec list2 group local aaa authentication login list1 group radius local ! username user password pass username user privilege 6 ! radius-server host 10.1.1.1 radius-server key 7 093b100133 ! line con 0 line vty 0 4 authorization exec list2 login authentication list1 ! End

Configuring AAA Command Authorization

Provide command authorization for login users according to the following default authorization method: Authorize level-15 commands first by using a TACACS+ server. If the TACACS+ server does not respond, local authorization is performed. Authorization is applied to the users who log in through the Console and the users who log in through other types of clients.

Scenario Figure 1-8	
Configuration Steps	Step 1: Enable AAA. Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to

	be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.
NAS	<pre> Ruijie#configure terminal Ruijie(config)#username user1 password pass1 Ruijie(config)#username user1 privilege 15 Ruijie(config)#aaa new-model Ruijie(config)#tacacs-server host 192.168.217.10 Ruijie(config)#tacacs-server key aaa Ruijie(config)#aaa authentication login default local Ruijie(config)#aaa authorization commands 15 default group tacacs+ local Ruijie(config)#aaa authorization console </pre>
Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre> Ruijie#show aaa method-list Authentication method-list: aaa authentication login default local Accounting method-list: Authorization method-list: aaa authorization commands 15 default group tacacs+ local </pre>
	<pre> Ruijie#show run ! aaa new-model ! aaa authorization console aaa authorization commands 15 default group tacacs+ local aaa authentication login default local ! </pre>

	<pre>! nfpp ! vlan 1 ! username user1 password 0 pass1 username user1 privilege 15 no service password-encryption ! tacacs-server host 192.168.217.10 tacacs-server key aaa ! line con 0 line vty 0 4 ! ! end</pre>

➤ **Configuring AAA Network Authorization**

Scenario Figure 1-9	 The diagram illustrates a network topology for AAA network authorization. A User (represented by a laptop icon) is connected to a NAS (Network Access Server, represented by a switch icon) through interface Gi 0/1. The NAS is then connected to a Server (represented by a server rack icon) through interface Gi 0/2. The Server's IP address is shown as 10.1.1.1.
Configuration Steps	Step 1: Enable AAA. Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1</pre>

	<pre>Ruijie(config)#radius-server key test Ruijie(config)#aaa authorization network default group radius none Ruijie(config)# end</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list Authentication method-list: Accounting method-list: Authorization method-list: aaa authorization network default group radius none</pre>

Common Errors

N/A

1.4.3 Configuring AAA Accounting

Configuration Effect

- Record the network resource usage of users.
- Record the user login and logout processes and the commands executed by users during device management.

Notes

About accounting methods:

- If an accounting scheme contains multiple accounting methods, these methods are executed according to the method configuration sequence. The next accounting method is executed only when the current method does not receive response. If accounting fails using a method, the next method will be not tried.
- After the default accounting method list is configured, it is applied to all VTY lines automatically. If a non-default accounting method list is applied to a line, it will replace the default one. If you apply an undefined method list to a line, the system will display a message indicating that accounting on this line is ineffective. Accounting will take effect only when a defined method list is applied.

EXEC accounting:

- EXEC accounting is performed only when login authentication on the NAS is completed. EXEC accounting is not performed if login authentication is not configured or the **none** method is used for authentication. If Start accounting is not performed for a user upon login, Stop accounting will not be performed when the user logs out.

Command accounting

- Only the TACACS+ protocol supports command accounting.

Configuration Steps

▾ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

▾ Defining a Method List of EXEC Accounting

- Run the **aaa accounting exec** command to configure a method list of EXEC accounting.
- This configuration is mandatory if you need to configure an EXEC accounting method list (including the configuration of the default method list).
- The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)
- By default, no EXEC accounting method list is configured.

▾ Defining a Method List of Command Accounting

- Run the **aaa accounting commands** command to configure a method list of command accounting.
- This configuration is mandatory if you need to configure a command accounting method list (including the configuration of the default method list).
- By default, no command accounting method list is configured. Only the TACACS+ protocol supports command accounting.

▾ Defining a Method List of Network Accounting

- Run the **aaa accounting network** command to configure a method list of network accounting.
- This configuration is mandatory if you need to configure a network accounting method list (including the configuration of the default method list).
- By default, no network accounting method list is configured.

▾ Applying EXEC Accounting Methods to a Specified VTY Line

- Run the **accounting exec** command in line configuration mode to apply EXEC accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

↘ Applying Command Accounting Methods to a Specified VTY Line

- Run the **accounting commands** command in line configuration mode to apply command accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

↘ Enabling Accounting Update

- Optional.
- It is recommended that accounting update be configured for improved accounting accuracy.
- By default, accounting update is disabled.

↘ Configuring the Accounting Update Interval

- Optional.
- It is recommended that the accounting update interval not be configured unless otherwise specified.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

↘ Defining a Method List of EXEC Accounting

Command	aaa accounting exec { default list-name } start-stop method1 [method2...]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name:</i> Indicates the name of an EXEC accounting method list in characters. <i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods. none: Indicates that EXEC accounting is not performed. group: Indicates that a server group is used for EXEC accounting. Currently, the RADIUS and TACACS+ server groups are supported.
Command	Global configuration mode

Mode	
Usage Guide	The RGOS enables EXEC accounting only when login authentication is completed. EXEC accounting is not performed if login authentication is not performed or the none authentication method is used. After accounting is enabled, when a user logs in to the CLI of the NAS, the NAS sends a start-accounting message to the authentication server. When the user logs out, the NAS sends a stop-accounting message to the authentication server. If the NAS does not send a start-accounting message when the user logs in, the NAS will not send a stop-accounting message when the user logs out. After you configure EXEC accounting methods, apply the methods to the VTY lines that require EXEC accounting; otherwise, the methods will not take effect.

▾ Defining a Method List of Command Accounting

Command	aaa accounting commands <i>level</i> { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	<i>level</i>: Indicates the command level for which accounting will be performed. The value ranges from 0 to 15. After a command of the configured level is executed, the accounting server records related information based on the received accounting packet. default: With this parameter used, the configured method list will be defaulted. <i>list-name</i>: Indicates the name of a command accounting method list in characters. <i>method</i>: Indicates authentication methods from none and group. A method list contains up to four methods. none: Indicates that command accounting is not performed. group: Indicates that a server group is used for command accounting. Currently, the TACACS+ server group is supported.
Command Mode	Global configuration mode
Usage Guide	The RGOS enables command accounting only when login authentication is completed. Command accounting is not performed if login authentication is not performed or the none authentication method is used. After accounting is enabled, the NAS records information about the commands of the configured level that users run and sends the information to the authentication server. After you configure command accounting methods, apply the methods to the VTY lines that require command accounting; otherwise, the methods will not take effect.

▾ Defining a Method List of Network Accounting

Command	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	default: With this parameter used, the configured method list will be defaulted. <i>list-name</i>: Indicates the name of a network accounting method list in characters. start-stop: Indicates that a start-accounting message and a stop-accounting message are sent when a user accesses a network and when the user disconnects from the network respectively. The start-accounting message indicates that the user is allowed to access the network, regardless of whether accounting is successfully enabled. <i>method</i>: Indicates authentication methods from none and group. A method list contains up to four methods. none: Indicates that network accounting is not performed. group: Indicates that a server group is used for network accounting. Currently, the RADIUS and TACACS+

	server groups are supported.
Command Mode	Global configuration mode
Usage Guide	The RGOS sends record attributes to the authentication server to perform accounting of user activities. The start-stop keyword is used to configure user accounting options.

▾ Enabling Accounting Update

Command	aaa accounting update
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to enable accounting update.

▾ Configuring the Accounting Update Interval

Command	aaa accounting update periodic <i>interval</i>
Parameter Description	<i>Interval</i> : Indicates the accounting update interval, in the unit of minutes. The shortest is 1 minute.
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to configure the accounting update interval.

Configuration Example

▾ Configuring AAA EXEC Accounting

Configure login authentication and EXEC accounting for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC accounting is performed on a RADIUS server.

Scenario Figure 1-10	 <pre> graph LR User[User] --- Gi 0/1 NAS[NAS] NAS --- Gi 0/2 Server[Server 10.1.1.1] </pre>
Configuration Steps	Step 1: Enable AAA. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. Step 2: Configure an AAA accounting method list according to different access modes and service types. Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.

NAS	<pre> Ruijie#configure terminal Ruijie(config)#username user password pass Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa authentication login list1 group local Ruijie(config)#aaa accounting exec list3 start-stop group radius Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication list1 Ruijie(config-line)# accounting exec list3 Ruijie(config-line)#exit </pre>
Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre> Ruijie#show aaa method-list Authentication method-list: aaa authentication login list1 group local Accounting method-list: aaa accounting exec list3 start-stop group radius Authorization method-list: </pre>
	<pre> Ruijie# show running-config aaa new-model ! aaa accounting exec list3 start-stop group radius aaa authentication login list1 group local ! username user password pass ! radius-server host 10.1.1.1 radius-server key 7 093b100133 </pre>

	<pre>! line con 0 line vty 0 4 accounting exec list3 login authentication list1 ! End</pre>

 Configuring AAA Command Accounting

Configure command accounting for login users according to the default accounting method. Login authentication is performed in local mode, and command accounting is performed on a TACACS+ server.

Scenario Figure 1-11	
Configuration Steps	Step 1: Enable AAA. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. Step 2: Configure an AAA accounting method list according to different access modes and service types. Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#username user1 password pass1 Ruijie(config)#username user1 privilege 15 Ruijie(config)#aaa new-model Ruijie(config)#tacacs-server host 192.168.217.10 Ruijie(config)#tacacs-server key aaa Ruijie(config)#aaa authentication login default local Ruijie(config)#aaa accounting commands 15 default start-stop group tacacs+</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Ruijie#show aaa method-list</pre>

	<pre>Authentication method-list: aaa authentication login default local Accounting method-list: aaa accounting commands 15 default start-stop group tacacs+ Authorization method-list:</pre>
	<pre>Ruijie#show run ! aaa new-model ! aaa authorization config-commands aaa accounting commands 15 default start-stop group tacacs+ aaa authentication login default local ! ! nfpp ! vlan 1 ! username user1 password 0 pass1 username user1 privilege 15 no service password-encryption ! tacacs-server host 192.168.217.10 tacacs-server key aaa ! line con 0 line vty 0 4 ! !</pre>

	end

Common Errors

N/A

1.4.4 Configuring an AAA Server Group

Configuration Effect

- Create a user-defined server group and add one or more servers to the group.
- When you configure authentication, authorization, and accounting method lists, name the methods after the server group name so that the servers in the group are used to handle authentication, authorization, and accounting requests.
- Use self-defined server groups to separate authentication, authorization, and accounting.

Notes

In a user-defined server group, you can specify and apply only the servers in the default server group.

Configuration Steps

📌 Creating a User-Defined AAA Server Group

- Mandatory.
- Assign a meaningful name to the user-defined server group. Do not use the predefined **radius** and **tacacs+** keywords in naming.

📌 Adding an AAA Server Group Member

- Mandatory.
- Run the **server** command to add AAA server group members.
- By default, a user-defined server group does not have servers.

📌 Configuring the VRF Attribute of an AAA Server Group

- Optional.
- Run the **ip vrf forwarding** command to configure the VRF attribute of an AAA server group.
- By default, the AAA server group belongs to the global VRF table.

Verification

Run the **show aaa group** command to verify the configuration.

Related Commands

📌 Creating a User-Defined AAA Server Group

Command	aaa group server {radius tacacs+} name
Parameter	<i>name</i> : Indicates the name of the server group to be created. The name must not contain the radius and tacacs+ keywords because they are the names of the default RADIUS and TACACS+ server groups.
Description	
Command Mode	Global configuration mode
Usage Guide	Use this command to configure an AAA server group. Currently, the RADIUS and TACACS+ server groups are supported.

➤ Adding an AAA Server Group Member

Command	server ip-addr [auth-port port1] [acct-port port2]
Parameter	<i>ip-addr</i> : Indicates the IP address of a server.
Description	<i>port1</i> : Indicates the authentication port of a server. (This parameter is supported only by the RADIUS server group.) <i>port2</i> : Indicates the accounting port of a server. (This parameter is supported only by the RADIUS server group.)
Command Mode	Server group configuration mode
Usage Guide	When you add servers to a server group, the default ports are used if you do not specify ports.

➤ Configuring the VRF Attribute of an AAA Server Group

Command	ip vrf forwarding vrf_name
Parameter	<i>vrf_name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Server group configuration mode
Usage Guide	Use this command to assign a VRF table to the specified server group.

Configuration Example

➤ Creating an AAA Server Group

Create RADIUS server groups named g1 and g2. The IP addresses of the servers in g1 are 10.1.1.1 and 10.1.1.2, and the IP addresses of the servers in g2 are 10.1.1.3 and 10.1.1.4.

Scenario Figure 1-12	
Prerequisites	1. The required interfaces, IP addresses, and VLANs have been configured on the network, network connections have been set up, and the routes from the NAS to servers are reachable. 2. Enable AAA.
Configuration Steps	Step 1: Configure a server (which belongs to the default server group). Step 2: Create user-defined AAA server groups. Step 3: Add servers to the AAA server groups.
NAS	<pre> Ruijie#configure terminal Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server host 10.1.1.2 Ruijie(config)#radius-server host 10.1.1.3 Ruijie(config)#radius-server host 10.1.1.4 Ruijie(config)#radius-server key secret Ruijie(config)#aaa group server radius g1 Ruijie(config-gs-radius)#server 10.1.1.1 Ruijie(config-gs-radius)#server 10.1.1.2 Ruijie(config-gs-radius)#exit Ruijie(config)#aaa group server radius g2 Ruijie(config-gs-radius)#server 10.1.1.3 Ruijie(config-gs-radius)#server 10.1.1.4 Ruijie(config-gs-radius)#exit </pre>
Verification	Run the show aaa group and show run commands on the NAS to display the configuration.

NAS	<pre>Ruijie#show aaa group Type Reference Name ----- radius 1 radius tacacs+ 1 tacacs+ radius 1 g1 radius 1 g2</pre>
	<pre>Ruijie#show run ! radius-server host 10.1.1.1 radius-server host 10.1.1.2 radius-server host 10.1.1.3 radius-server host 10.1.1.4 radius-server key secret ! aaa group server radius g1 server 10.1.1.1 server 10.1.1.2 ! aaa group server radius g2 server 10.1.1.3 server 10.1.1.4 ! !</pre>

Common Errors

- For RADIUS servers that use non-default authentication and accounting ports, when you run the **server** command to add servers, specify the authentication or accounting port.
- Only the RADIUS server group can be configured with the VRF attribute.

1.4.5 Configuring the Domain-Based AAA Service

Configuration Effect

Create AAA schemes for 802.1X users in different domains.

Notes

About referencing method lists in domains:

- The AAA method lists that you select in domain configuration mode should be defined in advance. If the method lists are not defined in advance, when you select them in domain configuration mode, the system prompts that the configurations do not exist.
- The names of the AAA method lists selected in domain configuration mode must be consistent with those of the method lists defined for the AAA service. If they are inconsistent, the AAA service cannot be properly provided to the users in the domain.

About the default domain:

- Default domain: After the domain-based AAA service is enabled, if a username does not carry domain information, the AAA service is provided to the user based on the default domain. If the domain information carried by the username is not configured in the system, the system determines that the user is unauthorized and will not provide the AAA service to the user. If the default domain is not configured initially, it must be created manually.
- When the domain-based AAA service is enabled, the default domain is not configured by default and needs to be created manually. The default domain name is **default**. It is used to provide the AAA service to the users whose usernames do not carry domain information. If the default domain is not configured, the AAA service is not available for the users whose usernames do not carry domain information.

About domain names:

- The domain names carried by usernames and those configured on the NAS are matched in the longest matching principle. For example, if two domains, **domain.com** and **domain.com.cn** are configured on a NAS and a user sends a request carrying **aaa@domain.com**, the NAS determines that the user belongs to **domain.com**, instead of **domain.com.cn**.
- If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the AAA service is not provided to the user.

Configuration Steps

📌 Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

📌 Enabling the Domain-Based AAA Service

- Mandatory.
- Run the **aaa domain enable** command to enable the domain-based AAA service.
- By default, the domain-based AAA service is disabled.

➤ Creating a Domain and Entering Domain Configuration Mode

- Mandatory.
- Run the **aaa domain** command to create a domain or enter the configured domain.
- By default, no domain is configured.

➤ Associating the Domain with an 802.1X Authentication Method List

- Run the **authentication login** command to associate the domain with the login authentication method list.
- Run the **authentication enable** command to associate the domain with the enable authentication method list.
- This configuration is mandatory if you need to specify the login or enable authentication method list to the domain.
- If no authentication method list is specified, the default list is enabled.

➤ Associating the Domain with a Network Accounting Method List

- Run the **accounting network** command to associate the domain with a network accounting method.
- This configuration is mandatory if you need to apply a specified network accounting method list to the domain.
- If a domain is not associated with a network accounting method list, by default, the global default method list is used for accounting.

➤ Associating the Domain with a Commands, or EXEC Accounting Method List

- Run the **accounting {commands | exec} { default | list-name }** command to associate the domain with a commands, or EXEC accounting method.
- This configuration is mandatory if you need to apply a specified commands, or EXEC accounting method list to the domain.
- If a domain is not associated with a commands, or EXEC accounting method list, by default, the global default method list is used for accounting.

➤ Associating the Domain with a Network Authorization Method List

- Run the **authorization network** command to associate the domain with a network authorization method list.
- This configuration is mandatory if you need to apply a specified network authorization method list to the domain.
- If a domain is not associated with a network authorization method list, by default, the global default method list is used for authorization.

➤ Associating the Domain with a Commands, or EXEC Authorization Method List

- Run the **authorization {commands | exec} { default | list-name }** command to associate the domain with a commands, or EXEC authorization method list.
- This configuration is mandatory if you need to apply a specified commands or EXEC authorization method list to the domain.

- If a domain is not associated with a commands or EXEC authorization method list, by default, the global default method list is used for authorization.

📌 Configuring the Domain Status

- Optional.
- When a domain is in Block state, the users in the domain cannot log in.
- By default, after a domain is created, its state is Active, indicating that all the users in the domain are allowed to request network services.

📌 Configuring Whether to Contain the Domain Name in Usernames

- Optional.
- By default, the usernames exchanged between the NAS and an authentication server carry domain information.

📌 Configuring the Maximum Number of Domain Users

- Optional.
- By default, the maximum number of access users allowed in a domain is not limited.

Verification

Run the **show aaa domain** command to verify the configuration.

Related Commands

📌 Enabling AAA

Command	aaa new-model
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

📌 Enabling the Domain-Based AAA Service

Command	aaa domain enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the domain-based AAA service.

📌 Creating a Domain and Entering Domain Configuration Mode

Command	aaa domain { default domain-name }
Parameter	default: Uses this parameter to configure the default domain.
Description	<i>domain-name:</i> Indicates the name of the domain to be created.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure a domain to provide the domain-based AAA service. The default parameter specifies the default domain. If a username does not carry domain information, the NAS uses the method list associated with the default domain to provide the AAA service to the user. The <i>domain-name</i> parameter specifies the name of the domain to be created. If the domain name carried by a username matches the configured domain name, the NAS uses the method list associated with this domain to provide the AAA service to the user. The system supports a maximum of 32 domains.

✚ Associating the Domain with an Login Authentication Method List

Command	authentication login { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a login authentication method list.

✚ Associating the Domain with an Enable Authentication Method List

Command	authentication enable { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with an Enable authentication method list.

✚ Associating the Domain with a Network Accounting Method List

Command	accounting network { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a network accounting method list.

✚ Associating the Domain with a Commands Accounting Method List

Command	accounting commands { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.

Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a Commands accounting method list.

↘ Associating the Domain with an EXEC Accounting Method List

Command	accounting exec { default <i>list-name</i> }
Parameter Description	default: Indicates that the default method list is used. <i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with an EXEC accounting method list.

↘ Associating the Domain with a Network Authorization Method List

Command	authorization network { default <i>list-name</i> }
Parameter Description	default: Indicates that the default method list is used. <i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	

↘ Associating the Domain with a Commands Authorization Method List

Command	authorization commands { default <i>list-name</i> }
Parameter Description	default: Indicates that the default method list is used. <i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	N/A

↘ Associating the Domain with an EXEC Authorization Method List

Command	authorization exec { default <i>list-name</i> }
Parameter Description	default: Indicates that the default method list is used. <i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	N/A

↘ Configuring the Domain Status

Command	state { block active }
Parameter Description	block: Indicates that the configured domain is invalid. active: Indicates that the configured domain is valid.

Command Mode	Domain configuration mode
Usage Guide	Use this command to make the configured domain valid or invalid.

✚ Configuring Whether to Contain the Domain Name in Usernames

Command	username-format { without-domain with-domain }
Parameter Description	without-domain: Indicates to remove domain information from usernames. with-domain: Indicates to keep domain information in usernames.
Command Mode	Domain configuration mode
Usage Guide	Use this command in domain configuration mode to determine whether to include domain information in usernames when the NAS interacts with authentication servers in a specified domain.

Configuration Example

✚ Configuring the Domain-Based AAA Services

Configure authentication and accounting through a RADIUS server to 802.1X users (username: *user@domain.com*) that access the NAS. The usernames that the NAS sends to the RADIUS server do not carry domain information, and the number of access users is not limited.

Scenario Figure 1-13	 <pre> graph LR User[Laptop] --- Gi 0/1 NAS[NAS] NAS --- Gi 0/2 Server[Server] Server --- IP[10.1.1.1] </pre>
Configuration Steps	The following example shows how to configure RADIUS authentication and accounting, which requires the configuration of a RADIUS server in advance. Step 1: Enable AAA. Step 2: Define an AAA method list. Step 3: Enable the domain-based AAA service. Step 4: Create a domain. Step 5: Associate the domain with the AAA method list. Step 6: Configure the domain attribute.
NAS	<pre> Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 10.1.1.1 Ruijie(config)#radius-server key test Ruijie(config)#aaa accounting network list3 start-stop group radius Ruijie(config)# aaa domain enable </pre>

	<pre> Ruijie(config)# aaa domain domain.com Ruijie(config-aaa-domain)# accounting network list3 Ruijie(config-aaa-domain)# username-format without-domain </pre>
Verification	Run the show run and show aaa domain command on the NAS to display the configuration.
NAS	<pre> Ruijie#show aaa domain domain.com =====Domain domain.com===== State: Active Username format: With-domain Access limit: No limit Selected method list: accounting network list3 </pre>
	<pre> Ruijie#show run Building configuration... Current configuration : 1449 bytes version RGOS 10.4(3) Release(101069) (Wed Oct 20 09:12:40 CST 2010 -ngcf67) co-operate enable ! aaa new-model aaa domain enable ! aaa domain domain.com accounting network list3 ! aaa accounting network list3 start-stop group radius ! nfpp ! </pre>

	<pre>no service password-encryption ! radius-server host 10.1.1.1 radius-server key test ! line con 0 line vty 0 4 ! end</pre>

1.4.6 Configuring a Login Switch for the AAA Slave Device

Configuration Effect

When the switch is turned on, the slave device is allowed to login; otherwise, the slave device cannot login.

The configuration remains valid unless a change is made.

Notes

The **aaa new-model** command should be run first.

Configuration Steps

Configuring a Login Switch for the AAA Slave Device

- Optional.
- By default, the slave device is not allowed to login.

Verification

Run the **show run** command to verify the configuration.

Related Commands

Configuring a Login Switch for the AAA Slave Device

Command	aaa slave-login allow
Parameter	N/A
Description	
Command	Global configuration mode

Mode	
Usage Guide	By default, the switch is off, so the slave device is not allowed to login. When the switch is turned on, the slave device can login.

Configuration Example

Configuring a Login Switch for the AAA Slave Device

Scenario Figure 1-14	
Configuration Steps	The following example shows how to configure a login switch for the AAA slave device Step 1: Enable AAA. Step 2: Turn on the login switch.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#aaa slave-login allow</pre>
Verification	Run the show run command on the NAS to display the configuration.
NAS	<pre>Ruijie#sh run inc aaa</pre>
	<pre>aaa new-model aaa slave-login allow</pre>

Common Errors

N/A

1.4.7 Configuring Authorization Result Caching

Configuration Effect

After this feature is configured, the AAA module caches authorization results returned from the server. Therefore, later authorizations at the same level can be operated based on the cache.

Notes

The cached authorization results, originating from specific levels of sessions and commands, can be applied only to sessions and commands at these levels.

Configuration Steps

Configuring Authorization Result Caching

- Optional.
- By default, authorization results are not cached.

Verification

Run the **show run** command to verify the configuration.

Related Commands

Configuring Authorization Result Caching

Command	aaa command-author cache
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	The AAA device caches authorization results returned from the server. Therefore, later authorizations at the same level can be operated based on the cached resources.

Configuration Example

Configuring Authorization Result Caching

Scenario Figure 1-15	
Configuration Steps	The following example shows how to configure authorization result caching Step 1: Enable AAA. Step 2: Turn on the login switch. Step 3: Configure authorization result caching.
NAS	<pre>Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#aaa command-author cache Ruijie(config)# aaa authorization commands 15 default group tacacs+</pre>
Verification	Run the show run command on the NAS to display the configuration.
NAS	<pre>Ruijie#sh run inc aaa</pre>

```
aaa new-model  
  
aaa authorization commands 15 default group tacacs+  
  
aaa command-author cache
```

Displays the AAA users.	show aaa user

2 Configuring RADIUS

2.1 Overview

The Remote Authentication Dial-In User Service (RADIUS) is a distributed client/server system.

RADIUS works with the Authentication, Authorization, and Accounting (AAA) to conduct identity authentication on users who attempt to access a network, to prevent unauthorized access. In RGOS implementation, a RADIUS client runs on a device or Network Access Server (NAS) and transmits identity authentication requests to the central RADIUS server, where all user identity authentication information and network service information are stored. In addition to the authentication service, the RADIUS server provides authorization and accounting services for access users.

RADIUS is often applied in network environments that have high security requirements and allow the access of remote users. RADIUS is a completely open protocol and the RADIUS server is installed on many operating systems as a component, for example, on UNIX, Windows 2000, and Windows 2008. Therefore, RADIUS is the most widely applied security server currently.

The Dynamic Authorization Extensions to Remote Authentication Dial In User Service is defined in the IETF RFC3576. This protocol defines a user offline management method. Devices communicate with the RADIUS server through the Disconnect-Messages (DMs) to bring authenticated users offline. This protocol implements compatibility between devices of different vendors and the RADIUS server in terms of user offline processing.

In the DM mechanism, the RADIUS server actively initiates a user offline request to a device, the device locates a user according to the user session information, user name, and other information carried in the request and brings the user offline. Then, the device returns a response packet that carries the processing result to the RADIUS server, thereby implementing user offline management of the RADIUS server.

Protocols and Standards

- RFC2865: Remote Authentication Dial In User Service (RADIUS)
- RFC2866: RADIUS Accounting
- RFC2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC2869: RADIUS Extensions
- RFC3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

2.2 Applications

Application	Description
Providing Authentication, Authorization, and Accounting Services for Access Users	Authentication, authorization, and accounting are conducted on access users on a network, to prevent unauthorized access or operations.

Application	Description
Forcing Users to Go Offline	The server forces an authenticated user to go offline.

2.2.1 Providing Authentication, Authorization, and Accounting Services for Access Users

Scenario

RADIUS is typically applied in the authentication, authorization, and accounting of access users. A network device serves as a RADIUS client and transmits user information to a RADIUS server. After completing processing, the RADIUS server returns the authentication acceptance/authentication rejection/accounting response information to the RADIUS client. The RADIUS client performs processing on the access user according to the response from the RADIUS server.

Figure 2-1 Typical RADIUS Networking Topology

Remarks	PC 1 and PC 2 are connected to the RADIUS client as access users in wired or wireless mode, and initiate authentication and accounting requests. The RADIUS client is usually an access switch or aggregate switch. The RADIUS server can be a component built in the Windows 2000/2003, Server (IAS), or UNIX operating system or dedicated server software provided by vendors.

Deployment

- Configure access device information on the RADIUS server, including the IP address and shared key of the access devices.
- Configure the AAA method list on the RADIUS client.
- Configure the RADIUS server information on the RADIUS client, including the IP address and shared key.
- Enable access control on the access port of the RADIUS client.
- Configure the network so that the RADIUS client communicates with the RADIUS server successfully.

2.2.2 Forcing Users to Go Offline

Scenario

The RADIUS server forces authenticated online users to go offline for the sake of management.

See Figure 2-1 for the networking topology.

Deployment

- Add the following deployment on the basis of 1.2.1 "Deployment".
- Enable the RADIUS dynamic authorization extension function on the RADIUS client.

2.3 Features

Basic Concepts

Client/Server Mode

- **Client:** A RADIUS client initiates RADIUS requests and usually runs on a device or NAS. It transmits user information to the RADIUS server, receives responses from the RADIUS server, and performs processing accordingly. The processing includes accepting user access, rejecting user access, or collecting more user information for the RADIUS server.
- **Server:** Multiple RADIUS clients map to one RADIUS server. The RADIUS server maintains the IP addresses and shared keys of all RADIUS clients as well as information on all authenticated users. It receives requests from a RADIUS client, conducts authentication, authorization, and accounting, and returns processing information to the RADIUS client.

Structure of RADIUS Packets

The following figure shows the structure of RADIUS packets.

- **Code:** Identifies the type of RADIUS packets, which occupies one byte. The following table lists the values and meanings.

Code	Packet Type	Code	Packet Type
1	Access-Request	4	Accounting-Request
2	Access-Accept	5	Accounting-Response
3	Access-Reject	11	Access-Challenge

- **Identifier:** Indicates the identifier for matching request packets and response packets, which occupies one byte. The identifier values of request packets and response packets of the same type are the same.
- **Length:** Identifies the length of a whole RADIUS packet, which includes **Code**, **Identifier**, **Length**, **Authenticator**, and **Attributes**. It occupies two bytes. Bytes that are beyond the **Length** field will be truncated. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.

- **Authenticator:** Verifies response packets of the RADIUS server by a RADIUS client, which occupies 16 bytes. This field is also used for encryption/decryption of user passwords.
- **Attributes:** Carries authentication, authorization, and accounting information, with the length unfixed. The **Attributes** field usually contains multiple attributes. Each attribute is represented in the Type, Length, Value (TLV) format. Type occupies one byte and indicates the attribute type. The following table lists common attributes of RADIUS authentication, authorization, and accounting. Length occupies one byte and indicates the attribute length, with the unit of bytes. Value indicates the attribute information.

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id

Shared Key

A RADIUS client and a RADIUS server mutually confirm their identities by using a shared key during communication. The shared key cannot be transmitted over a network. In addition, user passwords are encrypted for transmission for the sake of security.

RADIUS Server Group

The RADIUS security protocol, also called RADIUS method, is configured in the form of a RADIUS server group. Each RADIUS method corresponds to one RADIUS server group and one or more RADIUS servers can be added to one RADIUS server group. For details about the RADIUS method, see the *Configuring AAA*. If you add multiple RADIUS servers to one RADIUS server group, when the communication between a device and the first RADIUS server in this group fails or the first RADIUS server becomes unreachable, the device automatically attempts to communicate with the next RADIUS server till the communication is successful or the communication with all the RADIUS servers fails.

RADIUS Attribute Type

- Standard attributes
- The RFC standards specify the RADIUS attribute numbers and attribute content but do not specify the format of some attribute types. Therefore, the format of attribute contents needs to be configured to adapt to different RADIUS server requirements. Currently, the format of the RADIUS Calling-Station-ID attribute (attribute No.: 31) can be configured.

The RADIUS Calling-Station-ID attribute is used to identify user identities when a network device transmits request packets to the RADIUS server. The RADIUS Calling-Station-ID attribute is a string, which can adopt multiple formats. It needs to uniquely identify a user. Therefore, it is often set to the MAC address of a user. The following table describes the format of MAC addresses.

Format	Description
ietf	Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC
Normal	Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac

Unformatted	Indicates the format without separators. This format is used by default. Example: 00d0f83322ac

- Private attributes

RADIUS is an extensible protocol. According to RFC2865, the Vendor-Specific attribute (attribute No.: 26) is used by device vendors to extend the RADIUS protocol to implement private functions or functions that are not defined in the standard RADIUS protocol. Table 1-3 lists private attributes supported by Ruijie products. The **TYPE** column indicates the default configuration of private attributes of Ruijie products and the **Extended TYPE** column indicates the default configuration of private attributes of other non-Ruijie products.

ID	Function	TYPE	Extended TYPE
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	vlan-id	4	4
5	last-supPLICANT-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13

Overview

Feature	Description

RADIUS Authentication, Authorization, and Accounting	Conducts identity authentication and accounting on access users, safeguards network security, and facilitates management for network administrators.
Source Address of RADIUS Packets	Specifies the source IP address used by a RADIUS client to transmit packets to a RADIUS server.
RADIUS Timeout Retransmission	Specifies the packet retransmission parameter for a RADIUS client when a RADIUS server does not respond to packets transmitted from the RADIUS client within a period of time.
RADIUS Server Accessibility Detection	Enables a RADIUS client to actively detect whether a RADIUS server is reachable and maintain the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.
RADIUS Forced Offline	Enables a RADIUS server to actively force authenticated users to go offline.

2.3.1 RADIUS Authentication, Authorization, and Accounting

Conduct identity authentication and accounting on access users, safeguard network security, and facilitate management for network administrators.

Working Principle

Figure 2-2

The RADIUS authentication and authorization process is described as follows:

1. A user enters the user name and password and transmits them to the RADIUS client.
2. After receiving the user name and password, the RADIUS client transmits an authentication request packet to the RADIUS server. The password is encrypted for transmission. For the encryption method, see RFC2865.
3. The RADIUS server accepts or rejects the authentication request according to the user name and password. When accepting the authentication request, the RADIUS server also issues authorization information apart from the authentication acceptance information. The authorization information varies with the type of access users.

The RADIUS accounting process is described as follows:

1. If the RADIUS server returns authentication acceptance information in Step (3), the RADIUS client sends an accounting start request packet to the RADIUS server immediately.
2. The RADIUS server returns the accounting start response packet, indicating accounting start.
3. The user stops accessing network resources and requests the RADIUS client to disconnect the network connection.
4. The RADIUS client transmits the accounting end request packet to the RADIUS server.
5. The RADIUS server returns the accounting end response packet, indicating accounting end.
6. The user is disconnected and cannot access network resources.

Related Configuration

📄 Configuring RADIUS Server Parameters

No RADIUS server is configured by default.

You can run the **radius-server host** command to configure a RADIUS server.

At least one RADIUS server must be configured so that RADIUS services run normally.

📄 Configuring the AAA Authentication Method List

No AAA authentication method list is configured by default.

You can run the **aaa authentication** command to configure a method list for different user types and select **group radius** when setting the authentication method.

The RADIUS authentication can be conducted only after the AAA authentication method list of relevant user types is configured.

📄 Configuring the AAA Authorization Method List

No AAA authorization method list is configured by default.

You can run the **aaa authorization** command to configure an authorization method list for different user types and select **group radius** when setting the authorization method.

The RADIUS authorization can be conducted only after the AAA authorization method list of relevant user types is configured.

📄 Configuring the AAA Accounting Method List

No AAA accounting method list is configured by default.

You can run the **aaa accounting** command to configure an accounting method list for different user types and select **group radius** when setting the accounting method.

The RADIUS accounting can be conducted only after the AAA accounting method list of relevant user types is configured.

2.3.2 Source Address of RADIUS Packets

Specify the source IP address used by a RADIUS client to transmit packets to a RADIUS server.

Working Principle

When configuring RADIUS, specify the source IP address to be used by a RADIUS client to transmit RADIUS packets to a RADIUS server, in an effort to reduce the workload of maintaining a large amount of NAS information on the RADIUS server.

Related Configuration

The global routing is used to determine the source address for transmitting RADIUS packets by default.

Run the **ip radius source-interface** command to specify the source interface for transmitting RADIUS packets. The device uses the first IP address of the specified interface as the source address of RADIUS packets.

2.3.3 RADIUS Timeout Retransmission

Working Principle

After a RADIUS client transmits a packet to a RADIUS server, a timer is started to detect the response of the RADIUS server. If the RADIUS server does not respond within a certain period of time, the RADIUS client retransmits the packet.

Related Configuration

📌 Configuring the RADIUS Server Timeout Time

The default timeout time is 5 seconds.

You can run the **radius-server timeout** command to configure the timeout time. The value ranges from 1 second to 1,000 seconds.

The response time of a RADIUS server is relevant to its performance and the network environment. Set an appropriate timeout time according to actual conditions.

📌 Configuring the Retransmission Count

The default retransmission count is 3.

You can run the **radius-server retransmit** command to configure the retransmission count. The value ranges from 1 to 100.

📌 Configuring Whether to Retransmit Accounting Update Packets

Accounting update packets are not retransmitted by default.

You can run the **radius-server account update retransmit** command to configure retransmission of accounting update packets for authenticated users.

2.3.4 RADIUS Server Accessibility Detection

Working Principle

A RADIUS client actively detects whether a RADIUS server is reachable and maintains the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.

Related Configuration

Configuring the Criteria for the Device to Judge That a RADIUS Server Is Unreachable

The default criteria configured for judging that a RADIUS server is unreachable meet the two conditions simultaneously: 1. The device does not receive a correct response packet from the RADIUS security server within 60 seconds. 2. The device transmits the request packet to the same RADIUS security server for consecutive 10 times.

You can run the **radius-server dead-criteria** command to configure the criteria for the device to judge that the RADIUS security server is unreachable.

Configuring the Test User Name for Actively Detecting the RADIUS Security Server

No test user name is specified for actively detecting the RADIUS security server by default.

You can run the **radius-server host x.x.x.xtestusername xxx** command to configure the test user name.

2.3.5 RADIUS Forced Offline

Working Principle

Figure 2-3 DM Message Exchange of the RADIUS Dynamic Authorization Extension Protocol

The preceding figure shows the exchange of DM messages between the RADIUS server and the device. The RADIUS server transmits the Disconnect-Request message to UDP Port 3799 of the device. After processing, the device returns the Disconnect-Response message that carries the processing result to the RADIUS server.

Related Configuration

N/A

2.4 Configuration

Configuration	Description and Command	
RADIUS Basic Configuration	 (Mandatory) It is used to configure RADIUS authentication, authorization, and accounting.	
	radius-serverhost	Configures the IP address of the remote RADIUS security server.
	radius-serverkey	Configures the shared key for communication between the device and the RADIUS server.
	radius-serverretransmit	Configures the request transmission count, after which the device confirms that a RADIUS server is unreachable.
	radius-servertimeout	Configures the waiting time, after which the device retransmits a request.
	radius-server account update retransmit	Configures retransmission of accounting update packets for authenticated users.
	ip radius source-interface	Configures the source address of RADIUS packets.
Configuring the RADIUS Attribute Type	 (Optional) It is used to define attribute processing adopted when the device encapsulates and parses RADIUS packets.	
	radius-serverattribute31	Configures the MAC address format of RADIUS attribute No. 31 (Calling-Station-ID).
	radius set qoscos	Sets the private attribute port-priority issued by the server to the COS value of an interface. For COS-relevant concepts, see the <i>Configuring QoS</i> .
	radius support cui	Configures the device to support the CUI attribute.
	radius vendor-specific	Configures the mode of parsing private attributes by the device.
Configuring RADIUS Accessibility Detection	 (Optional) It is used to detect whether a RADIUS server is reachable and maintain the accessibility of the RADIUS server.	
	radius-server dead-criteria	Configures the global criteria for judging that a RADIUS security server is unreachable.
	radius-server deadtime	Configures the duration for the device to stop transmitting request packets to an unreachable RADIUS server.
	radius-server host	Configures the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.

2.4.1 RADIUS Basic Configuration

Configuration Effect

- RADIUS authentication, authorization, and accounting can be conducted after RADIUS basic configuration is complete.

Notes

- Before configuring RADIUS on the device, ensure that the network communication of the RADIUS server is in good condition.
- When running the **ip radius source-interface** command to configure the source address of RADIUS packets, ensure that the device of the source IP address communicates with the RADIUS server successfully.

Configuration Steps

↘ Configuring the Remote RADIUS Security Server

- Mandatory.
- Configure the IP address, authentication port, accounting port, and shared key of the RADIUS security server.

↘ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

- Optional.
- Configure a shared key in global configuration mode for servers without a shared key.

The shared key on the device must be consistent with that on the RADIUS server.

↘ Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

- Optional.
- Configure the request transmission count, after which the device confirms that a RADIUS server is unreachable, according to the actual network environment.

↘ Configuring the Waiting Time, After which the Device Retransmits a Request

- Optional.
- Configure the waiting time, after which the device retransmits a request, according to the actual network environment.

↘ Configuring the Source Address of RADIUS Packets

- Optional.
- Configure the source address of RADIUS packets according to the actual network environment.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.

- Enable the device to interact with the RADIUS server. Conduct packet capture to confirm that the device communicates with the RADIUS server over the RADIUS protocol.

Related Commands

Configuring the Remote RADIUS Security Server

Command	radius-server host [oob [viamgmt_name]] { <i>ipv4-address</i> } [auth-port <i>port-number</i>] [acct-port <i>port-number</i>] [test username <i>name</i> [idle-time <i>time</i>] [ignore-auth-port] [ignore-acct-port]] [key [0 7] <i>text-string</i>]
Parameter Description	oob: Indicates oob authentication, that is, the source interface for transmitting packets to the RADIUS server is an mgmt port. viamgmt_name: Specifies a specific mgmt port when oob supports multiple mgmt ports. <i>ipv4-address</i>: Indicates the IPv4 address of the RADIUS security server. auth-port<i>port-number</i>: Indicates the UDP port for RADIUS identity authentication. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct identity authentication. acct-port <i>port-number</i>: Indicates the UDP port for RADIUS accounting. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct accounting. test username <i>name</i>: Enables the function of actively detecting the RADIUS security server and specifies the user name used for active detection. idle-time<i>time</i>: Indicates the interval for the device to transmit test packets to a reachable RADIUS security server. The default value is 60 minutes. The value ranges from 1 minute to 1,440 minutes (24 hours). ignore-auth-port: Disables the function of detecting the authentication port of the RADIUS security server. It is enabled by default. ignore-acct-port: Disables the function of detecting the accounting port of the RADIUS security server. It is enabled by default. key [0 7] <i>text-string</i> : Configures the shared key of the server. The global shared key is used if it is not configured.
Command Mode	Global configuration mode
Usage Guide	A RADIUS security server must be defined to implement the AAA security service by using RADIUS. You can run the radius-server host command to define one or more RADIUS security servers. If a RADIUS security server is not added to a RADIUS server group, the device uses the global routing table when transmitting RADIUS packets to the RADIUS server. Otherwise, the device uses the VRF routing table of the RADIUS server group.

Configuring the Shared Key for Communication Between the Device and the RADIUS Server

Command	radius-server key [0 7] <i>text-string</i>
Parameter Description	<i>text-string</i>: Indicates the text of the shared key. 0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.
Command	Global configuration mode

Mode	
Usage Guide	A shared key is the basis for correct communication between the device and the RADIUS security server. The same shared key must be configured on the device and RADIUS security server so that they can communicate with each other successfully.

✎ Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

Command	radius-server retransmit <i>retries</i>
Parameter Description	<i>retries</i> : Indicates the RADIUS retransmission count. The value ranges from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	The prerequisite for AAA to use the next user authentication method is that the current security server used for authentication does not respond. The criteria for the device to judge that a security server does not respond are that the security server does not respond within the RADIUS packet retransmission duration of the specified retransmission count. There is an interval between consecutive two retransmissions.

✎ Configuring the Waiting Time, After which the Device Retransmits a Request

Command	radius-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Command Mode	Global configuration mode
Usage Guide	Use this command to adjust the packet retransmission timeout time.

✎ Configuring Retransmission of Accounting Update Packets for Authenticated Users

Command	radius-server account update retransmit
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure retransmission of accounting update packets for authenticated users. Accounting update packets are not retransmitted by default. The configuration does not affect users of other types.

Configuration Example

✎ Using RADIUS Authentication, Authorization, and Accounting for Login Users

Scenario Figure 2-4	
Configuration Steps	● Enable AAA. ● Configure the RADIUS server information. ● Configure to use the RADIUS authentication, authorization, and accounting methods. ● Apply the configured authentication method on the interface.
RADIUS Client	<pre>Ruijie#configure terminal Ruijie (config)#aaa new-model Ruijie (config)# radius-server host 192.168.5.22 Ruijie (config)#radius-server host 3000::100 Ruijie (config)# radius-server key aaa Ruijie (config)#aaa authentication login test group radius Ruijie (config)#aaa authorizationexec test group radius Ruijie (config)#aaa accountingexec test start-stop group radius Ruijie (config)# line vty 0 4 Ruijie (config-line)#login authentication test Ruijie (config-line)# authorization exec test Ruijie (config-line)# accounting exec test</pre>
Verification	Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. After obtaining a certain access level granted by the server, only run commands under this access level. Display the authentication log of the user on the RADIUS server. Perform management operations on the device as the user and then log out. Display the accounting information on the user on the RADIUS server.
	<pre>Ruijie#show running-config</pre>

```
!  
radius-server host 192.168.5.22  
radius-server host 3000::100  
radius-server key aaa  
aaa new-model  
aaa accounting exec test start-stop group radius  
aaa authorization exec test group radius  
aaa authentication login test group radius  
no service password-encryption  
iptcp not-send-rst  
!  
vlan 1  
!  
line con 0  
line vty 0 4  
    accounting exec test  
    authorization exec test  
    login authentication test  
!
```

Common Errors

- The key configured on the device is inconsistent with that configured on the server.
- No method list is configured.

2.4.2 Configuring the RADIUS Attribute Type

Configuration Effect

- Define the attribute processing adopted when the device encapsulates and parses RADIUS packets.

Notes

- Private attributes involved in "Configuring the RADIUS Attribute Type" refer to Ruijie private attributes.

Configuration Steps

📌 Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

- Optional.
- Set the MAC address format of **Calling-Station-Id** to a type supported by the server.

✚ Configuring the RADIUS Private Attribute Type

- Optional.
- If the server is a Ruijie application server, the RADIUS private attribute type needs to be configured.

✚ Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface

- Optional.
- Set the private attribute **port-priority** issued by the server to the COS value of an interface as required.

✚ Configures the Device to Support the CUI Attribute

- Optional.
- Configure whether the device supports the RADIUS CUI attribute as required.

✚ Configuring the Mode of Parsing Private Attributes by the Device

- Optional.
- Configure the index of a Ruijie private attribute parsed by the device as required.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.
- Enable the device to interact with the RADIUS server. Conduct packet capture to display the MAC address format of Calling-Station-Id.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that Ruijie private attributes are correctly parsed by the device.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that the CUI attribute is correctly parsed by the device.

Related Commands

✚ Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

Command	radius-server attribute 31 mac format {ietf normal unformatted }
Parameter	ietf : Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC.
Description	normal : Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac. unformatted : Indicates the format without separators. This format is used by default. Example: 00d0f83322ac.

Command Mode	Global configuration mode
Usage Guide	Some RADIUS security servers can identify only MAC addresses in the IETF format. In this case, set the MAC address format of Calling-Station-ID to IETF.

✚ Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface

Command	radius set qosc
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to use the issued QoS value as the CoS value. The QoS value is used as the DSCP value by default.

✚ Configures the Device to Support the CUI Attribute

Command	radius support cui
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to enable the RADIUS-compliant device to support the CUI attribute.

✚ Configuring the Mode of Parsing Private Attributes by the Device

Command	Radius vendor-specific extend
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to identify attributes of all vendor IDs by type.

Configuration Example

✚ Configuring the RADIUS Attribute Type

Scenario	One authentication device
Configuration Steps	● Configure the MAC address format of RADIUS Calling-Station-Id. ● Set the QoS value issued by the RADIUS server as the COS value of the interface. ● Configure the RADIUS function to support the CUI attribute. ● Configure the device to support private attributes of other vendors.

	<pre>Ruijie(config)#radius-server attribute 31 mac format ietf Ruijie(config)#radiussetqoscos Ruijie(config)#radiussupport cui Ruijie(config)#radiusvendor-specific extend</pre>
Verification	Conduct packet capture or display debug information of the device to check whether the RADIUS standard attributes and private attributes are encapsulated/parsed correctly.

2.4.3 Configuring RADIUS Accessibility Detection

Configuration Effect

The device maintains the accessibility status of each configured RADIUS server: reachable or unreachable. The device will not transmit authentication, authorization, and accounting requests of access users to an unreachable RADIUS server unless all the other servers in the same RADIUS server group as the unreachable server are all unreachable.

The device actively detects a specified RADIUS server. The active detection function is disabled by default. If the active detection function is enabled for a specified RADIUS server, the device will, according to the configuration, periodically transmits detection requests (authentication requests or accounting requests) to the RADIUS server. The transmission interval is as follows:

- For a reachable RADIUS server, the interval is the active detection interval of the reachable RADIUS server (the default value is 60 minutes).
- For an unreachable RADIUS server, the interval is always 1 minute.

Notes

All the following conditions need to be met before the active detection function is enabled for a specified RADIUS server:

- The test user name of the RADIUS server is configured on the device.
- At least one tested port (authentication port or accounting port) of the RADIUS server is configured on the device.

If the following two conditions are all met, it is deemed that a reachable RADIUS server becomes unreachable:

- After the previous correct response is received from the RADIUS server, the time set in **radius-server dead-criteria timeseconds** has elapsed.
- After the previous correct response is received from the RADIUS server, the count that the device transmits requests to the RADIUS server but fails to receive correct responses (including retransmission) reaches the value set in **radius-server dead-criteria triesnumber**.

If any of the following conditions is met, it is deemed that an unreachable RADIUS server becomes reachable:

- The device receives correct responses from the RADIUS server.
- The duration that the RADIUS server is in the unreachable state exceeds the time set in **radius-server deadtime** and the active detection function is disabled for the RADIUS server.

- The authentication port or accounting port of the RADIUS server is updated on the device.

Configuration Steps

✚ Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable

- Mandatory.
- Configuring the global criteria for judging that a RADIUS security server is unreachable is a prerequisite for enabling the active detection function.

✚ Configuring the IP Address of the Remote RADIUS Security Server, Authentication Port, Accounting Port, and Active Detection Parameters

- Mandatory.
- Configuring active detection parameters of the RADIUS server is a prerequisite for enabling the active detection function.

✚ Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server

- Optional.
- The configured duration for the device to stop transmitting request packets to an unreachable RADIUS server takes effect only when the active detection function is disabled for the RADIUS server.

Verification

- Run the **show radius server** command to display the accessibility information of each RADIUS server.

Related Commands

✚ Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable

Command	radius-server dead-criteria { timeseconds [triesnumber] triesnumber }
Parameter Description	timeseconds: Indicates the time condition parameter. If the device fails to receive a correct response packet from a RADIUS security server within the specified time, it is deemed that the RADIUS security server meets the inaccessibility duration condition. The value ranges from 1 second to 120 seconds. triesnumber: Indicates the consecutive request timeout count. If the timeout count of request packets transmitted by the device to the same RADIUS security server reaches the preset count, it is deemed that the RADIUS security server meets the consecutive timeout count condition of inaccessibility. The value ranges from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	If a RADIUS security server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS security server is unreachable. Users can use this command to adjust parameter values in the duration condition and consecutive request timeout count condition.

✎ Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server

Command	Radius-server deadtime <i>minutes</i>
Parameter Description	<i>minutes</i> : Indicates the duration for the device to stop transmitting requests to an unreachable RADIUS security server, with the unit of minutes. The value ranges from 1 minute to 1,440 minutes (24 hours).
Command Mode	Global configuration mode
Usage Guide	If the active detection function is enabled for a RADIUS security server on the device, the time parameter in radius-server deadtime does not take effect on the RADIUS server. If the active detection function is disabled for a RADIUS security server, the device automatically restores the RADIUS security server to the reachable state when the duration that the RADIUS security server is in the unreachable state exceeds the time specified in radius-server deadtime .

Configuration Example

✎ Configuring Accessibility Detection on the RADIUS Server

Scenario Figure 2-5	
Configuration Steps	- Configure the global criteria for judging that a RADIUS security server is unreachable. - Configure the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.
RADIUS Client	<pre>Ruijie(config)#radius-server dead-criteria time120 tries 5 Ruijie(config)# radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90</pre>
Verification	Disconnect the network communication between the device and the server with the IP address of 192.168.5.22. Conduct RADIUS authentication through the device. After 120 seconds, run the show radius server command to check that the server state is dead.
	<pre>Ruijie#show running-config ... radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90 radius-server dead-criteria time 120 tries 5 ...</pre>

2.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistics of the RADIUS dynamic authorization extension function and restarts statistics.	clear radius dynamic-authorization-extension statistics

Displaying

Description	Command
Displays global parameters of the RADIUS server.	show radius parameter
Displays the configuration of the RADIUS server.	show radius server
Displays the configuration of the RADIUS private attribute type.	show radius vendor-specific
Displays statistics relevant to the RADIUS dynamic authorization extension function.	show radius dynamic-authorization-extension statistics
Displays statistics relevant to RADIUS authentication.	show radius auth statistics
Displays statistics relevant to RADIUS accounting.	show radius acct statistics
Displays configuration of RADIUS server groups.	show radius group

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the RADIUS event.	debugradiusevent
Debugs RADIUS packet printing.	debugradiusdetail
Debugs the RADIUS dynamic authorization extension function.	debug radiusextension event
Debugs the RADIUS dynamic authorization extension packet printing.	debug radius extension detail

3 Configuring TACACS+

3.1 Overview

TACACS+ is a security protocol enhanced in functions based on the Terminal Access Controller Access Control System (TACACS) protocol. It is used to implement the authentication, authorization, and accounting (AAA) of multiple users.

Protocols and Standards

- RFC 1492 Terminal Access Controller Access Control System

3.2 Applications

Application	Description
Managing and Controlling Login of End Users	Password verification and authorization need to be conducted on end users.

3.2.1 Managing and Controlling Login of End Users

Scenario

TACACS+ is typically applied in the login management and control of end users. A network device serves as the TACACS+ client and sends a user name and password to the TACACS+ server for verification. The user is allowed to log in to the network device and perform operations after passing the verification and obtaining authorization. See the following figure.

Figure 3-1

Remarks	● A is a client that initiates TACACS+ requests. ● B, C, and D are servers that process TACACS+ requests.

Deployment

- Start the TACACS+ server on Server B, Server C, and Server D, and configure information on the access device (Device A) so that the servers provide TACACS+-based AAA function for the access device. Enable the AAA function on Device A to start authentication for the user login.
- Enable the TACACS+ client function on Device A, add the IP addresses of the TACACS+ servers (Server B, Server C, and Server D) and the shared key so that Device A communicates with the TACACS+ servers over TACACS+ to implement the AAA function.

3.3 Features

Basic Concepts

Format of TACACS+ Packets

Figure 3-2

4	8	16	24	32 bit
Major	Minor	Packet type	Sequence no.	Flags
Session ID				
Length				

- Major Version: Indicates the major TACACS+ version number.
- Minor Version: Indicates the minor TACACS+ version number.
- Packet Type: Indicates the type of packets, with the options including:
TAC_PLUS_AUTHEN: = 0x01 (authentication);
TAC_PLUS_AUTHOR: = 0x02 (authorization);
TAC_PLUS_ACCT: = 0x03 (accounting)
- Sequence Number: Indicates the sequence number of a data packet in the current session. The sequence number of the first TACACS+ data packet in a session must be 1 and the sequence number of subsequent each data packet increases by one. Therefore, the client sends data packets only with an odd sequence number and TACACS+ Daemon sends packets only with an even sequence number.
- Flags: Contains various bitmap format flags. One of the bits in the value specifies whether data packets need to be encrypted.
- Session ID: Indicates the ID of a TACACS+ session.
- Length: Indicates the body length of a TACACS+ data packet (excluding the header). Packets are encrypted for transmission on a network.

Overview

Feature	Description

TACACS+ Authentication, Authorization, and Accounting	Conducts authentication, authorization, and accounting on end users.

3.3.1 TACACS+ Authentication, Authorization, and Accounting

Working Principle

The following figure uses basic authentication, authorization, and accounting of user login to describe interaction of TACACS+ data packets.

Figure 3-3

The entire basic message interaction process includes three sections:

1. The authentication process is described as follows:
 - 1) A user requests to log in to a network device.
 - 2) After receiving the request, the TACACS+ client sends an authentication start packet to the TACACS+ server.
 - 3) The TACACS+ server returns an authentication response packet, requesting the user name.
 - 4) The TACACS+ client requests the user to enter the user name.

- 5) The user enters the login user name.
 - 6) After receiving the user name, the TACACS+ client sends an authentication continuation packet that carries the user name to the TACACS+ server.
 - 7) The TACACS+ server returns an authentication response packet, requesting the login password.
 - 8) The TACACS+ client requests the user to enter the login password.
 - 9) The user enters the login password.
 - 10) After receiving the login password, the TACACS+ client sends an authentication continuation packet that carries the login password to the TACACS+ server.
 - 11) The TACACS+ server returns an authentication response packet, prompting that the user passes authentication.
2. The user authorization starts after successful authentication:
 - 1) The TACACS+ client sends an authorization request packet to the TACACS+ server.
 - 2) The TACACS+ server returns an authorization response packet, prompting that the user passes authorization.
 - 3) After receiving the authorization success packet, the TACACS+ client outputs the network device configuration screen for the user.
3. Accounting and audit need to be conducted on the login user after successful authorization:
 - 1) The TACACS+ client sends an accounting start packet to the TACACS+ server.
 - 2) The TACACS+ server returns an accounting response packet, prompting that the accounting start packet has been received.
 - 3) The user logs out.
 - 4) The TACACS+ client sends an accounting end packet to the TACACS+ server.
 - 5) The TACACS+ server returns an accounting response packet, prompting that the accounting end packet has been received.

3.4 Configuration

Configuration	Description and Command	
Configuring TACACS+ Basic Functions	 (Mandatory) It is used to enable the TACACS+ security service.	
	tacacs-server host	Configures the TACACS+ server.
	tacacs-server key	Specifies the key shared by the server and network device.
	tacacs-server timeout	Configures the global waiting timeout time of the TACACS+ server for communication between a network device and the TACACS+ server.

Configuration	Description and Command	
Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+	 (Optional) It is used to separately process authentication, authorization, and accounting requests.	
	aaa group server tacacs+	Configures TACACS+ server groups and divides TACACS+ servers into different groups.
	nas-ip	Configures the source IP address for TACACS+ packets sent from the TACACS+ server group.
	server	Adds servers to TACACS+ server groups.

3.4.1 Configuring TACACS+ Basic Functions

Configuration Effect

- The TACACS+ basic functions are available after the configuration is complete. When configuring the AAA method list, specify the method of using TACACS+ to implement TACACS+ authentication, authorization, and accounting.
- When authentication, authorization, and accounting operations are performed, TACACS+ initiates the authentication, authorization, and accounting requests to configured TACACS+ servers according to the configured sequence. If response timeout occurs on a TACACS+ server, TACACS+ traverses the TACACS+ server list in sequence.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

📌 Enabling AAA

- Mandatory. The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Command	aaa new-model
Parameter	N/A
Description	
Defaults	The AAA function is disabled.
Command Mode	Global configuration mode
Usage Guide	The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Configuring the IP Address of the TACACS+ Server

- Mandatory. Otherwise, a device cannot communicate with the TACACS+ server to implement the AAA function.

Command	tacacs-server host [oob] [via <i>mgmt_name</i>] { <i>ipv4-address</i> <i>ipv6-address</i> } [port <i>integer</i>] [timeout <i>integer</i>] [key [0 7] <i>text-string</i>]
Parameter Description	<i>ipv4-address</i>: Indicates the IPv4 address of the TACACS+ server. <i>ipv6-address</i>: Indicates the IPv6 address of the TACACS+ server. oob: Uses an MGMT port as the source interface for communicating with the TACACS+ server. A non-MGMT port is used for communication by default. via <i>mgmt_name</i>: Specifies a specific MGMT port when oob supports multiple MGMT ports. port<i>integer</i>: Indicates the TCP port used for TACACS+ communication. The default TCP port is 49. timeout <i>integer</i>: Indicates the timeout time of the communication with the TACACS+ server. The global timeout time is used by default. key [0 7] <i>text-string</i>: Indicates the shared key of the server. The global key is used if it is not configured. An encryption type can be specified for the configured key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.
Defaults	No TACACS+ server is configured.
Command Mode	Global configuration mode
Usage Guide	1. You can specify the shared key of the server when configuring the IP address of the server. If no shared key is specified, the global key configured using the tacacs-server key command is used as the shared key of the server. The shared key must be completely the same as that configured on the server. 2. You can specify the communication port of the server when configuring the IP address. 3. You can specify the communication timeout time of the server when configuring the IP address.

Configuring the Shared Key of the TACACS+ Server

- Optional.
- If no global communication protocol is configured using this command, set **key** to specify the shared key of the server when running the **tacacs-server host** command to add server information. Otherwise, a device cannot communicate with the TACACS+ server.
- If no shared key is specified by using **key** when you run the **tacacs-server host** command to add server information, the global key is used.

Command	tacacs-server [key [0 7] <i>text-string</i>]
Parameter Description	<i>text-string</i>: Indicates the text of the shared key. 0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption.
Defaults	No shared key is configured for any TACACS+ server.
Command Mode	Global configuration mode

Usage Guide	This command is used to configure a global shared key for servers. To specify a different key for each server, set key when running the tacacs-server host command.

✚ Configuring the Timeout Time of the TACACS+ Server

- Optional.
- You can set the timeout time to a large value when the link between the device and the server is unstable.

Command	tacacs-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the global server response timeout time. To set different timeout time for each server, set timeout when running the tacacs-server host command.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable the device to interact with the TACACS+ server and conduct packet capture to check the TACACS+ interaction process between the device and the TACACS+ server.
- View server logs to check whether the authentication, authorization, and accounting are normal.

Configuration Example

✚ Using TACACS+ for Login Authentication

Scenario Figure 3-4	 <pre> graph LR User[Laptop] --- A[A: TACACS+ Client] A --- B[B: TACACS+ Server 192.168.5.22] </pre>
Remarks	● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ requests.
Configuration Steps	● Enable AAA. ● Configure the TACACS+ server information. ● Configure the method of using TACACS+ for authentication.

	● Apply the configured authentication method on an interface.
A	<pre> Ruijie# configure terminal Ruijie(config)# aaa new-model Ruijie(config)# tacacs-server host 192.168.5.22 Ruijie(config)# tacacs-server key aaa Ruijie(config)# aaa authentication login test group tacacs+ Ruijie(config)# line vty 0 4 Ruijie(config-line)# login authentication test </pre>
Verification	Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. View the authentication log of the user on the TACACS+ server.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- No method list is configured.

3.4.2 Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+

Configuration Effect

- The authentication, authorization, and accounting in the security service are processed by different TACACS+ servers, which improves security and achieves load balancing to a certain extent.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

📌 Configuring TACACS+ Server Groups

- Mandatory. There is only one TACACS+ server group by default, which cannot implement separate processing of authentication, authorization, and accounting.
- Three TACACS+ server groups need to be configured for separately processing authentication, authorization, and accounting.

Command	aaa group server tacacs+group-name
Parameter Description	<i>group-name</i> : Indicates the name of a group. A group name cannot be radius or tacacs+, which are the names of embedded groups.
Defaults	No TACACS+ server group is configured.
Command Mode	Global configuration mode
Usage Guide	Group TACACS+ servers so that authentication, authorization, and accounting are completed by different server groups.

✚ Adding Servers to TACACS+ Server Groups

- Mandatory. If no server is added to a server group, a device cannot communicate with TACACS+ servers.
- In server group configuration mode, add the servers that are configured using the **tacacs-server host** command.

Command	server { ipv4-address ipv6-address }
Parameter Description	<i>ipv4-address</i> : Indicates the IPv4 address of the TACACS+ server. <i>ipv6-address</i> : Indicates the IPv6 address of the TACACS+ server.
Defaults	No server is configured.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For the address of a server configured in a TACACS+ server group, the server must be configured using the tacacs-server host command in global configuration mode. If multiple servers are added to one server group, when one server does not respond, the device continues to send a TACACS+ request to another server in the server group.

✚ Configuring the Source IP Address for TACACS+ Packets Sent from the TACACS+ Server Group

Command	nas-ip {ipv4-address ipv6-address}
Parameter Description	<i>ipv4-address</i> : Indicates the source IPv4 address for the TACACS+ packets. <i>ipv6-address</i> : Indicates the source IPv6 address for the TACACS+ packets.
Defaults	No source IP address is configured.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode.

✚ Configuring VRF of a TACACS+ Server Group

- Optional. Configure Virtual Routing and Forwarding (VRF) if a device needs to send TACACS+ packets through a specified address.
- In server group configuration mode, use a configured VRF name to specify the routing for the communication of servers in this group.

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the VRF name.
Defaults	No VRF is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For VRF configured in a TACACS+ server group, a valid name must be configured for VRF by using the vrf definition command in global configuration mode.

↘ Configuring oob of a TACACS+ Server Group

- Optional. Configure oob if a device needs to send TACACS+ packets through a specified MGMT port.
- In server group configuration mode, specify routing for the communication of servers in the group.

Command	ip oob via <i>mgmt_name</i>
Parameter Description	<i>mgmt-name</i> : Indicates the name of a management port.
Defaults	No oob is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. If no MGMT port is specified, the MGMT0 port is used by default.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable a device to interact with TACACS+ servers. Conduct packet capture, check that the authentication, authorization, and accounting packets are interacted with different servers, and check the source addresses in packets.

Configuration Example

Configuring Different TACACS+ Server Groups for Separately Processing Authentication, Authorization, and Accounting

Scenario Figure 3-5	The diagram illustrates a network setup for TACACS+ services. A User (represented by a laptop icon) is connected to a TACACS+ Client, labeled 'A' (represented by a switch icon). This client 'A' is then connected to a group of three TACACS+ Servers, labeled 'B', 'C', and 'D' (represented by server rack icons). Server B has the IP address 192.168.5.22, Server C has 192.168.5.34, and Server D has 192.168.5.44. The servers are collectively labeled as 'TACACS+ Server'.
Remarks	● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ authentication requests. ● C is a server that processes TACACS+ authorization requests. ● D is a server that processes TACACS+ accounting requests.
Configuration Steps	● Enable AAA. ● Configure the TACACS+ server information. ● Configure TACACS+ server groups. ● Add servers to TACACS+ server groups. ● Configure the method of using TACACS+ for authentication. ● Configure the method of using TACACS+ for authorization. ● Configure the method of using TACACS+ for accounting. ● Apply the configured authentication method on an interface. ● Apply the configured authorization method on an interface. ● Apply the configured accounting method on an interface.
	<pre> Ruijie# configure terminal Ruijie(Ruijie(config)# aaa new-model Ruijie(config)# tacacs-server host 192.168.5.22 Ruijie(config)# tacacs-server host 192.168.5.34 Ruijie(config)# tacacs-server host 192.168.5.44 Ruijie(config)# tacacs-server key aaa Ruijie(config)# aaa group server tacacs+ tacgrp1 Ruijie(config-gs-tacacs)# server 192.168.5.22 </pre>

	<pre> Ruijie(config-gs-tacacs)# exit Ruijie(config)# aaa group server tacacs+ tacgrp2 Ruijie(config-gs-tacacs)# server 192.168.5.34 Ruijie(config-gs-tacacs)# exit Ruijie(config)# aaa group server tacacs+ tacgrp3 Ruijie(config-gs-tacacs)# server 192.168.5.44 Ruijie(config-gs-tacacs)# exit Ruijie(config)# aaa authentication login test1 group tacacs+ Ruijie(config)# aaa authentication enable default group tacgrp1 Ruijie(config)# aaa authorization exec test2 group tacgrp2 Ruijie(config)# aaa accounting commands 15 test3 start-stop group tacgrp3 Ruijie(config)# line vty 0 4 Ruijie(config-line)# login authentication test1 Ruijie(config-line)# authorization exec test2 Ruijie(config-line)# accounting commands 15 test3 </pre>
Verification	Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. Enter the enable command and enter the correct enable password to initiate enable authentication. Enter the privilege EXEC mode after passing the authentication. Perform operations on the device and then exit the device. View the authentication log of the user on the server with the IP address of 192.168.5.22. View the enable authentication log of the user on the server with the IP address of 192.168.5.22. View the exec authorization log of the user on the server with the IP address of 192.168.5.34. View the command accounting log of the user on the server with the IP address of 192.168.5.44.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- Undefined servers are added to a server group.
- No method list is configured.

3.5 Monitoring

Displaying

Description	Command
Displays interaction with each TACACS+ server.	show tacacs

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs TACACS+.	debug tacacs+

4 Configuring SCC

4.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services, so that these access control and network security services can coexist on one device to meet diversified access and security control requirements in various scenarios.

Typical access control services are Address Resolution Protocol (ARP) check, and IP Source Guard. The network security services include Access Control List (ACL), Network Foundation Protection Policy (NFPP), and anti-ARP gateway spoofing. When two or more access control or network security services are simultaneously enabled on the device, or when both access control and network security services are simultaneously enabled on the device, the SCC coordinates the coexistence of these services according to relevant policies.

 For details about the access control and network security services, see the related configuration guide. This document describes the SCC only.

Protocol and Standards

N/A

4.2 Application

Typical Application	Scenario
Access Control of Extended Layer 2 Campus Networks	Students on a campus network can access the Internet based on dot1x client authentication or Web authentication. ARP spoofing between the students should be prevented. In addition, terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

4.2.1 Access Control of Extended Layer 2 Campus Networks

Scenario

Students on a campus network of a university usually need to be authenticated through the dot1x client or Web before accessing the Internet, so as to facilitate accounting and guarantee the benefits of the university.

- The students can access the Internet through dot1x client authentication or Web authentication.
- ARP spoofing between the students is prevented, so as to guarantee the stability of the network.
- Terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

Figure 4-1

Remarks	A traditional campus network is hierarchically designed, which consists of an access layer, a convergence layer and a core layer, where the access layer performs user access control. On an extended Layer 2 campus network, however, user access control is performed by a core switch, below which access switches exist without involving any convergence device in between. The ports between the core switch and the access switches (such as switches B, C, and D in Figure 1-1) are all trunk ports. The user access switches B, C, and D connect to PCs in various departments via access ports, and VLANs correspond to sub VLANs configured on the downlink ports of the core switch, so that access users are in different VLANs to prevent ARP spoofing. The core switch A connects to various servers, such as the authentication server and the DHCP server. Super VLANs and sub VLANs are configured on the downlink ports. One super VLAN correspond to multiple sub VLANs, and each sub VLAN represents an access user.

Deployment

On the core switch, different access users are identified by VLAN and port numbers. Each access user (or a group of access users) corresponds to one VLAN. The ports on each access switch that connect to downstream users are configured as access ports, and one user VLAN is assigned to each access user according to VLAN planning. The core switch does not forward ARP requests. The core switch replies to the ARP requests from authenticated users only, so as to prevent ARP spoofing. On the core switch A, user VLANs are regarded as sub VLANs, super VLANs are configured, and SVIs corresponding to the super VLANs are configured as user gateways.

- On the downlink ports of the core switch (switch A in this example) that connect to the teachers' living area and the students' living area, both dot1x authentication and Web authentication are enabled, so that users can freely select either authentication mode for Internet access.
- Any special department (such as the headmaster's office in this example) can be allocated to a particular VLAN, and this VLAN can be configured as an authentication-exemption VLAN so that users in this department can access the Internet without authentication.

4.3 Basic Concepts

Authentication Mode

There are two authentication modes: access authentication and gateway authentication. On a traditional hierarchical network, access authentication is usually performed by access switches. On an extended Layer 2 network, the access function moves forward to a core switch while the access devices need only to support basic VLAN and Layer 2 forwarding functions. As the access authentication is performed by access switches on a traditional hierarchical network while performed by a core switch on a de-layered extended Layer 2 network, some extrinsic functions and behaviors will differ accordingly with the two different authentication modes. Therefore, the authentication mode falls into gateway authentication and access authentication. If the access authentication moves to the core switch, the core switch needs to be enabled with the gateway authentication mode to support a large number of user entries, typically including a large-capacity MAC address table, ARP table and routing table. Otherwise, the supported user capacity is subject to hardware ACL entry restrictions. In general, the capacity of hardware ACL entries is limited and cannot support a large user capacity. The access authentication mode is generally applicable only in scenarios where the access authentication is deployed on access switches.

Authentication-Exemption VLAN

Some special departments may be allocated to authentication-exemption VLANs to simplify network management, so that users in these departments can access network resources without authentication. For example, the headmaster's office can be divided into the authentication-exemption VLANs on the campus network, so that users in the headmaster's office can access the Internet without authentication.

IPv4 User Capacity

The number of IPv4 access users can be restricted to protect the access stability of online users on the Internet and improve the operational stability of the device.

The number of IPv4 access users is not restricted by default; that is, a large number of users can get online after being authenticated, till reaching the maximum hardware capacity of the device.

Authenticated-User Migration

Online-user migration means that an online user can get authenticated again from different physical locations to access the network. On the campus network, however, for ease of management, students are usually requested to get authenticated from a specified location before accessing the Internet, but cannot get authenticated on other access ports. This means that the users cannot migrate. In another case, some users have the mobile office requirement and can get authenticated from different access locations. Then the users can migrate.

User Online-Status Detection

For a chargeable user, accounting starts immediately after the user passes the authentication and gets online. The accounting process does not end until the user actively gets offline. Some users, however, forget to get offline when leaving their PCs, or cannot get offline because of terminal problems. Then the users suffer certain economical losses as the accounting process continues. To more precisely determine whether a user is really online, we can preset a traffic value, so that the user is considered as not accessing the Internet and therefore directly brought offline when the user's traffic is lower than the preset value in a period of time or there is not traffic of the user at all in a period of time.

Features

Feature	Function
Authentication Mode	This feature determines whether access control is deployed on access switches or core switches depending on network deployment needs.
Authentication-Exemption VLAN	Users in a specified VLAN can be configured as authentication-exemption users.
IPv4 User Capacity	The IPv4 user capacity of a specified interface can be restricted to guarantee the access stability of users on the Internet.
Authenticated-User Migration	You can specify whether the authenticated can migrate.
User Online-Status Detection	You can specify whether to detect the traffic of online users, so that a user is forced offline when the traffic of the user is lower than a preset value in a period of time.

4.3.1 Authentication Mode

There are two authentication modes: access authentication and gateway authentication. In access authentication mode, access control is enabled on access switches. In gateway authentication mode, access control is enabled on core switches. On a large-scale network such as a campus network, there are hundreds of access switches. Compared with the access authentication mode, the gateway authentication mode simplifies the routine maintenance and management on the access switches, because the access switches need only to support basic VLAN and Layer 2 forwarding functions. Therefore, the gateway authentication mode is recommended.

Working Principle

The authentication mode on a device depends on the network layer where the access control device works. If access control is deployed on core switches (for example, on an extended Layer 2 network), gateway authentication mode on core switches is required. If access control is deployed on access switches, the authentication mode should be set to access authentication on the access switches.

The access authentication mode applies by default. In addition, only the N18000 switches support authentication mode switching.

Restart the device after the authentication mode is changed, so that the new authentication mode takes effect. Save the current configuration before restarting the device.

4.3.2 Authentication-Exemption VLAN

Authentication-exemption VLANs are used to accommodate departments with special access requirements, so that users in these departments can access the Internet without authentication such as dot1x or Web authentication.

Working Principle

Suppose the authentication-exemption VLAN feature is enabled on a device. When the device detects that a packet comes from an authentication-exemption VLAN, access control is not performed. In this way, users in the authentication-exemption VLAN can access the Internet without authentication. The authentication-exemption VLAN feature can be regarded as a kind of applications of secure channels.

-
-  Only the switches support the authentication-exemption VLAN feature.
 -  A maximum of 100 authentication-exemption VLANs can be configured.
 -  The authentication-exemption VLANs occupy hardware entries. When access control such as authentication is disabled, configuring authentication-exemption VLANs has the same effect as the case where no authentication-exemption VLANs are configured. Therefore, it is recommended that authentication-exemption VLANs be configured for users who need to access the Internet without authentication, only when the access control function has been enabled.
 -  Although packets from authentication-exemption VLANs are exempt from access control, they still need to be checked by a security ACL. If the packets of the users in an authentication-exemption VLAN are denied according to the security ACL, the users still cannot access the Internet.
 -  In gateway authentication mode, the device does not initiate any ARP request to a user in an authentication-exemption VLAN, and the ARP proxy will not work. Therefore, in gateway authentication mode, users in different authentication-exemption VLANs cannot access each other unless the users have been authenticated.
-

4.3.3 IPv4 User Capacity

To improve the operational stability of the device and guard against brutal force impacts from unauthorized users, you can restrict the total number of IPv4 access users on a certain port of the device.

Working Principle

If the total number of IPv4 access users is restricted, new users going beyond the total number cannot access the Internet.

-
-  Only the switches support the restriction on the number of IPv4 access users.
 -  The number of IPv4 access users is not restricted on the device by default, but depends on the hardware capacity of the device.
 -  The number of IPv4 access users includes the IPv4 authenticated users based on dot1x authentication, IPv4 users based on Web authentication, and IPv4 users based on various binding functions. Because the number of IPv4 access users is configured in interface configuration mode, the restriction includes both the number of IPv4 users generated on the port and IPv4 users globally generated. For example, you can set the maximum number of IPv4 access users on the Gi 0/1 port to 2, run commands to bind an IPv4 user to the port, and then run commands to bind a global IPv4 user to the port. Actually there are already two access users on the port. If you attempt to bind another IPv4 user or another global IPv4 user to the port, the binding operation fails.
-

4.3.4 Authenticated-User Migration

On an actual network, users do not necessarily access the Internet from a fixed place. Instead, users may be transferred to another department or office after getting authenticated at one place. They do not actively get offline but remove network cables and carry their mobile terminals to the new office to access the network. Then this brings about an issue about authenticated-user migration. If authenticated-user migration is not configured, a user who gets online at one place cannot get online at another place without getting offline first.

Working Principle

When authenticated-user migration is enabled, the dot1x or Web authentication module of the device detects that the port number or VLAN corresponding to a user's MAC address has changed. Then the user is forced offline and needs to be authenticated again before getting online.

-
-  Only the switches or wireless devices support authenticated-user migration. In addition, cross-switch migration is not supported. For example, authentication and migration are enabled on two N18000, and a user gets online after being authenticated on one of the two N18000. If the user attempts to migrate to the other N18000, the migration fails.
 -  The authenticated-user migration function requires a check of users' MAC addresses, and is invalid for users who have IP addresses only.
 -  The authenticated-user migration function enables a user who gets online at one place to get online at another place without getting offline first. If the user gets online at one place and then gets offline at that place, or if the user does not get online before moving to another place, the situation is beyond the control range of authenticated-user migration.
 -  During migration, the system checks whether the VLAN ID or port number that corresponds to a user's MAC address has changed, so as to determine whether the user has migrated. If the VLAN ID or port number is the same, it indicates that the user does not migrate; otherwise, it indicates that the user has migrated. According to the preceding principle, if another user on the network uses the MAC address of an online user, the system will wrongly disconnect the online user unless extra judgment is made.
-

4.3.5 User Online-Status Detection

After a user accesses the Internet, the user may forget to get offline or cannot actively get offline due to terminal faults. In this case, the user will keep being charged and therefore will suffer a certain economical loss. To protect the benefits of users on the Internet, the device provides a function to detect whether the users are really online. If the device considers that a user is not online, the device actively disconnects the user.

Working Principle

A specific detection interval is preset on the device. If a user's traffic is lower than a certain value in this interval, the device considers that the user is not using the network and therefore directly disconnects the user.

-
-  Only the switches and wireless devices support the user online-status detection function.
 -  Currently, the N18000 supports zero-traffic detection only.
 -  Currently, due to hardware chip restrictions of the N18000, the time to disconnect a user without any traffic relates to the configured MAC address aging time. If the traffic detection interval is set to m minutes and the MAC address aging time

is set to n minutes, the interval from the moment when an authenticated user leaves the network without actively getting offline to the moment when the user is disconnected upon detection of zero traffic is about $[m, m+n]$ minutes. In other words, if an online user does not incur any Internet access traffic, the user is disconnected about $[m, m+n]$ minutes later.

4.4 Configuration

Configuration Item	Suggestions and Related Commands	
Configuring the Authentication Mode	 Optional configuration, which is used to configure the authentication mode for the device.	
	[no] auth-mode gateway	Configures the authentication mode.
Configuring Authentication-Exemption VLANs	 Optional configuration, which is used to specify the users of which VLANs can access the Internet without authentication.	
	[no] direct-vlan	Configures authentication-exemption VLANs.
Configuring the IPv4 User Capacity	 Optional configuration, which is used to specify the maximum number of users who are allowed to access a certain interface.	
	[no] nac-author-user maximum	Configures the number of IPv4 users who are allowed to access a certain interface.
Configuring Authenticated-User Migration	 Optional configuration, which is used to specify whether online users with static MAC addresses can migrate.	
	[no] station-move permit	Configures whether authenticated users can migrate.
Configuring User Online-Status Detection	 Optional configuration, which is used to specify whether to enable the user online-status detection function.	
	offline-detect interval threshold	Configures the parameters of the user online-status detection function.
	no offline-detect	Disables the user online-status detection function.
	default offline-detect	Restores the default user online-status detection mode.

4.4.1 Configuring the Authentication Mode

Configuration Effect

Perform this configuration or not perform this configuration, which shall depend on actual network deployment. On a hierarchical network, access switches perform access control and you do not need to specify the authentication mode but can simply keep the default configuration. On a de-layered extended Layer 2 network, the gateway device performs access control and then you need to set the authentication mode to gateway authentication, so that users can be authenticated and get online after the access control service such as dot1x or Web authentication is enabled on the gateway device.

Precautions

- If access control is deployed on the core switch, you need to change the authentication mode on the core switch to gateway authentication. If access control is not deployed on the core switch, you do not need to configure the authentication mode.
- You need to restart the device after the authentication mode is changed, so that the new authentication mode takes effect. Save the current configuration before restarting the device.

Configuration Method

Configuring the Authentication Mode

- Optional configuration. It determines the access position of the device on the actual network.
- Perform the configuration according to actual network deployment. If the core switch performs access control, set the authentication mode to gateway authentication on the core switch; otherwise, simply keep the default configuration.

Command	[no] auth-mode gateway
Parameter Description	no: If the command carries this parameter, it indicates that the authentication mode is restored to access authentication; that is, the local device is only an access device and not a gateway device any longer. auth-mode gateway: If the command carries this parameter, it indicates that the authentication mode is set to gateway authentication; that is, the local device is both a gateway device and an access device.
Defaults	Access authentication mode
Command Mode	Global configuration mode
Usage Guide	Use this command to determine the access position of the device on the network. Perform this configuration or not perform this configuration, which depends on whether the access control function is deployed on access switches on the network or deployed on the gateway device. Use this command to change the authentication mode configured on the device from access authentication to gateway authentication. Use the no auth-mode gateway command to change the authentication mode configured on the device from gateway authentication back to access authentication.

Verification

Check the configuration using the following method:

- Enable dot1x or Web authentication on one port of the device, and perform corresponding authentication on the client. After getting online, check whether you can access network resources. Then get offline, and check whether you cannot access specified network resources.

Configuration Examples

The following configuration example describes SCC-related configuration only.

Setting the Authentication Mode to Gateway Authentication so that the Access Control Function Moves Up to the Core Gateway Device on a De-layered extended Layer 2 Network

Scenario
Figure 4-2

Configuration Steps

- On switch A (which is a core gateway device), set the authentication mode to gateway authentication.

Switch A

```
SwitchA(config)#auth-mode gateway
Please save config and reload system.
SwitchA(config)#exit
*Nov 7 10:13:27: %SYS-5-CONFIG_I: Configured from console by console
SwitchA#reload
Reload system?(Y/N)y
SwitchA#
```

Verification

- Use the **show running** command to check whether the configuration has taken effect.

Switch A

```
SwitchA(config)#show running-config | include auth-mode
auth-mode gateway
SwitchA(config)#
```

4.4.2 Configuring Authentication-Exemption VLANs

Configuration Effect

Configure authentication-exemption VLANs, so that users in these VLANs can access the Internet without experiencing dot1x or Web authentication.

Notices

Authentication-exemption VLANs only mean that users in these VLANs do not need to experience a check related to access authentication, but still need to experience a check based on a security ACL. If specified users or VLANs are denied according to the security ACL, corresponding users still cannot access the Internet. Therefore, during ACL configuration, you need to ensure that specified VLANs or specified users in the authentication-exemption VLANs are not blocked if you hope that users in the authentication-exemption VLANs can access the Internet without being authenticated.

Configuration Steps

Configuring Authentication-Exemption VLANs

- Optional configuration. To spare all users in certain VLANs from dot1x or Web authentication, configure these VLANs as authentication-exemption VLANs.
- Perform this configuration on access, convergence, or core switches depending on user distribution.

Command	[no] direct-vlan <i>vlanlist</i>
Parameter Description	no: If the command carries this parameter, it indicates that the authentication-exemption VLAN configuration will be deleted. vlanlist: This parameter indicates the list of authentication-exemption VLANs to be configured or deleted.
Defaults	No authentication-exemption VLAN has been configured.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure or delete authentication-exemption VLANs.

Verification

Check the authentication-exemption VLAN configuration using the following method:

- Enable dot1x authentication on downlink ports that connect to user terminals, add the downlink ports that connect to the user terminals to a specific VLAN, and configure the VLAN as an authentication-exemption VLAN. Then open the Internet Explorer, and enter a valid extranet address (such as www.baidu.com). If the users can open the corresponding webpage on the Internet, it indicates that the authentication-exemption VLAN is valid; otherwise, the authentication-exemption VLAN does not take effect.
- Use the **show direct-vlan** command to check the authentication-exemption VLAN configuration on the device.

Command	show direct-vlan
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Global configuration mode

Usage
Example

```
Ruijie#show direct-vlan  
  
direct-vlan 100
```

Configuration Examples

 The following configuration example describes SCC-related configuration only.

Configuring Authentication-exemption VLANs so that Specific Users Can Access the Internet Without Being Authenticated

Scenario Figure 4-3	
Configuration Steps	- On switch A (which is the core gateway device), set the GI 2/1 port as a trunk port, and enable dot1x authentication on this port. - On switch A (which is the core gateway device), configure VLAN 100 to which the headmaster's office belongs as an authentication-exemption VLAN.
Switch A	<pre>SwitchA(config)#vlan 100 SwitchA(config-vlan)#exit SwitchA(config)#direct-vlan 100 SwitchA(config)#int GigabitEthernet 0/1 SwitchA(config-if-GigabitEthernet 0/1)#switchport mode trunk</pre>

Verification	● Open the Internet Explorer from any PC in the headmaster's office, enter a valid extranet address, and confirm that the corresponding webpage can be opened. ● Use the show direct-vlan command to check whether the authentication-exemption VLAN is valid.
Switch A	<pre>SwitchA(config)#show direct-vlan direct-vlan 100</pre>

4.4.3 Configuring the IPv4 User Capacity

Configuration Effect

Configure the IPv4 user capacity, so as to restrict the number of users who are allowed to access an access port.

Precautions

N/A

Configuration Method

Configuring the IPv4 User Capacity

- Optional configuration. To limit the maximum of users who are allowed to access an access port, configure the IPv4 user capacity. The access user capacity is not limited on an access port by default. Suppose the user capacity limit is configured on a specific interface. When the number of authenticated users on the interface reaches the maximum, new users cannot be authenticated on this interface and cannot get online, until existing authenticated users get offline on the interface.
- Perform this configuration on access switches, which may be access switches on the network edge or core gateway devices.

Command	nac-author-user maximum <i>max-user-num</i> no nac-author-user maximum
Parameter Description	no: If the command carries this parameter, it indicates that the limit on the IPv4 access user capacity will be removed from the port. <i>max-user-num:</i> This parameter indicates the maximum number of IPv4 users who allowed to access the port. The value range is from 1 to 1024.
Defaults	The number of IPv4 access users is not limited.
Command Mode	Interface configuration mode
Usage Guide	Use this command to limit the number of IPv4 access users on a specific access port.

Verification

Check the IPv4 user capacity configuration on a port using the following method:

- dot1x authentication: When the number of users who get online based on 1x client authentication on the port reaches the specified user capacity, no any new user can get online from this port.
- Web authentication: When the number of users who get online based on Web authentication on the port reaches the specified user capacity, no any new user can get online from this port.
- Use the **show nac-author-user [interface interface-name]** command to check the IPv4 user capacity configured on the device.

Command	show nac-author-user [interface interface-name]									
Parameter Description	interface-name: This parameter indicates the interface name.									
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode									
Usage Guide	Global configuration mode									
Usage Example	<pre>Ruijie#show nac-author-user interface GigabitEthernet 0/1</pre> <table><thead><tr><th>Port</th><th>Cur_num</th><th>Max_num</th></tr><tr><th>-----</th><th>-----</th><th>-----</th></tr></thead><tbody><tr><td>Gi0/1</td><td>0</td><td>4</td></tr></tbody></table>	Port	Cur_num	Max_num	-----	-----	-----	Gi0/1	0	4
Port	Cur_num	Max_num								
-----	-----	-----								
Gi0/1	0	4								

Configuration Examples

 The following configuration example describes SCC-related configuration only.

Restricting the Number of IP4 Users on a Port to Prevent Excessive Access Terminals from Impacting the Network

Scenario Figure 4-4	
Configuration Steps	● Assume that the dot1x authentication environment has been well configured on the access switch A, and dot1x authentication is enabled on the Gi 0/2 port. ● Set the maximum number of IPv4 access users on the Gi 0/2 port to 4.

Switch A	<pre>SwitchA(config)#int GigabitEthernet 0/2 SwitchA(config-if-GigabitEthernet 0/2)#nac-author-user maximum 4</pre>									
Verification	● Perform dot1x authentication for all the four PCs in the dormitory, so that the PCs get online. Then take an additional terminal to access the network, and attempt to perform dot1x authentication for this terminal. Verify that the terminal cannot be successfully authenticated to get online. ● Use the show nac-author-user command to check whether the configuration has taken effect.									
Switch A	<pre>SwitchA(config)#show nac-author-user</pre> <table><thead><tr><th>Port</th><th>Cur_num</th><th>Max_num</th></tr></thead><tbody><tr><td>-----</td><td>-----</td><td>-----</td></tr><tr><td>Gi0/1</td><td>0</td><td>4</td></tr></tbody></table>	Port	Cur_num	Max_num	-----	-----	-----	Gi0/1	0	4
Port	Cur_num	Max_num								
-----	-----	-----								
Gi0/1	0	4								

4.4.4 Configuring Authenticated-User Migration

Configuration Effect

By default, when a user gets online after passing dot1x or Web authentication at a physical location (which is represented by a specific access port plus the VLAN number) and quickly moves to another physical location without getting offline, the user cannot get online through dot1x or Web authentication from the new physical location, unless the authenticated-user migration feature has been configured in advance.

Precautions

- If the authenticated-user migration feature is not yet configured, an online user cannot get online from the new physical location after quickly moving from one physical location to another physical location without getting offline first. However, if the user gets offline before changing the physical location or gets offline during the location change (for example, the user online-status detection function disconnects the user), the user can still normally get online after being authenticated at the new physical location, even if the authenticated-user migration feature is not configured.
- After moving to the new physical location, the online user needs to perform dot1x or Web authentication so as to get online.

Configuration Method

Configuring Authenticated-User Migration

- Optional configuration. To allow users to be authenticated and get online from different physical locations, enable the authenticated-user migration function.
- Perform this configuration on access, convergence, or core switches depending on user distribution.

Command	[no] station-move permit
Parameter	no station-move permit: Indicates that authenticated-user migration is not permitted.

Description	station-move permit: Indicates that authenticated-user migration is permitted.
Defaults	Authenticated-user migration is not permitted; that is, when a user getting online from one physical location on the network moves to another physical location and attempts to get online from the new physical location without getting offline first, the authentication fails and the user cannot get online from the new physical location.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure authenticated-user migration.

Verification

Check the authenticated-user migration configuration using the following method:

- A PC is authenticated and gets online from a dot1x-based port of the device using dot1x SU client, and does not actively get offline. Move the PC to another port of the device on which dot1x authentication is enabled, and perform dot1x authentication again. Check whether the PC can successfully get online.

Configuration Examples

 The following configuration example describes SCC-related configuration only.

Configuring Online-User Migration so that an Online User Can Perform Authentication and Get Online from Different Ports Without Getting Offline First

Scenario Figure 4-5	
Configuration Steps	● Enable dot1x authentication on access ports Gi 0/2 and Gi 0/3, and configure authentication parameters. The authentication is MAC-based.

	Configure online-user migration.
Switch A	swl(config)#station-move permit
Verification	A lap-top PC in the R&D department performs authentication using dot1x SU client, and gets online. Remove the network cable from the PC, connect the PC to the LAN where the test department resides, and perform dot1x authentication for the PC again using dot1x SU client. Confirm that the PC can successfully get online.
Switch A	swl(config)#show running-config include station station-move permit

4.4.5 Configuring User Online-Status Detection

Configuration Effect

After the user online-status detection function is enabled, if a user's traffic is lower than a certain threshold within the specified period of time, the device automatically disconnects the user, so as to avoid the economical loss incurred by constant charging to the user.

Precautions

It should be noted that if disconnecting zero-traffic users is configured, generally software such as 360 Security Guard will run on a user terminal by default. Then such software will send packets time and again, and the device will disconnect the user only when the user's terminal is powered off.

Configuration Method

Configuring User Online-Status Detection

- Optional configuration. A user is disconnected if the user does not involve any traffic within eight hours by default.
- Perform this configuration on access, convergence, or core switches depending on user distribution. The configuration acts on only the configured device instead of other devices on the network.
- If the traffic threshold parameter threshold is set to 0, it indicates that zero-traffic detection will be performed.

Command	offline-detect interval <i>interval</i> threshold <i>threshold</i> no offline-detect default offline-detect
Parameter Description	<i>interval</i> : This parameter indicates the offline-detection interval. The value range is from 6 to 65535 in minutes on a switch or from 1 to 65535 in minutes on a non-switch device. The default value is 8 hours, that is, 480 minutes. <i>threshold</i> : This parameter indicates the traffic threshold. The value range is from 0 to 4294967294 in bytes. The default value is 0, indicating that the user is disconnected when no traffic of the user is detected. no offline-detect : Disables the user online-status detection function.

	default offline-detect: Restores the default value. In other words, an online user will be disconnected when the device detects that the user does not have any traffic within eight hours.
Defaults	8 hours
Command Mode	Global configuration mode
Usage Guide	Use this command to configure user online-status detection, so that a user is disconnected when its traffic is lower than a specific threshold within a specific period of time. Use the no offline-detect command to disable the user online-status detection function, or use the default offline-detect command to restore the default detection mode.

Verification

Check the user online-status detection configuration using the following method:

- After the user online-status detection function is enabled, power off the specified authenticated terminal after the corresponding user gets online. Then wait for the specified period of time, and run the online user query command associated with dot1x or Web authentication on the device to confirm that the user is already offline.

Configuration Examples

 The following configuration example describes SCC-related configuration only.

Configuring User Online-Status Detection so that a User Is Disconnected if the User Does Not Have Traffic Within Five Minutes

Scenario Figure 4-6	
Configuration Steps	Enable dot1x authentication on the access port Gi 0/2, and configure authentication parameters. The

	authentication is MAC-based. ● Configure user online-status detection so that a user is disconnected if the user does not have traffic within five minutes.
Switch A	<pre>sw1(config)# offline-detect interval 5 threshold 0</pre>
Verification	● Perform dot1x authentication using dot1x SU client for a PC in the R&D department, so that the PC gets online. Then power off the PC, wait for 6 minutes, and run the online user query command available with dot1x authentication on switch 1 to confirm that the user of the PC is already offline.
Switch A	<pre>sw1(config)#show running-config include offline-detect offline-detect interval 5</pre>

4.5 Monitoring

Displaying

Command	Function
show direct-vlan	Displays the authentication-exemption VLAN configuration.
show nac-author-user [interface <i>interface-name</i>]	Displays information about IPv4 user entries on a specific interface.

Debugging

 System resources are occupied when debugging information is output. Therefore, close the debugging switch immediately after use.

Command	Function
debug scc event	Debugs the SCC running process.
debug scc user [mac author mac]	Debugs SCC user entries.
debug scc acl-show summary	Debugs ACLs stored in the current SCC and delivered by various services.
debug scc acl-show all	Debugs all ALCs stored in the current SCC.

5 Configuring Global IP-MAC Binding

5.1 Overview

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

The address bounding feature is used to verify the input packets. Note that the address binding feature takes precedence over the 802.1X authentication, port security, and access control list (ACL).

5.2 Applications

Application	Description
Global IP-MAC Binding	Only hosts with the specified IP addresses can access the network, and the hosts connected to a device can move freely.

5.2.1 Global IP-MAC Binding

Scenario

- The administrator assigns a fixed IP address for each host to facilitate management.
- Only hosts with the specified IP addresses can access the external network, which prevents IP address embezzlement by unauthorized hosts.
 - Hosts can move freely under the same device.

Figure 5-1

Remarks	A is an access device. A user is a host configured with a static IP address. IP Network is an external IP network.

Deployment

- Manually configure the global IP-MAC binding. (Take three users as an example.)

User	MAC Address	IP Address
User 1	00d0.3232.0001	192.168.1.10
User 2	00d0.3232.0002	192.168.1.20
User 3	00d0.3232.0003	192.168.1.30

- Enable the IP-MAC binding function globally.
- Configure the uplink port (Gi0/5 port in this example) of the device as the exclude port.

5.3 Features

Basic Concepts

IPv6 Address Binding Mode

IPv6 address binding modes include Compatible, Loose, and Strict. The default mode is Strict. If IPv4-MAC binding is not configured, the IPv6 address binding mode does not take effect, and all IPv4 and IPv6 packets are allowed to pass through. If IPv4-MAC binding is configured, the IPv6 address binding mode takes effect, and the device forwards IPv4 and IPv6 packets based on the forwarding rules described in the following table:

Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the global IPv4-MAC binding are forwarded.	Packets matching the global IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)
Loose	Packets matching the global IPv4-MAC binding are forwarded.	If IPv6+MAC address binding is configured, packets matching the IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.) If IPv6-MAC binding does not exist, all IPv6 packets are forwarded.
Compatible	Packets matching the global IPv4-MAC binding are forwarded.	If the IPv6 packets contain a MAC address matching the MAC address in the IPv4-MAC binding, the IPv6 packets are forwarded. Packets matching the global IPv6-MAC binding conditions are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)

Exclude Port

By default, the IP-MAC binding function takes effect on all ports of the device. You can configure exclude ports so that the address binding function does not take effect on these ports. In practice, the IP-MAC bindings of the input packets on the

uplink port are not fixed. Generally, the uplink port of the device is configured as the exclude port so that the packets on the uplink port are not checked for IP-MAC binding.

Overview

Feature	Description
Configuring Global IP-MAC Binding	Control forwarding of IPv4 or IPv6 packets.
Configuring the IPv6 Address Binding Mode	Change the IPv6 packet forwarding rules.
Configuring the Exclude Port	Disable the global address binding function on the specified port.

5.3.1 Configuring Global IP-MAC Binding

Working Principle

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

Related Configuration

✚ Configuring IP-MAC Binding

Run the **address-bind** command in global configuration mode to add or delete an IPv4-MAC binding.

✚ Enabling the IP-MAC Binding Function

Run the **address-bind install** command in global configuration mode to enable the IP-MAC binding function. By default, this function is disabled.

5.3.2 Configuring the IPv6 Address Binding Mode

Working Principle

After the global IPv4-MAC binding is configured and enabled, IPv6 packets are forwarded based on the IPv6 address binding mode. IPv6 binding modes include Compatible, Loose, and Strict.

Related Configuration

✚ Configuring the IPv6 Address Binding Mode

By default, the IPv6 address binding mode is Strict.

Run the **address-bind ipv6-mode** command to specify an IPv6 address binding mode.

5.3.3 Configuring the Exclude Port

Working Principle

Configure an exclude port so that the address binding function does not take effect on this port.

Related Configuration

📌 Configuring the Exclude Port

Run the **address-bind uplink** command to configure an exclude port. By default, no port is the exclude port.

5.4 Configuration

Configuration	Description and Command	
Configuring Global IP-MAC Binding	 (Mandatory) It is used to configure and enable address binding.	
	address-bind	Configures a global IPv4-MAC binding.
	address-bind install	Enables the address binding function.
Configuring the IPv6 Address Binding Mode	 (Optional) It is used to configure the IPv6 address binding mode.	
	address-bind ipv6-mode	Configures the IPv6 address binding mode.
Configuring the Exclude Port	 (Optional) It is used to disable the address binding function on a specified port.	
	address-bind uplink	Configures an exclude port.

5.4.1 Configuring Global IP-MAC Binding

Configuration Effect

- Configure a global IPv4-MAC binding.
- Enable the address binding function to control forwarding of the IPv4 or IPv6 packets.

Notes

- If you run the **address-bind install** command without IP-MAC binding configured, IP-MAC binding does not take effect and all packets are allowed to pass through.

Configuration Steps

📌 Configuring Global IP-MAC Binding

- (Mandatory) Perform this configuration in global configuration mode.

📌 Enabling the Address Binding Function

- (Mandatory) Perform this configuration in global configuration mode.

Verification

Run the **show run** or **show address-bind** command to check whether the configuration takes effect.

Related Commands

Configuring Global IP-MAC Binding

Command	address-bind { ip-address ipv6-address } mac-address
Parameter Description	<i>ip-address</i> : Indicates the bound IPv4 address. <i>ipv6-address</i> : Indicates the bound IPv6 address. <i>mac-address</i> : Indicates the bound MAC address.
Command Mode	Global configuration mode
Configuration Usage	Run this command to configure the binding relationship between an IPv4/IPv6 address and a MAC address.

Enabling the Address Binding Function

Command	address-bind install
Parameter Description	N/A
Command Mode	Global configuration mode
Configuration Usage	Run this command to enable the global IP-MAC binding function. This function is used to control forwarding of IPv4 or IPv6 packets.

Configuration Example

Configuring Global IP-MAC Binding and Enabling Address Binding

Configuration Steps	- Configure a global IPv4-MAC binding. - Enable the address binding function.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001 Ruijie(config)# address-bind install </pre>
Verification	Display the global IP-MAC binding on the device.
	<pre> Ruijie#show address-bind Total Bind Addresses in System : 1 IP Address Binding MAC Addr ----- 192.168.5.1 00d0.f800.0001 </pre>

5.4.2 Configuring the IPv6 Address Binding Mode

Configuration Effect

- Change the IPv6 address binding mode so as to change the forwarding rules for IPv6 packets.

Configuration Steps

📌 Configuring the IPv6 Address Binding Mode

- (Optional) Perform this configuration when you want to change the forwarding rules for IPv6 packets.

Verification

- Run the **show run** command to check whether the configuration takes effect.

Related Commands

📌 Configuring the IPv6 Address Binding Mode

Command	address-bind ipv6-mode { compatible loose strict }
Parameter	compatible: Indicates the Compatible mode.
Description	loose: Indicates the Loose mode. strict: Indicates the strict mode.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

📌 Configuring the IPv6 Address Binding Mode

Configuration Steps	● Configure a global IP-MAC binding. ● Enable the address binding function. ● Set the IPv6 address binding mode to Compatible.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001 Ruijie(config)# address-bind install Ruijie(config)# address-bind ipv6-mode compatible </pre>
Verification	Run the show run command to display the configuration on the device.

5.4.3 Configuring the Exclude Port

Configuration Effect

- The address binding function is disabled on the exclude port, and all IP packets can be forwarded.

Notes

- The configuration can be performed only on a switching port or an L2 aggregate port.

Configuration Steps

📌 Configuring the Exclude Port

- (Optional) Perform this configuration in global configuration mode when you want to disable the address binding function on a specified port.

Verification

Run the **show run** or **show address-bind uplink** command to check whether the configuration takes effect.

Related Commands

📌 Configuring the Exclude Port

Command Syntax	address-bind uplink <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Indicates the ID of a switching port or an L2 aggregate port.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

📌 Configuring the Exclude Port

Configuration Steps	● Create a global IPv4-MAC binding. ● Enable the address binding function. ● Configure an exclude port.
	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# address-bind 192.168.5.1 00d0.f800.0001 Ruijie(config)# address-bind install Ruijie(config)# address-bind uplink GigabitEthernet 0/1</pre>

Verification	Display the global IP-MAC binding on the device.
	<pre> Ruijie#show address-bind Total Bind Addresses in System : 1 IP Address Binding MAC Addr ----- 192.168.5.1 00d0.f800.0001 Ruijie#show address-bind uplink Port State ----- Gi0/1 Enabled Default Disabled </pre>

Displays the exclude port.	show address-bind uplink

6 Configuring Password Policy

6.1 Overview

The Password Policy is a password security function provided for local authentication of the device. It is configured to control users' login passwords and login states.

 The following sections introduce password policy only.

6.2 Features

6.2.1 Basic Concepts

➤ Minimum Password Length

Administrators can set a minimum length for user passwords according to system security requirements. If the password input by a user is shorter than the minimum password length, the system does not allow the user to set this password but displays a prompt, asking the user to specify another password of an appropriate length.

➤ Strong Password Detection

The less complex a password is, the more likely it is to crack the password. For example, a password that is the same as the corresponding account or a simple password that contains only characters or digits may be easily cracked. For the sake of security, administrators can enable the strong password detection function to ensure that the passwords set by users are highly complex. After the strong password detection function is enabled, a prompt will be displayed for the following types of passwords:

1. Passwords that are the same as corresponding accounts;
2. Simple passwords that contain characters or digits only.

➤ Password Life Cycle

The password life cycle defines the validity time of a user password. When the service time of a password exceeds the life cycle, the user needs to change the password.

If the user inputs a password that has already expired during login, the system will give a prompt, indicating that the password has expired and the user needs to reset the password. If the new password input during password resetting does not meet system requirements or the new passwords consecutively input twice are not the same, the system will ask the user to input the new password once again.

➤ Guard Against Repeated Use of Passwords

When changing the password, the user will set a new password while the old password will be recorded as the user's history records. If the new password input by the user has been used previously, the system gives an error prompt and asks the user to specify another password.

The maximum number of password history records per user can be configured. When the number of password history records of a user is greater than the maximum number configured for this user, the new password history record will overwrite the user's oldest password history record.

📌 Storage of Encrypted Passwords

Administrators can enable the storage of encrypted passwords for security consideration. When administrators run the **show running-config** command to display configuration or run the **write** command to save configuration files, various user-set passwords are displayed in the cipher text format. If administrators disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.

6.3 Configuration

Configuration	Description and Command	
Configuring the Password Security Policy	 Optional configuration, which is used to configure a combination of parameters related to the password security policy.	
	password policy life-cycle	Configures the password life cycle.
	password policy min-size	Configures the minimum length of user passwords.
	password policy no-repeat-times	Sets the no-repeat times of latest password configuration, so that the passwords specified in these times of latest password configuration can no longer be used in future password configuration.
	password policy strong	Enables the strong password detection function.
	service password-encryption	Sets the storage of encrypted passwords.

6.3.1 Configuring the Password Security Policy

Networking Requirements

- Provide a password security policy for local authentication of the device. Users can configure different password security policies to implement password security management.

Notes

- The configured password security policy is valid for global passwords (configured using the commands **enable password** and **enable secret**) and local user passwords (configured using the **username name password password** command). It is invalid for passwords in Line mode.

Configuration Steps

↘ Configuring the Password Life Cycle

- Optional
- Perform this configuration on each device that requires the configuration of a password life cycle unless otherwise stated.

↘ Configuring the Minimum Length of User Passwords

- Optional
- Perform this configuration on each device that requires a limit on the minimum length of user passwords unless otherwise stated.

↘ Setting the No-Repeat Times of Latest Password Configuration

- Optional
- Perform this configuration on each device that requires a limit on the no-repeat times of latest password configuration unless otherwise stated.

↘ Enabling the Strong Password Detection Function

- Optional
- Perform this configuration on each device that requires strong password detection unless otherwise stated.

↘ Setting the Storage of Encrypted Passwords

- Optional
- Perform this configuration on each device that requires the storage of passwords in encrypted format unless otherwise stated.

Verification

Configure a local user on the device, and configure a valid password and an invalid password for the user.

- When you configure the valid password, the device correctly adds the password.
- When you configure the invalid password, the device displays a corresponding error log.

Related Commands

↘ Configuring the Password Life Cycle

Command Syntax	password policy life-cycle <i>days</i>
Parameter Description	life-cycle <i>days</i> : Indicates the password life cycle in the unit of days. The value range is from 1 to 65535.
Command Mode	Global configuration mode
Usage Guide	The password life cycle is used to define the validity period of user passwords. If the user logs in with a password whose service time already exceeds the life cycle, a prompt is given, asking the user to change the password.

📌 Configuring the Minimum Length of User Passwords

Command Syntax	password policy min-size <i>length</i>
Parameter Description	min-size <i>length</i> : Indicates the minimum length of passwords. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the minimum length of passwords. If the minimum length of passwords is not configured, users can input a password of any length.

📌 Setting the No-Repeat Times of Latest Password Configuration

Command Syntax	password policy no-repeat-times <i>times</i>
Parameter Description	no-repeat-times <i>times</i> : Indicates the no-repeat times of latest password configuration. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, all old passwords used in the several times of latest password configuration will be recorded as the user's password history records. If the new password input by the user has been used previously, the system gives an error prompt and the password modification fails. You can configure the maximum number of password history records per user. When the number of password history records of a user is greater than the maximum number configured for the user, the new password history record will overwrite the user's oldest password history record.

📌 Enabling the Strong Password Detection Function

Command Syntax	password policy strong
Parameter Description	-
Command Mode	Global configuration mode

Usage Guide	After the strong password detection function is enabled, a prompt is displayed for the following types of passwords: 4. Passwords that are the same as corresponding accounts; 5. Simple passwords that contain characters or digits only.

📌 Setting the Storage of Encrypted Passwords

Command Syntax	service password-encryption
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	Before the storage of encrypted passwords is set, all passwords used in the configuration process will be displayed and stored in plaintext format, unless the passwords are configured in cipher text format. You can enable the storage of encrypted passwords for security consideration. When you run the show running-config command to display configuration or run the write command to save configuration files, various user-set passwords are displayed in the cipher text format. If you disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.

📌 Checking User-Configured Password Security Policy Information

Command Syntax	show password policy
Parameter Description	-
Command Mode	Privileged EXEC mode/ Global configuration mode/ Interface configuration mode
Usage Guide	Use this command to display the password security policy configured on the device.

Configuration Examples

 The following configuration example describes configuration related to a password security policy.

📌 Configuring Password Security Check on the Device

Typical Application	Assume that the following password security requirements arise in a network environment: 1. The minimum length of passwords is 8 characters; 2. The password life cycle is 90 days; 3. Passwords are stored and transmitted in cipher text format;

	4. The number of no-repeat times of password history records is 3; 5. Passwords shall not be the same as user names, and shall not contain simple characters or digits only.
Configuration Steps	● Set the minimum length of passwords to 8. ● Set the password life cycle to 90 days. ● Enable the storage of encrypted passwords. ● Set the no-repeat times of password history records to 3. ● Enable the strong password detection function. <pre> Ruijie# configure terminal Ruijie(config)# password policy min-size 8 Ruijie(config)# password policy life-cycle 90 Ruijie(config)# service password-encryption Ruijie(config)# password policy no-repeat-times 3 Ruijie(config)# password policy strong </pre>
Verification	When you create a user and the corresponding password after configuring the password security policy, the system will perform relevant detection according to the password security policy. ● Run the show password policy command to display user-configured password security policy information. <pre> Ruijie# show password policy Global password policy configurations: Password encryption: Enabled Password strong-check: Enabled Password min-size: Enabled (8 characters) Password life-cycle: Enabled (90 days) Password no-repeat-times: Enabled (max history record: 3) </pre>

Common Errors

- The time configured for giving a pre-warning notice about password expiry to the user is greater than the password life cycle.

6.4 Monitoring

Displaying the Running Status

Command	Function
show password policy	Displays user-configured password security policy information.

7 Configuring Port Security

7.1 Overview

Port security is used to restrict access to a port. Source MAC addresses of packets can be used to restrict the packets that enter the ports of a switch. You can set the number of static MAC addresses or the number of MAC addresses that are dynamically learned to restrict the packets that can enter the port. Ports enabled with port security are called secure ports.

7.2 Applications

Application	Description
Allowing Only Specified Hosts to Use Ports	For network security, certain ports of a device can be used only by specified hosts.

7.2.1 Allowing Only Specified Hosts to Use Ports

Scenario

In a scenario that has requirements for the network security, devices cannot be completely isolated physically. In this case, the devices need to be configured to restrict the PCs that connected to the ports of the devices.

- Only specified PCs can connect to the ports and normally use the network.
- Other PCs cannot use the network even if connected to the ports.
- After the configuration is complete, the administrator does not need to perform regular maintenance.

Figure 7-1

Remarks	S is the access device. A is a PC that can use the port F0/1. B is an unknown PC.

Deployment

- Enable ARP Check for port F0/1 (omitted).
- Enable port security on access device S and set the violation handling mode to protect.
- Set the maximum number of secure addresses allowed by port F0/1 to 1.
- Configure a static port security address on the port F0/1.

7.3 Features

Basic Concepts

Secure Port

Ports configured with port security are called secure ports. At present, Ruijie devices require that secure ports cannot be destination ports of mirroring.

Secure Addresses

Addresses bound to secure ports are called secure addresses. Secure addresses can be layer-2 addresses, namely MAC addresses, and can also be layer-3 addresses, namely, IP or IP+MAC addresses. When a secure address is bound to IP+MAC and a static secure MAC address is configured, the static secure MAC address must be the same as the MAC address bound to IP+MAC; otherwise, communication may fail due to inconsistency with the binding. Similarly, if only IP binding is set, only packets whose secure MAC addresses are statically configured or learned and whose source IP addresses are the bound IP address can enter the device.

Dynamic Binding

A method for a device to automatically learn addresses and convert learned addresses into secure addresses.

Static Binding

A command for manually binding secure addresses.

Aging of Secure Addresses

Regularly delete secure address records. Secure addresses for port security support aging configuration. You can specify only dynamically learned addresses for aging or specify both statically configured and dynamically learned secure addresses for aging.

Sticky MAC Address

Convert dynamically learned secure addresses into statically configured addresses. Addresses will not age. After the configurations are saved, dynamic secure addresses will not be learned again upon restart. If this function is not enabled, the secure MAC addresses dynamically learned must be learned again after device restart.

Security Violation Events

When the number of learned MAC addresses learned by a port exceeds the maximum number of secure addresses, security violation events will be triggered. You can configure the following modes for handling security violation events:

- protect: When security violation occurs, a corresponding secure port will stop learning MAC addresses and discard all packets of newly accessed users. This is the default mode for handling violation.
- restrict: When violation occurs, a port violation trap notification will be sent in addition to the behavior in the protect mode.
- shutdown: When violation occurs, the port will be disabled in addition to the behaviors in the preceding two modes.

➤ Maximum Number of Secure Addresses

The maximum number of secure addresses indicates the total number of secure addresses statically configured and dynamically learned. When the number of secure addresses under a secure port does not reach the maximum number of secure addresses, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. If new users access the secure port in this case, security violation events will occur.

Overview

Feature	Description
Enabling Port Security	Creates a secure address list for a port.
Filtering Layer-2 Users	Processes the packets received by a port from non-secure addresses.
Filtering Layer-3 Users	Checks the layer-2 and layer-3 addresses of packets passing a port.
Aging of Secure Addresses	Regularly deletes secure addresses.

7.3.1 Enabling Port Security

Enable port security for a port to restrict packets that access the network through the port.

Working Principle

When port security is enabled, the device security module will check the sources of received packets. Only packets from addresses in the secure address list can be normally forwarded; otherwise, the packets will be discarded or the port performs other violation handling behaviors.

When the port security and 802.1x are configured at the same time, packets can enter a switch only when the MAC addresses of the packets meet the static MAC address configurations of 802.1x or port security. If a port is configured with a secure channel or is bound to global IP+MAC, packets in compliance with the secure channel or bound to global IP+MAC can avoid checking of port security.

Related Configuration

➤ Enabling Port Security for a Port

By default, port security is disabled.

You can run the **switchport port-security** command to enable or disable the port security function for a port.

You cannot enable this function for a destination port of SPAN.

📌 Setting the Maximum Number of Secure Addresses for a Port

By default, the maximum number of secure addresses for a port is 128.

You can run the **switchport port-security maximum** command to adjust the maximum number of secure addresses for the port.

A smaller number of secure addresses mean fewer users that access the network through this port.

📌 Setting the Mode for Handling Violation

By default, when the number of secure addresses reaches the maximum number, the secure port will discard packets from unknown addresses (none of the secure addresses of the port).

You can run the **switchport port-security violation** command to modify the violation handling mode.

📌 Setting Secure Addresses That Can Be Dynamically Saved

By default, no secure address dynamically learned will be saved.

You can run the **switchport port-security mac-address sticky** command to save dynamically learned addresses to the configuration file. As long as the configuration file is saved, the device does not need to re-learn the secure addresses after the device is restarted.

7.3.2 Filtering Layer-2 Users

Set the secure addresses on a port to ensure that only devices whose MAC addresses are the same as the secure addresses can access the network through this port.

Working Principle

Add secure addresses for a secure port. When the number of secure addresses for a secure port does not reach the maximum number, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses for the secure port reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. The MAC addresses of users connecting to this port must be in the secure address list; otherwise, violation events will be triggered.

Related Configuration

📌 Adding Secure Addresses for a Secure port

By default, a port dynamically learns secure addresses. If an administrator has special requirements, the administrator can manually configure secure addresses.

You can run the **switch portport-security interface** command to add or delete secure addresses for a device.

7.3.3 Filtering Layer-3 Users

Add binding of secure addresses and check layer-2 and layer-3 addresses of packets passing a port.

Working Principle

Layer-3 secure addresses support only IP binding and IP+MAC binding, and supports only static binding (not dynamic binding).

When a layer-3 secure port receives packets, layer-2 and layer-3 addresses need to be parsed. Only packets whose addresses are bound are valid packets. Other packets are considered as invalid packets and will be discarded, but no violation event will be triggered.

Related Configuration

📌 Configuring Binding of Secure Addresses on Secure Ports

Binding of layer-3 secure addresses must be added manually.

You can run the **switchport port-security binding** command to add binding of secure addresses.

If only IP addresses are input, only IP addresses are bound. If IP addresses and MAC addresses are input, IP+MAC will be bound.

7.3.4 Aging of Secure Addresses

Regularly delete secure addresses. When this function is enabled, you need to set the maximum number of secure addresses. In this way, the device can automatically add and delete secure addresses on this port.

Working Principle

Enable the aging timer to regularly query and delete secure addresses whose aging time expires.

Related Configuration

📌 Configuring Aging Time of Secure Addresses

By default, no secure address of a port will be aged.

You can run the **switchport port-security aging** command to enable aging time.

The **static** parameter can be used to age static addresses.

7.4 Configuration

Configuration	Description and Command	
Configuring Secure ports and Violation Handling Modes	 (Mandatory) It is used to enable the port security service.	
	switchport port-security	Enables port security.

	switchport port-security maximum	Sets the maximum number of secure addresses for a port.
	switchport port-security violation	Configures the violation handling mode for port security.
	switchport port-security mac-address sticky	Configures automatic saving of dynamic addresses.
Configuring Secure Addresses on Secure Ports	 (Optional) It is used to configure security filtering items.	
	switchport port-security mac-address	Configures the static secure addresses in the interface configuration mode.
	switchport port-security interface mac-address	Configures the static secure addresses in the global configuration mode.
	switchport port-security binding	Configures binding of secure addresses in the interface configuration mode.
	switchport port-security interface binding	Configures binding of secure addresses in the global configuration mode.
	switchport port-security aging	Configures aging time for all secure addresses on a port.

7.4.1 Configuring Secure ports and Violation Handling Modes

Configuration Effect

- Restrict the number of MAC addresses that can be learned from a port.
- Filter invalid packets based on MAC addresses, IP addresses or IP+MAC.

Notes

- A secure port cannot be the destination port of SPAN.
- The port security function cannot be configured for a DHCP Snooping trusted port.
- The port security function cannot be configured for excluded ports of global IP+MAC.
- The security function can be enabled only for wired switching ports and layer-2 AP ports in the interface configuration mode.
- The port security can work with other access control functions such as the 802.1x, global IP+MAC binding, and IP source guard. When these functions are used together, packets can enter a switch only when passing all security checks. If a security channel is configured for a port, packets in compliance with the security channel will avoid checking of the port security.

Configuration Steps

📌 Enabling the Port Security Service

- Mandatory.

- If there is no special requirement, enable the port security service for a port on the access device.

✚ Configuring the Maximum Number of Secure Addresses for a Port

- Optional. To adjust the maximum number of secure addresses running on a secure port, you can configure this item.
- Configure this item on a port enabled with port security.

✚ Configuring Violation Handling Modes

- Optional. If you hope that other handling modes except discarding packets are implemented in case of violation, you can configure other handling modes.
- Configure this item on a port enabled with port security.

✚ Saving Dynamically Learned Addresses

- Optional. If you hope that secure addresses are not re-learned after the device is restarted, you can configure this item.
- Configure this item on a port enabled with port security.

Verification

Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

Related Commands

✚ Setting Port Security

Command	switchport port-security
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	By using the port security feature, you can strictly control the input of a port of a device by restricting the MAC addresses and IP addresses (optional) that access the port.

✚ Setting the Maximum Number of Secure Addresses for a Port

Command	switchport port-security maximum <i>value</i>
Parameter Description	<i>value</i> : Indicates the number of secure addresses, ranging from 1 to 128.
Command Mode	Interface configuration mode
Usage Guide	If you set the maximum number to 1 and configure a secure address for this port, the workstation (whose address is the configured secure address) connected to this port will exclusively use all bandwidth of the port. The limitation only works for secure addresses. It does not restrict the number of secure address binding.

✚ Configuring the Violation Handling Mode for Port Security

Command	switchport port-security violation { protect restrict shutdown }
Parameter	protect: Discards violated packets.
Description	restrict: Discards violated packets and send trap notifications. shutdown: Discards packets and disables the port.
Command Mode	Interface configuration mode
Usage Guide	-

✚ Saving Dynamic Secure Addresses to a Configuration File

Command	switchport port-security mac-address sticky mac-address [vlan vlan-id]
Parameter	<i>mac-address</i> : Indicates a static secure address.
Description	<i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

✚ Enabling Port Security for the Port gigabitethernet 0/3, Setting the Maximum Number of Addresses to 8, and Setting the Violation Handling Mode to protect

Configuration Steps	● Enable port security. ● Set the maximum number of secure addresses. ● Modify the violation handling mode.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security maximum 8 Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security violation protect Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security mac-address sticky Ruijie(config-if-GigabitEthernet 0/3)# end </pre>
Verification	Check the port security configuration on the device.
	<pre> Ruijie# show port-security interface gigabitethernet 0/3 </pre>

```
Interface : Gi0/3
Port Security: Enabled
Port status : down
Violation mode: Protect
Maximum MAC Addresses:8
Total MAC Addresses:0
Configured MAC Addresses:0
Aging time : 0 mins
SecureStatic address aging : Disabled
```

Common Errors

- Port security is enabled on a SPAN port.
- Port security is enabled on a DHCP trusted port.
- The configured maximum number of secure addresses is smaller than the number of existing secure addresses.

7.4.2 Configuring Secure Addresses on Secure Ports

Configuration Effect

- Allow specified users to use ports.
- Regularly update secure addresses of users.

Notes

- Sticky MAC addresses are special MAC addresses not affected by the aging mechanism. No matter dynamic or static aging is configured, sticky MAC addresses will not be aged.

-

Configuration Steps

📌 Configuring Secure Addresses

- Optional. You need to manually add secure addresses for configuration.
- Configure this item on a port enabled with port security.

📌 Configuring Binding of Secure Addresses

- Optional. You need to add layer-3 secure addresses for configuration.
- Configure this item on a port enabled with port security.

📌 Configuring Aging Time

- Optional.
- Configure this item on a port enabled with port security.

Verification

- Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

Related Commands

➤ Adding Secure Addresses for Secure Ports in the Global Configuration Mode

Command	switchport port-security interface <i>interface-id</i> mac-address <i>mac-address</i> [vlan <i>vlan-id</i>]
Parameter	<i>interface-id</i> : Indicates the interface ID.
Description	<i>mac-address</i> : Indicates a static secure address. <i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Global configuration mode
Usage Guide	-

➤ Adding Secure Addresses for Secure Ports in the Interface Configuration Mode

Command	switchportport-security mac-address <i>mac-address</i> [vlan <i>vlan_id</i>]
Parameter	<i>mac-address</i> : Indicates a static secure address.
Description	<i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Interface configuration mode
Usage Guide	-

➤ Adding Binding of Secure Addresses for Secure Ports in the Global Configuration Mode

Command	switchport port-security interface <i>interface-id</i> binding [<i>mac-address</i> vlan <i>vlan_id</i>] { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter	<i>interface-id</i> : Indicates the interface ID.
Description	<i>mac-address</i> : Indicates a bound source MAC address. <i>vlan_id</i> : Indicates the VID of a bound source MAC address. <i>ipv4-address</i> : Indicates a bound IPv4 address. <i>ipv6-address</i> : Indicates a bound IPv6 address.
Command Mode	Global configuration mode
Usage Guide	-

➤ Adding Binding of Secure Addresses for Secure Ports in the Interface Configuration Mode

Command	switchport port-security binding [<i>mac-address</i> vlan <i>vlan_id</i>] { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter	<i>mac-address</i> : Indicates a bound source MAC address.

Description	<i>vlan_id</i> : Indicates the VID of a bound source MAC address. <i>ipv4-address</i> : Indicates a bound IPv4 address. <i>ipv6-address</i> : Indicates a bound IPv6 address.
Command Mode	Interface configuration mode
Usage Guide	-

📌 Configuring Aging Time for All Secure Addresses on a Port

Command	switchport port-security aging { static time time }
Parameter Description	static : Indicates that the aging time will be applied to manually configured secure addresses and automatically learned addresses; otherwise, the aging time will be applied to only automatically learned addresses. time time : Indicates the aging time of the secure addresses on this port, ranging from 0 to 1440 minutes. If it is set to 0, it indicates that the aging function is disabled actually.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

📌 Configuring a Secure MAC Address 00d0.f800.073c for the Port gigabitethernet 0/3

Configuration Steps	● Enable port security. ● Add a secure address.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security mac-address 00d0.f800.073c vlan 1 Ruijie(config-if-GigabitEthernet 0/3)# end </pre>
Verification	Check the port security configuration on the device.
	<pre> Ruijie# show port-security address Vlan Mac Address IP Address Type Port Remaining Age(mins) ----- 1 00d0.f800.073c 192.168.12.202 Configured Gi0/3 8 </pre>

1 00d0.f800.3cc9 192.168.12.5 Configured Gi0/1 7

📌 Configuring a Security Binding of the IP Address 192.168.12.202 for the Port gigabitethernet 0/3

Configuration Steps	● Enable port security. ● Add a binding of the secure address.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security binding 192.168.12.202 Ruijie(config-if-GigabitEthernet 0/3)# end </pre>
Verification	Check the port security configuration on the device.
	<pre> Ruijie# show port-security address Vlan Mac Address IP Address Type Port Remaining Age(mins) ----- 1 00d0.f800.073c 192.168.12.202 Configured Gi0/3 8 1 00d0.f800.3cc9 192.168.12.5 Configured Gi0/1 7 </pre>

📌 Configuring a Secure MAC Address 00d0.f800.073c and a Security Binding of the IP Address 0000::313b:2413:955a:38f4 for the Port gigabitethernet 0/3

Configuration Steps	● Enable port security. ● Add a binding of the secure address.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport mode access Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security binding 00d0.f800.073c vlan 1 0000::313b:2413:955a:38f4 Ruijie(config-if)# end </pre>

Verification	Check the port security configuration on the device.
	<pre> Ruijie# show port-security address Vlan Mac Address IP Address Type Port Remaining Age(mins) ----- 1 00d0.f800.073c 192.168.12.202 Configured Gi0/3 8 1 00d0.f800.3cc9 192.168.12.5 Configured Gi0/1 7 </pre>

➤ Configuring the Aging Time of the Port gigabitethernet 0/3 to 8 Minutes, Which Is Also Applied to Statically Configured Secure Addresses

Configuration Steps	● Enable port security. ● Configure aging time.
	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface gigabitethernet 0/3 Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security aging time 8 Ruijie(config-if-GigabitEthernet 0/3)# switchport port-security aging static Ruijie(config-if-GigabitEthernet 0/3)# end </pre>
Verification	Check the port security configuration on the device.

7.5 Monitoring

Displaying

Description	Command
Displays all secure addresses or all secure addresses of a specified port.	show port-security address [interface <i>interface-id</i>]
Displays all bindings or all bindings of a specified port.	show port-security binding [interface <i>interface-id</i>]
Displays all valid secure addresses of ports and the security binding records of the ports.	show port-security all
Displays the port security configurations of an interface.	show port-security interface <i>interface-id</i>
Displays the statistics about port security.	show port-security

8 Configuring Storm Control

8.1 Overview

When a local area network (LAN) has excess broadcast data flows, multicast data flows, or unknown unicast data flows, the network speed will slow down and packet transmission will have an increased timeout probability. This situation is called a LAN storm. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast data flows, multicast data flows, or unknown unicast data flows. If the rate of data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds. This prevents flood data from entering the LAN causing a storm.

8.2 Applications

Application	Description
Network Attack Prevention	Enable storm control to prevent flooding.

8.2.1 Network Attack Prevention

Scenario

The application requirements of network attack prevention are described as follows:

- Protect devices from flooding of broadcast packets, multicast packets, or unknown unicast packets.

Figure 8-1

Remarks	Switch A and Switch B are access devices. PC 1, PC 2, PC 3, and PC 4 are desktop computers.

Deployment

- Enable storm control on the ports of all access devices (Switch A and Switch B).

8.3 Features

Basic Concepts

Storm Control

If the rate of data flows (broadcast packets, multicast packets, or unknown unicast packets) received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Storm Control Based on the Bandwidth Threshold

If the rate of data flows received by a device port is within the configured bandwidth threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Storm Control Based on the Packets-per-Second Threshold

If the rate of data flows received by a device port is within the configured packets-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Storm Control Based on the Kilobits-per-Second Threshold

If the rate of data flows received by a device port is within the configured kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Overview

Feature	Description
Unicast Packet Storm Control	Limits unknown unicast packets to prevent flooding.
Multicast Packet Storm Control	Limits multicast packets to prevent flooding.
Broadcast Packet Storm Control	Limits broadcast packets to prevent flooding.

8.3.1 Unicast Packet Storm Control

The unicast packet storm control feature monitors the rate of unknown unicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of unknown unicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

✚ Enabling Unicast Packet Storm Control on Ports

By default, unicast packet storm control is disabled on ports.

Run the **storm-control unicast** [{ **level percent** | **pps packets** | **rate-bps** }] command to enable unicast packet storm control on ports.

Run the **no storm-control unicast** or **default storm-control unicast** command to disable unicast packet storm control on ports.

The default command parameters are determined by related products.

8.3.2 Multicast Packet Storm Control

The multicast packet storm control feature monitors the rate of multicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of multicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

✚ Enabling Multicast Packet Storm Control on Ports

By default, multicast packet storm control is disabled on ports.

Run the **storm-control multicast** [{ **level percent** | **pps packets** | **rate-bps** }] command to enable multicast packet storm control on ports.

Run the **no storm-control multicast** or **default storm-control multicast** command to disable multicast packet storm control on ports.

The default command parameters are determined by related products.

8.3.3 Broadcast Packet Storm Control

The broadcast packet storm control feature monitors the rate of broadcast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of broadcast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

✚ Enabling Broadcast Packet Storm Control on Ports

By default, broadcast packet storm control is disabled on ports.

Run the **storm-control broadcast** [{ *level percent* | *pps packets* | *rate-bps* }] command to enable broadcast packet storm control on ports.

Run the **no storm-control broadcast** or **default storm-control broadcast** command to disable broadcast packet storm control on ports.

The default command parameters are determined by related products.

8.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of Storm Control	 (Mandatory) It is used to enable storm control.	
	storm-control { broadcast multicast unicast } [{ <i>level percent</i> <i>pps packets</i> <i>rate-bps</i> }]	Enables storm control.

8.4.1 Configuring Basic Functions of Storm Control

Configuration Effect

- Prevent flooding caused by excess broadcast packets, multicast packets, and unknown unicast packets.

Notes

- When you run a command (for example, **storm-control unicast**) to enable storm control, if you do not set the parameters, the default values are used.

Configuration Steps

✚ Enabling Unicast Packet Storm Control

- Mandatory.
- Enable unicast packet storm control on every device unless otherwise specified.

✚ Enabling Multicast Packet Storm Control

- Mandatory.

- Enable multicast packet storm control on every device unless otherwise specified.

➤ Enabling Broadcast Packet Storm Control

- Mandatory.
- Enable broadcast packet storm control on every device unless otherwise specified.

Verification

- Run the **show storm-control** command to check whether the configuration is successful.

Related Commands

➤ Enabling Unicast Packet Storm Control

Command	storm-control unicast [{ <i>level percent</i> <i>pps packets</i> <i>rate-bps</i> }]
Parameter Description	level percent: Indicates the bandwidth percentage. pps packets: Indicates the number of packets per second. rate-bps: Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

➤ Enabling Multicast Packet Storm Control

Command	storm-control multicast [{ <i>level percent</i> <i>pps packets</i> <i>rate-bps</i> }]
Parameter Description	level percent: Indicates the bandwidth percentage. pps packets: Indicates the number of packets per second. rate-bps: Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

➤ Enabling Broadcast Packet Storm Control

Command	storm-control broadcast [{ <i>level percent</i> <i>pps packets</i> <i>rate-bps</i> }]
Parameter Description	level percent: Indicates the bandwidth percentage. pps packets: Indicates the number of packets per second. rate-bps: Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

Configuration Example

➤ Enabling Storm Control on Devices

9 Configuring SSH

9.1 Overview

Secure Shell (SSH) connection is similar to a Telnet connection except that all data transmitted over SSH is encrypted. When a user in an insecure network environment logs into a device remotely, SSH helps ensure information security and powerful authentication, protecting the device against attacks such as IP address spoofing and plain-text password interception.

An SSH-capable device can be connected to multiple SSH clients. In addition, the device can also function as an SSH client, and allows users to set up an SSH connection with a SSH-server device. In this way, the local device can safely log in to a remote device through SSH to implement management.

 Currently, a device can work as either the SSH server or an SSH client, supporting SSHv1 and SSHv2 versions. Ruijie SSH service supports both IPv4 and IPv6.

 Unless otherwise specified, SSH in this document refers to SSHv2.

Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3
- draft-ietf-secsh-filexfer-05: SSH File Transfer Protocol
- draft-ylonen-ssh-protocol-00: The version of the SSH Remote Login Protocol is 1.5. Comware implements the SSH server functions, but not the SSH client functions.

9.2 Applications

Application	Description
SSH Device Management	Use SSH to manage devices.
SSH Local Line Authentication	Use the local line password authentication for SSH user authentication.

Application	Description
SSH AAA Authentication	Use the authentication, authorization and accounting (AAA) mode for SSH user authentication.
SSH Public Key Authentication	Use the public key authentication for SSH user authentication.
SSH File Transfer	Use the Secure Copy (SCP) commands on the client to exchange data with the SSH server.
SSH Client Application	Use the SSH client to safely log in to a remote device for management.

9.2.1 SSH Device Management

Scenario

You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows system does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the configurations of the SSH client. Figure 9-1 shows the network topology.

Figure 9-1 Networking Topology of SSH Device Management

Deployment

Configure the SSH client as follows:

- Start the PuTTY software.
- On the **Session** option tab of PuTTY, type in the host IP address of the SSH server and SSH port number **22**, and select the connection type **SSH**.
- On the **SSH** option tab of PuTTY, select the preferred SSH protocol version **2**.
- On the **SSH authentication** option tab of PuTTY, select the authentication method **Attempt "keyboard-interactive" auth**.
- Click **Open** to connect to the SSH server.
- Type in the correct user name and password to enter the terminal login interface.

9.2.2 SSH Local Line Authentication

Scenario

SSH clients can use the local line password authentication mode, as shown in Figure 9-2. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server function is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.

Figure 9-2 Networking Topology of SSH Local Line Password Authentication

Deployment

- Configure the SSH server as follows:
 1. Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.
 2. Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH clients, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses an RSA key, whereas SSHv2 adopts an RSA or DSA key.
 3. Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server using this IP address. The routes from the SSH clients to the SSH server are reachable.

- Configure the SSH client as follows:

Diversified SSH client software is available, including PuTTY, Linux, and OpenSSH. This document takes PuTTY as an example to explain the method for configuring the SSH clients.

1. Open the PuTTY connection tab, and select SSHv1 for authenticated login. (The method is similar if SSHv2 is selected.)
2. Set the IP address and connected port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22. Click **Open** to start the connection. As the current authentication mode does not require a user name, you can type in any user name, but cannot be null. (In this example, the user name is "anyname".)

9.2.3 SSH AAA Authentication

Scenario

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 9-3. To ensure security of data exchange, the PCs function as the SSH clients, and uses the SSH protocol to log in to the network device where the SSH

server is enabled. To better perform security management, the AAA authentication mode is used for user login on the SSH clients. Two authentication methods, including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, it turns to the local authentication.

Figure 9-3 Networking Topology of SSH AAA Authentication

Deployment

- The routes from the SSH clients to the SSH server are reachable, and the route from the SSH server to the Radius server is also reachable.
- Configure the SSH server on the network device that functions as an SSH client.
- Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.

9.2.4 SSH Public Key Authentication

Scenario

SSH clients can use the public keys for authentication, and the public key algorithm can be RSA or DSA, as shown in Figure 9-4. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.

Figure 9-4 Network Topology for Public Key Authentication of SSH Users

Deployment

- To implement public key authentication for the client, generate a key pair (RSA or DSA) on the client, configure the public key on the SSH server, and select the public key authentication mode.

- After the key is generated on the client, the SSH server will copy the file of the public key from the client to the flash and associates the file with the SSH user name. Each user can be associated with one RSA public key and one DSA public key.

9.2.5 SSH File Transfer

Scenario

The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server, as shown in Figure 9-5.

Figure 9-5 Networking Topology of SSH File Transfer

Deployment

- Enable the SCP service on the server.
- On the client, use SCP commands to upload files to the server, or download files from the server.

9.2.6 SSH Client Application

Scenario

The SSH service is enabled on a remote SSH server, and the **ssh** command is used on the local client to set up an SSH connection with the server for secure data transmission, as shown in Figure 9-6.

Figure 9-6 Networking Topology of SSH Client Application

Deployment

- Enable the SSH service on the server.
- On the client, run the **ssh** command to set up an SSH connection with the server for secure data transmission.

9.3 Features

Basic Concepts

📌 User Authentication Mechanism

- Password authentication

During the password authentication, a client sends a user authentication request and encrypted user name and password to the server. The server decrypts the received information, compares the decrypted information with those stored on the server, and then returns a message indicating the successful or unsuccessful authentication.

- Public key authentication

During the public key authentication, digital signature algorithms, such as RSA and DSA, are used to authenticate a client. The client sends a public key authentication request to the server. This request contains information including the user name, public key, and public key algorithm. On receiving the request, the server checks whether the public key is correct. If wrong, the server directly sends an authentication failure message. If right, the server performs digital signature authentication on the client, and returns a message indicating the successful or unsuccessful authentication.

 Public key authentication is applicable only to the SSHv2 clients.

SSH Communication

To ensure secure communication, interaction between an SSH server and an SSH client undergoes the following seven stages:

- Connection setup

The server listens on Port 22 to the connection request from the client. After originating a socket initial connection request, the client sets up a TCP socket connection with the server.

- Version negotiation

If the connection is set up successfully, the server sends a version negotiation packet to the client. On receiving the packet, the client analyzes the packet and returns a selected protocol version to the server. The server analyzes the received information to determine whether version negotiation is successful.

- Key exchange and algorithm negotiation

If version negotiation is successful, key exchange and the algorithm negotiation are performed. The server and the client exchange the algorithm negotiation packet with each other, and determine the final algorithm based on their capacity. In addition, the server and the client work together to generate a session key and a session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

After the encrypted channel is set up, the client sends an authentication request to the server. The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

After the successful authentication, the client sends a session request to the server. The server waits and processes the client request. After the session request is successfully processed, SSH enters the session interaction stage.

- Session interaction

After the session request is successfully processed, SSH enters the session interaction stage. Encrypted data can be transmitted and processed in both directions. The client sends a command to be executed to the client. The server decrypts, analyzes, and processes the received command, and then sends the encrypted execution result to the client. The client decrypts the execution result.

- Session ending

When the interaction between the server and the client is terminated, the socket connection disconnects, and the session ends.

Overview

Feature	Description
SSH Server	Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client.
SCP Service	After the SCP service is enabled, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.
SSH Client	You can use the SSH client on the device to set up a secure connection with the SSH server on a network device.

9.3.1 SSH Server

Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client. You can also shut down the SSH server function to disconnect from all SSH clients.

Working Principle

For details about the working principle of the SSH server, see the "SSH Communication" in "Basic Concepts." In practice, after enabling the SSH server function, you can configure the following parameters according to the application requirements:

- Version: Configure the SSH version as SSHv1 or SSHv2 to connect SSH clients.
- Authentication timeout: The SSH server starts the timer after receiving a user connection request. The SSH server is disconnected from the client either when the authentication succeeds or when the authentication timeout is reached.
- Maximum number of authentication retries: The SSH server starts authenticating the client after receiving its connection request. If authentication does not succeed when the maximum number of user authentication retries is reached, a message is sent, indicating the authentication failure.
- Public key authentication: The public key algorithm can be RSA or DSA. It provides a secure connection between the client and the server. The public key file on the client is associated with the user name. In addition, the public key authentication mode is configured on the client, and the corresponding private key file is specified. In this way, when the client attempts to log in to the server, public key authentication can be implemented to set up a secure connection.

Related Configuration

📄 Enabling the SSH Server

By default, the SSH server is disabled.

In global configuration mode, run the **[no] enable service ssh-server** command to enable or disable the SSH server.

To generate the SSH key, you also need to enable the SSH server.

📌 Specifying the SSH Version

By default, the SSH server supports both SSHv1 and SSHv2, connecting either SSHv1 clients or SSHv2 clients.

Run the **ip ssh version** command to configure the SSH version supported by the SSH server.

If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

📌 Configuring the SSH Authentication Timeout

By default, the user authentication timeout is 120s.

Run the **ip ssh time-out** command to configure the user authentication timeout of the SSH server. Use the **no** form of the command to restore the default timeout. The SSH server starts the timer after receiving a user connection request. If authentication does not succeed before the timeout is reached, authentication times out and fails.

📌 Configuring the Maximum Number of SSH Authentication Retries

By default, the maximum number of user authentication retries is 3.

Run the **ip ssh authentication-retries** command to configure the maximum number of user authentication retries on the SSH server. Use the **no** form of the command to restore the default number of user authentication retries. If authentication still does not succeed when the maximum number of user authentication retries is reached, user authentication fails.

📌 Specifying the SSH Encryption Mode

By default, the encryption mode supported by the SSH server is Compatible, that is, supporting cipher block chaining (CBC), counter (CTR) and other encryption modes.

Run the **ip ssh cipher-mode** command to configure the encryption mode supported by the SSH server. Use the **no** form of the command to restore the default encryption mode supported by the SSH server.

📌 Specifying the SSH Message Authentication Algorithm

By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5, SHA1, SHA1-96, and MD5-96, are supported.

Run the **ip ssh hmac-algorithm** command to configure the message authentication algorithm supported by the SSH server. Use the **no** form of the command to restore the default message authentication algorithm supported by the SSH server.

📌 Configuring Support for Diffie-Hellman(DH) Key Exchange Algorithm on the SSH Server

By default, Ruijie's SSHv2 server supports diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 for keyexchange while the SSHv1 server support none. Run the **ip ssh key-exchange** command to configure support for Diffie-Hellman on the SSH server. Use the **no ip ssh key-exchange** command to restore the default setting.

📌 Setting ACL Filtering of the SSH Server

By default, ACL filtering is not performed for all connections to the SSH server.

Run the **{ip | ipv6} ssh access-class** command to perform ACL filtering for all connections to the SSH server. Run **no {ip | ipv6} ssh access-class** to restore the default settings.

📌 Enabling the Public Key Authentication on the SSH Server

Run the **ip ssh peer** command to associate the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

9.3.2 SCP Service

The SSH server provides the SCP service to implement secure file transfer between the server and the client.

Working Principle

- SCP is a protocol that supports online file transfer. It runs on Port 22 based on the BSC RCP protocol, whereas RCP provides the encryption and authentication functions based on the SSH protocol. RCP implements file transfer, and SSH implements authentication and encryption.
- Assume that the SCP service is enabled on the server. When you use an SCP client to upload or download files, the SCP client first analyzes the command parameters, sets up a connection with a remote server, and starts another SCP process based on this connection. This process may run in source or sink mode. (The process running in source mode is the data provider. The process running in sink mode is the destination of data.) The process running in source mode reads and sends files to the peer end through the SSH connection. The process running in sink mode receives files through the SSH connection.

Related Configuration

📌 Enabling the SCP Server

By default, the SCP server function is disabled.

Run the **ip scp server enable** command to enable SCP server function on a network device.

9.3.3 SSH Client

The SSH client is used to set up a secure connection with a remote network device on which the SSH server runs.

Working Principle

For details about the working principle of the SSH client, see the "SSH Communication" in "Basic Concepts."

Related Configuration

📌 Specifying the Source Interface of the SSH Client

By default, the source address of SSH packets is searched based on the destination address.

Run the **ip ssh source-interface** *interface-name* command to specify the source interface of the SSH client.

✚ Establishing a Session with the SSH Server

Run the **ssh** command to log in to a remote device that supports the SSH Server

✚ Recovering an Established SSH Session

- Run the **ssh-session** *session-id* command to recover an established SSH session.

✚ Disconnecting a Suspended SSH Session

- Run the **disconnect ssh-session** *session-id* command to disconnect a specified SSH session.

9.3.4 SCP Client

The SCP client is used to support file transfer with the remote network device on which the SCP server is enabled.

Working Principle

SCP is a protocol that supports online file transfer. It runs on Port 22 based on BSD RCP, while RCP provides the encryption and authentication functions based on the SSH protocol. RCP implements file transfer, and SSH implements authentication and encryption.

When you use an SCP client to upload or download files, the SCP client first parses the command parameters, sets up a connection with a remote server, and starts another SCP process based on this connection. This process may run in source or sink mode. The process serves as a data provider in source mode and reads and sends files to the peer end through the SSH connection, while serving as the destination of data in sink mode and receives the files through the SSH connection.

Related Configuration

✚ Specifying Source Interface of SCP Client

By default, configure the IP address of the source interface as the source address in SSH packets.

Run the **ip scp client source-interface** *interface-name* command to specify the source interface of the SCP client.

✚ Establishing Connection with the SCP Server via SCP Client to Implement File Transfer

Run the **scp** command to implement file transfer with the SSH server.

9.4 Configuration

Configuration	Description and Command	
Configuring the SSH Server	 It is mandatory to enable the SSH server.	
	enable service ssh-server	Enables the SSH server.
	disconnect ssh[<i>vt</i>] <i>session-id</i>	Disconnects an established SSH session.
	crypto key generate {rsa dsa}	Generates an SSH key.

Configuration	Description and Command	
	ip ssh version {1 2}	Specifies the SSH version.
	ip ssh time-out <i>time</i>	Configures the SSH authentication timeout.
	ip ssh authentication-retries <i>retry times</i>	Configures the maximum number of SSH authentication retries.
	ip ssh cipher-mode {cbc ctr others }	Specifies the SSH encryption mode.
	ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96}	Specifies the SSH message authentication algorithm.
	ip ssh key-exchange { dh_group_exchange_sha1 dh_group14_sha1 dh_group1_sha1 }	Configures support for Diffie-Hellman on the SSH server.
	{ip ipv6} ssh access-class { access-list-number access-list-name }	Enables ACL filtering of the SSH server.
	ip ssh peer test public-key rsa flash : <i>rsa.pub</i>	Associates an RSA public key file with a user.
	ip ssh peer test public-key dsa flash : <i>dsa.pub</i>	Associates a DSA public key file with a user.
Configuring the SCP Service	 Mandatory.	
	ip scp server enable	Enables the SCP server.
Configuring the SSH Client	 (Optional)It is used to set up a secure connection with a remote network device that supports the SSH server.	
	ip ssh source-interface <i>interface-name</i>	Specifies the source interface of the SSH client.
	ssh [oob] [-v {1 2 }][-c {3des aes128-cbc aes192-cbc aes256-cbc }][-l <i>username</i>][-m {hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }][-p <i>port-num</i>][<i>ip-addr</i> <i>hostname</i>][via <i>mgmt-name</i>][/source {<i>ipA.B.C.D</i> ipv6 <i>X:X:X:X::X</i> interface <i>interface-name</i> }][/vrf <i>vrf-name</i>]	Establishes an encrypted session with a remote network device.

9.4.1 Configuring the SSH Server

Configuration Effect

- Enable the SSH server function on a network device so that you can set up a secure connection with a remote network device through the SSH client. All interactive data is encrypted before transmitted, featuring authentication and security.
- You can use diversified SSH user authentications modes, including local line password authentication, AAA authentication, and public key authentication.

- You can generate or delete an SSH key.
- You can specify the SSH version.
- You can configure the SSH authentication timeout.
- You can configure the maximum number of SSH authentication retries.
- You can specify ACL filtering of the SSH server.

Notes

- The precondition of configuring a device as the SSH server is that communication is smooth on the network that the device resides, and the administrator can access the device management interface to configure related parameters.
- The **no crypto key generate** command does not exist. You need to run the **crypto key zeroize** command to delete a key.
- The SSH module does not support hot standby. Therefore, for products that supports hot standby on the supervisor modules, if no SSH key file exist on the new active module after failover, you must run the **crypto key generate** command to re-generate a key before using SSH.

Configuration Steps

📄 Enabling the SSH Server

- Mandatory.
- By default, the SSH server is disabled. In global configuration mode, enable the SSH server and generate an SSH key so that the SSH server state changes to ENABLE.

📄 Specifying the SSH Version

- Optional.
- By default, the SSH server supports SSHv1 and SSHv2, connecting either SSHv1 or SSHv2clients. If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

📄 Configuring the SSH Authentication Timeout

- Optional.
- By default, the SSH authentication timeout is 120s. You can configure the user authentication timeout as required. The value ranges from 1 to 120. The unit is second.

📄 Configuring the Maximum Number of SSH Authentication Retries

- Optional.
- Configure the maximum number of SSH authentication retries to prevent illegal behaviors such as malicious guessing. By default, the maximum number of SSH authentication retries is 3, that is, a user is allowed to enter the user name and password three times for authentication. You can configure the maximum number of retries as required. The value ranges from 0 to 5.

✚ Specifying the SSH Encryption Mode

- Optional.
- Specify the encryption mode supported by the SSH server. By default, the encryption mode supported by the SSH server is Compatible, that is, supporting CBC, CTR and other encryption modes.

✚ Specifying the SSH Message Authentication Algorithm

- Optional.
- Specify the message authentication algorithm supported by the SSH server. By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5, SHA1, SHA1-96, and MD5-96, are supported.

✚ Setting ACL Filtering of the SSH Server

- Optional.
- Set ACL filtering of the SSH server. By default, ACL filtering is not performed for all connections to the SSH server. According to needs, set ACL filtering to perform for all connections to the SSH server.

✚ Enabling the Public Key Authentication for SSH Users

- Optional.
- Only SSHv2 supports authentication based on the public key. This configuration associates a public key file on the client with a user name. When a client is authenticated upon login, a public key file is specified based on the user name.

Verification

- Run the **show ip ssh** command to display the current SSH version, authentication timeout, and maximum number of authentication retries of the SSH server.
- Run the **show crypto key mypubkey** command to display the public information of the public key to verify whether the key has been generated.
- Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

Related Commands

✚ Enabling the SSH Server

Command	enable service ssh-server
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To disable the SSH server, run the no enable service ssh-server command in global configuration mode.

	After this command is executed, the SSH server state changes to DISABLE.

✚ Disconnecting an Established SSH Session

Command	disconnect ssh[vty] session-id
Parameter Description	vty: Indicates an established virtual teletype terminal (VTY) session. session-id: Indicates the ID of the established SSH session. The value ranges from 0 to 35.
Command Mode	Privileged EXEC mode
Usage Guide	Specify an SSH session ID to disconnect the established SSH session. Alternatively, specify a VTY session ID to disconnect a specified SSH session. Only an SSH session can be disconnected.

✚ Generating an SSH Key

Command	crypto key generate {rsa dsa}
Parameter Description	rsa: Generates an RSA key. dsa: Generates a DSA key.
Command Mode	Global configuration mode
Usage Guide	The no crypto key generate command does not exist. You need to run the crypto key zeroize command to delete a key. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. If an RSA key is generated, both SSHv1 and SSHv2 are supported. If only a DSA key is generated, only SSHv2 can use the key.

✚ Specifying the SSH Version

Command	ip ssh version {1 2}
Parameter Description	1: Indicates that the SSH server only receives the connection requests sent by SSHv1 clients. 2: Indicates that the SSH server only receives the connection requests sent by SSHv2 clients.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh version command to restore the default settings. By default, the SSH server supports both SSHv1 and SSHv2.

✚ Configuring the SSH Authentication Timeout

Command	ip ssh time-out time
Parameter Description	time: Indicates the SSH authentication timeout. The value ranges from 1 to 120. The unit is second.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh time-out command to restore the default SSH authentication timeout, which is 120s.

✚ Configuring the Maximum Number of SSH Authentication Retries

Command	ip ssh authentication-retries <i>retry times</i>
Parameter Description	<i>retry times</i> : Indicates the maximum number of user authentication retries. The value ranges from 0 to 5.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh authentication-retries command to restore the default number of user authentication retries, which is 3.

✎ Specifying the SSH Encryption Mode

Command	ip ssh cipher-mode {cbc ctr others }
Parameter Description	cbc: Sets the encryption mode supported by the SSH server to the CBC mode. Corresponding algorithms include DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, and Blowfish-CBC. ctr: Sets the encryption mode supported by the SSH server to the CTR mode. Corresponding algorithms include AES128-CTR, AES192-CTR, and AES256-CTR. others: Sets the encryption mode supported by the SSH server to others. The corresponding algorithm is RC4.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the encryption mode supported by the SSH server. On Ruijie devices, the SSHv1 server supports the DES-CBC, 3DES-CBC, and Blowfish-CBC encryption algorithms; the SSHv2 server supports the AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4 encryption algorithms. These algorithms can be grouped into three encryption modes: CBC, CTR, and others. As the cryptography continuously develops, it is approved that encryption algorithms in the CBC and others modes can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption mode supported by the SSH server to CTR to increase the security level of the SSH server.

✎ Specifying the SSH Message Authentication Algorithm

Command	ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96}
Parameter Description	md5: Indicates that the message authentication algorithm supported by the SSH server is MD5. md5-96: Indicates that the message authentication algorithm supported by the SSH server is MD5-96. sha1: Indicates that the message authentication algorithm supported by the SSH server is SHA1. sha1-96: Indicates that the message authentication algorithm supported by the SSH server is SHA1-96.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the message authentication algorithm supported by the SSH server. On Ruijie devices, the SSHv1 server does support any message authentication algorithm; the SSHv2 server supports the MD5, SHA1, SHA1-96, and MD5-96 message authentication algorithms. You can select message authentication algorithms supported by the SSH server as required.

Configuring Support for DH Key Exchange Algorithm on the SSH Server

Command	ip ssh key-exchange { dh_group_exchange_sha1 dh_group14_sha1 dh_group1_sha1 }
Parameter Description	dh_group_exchange_sha1: Indicates configuration of diffie-hellman-group-exchange-sha1 for keyexchange. The key has 2,048 bytes, which cannot be edited. dh_group14_sha1: Indicates configuration of diffie-hellman-group14-sha1 for keyexchange. The key has 2,048 bytes. dh_group1_sha1: Indicates configuration of diffie-hellman-group1-sha1 for keyexchange. The key has 1,024 bytes.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure a DH key exchange method on the SSH. Ruijie's SSHv1 server does not support DH key exchange method, while the SSHv2 server supports diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 for keyexchange.

Configuring ACL Filtering of the SSH Server

Command	{ip ipv6} ssh access-class { access-list-number access-list-name }
Parameter Description	access-list-number: Indicates the ACL number and the number range is configurable. The standard ACL number ranges are 1 to 99 and 1300 to 1999. The extended ACL number ranges are 100 to 199 and 2000 to 2699. Only IPv4 addresses are supported. access-list-name: Indicates an ACL name. Both IPv4 and IPv6 addresses are supported.
Command Mode	Global configuration mode
Usage Guide	Run this command to perform ACL filtering for all connections to the SSH server. In line mode, ACL filtering is performed only for specific lines. However, ACL filtering rules of the SSH are effective to all SSH connections.

Configuring RSA Public Key Authentication

Command	ip ssh peer test public-key rsaflash:rsa.pub
Parameter Description	test: Indicates the user name. rsa: Indicates that the public key type is RSA. rsa.pub: Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the RSA public key file associated with user <i>test</i>. Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

Configuring DSA Public Key Authentication

Command	ip ssh peer test public-key dsaflash:dsa.pub
Parameter	<i>test</i> : Indicates the user name.
Description	dsa : Indicates that the public key type is DSA. <i>dsa.pub</i> : Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the DSA key file associated with user test . Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

Configuration Example

 The following configuration examples describe only configurations related to SSH.

Generating a Public Key on the SSH Server

Configuration Steps	Run the crypto key generate { rsa dsa } command to generate a RSA public key for the server.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# crypto key generate rsa</pre> Choose the size of the rsa key modulus in the range of 512 to 2048 and the size of the dsa key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: - If the generation of the RSA key is successful, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ...[ok] % Generating 512 bit RSA keys ...[ok]</pre> - If the generation of the RSA key fails, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ...[fail] % Generating 512 bit RSA keys ...[fail]</pre>
Verification	Run the show crypto key mypubkey rsa command to display the public information about the RSA key. If the public information about the RSA key exists, the RSA key has been generated.

SSH Server	<pre> Ruijie(config)#show crypto key mypubkey rsa % Key pair was generated at: 1:49:47 UTC Jan 4 2013 Key name: RSA1 private Usage: SSH Purpose Key Key is not exportable. Key Data: AAAAAwEA AQAAAHJM 6izXtlpp rUSOEGZ/ UhFpRRrW nngP4BU7 mG836apf jajSYwcU 803LojHL ayJ8G4pG 7j4T4ZSf FKg09kfr 92JpRNHQ gbwaPc5/ 9UnTtX9t qFIKDJlj 0dKBcCfN tr0r/CT+ cs5t1GKV SOICGifz oB+pYaE= % Key pair was generated at: 1:49:47 UTC Jan 4 2013 Key name: RSA private Usage: SSH Purpose Key Key is not exportable. Key Data: AAAAAwEAAQAAAHJfLwKnzOgO F3R1KhTN /7PmQYoE v0a2VXTX 8ZCa7S1l EghLDLJc w3T5JQXk Rr3iBD5s b1EeOL4b 2lykZt/u UetQ0Q80 sISgIfZ9 8o5No3Zz MPMOLnQR G4c7/28+ GOHzYkTk 4IiQuTIL HRgtbyEYXCFaaxU= </pre>

➤ Specifying the SSH Version

Configuration Steps	Run the ip ssh version { 1 2 } command to set the version supported by the SSH server to SSHv2.
SSH Server	<pre> Ruijie#configure terminal Ruijie(config)#ip ssh version 2 </pre>
Verification	Run the show ip ssh command to display the SSH version currently supported by the SSH server.
SSH Server	<pre> Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: disabled </pre>

➤ Configuring the SSH Authentication Timeout

Configuration Steps	Run the ip ssh time-out <i>time</i> command to set the SSH authentication timeout to 100s.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)#ip ssh time-out 100</pre>
Verification	Run the show ip ssh command to display the configured SSH authentication timeout.
SSH Server	<pre>Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

📌 Configuring the Maximum Number of SSH Authentication Retries

Configuration Steps	Run the ip ssh authentication-retries <i>retry times</i> command to set the maximum number of user authentication retries on the SSH server to 2.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)#ip ssh authentication-retries 2</pre>
Verification	Run the show ip ssh command to display the configured maximum number of authentication retries.
SSH Server	<pre>Ruijie(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

📌 Specifying the SSH Encryption Mode

Configuration Steps	Run the ip ssh cipher-mode {cbc ctr others} command to set the encryption mode supported by the SSH server to CTR.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh cipher-mode ctr</pre>
Verification	Select the CTR encryption mode on the SSH client, and verify whether you can successfully log in to the SSH server from the SSH client.

📌 Specifying the SSH Message Authentication Algorithm

Configuration Steps	Run the ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96 } command to set the message authentication algorithm supported by the SSH server to SHA1.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh hmac-algorithmsha1</pre>
Verification	Select the SHA1 message authentication algorithm on the SSH client, and verify whether you can successfully log in to the SSH server from the SSH client.

Configuring Support for DH Key Exchange Algorithm on the SSH Server

Configuration Steps	Run the ip ssh key-exchange { dh_group_exchange_sha1 dh_group14_sha1 dh_group1_sha1 } command to configure a key exchange method on the SSH server.
SSH Server	<pre>Ruijie# configure terminal Ruijie(config)# ip ssh key-exchange dh_group14_sha1</pre>
Verification	Choose diffie-hellman-group14-sha1 on the client terminal and check if successful login is performed.

Configuring the Public Key Authentication

Configuration Steps	Run the ip ssh peer username public-key { rsa dsa } filename command to associate a public key file of the client with a user name. When the client is authenticated upon login, a public key file (for example, RSA) is specified based on the user name.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh peer test public-key rsaflash:rsa.pub</pre>
Verification	Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

Configuring SSH Device Management

Scenario Figure 9-7	 The diagram illustrates a network topology for SSH device management. On the left, an 'SSH Client' with IP address '192.168.23.83' is represented by a laptop icon. A line connects it to a central cloud icon labeled 'IP Network'. Another line connects the cloud to an 'SSH Server' with IP address '192.168.23.122' on the right, represented by a server rack icon. You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible client software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the configurations of the SSH client.

Configuration Steps	● Start the PuTTY software. ● On the Session option tab of PuTTY, type in the host IP address 192.168.23.122 and SSH port number 22, and select the connection type SSH. ● On the SSH option tab of PuTTY, select the preferred SSH protocol version 2. ● On the SSH authentication option tab of PuTTY, select the authentication method Attempt "keyboard-interactive" auth. ● Click Open to connect to the SSH server. ● Type in the correct user name and password to enter the terminal login interface.
SSH Client	Figure 9-8  Host Name (or IP address) indicates the IP address of the host to be logged in. In this example, the IP address is 192.168.23.122. Port indicates the port ID 22, that is, the default ID of the port listened by SSH. Connection type is SSH. Figure 9-9

As shown in Figure 9-9, select **2** as the preferred SSH protocol version in the **Protocol options** pane because SSHv2 is used for login.

Figure 9-10

As shown in Figure 9-10, select **Attempt "keyboard-interactive" auth** as the authentication method to support authentication based on the user name and password.

Then, click **Open** to connect to the configured server host, as shown in Figure 9-11.

Figure 9-11

The **PuTTY Security Alert** box indicates that you are logging in to the client of the server 192.168.23.122, and asks you whether to receive the key sent from the server.

If you select **Yes**, a login dialog box is displayed, as shown in Figure 9-12.

Figure 9-12

Type in the correct user name and password, and you can log in to the SSH terminal interface, as shown in Figure 9-13.

Figure 9-13

	
Verification	● Run the show ip ssh command to display the configurations that are currently effective on the SSH server. ● Run the show ssh command to display information about every SSH connection that has been established.
	<pre>Ruijie#show ip ssh SSH Enable - version 1.99 Authentication timeout: 120 secs Authentication retries: 3 Ruijie#show ssh Connection Version Encryption Hmac State Username 0 2.0 aes256-cbc hmac-shal Session started test</pre>

 Configuring SSH Local Line Authentication

Scenario
Figure 9-14

SSH users can use the local line password for user authentication, as shown in Figure 9-14. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.

Configuration
Steps

- Configure the SSH server as follows:
- Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.
 - Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses the RSA key, whereas SSHv2 uses the RSA or DSA key.
 - Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server based on this IP address. The route from the SSH client to the SSH server is reachable.
- Configure the SSH client as follows:
- Diversified SSH client software is available, including PuTTY, Linux, and SecureCRT. This document takes PuTTY as an example to explain the method for configuring the SSH client. For details about the configuration method, see "Configuration Steps."

SSH Server

Before configuring SSH-related function, ensure that the route from the SSH user to the network segment of the SSH server is reachable. The interface IP address configurations are shown in Figure 9-15. The detailed procedures for configuring IP addresses and routes are omitted.

```
Ruijie(config)# enable service ssh-server
Ruijie(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:
Choose the size of the key modulus in the range of 360 to 2048 for your
```

	Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ... [ok] % Generating 512 bit RSA keys ... [ok] Ruijie(config)#interface fastEthernet0/1 Ruijie(config-if-fastEthernet0/1)#ip address 192.168.23.122 255.255.255.0 Ruijie(config-if-fastEthernet0/1)#exit Ruijie(config)#line vty 0 Ruijie(config-line)#password passzero Ruijie(config-line)#privilege level 15 Ruijie(config-line)#login Ruijie(config-line)#exit Ruijie(config)#line vty 4 Ruijie(config-line)#password pass Ruijie(config-line)#privilege level 15 Ruijie(config-line)#login Ruijie(config-line)#exit
SSH Client(PC1/ PC2)	Figure 9-15

Set the IP address and port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22 (For details about the configuration method, see "Configuring SSH Device Management."). Click **Open** to start the SSH server. As the current authentication mode does not require a user name, you can type in any user name, but cannot leave the user name unspecified. (In this example, the user name is "anyname".)

- Verification
- Run the **show running-config** command to display the current configurations.
 - Verify that the SSH client configurations are correct.

SSH Server

```
Ruijie#show running-config
Building configuration...

!
enable secret 5 $1$eyy2$xs28FDw4s2q0tx97
enable service ssh-server

!

interface fastEthernet0/1

ip address 192.168.23.122 255.255.255.0
```

	<pre>! line vty 0 privilege level 15 login password passzero line vty 1 4 privilege level 15 login password pass ! end</pre>																				
SSH Client	Set up a connection, and enter the correct password. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Then, the SSH server operation interface is displayed, as shown in Figure 9-16. Figure 9-16  <pre>Ruijie#show users</pre> <table><tr><th>Line</th><th>User</th><th>Host(s)</th><th>Idle</th><th>Location</th></tr><tr><td colspan="5">-----</td></tr><tr><td>* 0</td><td>con 0</td><td>---</td><td>idle</td><td>00:00:00</td></tr><tr><td colspan="5">---</td></tr></table>	Line	User	Host(s)	Idle	Location	-----					* 0	con 0	---	idle	00:00:00	---				
Line	User	Host(s)	Idle	Location																	

* 0	con 0	---	idle	00:00:00																	

	1 vty 0	---	idle	00:08:02	192.168.23.83
	2 vty 1	---	idle	00:00:58	192.168.23.121

Configuring AAA Authentication of SSH Users

Scenario Figure 9-17	 SSH users can use the AAA authentication mode for user authentication, as shown in Figure 9-17. To ensure security of data exchange, the PC functions as the SSH client, and uses the SSH protocol to log in to the network device where the SSH server is enabled. To better perform security management, the AAA authentication mode is used on the user login interface of the SSH client. Two authentication methods, including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, select the local authentication method.
Configuration Steps	● The route from the SSH client to the SSH server is reachable, and the route from the SSH server to the Radius server is also reachable. ● Configure the SSH server on the network device. The configuration method is already described in the previous example, and therefore omitted here. ● Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.
SSH Server	<pre>Ruijie(config)# enable service ssh-server Ruijie(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take</pre>

	<pre> a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ...[ok] % Generating 512 bit RSA keys ...[ok] Ruijie(config)#crypto key generate dsa Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit DSA keys ...[ok] Ruijie(config)#interface gigabitEthernet1/1 Ruijie(config-if-gigabitEthernet1/1)#ip address 192.168.217.81 255.255.255.0 Ruijie(config-if-gigabitEthernet1/1)#exit Ruijie#configure terminal Ruijie(config)#aaa new-model Ruijie(config)#radius-server host 192.168.32.120 Ruijie(config)#radius-server key aaradius Ruijie(config)#aaa authentication login methodgroup radius local Ruijie(config)#line vty 0 4 Ruijie(config-line)#login authentication method Ruijie(config-line)#exit Ruijie(config)#username user1 privilege 1 password 111 Ruijie(config)#username user2 privilege 10 password 222 Ruijie(config)#username user3 privilege 15 password 333 Ruijie(config)#enable secret w </pre>
Verification	● Run the show running-config command to display the current configurations. ● This example assumes that the SAM server is used. ● Set up a remote SSH connection on the PC. ● Check the login user.
	<pre> Ruijie#show run aaa new-model </pre>

```
!

    login authentication method  
!  
End
```

On the SSH client, choose **System Management>Device Management**, and add the device IP address **192.168.217.81** and the device key **aaaradius**.

Choose **Security Management>Device Management Rights**, and set the rights of the login user.

Choose **Security Management>Device Administrator**, and add the user name **user** and password **pass**.

Configure the SSH client and set up a connection to the SSH server. For details, see the previous example.

Type in the user name **user** and password **pass**. Verify that you can log in to the SSH server successfully.

```
Ruijie#show users
```

	Line	User	Host(s)	Idle	Location
	0 con 0		idle	00:00:31	
	* 1 vty 0	user	idle	00:00:33	192.168.217.60

Configuring Public Key Authentication of SSH Users

Scenario Figure 9-18	 SSH Client 192.168.23.83 IP Network SSH Server 192.168.23.122 SSH users can use the public key for user authentication, and the public key algorithm is RSA or DSA, as shown in Figure 9-18. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.
Configuration Steps	- To implement public key authentication on the client, generate a key pair (for example, RSA key) on the client, place the public key on the SSH server, and select the public key authentication mode. i After the key pair is generated on the client, you must save and upload the public key file to the server and complete the server-related settings before you can continue to configure the client and connect the client with the server. - After the key is generated on the client, copy the public key file from the client to the flash of the SSH server, and associate the file with an SSH user name. A user can be associated with one RSA public key and one DSA public key.
SSH Client	Run the puttygen.exe software on the client. Select SSH-2 RSA in the Parameters pane, and click Generate to generate a key, as shown in Figure 9-19. Figure 9-19

When a key is being generated, you need to constantly move the mouse over a blank area outside the green progress bar; otherwise, the progress bar does not move and key generation stops, as shown in Figure 9-20.

Figure 9-20

To ensure security of the RSA public key authentication, the length of the generated RSA key pair must be equal to or larger than 768 bits. In this example, the length is set to 1024 bits.

Figure 9-21

After the key pair is generated, click **Save public key**, type in the public key name **test_key.pub**, select the storage path, and click **Save**. Then click **Save private key**. The following prompt box is displayed. Select **Yes**, type in the public key name **test_private**, and click **Save**.

Figure 9-22

You must select the OpenSSH key file; otherwise, the key file cannot be used. The **puttygen.exe** software can be used to generate a key file in OpenSSH format, but this file cannot be directly used by the PuTTY client. You must use **puttygen.exe** to convert the private key to the PuTTY format. Format conversion is not required for the public key file stored on the server, and the format of this file is still OpenSSH, as shown in Figure 9-23.

Figure 9-23

	
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip ssh peer test public-key rsaflash:test_key.pub</pre>
Verification	After completing the basic configurations of the client and the server, specify the private key file test_private on the PuTTY client, and set the host IP address to 192.168.23.122 and port ID to 22 to set up a connection between the client and the server. In this way, the client can use the public key authentication mode to log in to the network device.
	Figure 9-24

Common Errors

- The **no crypto key generate** command is used to delete a key.

9.4.2 Configuring the SCP Service

Configuration Effect

After the SCP function is enabled on a network device, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.

Notes

- The SSH server must be enabled in advance.

Configuration Steps

➤ Enabling the SCP Server

- Mandatory.
- By default, the SCP server function is disabled. Run the **ip scp server enable** command to enable the SCP server function in global configuration mode.

Verification

Run the **show ip ssh** command to check whether the SCP server function is enabled.

Related Commands

▾ Enabling the SCP Server

Command	ip scp server enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to enable the SCP server. Run the no ip scp server enable command to disable the SCP server.

Configuration Example

▾ Enabling the SCP Server

Configuration Steps	Run the ip scp server enable command to enable the SCP server.
	<pre>Ruijie#configure terminal Ruijie(config)#ip scp server enable</pre>
Verification	Run the show ip ssh command to check whether the SCP server function is enabled.
	<pre>Ruijie(config)#show ipssh SSH Enable - version 1.99 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: enabled</pre>

▾ Configuring SSH File Transfer

Scenario Figure 9-25	The diagram illustrates a network topology for SSH file transfer. On the left, an 'SSH Client' with IP address 192.168.23.83 is shown. A line connects it to a central cloud labeled 'IP Network'. Another line connects the 'IP Network' to an 'SSH Server' on the right, which has IP address 192.168.23.122. The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server.
Configuration	Enable the SCP service on the server.

Steps	 The SCP server uses SSH threading. When connecting to a network device for SCP transmission, the client occupies a VTY session (You can find out that the user type is SSH by running the show user command). - On the client, use SCP commands to upload files to the server, or download files from the server. Syntax of the SCP command: <pre>scp [-l246BCpqrv] [-c cipher] [-F ssh_config] [-i identity_file] [-l limit] [-o ssh_option] [-P port] [-S program] [[user@]host1:]file1 [...] [[user@]host2:]file2</pre> Descriptions of some options: -l: Uses SSHv1 (If not specified, SSHv2 is used by default); -2: Uses SSHv2 (by default); -C: Uses compressed transmission. -c: Specifies the encryption algorithm to be used. -r: Transmits the whole directory; -i: Specifies the key file to be used. -l: Limits the transmission speed (unit: Kbit/s). For other parameters, see the file scp.0.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)# ip scp server enable</pre>
Verification	File transmission example on the Ubuntu 7.10 system: Set the username of a client to test and copy the config.text file from the network device with the IP address of 192.168.195.188 to the /root directory on the local device.
	<pre>root@dhcpd:~#scp test@192.168.23.122:/config.text /root/config.text test@192.168.195.188's password: config.text 100% 1506 1.5KB/s 00:00 Read from remote host 192.168.195.188: Connection reset by peer</pre>

9.4.3 Configuring the SSH Client

Configuration Effect

On the network device that supports the SSH server, enable the SSH server function, and specify the user authentication method and supported SSH versions. Then, you can use the built-in SSH client function of the device to set up a secure connection with the SSH server, implementing remote device management.

Notes

- The SSH server function must be configured in advance on the device that needs to remotely support the SSH server.
- The SSH client must communicate with the SSH server properly.

Configuration Steps

▾ Specifying the Source Interface of the SSH Client

- (Optional) This configuration must be performed on the SSH-client device.

▾ Establishing a Session with the SSH Server

- (Optional) Use the **ssh** command on the client to set up a connection with a remote server.
- Before using this command, enable the SSH server function and configure the SSH key and authentication mode on the server.

▾ Recovering an Established SSH Session

- (Optional) Run the related command to recover a session after temporary stop if necessary.

▾ Disconnecting a Suspended SSH Session

- (Optional) This configuration must be performed on the SSH client if you need to disconnect a specified SSH session.

Verification

Run the **show ssh-session** command to display information about every established SSH client session.

Related Commands

▾ Specifying the Source Interface of the SSH Client

Command	ip ssh source-interface <i>interface-name</i>
Parameter	<i>interface-name</i> : Specifies an interface, the IP address of which will be used as the source address of an SSH client session.
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to specify an interface, the IP address of which will be used as the global source address of an SSH client session. When the ssh command is used to connect to an SSH server, this global configuration will be used if a source interface or a source address is not specified for this connection. Run the no ip ssh source-interface command to restore the default setting.

▾ Establishing a Session with the SSH Server

Command	ssh [oob] [-v {1 2}][-c {3des aes128-cbc aes192-cbc aes256-cbc}] [-l username] [-m {hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160}] [-p port-num] [{ ip-addr hostname}] [via mgmt-name] [/source {ip A.B.C.D ipv6 X:X:X:X::X interface interface-name}] [/vrf vrf-name]
Parameter Description	N/A
Command Mode	User EXEC mode
Usage Guide	The ssh command is used to set up a secure and encrypted connection from the local device (an SSH client) to another device (an SSH server) or any other server that supports SSHv1 or SSHv2. This connection provides a mechanism similar to the Telnet connection except that all data transmitted over this connection is encrypted. Based on authentication and encryption, the SSH client can set up a secure connection on an insecure network.  SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms.  SSHv2 supports the following Advanced Encryption Standards (AES):AES128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, and AES256-CTR.  SSHv1 does not support the Hashed Message Authentication Code (HMAC).  If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is set up.

📌 Recovering an Established SSH Client Session

Command	ssh-session session-id
Parameter Description	session-id: Indicates the ID of an established SSH client session.
Command Mode	User EXEC mode
Usage Guide	This command is used to restore the use of an established SSH client session. When the ssh command is used to initiate an SSH client session, you can press Ctrl+Shift+6+X to temporarily exit the session. To recover this session, run the ssh-session command. In addition, if the session is already established, you can run the show ssh-session command to display information about the established session.

📌 Disconnecting a Suspended SSH Session

Command	disconnect ssh-session session-id
Parameter Description	session-id: Indicates the ID of a suspended SSH client session.
Command Mode	User EXEC mode
Usage Guide	You can specify an SSH client session ID to disconnect the specified SSH client session.

Configuration Example

Specifying the Source Interface of the SSH Client

Configuration Steps	Run the ip ssh source-interface <i>interface-name</i> command to specify an interface, the IP address of which will be used as the global source address of an SSH client session.
	<pre>Ruijie#configure terminal Ruijie(config)#ipsshsource-interface gigabitEthernet 0/1</pre>
Verification	N/A

Establishing a Session with the SSH Server

Scenario Figure 9-26	 The SSH server function is enabled on the server. The ssh command is used on the client to set up a secure connection with the server.
Configuration Steps	- Enable the SSH server function on the server. - Configure the SSH key on the server. - Configure the authentication mode of the SSH server, and use the local line authentication mode for Line 0 to Line 4. - Configure the IP address of the Gi 0/1 interface of the SSH server. The client will use this address as the source address to connect to the SSH server. - Configure the SSH client, and specify the source address of the SSH client. - By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. - With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. - The authentication mode used by the SSH server is local line authentication. The local user name is admin, and the password is 123456. - The SSH client is connected to the SSH server based on this IP address. The routes from the SSH clients to the SSH server are reachable. - Configure the IP address of the Gi 0/1 interface of the SSH server. The client will use this address as the source address to connect to the SSH server.
SSH Server	<pre>Ruijie#configure terminal Ruijie(config)#enable service ssh-server</pre>

	<pre> Ruijie(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ...[ok] % Generating 512 bit RSA keys ...[ok] Ruijie(config)#line vty 0 4 Ruijie(config-line)#login local Ruijie(config-line)#exit Ruijie(config)#username admin password 123456 Ruijie(config)#username admin privilege 15 Ruijie(config-line)#exit Ruijie(config)#interface gigabitEthernet0/1 Ruijie(config-if-gigabitEthernet0/1)#ip address 192.168.23.122 255.255.255.0 Ruijie(config-if-gigabitEthernet0/1)#exit </pre>

	<pre> Ruijie#ssh -l admin 192.168.23.122 %Trying 192.168.23.122, 22,...open admin@192.168.23.122's password: Ruijie# Ruijie#sh users Line User Host(s) Idle Location 0 con 0 * 1 vty 0 admin idle 00:00:36 192.168.217.20 </pre>

9.4.4 Configuring the SCP Client

Configuration Effect

On the network device that supports the SCP server, enable the SCP service so that users can directly download files from the network device and upload local files to the network device. In addition, all exchanged data is encrypted, featuring authentication and security.

Notes

- The SSH server function must be configured and the SCP service must be enabled on the device in order to remotely support the SCP server.
- The SCP client must communicate with the SCP server properly.

Configuration Steps

➤ Specifying Source Interface of SCP Client

- (Optional) Specify a source interface of the SCP client.

➤ Implementing File Transfer with SCP Server via SCP Client

- (Optional) Run the **scp** command to implement file transfer with the remote SCP server via the SCP client.

- Before running this command, enable the SSH server function, configure an SSH key and authentication mode, and enable the SCP server function.

Verification

Check whether file transfer is successful.

Related Commands

Specifying Source Interface of SCP Client

Command	ip scp client source-interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates a source interface. Set the IP address of the interface to the source IP address of the SCP client.
Command Mode	Global configuration mode
Usage Guide	Run this command to specify the IP address of the designated interface as the global source address of the SCP client. During interaction with the remote SSH server via the scp command, global settings are used if no source interface or source address is specified. Run the no ip ssh source-interface command to restore the default settings.

Implementing File Transfer with SCP Server via SCP Client

Command	scp [<i>oob</i>] [-v { 1 2 }] [-c { 3des aes128-cbc aes192-cbc aes256-cbc }] [-l <i>username</i>] [-m { hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }] [-p <i>port-num</i>] { <i>filename username@host:/filename</i> <i>username@host:/filename filename</i> } [via <i>mgmt-name</i>] [/source { ip <i>A.B.C.D</i> ipv6 <i>X:X:X:X::X</i> }] [interface <i>interface-name</i>] [/vrf <i>vrf-name</i>]
Parameter Description	N/A
Command Mode	Common user mode
Usage Guide	Run the scp command to establish a secure and encrypted connection from the local device (SCP client) to another device (SCP server) to implement file transfer.

Configuration Example

Specifying Source Interface of SCP Client

Configuration Steps	Run the ip scp client source-interface <i>interface-name</i> command to specify the IP address of the interface as the global source address of the SCP client.
	<pre>Ruijie# configure terminal Ruijie(config)# ip scp client source-interface gigabitEthernet 0/1</pre>
Verification	N/A

Configuration Steps	Run the ip scp client source-interface <i>interface-name</i> command to specify the IP address of the interface as the global source address of the SCP client.
	<pre>Ruijie# configure terminal Ruijie(config)# ip scp client source-interface gigabitEthernet 0/1</pre>
Verification	N/A

Implementing File Transfer with SCP Server via SCP Client

Scenario Figure 9-27	 Enable the SSH server and SCP server functions on the server end, and run the scp command on the SCP client to implement file transfer with the server.
Configuration Steps	- Enable the SSH server function on the server end. - Configure an SSH key on the server end. - Configure an authentication mode for the SSH server, and configure the local authentication mode for lines 0 to 4. - Enable the SCP server function. - Configure the IP address of the Gi 0/1 interface of the SSH server, so that the client uses this address as the source address to connect to the SSH server. - Configure the SSH client, and specify the source address of the SSH client. i By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. i With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns an authentication success or failure message. SSHv1 uses an RSA key, while SSHv2 uses an RSA or DSA key. i The SSH server uses the local authentication mode. The local username is admin, and the password is 123456. i The SSH client connects to the SSH server at this IP address. The route from the SSH client to the SSH server is reachable. i Configure the IP address of the Gi 0/1 interface of the SSH client, so that the client uses this address as the source address to connect to the SSH server.
SCP Server	<pre>Ruijie# configure terminal</pre>

	<pre> Ruijie(config)#enable service ssh-server Ruijie(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ... [ok] % Generating 512 bit RSA keys ... 9.5 Monitoring

Displaying

Description	Command
Displays the effective SSH server configurations.	show ipssh
Displays the established SSH connection.	show ssh
Displays the public information of the SSH public key.	show crypto key mypubkey
Displays the established SSH client session.	show ssh-session

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SSH sessions.	debug ssh
Debugs SSH client sessions.	debug ssh client

10 Configuring URPF

10.1 Overview

Unicast Reverse Path Forwarding (URPF) is a function that protects the network against source address spoofing.

URPF obtains the source address and inbound interface of a received packet, and searches a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. Otherwise, the packet is forwarded.

URPF is implemented in two modes:

- Strict mode: It is often deployed on a point-to-point (P2P) interface, and inbound and outbound data streams must go through the network of the P2P interface.
- Loose mode: It is applicable to the asymmetric routes or multihomed network that have the problem of asymmetric traffic.

Protocols and Standards

- RFC 2827: Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing
- RFC 3704: Ingress Filtering for Multi-homed Networks

10.2 Applications

Application	Description
Strict Mode	Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network.
Loose Mode	On a multihomed network, the user network is connected to multiple Internet service providers (ISPs), and the inbound and outbound traffic is not symmetric. Deploy the URPF loose mode on the outbound interface connected to ISPs to prevent invalid packets from attacking the user network.

10.2.1 Strict Mode

Scenario

An attacker initiates an attack by sending packets with the spoofed source address 11.0.0.1. As a result, the server sends a lot of SYN or ACK packets to the hosts that do not initiate the attack, and the host with the real source address 11.0.0.1 is also affected. Even worse, if the network administrator determines that this address initiates an attack to the network, and therefore blocks all data streams coming from this source address, the denial of service (DoS) of this source address occurs.

Figure 10-1

Remarks	The attacker sends spoofing packets using a spoofed address of the casualty.

Deployment

- Deploy the URPF strict mode on device A to protect the device against source address spoofing.

10.2.2 Loose Mode

Scenario

The asymmetric route is a common network application used to control the network traffic or to meet the routing policy requirements.

As shown in Figure 10-2, if the URPF strict mode is enabled on the G1/1 interface of R1, R1 receives a packet from the network segment 192.168.20.0/24 on the G1/1 interface, but the interface obtained through the URPF check is G1/2. Therefore, this packet fails in the URPF check and is dropped.

Figure 10-2

Deployment

- Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet.
- The URPF loose mode can resolve the asymmetric traffic problem of the asymmetric route and prevents access of invalid data streams.

10.3 Features

Basic Concepts

📄 URPF Strict Mode

Obtain the source address and inbound interface of a received packet, and search a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. The strict mode requires that the inbound interface of a received packet must be the outbound interface of the route entry to the source address of the packet.

📄 URPF Loose Mode

Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet. However, the route cannot be a route of a host on the local network.

📄 URPF Packet Loss Rate

The URPF packet loss rate is equal to the number of packets dropped due to the URPF check per second. The unit is packets/second, that is, pps.

📄 Calculation Interval of the URPF Packet Loss Rate

It is the interval from the previous time the packet loss rate is calculated to the current time the packet loss rate is calculated.

📄 Sampling Interval of the URPF Packet Loss Rate

It is the interval at which the number of lost packets is collected for calculating the packet loss rate. This interval must be equal to or longer than the calculation interval of the packet loss rate.

📄 Threshold of the URPF Packet Loss Rate

It refers to the maximum packet loss rate that is acceptable. When the packet loss rate exceeds the threshold, alarms can be sent to users through syslogs or trap messages. You can adjust the threshold of the packet loss rate based on the actual conditions of the network.

📄 Alarm Interval of the URPF Packet Loss Rate

It is the interval at which alarms are sent to users. You can adjust the alarm based on the actual conditions of the network to prevent frequently output of logs or trap messages.

📌 Calculation of the URPS Packet Loss Rate

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

Overview

Feature	Description
Enabling URPF	Enable URPF to perform a URPF check, thus protecting the device against source address spoofing.
Notifying the URPF Packet Loss Rate	To facilitate monitoring of information about lost packets after URPF is enabled, Ruijie devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

10.3.1 Enabling URPF

Enable URPF to perform a URPF check on IP packets, thus protecting the device against source address spoofing.

Working Principle

URPF can be applied to IP packets based on configurations, but the following packets are not checked by URPF:

1. After URPF is enabled, the source address of a packet is checked only if the destination address of the packet is an IPv4/IPv6 unicast address, and is not checked if the packet is a multicast packet or an IPv4 broadcast packet.
2. If the source IP address of a DHCP/BOOTP packet is 0.0.0.0 and the destination IP address is 255.255.255.255, the packet is not checked by URPF.
3. A loopback packet sent by the local device to itself is not checked by URPF.

📌 URPF Configured in Interface configuration mode

URPF is performed on packets received on the configured interface. Interface configuration mode and global configuration mode are mutually exclusive.

- By default, the default route is not used for the URPF check. You can configure data to use the default route for the URPF check if necessary.
 - By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACL entry (ACE), the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.
-
- ✔ A switch supports configuration of URPF on a routed port of L3 aggregate port (AP). Switches of some models also support this configuration on SVI. (For details, contact Ruijie's technical staff.) The following constraints exist:
-
- URPF does not support association with the ACL option.

- After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such as scenario, be cautious in enabling URPF.
- After URPF is enabled, the route forwarding capacity of the device will be reduced by half.
- After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode.

Related Configuration

📌 Enabling URPF for a Specified Interface

By default, URPF is disabled for a specified interface.

Run the **ip verify unicast source reachable-via {rx | any} [allow-default][acl-name]** command to enable or disable the IPv4 URPF function for a specified interface.

By default, the default route is not used for the URPF check. You can use the **allow-default** keyword to use the default route for the URPF check if necessary.

By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.

10.3.2 Notifying the URPF Packet Loss Rate

To facilitate monitoring of information about lost packets after URPF is enabled, Ruijie devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

Working Principle

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: $\text{Current packet loss rate} = (\text{Current number of lost packets measured at the calculation interval} - \text{Number of lost packets measured before the sampling interval}) / \text{Sampling interval}$

After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Related Configuration

📌 Configuring the Calculation Interval of the URPF Packet Loss Rate

By default, the calculation interval of the URPF packet loss rate is 30s. If the calculation interval is found too short, run the **ip verify urpf drop-rate compute interval seconds** command to modify the calculation interval.

The calculation interval of the URPF packet loss rate ranges from 30 to 300.

✚ Configuring the Alarm Interval of the URPF Packet Loss Rate

By default, the alarm interval of the URPF packet loss rate is 300s. If the alarm interval is found inappropriate, run the **ip verify urpf drop-rate notify hold-down seconds** command to modify the alarm interval of the URPF packet loss rate.

The unit of the alarm interval is second. The value ranges from 30 to 300.

✚ Configuring the Function of Monitoring the URPF Packet Loss Information

By default, the function of monitoring the URPF packet loss information is disabled.

Run the **ip [ipv6] verify urpf drop-rate notify** command to enable or disable the function of monitoring the URPF packet loss information.

✚ Configuring the Threshold of the URPF Packet Loss Rate

By default, the threshold of the URPF packet loss rate is 1000 pps. If the threshold is found inappropriate, run the **ip [ipv6] verify urpf notification threshold rate-value** command to modify the threshold of the URPF packet loss rate.

The unit of the threshold is pps. The value ranges from 0 to 4,294,967,295.

10.4 Configuration

Configuration Item	Description and Command	
Enabling URPF	 (Mandatory) It is used to enable URPF.	
	ip verify unicast source reachable-via { rx any } [allow-default] [acl_name] (Interface configuration mode)	Enables URPF for a specified interface.
Configuring the Function of Monitoring the URPF Packet Loss Information	 (Optional) It is used to enable the function of monitoring the URPF packet loss information.	
	ip verify urpf drop-rate compute interval seconds	Configures the calculation interval of the URPF packet loss rate.
	ip verify urpf drop-rate notify	Configures the function of monitoring URPF packet loss information.
	ip verify urpf drop-rate notify hold-down seconds	Configures the alarm interval of the URPF packet loss rate.
	ip verify urpf notification threshold rate-value	Configures the threshold of the URPF packet loss rate.

10.4.1 Enabling URPF

Configuration Effect

- Enable URPF to perform a URPF check, thus protecting the device against source address spoofing.

- URPF enabled in interface configuration mode supports both the strict and loose modes.

Notes

- URPF is implemented with the help of the existing unicast routes on the network. Therefore, unicast routes must be configured on the network.

Configuration Steps

↳ Enabling IPv4 URPF for a Specified Interface

- Mandatory.

Verification

Enable URPF and check the source address as follows:

- If the strict mode is used, check whether a packet is forwarded only when the forwarding table contains the source address of the received IP packet and the outbound interface of the searched forwarding entry matches the inbound interface of the packet; otherwise, the packet is dropped.
- If the loose mode is used, check whether a packet is forwarded when a forwarding entry can be found in the forwarding table for the source address of the received IP packet; otherwise, the packet is dropped.

Related Commands

↳ Enabling IPv4 URPF for a Specified Interface

Command	ip verify unicast source reachable-via { rx any } [allow-default] [acl-id]
Parameter Description	rx: Indicates that the URPF check is implemented in strict mode. The strict mode requires that the outbound interface of the forwarding entry found in the forwarding table based on the source address of a received IP packet must match the inbound interface of the packet. any: Indicates that the URPF check is implemented in loose mode. The loose mode only requires that a forwarding entry can be found in the forwarding table based on the source address of a received IP packet. allow-default: (Optional) Indicates that the default route can be used for the URPF check. acl-id: (Optional) Indicates the ID of the ACL. Values include 1 to 99 (IP standard access list), 100 to 199 (IP extended access list), 1300 to 1999 (IP standard access list, expanded range), and 2000 to 2699 (IP extended access list, expanded range).
Command Mode	Interface configuration mode
Usage Guide	Based on the source address of a received IP packet, URPF checks whether any route to the source address exists in the forwarding table and accordingly determines whether the packet is valid. If no forwarding entry is matched, the packet is determined as invalid. You can enable URPF in interface configuration mode to perform a URPF check on packets received on the interface. By default, the default route is not used for the URPF check. You can use the allow-default keyword to use the default route for the URPF check if necessary.

	By default, packets that fail in the URPF check will be dropped. If the ACL (<i>acl-name</i>) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.  A switch supports configuration of URPF on a routed port or L3 AP port. In addition, the following constraints exists: 1. URPF does not support association with the ACL option. 2. After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such as scenario, be cautious in enabling URPF. 3. After URPF is enabled, the route forwarding capacity of the device will be reduced by half. 4. After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode.  URPF configured in global configuration mode does not support URPF check using the default routing.  URPF configured in global configuration mode is mutually exclusive with URPF configured in interface configuration mode.

Configuration Example

Configuring the Strict Mode

	Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network. To meet the preceding requirement, enable URPF in strict mode on the interface between the aggregation device and the access device.
Scenario Figure 10-3	
Verification	As shown in Figure 10-3, enable URPF in strict mode on the aggregation devices, including Ruijie A and

	Ruijie B. The configurations are as follows:
Ruijie-A	<pre> Ruijie-A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-A (config)# interface gigabitEthernet0/1 Ruijie-A (config-if-GigabitEthernet 0/1)#ip address 195.52.1.1 255.255.255.0 Ruijie-A (config-if-GigabitEthernet 0/1)#ip verify unicast source reachable-via rx Ruijie-A (config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 0/1)#exit Ruijie-A (config)# interface gigabitEthernet0/2 Ruijie-A (config-if-GigabitEthernet 0/2)#ip address 195.52.2.1 255.255.255.0 Ruijie-A (config-if-GigabitEthernet 0/2)#ip verify unicast source reachable-via rx Ruijie-A (config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 0/2)#exit </pre>
Ruijie-B	<pre> Ruijie-B# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-B (config)# interface gigabitEthernet0/1 Ruijie-B (config-if-GigabitEthernet 0/1)#ip address 195.52.3.1 255.255.255.0 Ruijie-B (config-if-GigabitEthernet 0/1)#ip verify unicast source reachable-via rx Ruijie-B (config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify Ruijie-B (config-if-GigabitEthernet 0/1)#exit Ruijie-B (config)# interface gigabitEthernet0/2 Ruijie-B (config-if-GigabitEthernet 0/2)#ip address 195.52.4.1 255.255.255.0 Ruijie-B (config-if-GigabitEthernet 0/2)#ip verify unicast source reachable-via rx Ruijie-B (config-if-GigabitEthernet 0/2)# ip verify urpf drop-rate notify Ruijie-B (config-if-GigabitEthernet 0/2)#exit </pre>
Verification	If source address spoofing exists on the network, run the show ip urpf command to display the number of spoofing packets dropped by URPF.
A	<pre> Ruijie-A#show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps </pre>

	Number of drop packets in this interface is 124 Number of drop-rate notification counts in this interface is 0 Ruijie-A#show ip urpf interface gigabitEthernet 0/2 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 133 Number of drop-rate notification counts in this interface is 0
B	Ruijie-B#show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 124 Number of drop-rate notification counts in this interface is 0 Ruijie-B#show ip urpf interface gigabitEthernet 0/2 IP verify source reachable-via RX IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 250 Number of drop-rate notification counts in this interface is 0

Configuring the Loose Mode

	On the egress device Ruijie A of user network A, to prevent invalid packets from attacking the user network, enable URPF in loose mode on the outbound interfaces G3/1 and G3/2 that connect to two ISPs.
Scenario Figure 10-4	

Ruijie-A	<pre> Ruijie-A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie-A (config)# interface gigabitEthernet3/1 Ruijie-A (config-if-GigabitEthernet 3/1)# ip address 195.52.1.2 255.255.255.252 Ruijie-A (config-if-GigabitEthernet 3/1)# ip verify unicast source reachable-via any Ruijie-A (config-if-GigabitEthernet 3/1)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 3/1)# exit Ruijie-A (config)# interface gigabitEthernet3/2 Ruijie-A (config-if-GigabitEthernet 3/2)# ip address 152.95.1.2 255.255.255.252 Ruijie-A (config-if-GigabitEthernet 3/2)# ip verify unicast source reachable-via any Ruijie-A (config-if-GigabitEthernet 3/2)# ip verify urpf drop-rate notify Ruijie-A (config-if-GigabitEthernet 3/2)# end </pre>
Verification	If source address spoofing exists on the network, run the show ip urpf command to display the number of spoofing packets dropped by URPF.
A	<pre> Ruijie #show ip urpf IP verify URPF drop-rate compute interval is 300s IP verify URPF drop-rate notify hold-down is 300s Interface gigabitEthernet3/1 IP verify source reachable-via ANY IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 4121 Number of drop-rate notification counts in this interface is 2 Interface gigabitEthernet3/2 IP verify source reachable-via ANY IP verify URPF drop-rate notify enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 352 Number of drop-rate notification counts in this interface is 0 </pre>

10.4.2 Configuring the Function of Monitoring the URPF Packet Loss Information

Configuration Effect

- After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Notes

- URPF must be enabled.

Configuration Steps

✚ Configuring the Calculation Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

✚ Configuring the Alarm Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

✚ Configuring the Function of Monitoring the URPF Packet Loss Information

- Optional.
- Interface configuration mode

✚ Configuring the Threshold of the URPF Packet Loss Rate

- Optional.
- Interface configuration mode

Verification

Simulate a source address spoofing attack, enable URPF, and check as follows:

- Enable the alarm function. After the packet loss rate exceeds the threshold, check whether an alarm can be generated normally.

Related Commands

✚ Configuring the Calculation Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate compute interval <i>seconds</i>
Parameter	interval <i>seconds</i> : Indicates the calculation interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Description	
Command	Global configuration mode

Mode	
Usage Guide	The calculation interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based calculation of the URPF packet loss rate.

✚ Configuring the Alarm Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate notify hold-down <i>seconds</i>
Parameter Description	hold-down <i>seconds</i> : Indicates the alarm interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	The alarm interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based alarms of the URPF packet loss rate.

✚ Configuring the Function of Monitoring the IPv4 URPF Packet Loss Information

Command	ip verify urpf drop-rate notify
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

✚ Configuring the Threshold of the IPv4 URPF Packet Loss Rate

Command	ip verify urpf notification threshold <i>rate-value</i>
Parameter Description	threshold <i>rate-value</i> : Indicates the threshold of the URPF packet loss rate. The unit is pps. The value ranges from 0 to 4,294,967,295. The default value is 1,000 pps.
Command Mode	Interface configuration mode
Usage Guide	If the threshold is 0, a notification is sent for every packet that is dropped because it fails in the URPF check. You can adjust the threshold based on the actual situation of the network.

Configuration Example

✚ Setting the Calculation Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the calculation interval of the URPF packet loss rate to 120s in global configuration mode.
	<pre> Ruijie#configure terminal Ruijie(config)# ip verify urpf drop-rate compute interval 120 Ruijie(config)# end </pre>

Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Ruijie# show ip urpf IP verify URPF drop-rate compute interval is 120s</pre>

Setting the Alarm Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the alarm interval of the URPF packet loss rate to 120s in global configuration mode. The configuration takes effect on both IPv4 URPF and IPv6 URPF.
	<pre>Ruijie#configure terminal Ruijie(config)# ip verify urpf drop-rate notify hold-down 120 Ruijie(config)# end</pre>
Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Ruijie# show ip urpf IP verify URPF drop-rate notify hold-down is 120s</pre>

10.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistics of the number of packets dropped during the IPv4 URPF check.	clear ip urpf [interface <i>interface-name</i>]

Displaying

Description	Command
Displays the IPv4 URPF configuration and statistics.	show ip urpf [interface <i>interface-name</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the URPF events.	debug urpf event
Debugs the URPF timers.	debug urpf timer

11 Configuring CPP

11.1 Overview

The CPU Protect Policy (CPP) provides policies for protecting the CPU of a switch.

In network environments, various attack packets spread, which may cause high CPU usages of the switches, affect protocol running and even difficulty in switch management. To this end, switch CPUs must be protected, that is, traffic control and priority-based processing must be performed for various incoming packets to ensure the processing capabilities of the switch CPUs.

CPP can effectively prevent malicious attacks in the network and provide a clean environment for legitimate protocol packets.

CPP is enabled by default. It provides protection during the entire operation of switches.

11.2 Applications

Application	Description
Preventing Malicious Attacks	When various malicious attacks such as ARP attacks intrude in a network, CPP divides attack packets into queues of different priorities so that the attack packets will not affect other packets.
Preventing CPU Processing Bottlenecks	Even when no attacks exist, it would become a bottleneck for CPU to handle excessive normal traffic. CPP can limit the rate of packets being sent to the CPU to ensure normal operation of switches.

11.2.1 Preventing Malicious Attacks

Scenario

Network switches at all levels may be attacked by malicious packets, typically ARP attacks.

As shown in Figure 11-1, switch CPUs process three types of packets: forwarding-plane, control-plane and protocol-plane. Forwarding-plane packets are used for routing, including ARP packets and IP route disconnection packets. Control-plane packets are used to manage services on switches, including Telnet packets and HTTP packets. Protocol-plane packets serve for running protocols, including BPDU packets and OSPF packets.

When an attacker initiates attacks by using ARP packets, the ARP packets will be sent to the CPU for processing. Since the CPU has limited processing capabilities, the ARP packets may force out other packets (which may be discarded) and consume many CPU resources (for processing ARP attack packets). Consequently, the CPU fails to work normally. In the scenario as shown in Figure 11-1, possible consequences include: common users fail to access the network; administrators fail to manage switches; the OSPF link between switch A and the neighbor B is disconnected and route learning fails.

Figure 11-1 Networking Topology of Switch Services and Attacks

Deployment

- By default, CPP classifies ARP packets, Telnet packets, IP route disconnection packets, and OSPF packets into queues of different priorities. In this way, ARP packets will not affect other packets.
- By default, CPP limits the rates of ARP packets and the rates of the priority queue where the ARP packets reside to ensure that the attack packets do not occupy too many CPU resources.
- Packets in the same priority queue with ARP packets may be affected by ARP attack packets. You can divide the packets and the ARP packets into different priority queues by means of configuration.
- When ARP attack packets exist, CPP cannot prevent normal ARP packets from being affected. CPP can only differentiate the packet type but cannot distinguish attack packets from normal packets of the same type. In this case, the Network Foundation Protection Policy (NFPP) function can be used to provide higher-granularity attack prevention.

For description of NFPP configurations, see the *Configuring NFPP*.

11.2.2 Preventing CPU Processing Bottlenecks

Scenario

Even though no attacks exist, many packets may need to be sent to the CPU for processing at an instant.

For example, the accesses to the core device of a campus network are counted in ten thousands. The traffic of normal ARP packets may reach dozens of thousands packets per second (PPS). If all packets are sent to the CPU for processing, the CPU resources cannot support the processing, which may cause protocol flapping and abnormal CPU running.

Deployment

- By default, the CPP function limits the rates of ARP packets and the rates of the priority queue where the APR packets reside to control the rate of ARP packets sent to the CPU and ensure that the CPU resource consumption is within a specified range and that the CPU can normally process other protocols.
- By default, the CPP function also limits the rates of other packets at the user level, such as Web authentication and 802.1X authentication packets.

11.3 Features

Basic Concepts

📌 QoS, DiffServ

Quality of Service (QoS) is a network security mechanism, a technology used to solve the problems of network delay and congestion.

DiffServ refers to the differentiated service model, which is a typical model implemented by QoS for classifying service streams to provide differentiated services.

📌 Bandwidth, Rate

Bandwidth refers to the maximum allowable data rate, which refers to the rate threshold in this document. Packets whose rates exceed the threshold will be discarded.

The rate indicates an actual data rate. When the rate of packets exceeds the bandwidth, packets out of the limit will be discarded. The rate must be equal to or smaller than the bandwidth.

The bandwidth and rate units in this document are packets per second (pps).

📌 L2, L3, L4

The structure of packets is hierarchical based on the TCP/IP model.

L2 refers to layer-2 headers, namely, the Ethernet encapsulation part; L3 refers to layer-3 headers, namely, the IP encapsulation part; L4 refers to layer-4 headers, usually, the TCP/UDP encapsulation part.

📌 Priority Queue, SP

Packets are cached inside a switch and packets in the output direction are cached in queues. Priority queues are mapped to Strict Priorities (SPs). Queues are not equal but have different priorities.

The SP is a kind of QoS scheduling algorithm. When a higher priority queue has packets, the packets in this queue are scheduled first. Scheduling refers to selecting packets from queues for output and refers to selecting and sending the packets to the CPU in this document.

📌 CPU interface

Before sending packets to the CPU, a switch will cache the packets. The process of sending packets to the CPU is similar to the process of packet output. The CPU interface is a virtual interface. When packets are sent to the CPU, the packets will be output from this virtual interface. The priority queue and SP mentioned above are based on the CPU interface.

Overview

CPP protects the CPU by using the standard QoS DiffServ model.

Figure 11-2 CPP Implementation Model

Feature	Description
Classifier	Classifies packet types and provides assurance for the subsequent implementation of QoS policies.
Meter	Limits rates based on packet types and controls the bandwidth for a specific packet type.
Queue	Queue packets to be sent to the CPU and select different queues based on packet types.
Scheduler	Selects and schedules queues to be sent to the CPU.
Shaper	Performs rate limit and bandwidth control on priority queues and the CPU interface.

11.3.1 Classifier

Working Principle

The Classifier classifies all packets to be sent to the CPU based on the L2, L3 and L4 information of the packets. Classifying packets is the basis for implementing QoS policies. In subsequent actions, different policies are implemented based on the classification to provide differentiated services. A switch provides fixed classification. The management function classifies packet types based on the protocols supported by the switch, for example, STP BPDU packets and ICMP packets. Packet types cannot be customized.

11.3.2 Meter

Working Principle

The Meter limits the rates of different packets based on the preset rate thresholds. You can set different rate thresholds for different packet types. When the rate of a packet type exceeds the corresponding threshold, the packets out of the limit will be discarded.

By using the Meter, you can control the rate of a packet type sent to the CPU within a threshold to prevent specific attack packets from exerting large impacts on the CPU resources. This is the level-1 protection of the CPP.

Related Configuration

- By default, each packet type corresponds to a rate threshold (bandwidth) and Meter policies are implemented based on the rate threshold.
- In application, you can run the **cpu-protect type packet-type bandwidth bandwidth-value** command to set Meter policies for specified packet types.

11.3.3 Queue

Working Principle

Queues are used to classify packets at level 2. You can select the same queue for different packet types; meanwhile, queues cache packets inside switches and provide services for the Scheduler and Shaper.

CPP queues are SP queues. The SPs of the packets are determined based on the time when they are added to a queue. Packets with a larger queue number have a higher priority.

Related Configuration

- By default, each packet type is mapped to an SP queue.
- In application, you can run the **cpu-protect type packet-type traffic-class traffic-class-num** command to select SP queues for specific packet types.

11.3.4 Scheduler

Working Principle

The Scheduler schedules packets based on SPs of queues. That is, packets in a queue with a higher priority are scheduled first.

Before being scheduled, packets to be sent to the CPU are cached in queues. When being scheduled, the packets are sent to the CPU for processing.

 Only the SP scheduling policy is supported and cannot be modified.

11.3.5 Shaper

Working Principle

The Shaper is used to shape packets to be sent to the CPU, that is, when the actual rate of packets is greater than the shaping threshold, the packets must stay in the queue and cannot be scheduled. When packet rates fluctuate, the Shaper ensures that the rates of packets sent to the CPU are smooth (no more than the shaping threshold).

When the Shaper is available, packets in a queue with a lower priority may be scheduled before all packets in a queue with a higher priority are scheduled. If the rate of packets in a queue with certain priority exceeds the shaping threshold, scheduling of the packets in this queue may be stopped temporarily. Therefore, the Shaper can prevent packets in queues with lower priorities from starvation (which means that only packets in queues with higher priorities are scheduled and packets in queues with higher priorities are not scheduled).

Since the Shaper limits the scheduling rates of packets, it actually plays the rate limit function. The Shaper provides level-2 rate limit for priority queues and all packets sent to the CPU (CPU interface). The Shaper and Meter functions provide 3-level rate limit together and provide level-3 protection for the CPU.

Figure 11-3 3-Level Rate Limit of the CPP

Related Configuration

Configuring the Shaper for priority queues

- By default, each priority queue determines a shaping threshold (bandwidth).
- In application, you can run the `cpu-protect traffic-class traffic-class-num bandwidth bandwidth_value` command to perform Shaper configuration for a specific priority queue.

Configuring the Shaper for the CPU Interface

- By default, the CPU interface determines a shaping threshold (bandwidth).
- Run the `cpu-protect cpu bandwidth bandwidth_value` command to perform Shaper configuration for the CPU interface.

11.4 Configuration

Configuration	Description and Command	
Configuring CPP	 (Optional and configured by default) It is used to adjust the configuration parameters of CPP.	
	<code>cpu-protect type packet-type bandwidth</code>	Configures the Meter for a packet type.
	<code>cpu-protect type packet-type traffic-class</code>	Configures the priority queue for a packet type.
	<code>cpu-protect traffic-class traffic-class-num bandwidth</code>	Configures the Shaper for a priority queue.
	<code>cpu-protect cpu bandwidth</code>	Configures the Shaper for the CPU interface.

11.4.1 Configuring CPP

Configuration Effect

- By configuring the Meter function, you can set the bandwidth and rate limit for a packet type. Packets out of the limit will be directly discarded.
- By configuring the Queue function, you can select a priority queue for a packet type. Packets in a queue with a higher priority will be scheduled first.
- By configuring the Shaper function, you can set the bandwidth and rate limit for a CPU interface and a priority queue. Packets out of the limit will be directly discarded.

Notes

- Pay special attention when the bandwidth of a packet type is set to a smaller value, which may affect the normal traffic of the same type. To provide per-user CPP, combine the NFPP function.
- When the Meter and Shaper functions are combined, 3-level protection will be provided. Any level protection fights alone may bring negative effects. For example, if you want to increase the Meter of a packet type, you also need to adjust the Shaper of the corresponding priority queue. Otherwise, the packets of this type may affect other types of packets in the same priority queue.

Configuration Steps

✚ Configuring the Meter for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: when packets of a type are not attackers but are discarded, you need to increase the Meter of this packet type. If attacks of a packet type cause abnormal CPU running, you need to decrease the Meter of this packet type.
- This configuration is available on all switches in a network environment.

✚ Configuring the priority queue for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: When attacks of a packet type cause abnormality of other packets in the same queue, you can put the packet type in an unused queue. If a packet type cannot be discarded but the packet type is in the same queue with other packet types in use, you can put this packet type in a queue with a higher priority.
- This configuration is available on all switches in a network environment.

✚ Configuring the Shaper for a priority queue

- You can use or modify the default value and cannot disable it.
- You need to modify the configuration in the following cases: If the Meter value of a packet type is greater which causes that other packets in the corresponding priority queue do not have sufficient bandwidth, you need to increase the

Shaper for this priority queue. If attack packets are put in a priority queue and no other packets are in use, you need to increase the Shaper of this priority queue.

- This configuration is available on all switches in a network environment.

✚ Configuring the Shaper for the CPU interface

- You can use or modify the default value and cannot disable it.
- You are not advised to change the Shaper of the CPU interface.
- This configuration is available on all switches in a network environment.

Verification

- Modify the configurations when the system runs abnormally, and view the system running after the modification to check whether the configurations take effect.
- Check whether the configurations take effect by viewing corresponding configurations and statistic values. For details, see the following commands.

Usage Guide	N/A

✎ Configuring the Shaper for a CPU interface

Command	cpu-protect cpu bandwidth <i>bandwidth_value</i>
Parameter Description	<i>bandwidth_value</i> : Sets the bandwidth, in the unit of pps.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✎ Preventing packet attacks and network flapping by using CPP

Scenario	- ARP, IP, OSPF, dot1x, VRRP, Telnet and ICMP streams are available in the system. In the current configurations, ARP and 802.1X are in priority queue 2; IP, ICMP and Telnet streams are in priority queue 4; OSPF streams are in priority queue 3; VRRP streams are in priority queue 6. The Meter for each packet type is 10,000 pps; the shaper for each priority queue is 20,000 pps; the Shaper for the CPU interface is 100,000 pps. - ARP attacks and IP scanning attacks exist in the system, which causes abnormal running of the system, authentication failure, Ping failure, management failure, and OSPF flapping.
Configuration Steps	- Put ARP attack packets in priority queue 1 and limit the bandwidth for ARP packets or the corresponding priority queue. - Put OSPF packets in priority queue 5. - Put IP Ping failure attack packets in priority queue 3 and limit the bandwidth for IP packets or the corresponding priority queue.
	<pre> Ruijie# configure terminal Ruijie(config)# cpu-protect type arp traffic-class 1 Ruijie(config)# cpu-protect type arp bandwidth 5000 Ruijie(config)# cpu-protect type ospf traffic-class 5 Ruijie(config)# cpu-protect type v4uc-route traffic-class 3 Ruijie(config)# cpu-protect type traffic-class 3 bandwidth 5000 Ruijie(config)# end </pre>
Verification	Run the show cpu-protect command to view the configuration and statistics.
	<pre> Ruijie#show cpu-protect %cpu port bandwidth: 100000(pps) Traffic-class Bandwidth(pps) Rate(pps) Drop(pps) ----- 0 6000 0 0 </pre>

11.4.2 Configuring CPP Warning

Configuration Effect

- By configuring CPP warning, periodic detection is enabled to check whether protocol packets or packets in queues are lost.
- By configuring CPP warning of protocol packet loss, when protocol packets are lost, alarm logs are printed.
- By configuring CPP warning of packet loss in a queue, when packets in a queue are lost, alarm logs are printed.

Notes

N/A

Configuration Steps

✚ Enabling CPP Warning and Configuring Time Interval Between Two Detections of Packet Loss

- You can run the **cpp-warn warn-period** *value* command to enable CPP warning and configure time interval between two detections of packet loss.
- By default, CPP warning is disabled.

✚ Enabling CPP Warning of Protocol Packet Loss

- You can run the **cpp-warn type** *packet-type* **warn** command to enable CPP warning of protocol packet loss.
- By default, CPP warning of protocol packet loss is disabled.

✚ Enabling CPP Warning of Packet Loss in a Queue

- You can run the **cpp-warn traffic-class** *traffic-class-num* **warn** command to enable CPP warning of packet loss in a queue.
- By default, CPP warning of packet loss in a queue is disabled.

Related Commands

✚ Configuring Time Interval Between Two Detections of Packet Loss

Command	cpp-warn warn-period <i>value</i>
Parameter Description	<i>value</i> : Specifies the interval between two detections of packet loss in the unit of second. The default value is 0, which means this detection is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Enabling CPP Warning of Protocol Packet Loss

Command	cpp-warn type <i>packet-type</i> warn
Parameter Description	<i>packet-type</i> : Specifies a packet type. Packet types are defined.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Enabling CPP Warning of Packet Loss in a Queue

Command	cpp-warn traffic-class <i>traffic-class-num</i> warn
Parameter Description	<i>traffic-class-num</i> : Specifies a priority queue.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuration Example

Configuring CPP Warning

Configuration Steps	● Detect whether protocol packets or packets in queues are lost every 10s. ● Print alarm logs if ARP packets are lost. ● Print alarm logs if packets in queue 1 are lost.
	<pre>Ruijie# configure terminal Ruijie(config)# cpp-warn warn-period 10 Ruijie(config)# cpp-warn traffic-class 1 warn Ruijie(config)# cpp-warn type arp warn</pre>
Verification	Run the show run command to view the configuration.
	<pre>Ruijie# show run inc cpp cpp-warn warn-period 10 cpp-warn type arp warn cpp-warn traffic-class 1 warn</pre>

11.5 Monitoring

Clearing

Description	Command
Clears the CPP statistics.	clear cpu-protect counters [<i>device device_num</i>]
Clears the CPP statistics on the master device.	clear cpu-protect counters mboard

Displaying

Description	Command
Displays the configuration and statistics of a packet type.	show cpu-protect type <i>packet-type</i> [<i>device device_num</i>]
Displays the configuration and statistics of a priority queue.	show cpu-protect traffic-class <i>traffic-class-num</i> [<i>device device_num</i>]
Displays the configuration on a CPU interface.	show cpu-protect cpu
Displays all configurations and statistics on the master device.	show cpu-protect { <i>mboard</i> <i>summary</i> }
Displays all configurations and statistics of CPP.	show cpu-protect [<i>device device_num</i>]

Displays CPP statistics of an interface.	show cpu-protect statistics [interface <i>interface-id</i>]
Displays a CPP statistics type.	show cpu-protect statistics type <i>packet-type</i>

Debugging

-  The preceding monitoring commands are available on both chassis and cassette devices in either the standalone mode or the VSU mode.
-  If the **device** value is not specified, the **clear** command is used to clear the statistics of all nodes in the system and the **show** command is used to display the configurations on the master device.
-  In the standalone mode, the parameter **device** is unavailable.
-  In the VSU mode, the parameter **device** indicates a chassis or cassette device. If the **device** value is not specified, it indicates the master chassis or the master device.

12 Configuring DHCP Snooping

12.1 Overview

DHCP Snooping: DHCP Snooping snoops DHCP interactive packets between clients and servers to record and monitor users' IP addresses and filter out illegal DHCP packets, including client request packets and server response packets. The legal user database generated from DHCP Snooping records may serve security applications like IP Source Guard.

Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions

12.2 Applications

Application	Description
Guarding against DHCP service spoofing	In a network with multiple DHCP servers, DHCP clients are allowed to obtain network configurations only from legal DHCP servers.
Guarding against DHCP packet flooding	Malicious network users may frequently send DHCP request packets.
Guarding against forged DHCP packets	Malicious network users may send forged DHCP request packets, for example, DHCP-RELEASE packets.
Guarding against IP/MAC spoofing	Malicious network users may send forged IP packets, for example, tampered source address fields of packets.
Preventing Lease of IP Addresses	Network users may lease IP addresses rather than obtaining them from a DHCP server.
Detecting ARP attack	Malicious users forge ARP response packets to intercept packets during normal users' communication.

12.2.1 Guarding Against DHCP Service Spoofing

Scenario

Multiple DHCP servers may exist in a network. It is essential to ensure that user PCs obtain network configurations only from the DHCP servers within a controlled area.

Take the following figure as an example. The DHCP client can only communicate with trusted DHCP servers.

- Request packets from the DHCP client can be transmitted only to trusted DHCP servers.
- Only the response packets from trusted DHCP servers can be transmitted to the client.

Figure 12-1

Remarks:	S is an access device. A is a user PC. B is a DHCP server within the controlled area. C is a DHCP server out of the controlled area.

Deployment

- Enable DHCP Snooping on S to realize DHCP packet monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.

12.2.2 Guarding Against DHCP Packet Flooding

Scenario

Potential malicious DHCP clients in a network may send high-rate DHCP packets. As a result, legitimate users cannot obtain IP addresses, and access devices are highly loaded or even break down. It is necessary to take actions to ensure network stability.

With the DHCP Snooping rate limit function for DHCP packets, a DHCP client can only send DHCP request packets at a rate below the limit.

- The request packets from a DHCP client are sent at a rate below the limit.
- Packets sent at rates beyond the limit will be discarded.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Limit the rates of DHCP packets from the untrusted ports.

12.2.3 Guarding Against Forged DHCP Packets

Scenario

Potential malicious clients in a network may forge DHCP request packets, consuming applicable IP addresses from the servers and probably preempting legal users' IP addresses. Therefore, it is necessary to filter out illegal DHCP packets.

For example, as shown in the figure below, the DHCP request packets sent from DHCP clients will be checked.

- The source MAC address fields of the request packets from DHCP clients must match the **chaddr** fields of DHCP packets.
- The Release packets and Decline packets from clients must match the entries in the DHCP Snooping binding database.

Figure 12-2

Remarks:	S is an access device. A and C are user PCs. B is a DHCP server within the controlled area.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.
- Enable DHCP Snooping Source MAC Verification on untrusted ports of S to filter out illegal packets.

12.2.4 Guarding Against IP/MAC Spoofing

Scenario

Check IP packets from untrusted ports to filter out forged IP packets based on IP or IP-MAC fields.

For example, in the following figure, the IP packets sent by DHCP clients are validated.

- The source IP address fields of IP packets must match the IP addresses assigned by DHCP.
- The source MAC address fields of layer-2 packets must match the **chaddr** fields in DHCP request packets from clients.

Figure 12-3

Remarks:	S is an access device. A and C are user PCs. B is a DHCP server within the controlled area.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as DHCP Snooping untrusted.
- Enable IP Source Guard on S to filter IP packets.
- Enable IP Source Guard in IP-MAC based mode to check the source MAC and IP address fields of IP packets.

12.2.5 Preventing Lease of IP Addresses

Scenario

Validate the source addresses of IP packets from untrusted ports compared with DHCP-assigned addresses.

If the source addresses, connected ports, and layer-2 source MAC addresses of ports in IP packets do not match the assignments of the DHCP server, such packets will be discarded.

The networking topology scenario is the same as that shown in the previous figure.

Deployment

- The same as that in the section "Guarding Against IP/MAC Spoofing".

12.2.6 Detecting ARP Attacks

Scenario

Check the ARP packets from untrusted ports and filter out the ARP packets unmatched with the assignments of the DHCP server.

For example, in the following figure, the ARP packets sent from DHCP clients will be checked.

- The ports receiving ARP packets, the layer-2 MAC addresses, and the source MAC addresses of ARP packets senders shall be consistent with the DHCP Snooping histories.

Figure 12-4

Remarks:	S is an access device. A and C are user PCs. B is a DHCP server within the controlled area.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as untrusted.
- Enable IP Source Guard and ARP Check on all the untrusted ports on S to realize ARP packet filtering.

! All the above security control functions are only effective to DHCP Snooping untrusted ports.

12.3 Features

Basic Concepts

📌 DHCP Request Packets

Request packets are sent from a DHCP client to a DHCP server, including DHCP-DISCOVER packets, DHCP-REQUEST packets, DHCP-DECLINE packets, DHCP-RELEASE packets and DHCP-INFORM packets.

📌 DHCP Response Packets

Response packets are sent from a DHCP server to a DHCP client, including DHCP-OFFER packets, DHCP-ACK packets and DHCP-NAK packets.

📌 DHCP Snooping Trusted Ports

IP address request interaction is complete via broadcast. Therefore, illegal DHCP services will influence normal clients' acquisition of IP addresses and lead to service spoofing and stealing. To prevent illegal DHCP services, DHCP Snooping ports are divided into two types: trusted ports and untrusted ports. The access devices only transmit DHCP response packets received on trusted ports, while such packets from untrusted ports are discarded. In this way, we may configure the ports connected to a legal DHCP Server as trusted and the other ports as untrusted to shield illegal DHCP Servers.

On switches, all switching ports or layer-2 aggregate ports are defaulted as untrusted, while trusted ports can be specified.

📌 DHCP Snooping Packet Suppression

To shield all the DHCP packets on a specific client, we can enable DHCP Snooping packet suppression on its untrusted ports.

📌 VLAN-based DHCP Snooping

DHCP Snooping can work on a VLAN basis. By default, when DHCP Snooping is enabled, it is effective to all the VLANs of the current client. Specify VLANs help control the effective range of DHCP Snooping flexibly.

📌 DHCP Snooping Binding Database

In a DHCP network, clients may set static IP addresses randomly. This increases not only the difficulty of network maintenance but also the possibility that legal clients with IP addresses assigned by the DHCP server may fail to use the network normally due to address conflict. Through snooping packets between clients and servers, DHCP Snooping summarizes the user entries including IP addresses, MAC address, VLAN ID (VID), ports and lease time to build the DHCP Snooping binding database. Combined with ARP detection and ARP check, DHCP Snooping controls the reliable assignment of IP addresses for legal clients.

📌 DHCP Snooping Rate Limit

DHCP Snooping rate limit function can be configured through the rate limit command of Network Foundation Protection Policy (NFPP). For NFPP configuration, see the *Configuring NFPP*.

📌 DHCP Option82

DHCP Option82, an option for DHCP packets, is also called DHCP Relay Agent Information Option. As the option number is 82, it is known as Option82. Option82 is developed to enhance the security of DHCP servers and improve the strategies of IP address assignment. The option is often configured for the DHCP relay services of a network access device like DHCP Relay

and DHCP Snooping. This option is transparent to DHCP clients, and DHCP relay components realize the addition and deduction of the option.

Illegal DHCP Packets

Through DHCP Snooping, validation is performed on the DHCP packets passing through a client. Illegal DHCP packets are discarded, user information is recorded into the DHCP Snooping binding database for further applications (for example, ARP detection). The following types of packets are considered illegal DHCP packets.

- The DHCP response packets received on untrusted ports, including DHCP-ACK, DHCP-NACK and DHCP-OFFER packets
- The DHCP request packets carrying gateway information **giaddr**, which are received on untrusted ports
- When MAC verification is enabled, packets with source MAC addresses different with the value of the **chaddr** field in DHCP packets
- DHCP-RELEASE packets with the entry in the DHCP Snooping binding database Snooping while with untrusted ports inconsistent with settings in this binding database
- DHCP packets in wrong formats, or incomplete

Overview

Feature	Description
Filtering DHCP packets	Perform legality check on DHCP packets and discard illegal packets (see the previous section for the introduction of illegal packets). Transfer requests packets received on trusted ports only.
Building the DHCP Snooping binding database	Snoop the interaction between DHCP clients and the server, and generate the DHCP Snooping binding database to provide basis for other filtering modules.

12.3.1 Filtering DHCP Packets

Perform validation on DHCP packets from untrusted ports. Filter out the illegal packets as introduced in the previous section "Basic Concepts".

Working Principle

During snooping, check the receiving ports and the packet fields of packets to realize packet filtering, and modify the destination ports of packets to realize control of transmit range of the packets.

Checking Ports

In receipt of DHCP packets, a client first judges whether the packet receiving ports are DHCP Snooping trusted ports. If yes, legality check and binding entry addition are skipped, and packets are transferred directly. For not, both the check and addition are needed.

Checking Packet Encapsulation and Length

A client checks whether packets are UDP packets and whether the destination port is 67 or 68. Check whether the packet length match the length field defined in protocols.

📌 Checking Packet Fields and Types

According to the types of illegal packet introduced in the section "Basic Concepts", check the fields **giaddr** and **chaddr** in packets and then check whether the restrictive conditions for the type of the packet are met.

Related Configuration

📌 Enabling Global DHCP Snooping

By default, DHCP Snooping is disabled.

It can be enabled on a device using the **ip dhcp snooping** command.

Global DHCP Snooping must be enabled before VLAN-based DHCP Snooping is applied.

📌 Configuring VLAN-based DHCP Snooping

By default, when global DHCP Snooping is effective, DHCP Snooping is effective to all VLANs.

Use the [**no**] **ip dhcp snooping vlan** command to enable DHCP Snooping on specified VLANs or delete VLANs from the specified VLANs. The value range of the command parameter is the actual range of VLAN numbers.

📌 Configuring DHCP Snooping Source MAC Verification

By default, the layer-2 MAC addresses of packets and the **chaddr** fields of DHCP packets are not verified.

When the **ip dhcp snooping verify mac-address** command is used, the source MAC addresses and the **chaddr** fields of the DHCP request packets sent from untrusted ports are verified. The DHCP request packets with different MAC addresses will be discarded.

12.3.2 Building the Binding Database

DHCP Snooping detects the interactive packets between DHCP clients and the DHCP server, and generate entries of the DHCP Snooping binding database according to the information of legal DHCP packets. All these legal entries are provided to other security modules of a client as the basis of filtering packets from network.

Working Principle

During snooping, the binding database is updated timely based on the types of DHCP packets.

📌 Generating Binding Entries

When a DHCP-ACK packet on a trusted port is snooped, the client's IP address, MAC address, and lease time field are extracted together with the port ID (a wired interface index) and VLAN ID. Then, a binding entry of it is generated.

📌 Deleting Binding Entries

When the recorded lease time of a binding entry is due, it will be deleted if a legal DHCP-RELEASE/DHCP-DECLINE packet sent by the client or a DHCP-NCK packet received on a trusted port is snooped, or the **clear** command is used.

Related Configuration

No configuration is needed except enabling DHCP Snooping.

12.4 Configuration

Configuration	Description and Command	
Configuring basic functions of DHCP Snooping	 (Mandatory) It is used to enable DHCP Snooping.	
	ip dhcp snooping	Enables DHCP Snooping.
	ip dhcp snooping suppression	Enables DHCP Snooping packet suppression.
	ip dhcp snooping vlan	Enables VLAN-based DHCP Snooping.
	ip dhcp snooping verify mac-address	Configures DHCP Snooping source MAC verification.
	ip dhcp snooping database write-delay	Writes the DHCP Snooping binding database to Flash periodically.
	ip dhcp snooping database write-to-flash	Writes the DHCP Snooping binding database to Flash manually.
	renew ip dhcp snooping database	Imports the backup file storage to the DHCP Snooping Binding database.
	ip dhcp snooping trust	Configures DHCP Snooping trusted ports.
	ip dhcp snooping bootp	Enables BOOTP support.
	ip dhcp snooping check-giaddr	Enables DHCP Snooping to support the function of processing Relay requests.
Configuring Option82	 (Optional) It is used to optimize the address assignment by DHCP servers.	
	ip dhcp snooping Information option	Adds Option82 functions to DHCP request packets.
	ip dhcp snooping information option format remote-id	Configures the sub-option remote-id of Option82 as a user-defined character string.
	ip dhcp snooping vlan information option format-type circuit-id string	Configures the sub-option circuit-id of Option82 as a user-defined character string.

12.4.1 Configuring Basic Features

Configuration Effect

- Enable DHCP Snooping.
- Generate the DHCP Snooping binding database.

- Control the transmit range of DHCP packets.
- Filter out illegal DHCP packets.

Notes

- The ports on clients connecting a trusted DHCP server must be configured as trusted.
- DHCP Snooping is effective on the wired switching ports, layer-2 aggregate ports, and layer-2 encapsulation sub-interfaces. The configuration can be implemented in interface configuration mode.
- DHCP Snooping and DHCP Relay are mutually exclusive in VRF scenarios.

Configuration Steps

▾ Enabling Global DHCP Snooping

- Mandatory.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Enabling or Disabling VLAN-based DHCP Snooping

- DHCP Snooping can be disabled if not necessary for some VLANs.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Configuring DHCP Snooping Trusted Ports

- Mandatory.
- Configure the ports connecting a trusted DHCP server as trusted.

▾ Enabling DHCP Snooping Source MAC Validation

- This configuration is required if the **chaddr** fields of DHCP request packets match the layer-2 source MAC addresses of data packets.
- Unless otherwise noted, the feature should be enabled on all the untrusted ports of access devices.

▾ Writing the DHCP Snooping Binding Database to Flash Periodically

- Enable this feature to timely save the DHCP Snooping binding database information in case that client reboot.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Enabling BOOTP Support

- Optional
- Unless otherwise noted, the feature should be configured on access devices.

▾ Enabling DHCP Snooping to Process Relay Requests

- Optional.
- Unless otherwise noted, the feature should be enabled on access devices.

Verification

Configure a client to obtain network configurations through the DHCP protocol.

- Check whether the DHCP Snooping Binding database is generated with entries on the client.

Related Commands

▾ Enabling or Disabling DHCP Snooping

Command	[no] ip dhcp snooping
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After global DHCP Snooping is enabled, you can check DHCP Snooping using the show ip dhcp snooping command.

▾ Configuring VLAN-based DHCP Snooping

Command	[no] ip dhcp snooping vlan { <i>vlan-rng</i> { <i>vlan-min</i> [<i>vlan-max</i>] } }
Parameter Description	<i>vlan-rng</i> : Indicates the range of VLANs <i>vlan-min</i> : The minimum VLAN ID <i>vlan-max</i> : The maximum VLAN ID
Command Mode	Global configuration mode
Usage Guide	Use this command to enable or disable DHCP Snooping on specified VLANs. This feature is available only after global DHCP Snooping is enabled.

▾ Configuring DHCP Snooping Packet Suppression

Command	[no] ip dhcp snooping suppression
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Use this command to reject all DHCP request packets at the port, that is, to forbid all users under the port to apply for addresses via DHCP.

▾ Configuring DHCP Snooping Source MAC Verification

Command	[no] ip dhcp snooping verify mac-address
Parameter Description	N/A
Command	Global configuration mode

Mode	
Usage Guide	Through the source MAC address verification, the MAC addresses in link headers and the CLIENT MAC fields in the request packets sent by a DHCP CLIENT are checked for consistence. When the source MAC address verification fails, packets will be discarded.

✚ Writing DHCP Snooping Database to Flash Periodically

Command	[no] ip dhcp snooping database write-delay [time]
Parameter Description	<i>time</i> : Indicates the interval between two times of writing the DHCP Snooping database to the Flash.
Command Mode	Global configuration mode
Usage Guide	Use this command to write the DHCP Snooping database to FLASH document. This can avoid binding information loss which requires re-obtaining IP addresses to resume communication after the device restarts.

✚ Writing the DHCP Snooping Database to Flash Manually

Command	ip dhcp snooping database write-to-flash
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to write the dynamic user information in the DHCP Snooping database in FLASH documents in real time. If a device is upgraded from a non-QinQ version to a QinQ version (or vice versa), binding entries cannot be restored from FLASH documents because of version differences between FLASH documents.

✚ Importing Flash Storage to the DHCP Snooping Binding Database

Command	renew ip dhcp snooping database
Parameter Description	N/A
Command Mode	Privileged configuration mode
Usage Guide	Use this command to import the information from backup file documents to the DHCP Snooping binding database.

✚ Configuring DHCP Snooping Trusted Ports

Command	[no] ip dhcp snooping trust
Parameter Description	N/A
Command	Interface configuration mode

Mode	
Usage Guide	Use this command to configure a port connected to a legal DHCP server as a trusted port. The DHCP response packets received by trusted ports are transferred, while those received by untrusted ports are discarded.

✎ Enabling or Disabling BOOTP Support

Command	[no] ip dhcp snooping bootp
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to support the BOOTP protocol.

✎ Enabling DHCP Snooping to Process Relay Requests

Command	[no] ip dhcp snooping check-giaddr
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the feature is enabled, services using DHCP Snooping binding entries generated based on Relay requests, such as IP Source Guard/802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet. After the feature is enabled, the ip dhcp snooping verify mac-address command cannot be used. Otherwise, DHCP Relay requests will be discarded and as a result, users fail to obtain addresses.

Configuration Example

✎ DHCP Client Obtaining IP addresses Dynamically from a Legal DHCP Server

Scenario Figure 12-5	
Configuration	Enable DHCP Snooping on an access device (Switch B in this case).

Steps	Configure the uplink port (port Gi 0/1 in this case) as a trusted port.
B	<pre> B#configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)#ip dhcp snooping B(config)#interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ip dhcp snooping trust B(config-if-GigabitEthernet 0/1)#end </pre>
Verification	Check the configuration on Switch B. - Check whether DHCP Snooping is enabled, and whether the configured DHCP Snooping trusted port is uplink. - Check the DHCP Snooping configuration on Switch B, and especially whether the trusted port is correct.
B	<pre> B#show running-config ! ip dhcp snooping ! interface GigabitEthernet 0/1 B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds DHCP Snooping option 82 status : DISABLE DHCP Snooping Support BOOTP bind status : DISABLE Interface Trusted Rate limit (pps) ----- GigabitEthernet 0/1 YES unlimited B#show ip dhcp snooping binding Total number of bindings: 1 MacAddress IpAddress Lease(sec) Type VLAN Interface ----- 0013.2049.9014 172.16.1.2 86207 dhcp-snooping 1 GigabitEthernet 0/11 </pre>

Common Errors

- The uplink port is not configured as a DHCP trusted port.
- Another access security option is already configured for the uplink port, so that a DHCP trusted port cannot be configured.

12.4.2 Configuring Option82

Configuration Effect

- Enable a DHCP server to obtain more information and assign addresses better.
- The Option82 function is client-oblivious.

Notes

- The Option82 functions for DHCP Snooping and DHCP Relay are mutually exclusive.

Configuration Steps

- To realize optimization of address allocation, implement the configuration.
- Unless otherwise noted, enable this function on access devices with DHCP Snooping enabled.

Verification

Check whether the DHCP Snooping configuration options are configured successfully.

Related Commands

✚ Adding Option82 to DHCP Request Packets

Command	[no] ip dhcp snooping information option [standard-format]
Parameter Description	standard-format : Indicates a standard format of the Option82 options
Command Mode	Global configuration mode
Usage Guide	Use this command to add Option82 to DHCP request packets so that a DHCP server assigns addresses according to such information.

✚ Configuring Sub-option remote-id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping information option format remote-id { string <i>ASCII-string</i> hostname }
Parameter Description	string <i>ASCII-string</i> : Indicates the content of the extensible format, the Option82 option remote-id , is a user-defined character string hostname : Indicates the content of the extensible format, the Option82 option remote-id , is a host name.
Configuration mode	Global configuration mode

Usage Guide	Use this command to configure the sub-option remote-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

✚ Configuring Sub-Option circuit-id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping vlan <i>vlan-id</i> information option format-type circuit-id string <i>ascii-string</i>
Parameter	<i>vlan-id</i> : Indicates the VLAN where a DHCP request packet is
Description	<i>ascii-string</i> : Indicates the user-defined string
Configuration mode	Interface configuration mode
Usage Guide	Use this command to configure the sub-option circuit-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

Configuration Example

✚ Configuring Option82 to DHCP Request Packets

Configuration Steps	- Configuring basic functions of DHCP Snooping. - Configuring Option82.
B	<pre>Ruijie# configure terminal Ruijie(config)# ip dhcp snooping information option Ruijie(config)# end</pre>
Verification	Check the DHCP Snooping configuration.
B	<pre>B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds DHCP Snooping option 82 status : ENABLE DHCP Snooping Support bootp bind status : DISABLE Interface Trusted Rate limit (pps) ----- GigabitEthernet 0/1 YES unlimited</pre>

Common Errors

- N/A

12.5 Monitoring

Clearing

Running the clear commands may lose vital information and thus interrupt services.

Description	Command
Clears the DHCP Snooping binding database.	clear ip dhcp snooping binding [<i>ip</i>] [<i>mac</i>] [vlan <i>vlan-id</i>] [interface <i>interface-id</i>]

Displaying

Description	Command
Displays DHCP Snooping configuration.	show ip dhcp snooping
Displays the DHCP Snooping binding database.	show ip dhcp snooping binding

Debugging

System resources are occupied when debugging information is output. Disable the debugging switch immediately after use.

Description	Command
Debugs DHCP Snooping events.	debug snooping ipv4 event
Disables debugging DHCP Snooping events.	no debug snooping ipv4 event
Debugs DHCP Snooping packets.	debug snooping ipv4 packet
Disables debugging DHCP Snooping packets.	no debug snooping ipv4 packet
Enables debugging MAC-based DHCP Snooping.	debug snooping ipv4 mac-address <i>H.H.H</i>
Disables debugging MAC-based DHCP Snooping.	no debug snooping ipv4 mac-address <i>H.H.H</i>
Enables debugging all DHCP Snooping	debug snooping ipv4 all
Disables debugging all DHCP Snooping	no debug snooping ipv4 all

13 Configuring ARP Check

13.1 Overview

The Address Resolution Protocol (ARP) packet check filters all ARP packets under ports (including wired layer-2 switching ports, layer-2 aggregate ports (APs), and layer-2 encapsulation sub-interfaces, as well as WLAN interfaces) and discards illegal ARP packets, so as to effectively prevent ARP deception via networks and to promote network stability. On devices supporting ARP check, illegal ARP packets in networks will be ignored according to the legal user information (IP-based or IP-MAC based) generated by security application modules such as IP Source Guard, global IP+MAC binding, 802.1X authentication, GSN binding, Web authentication and port security.

Figure 13-1

The above figure shows that security modules generate legal user information (IP-based or IP-MAC based). ARP Check uses the information to detect whether the Sender IP fields or the <Sender IP, Sender MAC>fields in all ARP packets at ports matches those in the list of legal user information. If not, all unlisted ARP packets will be discarded.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

13.2 Applications

Application	Description

[Filtering ARP packets in Networks](#)

Illegal users in networks launch attacks using forged ARP packets.

13.2.1 Filtering ARP Packets in Networks

Scenario

Check ARP packets from distrusted ports and filter out ARP packets with addresses not matching the results assigned by the DHCP server.

For example, in the following figure, the ARP packets sent by DHCP clients are checked.

- The ports receiving ARP packets, the source MAC addresses of ARP packets, and the source IP addresses of ARP packets shall be consistent with the snooped DHCP-assigned records.

Figure 13-2

Remarks: S is an access device.
A and C are user PCs.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all the downlink ports on S as DHCP distrusted ports.
- Enable IP Source Guard and ARP Check on all distrusted ports on S to realize ARP packet filtration.

13.3 Features

Basic Concepts

Compatible Security Modules

Presently, the ARP Check supports the following security modules.

- IP-based: IP-based mode: port security, and static configuration of IP Source Guard.
- IP-MAC based: IP-MAC based mode: port security, global IP+MAC binding, 802.1X authorization, IP Source Guard, and GSN binding.

Two Modes of APR Check

The ARP Check has two modes: Enabled and Disabled. The default is Enabled.

1. Enabled Mode

Through ARP Check, ARP packets are detected based on the IP/IP-MAC based binding information provided by the following modules.

- Global IP-MAC binding
- 802.1X authorization
- IP Source Guard
- GSN binding
- Port security
- Port security IP+MAC binding or IP binding

 When only ARP Check is enabled on a port but the above-mentioned modules are not enabled, legal user information cannot be generated, and thereby all ARP packets from this port will be discarded.

 When the ARP Check and VRRP functions are enabled on an interface, if the physical IP address and virtual IP address of the interface can be used as the gateway address, the physical IP address and VRRP IP address need to be permitted to pass. Otherwise, ARP packets sent to the gateway will be filtered out.

2. Disabled Mode

ARP packets on a port are not checked.

Overview

Feature	Description
Filtering ARP Packets	Check the source IP and source MAC addresses of ARP packets to filter out illegal ARP packets.

13.3.1 Filtering ARP Packets

Enable ARP Check on specified ports to realize filtration of illegal ARP packets.

Working Principle

A device matches the source IP and source MAC addresses of the ARP packets received at its ports with the legal user information of the device. With successful matching, packets will be transferred, or otherwise they will be discarded.

Related Configuration

Enabling ARP Check on Ports

By default, the ARP Check is disabled on ports.

Use the arp-check command to enable ARP Check.

Unless otherwise noted, this function is usually configured on the ports of access devices.

13.4 Configuration

Configuration	Description and Command	
Configuring ARP Check	 (Mandatory) It is used to enable APR Check.	
	arp-check	Enables ARP Check.

13.4.1 Configuring ARP Check

Configuration Effect

- Illegal ARP packets are filtered out.

Notes

- When ARP Check is enabled, the number of policies or users of related security applications may decrease.
- ARP Check cannot be configured on mirrored destination ports.
- ARP Check cannot be configured on the trusted ports of DHCP Snooping.
- ARP Check cannot be configured on global IP+MAC exclude ports.
- ARP Check can be enabled only on wired switching ports, layer-2 APs, layer-2 encapsulation sub-interfaces, as well as WLAN interfaces. Enable ARP check for the wired in interface configuration mode, while for the wireless in WLAN security configuration mode.

Configuration Steps

📌 Enabling ARP Check

- (Mandatory) The function is disabled by default. To use the ARP Check function, an administrator needs to run a command to enable it.

Verification

- Use the **show run** command to display the system configuration.
- Use the **show interface { interface-type interface-number } arp-check list** command to display filtering entries.

Related Commands

📌 Enabling ARP Check

Command	arp-check
Parameter	N/A
Description	
Command	Interface configuration mode, or WLAN security configuration mode

Usage Guide	Generate ARP filtration information according to the legal user information of security application modules to filter out illegal ARP packets in networks.

Configuration Example

The following configuration example introduces only ARP Check related configurations.

Enabling ARP Check on ports

Configuration Steps	● Enable ARP Check. Restricted ARP packets must conform to entries of IP Source Guard, port security, or global IP+MAC binding.

```

Ruijie# configure terminal
Ruijie(config)#address-bind 192.168.1.3 00D0.F800.0003
Ruijie(config)#address-bind install
Ruijie(config)#ip source binding 00D0.F800.0002 vlan 1 192.168.1.4 interface gigabitEthernet 0/1
Ruijie(config)# interface GigabitEthernet 0/1
Ruijie(config-if-GigabitEthernet 0/1)#arp-check
Ruijie(config-if-GigabitEthernet 0/1)#ip verify source port-security
Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security
Ruijie(config-if-GigabitEthernet 0/1)#switchport port-security binding 00D0.F800.0001 vlan 1
192.168.1.1
Ruijie(config-if-GigabitEthernet 0/1)#exit
Ruijie(config)#interface gigabitEthernet 0/4
Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security
Ruijie(config-if-GigabitEthernet 0/4)#switchport port-security binding 192.168.1.5
Ruijie(config-if-GigabitEthernet 0/4)#arp-check
Ruijie(config-if-GigabitEthernet 0/4)#exit
Ruijie(config)#interface gigabitEthernet 0/5
Ruijie(config-if-GigabitEthernet 0/5)#arp-check
Ruijie(config-if-GigabitEthernet 0/5)#end
Ruijie# configure terminal
Ruijie# configure terminal
Ruijie(config)#wlansec 1
Ruijie(config)# ip source binding 0026.c79f.6e4c vlan 1 172.168.131.1 interface wlan 1
Ruijie(config-wlansec)#arp-check
Ruijie(config-wlansec)#end

```

Verification

Use the **show interface arp-check list** command to display the effective ARP Check list for interfaces.

```
Ruijie# show interface arp-check list
```

INTERFACE	SENDER MAC	SENDER IP	POLICY SOURCE

GigabitEthernet 0/1	00d0.f800.0003	192.168.1.3	address-bind

	<pre> ----- WLAN 1 0026.c79f.6e4c 172.168.131.1 DHCP snooping </pre>

Common Errors

- If ARP packets at a port need to be checked but APR-Check is disabled, then APR-Check will not be effective.

13.5 Monitoring

Displaying

Description	Command
Displays the effective ARP Check list based on ports.	show interface [<i>interface-type interface-number</i>] arp-checklist

14 Configuring Dynamic ARP Inspection

14.1 Overview

Dynamic Address Resolution Protocol (ARP) inspection (DAI) checks the validity of received ARP packets. Invalid ARP packets will be discarded.

DAI ensures that only valid ARP packets can be forwarded by devices. DAI mainly performs the following steps:

- Intercepts all ARP request packets and ARP reply packets on untrusted ports in the virtual local area networks (VLANs) where the DAI function is enabled.
- Checks the validity of intercepted ARP packets according to user records stored in a security database.
- Discards the ARP packets that do not pass the validity check.
- Sends the ARP packets that pass the validity check to the destination.
- The DAI validity criteria are the same as those of ARP Check. For details, see the *Configuring ARP Check*.

DAI and ARP Check have same functions. The only difference is that DAI takes effect by VLAN whereas ARP Check takes effect by port.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

14.2 Applications

Application	Description
ARP Spoofing Prevention	Prevent ARP spoofing that is mounted by taking advantage of ARP defects.

14.2.1 ARP Spoofing Prevention

Scenario

Due to inherent defects, ARP does not check the validity of received ARP packets. Attackers can take advantage of the defects to mount ARP spoofing. A typical example is man-in-the-middle (MITM) attack. See Figure 14-1.

Figure 14-1

Remarks	Device S is a Ruijie access switch enabled with DAI. User A and User B are connected to Device S, and they are in the same subnet. User C is a malicious user connected to Device S. IP A and MAC A are the IP address and MAC address of User A. IP B and MAC B are the IP address and MAC address of User B. IP C and MAC C are the IP address and MAC address of User C.

When User A needs to initiate network layer communication with User B, User A broadcasts an ARP request in the subnet to query the MAC address of User B. Upon receiving the ARP request packet, User B updates its ARP cache with IP A and MAC A, and sends an ARP reply. Upon receiving the ARP reply packet, User A updates its ARP cache with IP B and MAC B.

In this model, User C can make the ARP entry mapping between User A and User B incorrect by continuously broadcasting ARP reply packets to the network. The reply packets contain IP A, IP B, and MAC C. After receiving these reply packets, User A stores the ARP entry (IP B, MAC C), and User B stores the ARP entry (IP A, MAC C). As a result, the communication between User A and User B is directed to User C, without the knowledge of User A and User B. Here User C acts as the man in the middle by modifying received packets and forwarding them to User A or User B.

If Device S is enabled with DAI, it will filter out forged ARP packets to prevent ARP spoofing as long as the IP addresses of User A and User B meet the validity criteria described in section 14.1 Overview. Figure 14-2 shows the working process of DAI.

Figure 14-2

Remarks	Device S is a Ruijie access switch enabled with DAI. User A and User B are connected to Device S, and they are in the same subnet. User C is a malicious user connected to Device S. IP A and MAC A are the IP address and MAC address of User A. IP B and MAC B are the IP address and MAC address of User B. IP C and MAC C are the IP address and MAC address of User C.

The ARP packets of User A and User B are forwarded normally by Device S. The forged ARP packets of User C are discarded because the packets do not match the records in the security database of Device S.

Deployment

- Enable DHCP Snooping on Device S.
- Enable DAI and IP Source Guard on Device S.

14.3 Features

Basic Concepts

Trust Status of Ports and Network Security

ARP packet check is performed according to the trust status of ports. DAI considers packets received from trusted ports as valid without checking their validity, but it checks the validity of packets received from untrusted ports.

For a typical network configuration, you should configure Layer-2 ports connected to network devices as trusted ports, and configure Layer-2 ports connected to hosts as untrusted ports.

 Network communication may be affected if a Layer-2 port connected to a network device is configured as an untrusted port.

Overview

Feature	Description
Invalid ARP Packet Filter	Checks the source IP addresses and MAC addresses of ARP packets to filter out invalid packets.
DAI Trusted Port	Permits the ARP packets received from specific ports to pass through without checking their validity.

14.3.1 Invalid ARP Packet Filter

Enable DAI in a specific VLAN to filter out invalid ARP packets. The DAI validity criteria are the same as those of ARP Check.

Working Principle

Upon receiving an ARP packet, the device matches the IP address and MAC address of the packet with the valid user records in its security database. If the packet matches a record, it will be forwarded normally. If it does not match any record, it will be discarded.

DAI and ARP Check use the same set of valid user records. For details, see the packet validity check description in the *Configuring ARP Check*.

Related Configuration

📌 Enabling DAI in a VLAN

By default, DAI is disabled in VLANs.

Run the **ip arp inspection vlan *vlan-id*** command to enable DAI in a specific VLAN.

⚠ After DAI is enabled in a VLAN, DAI may not take effect on all ports in the VLAN. A DHCP Snooping trusted port does not perform DAI check.

📌 Disabling DAI in a VLAN

By default, DAI is disabled in VLANs.

After DAI is enabled in a VLAN, you can run the **no ip arp inspection vlan *vlan-id*** command to disable DAI.

⚠ Disabling DAI in a VLAN does not mean disabling packet validity check on all ports in the VLAN. The ports with ARP Check effective still check the validity of received ARP packets.

14.3.2 DAI Trusted Port

Configure specific device ports as DAI trusted ports.

Working Principle

The validity of ARP packets received from trusted ports is not checked. The ARP packets received from untrusted ports are checked against the user records in a security database.

Related Configuration

📌 Configuring DAI Trusted Ports

By default, all ports are untrusted ports.

Run the **ip arp inspection trust** command to set ports to trusted state.

⚠ A port already enabled with access security control cannot be set to DAI trusted state. To set the port to DAI trusted state, first disable access security control.

⚠ In normal cases, uplink ports (ports connected to network devices) can be configured as DAI trusted ports.

14.4 Configuration

Configuration	Description and Command	
Configuring DAI	 (Optional) It is used to enable ARP packet validity check.	
	<code>ip arp inspection vlan</code>	Enables DAI.
	<code>ip arp inspection trust</code>	Configures DAI trusted ports.

14.4.1 Configuring DAI

Configuration Effect

- Check the validity of incoming ARP packets in a specific VLAN.

Notes

- DAI cannot be enabled on DHCP Snooping trusted ports.

Configuration Steps

➤ Enabling ARP Packet Validity Check in a Specific VLAN

- Optional.
- Perform this configuration when you need to enable ARP packet validity check on all ports in a VLAN.
- Perform this configuration on Ruijie access devices unless otherwise specified.

➤ Configuring DAI Trusted Ports

- Optional.
- It is recommended to configure uplink ports as DAI trusted ports after DAI is enabled. Otherwise, the uplink ports enabled with other security features and set to trusted state accordingly may filter out valid ARP packets due to the absence of DAI user entries.
- Perform this configuration on Ruijie access devices unless otherwise specified.

➤ Configuring the ARP Packet Reception Rate

- For details, see the rate limit command description in the *Configuring the NFPP*.

Verification

- Construct invalid ARP packets by using a packet transfer tool and check whether the packets are filtered out on DAI-enabled devices.
- Run the **show** command to check the device configuration.

Related Commands

➤ Enabling DAI

Command	ip arp inspection vlan { <i>vlan-id</i> <i>word</i> }
Parameter	<i>vlan-id</i> : Indicates a VLAN ID.
Description	<i>word</i> : Indicates the VLAN range string, such as 1, 3–5, 7, and 9–11.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring DAI Trusted Ports

Command	ip arp inspection trust
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure a DAI trusted port so that the ARP packets received by the port can pass through without validity check.

Configuration Example

➤ Allowing Users' PCs to Use only Addresses Allocated by a DHCP Server to Prevent ARP Spoofing

Scenario Figure 14-3	
Configuration Steps	⚠ Enable DHCP Snooping on the access switch (Switch A) and configure its uplink port (GigabitEthernet 0/3) connected to the valid DHCP server as a trusted port. ⚠ Enable IP Source Guard on Switch A. ⚠ Enable DAI.
Switch A	<pre>A#configure terminal Enter configuration commands, one per line. End with CNTL/Z. A(config)#vlan 2</pre>

	<pre> A(config-vlan)#exit A(config)#interface range gigabitEthernet 0/1-2 A(config-if-range)#switchport access vlan 2 A(config-if-range)#ip verify source A(config-if-range)#exit A(config)#ip dhcp snooping A(config)#ip arp inspection vlan 2 A(config)#interface gigabitEthernet 0/3 A(config-if-GigabitEthernet 0/3)#switchport access vlan 2 A(config-if-GigabitEthernet 0/3)#ip dhcp snooping trust A(config-if-GigabitEthernet 0/3)#ip arp inspection trust </pre>
Verification	● Check whether DHCP Snooping, IP Source Guard, and DAI are enabled and whether trusted ports are configured correctly. ● Check whether the uplink port on Switch A is a DHCP Snooping trusted port. ● Check whether DAI is enabled successfully in the VLAN and the uplink ports are DAI trusted ports.
Switch A	<pre> A#show running-config A#show ip dhcp snooping A#show ip arp inspection vlan </pre>

Common Errors

- A port with security control enabled is configured as a DAI trusted port.

14.5 Monitoring

Displaying

Description	Command
Displays the DAI state of a specific VLAN.	show ip arp inspection vlan [<i>vlan-id</i> <i>word</i>]
Displays the DAI configuration state of each Layer-2 port.	show ip arp inspection interface

15 Configuring IP Source Guard

15.1 Overview

- i** The IP Source Guard function realizes hardware-based IP packet filtering to ensure that only the users having their information in the binding database can access networks normally, preventing users from forging IP packets.

15.2 Applications

Application	Description
Guarding Against IP/MAC Spoofing Attack	In network environments, users are not allowed to launch attacks by privately setting IP addresses or forging IP packets.

15.2.1 Guarding Against IP/MAC Spoofing Attack

Scenario

Check the IP packets from DHCP untrusted ports. Forged IP packets will be filtered out based on the IP or IP-MAC field.

For example, in the following figure, the IP packets sent by DHCP clients are checked.

- The Source IP Address fields of IP packets should match DHCP-assigned IP addresses.
- The Source MAC Address fields of layer-2 packets should match the MAC addresses in DHCP request packets from clients.

Figure 15-1

Remarks:	S is a network access server (NAS). A and C are user PCs. B is a DHCP server within the control area.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.

- Set all downlink ports on S as DHCP untrusted ports.
- Enable IP Source Guard on S to realize IP packet filtering.
- Enable IP-MAC match mode for IP Source Guard on S, filtering IP packets based on IP and MAC addresses.

15.3 Features

Basic Concepts

Source IP Address

Indicate the source IP address field of an IP packet.

Source MAC Address

Indicate the source MAC address field of an IP packet.

IP-based Filtering

Indicate a policy of IP packet filtering, where only the source IP addresses of all IP packets (except DHCP packets) passing through a port are checked. It is the default filtering policy of IP Source Guard.

IP-MAC based Filtering

A policy of IP packet filtering, where both the source IP addresses and source MAC addresses of all IP packets are checked, and only those user packets with these IP addresses and MAC addresses existing in the binding database are permitted.

Address Binding Database

As the basis of security control of the IP Source Guard function, the data in the address binding database comes from two ways: the DHCP Snooping binding database and static configuration. When IP Source Guard is enabled, the data of the DHCP Snooping binding database is synchronized to the address binding database of IP Source Guard, so that IP packets can be filtered strictly through IP Source Guard on a device with DHCP Snooping enabled.

Excluded VLAN

By default, when IP Source Guard is enabled on a port, it is effective to all the VLANs under the port. Users may specify excluded VLANs, within which IP packets are not checked and filtered, which means that such IP packets are not controlled by IP Source Guard. At most 32 excluded VLANs can be specified for a port.

Overview

Feature	Description
Checking Source Address Fields of Packets	Filter the IP packets passing through ports by IP-based or IP-MAC based filtering.

15.3.1 Checking Source Address Fields of Packets

Filter the IP packets passing through ports based on source IP addresses or on both source IP addresses and source MAC addresses to prevent malicious attack by forging packets. When there is no need to check and filter IP packets within a VLAN, an excluded VLAN can be specified to release such packets.

Working Principle

When IP Source Guard is enabled, the source addresses of packets passing through a port will be checked. The port can be a wired switching port, a layer-2 aggregate port (AP), or a layer-2 encapsulation sub-interface. Such packets will pass the port only when the source address fields of the packets match the set of the address binding records generated by DHCP Snooping, or the static configuration set by the administrator. There are two matching modes as below.

IP-based Filtering

Packets are allowed to pass a port only if the source IP address fields of them belong to the address binding database.

IP-MAC Based Filtering

Packets are allowed to pass a port only when both the layer-2 source MAC addresses and layer-3 source IP addresses of them match an entry in the address binding database.

Specifying Excluded VLAN

Packets within such a VLAN are allowed to pass a port without check or filtering.

Related Configuration

Enabling IP Source Guard on a Port

By default, the IP Source Guard is disabled on ports.

It can be enabled using the **ip verify source** command.

-
-  Usually IP Source Guard needs to work with DHCP Snooping. Therefore, DHCP Snooping should also be enabled. DHCP Snooping can be enabled at any time on Ruijie devices, either before or after IP Source Guard is enabled.
-

Configuring a Static Binding

By default, legal users passing IP Source Guard check are all from the binding database of DHCP Snooping.

Bound users can be added using the **ip source binding** command.

Specifying an Excluded VLAN

By default, IP Source Guard is effective to all the VLANs under a port.

Excluded VLANs may be specified which are exempted from IP Source Guard using the **ip verify source exclude-vlan** command.

-
-  Excluded VLANs can be specified only after IP Source Guard is enabled on a port. Specified excluded VLANs will be deleted automatically when IP Source Guard is disabled on a port.
-

 The above-mentioned port can be a wired switching port, a layer-2 AP port or a layer-2 encapsulation sub-interface.

15.4 Configuration

Configuration	Description and Command	
Configuring IP Source Guard	 (Mandatory) It is used to enable IP Source Guard.	
	ip verify source	Enables IP Source Guard on a port.
	ip source binding	Configures a static binding.
	ip verify source exclude-vlan	Specifies an excluded VLAN for IP Source Guard.

15.4.1 Configuring IP Source Guard

Configuration Effect

- Check input IP packets to filter out invalid IP packets.

Notes

- The enabling of IP Source Guard may affect forwarding of IP packets. In general, this function needs to be used in combination with DHCP Snooping.
- IP Source Guard cannot be configured on DHCP Snooping trusted ports.
- IP Source Guard cannot be configured on global IP+MAC exclude ports.
- IP Source Guard can be configured only on wired exchange ports, Layer-2 AP ports, and Layer-2 encapsulation subinterfaces. The function is configured in interface configuration mode in the case of wired access.

Configuration Steps

- Enable DHCP Snooping.
- Enable IP Source Guard.

Verification

Use the monitoring commands to display the address binding database of IP Source Guard.

Related Commands

Enabling IP Source Guard on a Port

Command	ip verify source [port-security]
Parameter Description	port-security: Enable IP-MAC based filtering.
Command	Interface configuration mode
Usage Guide	Detection of users based on IP address or both IP and MAC addresses can be realized by enabling IP

	Source Guard for a port.

📌 Configuring a Static Binding

Command	ip source binding <i>mac-address</i> { vlan <i>vlan-id</i> } <i>ip-address</i> { interface <i>interface-id</i> ip-mac ip-only }
Parameter Description	mac-address : The MAC address of a static binding vlan-id : The VLAN ID of a static binding. It indicates the outer VLAN ID of a QINQ-termination user. ip-address : The IP address of a static binding <i>interface-id</i> : The Port ID (PID) of a static binding ip-mac : IP-MAC based mode ip-only : IP-based mode
Configuration Mode	Global configuration mode
Usage Guide	Through this command, legitimate users can pass IP Source Guard detection instead of being controlled by DHCP.

📌 Specifying an Exception VLAN for IP Source Guard

Command	ip verify source exclude-vlan <i>vlan-id</i>
Parameter Description	vlan-id : A VLAN ID exempted from IP Source Guard on a port
Command	Interface configuration mode
Usage Guide	By using this command, the specified VLANs under a port where IP Source Guard function is enabled can be exempted from check and filtering.

Configuration Example

📌 Enabling IP Source Guard on Port 1

Configuration Steps	● Enable DHCP Snooping. ● Enable IP Source Guard.
	<pre>Ruijie(config)# interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# ip verify source Ruijie(config-if-GigabitEthernet 0/1)# end</pre>
Verification	Displays the address filtering table of IP Source Guard.
	<pre>Ruijie# show ip verify source</pre>

📌 Configuring a Static Binding

Configuration Steps	● Enable DHCP Snooping. ● Enable IP Source Guard. ● Configure a static binding.

	<pre>Ruijie# configure terminal Ruijie(config)# ip source binding 00d0. f801. 0101 vlan 1 192. 168. 4. 243 interface GigabitEthernet 0/3 Ruijie(config)# end</pre>																								
Verification	Display the address filtering table of IP Source Guard.																								
	<pre>Ruijie# show ip verify source</pre> <table><thead><tr><th>NO.</th><th>INTERFACE</th><th>FilterType</th><th>FilterStatus</th><th>IPADDRESS</th><th>MACADDRESS</th></tr><tr><th>VLAN</th><th>TYPE</th><th></th><th></th><th></th><th></th></tr></thead><tbody><tr><td>1</td><td>GigabitEthernet 0/3</td><td>UNSET</td><td>Inactive-restrict-off</td><td>192. 168. 4. 243</td><td>00d0. f801. 0101 1 Static</td></tr><tr><td>2</td><td>GigabitEthernet 0/1</td><td>IP-ONLY</td><td>Active</td><td>Deny-All</td><td></td></tr></tbody></table>	NO. 16 Configuring Gateway-targeted ARP Spoofing Prevention

16.1 Overview

Gateway-targeted Address Resolution Protocol (ARP) spoofing prevention effectively prevents gateway-targeted ARP spoofing by checking on the logical port whether the source IP addresses of ARP packets (Sender IP fields of ARP packets) are the self-configured gateway IP addresses.

Protocols and Standards

RFC 826: Ethernet Address Resolution Protocol

16.2 Applications

Application	Description
Typical Application of Gateway-targeted ARP Spoofing Prevention	Blocks ARP spoofing packets with forged gateway address and intranet server IP addresses to ensure that users can access the Internet.

16.2.1 Typical Application of Gateway-targeted ARP Spoofing Prevention

Scenario

PC users access the office server through the access device Switch A, and connect to external networks through the gateway.

- If any users legally use forged gateway IP addresses or server IP addresses to perform ARP spoofing, the other users cannot access the Internet and the server.
- The ARP spoofing packets with forged gateway address and intranet server IP addresses must be blocked to ensure that users can access the Internet.

Figure 16-1 Typical Topology of Gateway-targeted ARP Spoofing Prevention

Deployment

- On the access switch (Switch A), enable gateway-targeted spoofing prevention on the ports (Gi 0/3 and Gi 0/4 in this case) directly connected to the PC. The gateway addresses include intranet gateway address and intranet server address.

16.3 Features

Basic Concepts

➤ ARP

ARP is a TCP/IP protocol that obtains physical addresses according to IP addresses. Its function is as follows: The host broadcasts ARP requests to all hosts on the network and receives the returned packets to determine physical addresses of the target IP addresses, and saves the IP addresses and hardware addresses in the local ARP cache, which can be directly queried in response to future requests. On the same network, all the hosts using the ARP are considered as mutually trustful to each other. Each host on the network can independently send ARP response packets; the other hosts receive the response packets and record them in the local ARP cache without detecting their authenticity. In this way, attackers can send forged ARP response packets to target hosts so that the messages sent from these hosts cannot reach the proper host or reach a wrong host, thereby causing ARP spoofing.

➤ Gateway-targeted ARP Spoofing

When User A sends an ARP packet requesting the media access control (MAC) address of a gateway, User B on the same VLAN also receives this packet, and User B can send an ARP response packet, passing off the gateway IP address as the source IP address of the packet, and User B's MAC address as the source MAC address. This is called gateway-targeted ARP spoofing. After receiving the ARP response, User A regards User B's machine as the gateway, so all the packets sent

from User A to the gateway during communication will be sent to User B. In this way, User A's communications are intercepted, thereby causing ARP spoofing.

Overview

Feature	Description
Gateway-targeted ARP Spoofing Prevention	Blocks ARP spoofing packets with forged gateway address and intranet server IP addresses to ensure that users can access the Internet.

16.3.1 Gateway-targeted ARP Spoofing Prevention

Working Principle

Gateway-targeted Spoofing Prevention

Gateway-targeted ARP spoofing prevention effectively prevents ARP spoofing aimed at gateways by checking on the logical port whether the source IP addresses of ARP packets are the self-configured gateway IP addresses. If an ARP packet uses the gateway address as the source IP address, the packet will be discarded to prevent users from receiving wrong ARP response packets. If not, the packet will not be handled. In this way, only the devices connected to the switch can send ARP packets, and the ARP response packets sent from the other PCs which pass for the gateway are filtered by the switch.

Related Configuration

Configuring Gateway-targeted Spoofing Prevention Addresses

- By default, no gateway-targeted ARP spoofing prevention address is configured.
- Run the **anti-arp-spoofing ip** command to configure the gateway-targeted ARP spoofing prevention addresses.

16.4 Configuration

Configuration	Description and Command	
Configuring Gateway-targeted Spoofing Prevention	 Optional.	
	anti-arp-spoofing ip	Configures gateway-targeted ARP spoofing prevention on the logical port and specifies the gateway IP address.

16.4.1 Configuring Gateway-targeted Spoofing Prevention

Configuration Effect

Enable gateway-targeted ARP spoofing prevention.

Configuration Steps

Configuring Gateway-targeted Spoofing Prevention

- Gateway-targeted ARP spoofing prevention is mandatory. It must be enabled.

Verification

- Run the **show run** command to check configuration.
- Run the **show anti-arp-spoofing** command to display all data on gateway-targeted ARP spoofing prevention.

Related Commands

Configuring Gateway-targeted Spoofing Prevention

Command	anti-arp-spoofing ip <i>ip-address</i>
Parameter Description	<i>ip-address</i> : Indicates the IP address of the gateway.
Command Mode	Interface configuration mode or wireless security configuration mode
Usage Guide	Gateway-targeted ARP Spoofing prevention is supported only on Layer-2 ports. For an access controller (AC) or access point (AP), such function is supported only in wireless security configuration mode.

Configuration Example

Configuring Gateway-targeted Spoofing Prevention

Scenario Figure 16-2	<pre> graph TD Internet((Internet)) --- Gateway[Gateway 192.168.1.1] Gateway --- S1(()) S1 --- SwitchA[Switch A] SwitchA --- S2(()) S2 --- Server[Office Server 192.168.1.254] SwitchA --- S3(()) S3 --- PC1[PC 1] SwitchA --- S4(()) S4 --- PC2[PC 2] style S1 fill:none,stroke:none style S2 fill:none,stroke:none style S3 fill:none,stroke:none style S4 fill:none,stroke:none </pre>

17 Configuring NFPP

17.1 Overview

Network Foundation Protection Policy (NFPP) provides guards for switches.

Malicious attacks are always found in the network environment. These attacks bring heavy burdens to switches, resulting in high CPU usage and operational troubles. These attacks are as follows:

Denial of Service (DoS) attacks may consume lots of memory, entries, or other resources of a switch, which will cause system service termination.

Massive attack traffic is directed to the CPU, occupying the entire bandwidth of the CPU. In this case, normal protocol traffic and management traffic cannot be processed by the CPU, causing protocol flapping or management failure. The forwarding in the data plane will also be affected and the entire network will become abnormal.

A great number of attack packets directed to the CPU consume massive CPU resources, making the CPU highly loaded and thereby influencing device management and performance.

NFPP can effectively protect the system from these attacks. Facing attacks, NFPP maintains the proper running of various system services with a low CPU load, thereby ensuring the stability of the entire network.

17.2 Applications

Application	Description
Attack Rate Limiting	Due to various malicious attacks such as ARP attacks and IP scanning attacks in the network, the CPU cannot process normal protocol and management traffics, causing protocol flapping or management failure. The NFPP attack rate limiting function is used to limit the rate of attack traffic or isolate attack traffic to recover the network.
CentralizedBandwidth Allocation	If normal service traffics are too large, you need to classify and prioritize the traffics. When a large number of packets are directed to the CPU, the CPU will be highly loaded, thereby causing device management or device running failure. The centralized bandwidth distribution function is used to increase the priority of such traffics so that switches can run stably.

17.2.1 Attack Rate Limiting

[Scenario](#)

NFPP supports attack detection and rate limiting for various types of packets, including Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Dynamic Host Configuration Protocol (DHCP) packets. It also allows users to define packet matching characteristics and corresponding attack detection and rate limiting policies. The attack rate limiting

function takes effect based on types of packets. This section uses ARP packets as an example scenario to describe the application.

If an attacker floods ARP attack packets while CPU capability is insufficient, most of the CPU resources will be consumed for processing these ARP packets. If the rate of attacker's ARP packet rates exceeds the maximum ARP bandwidth specified in the CPU Protect Policy (CPP) of the switch, normal ARP packets may be dropped. As shown in Figure 17-1, normal hosts will fail to access the network, and the switch will fail to send ARP replies to other devices.

Figure 17-1

Deployment

- By default, the ARP attack detection and rate limiting function is enabled with corresponding policies configured. If the rate of an attacker's ARP packets exceeds the rate limit, the packets are discarded. If it exceeds the attack threshold, a monitoring user is generated and prompt information is exported.
- If the rate of an attacker's ARP packets exceeds the rate limit defined in CPP and affects normal ARP replies, you can enable attack isolation to discard ARP attack packets based on the hardware and recover the network.

- i** For details about CPP-related configurations, see the *Configuring CPU Protection*.
- i** To maximize the use of NFPP guard functions, modify the rate limits of various services in CPP based on the application environment or use the configurations recommended by the system. You can run the **show cpu-protect summary** command to display the configurations.

17.2.2 Centralized Bandwidth Allocation

Scenario

A switch classifies services defined in CPP into three types: Manage, Route, and Protocol. Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics with bandwidths exceeding the thresholds will be discarded. By such service classification, service packets are processed by orders of precedence.

As shown in Figure 17-2, the switch receives a large number of Telnet packets, OSPF packets, and ARP packets, causing CPU overload. In this case, the CPU cannot process all packets, and a large quantity of packets are backlogged in the queue, causing various problems such as frequent Telnet disconnection, OSPF protocol flapping, and ARP access failure on hosts.

Figure 17-2

Deployment

- By default, CPU centralized bandwidth allocation is enabled to assign an independent bandwidth and bandwidth ratio to each type of services. At the time, the CPU first processes Telnet packets to ensure uninterrupted connection of Telnet service, and then processes OSPF packets to maintain OSPF protocol stability, and finally processes ARP packets.
- If the preceding problems still occur in default configurations, you can accordingly adjust the bandwidths and bandwidth ratios of various types of services.

17.3 Features

Basic Concepts

ARP Guard

In local area networks (LANs), IP addresses are mapped to MAC addresses through ARP, which has a significant role in safeguarding network security. ARP-based DoS attacks mean that a large number of unauthorized ARP packets are sent to the gateway through the network, causing the failure of the gateway to provide services for normal hosts. To prevent such attacks, limit the rate of ARP packets and identify and isolate the attack source.

IP Guard

Many hacker attacks and network virus intrusions start from scanning active hosts in the network. Therefore, many scanning packets rapidly occupy the network bandwidth, causing network communication failure.

To solve this problem, Ruijie Layer-3 switches provide IP guard function to prevent hacker scanning and Blaster Worm viruses and reduce the CPU load. Currently, there are mainly two types of IP attacks:

Scanning destination IP address changes: As the greatest threat to the network, this type of attacks not only consumes network bandwidth and increases device load but also is a prelude of most hacker attacks.

Sending IP packets to non-existing destination IP addresses at high rates: This type of attacks is mainly designed for consuming the CPU load. For a Layer-3 device, if the destination IP address exists, packets are directly forwarded by the switching chip without occupying CPU resources. If the destination IP address does not exist, IP packets are sent to the CPU, which then sends ARP requests to query the MAC address corresponding to the destination IP address. If too many packets are sent to the CPU, CPU resources will be consumed. This type of attack is less destructive than the former one.

To prevent the latter type of attack, limit the rate of IP packets and find and isolate the attack source.

ICMP Guard

ICMP is a common approach to diagnose network failures. After receiving an ICMP echo request from a host, the router or switch returns an ICMP echo reply. The preceding process requires the CPU to process the packets, thereby definitely consuming part of CPU resources. If an attacker sends a large number of ICMP echo requests to the destination device, massive CPU resources on the device will be consumed heavily, and the device may even fail to work properly. This type of attacks is called ICMP flood. To prevent this type of attacks, limit the rate of ICMP packets and find and isolate the attack source.

DHCP Guard

DHCP is widely used in LANs to dynamically assign IP addresses. It is significant to network security. Currently, the most common DHCP attack, also called DHCP exhaustion attack, uses faked MAC addresses to broadcast DHCP requests. Various attack tools on the Internet can easily complete this type of attack. A network attacker can send sufficient DHCP requests to use up the address space provided by the DHCP server within a period. In this case, authorized hosts will fail to request DHCP IP addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCP packets and find and isolate the attack source.

DHCPv6 Guard

DHCP version 6 (DHCPv6) is widely used in LANs to dynamically assign IPv6 addresses. Both DHCP version 4 (DHCPv4) and DHCPv6 have security problems. Attacks to DHCPv4 apply also to DHCPv6. A network attacker can send a large number of DHCPv6 requests to use up the address space provided by the DHCPv6 server within a period. In this case, authorized hosts will fail to request IPv6 addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCPv6 packets and find the attack source.

ND Guard

Neighbor Discovery (ND) is mainly used in IPv6 networks to perform address resolution, router discovery, prefix discovery, and redirection. ND uses five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect. These packets are called ND packets.

Self-Defined Guard

There are various types of network protocols, including routing protocols such as Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and Routing Information Protocol (RIP). Various devices need to exchange packets through different protocols. These packets must be sent to the CPU and processed by appropriate protocols. Once the network device runs a protocol, it is like opening a window for attackers. If an attacker sends a large number of protocol packets to a

network device, massive CPU resources will be consumed on the device, and what's worse, the device may fail to work properly.

Since various protocols are being continuously developed, protocols in use vary with the user environments. Ruijie devices hereby provide self-defined guard. Users can customize and flexibly configure guard types to meet guard requirements in different user environments.

Overview

Feature	Description
Host-based Rate Limiting and Attack Identification	Limits the rate according to the host-based rate limit and identify host attacks in the network.
Port-based Rate Limiting and Attack Identification	Limits the rate according to the port-based rate limit and identify port attacks.
Monitoring Period	Monitors host attackers in a specified period.
Isolation Period	Uses hardware to isolate host attackers or port attackers in a specified period.
Trusted Hosts	Trusts a host by not monitoring it.
Centralized BandwidthAllocation	Classifies and prioritizes packets.

17.3.1 Host-based Rate Limiting and Attack Identification

Limit the rate of attack packets of hosts and identify the attacks.

Identify ARP scanning.

Identify IP scanning.

Working Principle

Hosts can be identified in two ways: based on the source IP address, VLAN ID, and port and based on the link-layer source MAC address, VLAN ID, and port. Each host has a rate limit and an attack threshold (also called alarm threshold). The rate limit must be lower than the attack threshold. If the attack packet rate exceeds the rate limit of a host, the host discards the packets beyond the rate limit. If the attack packet rate exceeds the attack threshold of a host, the host identifies and logs the host attacks, and sends traps.

ARP scanning attack may have occurred if ARP packets beyond the scanning threshold received in the configured period meet either of the following conditions:

- The link-layer source MAC address is fixed but the source IP address changes.
- The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes.

Among IP packets beyond the scanning threshold received in the configured period, if the source IP address remains the same while the destination IP address continuously changes, IP scanning attack may have occurred.

 When NFPP detects a specific type of attack packets under a service, it sends a trap to the administrator. If the attack traffic persists, NFPP will not resend the alarm until 60 seconds later.

-
-  To prevent CPU resource consumption caused by frequent log printing, NFPP writes attack detection logs to the buffer, obtains them from the buffer at a specified rate, and prints them. NFPP does not limit the rate of traps.
-

Related Configuration

Use ARP guard as an example:

✚ Configuring the Global Host-based Rate Limit, Attack Threshold, and Scanning Threshold

In NFPP configuration mode:

Run the **arp-guard rate-limit {per-src-ip | per-src-mac} pps** command to configure rate limits of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard attack-threshold {per-src-ip | per-src-mac} pps** command to configure attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard scan-threshold pkt-cnt** command to configure the ARP scanning threshold.

✚ Configuring Host-based Rate Limit and Attack Threshold, and Scanning Threshold on an Interface

In interface configuration mode:

Run the **nfpp arp-guard policy {per-src-ip | per-src-mac} rate-limit-pps attack-threshold-pps** command to configure rate limits and attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port on an interface.

Run the **nfpp arp-guard scan-threshold pkt-cnt** command to configure the scanning threshold on an interface.

-
-  Only ARP guard and IP guard support anti-scanning at present.
-

17.3.2 Port-based Rate Limiting and Attack Identification

Working Principle

Each port has a rate limit and an attack threshold. The rate limit must be lower than the attack threshold. If the packet rate exceeds the rate limit on a port, the port discards the packets. If the packet rate exceeds the attack threshold on a port, the port logs the attacks and sends traps.

Related Configuration

Use ARP guard as an example:

✚ Configuring the Global Port-based Rate Limit and Attack Threshold

In NFPP configuration mode:

Run the **arp-guard rate-limit per-port pps** command to configure the rate limit of a port.

Run the **arp-guard attack-threshold per-port pps** command to configure the attack threshold of a port.

➤ Configuring Port-based Rate Limit and Attack Threshold on an Interface

In interface configuration mode:

Run the **nfpp arp-guard policy per-port** *rate-limit-pps attack-threshold-pps* command to configure the rate limit and attack threshold of a port.

17.3.3 Monitoring Period

Working Principle

The monitoring user provides information about attackers in the current system. If the isolation period is 0 (that is, not isolated), the guard module automatically performs software monitoring on attackers in the configured monitoring period. If the isolation period is set to a non-zero value, the guard module automatically isolates the hosts monitored by software and sets the timeout period as the isolation period. The monitoring period is valid only when the isolation period is 0.

Related Configuration

Use ARP guard as an example:

➤ Configuring the Global Monitoring Period

In NFPP configuration mode:

Run the **arp-guard monitor-period** *seconds* command to configure the monitoring period.

17.3.4 Isolation Period

Working Principle

Isolation is performed by the guard policies after attacks are detected. Isolation is implemented using the filter of the hardware to ensure that these attacks will not be sent to the CPU, thereby ensuring proper running of the device.

Hardware isolation supports two modes: host-based and port-based isolation. At present, only ARP or ND guard supports port-based hardware isolation.

A policy is configured in the hardware to isolate attackers. However, hardware resources are limited. When hardware resources are used up, the system prints logs to notify the administrator.

Related Configuration

Use ARP guard as an example:

➤ Configuring the Global Isolation Period

In NFPP configuration mode:

Run the **arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

✚ Configuring the Isolation Period on an Interface

In interface configuration mode:

Run the **nfpp arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

✚ Enabling Isolate Forwarding

In NFPP configuration mode:

Run the **arp-guard isolate-forwarding enable** command to enable isolate forwarding.

✚ Enabling Port-based Ratelimit Forwarding

In NFPP configuration mode:

Run the **arp-guard ratelimit-forwarding enable** command to enable port-based ratelimit forwarding.

 At present, only ARP guard supports the configuration of isolate forwarding and ratelimit forwarding.

17.3.5 Trusted Hosts

Working Principle

If you do not want to monitor a host, you can run related commands to trust the host. This trusted host will be allowed to send packets to the CPU.

Related Configuration

Use IP anti-scanning as an example:

✚ Configuring Trusted Hosts

In NFPP configuration mode:

Run the **ip-guard trusted-host** *ip mask* command to trust a host.

Run the **trusted-host** {*mac mac_mask* | *ip mask* | *IPv6/prefixlen*} command to trust a host for a self-defined guard.

17.3.6 Centralized Bandwidth Allocation

Working Principle

Services defined in CPP are classified into three types: Manage, Route, and Protocol. (For details, see the following table.) Each type of service has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics exceeding the bandwidth thresholds are discarded. By such service classification, service packets are processed by orders of precedence.

NFPP allows the administrator to flexibly assign bandwidth for three types of packets based on the actual network environment so that Protocol and Manage packets can be first processed. Prior processing of Protocol packets ensures

proper running of protocols, and prior processing of Manage packets ensures proper management for the administrator, thereby ensuring proper running of important device functions and improving the guard capability of the device.

After classified rate limiting, all types of packets are centralized in a queue. When one type of service is processed inefficiently, packets of this service will be backlogged in the queue and may finally use up resources of the queue. NFPP allows the administrator to configure the percentages of these three types of packets in the queue. When the queue length occupied by one type of packets exceeds the value of the total queue length multiplied by the percentage of this packet type, the excessive packets will be discarded. This efficiently prevents one type of packets from exclusively occupying queue resources.

Packet Type	Service Type Defined in CPP
Protocol	tp-guard, dot1x, rldp, rerp, slow-packet, bpdu, isis dhcps, gvrp, ripng, dvmrp, igmp, mpls, ospf, pim, pimv6, rip, vrrp, ospf3, dhcp-relay-s, dhcp-relay-c, option82, tunnel-bpdu, tunnel-gvrp
Route	unknown-ipmc, unknown-ipmccv6, ttl1, ttl0, udp-helper, ip4-packet-other, ip6-packet-other, non-ip-packet-other, arp
Manage	ip4-packet-local, ip6-packet-local

 For the definitions of service types, see the Configuring CPU Protection.

Related Configuration

✎ Configuring the Maximum Bandwidth of Specified Packets

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol|route} pps pps_value** command to configure the maximum bandwidth of specified packets.

✎ Configuring the Maximum Percentage of Specified Packets in the Queue

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol | route} percent percent_value** command to configure the maximum percentage of specified packets in the queue.

17.4 Configuration

Configuration	Description and Command	
Configuring ARP Guard	arp-guard enable	Enables ARP guard globally.
	arp-guard isolate-period	Configures the global ARP-guard isolation period.
	arp-guard isolate-forwarding enable	Enables ARP-guard isolate forwarding.
	arp-guard ratelimit-forwarding enable	Enables APR-guard ratelimit forwarding.
	arp-guard monitor-period	Configures the global ARP-guard monitoring period.

Configuration	Description and Command	
	arp-guard monitored-host-limit	Configures the maximum number of ARP-guard monitored hosts.
	arp-guard rate-limit	Configures the global ARP-guard rate limit.
	arp-guard attack-threshold	Configures the global ARP-guard attack threshold.
	arp-guard scan-threshold	Configures the global ARP-guard scanning threshold.
	nfpp arp-guard enable	Enables ARP guard on an interface.
	nfpp arp-guard policy	Configures the APR-guard rate limit and attack threshold on an interface.
	nfpp arp-guard scan-threshold	Configures the APR-guard scanning threshold on an interface.
	nfpp arp-guard isolate-period	Configures the APR-guard isolation period on an interface.
Configuring IP Guard	ip-guard enable	Enables IP guard globally.
	ip-guard isolate-period	Configures the global IP-guard isolation period.
	ip-guard monitor-period	Configures the global IP-guard monitoring period.
	ip-guard monitored-host-limit	Configures the maximum number of IP-guard monitored hosts.
	ip-guard rate-limit	Configures the global IP-guard rate limit.
	ip-guard attack-threshold	Configures the global IP-guard attack threshold.
	ip-guard scan-threshold	Configures the global IP-guard scanning threshold.
	ip-guard trusted-host	Configures IP-guard trusted hosts.
	nfpp ip-guard enable	Enables IP guard on an interface.
	nfpp ip-guard policy	Configures the IP-guard rate limit and attack threshold on an interface.
	nfpp ip-guard scan-threshold	Configures the IP-guard scanning threshold on an interface.
	nfpp ip-guard isolate-period	Configures the IP-guard isolation period on an interface.
Configuring ICMP Guard	icmp-guard enable	Enables ICMP guard globally.
	icmp-guard isolate-period	Configures the global ICMP-guard isolation period.
	icmp-guard monitor-period	Configures the global ICMP-guard monitoring period.
	icmp-guard monitored-host-limit	Configures the maximum number of ICMP-guard monitored hosts.
	icmp-guard rate-limit	Configures the global ICMP-guard rate limit.

Configuration	Description and Command	
	icmp-guard attack-threshold	Configures the global ICMP-guard attack threshold.
	icmp-guard trusted-host	Configures ICMP-guard trusted hosts.
	nfpp icmp-guard enable	Enables ICMP guard on an interface.
	nfpp icmp-guard policy	Configures the ICMP-guard rate limit and attack threshold on an interface.
	nfpp icmp-guard isolate-period	Configures the ICMP-guard isolation period on an interface.
Configuring DHCP Guard	dhcp-guard enable	Enables DHCP guard globally.
	dhcp-guard isolate-period	Configures the global DHCP-guard isolation period.
	dhcp-guard monitor-period	Configures the global DHCP-guard monitoring period.
	dhcp-guard monitored-host-limit	Configures the maximum number of DHCP-guard monitored hosts.
	dhcp-guard rate-limit	Configures the global DHCP-guard rate limit.
	dhcp-guard attack-threshold	Configures the global DHCP-guard attack threshold.
	nfpp dhcp-guard enable	Enables DHCP guard on an interface.
	nfpp dhcp-guard policy	Configures the DHCP-guard rate limit and attack threshold on an interface.
	nfpp dhcp-guard isolate-period	Configures the DHCP-guard isolation period on an interface.
Configuring DHCPv6 Guard	dhcpv6-guard enable	Enables DHCPv6 guard globally.
	dhcpv6-guard monitor-period	Configures the global DHCPv6-guard monitoring period.
	dhcpv6-guard monitored-host-limit	Configures the maximum number of DHCPv6-guard monitored hosts.
	dhcpv6-guard rate-limit	Configures the global DHCPv6-guard rate limit.
	dhcpv6-guard attack-threshold { per-src-mac per-port} pps	Configures the global DHCPv6-guard attack threshold.
	nfpp dhcpv6-guard enable	Enables DHCPv6 guard on an interface.
	nfpp dhcpv6-guard policy	Configures the DHCPv6-guard rate limit and attack threshold on an interface.
Configuring ND Guard	nd-guard enable	Enables ND guard globally.
	nd-guard ratelimit-forwarding enable	Enables ND-guard ratelimit forwarding.
	nd-guard rate-limit per-port	Configures the global ND-guard rate limit.
	nd-guard attack-threshold per-port	Configures the global ND-guard attack threshold.
	nfpp nd-guard enable	Enables ND guard on an interface.

Configuration	Description and Command	
	nfpp nd-guard policy per-port	Configures the ND-guard rate limit and attack threshold on an interface.
Configuring a Self-Defined Guard	define	Configures the name of a self-defined guard.
	match	Configures match fields of a self-defined guard.
	global-policy	Configures the global rate limit and attack threshold of a self-defined guard.
	monitor-period	Configures the global monitoring period of a self-defined guard.
	monitored-host-limit	Configures the maximum number of monitored hosts of a self-defined guard.
	trusted-host	Configures trusted hosts of a self-defined guard.
	define name enable	Enables a self-defined guard globally.
	nfpp define name enable	Enables a self-defined guard on an interface.
Configuring NFPP Logging	nfpp define	Configures the rate limit and attack threshold of a self-defined guard on an interface.
	log-buffer entries	Configures the log buffer size.
	log-buffer logs	Configures the log buffer rate.
	logging vlan	Configures VLAN-based logging filtering.
	logging interface	Configures interface-based logging filtering.
	logging enable	Enables log printing.

17.4.1 Configuring ARP Guard

Configuration Effect

- ARP attacks are identified based on hosts or ports. Host-based ARP attack identification supports two modes: identification based on the source IP address, VLAN ID, and port and identification based on the link-layer source MAC address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ARP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ARP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- ARP guard can also detect ARP scanning attacks. ARP scanning attacks indicate that the link-layer source MAC address is fixed but the source IP address changes, or that the link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes. Due to the possibility of false positive, hosts possibly performing ARP scanning are not isolated and are provided for the administrator's reference only.
- Configure ARP-guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- ARP guard prevents only ARP DoS attacks to the switch, but not ARP spoofing or ARP attacks in the network.
- For trusted ports configured for Dynamic ARP Inspection (DAI), ARP guard does not take effect, preventing false positive of ARP traffic over the trusted ports. For details about DAI trusted ports, see the Configuring Dynamic ARP Inspection.

Configuration Steps

↘ Enabling ARP Guard

- (Mandatory) ARP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ARP guard is disabled, the system automatically clears monitored hosts, scanned hosts, and isolated entries on ports.

↘ Configuring the ARP-Guard Isolation Period

- (Optional) ARP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↘ Enabling ARP-Guard Isolate Forwarding

- (Optional) ARP-guard isolate forwarding is enabled by default.
- To make isolation valid only at the management plane instead of the forwarding plane, you can enable this function.
- This function can be enabled in NFPP configuration mode.

↘ Enabling ARP-Guard Ratelimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

↘ Configuring the ARP-Guard Monitoring Period

- (Mandatory) The default ARP-guard monitoring period is 600 seconds.
- If the ARP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

➤ **Configuring the Maximum Number of ARP-Guard Monitored Hosts**

- (Mandatory) The maximum number of ARP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ARP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of ARP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ARP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

➤ **Configuring the ARP-Guard Attack Threshold**

- Mandatory.
- To achieve the best ARP-guard effect, you are advised to configure the host-based rate limit and attack threshold based on the following order: Source IP address-based rate limit < Source IP address-based attack threshold < Source MAC address-based rate limit < Source MAC address-based attack threshold.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ARP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over source IP address-based rate limiting while the latter takes priority over port-based rate limiting.

➤ **Configuring the ARP-Guard Scanning Threshold**

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- The ARP scanning table stores only the latest 256 records. When the ARP scanning table is full, the latest record will overwrite the earliest record.
- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet either of the following conditions:
 - The link-layer source MAC address is fixed but the source IP address changes.
 - The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes, and the change times exceed the scanning threshold.

Verification

When a host in the network sends ARP attack packets to a switch configured with ARP guard, check whether these packets can be sent to the CPU.

- If the packets exceed the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ Enabling ARP Guard Globally

Command	arp-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Isolation Period

Command	arp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP-Guard Isolate Forwarding

Command	arp-guard isolate-forwarding enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP-Guard Ratelimit Forwarding

Command	arp-guard ratelimit-forwarding enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global ARP-Guard Monitoring Period

Command	arp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Maximum Number of ARP-Guard Monitored Hosts

Command	arp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global ARP-Guard Rate Limit

Command	arp-guard rate-limit { per-src-ip per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-ip : Limits the rate of each source IP address. per-src-mac : Limits the rate of each source MAC address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global ARP-Guard Attack Threshold

Command	arp-guard attack-threshold { per-src-ip per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-src-mac : Configures the attack threshold of each source MAC address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is packets per second (pps).
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

✚ Configuring the Global ARP-Guard Scanning Threshold

Command	arp-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.

Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Enabling ARP Guard on an Interface

Command	nfpp arp-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	ARP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

▾ Configuring the ARP-Guard Isolation Period on an Interface

Command	nfpp arp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the ARP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp arp-guard policy { per-src-ip per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-src-mac : Configures the rate limit and attack threshold of each source MAC address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

▾ Configuring the ARP-Guard Scanning Threshold on an Interface

Command	nfpp arp-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

📌 CPU Protection Based on ARP Guard

Scenario	● ARP host attacks exist in the system, and some hosts fail to properly establish ARP connection. ● ARP scanning exists in the system, causing a very high CPU utilization rate.
Configuration Steps	● Set the host-based attack threshold to 5 pps. ● Set the ARP scanning threshold to 10 pps. ● Set the isolation period to 180 pps.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#arp-guard rate-limit per-src-mac 5 Ruijie (config-nfpp)#arp-guard attack-threshold per-src-mac 10 Ruijie (config-nfpp)#arp-guard isolate-period 180</pre>
Verification	● Run the show nfpp arp-guard summary command to display the configuration.
	<pre>(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) Interface Status Isolate-period Rate-limit Attack-threshold Scan-threshold ----- Global Disable 180 4/5/100 8/10/200 15 Maximum count of monitored hosts: 1000 Monitor period: 600s</pre>
	● Run the show nfpp arp-guard hosts command to display the monitored hosts.
	<pre>If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address MAC address remain-time(s) ----- 1 Gi0/43 5.5.5.16 - 175 Total: 1 host</pre>
	● Run the show nfpp arp-guard scan command to display the scanned hosts.
	<pre>VLAN interface IP address MAC address timestamp ----- 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:50:32 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:50:33 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:51:33 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:51:34</pre>

17.4.2 Configuring IP Guard

Configuration Effect

- IP attacks are identified based on hosts or physical interfaces. In host-based IP attack identification, IP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the IP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the IP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- IP guard can also detect IP scanning attacks. IP anti-scanning applies to IP packet attacks as follows: the destination IP address continuously changes but the source IP address remains the same, and the destination IP address is not the IP address of the local device.
- Configure IP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.
- IP anti-scanning applies to IP packet attacks where the destination IP address is not the local IP address. The CPP limits the rate of IP packets where the destination IP address is the local IP address.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

📌 Enabling IP Guard

- (Mandatory) IP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If IP guard is disabled, the system automatically clears monitored hosts.

📌 Configuring the IP-Guard Isolation Period

- (Optional) IP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.

- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 **Configuring the IP-Guard Monitoring Period**

- (Mandatory) The default IP-guard monitoring period is 600 seconds.
- If the IP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

📌 **Configuring the Maximum Number of IP-Guard Monitored Hosts**

- (Mandatory) The maximum number of IP-guard monitored hosts is 20,000 by default.
- Set the maximum number of IP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of IP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_IP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

📌 **Configuring the IP-Guard Attack Threshold**

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_IP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

📌 **Configuring the IP-Guard Scanning Threshold**

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet the following conditions:
 - The source IP address remains the same.

- The destination IP address continuously changes and is not the local IP address, and the change times exceed the scanning threshold.

📌 Configuring IP-Guard Trusted Hosts

- (Optional) No IP-guard trusted host is configured by default.
- For IP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends IP attack packets to a switch configured with IP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from untrusted hosts exceeds the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

📌 Enabling IP Guard Globally

Command	ip-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global IP-Guard Isolation Period

Command	ip-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global IP-Guard Monitoring Period

Command	ip-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

✚ Configuring the Maximum Number of IP-Guard Monitored Hosts

Command	ip-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global IP-Guard Rate Limit

Command	ip-guard rate-limit { per-src-ip per-port } <i>pps</i>
Parameter Description	per-src-ip : Limits the rate of each source IP address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global IP-Guard Attack Threshold

Command	ip-guard attack-threshold { per-src-ip per-port } <i>pps</i>
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.

Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

✚ Configuring the Global IP-Guard Scanning Threshold

Command	ip-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring IP-Guard Trusted Hosts

Command	ip-guard trusted-host <i>ip mask</i>
Parameter Description	<i>ip</i> : Indicates the IP address. <i>mask</i> : Indicates the mask of an IP address. all : Used with no to delete all trusted hosts.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send IP packets to the CPU, without any rate limiting or alarm reporting.

✚ Enabling IP Guard on an Interface

Command	nfpp ip-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	IP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

✚ Configuring the IP-Guard Isolation Period on an Interface

Command	nfpp ip-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

✚ Configuring the IP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp ip-guard policy {per-src-ip per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

📌 Configuring the IP-Guard Scanning Threshold on an Interface

Command	nfpp ip-guard scan-threshold pkt-cnt
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

📌 CPU Protection Based on IP Guard

Scenario	● IP host attacks exist in the system, and packets of some hosts cannot be properly routed and forwarded. ● IP scanning exists in the system, causing a very high CPU utilization rate. ● Packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	● Configure the host-based attack threshold. ● Configure the IP scanning threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#ip-guard rate-limit per-src-ip 20 Ruijie (config-nfpp)#ip-guard attack-threshold per-src-ip 30 Ruijie (config-nfpp)#ip-guard isolate-period 180 Ruijie (config-nfpp)#ip-guard trusted-host 192.168.201.46 255.255.255.255</pre>
Verification	● Run the show nfpp ip-guard summary command to display the configuration.
	<pre>(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) Interface Status Isolate-period Rate-limit Attack-threshold Scan-threshold Global Disable 180 20/-/100 30/-/200 100</pre>

	Maximum count of monitored hosts: 1000 Monitor period: 600s															
	Run the show nfpp ip-guard hosts command to display the monitored hosts.

Common Errors

N/A

17.4.3 Configuring ICMP Guard

Configuration Effect

- ICMP attacks are identified based on hosts or ports. In host-based attack identification, ICMP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ICMP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ICMP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- Configure ICMP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

➤ Enabling ICMP Guard

- (Mandatory) ICMP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ICMP guard is disabled, the system automatically clears monitored hosts.

📌 Configuring the ICMP-Guard Isolation Period

- (Optional) ICMP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 Configuring the ICMP-Guard Monitoring Period

- (Mandatory) The default ICMP-guard monitoring period is 600 seconds.
- If the ICMP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

📌 Configuring the Maximum Number of ICMP-Guard Monitored Hosts

- (Mandatory) The maximum number of ICMP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ICMP-guard monitored hosts reasonably. As the number of actually monitored hosts increases, more CPU resources are used.
- The maximum number of ICMP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

📌 Configuring the ICMP-Guard Attack Threshold

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.

- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ICMP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

📌 Configuring ICMP-Guard Trusted Hosts

- (Optional) No ICMP-guard trusted host is configured by default.
- For ICMP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ICMP attack packets to a switch configured with ICMP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

📌 Enabling ICMP Guard Globally

Command	icmp-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global ICMP-Guard Isolation Period

Command	icmp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

✚ Configuring the Global ICMP-Guard Monitoring Period

Command	icmp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

✚ Configuring the Maximum Number of ICMP-Guard Monitored Hosts

Command	icmp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

✚ Configuring the Global ICMP-Guard Rate Limit

Command	icmp-guard rate-limit { <i>per-src-ip</i> <i>per-port</i> } <i>pps</i>

Parameter Description	per-src-ip : Limits the rate of each source IP address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Global ICMP-Guard Attack Threshold

Command	icmp-guard attack-threshold {per-src-ip per-port} pps
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring ICMP-Guard Trusted Hosts

Command	icmp-guard trusted-host ip mask
Parameter Description	<i>ip</i> : Indicates the IP address. <i>mask</i> : Indicates the mask of an IP address. all : Used with no to delete all trusted hosts.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored. You can configure a maximum of 500 trusted hosts.

✚ Enabling ICMP Guard on an Interface

Command	nfpp icmp-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	ICMP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

✚ Configuring the ICMP-Guard Isolation Period on an Interface

Command	nfpp icmp-guard isolate-period [seconds permanent]
Parameter	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to

Description	86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

✎ Configuring the ICMP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp icmp-guard policy {per-src-ip per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

✎ CPU Protection Based on ICMP Guard

Scenario	- ICMP host attacks exist in the system, and some hosts cannot successfully ping devices. - Packet traffic of some hosts is very large in the system, and these packets need to pass through.
Configuration Steps	- Configure the host-based attack threshold. - Set the isolation period to a non-zero value. - Configure trusted hosts.

17.4.4 Configuring DHCP Guard

Configuration Effect

- DHCP attacks are identified based on hosts or ports. In host-based attack identification, DHCP attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the DHCP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- Configure DHCP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- For trusted ports configured for DHCP snooping, DHCP guard does not take effect, preventing false positive of DHCP traffic on the trusted ports. For details about trusted ports of DHCP snooping, see "Configuring Basic Functions of DHCP Snooping" in the Configuring DHCP Snooping.

Configuration Steps

📌 Enabling DHCP Guard

- (Mandatory) DHCP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If DHCP guard is disabled, the system automatically clears monitored hosts.

📌 **Configuring the DHCP-Guard Isolation Period**

- (Optional) DHCP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 **Configuring the DHCP-Guard Monitoring Period**

- (Mandatory) DHCP-guard monitoring is enabled by default.
- If the DHCP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

📌 **Configuring the Maximum Number of DHCP-Guard Monitored Hosts**

- (Mandatory) The maximum number of DHCP-guard monitored hosts is 20,000 by default.
- Set the maximum number of DHCP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of DHCP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

📌 **Configuring the DHCP-Guard Attack Threshold**

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.

- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.

Verification

When a host in the network sends DHCP attack packets to a switch configured with DHCP guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

📌 Enabling DHCP Guard Globally

Command	dhcp-guard enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global DHCP-Guard Isolation Period

Command	dhcp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

📌 Configuring the Global DHCP-Guard Monitoring Period

Command	dhcp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout

	period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 Configuring the Maximum Number of DHCP-Guard Monitored Hosts

Command	dhcp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "%NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

📌 Configuring the Global DHCP-Guard Rate Limit

Command	dhcp-guard rate-limit { per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-mac: Limits the rate of each source MAC address. per-port: Limits the rate of each port. <i>pps</i>: Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global DHCP-Guard Attack Threshold

Command	dhcp-guard attack-threshold { per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-mac: Configures the attack threshold of each source MAC address. per-port: Configures the attack threshold of each port. <i>pps</i>: Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Enabling DHCP Guard on an Interface

Command	nfpp dhcp-guard enable
Parameter Description	N/A

Command Mode	Interface configuration mode
Usage Guide	DHCP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

✎ Configuring the DHCP-Guard Isolation Period on an Interface

Command	nfpp dhcp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

✎ Configuring the DHCP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp dhcp-guard policy { per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

✎ CPU Protection Based on DHCP Guard

Scenario	DHCP host attacks exist in the system, and some hosts fail to request IP addresses.					
Configuration Steps	- Configure the host-based attack threshold. - Set the isolation period to a non-zero value.					
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#dhcp-guard rate-limit per-src-mac 8 Ruijie (config-nfpp)#dhcp-guard attack-threshold per-src-mac 16 Ruijie (config-nfpp)#dhcp-guard isolate-period 180</pre>					
Verification	Run the show nfpp dhcp-guard summary command to display the configuration.					
	(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) <table><tr><td>Interface</td><td>Status</td><td>Isolate-period</td><td>Rate-limit</td><td>Attack-threshold</td></tr></table>	Interface	Status	Isolate-period	Rate-limit	Attack-threshold

Common Errors

N/A

17.4.5 Configuring DHCPv6 Guard

Configuration Effect

- DHCPv6 attacks are identified based on hosts or ports. In host-based attack identification, DHCPv6 attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the DHCPv6 packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCPv6 packet rate exceeds the attack threshold, the system prints alarm information and sends traps.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- For trusted ports configured for DHCPv6 snooping, DHCPv6 guard does not take effect, preventing false positive of DHCPv6 traffic on the trusted ports. For details about trusted ports of DHCPv6 snooping, see "Configuring Basic Functions of DHCPv6 Snooping" in the Configuring DHCPv6 Snooping.

Configuration Steps

📌 Enabling DHCPv6 Guard

- (Mandatory) DHCPv6 guard is enabled by default.
- DHCPv6 guard can be enabled in NFPP configuration mode or interface configuration mode.
- If DHCPv6 guard is disabled, the system automatically clears monitored hosts.

✚ Configuring the DHCPv6-Guard Monitoring Period

- (Mandatory) The default DHCPv6-guard monitoring period is 600 seconds.
- If the DHCPv6-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period does not take effect.
- The DHCPv6-guard monitoring period can be configured in NFPP configuration mode.

✚ Configuring the Maximum Number of DHCPv6-Guard Monitored Hosts

- (Mandatory) The maximum number of DHCPv6-guard monitored hosts is 20,000 by default.
- Set the maximum number of DHCPv6-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of DHCPv6-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

✚ Configuring the DHCPv6-Guard Attack Threshold

- Mandatory.
- The DHCPv6-guard attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCPV6_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.

Verification

When a host in the network sends DHCPv6 attack packets to a switch configured with DHCPv6 guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

✚ Enabling DHCPv6 Guard Globally

Command	dhcpv6-guard enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global DHCPv6-Guard Monitoring Period

Command	dhcpv6-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 Configuring the Maximum Number of DHCPv6-Guard Monitored Hosts

Command	dhcpv6-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system prints the log "%NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

📌 Configuring the Global DHCPv6-Guard Rate Limit

Command	dhcpv6-guardrate-limit { per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-mac: Limits the rate of each source MAC address. per-port: Limits the rate of each port. <i>pps</i>: Indicates the rate limit, ranging from 1 to 19,999.
Command	NFPP configuration mode

Mode	
Usage Guide	N/A

✚ Configuring the Global DHCPv6-Guard Attack Threshold

Command	dhcpv6-guard attack-threshold { per-src-mac per-port} pps
Parameter Description	per-src-mac: Configures the attack threshold of each source MAC address. per-port: Configures the attack threshold of each port. <i>pps:</i> Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Enabling DHCPv6 Guard on an Interface

Command	nfpp dhcpv6-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

✚ Configuring the DHCP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp dhcpv6-guard policy {per-src-mac per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip: Configures the rate limit and attack threshold of each source IP address. per-port: Configures the rate limit and attack threshold of each port. <i>rate-limit-pps:</i> Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps:</i> Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

✚ CPU Protection Based on DHCPv6 Guard

Scenario	DHCPv6 host attacks exist in the system, and DHCPv6 neighbor discovery fails on some hosts.
Configuration Steps	Configure the host-based attack threshold.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#dhcpv6-guard rate-limit per-src-mac 8</pre>

	Ruijie (config-nfpp)#dhcpv6-guard attack-threshold per-src-mac 16												
Verification	Run the show nfpp dhcpv6-guard summary command to display the configuration.												
	(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) <table><tr><td>Interface</td><td>Status</td><td>Rate-limit</td><td>Attack-threshold</td></tr><tr><td>Global</td><td>Disable</td><td>-/8/150</td><td>-/16/300</td></tr></table> Maximum count of monitored hosts: 1000 Monitor period: 600s	Interface	Status	Rate-limit	Attack-threshold	Global	Disable	-/8/150	-/16/300				
Interface	Status	Rate-limit	Attack-threshold										
Global	Disable	-/8/150	-/16/300										
	Run the show nfpp dhcpv6-guard hosts command to display the monitored hosts.												
	If col_filter 1 shows '*', it means "hardware do not isolate host". <table><tr><td>VLAN</td><td>interface</td><td>MAC address</td><td>remain-time(s)</td></tr><tr><td>----</td><td>-----</td><td>-----</td><td>-----</td></tr><tr><td>*1</td><td>Gi0/5</td><td>001a.a9c2.4609</td><td>160</td></tr></table> Total: 1 host	VLAN	interface	MAC address	remain-time(s)	----	-----	-----	-----	*1	Gi0/5	001a.a9c2.4609	160
VLAN	interface	MAC address	remain-time(s)										
----	-----	-----	-----										
*1	Gi0/5	001a.a9c2.4609	160										

Common Errors

N/A

17.4.6 Configuring ND Guard

Configuration Effect

- AR ND guard classifies ND packets into three types based on their purposes: 1. NS and NA; 2. RS; 3. RA and Redirect. Type 1 packets are used for address resolution. Type 2 packets are used by hosts to discover the gateway. Type 3 packets are related to routing: RAs are used to advertise the gateway and prefix while Redirect packets are used to advertise a better next hop.
- At present, only port-based ND packet attack identification is supported. You can configure the rate limits and attack thresholds for these three types of packets respectively. If the ND packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ND packet rate exceeds the attack threshold, the system prints logs and sends traps.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.

Configuration Steps

📌 Enabling ND Guard

- (Mandatory) ND guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.

▾ Enabling ND-Guard Ratelimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

▾ Configuring the ND-Guard Attack Threshold

- Mandatory.
- The ND-guard attack threshold can be enabled in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If memories cannot assigned to detected attackers, the system prints the log "%NFPP_ND_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ND attack packets to a switch configured with ND guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.

Common Errors

N/A

17.4.7 Configuring a Self-Defined Guard

Configuration Effect

- Configure a self-defined guard to resolve network attack problems in special scenarios.

Notes

- For a command that is configured both in self-defined guard configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in self-defined guard configuration mode.
- A self-defined guard takes priority over basic guards. When configuring the match fields of self-defined guards, see the Configuration Guide.

Configuration Steps

📌 Configuring the Guard Name

- (Mandatory) Configure the name of a self-defined guard to create the self-defined guard.

- The guard name must be unique, and the match fields and values must be different from those of ARP, ICMP, DHCP, IP, and DHCPv6 guards. If the parameters you want to configure already exist, a message is displayed to indicate the configuration failure.

📌 Configuring the Match Fields

- Mandatory.
- Self-defined packets are classified based on the following fields: etype (Ethernet link-layer type), smac (source MAC address), dmac (destination MAC address), protocol (IPv4/IPv6 protocol number), sip (source IPv4/IPv6 address), dip (destination IPv4/IPv6 address), sport (source transport-layer port), and dport (destination transport-layer port).
- **protocol** is valid only when the value of **etype** is **ipv4** or **ipv6**. **src-ip** and **dst-ip** are valid only when the value of **etype** is **ipv4**. **src-ipv6** and **dst-ipv6** are valid only when the value of **etype** is **ipv6**. **src-port** and **dst-port** are valid only when the value of **protocol** is **tcp** or **udp**.
- If the **match** fields and values of a self-defined guard are totally the same as those of an existing guard, the system prints the log "%ERROR: the match type and value are the same with define name (name of an existing guard)." to notify the administrator of the configuration failure.
- If **protocol** is configured but **etype** is IPv4 or IPv6 in the **match** policy, the system prints the log "%ERROR: protocol is valid only when etype is IPv4(0x0800) or IPv6(0x86dd)."
- If **src-ip** and **dst-ip** are configured but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: IP address is valid only when etype is IPv4(0x0800)."
- If **src-ipv6** and **dst-ipv6** are configured but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: IPv6 address is valid only when etype is IPv6(0x86dd)."
- If **src-port** and **dst-port** are configured but **protocol** is not TCP or UDP in the **match** policy, the system prints the log "%ERROR: Port is valid only when protocol is TCP(6) or UDP(17)."
- The following table lists guard policies corresponding to some common network protocols. The rate limits and attack thresholds listed below can meet the requirements in most network scenarios and are for reference only. You can configure valid rate limits and attack thresholds based on actual scenarios.

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
RIP	etype 0x0800 protocol 17 dst-port 520	rate-limit 100 attach-threshold 150	Not applicable to this policy	rate-limit 300 attach-threshold 500
RIPng	etype 0x86dd protocol 17 dst-port 521	rate-limit 100 attach-threshold 150	Not applicable to this policy	rate-limit 300 attach-threshold 500
BGP	etype 0x0800 protocol 6 dst-port 179	rate-limit 1000 attach-threshold 1200	Not applicable to this policy	rate-limit 2000 attach-threshold 3000
BPDU	dst-mac 0180.c200.0000	Not applicable to this policy	rate-limit 20 attach-threshold 40	rate-limit 100 attach-threshold 100

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
RERP	dst-mac 01d0.f800.0001	Not applicable to this policy	rate-limit 20 attatch-threshold 40	rate-limit 100 attatch-threshold 100
REUP	dst-mac 01d0.f800.0007	Not applicable to this policy	rate-limit 20 attatch-threshold 40	rate-limit 100 attatch-threshold 100
BGP	etype 0x0800 protocol 6 dst-port 179	Not applicable to this policy	Not applicable to this policy	Not applicable to this policy
OSPFv2	etype 0x0800 protocol 89	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
OSPFv3	etype 0x86dd protocol 89	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
VRRP	etype 0x0800 protocol 112	rate-limit 64 attatch-threshold 100	Not applicable to this policy	rate-limit 1024 attatch-threshold 1024
IPv6 VRRP	etype 0x86dd protocol 112	rate-limit 64 attatch-threshold 100	Not applicable to this policy	rate-limit 1024 attatch-threshold 1024
SNMP	etype 0x0800 protocol 17 dst-port 161	rate-limit 1000 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
RSVP	etype 0x0800 protocol 46	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 1200 attatch-threshold 1500
LDP (UDP hello)	etype 0x0800 protocol 17 dst-port 646	rate-limit 10 attatch-threshold 15	Not applicable to this policy	rate-limit 100 attatch-threshold 150

- To contain as many existing protocol types as possible and facilitate expansion of new protocol types, self-defined guards allow hosts to freely combine type fields of packets. If the configuration is inappropriate, the network may become abnormal. Therefore, the network administrator needs to have a good knowledge of network protocols. As a reference, the following table lists valid configurations of currently known protocols for common self-defined guard policies. For other protocols not listed in the table, configure them with caution.

📌 Configuring the Global Rate Limit and Attack Threshold

- (Mandatory) If these parameters are not configured, the self-defined guard cannot be enabled.
- You must configure one of the per-src-ip, per-src-mac, and per-port fields. Otherwise, the policy cannot take effect.
- per-src-ip is valid only when etype is IPv4 or IPv6.
- The rate limit configured based on the source MAC address, VLAN ID, and port takes priority over that configured based on the source IP address, VLAN ID, and port.
- The port-based host identification policy of a self-defined guard must be consistent with the global port-based host identification policy.

- If the **per-src-ip** policy is not configured globally but configured for a port, the system prints the log "%ERROR: name (name of a self-defined guard) has not per-src-ip policy." to notify the administrator of the configuration failure.
- If the **per-src-mac** policy is not configured globally but configured for a port, the system prints the log "%ERROR: name (name of a self-defined guard) has not per-src-mac policy." to notify the administrator of the configuration failure.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DEFINE_GUARD-4-NO_MEMORY: Failed to allocate memory." to notify the administrator.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.

📌 Configuring the Global Monitoring Period

- (Mandatory) The default monitoring period is 600 seconds.
- If the isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in self-defined guard configuration mode.
- If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

📌 Configuring the Maximum Number of Monitored Hosts

- (Mandatory) The maximum number of monitored hosts is 20,000 by default.
- Set the maximum number of monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of monitored hosts can be configured in self-defined guard configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DEFINE-4-SESSION_LIMIT: Attempt to exceed limit of name's 20000 monitored hosts." to notify the administrator.

📌 Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- You can configure a maximum of 500 trusted IP address or MAC address for a self-defined guard.

- Trusted hosts can be configured in self-defined guard configuration mode.
- If you do not want to monitor a host, you can run the following commands to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored.
- You must configure the **match** type before configuring trusted hosts. If the packet type is IPv4 in the **match** policy, you are not allowed to configure trusted IPv6 addresses. If the packet type is IPv6 in the match policy, you are not allowed to configure trusted IPv4 addresses.
- If the **match** type is not configured, the system prints the log "%ERROR: Please configure match rule first."
- If a trusted IPv4 host is added but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv4 trusted host."
- If a trusted IPv6 host is added but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv6 trusted host."
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to allocate memory." to notify the administrator.

📌 Enabling a Self-Defined Guard

- Mandatory.
- You have to configure at least one policy between host-based self-defined guard policy and port-based self-defined guard policy. Otherwise, the self-defined guard cannot be enabled.
- If a self-defined guard is disabled, the system automatically clears monitored hosts.
- Self-defined guards can be configured in self-defined guard configuration mode or interface configuration mode.
- If a self-defined guard policy is not completely configured, the self-defined guard cannot be enabled and a prompt is displayed to notify hosts of the missing policy configurations.
- If the name of a self-defined guard does not exist, the system prints the log "%ERROR: The name is not exist."

- If the match type is not configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't match any type."
- If no policy is configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't specify any policy."

Verification

When a host in the network sends packets to a switch configured with a self-defined NFPP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Configuring Match Fields of a Self-defined Guard

Command	match [etype type] [src-mac smac [src-mac-mask smac_mask] [dst-mac dmac [dst-mac-mask dst_mask]] [protocol protocol] [src-ip sip [src-ip-mask sip-mask] [src-ipv6 sipv6 [src-ipv6-mask len sipv6-mask len]] [dst-ip dip [dst-ip-mask dip-mask] [dst-ipv6 dipv6 [dst-ipv6-mask len dipv6-mask len]] [src-ports port] [dst-port dport]
Parameter Description	<i>type</i>: Indicates the type of Ethernet link-layer packets. <i>smac</i>: Indicates the source MAC address. <i>smac_mask</i>: Indicates the mask of the source MAC address. <i>dmac</i>: Indicates the destination MAC address. <i>dst_mask</i>: Indicates the mask of the destination MAC address. <i>protocol</i>: Indicates the protocol number of IPv4/IPv6 packets. <i>sip</i>: Indicates the source IPv4 address. <i>sip-mask</i>: Indicates the mask of the source IPv4 address. <i>sipv6</i>: Indicates the source IPv6 address. <i>sipv6-masklen</i>: Indicates the mask length of the source IPv6 address. <i>dip</i>: Indicates the destination IPv4 address. <i>dip-mask</i>: Indicates the mask of the destination IPv4 address. <i>dipv6</i>: Indicates the destination IPv6 address. <i>dipv6-masklen</i>: Indicates the mask length of the destination IPv6 address.

	<i>sport</i> : Indicates the ID of the source transport-layer port. <i>dsport</i> : Indicates the ID of the destination transport-layer port.
Command Mode	Self-defined guard configuration mode
Usage Guide	Create a new self-defined guard and specify the packet fields matched by this guard.

✚ Configuring the Global Rate Limit and Attack Threshold of a Self-defined Guard

Command	global-policy {per-src-ip per-src-mac per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip : Collects rate statistics for host identification based on the source IP address, VLAN ID, and port. per-src-mac : Collects rate statistics for host identification based on the source MAC address, VLAN ID, and port. per-port : Collects rate statistics based on each packet receiving port. <i>rate-limit-pps</i> : Indicates the rate limit. <i>attack-threshold-pps</i> : Indicates the attack threshold.
Command Mode	Self-defined guard configuration mode
Usage Guide	Before creating a self-defined guard type, you must specify rate statistic classification rules for this type, namely, source IP address-based host identification, source MAC address-based host identification, host-based self-defined packet rate statistics, or port-based rate statistics, and specify the rate limits and attack thresholds for the specified rules.

✚ Configuring the Global Monitoring Period of a Self-defined Guard

Command	monitor-period seconds
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

✚ Configuring the Maximum Number of Monitored Hosts of a Self-defined Guard

Command	monitored-host-limit number
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

✚ Configuring Trusted Hosts of a Self-defined Guard

Command	trusted-host {mac mac_mask ip mask IPv6/prefixlen}
Parameter	<i>mac</i> : Indicates the MAC address.

Description	<i>mac_mask</i> : Indicates the mask of an MAC address. <i>ip</i> : Indicates the IP address. <i>mask</i> : Indicates the mask of an IP address. <i>IPv6/prefixlen</i> : Indicates the IPv6 address and its mask length. all : Used with no to delete all trusted hosts.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

✚ Enabling a Self-Defined Guard Globally

Command	define name enable
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard.
Command Mode	NFPP configuration mode
Usage Guide	The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

✚ Enabling a Self-defined Guard on an Interface

Command	nfpp define name enable
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard.
Command Mode	Interface configuration mode
Usage Guide	The self-defined name must exist. The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

✚ Configuring the Rate Limit and Attack Threshold of a Self-defined Guard on an Interface

Command	nfpp define name policy {per-src-ip per-src-mac per-port} rate-limit-pps attack-threshold-pps
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard. per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-src-mac : Configures the rate limit and attack threshold of each source MAC address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

✚ CPU Protection Based on a Self-Defined Guard

Scenario	Basic guards cannot protect the system with RIP attacks.
Configuration Steps	- Configure a self-defined guard, with the key fields matching RIP packets. - Configure the rate limit. - Configure trusted hosts.
	<pre> Ruijie# configure terminal Ruijie(config)# nfpp Ruijie (config-nfpp)#define rip Ruijie (config-nfpp-define)#match etype 0x0800 protocol 17 dst-port 520 Ruijie (config-nfpp-define)#global-policy per-src-ip 100 150 Ruijie (config-nfpp-define)#trusted-host 192.168.201.46 255.255.255.255 Ruijie (config-nfpp-define)#exit Ruijie (config-nfpp)#define rip enable </pre>
Verification	Run the show nfpp define summary rip command to display the configuration.
	<pre> Define rip summary: match etype 0x800 protocol 17 dst-port 520 Maximum count of monitored hosts: 1000 Monitor period:600s (Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) Interface Status Rate-limit Attack-threshold Global Enable 100/-/- 150/-/- </pre>
	Run the show nfpp define trusted-host rip command to display the trusted hosts.
	<pre> Define rip: IP trusted host number is 1: IP address IP mask ----- 192.168.201.46 255.255.255.255 Total: 1 record(s)Global Enable 180 100/-/- 150/-/- </pre>
	Run the show nfpp define hosts rip command to display the monitored hosts.
	<pre> If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address remain-time(s) ----- </pre>

1	Gi0/5	192.168.201.47	160
Total: 1 host			

Common Errors

N/A

17.4.8 Configuring Centralized Bandwidth Allocation

Configuration Effect

- Configure centralized bandwidth allocation so that Manage and Protocol packets are first processed when the network is busy.

Notes

- The following condition must be met: Valid percentage range of a type of packets $\leq 100\%$ – Percentage of the sum of the other two types

Configuration Steps

➤ Configuring the Maximum Bandwidth of Specified Packets

- (Mandatory) Manage, Route, and Protocol packets share the same default bandwidth.

➤ Configuring the Maximum Percentage of Specified Packets in the Queue

- (Mandatory) By default, Manage packets occupy 30% of the bandwidth, Route packets occupy 25%, and Protocol packets occupy 45%.

Verification

Send a large number of protocol packets such as OSPF packets to a switch, causing high CPU utilization.

- When the host pings the switch, the pinging must be successful and no packet is lost.

Related Commands

➤ Configuring the Maximum Bandwidth of Specified Packets

Command	cpu-protect sub-interface { manage protocol route} pps <i>pps_value</i>
Parameter Description	<i>pps_value</i> : Indicates the rate limit, ranging from 1 to 100,000.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring the Maximum Percentage of Specified Packets in the Queue

Command	cpu-protect sub-interface { manage protocol route} percent <i>percent_value</i>
Parameter Description	<i>percent_value</i> : Indicates the percentage of a type of packets in the queue, ranging from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	The following condition must be met: Valid percentage range of a type of packets ≤ 100% – Percentage of the sum of the other two types

Configuration Example

📌 Prioritizing Packets Sent to the CPU Through Centralized Bandwidth Allocation

Scenario	Various types of mass packets exist in the network and belong to different centralized types.
Configuration Steps	- Configure the maximum bandwidth of specified packets. - Configure the maximum percentage of specified packets in the queue.
	<pre>Ruijie# configure terminal Ruijie(config)# cpu-protect sub-interface manage pps 5000 Ruijie(config)# cpu-protect sub-interface manage percent 25</pre>
Verification	N/A

Common Errors

N/A

17.4.9 Configuring NFPP Logging

Configuration Effect

- NFPP obtains a log from the dedicated log buffer at a certain rate, generates a system message, and clears this log from the dedicated log buffer.

Notes

- Logs are continuously printed in the log buffer, even if attacks have stopped.

Configuration Steps

📌 Configuring the Log Buffer Size

- Mandatory.
- If the log buffer is full, new logs replace the old ones.
- If the log buffer overflows, subsequent logs replace previous logs, and an entry with all attributes marked with a hyphen (-) is displayed in the log buffer. The administrator needs to increase the log buffer size or the system message generation rate.

✚ Configuring the Log Buffer Rate

- Mandatory.
- The log buffer rate depends on two parameters: the time period and the number of system messages generated in the time period.
- If both of the preceding two parameters are set to 0, system messages are immediately generated for logs but are not stored in the log buffer.

✚ Enabling Log Filtering

- (Optional) Log filtering is disabled by default.
- Logs can be filtered based on an interface or VLAN.
- If log filtering is enabled, logs not meeting the filtering rule are discarded.

✚ Enabling Log Printing

- (Mandatory) Logs are stored in the buffer by default.
- If you want to monitor attacks in real time, you can configure logs to be printed on the screen to export the log information in real time.

Verification

Check whether the configuration takes effect based on the log configuration and the number and interval of printed logs.

Related Commands

✚ Configuring the Log Buffer Size

Command	log-buffer entries <i>number</i>
Parameter Description	<i>number</i> : Indicates the buffer size in the unit of the number of logs, ranging from 0 to 1,024.
Command Mode	NFPP configuration mode
Usage Guide	N/A

✚ Configuring the Log Buffer Rate

Command	log-buffer logs <i>number_of_message</i> interval <i>length_in_seconds</i>
Parameter Description	<i>number_of_message</i>: Ranges from 0 to 1,024. The value 0 indicates that all logs are recorded in the log buffer and no system message is generated. <i>length_in_seconds</i>: Ranges from 0 to 86,400 (1 day). The value 0 indicates that logs are not recorded in the log buffer but system messages are instantly generated. This also applies to <i>number_of_message</i> and <i>length_in_seconds</i>. <i>number_of_message/length_in_second</i> indicates the system message generation rate.
Command	NFPP configuration mode

Mode	
Usage Guide	N/A

✚ Configuring VLAN-based Log Filtering

Command	logging vlan <i>vlan-range</i>
Parameter Description	<i>vlan-range</i> : Records logs in a specified VLAN range. The value format is 1-3,5 for example.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs in the specified VLAN range are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

✚ Configuring Interface-based Log Filtering

Command	logging interface <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Records logs of a specified interface.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs of the specified interface are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

✚ Enabling Log Printing

Command	log-buffer enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuration Example

✚ Configuring NFPP Logging

Scenario	● If attackers are too many, log printing will affect the usage of user interfaces, which requires restriction.
Configuration Steps	● Configure the log buffer size. ● Configure the log buffer rate. ● Configure VLAN-based log filtering.
	<pre>Ruijie# configure terminal Ruijie(config)# nfpp</pre>

	<pre>Ruijie (config-nfpp)#log-buffer entries 1024 Ruijie (config-nfpp)#log-buffer logs 3 interval 5 Ruijie (config-nfpp)#logging interface vlan 1</pre>
Verification	Run the show nfpp log summary command to display the configuration.
	<pre>Total log buffer size : 1024 Syslog rate : 3 entry per 5 seconds Logging: VLAN 1</pre>
	Run the show nfpp log buffer command to display logs in the log buffer.
	<pre>Protocol VLAN Interface IP address MAC address Reason Timestamp ----- ARP 1 Gi0/5 192.168.206.2 001a.a9c2.4609 SCAN 2013-5-1 5:4:24</pre>

18 Configuring DoS Protection

18.1 Overview

Denial of Service (DoS) attacks refer to attacks that cause DoS and aim to put computers or networks out of service.

DoS attacks are diversified in types and can be implemented in many ways, but have one common purpose, that is, prevent victim hosts or networks cannot receive, respond, or process external requests in time. In particular, on a layer-2 (L-2) network, DoS attack packets can be spread in the entire broadcast domain. If hackers maliciously initiate DoS attacks, some operating systems (OSs) may collapse. Ruijie products supports the following anti DoS attack functions:

- Denying land attacks
- Denying invalid TCP packets
- Denying invalid layer-4 (L4) ports

18.2 Applications

Application	Description
Protecting Servers Against DoS Attacks	On a campus network, configure the anti DoS attack function on the devices connected to servers to effectively reduce the negative impacts brought by DoS attacks to servers.

18.2.1 Protecting Servers Against DoS Attacks

As show inFigure 18-1, servers are connected to the core switch. The anti DoS attack function is configured on the core switch to prevent malicious DoS attacks and ensure that servers can provide services normally.

Figure 18-1

Deployment

Enable the function of denying land attacks on the core switch to protect servers against land attacks.

Enable the function of denying invalid TCP packets on the core switch to protect servers against invalid TCP packets.

Enable the function of denying invalid L4 ports on the core switch to protect servers against attacks caused by invalid L4 ports.

18.3 Features

Overview

Feature	Description
Denying Land Attacks	Drop packets with the same source and destination IP addresses or the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.
Denying Invalid TCP Packets	Drop invalid TCP packets on the device to prevent invalid TCP packets from attacking OSs on the network. (For details about the definition of invalid TCP packets, see "Denying Invalid TCP Packets".
Denying Invalid L4 Ports	Drop packets with the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.

18.3.1 Denying Land Attacks

This function protects servers against land attacks.

Working Principle

In a land attack, the attacker sets the source and destination IP addresses or the L4 source and destination port IDs in a SYN packet to the same address of the target host. Consequently, the attacked host will be trapped in an infinite loop or even collapse when attempting to set up a TCP connection with itself.

If the function of denying land attacks is enabled, the device checks packets based on characteristics of land packets (that is, SYN packets with the same source and destination IP addresses), and drops invalid packets.

Related Configuration

📌 Enabling the Function of Denying Land Attacks

By default, the function of denying land attacks is disabled.

Run the **ip deny land** command to enable or disable the function of denying land attacks.

18.3.2 Denying Invalid TCP Packets

This function protects servers against invalid TCP packets.

Working Principle

There are several flag fields in the TCP packet header:

- SYN: Connection establishment flag. The TCP SYN packet is used to set this flag to 1 to request establishment of a connection.
- ACK: Acknowledgement flag. In a TCP connection, this field must be available in every flag (except the first packet, that is, the TCP SYN packet) as the acknowledgement of the previous packet.
- FIN: Finish flag. When a host receives the TCP packet with the FIN flag, the host disconnects the TCP connection.
- RST: Reset flag. When the IP protocol stack receives a TCP packet that contains a non-existent destination port, it responds with a packet with the RST flag.
- PSH: This flag notifies the protocol stack to submit TCP data to the upper-layer program for processing as soon as possible.

In invalid TCP packets, flag fields are set improperly so that the processing resources of hosts are exhausted or even the system collapses. The following lists several common methods for setting flag fields in invalid TCP packets:

- TCP packets with both the SYN and FIN flags

Normally, a TCP packet cannot contain both the SYN and FIN flags. In addition, RFC does not stipulate how the IP protocol stack should process such invalid packets containing both the SYN and FIN flags. Therefore, the protocol stack of each OS may process such packets in different ways when receiving these packets. Attackers can use this feature to send packets containing both the SYN and FIN flags to identify the OS type and initiate attacks on this OS.

- TCP packets without any flag

Normally, a TCP packet contains at least one of the five flags, including SYN, FIN, ACK, RST, and PSH. The first TCP packet (TCP SYN packet) must contain the SYN flag, and the subsequent packets contain the ACK flag. Based on such

assumptions, some protocol stack does not specify the method for processing TCP packets without any flag, and therefore may collapse if such protocol stack receives TCP packets without any flag. Attackers use this feature to initiate attacks on target hosts.

- TCP packets with the FIN flag but without the ACK flag

Normally, except the first packet (TCP SYN packet), all other packets, including the packets with the FIN flag, contain the ACK flag. Some attackers may send TCP packets with the FIN flag but without the ACK flag to the target hosts, causing breakdown of the target hosts.

- TCP packets with the SYN flag and the source port ID set to a value between 0 and 1,023

Port IDs 0 to 1,023 are known port IDs allocated by the Internet Assigned Numbers Authority (IANA). In most systems, these port IDs can be used only by the system (or root) processes or programs run by privileged users. These ports (0–1023) cannot be used as the source port IDs in the first TCP packets (with the SYN flag) sent by clients.

If the function of denying invalid TCP packets is enabled, the device checks packets based on characteristics of invalid TCP packets, and drops invalid TCP packets.

Related Configuration

✎ Enabling the Function of Denying Invalid TCP Packets

By default, the function of denying invalid TCP packets is disabled.

Run the **ip deny invalid-tcp** command to enable or disable the function of denying invalid TCP packets.

18.3.3 Denying Invalid L4 Ports

This function protects servers against invalid L4 ports.

Working Principle

Attackers sends packets in which the IP address of the target host is the same as the L4 port ID of the host to the host target. As a result, the target host sends TCP connection setup requests to itself. Under such attacks, resources of the target host will soon be exhausted and the system will collapse.

If the function of denying invalid L4 ports is enabled, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device drops the packets.

Related Configuration

✎ Enabling the Function of Denying Invalid L4 Ports

By default, the function of denying invalid L4 ports is disabled.

Run the **ip deny invalid-l4port** command to enable or disable the function of denying invalid L4 ports.

18.4 Configuration

Configuration Item	Description and Command	
Configuring the Function of Denying Land Attacks	 Optional.	
	ip deny land	Enables the function of denying land attacks.
Configuring the Function of Denying Invalid TCP Packets	 Optional.	
	ip deny invalid-tcp	Enables the function of denying invalid TCP packets.
Configuring the Function of Denying Invalid L4 Ports	 Optional.	
	ip deny invalid-l4port	Enables the function of denying invalid L4 ports.

18.4.1 Configuring the Function of Denying Land Attacks

Configuration Effect

Enable the function of denying land attacks. Then, the device checks packets based on characteristics of land packets, and drops land packets.

Configuration Steps

📌 Enabling the Function of Denying Land Attacks

- Mandatory.
- Perform this configuration on a device connected to a server.

Verification

- Run the **showipdenyland** command to display the status of the function of denying land attacks.
- After this function is enabled, construct a land attack packet and confirm that this packet cannot be forwarded.

Related Commands

📌 Configuring the Function of Denying Land Attacks

Command	[no] ip deny land
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ Enabling the Function of Denying Land Attacks

Configuration Steps	Enable the function of denying land attacks in global configuration mode.				
	<pre>Ruijie# configure terminal Ruijie(config)# ip deny land Ruijie(config)# end</pre>				
Verification	Run the show ip deny land command to display the status of the function of denying land attacks. The following example shows how to display the status of the function of denying land attacks: <pre>Ruijie#show ip deny land</pre> <table> <thead> <tr> <th>DoS Protection Mode</th><th>State</th></tr> </thead> <tbody> <tr> <td>protect against land attack</td><td>On</td></tr> </tbody> </table>	DoS Protection Mode	State	protect against land attack	On
DoS Protection Mode	State				
protect against land attack	On				

18.4.2 Configuring the Function of Denying Invalid TCP Packets

Configuration Effect

Enable the function of denying invalid TCP packets. Then, the device checks packets based on characteristics of invalid TCP packets, and drops invalid TCP packets.

Configuration Steps

✚ Enables the Function of Denying Invalid TCP Packets

- Mandatory.
- Perform this configuration on a device connected to a server.

Verification

- Run the **show ip deny invalid-tcp** command to display the status of the function of denying invalid TCP packets.
- After this function is enabled, construct an invalid TCP packet and confirm that this packet cannot be forwarded.

Verification	Run the show ip deny invalid-tcp command to display the status of the function of denying invalid TCP packets.				
	The following example shows how to display the status of the function of denying invalid TCP packets: <pre>Ruijie#show ip deny invalid-tcp</pre> <table> <thead> <tr> <th>DoS Protection Mode</th><th>State</th></tr> </thead> <tbody> <tr> <td>protect against invalid tcp attack</td><td>On</td></tr> </tbody> </table>	DoS Protection Mode	State	protect against invalid tcp attack	On
DoS Protection Mode	State				
protect against invalid tcp attack	On				

18.4.3 Configuring the Function of Denying Invalid L4 Ports

Configuration Effect

Enable the function of denying invalid L4 ports. Then, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device drops the packets.

Configuration Steps

✎ Enabling the Function of Denying Invalid L4 Ports

- Mandatory.
- Perform this configuration on a device connected to a server.

Verification

- Run the **show ip deny invalid-l4port** command to display the status of the function of denying invalid L4 ports.
- After this function is enabled, construct a packet in which the L4 source port ID is the same as the destination port ID and confirm that this packet cannot be forwarded.

Displays the status of all antiDoS attack functions.	show ip deny

ACL & QoS Configuration

1. Configuring the ACL
2. Configuring QoS
3. Configuring MMU

1 Configuring the ACL

1.1 Overview

Access control list (ACL) is also called access list or firewall. It is even called packet filtering in some documents. The ACL defines rules to determine whether to forward or drop data packets arriving at a network interface.

ACLs are classified by function into two types:

- Security ACLs: Used to control data flows that are allowed to pass through a network device.
- Quality of service (QoS) ACLs: Used to classify and process data flows by priority.

ACLs are configured for a lot of reasons. Major reasons include:

- Network access control: To ensure network security, rules are defined to limit access of users to some services (for example, only access to the WWW and email services is permitted, and access to other services such as Telnet is prohibited), or to allow users to access services in a specified period of time, or to allow only specified hosts to access the network.
- QoS: QoS ACLs are used to preferentially classify and process important data flows. For details about the use of QoS ACLs, see the configuration manual related to QoS.

1.2 Applications

Application	Description
Access Control of an Enterprise Network	On an enterprise network, the network access rights of each department, for example, access rights of servers and use permissions of chatting tools (such as QQ and MSN), must be controlled according to requirements.

1.2.1 Access Control of an Enterprise Network

Scenario

Internet viruses can be found everywhere. Therefore, it is necessary to block ports that are often used by viruses to ensure security of an enterprise network as follows:

- Allow only internal PCs to access the server.
- Prohibit PCs of a non-financial department from accessing PCs of the financial department, and prohibit PCs of a non-R&D department from accessing PCs of the R&D department.
- Prohibit the staff of the R&D department from using chatting tools (such as QQ and MSN) during working hours from 09:00 to 18:00.

Figure 1-1

Remarks	Switch C at the access layer: It is connected to PCs of each department and to Switch B at the aggregation layer through the gigabit optical fiber (trunk mode). Switch B at the aggregation layer: Multiple virtual local area networks (VLANs) are divided. One VLAN is defined for one department. These VLANs are connected to Switch A at the core layer through the 10-gigabit optical fiber (trunk mode). Switch A at the core layer: It is connected to various servers, such as the File Transfer Protocol (FTP) server and Hypertext Transfer Protocol (HTTP) server, and to the Internet through firewalls.

Deployment

- Configure an extended ACL on the port G2/1 to filter data packets, thus protecting the network against the viruses. This port is located on a core-layer device (Switch A) and used to connect Switch A to the uplink port G2/1 of a router.
- Allow only internal PCs to access servers, and prohibit external PCs from accessing servers. Define and apply the extended IP ACLs on G2/2 or switch virtual interface (SVI) 2 that is used to connect Switch A to an aggregation layer device or server.
- Prohibit mutual access between specified departments. Define and apply the extended IP ACLs on G0/22 and G0/23 of Switch B.
- Configure and apply the time-based extended IP ACLs on SVI 2 of Switch B to prohibit the R&D department from using chatting tools (such as QQ and MSN) in a specified period of time.

1.3 Features

Basic Concepts

ACL

ACLs include basic ACLs and dynamic ACLs.

You can select basic or dynamic ACLs as required. Generally, basic ACLs can meet the security requirements. However, experienced hackers may use certain software to access the network by means of IP address spoofing. If dynamic ACLs are used, users are requested to pass identify authentication before accessing the network, which prevents hackers from intruding the network. Therefore, you can use dynamic ACLs in some sensitive areas to guarantee network security.

i IP address spoofing is an inherent problem of all ACLs, including dynamic ACLs. Hackers may use forged IP addresses to access the network during the validity period of authenticated user identities. Two methods are available to resolve this problem. One is to set the idle time of user access to a smaller value, which increases the difficulty in intruding networks. The other is to encrypt network data using the IPSec protocol, which ensures that all data is encrypted when arriving at a device.

ACLs are generally configured on the following network devices:

- Devices between the internal network and the external network (such as the Internet)
- Devices on the border of two network segments
- Devices connected to controlled ports

ACL statements must be executed in strict compliance with their sequence in the ACL. Comparison starts from the first statement. Once the header of a data packet matches a statement in the ACL, the subsequent statements are ignored and no longer checked.

Input/Output ACLs, Filtering Field Template, and Rules

When receiving a packet on an interface, the device checks whether the packet matches any access control entry (ACE) in the input ACL of this interface. Before sending a packet through a interface, the device checks whether the packet matches any ACE in the output ACL of this interface.

When different filtering rules are defined, all or only some rules may be applied simultaneously. If a packet matches an ACE, this packet is processed according to the action policy (permit or deny) defined in this ACE. ACEs in an ACL identify Ethernet packets based on the following fields in the Ethernet packets:

Layer 2 (L2) fields:

- 48-bit source MAC address (containing all 48 bits)
- 48-bit destination MAC address (containing all 48 bits)
- 16-bit L2 type field

Layer 3 (L3) fields:

- Source IP address field (All source IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Destination IP address field (All destination IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Protocol type field

Layer 4 (L4) fields:

- Either a TCP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.
- Either a UDP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

Filtering fields refer to the fields in packets that can be used to identify or classify packets when an ACE is generated. A filtering field template is a combination of these fields. For example, when an ACE is generated, packets are identified and classified based on the destination IP address field in each packet; when another ACE is generated, packets are identified and classified based on the source IP address field and UDP source port field in each packet. The two ACEs use different filtering field templates.

Rules refer to values of fields in the filtering field template of an ACE. For example, the content of an ACE is as follows:

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering field template is a combination of the following fields: source IP address field, IP protocol field, and TCP destination port field. The corresponding values (rules) are as follows: source IP address = Host 192.168.12.2; IP protocol = TCP; TCP destination port = Telnet.

Figure 1-2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet

i A filtering field template can be a combination of L3 and L4 fields, or a combination of multiple L2 fields. The filtering field template of a standard or an extended ACL, however, cannot be a combination of L2 and L3 fields, a combination

of L2 and L4 fields, or a combination of L2, L3, and L4 fields. To use a combination of L2, L3, and L4 fields, you can use the expert ACLs.

-  An SVI associated with ACLs in the outgoing direction supports the IP standard, IP extended, MAC extended, and expert ACLs.
-  If an expert ACL is configured and applied to the outgoing direction of an interface, and some ACEs in this ACL contain the L3 matching information (e.g. the IP address and L4 port), non-IP packets sent to the device from this interface cannot be controlled by the permit and deny ACEs in this ACL.
-  If ACEs of an ACL (IP ACL or expert extended ACL) are configured to match non-L2 fields (such as SIP and DIP), the ACL does not take effect on tagged MPLS packets.

ACL Logging

To allow users better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval respectively for the IPv4 ACL and the IPv6 ACL.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.
-  Only switches support the ACL logging function.

ACL Packet Matching Counters

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL, which can be an IP ACL, MAC ACL, expert ACL, or IPv6 ACL. In addition, you can run the **clear counters access-list** [*acl-id* | *acl-name*] command to reset ACL counters for a new round of statistics.

-  Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.
-  Only switches support the ACL packet matching counters.

Overview

Feature	Description
IP ACL	Control incoming or outgoing IPv4 packets of a device based on the L3 or L4 information in the IPv4 packet header.
MAC Extended ACL	Control incoming or outgoing L2 packets of a device based on the L2 information in the Ethernet packet header.
Expert Extended ACL	Combine the IP ACL and MAC extended ACL into an expert extended ACL, which controls (permits or denies) incoming or outgoing packets of a device using the same rule based on the L2, L3, and L4 information in the packet header.
IPv6 ACL	Control incoming or outgoing IPv6 packets of a device based on the L3 or L4 information in the IPv6 packet header.
ACL80	Customize the matching fields and mask for scenarios where fixed matching fields cannot meet the requirements.
ACL Redirection	Redirect incoming packets of a device that match ACEs to a specified outgoing interface.
Global Security ACL	Make an ACL take effect in the incoming direction of all interfaces, instead of applying the ACL on every interface.
Security Channel	Allow packets to bypass the check of access control applications, such as DOT1X and Web authentication, to meet requirements of some special scenarios.
SVI Router ACL	Enable users in the same VLAN to communicate with each other.

1.3.1 IP ACL

The IP ACL implements refined control on incoming and outgoing IPv4 packets of a device. You can permit or deny the entry of specific IPv4 packets to a network according to actual requirements to control access of IP users to network resources.

Working Principle

Define a series of IP access rules in the IP ACL, and then apply the IP ACL either in the incoming or outgoing direction of an interface or globally. The device checks whether the incoming or outgoing IPv4 packets match the rules and accordingly forwards or blocks these packets.

To configure an IP ACL, you must specify a unique name or ID for the ACL of a protocol so that the protocol can uniquely identify each ACL. The following table lists the protocols that can use IDs to identify ACLs and the range of IDs.

Protocol	ID Range
Standard IP	1–99, 1300–1999
Extended IP	100–199, 2000–2699

Basic ACLs include the standard IP ACLs and extended IP ACLs. Typical rules defined in an ACL contain the following matching fields:

- Source IP address
- Destination IP address
- IP protocol number
- L4 source port ID or ICMP type

- L4 destination port ID or ICMP code

The standard IP ACL (ID range: 1–99, 1300–1999) is used to forward or block packets based on the source IP address, whereas the extended IP ACL (ID range: 100–199, 2000–2699) is used to forward or block packets based on a combination of the preceding matching fields.

For an individual ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

- ✓ For routing products, the ICMP code matching field in an ACL rule is ineffective for ICMP packets whose ICMP type is 3. If the ICMP code of ICMP packets to be matched is configured in an ACL rule, the ACL matching result of incoming ICMP packets of a device whose ICMP type is 3 may be different from the expected result.

📌 Implicit "Deny All Traffic" Rule Statement

At the end of every IP ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 1 permit host 192.168.4.12
```

This ACL permits only packets sent from the source host 192.168.4.12, and denies packets sent from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 1 deny any**.

If the ACL contains only the following statement:

```
access-list 1 deny host 192.168.4.12
```

Packets sent from any host will be denied when passing through this port.

- ❗ When defining an ACL, you must consider the routing update packets. As the implicit "deny all traffic" statement exists at the end of an ACL, all routing update packets may be blocked.

📌 Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and denies all traffic, all subsequent statements will not be checked.

For example:

```
access-list 101 deny ip any any
access-list 101 permit tcp 192.168.12.0 0.0.0.255 eq telnet any
```

The first rule statement denies all IP packets. Therefore, Telnet packets from the host on the network 192.168.12.0/24 will be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

📌 Configuring an IP ACL

By default, no IP ACL is configured on a device.

Run the **ip access-list { standard | extended } {acl-name | acl-id}** command in global configuration mode to create a standard or an extended IP ACL and enter standard or extended IP ACL mode.

📌 Adding ACEs to an IP ACL

By default, a newly created IP ACL contains an implicit ACE that denies all IPv4 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv4 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv4 packets, add some ACEs to the ACL.

For a standard IP ACL, add ACEs as follows:

- No matter whether the standard IP ACL is a named or number ACL, you can run the following command in standard IP ACL mode to add an ACE:
`[ sn ] { permit | deny } {hostsource| any | sourcesource-wildcard } [ time-rangetime-range-name ] [ log ]`
- For a numbered standard IP ACL, you can also run the following command in global configuration mode to add an ACE:
`access-list acl-id { permit | deny } {hostsource| any | sourcesource-wildcard } [ time-rangetm-rng-name ][ log ]`

For an extended IP ACL, you can add ACEs as follows:

- No matter whether the extended IP ACL is a named or numbered ACL, you can run the following command in extended IP ACL mode to add an ACE:
`[ sn ] { permit | deny } protocol{hostsource| any | sourcesource-wildcard } {hostdestination | any | destination destination-wildcard } [ [ precedenceprecedence [ tos tos ] ] | dscpdscp ] [ fragment ] [ time-rangetime-range-name ] [ log ]`
- For a numbered extended IP ACL, you can also run the following command in global configuration mode to add an ACE:
`access-list acl-id { permit | deny } protocol{hostsource| any | sourcesource-wildcard } {hostdestination | any | destination destination-wildcard } [ [ precedenceprecedence [ tos tos ] ] | dscpdscp ] [ fragment ] [ time-rangetime-range-name ] [ log ]`

📌 Applying an IP ACL

By default, the IP ACL is not applied to any interface, that is, the IP ACL does not filter incoming or outgoing IP packets of the device.

Run the **ip access-group { acl-id | acl-name } { in | out }** command in interface configuration mode to apply a standard or an extended IP ACL to a specified interface.

1.3.2 MAC Extended ACL

The MAC extended ACL implements refined control on incoming and outgoing packets based on the L2 header of packets. You can permit or deny the entry of specific L2 packets to a network, thus protecting network resources against attacks or control users' access to network resources.

Working Principle

Define a series of MAC access rules in the MAC extended ACL, and then apply the ACL to the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an MAC extended ACL, you must specify a unique name or ID for this ACL to uniquely identify the ACL. The following table lists the range of IDs that identify MAC extended ACLs.

Protocol	ID Range
MAC extended ACL	700–799

Typical rules defined in an MAC extended ACL include:

- Source MAC address
- Destination MAC address
- Ethernet protocol type

The MAC extended ACL (ID range: 700–799) is used to filter packets based on the source or destination MAC address and the Ethernet type in the packets.

For an individual MAC extended ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

- ✓ If ACEs in an MAC extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the MAC extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

Implicit "Deny All Traffic" Rule Statement

At the end of every MAC extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only packets from the host with the MAC address 00d0.f800.0001, and denies packets from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 700 deny any any**.

Related Configuration

Configuring an MAC Extended ACL

By default, no MAC extended ACL is configured on a device.

Run the **mac access-list extended {acl-name | acl-id }** command in global configuration mode to create an MAC extended ACL and enter MAC extended ACL mode.

✚ Adding ACEs to an MAC Extended ACL

By default, a newly created MAC extended ACL contains an implicit ACE that denies all L2 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an MAC extended ACL as follows:

- No matter whether the MAC extended ACL is a named or numbered ACL, you can run the following command in MAC extended ACL mode to add an ACE:

```
[sn] { permit | deny } {any | host src-mac-addr | src-mac-addrmask}{any | host dst-mac-addr | dst-mac-addrmask}
[ethernet-type] [coscos ] [innercos] [ time-rangetm-rng-name ]
```

- For a numbered MAC extended ACL, you can also run the following command in global configuration mode to add an ACE:

```
access-list acl-id { permit | deny } {any | host src-mac-addr | src-mac-addrmask }{any | host dst-mac-addr |
dst-mac-addrmask } [ethernet-type] [coscos ] [innercos] [ time-rangetime-range-name ]
```

✚ Applying an MAC Extended ACL

By default, the MAC extended ACL is not applied to any interface, that is, the created MAC extended ACL does not filter incoming or outgoing L2 packets of a device.

Run the **mac access-group { acl-id | acl-name } { in| out }** command in interface configuration mode to apply an MAC extended ACL to a specified interface.

1.3.3 Expert Extended ACL

You can create an expert extended ACL to match the L2 and L3 information in packets using the same rule. The expert extended ACL can be treated as a combination and enhancement of the IP ACL and the MAC extended ACL because the expert extended ACL can contain ACEs in both the IP ACL and the MAC extended ACL. In addition, the VLAN ID can be specified in the expert extended ACL to filter packets.

Working Principle

Define a series of access rules in the expert extended ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an expert extended ACL, you must specify a unique name or ID for this ACL so that the protocol can uniquely identify each ACL. The following table lists the ID range of the expert extended ACL.

Protocol	ID Range
Expert extended ACL	2700–2899

When an expert extended ACL is created, defined rules can be applied to all packets. The device determines whether to forward or block packets by checking whether packets match these rules.

Typical rules defined in an expert extended ACL include:

- All information in the basic ACL and MAC extended ACL
- VLAN ID

The expert extended ACL (ID range: 2700–2899) is a combination of the basic ACL and MAC extended ACL, and can filter packets based on the VLAN ID.

For an individual expert extended ACL, multiple independent statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL.

- ✓ If rules in an expert extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the expert extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

📌 Implicit "Deny All Traffic" Rule Statement

At the end of every expert extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 2700 permit 0x0806 any any any any any
```

This ACL permits only ARP packets whose Ethernet type is 0x0806, and denies all other types of packets. This is because the following statement exists at the end of this ACL: **access-list 2700 deny any any any any**.

Related Configuration

📌 Configuring an Expert Extended ACL

By default, no expert extended ACL is configured on a device.

Run the **expert access-list extended {acl-name | acl-id}** command in global configuration mode to create an expert extended ACL and enter expert extended ACL mode.

📌 Adding ACEs to an Expert Extended ACL

By default, a newly created expert extended ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an expert extended ACL as follows:

- No matter whether the expert extended ACL is a named or numbered ACL, you can run the following command in expert extended ACL mode to add an ACE:

```
[sn] { permit | deny } [ protocol ] [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ]  
{ source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard |
```

```
hostdestination | any } { host destination-mac-address | any } [ precedenceprecedence ] [ tos tos ] [ fragment ]
[ rangelowerupper ] [ time-rangetime-range-name ]]
```

- For a numbered expert extended ACL, you can also run the following command in expert extended ACL mode to add an ACE:

```
access-list acl-id { permit | deny } [ protocol ] [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ]
{ source source-wildcard | hostsource | any } { host source-mac-address | any } { destination destination-wildcard |
hostdestination | any } { host destination-mac-address | any } [ precedenceprecedence ] [ tos tos ] [ fragment ]
[ rangelowerupper ] [ time-rangetime-range-name ]]
```

📌 Applying an Expert Extended ACL

By default, the expert extended ACL is not applied to any interface, that is, the created expert extended ACL does not filter incoming or outgoing L2 or L3 packets of a device.

Run the **expert access-group { acl-id | acl-name } { in | out }** command in interface configuration mode to apply an expert extended ACL to a specified interface.

1.3.4 IPv6 ACL

The IPv6 ACL implements refined control on incoming and outgoing IPv6 packets of a device. You can permit or deny the entry of specific IPv6 packets to a network according to actual requirements to control access of IPv6 users to network resources.

Working Principle

Define a series of IPv6 access rules in the IPv6 ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing IPv6 packets match the rules and accordingly forwards or blocks these packets.

To configure an IPv6 ACL, you must specify a unique name for this ACL.

- ❗ Unlike the IP ACL, MAC extended ACL, and expert extended ACL, you can specify only a name but not an ID for the IPv6 ACL created.
- ❗ Only one IP ACL, or one MAC extended ACL, or one expert extended ACL can be applied to the incoming or outgoing direction of an interface. Besides, one more IPv6 ACL can be applied.

📌 Implicit "Deny All Traffic" Rule Statement

At the end of every IPv6 ACL is an implicit "deny all IPv6 traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 host 200::1 any
```

This ACL permits only IPv6 packets from the source host 200::1, and denies IPv6 packets from all other hosts. This is because the following statement exists at the end of this ACL: deny ipv6 any any.

 Although the IPv6 ACL contains the implicit "deny all IPv6 traffic" rule statement by default, it does not filter ND packets.

Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and permits all IPv6 traffic, all subsequent statements will not be checked.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

As the first rule statement permits all IPv6 packets, all IPv6 packets sent from the host 200::1 does not match the subsequent deny rule with the serial number of 20, and therefore will not be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

Configuring an IPv6 ACL

By default, no IPv6 ACL is configured on a device.

Run the **ipv6 access-list *acl-name*** command in global configuration mode to create an IPv6 ACL and enter IPv6 ACL mode.

Adding ACEs to an IPv6 ACL

By default, a newly created IPv6 ACL contains an implicit ACE that denies all IPv6 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv6 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv6 packets, add some ACEs to the ACL.

Run the following command in IPv6 ACL mode to add an ACE:

```
[sn] {permit | deny } protocol {src-ipv6-prefix/prefix-len | hostsrc-ipv6-addr | any} {dst-ipv6-pfx/pfx-len | host dst-ipv6-addr | any} [range lower upper] [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name] [log]
```

Applying an IPv6 ACL

By default, the IPv6 ACL is not applied to any interface, that is, the IPv6 ACL does not filter incoming or outgoing IPv6 packets of a device.

Run the **ipv6 traffic-filter *acl-name* { in | out }** command in interface configuration mode to apply an IPv6 ACL to a specified interface.

1.3.5 ACL80

ACL80 refers to the expert advanced ACL, and is also called custom ACL. It filters packets based on the first 80 bytes of every packet. Among these 80 bytes, the SMAC, DMAC, SIP, DIP, and ETYPE fields in a packet are mandatory, and you can specify the remaining 16 bytes.

Working Principle

A packet consists of a number of bytes. ACL80 allows you to match the specified 16 bytes by bit in the first 80 bytes of a packet. Any bit of a 16-byte field can be set to a value (**0** or **1**), indicating whether the bit is compared. When any byte is filtered, three factors are considered: content of the matching field, mask of the matching field, and the start position for matching. Bits of the matching field content are in one-to-one mapping relationship with bits of the matching field mask. The filtering rule specifies the value of the field to be filtered. The filtering field template specifies whether the corresponding field in the filtering rule should be filtered. (**1** indicates that the bit specified in the filtering rule should be matched; **0** indicates that the bit specified in the filtering rule is not matched.) Therefore, when it is required to match a specific bit, you must set the corresponding bit to 1 in the filtering field template. For example, if the bit is set to **0** in the filtering field template, no bit is matched no matter which bit is specified in the filtering rule.

For example,

```
Ruijie(config)#expert access-list advanced name
Ruijie(config-exp-dacl)#permit 00d0f8123456 ffffffff 0
Ruijie(config-exp-dacl)#deny 00d0f8654321 ffffffff 6
```

The custom ACL matches any byte of the first 80 bytes in a L2 data frame according to user' definition, and filters packets accordingly. To properly use a custom ACL, you must have an in-depth understanding about the structure of a L2 data frame. The following shows the first 64 bytes of a L3 data frame (every letter represents a hexadecimal number, and every two letters represent one byte):

AA AA AA AA AA AA BB BB BB BB BB BB CC CC DD DD

DD DD EE FF GG HH HH HH II II JJ KK LL LL MM MM

NN NN OO PP QQ QQ RR RR RR RR SS SS SS SS TT TT

UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb

The following table describes the meaning and offset of each letter:

Letter	Meaning	Offset	Letter	Meaning	Offset
A	Destination MAC address	0	O	Time To Live (TTL) field	34
B	Source MAC address	6	P	Protocol number	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length	16	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46

Letter	Meaning	Offset	Letter	Meaning	Offset
G	Cntl field	20	U	TCP destination port	48
H	Org Code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version number	26	XY	IP header length and reserved bit	58
K	TOS field	27	Z	Reserved bit and flags bit	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Miscellaneous	62
N	Flags field	32			

In the above table, the offset of each field is the offset of this field in the tagged 802.3 SNAP packet. In a custom ACL, you can use the rule mask and offset jointly to extract any byte from the first 80 bytes of a data frame, compare the byte with the rule customized in the ACL, and then filter matched data frames for further processing. Customized rules may be some fixed attributes of data. For example, to obtain all TCP packets, you can define the rule as "06", rule mask as "FF", and offset as "35". Then, the device can use the rule mask and offset jointly to extract the content of TCP protocol number field in a received data frame, and compare the extracted content with the rule to obtain all TCP packets.

-  Only switches support the ACL80.
-  The ACL80 supports filtering of the Ethernet, 803.3 SNAP, and 802.3 LLC packets. If the values of the fields from DSAP to cntl are set to AAAA03, the ACL is used to filter the 803.3 SNAP packets. If the values of the fields from DSAP to cntl are set to E0E003, the ACL is used to filter the 803.3 LLC packets. The value of the cntl field cannot be configured to filter Ethernet packets.
-  The ACL80 can be configured to compare packets with any of the 16 bytes. If the 16 bytes are already used, no ACE can be configured to compare packets with fields in any other bytes.

Related Configuration

Configuring an Expert Advanced ACL

By default, no expert advanced ACL is configured on a device.

Run the **expert access-list advanced *acl-name*** command in global configuration mode to create an expert advanced ACL and enter expert advanced ACL mode.

Adding ACEs to an Expert Advanced ACL

By default, a newly created expert advanced ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

- Run the **[sn] { permit | deny } hex hex-mask offset** command in expert advanced ACL mode to add an ACE to the expert advanced ACL.

Applying an Expert Advanced ACL

By default, the expert advanced ACL is not applied to any interface, that is, the created expert advanced ACL does not filter incoming or outgoing packets of a device.

Run the **expert access-group *acl-name* { in| out }** command in interface configuration mode to apply an expert advanced ACL to a specified interface.

1.3.6 ACL Redirection

ACL redirection allows a device to analyze received packets and redirect the packets to a specified port for forwarding. To analyze specific incoming packets of a device, you can configure the ACL redirection function to redirect packets meeting rules to a specified port and capture packets on this port for analysis.

Working Principle

Bind different ACL policy to an interface and specify an output destination interface for each policy. When receiving packets on this interface, the device searches ACL policies bound to this interface one by one. If packets match criteria described in a certain policy, the device forwards packets on the destination interface specified by the policy, thus redirecting packets based on traffic.

-  Only switches support the ACL redirection function.
-  ACL redirection takes effect only in the incoming direction of an interface.

Related Configuration

📄 Configuring an ACL

Before configuring ACL redirection, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

📄 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

📄 Configuring ACL Redirection

By default, ACL redirection is not configured on a device.

Run the **redirect destinationinterface *interface-name* acl {*acl-id* | *acl-name* }** **in** command in interface configuration mode to configure ACL redirection.

-  You can configure the ACL redirection function only on an Ethernet interface, AP, or SVI.

1.3.7 Global Security ACL

To meet the requirements of security deployment, the port-based ACL is often configured to filter out virus packets and obtain packets with certain characteristics, for example, packets that attack the TCP port. Various virus packets exist in a global network environment, and the identification features of virus packets under each port are identical or similar. Therefore,

an ACL is generally created. After the deny ACE for matching virus signatures is added to the ACL, the port-based ACL is applied to each port on the switch to filter out virus packets.

For two reasons, it is not convenient to use the port-based ACLs in antivirus scenarios such as virus filtering. The first reason is that the port-based ACL must be configured on every port, which results in repeated configuration, poor operation performance, and over-consumption of ACL resources. The second reason is that the access control function of the ACL is weakened. As the port-based ACL is used for virus filtering, basic functions of the ACL, such as route update restriction and network access restriction, cannot be used properly. The global security ACL can be used for global antivirus deployment and defense without affecting the port-based ACL. By running only one command, you can make the global security ACL takes effect on all L2 interfaces. In contrast, the port-based ACL must be configured on every interface.

Working Principle

The global security ACL takes effect on all L2 interfaces. When both the global security ACL and the port-based ACL are configured, both take effect. Packets that match the global security ACL are directly filtered out as virus packets. Packets that do not match the global security ACL are still controlled by the port-based ACL. You can disable the global security ACL on some ports so that these ports are not controlled by the global security ACL.

-  The global security ACL is mainly used for virus filtering. Therefore, in an ACL associated with the global security ACL, only the deny ACEs take effect, and the permit ACEs do not take effect.
-  Unlike the secure ACL applied to a port, the global security ACL does not contain the default "deny all traffic" ACE, that is, all packets that do not match the ACL are permitted.
-  A global secure ACL can take effect either on a L2 port or a routed port. That is, it takes effect on all the following types of ports: access port, trunk port, hibird port, routed port, and AP (L2 or L3). The global secure ACL does not take effect on an SVI.
-  You can disable the global security ACL on an individual physical port or AP, but not on a member port of an AP.
-  The global secure ACL supports only the associated IP standard ACL and IP extended ACL.

Related Configuration

📄 Configuring an ACL

Before configuring the global security ACL, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

📄 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL.

📄 Configuring a Global Security ACL

By default, no global security ACL is configured on a device.

Run the **ip access-group acl-id { in | out }** command in global configuration mode to enable the global security ACL.

📄 Configuring an Exclusive Interface of the Global Security ACL

By default, no exclusive interface is configured for the global security ACL on a device.

Run the **no global ip access-group** command in interface configuration to disable the global security ACL on a specified interface.

1.3.8 Security Channel

In some application scenarios, packets meeting some characteristics may need to bypass the checks of access control applications. For example, before DOT1X authentication, users are allowed to log in to a specified website to download the DOT1X authentication client. The security channel can be used for this purpose. When the security channel configuration command is executed to apply a secure ACL globally or to an interface, this ACL becomes a security channel.

Working Principle

The security channel is also an ACL, and can be configured globally or for a specified interface. When arriving at an interface, packets are checked on the security channel. If meeting the matching conditions of the security channel, packets directly enter a switch without undergoing the access control, such as port security, Web authentication, 802.1x, and IP+MAC binding check. A globally applied security channel takes effect on all interfaces except exclusive interfaces.

-  The deny ACEs in an ACL that is applied to a security channel do not take effect. In addition, this ACL does not contain an implicit "deny all traffic" rule statement at the end of the ACL. If packets do not meet matching conditions of the security channel, they are checked according to the access control rules in compliance with the relevant process.
-  You can configure up to eight exclusive interfaces for the global security channel. In addition, you cannot configure interface-based security channel on these exclusive interfaces.
-  If a security channel is applied to an interface while a global security channel exists, this global security channel does not take effect on this interface.
-  If both port-based migratable authentication mode and security channel are applied to an interface, the security channel does not take effect.
-  An IPv6 ACL cannot be configured as a security channel.
-  Only switches support the security channel.

Related Configuration

[Configuring an ACL](#)

Before configuring the security channel, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

[Adding ACEs to an ACL](#)

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, or expert extended ACL.

[Configuring a Security Channel on an Interface](#)

By default, no security channel is configured on an interface of a device.

Run the **security access-group** {*acl-id* | *acl-name* } command in interface configuration mode to configure the security channel on an interface.

📌 Configuring a Global Security Channel

By default, no global security channel is configured on a device.

Run the **security global access-group** {*acl-id* | *acl-name* } command in interface configuration mode to configure a global security channel.

📌 Configuring an Exclusive Interface for the Global Security Channel

By default, no exclusive interface is configured for the global security channel on a device.

Run the **security uplink enable** command in interface configuration mode to configure a specified interface as the exclusive interface of the global security channel.

1.3.9 SVI Router ACL

By default, an ACL that is applied to an SVI also takes effect on L2 packets forwarded within a VLAN and L3 packets forwarded between VLANs. Consequently, users in the same VLAN may fail to communicate with each other. Therefore, a switchover method is provided so that the ACL that is applied to an SVI takes effect only on routing packets between VLANs.

Working Principle

By default, the SVI router ACL function is disabled, and an SVI ACL takes effect on L3 packets forwarded between VLANs and L2 packets forwarded within a VLAN. After the SVI router ACL function is enabled, the SVI ACL takes effect only on L3 packets forwarded between VLANs.

✔ Only switches support the SVI router ACL.

Related Configuration

📌 Configuring an ACL

Before configuring the SVI router ACL, configure and apply an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

📌 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

📌 Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL. Apply the ACL in SVI configuration mode.

📌 Configuring the SVI Router ACL

Run the **svi router-acls enable** command in global configuration mode to enable the SVI router ACL so that the ACL that is applied to an SVI takes effect only on packets forwarded at L3, and not on packets forwarded at L2 within a VLAN.

1.3.10 ACL Logging

ACL logging is used to monitor the running status of ACEs in an ACL and provide essential information for routine network maintenance and optimization.

Working Principle

To better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs; otherwise, logs are not output.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.
-  Only switches support the ACL logging function.
-  You can configure the ACL logging option only for an IP ACL or an IPv6 ACL.

Related Configuration

📄 Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

📄 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

📄 Configuring the Log Update Interval

Run the **{ip | ipv6} access-list log-update interval time** command in the configuration mode to configure the interval at which the ACL logs are output.

📌 Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL.

1.3.11 Packet Matching Counters

In addition to ACL logs, packet matching counters provide another choice for routine network maintenance and optimization.

Working Principle

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL. When a packet matches the ACE, the corresponding counter increments by 1. You can run the **clear counters access-list [*acl-id* | *acl-name*]** command to reset counters of all ACEs in an ACL for a new round of statistics.

- ❗ Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.
- ✅ You can enable packet matching counters on an IP ACL, MAC ACL, expert ACL, or IPv6 ACL.
- ✅ Only switches support the ACL packet matching counters.

Related Configuration

📌 Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

📌 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

📌 Enabling Packet Matching Counters

To enable packet matching counters on an IP ACL, MAC ACL, or expert ACL, run the **{*mac* | *expert* | *ip*} access-list counter { *acl-id* | *acl-name* }** command in global configuration mode.

To enable packet matching counters on an IPv6 ACL, run the **ipv6 access-list counter *acl-name*** command in global configuration mode.

📌 Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

📌 Clearing Packet Matching Counters

Run the **clear counters access-list [*acl-id* | *acl-name*]** command in privileged EXEC mode to reset packet matching counters.

1.3.12 Fragmented Packet Matching Mode

In fragmented packet matching mode, an ACL can implement more refined control on fragmented packets.

Working Principle

IP packets may be fragmented when transmitted on the network. When fragmentation occurs, only the first fragment of the packet contains the L4 information, such as the TCP/UDP port number, ICMP type, and ICMP code, and other fragmented packets do not contain the L4 information. By default, if an ACE contains the fragment flag, fragmented packets except the first fragments are filtered. If an ACE does not contain the fragment flag, all fragmented packets (including the first fragments) are filtered. In addition to this default fragmented packet matching mode, a new fragmented packet matching mode is provided. You can switch between the two fragmented packet matching modes as required on a specified ACL. In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and packets are fragmented, the first fragments are compared with all the matching fields (including L3 and L4 information) defined in the ACE, and other fragmented packets are compared with only the non-L4 information defined in the ACE.

- ❗ In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and the action is Permit, this type of ACE occupies more hardware entries. In an extreme case, this will reduce by half the number of hardware entries. If Established is configured for filter the TCP flag in an ACE, more hardware entries will be occupied.
- ❗ The ACL will be temporarily ineffective during switchover of the fragmented packet matching mode.
- ✅ In the new fragmented packet matching mode, if an ACE does not contain the fragment flag, the L4 information of packets needs to be compared, and the action is Permit, the ACE checks the L3 and L4 information of the first fragments of packets, and checks only the L3 information of other fragmented packets. If the action is Deny, the ACE checks only the first fragments of packets, and ignores other fragmented packets.
- ✅ In the new fragmented packet matching mode, if an ACE contains the fragment flag, the ACE checks only fragmented packets but not the first fragments of packets no matter whether the action in the ACE is Permit or Deny.
- ✅ Only the IP extended ACL and the expert extended ACL support switching between the two fragmented packet matching modes.
- ✅ Only switches support filtering of fragmented packets.

Related Configuration

📄 Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

📄 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and expert extended ACL. Note that the fragment option must be added.

📄 Switching the Fragmented Packet Matching Mode

Run the [**no**] {**ip** | **expert**} **access-list new-fragment-mode** { *acl-id* | *acl-name* } command in global configuration mode to switch the fragmented packet matching mode.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

1.4 Configuration

Configuration Item	Description and Command	
Configuring an IP ACL	 (Optional) It is used to filter IPv4 packets.	
	ip access-list standard	Configures a standard IP ACL.
	ip access-list extended	Configures an extended IP ACL.
	permit host any time-range log	Adds a permit ACE to a standard IP ACL.
	deny host any time-range log	Adds a deny ACE to a standard IP ACL.
	permit host any host any tos dscp precedence fragment time-range log	Adds a permit ACE to an extended IP ACL.
	deny host any host any tos dscp precedence fragment time-range log	Adds a deny ACE to an extended IP ACL.
	ip access-group in out	Applies a standard or an extended IP ACL.
Configuring an MAC Extended ACL	 (Optional) It is used to filter L2 packets.	
	mac access-list extended	Configures an MAC extended ACL.
	permit any host any host cos inner time-range	Adds a permit ACE to an MAC extended ACL.
	deny any host any host cos inner time-range	Adds a deny ACE to an MAC extended ACL.
	mac access-group in out	Applies an MAC extended ACL.
Configuring an Expert Extended ACL	 (Optional) It is used to filter L2 and L3 packets.	
	expert access-list extended	Configures an expert extended ACL.
	permit cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a permit ACE to an expert extended ACL.
	deny cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a deny ACE to an expert extended ACL.
	expert access-group in out	Applies an expert extended ACL.
Configuring an IPv6 Extended ACL	 (Optional) It is used to filter IPv6 packets.	
	ipv6 access-list	Configures an IPv6 ACL.
	permit host any host any range dscp flow-label fragment time-range log	Adds a permit ACE to an IPv6 ACL.

Configuration Item	Description and Command	
	deny host any host any range dscp flow-label fragment time-rangelog	Adds a deny ACE to an IPv6 ACL.
	ipv6 traffic-filter in out	Applies an IPv6 ACL.
Configuring an ACL80	 (Optional) It is used to customize the fields for filter L2 and L3 packets.	
	expert access-list advanced	Configures an expert advanced ACL.
	permit	Adds a permit ACE to an expert advanced ACL.
	deny	Adds a deny ACE to an expert advanced ACL.
	expert access-group in out	Applies an expert advanced ACL
Configuring ACL Redirection	 (Optional) It is used to redirect packets meeting the rules to a specified interface.	
	redirect destination interface acl in	Configures ACL redirection.
Configuring a Global Security ACL	 (Optional) It is used to make an ACL take effect globally.	
	ip access-group in out	Applies a global security ACL in global configuration mode.
	no global ip access-group	Configures an interface as the exclusive interface of the global security ACL in interface configuration mode.
Configuring a Security Channel	 (Optional) It is used to enable packets meeting some characteristics to bypass the checks of access control applications, such as the DOT1X and Web authentication.	
	security access-group	Enables the security channel in interface configuration mode.
	security global access-group	Enables the security channel in global configuration mode.
	security uplink enable	Configures an interface as the exclusive interface of the global security channel in interface configuration mode.
Configuring Comments for ACLs	 (Optional) It is used to configure comments for an ACL or ACE so that users can easily identify the functions of the ACL or ACE.	
	list-remark	Configures a comment for an ACL in ACL configuration mode.
	access-list list-remark	Configures a comment for an ACL in global configuration mode.
	remark	Configures a comment for an ACE in ACL configuration mode.

1.4.1 Configuring an IP ACL

Configuration Effect

Configure and apply an IP ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny the entry of specific IPv4 packets to a network to control access of IP users to network resources.

Notes

N/A

Configuration Steps

📌 Configuring an IP ACL

- (Mandatory) Configure an IP ACL if you want to control access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IP ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an IP ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv4 packets of the device are denied by default.

📌 Applying an IP ACL

- (Mandatory) Apply an IP ACL to a specified interface if you want this ACL take effect.
- You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the IP ACL:
- Run the **ping** command to verify that the IP ACL takes effect on the specified interface. For example, if an IP ACL is configured to prohibit a host with a specified IP address or hosts in a specified IP address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access related network resources to verify that the IP ACL takes effect on the specified interface. For example, access the Internet or access the FTP resources on the network through FTP.

Related Commands

📌 Configuring an IP ACL

Command	ip access-list { standard extended } {acl-name acl-id }
Parameter	standard: Indicates that a standard IP ACL is created.
Description	extended: Indicates that an extended IP ACL is created. acl-name: Indicates the name of a standard or an extended IP ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9),

	"in", or "out". <i>acl-id</i>: Indicates the ID that uniquely identifies a standard or extended IP ACL. If this option is configured, a numbered ACL is created. If a standard IP ACL is created, the value range of <i>acl-id</i> is 1–99 and 1300–1999. If an extended IP ACL is created, the value range of <i>acl-id</i> is 100–199 and 2000–2699.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a standard or an extended IP ACL and enter standard or extended IP ACL configuration mode. If you want to control access of users to network resources by checking the source IP address of each packet, configure a standard IP ACL. If you want to control access of users to network resources by checking the source or destination IP address, protocol number, and TCP/UDP source or destination port, configure an extended IP ACL.

📌 Adding ACEs to an IP ACL

- Add ACEs to a standard IP ACL.

Use either of the following methods to add ACEs to a standard IP ACL:

Command	<code>[sn] { permit deny } { host source any source source-wildcard } [time-range time-range-name] [log]</code>
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. host source: Indicates that IP packets sent from a host with the specified source IP address are filtered. any: Indicates that IP packets sent from any host are filtered. <i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered. time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs in standard IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	<code>access-list acl-id { permit deny } { host source any source source-wildcard } [time-range tm-rng-name] [log]</code>

Parameter Description	<i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 1300–1999. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. host source: Indicates that IP packets sent from a host with the specified source IP address are filtered. any: Indicates that IP packets sent from any host are filtered. <i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in global configuration mode. It cannot be used to add ACEs to a named IP ACL.

- Add ACEs to an extended IP ACL.

Use either of the following methods to add ACEs to an extended IP ACL:

Command	<pre>[sn] { permit deny } protocol { host source any source source-wildcard } { host destination any destination destination-wildcard } [[precedence precedence [tos tos]] dscp dscp] [fragment] [time-range time-range-name] [log]</pre>
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. <i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. host source: Indicates that IP packets sent from a host with the specified source IP address are filtered. <i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered. host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered. <i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.

	any: Indicates that IP packets sent to or from any host are filtered. precedence <i>precedence</i>: Indicates that IP packets with the specified precedence field in the header are filtered. tos <i>tos</i>: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered. dscp <i>dscp</i>: Indicates that IP packets with the specified the dscp field in the header are filtered. fragment: Indicates that only fragmented IP packets except the first fragments are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs in extended IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	access-list <i>acl-id</i> { permit deny } <i>protocol</i> { host <i>source</i> any <i>source</i> <i>source-wildcard</i> } { host <i>destination</i> any <i>destination</i> <i>destination-wildcard</i> } [[precedence <i>precedence</i> [tos <i>tos</i>]] dscp <i>dscp</i>] [fragment] [time-range <i>time-range-name</i>] [log]
Parameter Description	<i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 2000–1999. <i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. <i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. host <i>source</i>: Indicates that IP packets sent from a host with the specified source IP address are filtered. <i>source</i> <i>source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered. host <i>destination</i>: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered. <i>destination</i> <i>destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered. any: Indicates that IP packets sent to or from any host are filtered.

	precedence <i>precedence</i>: Indicates that IP packets with the specified precedence field in the header are filtered. tos <i>tos</i>: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered. dscp <i>dscp</i>: Indicates that IP packets with the specified the dscp field in the header are filtered. fragment: Indicates that only fragmented IP packets except the first fragments are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in extended IP ACL configuration mode. It cannot be used to add ACEs to a named extended IP ACL.

📌 Applying an IP ACL

Command	ip access-group { <i>acl-id</i> <i>acl-name</i> } { <i>in</i> <i>out</i> } [reflect]
Parameter Description	<i>acl-id</i>: Indicates that a numbered standard or extended IP ACL will be applied to the interface. <i>acl-name</i>: Indicates that a named standard or extended IP ACL will be applied to the interface. in: Indicates that this ACL controls incoming IP packets of the interface. out: Indicates that this ACL controls outgoing IP packets of the interface. reflect: Indicates that the reflexive ACL is enabled.
Command Mode	Interface configuration mode
Usage Guide	This command makes an IP ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

 The following configuration example describes only ACL-related configurations.

📌 Configuring an IP ACL to Prohibit Departments Except the Financial Department from Accessing the Financial Data Server

Scenario
Figure 1-3

Configuration Steps

- Configure an IP ACL.
- Add ACEs to the IP ACL.
- Apply the IP ACL to the outgoing direction of the interface connecting the financial data server.

SW1

```

sw1(config)#ip access-list standard 1
sw1(config-std-nacl)#permit 10.1.1.0 0.0.0.255
sw1(config-std-nacl)#deny 11.1.1.1 0.0.0.255
sw1(config-std-nacl)#exit
sw1(config)#int gigabitEthernet 0/3
sw1(config-if-GigabitEthernet 0/3)#ip access-group 1 out
  
```

Verification

- On a PC of the R&D department, ping the financial data server. Verify that the ping operation fails.
- On a PC of the financial department, ping the financial data server. Verify that the ping operation succeeds.

SW1

```

sw1(config)#show access-lists

ip access-list standard 1
10 permit 10.1.1.0 0.0.0.255
20 deny 11.1.1.0 0.0.0.255

sw1(config)#show access-group

ip access-group 1 out

Applied On interface GigabitEthernet 0/3
  
```

1.4.2 Configuring an MAC Extended ACL

Configuration Effect

Configure and apply an MAC extended ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny the entry of specific L2 packets to a network to control access of users to network resources based on L2 packets.

Notes

N/A

Configuration Steps

📌 Configuring an MAC Extended ACL

- (Mandatory) Configure an MAC extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the MAC address of each user's PC.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The MAC extended ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an MAC Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming L2 Ethernet packets of the device are denied by default.

📌 Applying an MAC extended ACL

- (Mandatory) Apply an MAC extended ACL to a specified interface if you want this ACL take effect.
- You can apply an MAC extended ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the MAC extended ACL:
- If an MAC extended ACL is configured to permit or deny some IP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, an MAC extended ACL is configured to prevent a device interface from receiving IP packets (Ethernet type is 0x0800), run the **ping** command for verification.
- If an MAC extended ACL is configured to permit or deny some non-IP packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- You can also construct L2 packets meeting some specified characteristics to check whether the MAC extended ACL takes effect. Typically, prepare two PCs, construct and send L2 packets on one PC, enable packet capturing on another PC, and check whether packets are forwarded as expected (forwarded or blocked) according to the action specified in the ACEs.

Related Commands

📌 Configuring an MAC Extended ACL

Command	mac access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<i>acl-name</i>: Indicates the name of an MAC extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i>: Indicates the ID that uniquely identifies an MAC extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 700–799.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an MAC extended ACL and enter MAC extended ACL configuration mode. You can configure an MAC extended ACL to control users' access to network resources by checking the L2 information of Ethernet packets.

📌 Adding ACEs to an MAC Extended ACL

Use either of the following methods to add ACEs to an MAC extended ACL:

- Add ACEs in MAC extended ACL configuration mode.

Command	[<i>sn</i>] { permit deny } { any host <i>src-mac-addr</i> } { any host <i>dst-mac-addr</i> } [<i>ethernet-type</i>] [cos <i>cos</i> [inner <i>cos</i>]] [time-range <i>tm-rng-name</i>]
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. any: Indicates that L2 packets sent from any host are filtered. host <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. host <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. <i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered. cos <i>cos</i>: Indicates that L2 packets with the specified class of service (cos) field in the outer tag are filtered. inner <i>cos</i>: Indicates that L2 packets with the specified cos field in the inner tag are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.

Command Mode	MAC extended ACL configuration mode
Usage Guide	Run this command to add ACEs in MAC extended ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an MAC extended ACL in global configuration mode.

Command	access-list <i>acl-id</i> { permit deny } { any host <i>src-mac-addr</i> } { any host <i>dst-mac-addr</i> } [<i>ethernet-type</i>] [<i>cos cos</i> [<i>inner cos</i>]] [time-range <i>tm-rng-name</i>]
Parameter Description	<i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 700–799. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. host <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered. <i>hostsource</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. host <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. <i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered. cos <i>cos</i>: Indicates that L2 packets with the specified cos field in the outer tag are filtered. inner <i>cos</i>: Indicates that L2 packets with the specified cos field in the inner tag are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.
Command Mode	Global configuration mode
Usage Guide	Run this command to add ACEs to a numbered MAC extended ACL in global configuration mode. It cannot be used to add ACEs to a named MAC extended ACL.

📌 Applying an MAC Extended ACL

Command	mac access-group { <i>acl-id</i> <i>acl-name</i> } { in out }
Parameter Description	<i>acl-id</i>: Indicates that a numbered MAC extended IP ACL will be applied to the interface. <i>acl-name</i>: Indicates that a named MAC extended IP ACL will be applied to the interface. in: Indicates that this ACL controls incoming L2 packets of the interface. out: Indicates that this ACL controls outgoing L2 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an MAC extended ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an MAC Extended ACL to Restrict Resources Accessible by Visitors

Scenario Figure 1-4	
Configuration Steps	● Configure an MAC extended ACL. ● Add ACEs to the MAC extended ACL. ● Apply the MAC extended ACL to the outgoing direction of the interface connected to the visitor area so that visitors are allowed to access Internet and the public server of the company, but prohibited from accessing the financial data server of the company. That is, visitors cannot access the server with the MAC address 00e0.f800.000d.
SW1	<pre>sw1(config)#mac access-list extended 700 sw1(config-mac-nacl)#deny any host 00e0.f800.000d sw1(config-mac-nacl)#permit any any sw1(config-mac-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#mac access-group 700 in</pre>
Verification	● On a visitor's PC, ping the financial data server. Verify that the ping operation fails. ● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds. ● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.
SW1	<pre>sw1(config)#show access-lists mac access-list extended 700 10 deny any host 00e0.f800.000d etype-any 20 permit any any etype-any sw1(config)#show access-group</pre>

```
mac access-group 700 in  
Applied On interface GigabitEthernet 0/2
```

1.4.3 Configuring an Expert Extended ACL

Configuration Effect

Configure and apply an expert extended ACL to an interface to control incoming and outgoing packets of the interface based on the L2 and L3 information, and allow or prohibit the entry of specific packets to the network. In addition, you can configure an expert extended ACL to control all L2 packets based on the VLAN to permit or deny the access of users in some network segments to network resources. Generally, you can use an expert extended ACL if you want to incorporate ACEs of the IP ACL and MAC extended ACL into one ACL.

Configuration Steps

📌 Configuring an Expert Extended ACL

- (Mandatory) Configure an expert extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the VLAN ID.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert extended ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an Expert Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming packets of the device are denied by default.

📌 Applying an Expert Extended ACL

- (Mandatory) Apply an expert extended ACL to a specified interface if you want this ACL take effect.
- You can apply an expert extended ACL in the incoming or outgoing direction of a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the expert extended ACL:
- If IP-based access rules are configured in an expert extended ACL to permit or deny some IP packets, run the **ping** command to verify whether these rules take effect.
- If MAC-based access rules are configured in an expert extended ACL to permit or deny some L2 packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- If VLAN ID-based access rules are configured in an expert extended ACL to permit or deny some L2 packets in some network segments (e.g., to prevent communication between VLAN 1 users and VLAN 2 users), ping PCs of VLAN 2 on a PC of VLAN 1. If the ping operation fails, the rules take effect.

Related Commands

📌 Configuring an Expert Extended ACL

Command	expert access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<i>acl-name</i>: Indicates the name of an expert extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i>: Indicates the ID of an expert extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 2700-2899.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an expert extended ACL and enter expert extended ACL configuration mode.

📌 Adding ACEs to an Expert Extended ACL

Use either of the following methods to add ACEs to an expert extended ACL:

- Add ACEs in expert extended ACL configuration mode.

Command	[<i>sn</i>] { permit deny } [<i>protocol</i>] [<i>ethernet-type</i>] [cos [<i>out</i>] [inner in]] [[VID [<i>out</i>] [inner in]]] { <i>source source-wildcard</i> host <i>source</i> any } { host <i>source-mac-address</i> any } { <i>destination destination-wildcard</i> host <i>destination</i> any } { host <i>destination-mac-address</i> any } [precedence <i>precedence</i>] [tos tos] [fragment] [range lower upper] [time-range <i>time-range-name</i>]
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. <i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. <i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered. cos out: Indicates that L2 packets with the specified cos field in the outer tag are filtered. cos inner in: Indicates that L2 packets with the specified cos field in the inner tag are filtered. VID out: Indicates that L2 packets with the specified VLAN ID field in the outer tag are filtered. VID inner in: Indicates that L2 packets with the specified VLAN ID field in the inner tag are filtered. <i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.

	host source: Indicates that IP packets sent from a host with the specified source IP address are filtered. any: Indicates that IP packets sent from any host are filtered. host source-mac-address: Indicates that IP packets sent from a host with the specified source MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. destination destination-wildcard: Indicates that IP packets sent to hosts in a specified IP network segment are filtered. host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. any: Indicates that IP packets sent to any host are filtered. host destination-mac-address: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered. tos tos: Indicates that IP packets with the specified the TOS field in the header are filtered. dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered. fragment: Indicates that only fragmented IP packets except the first fragments are filtered. time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.
Command Mode	Expert extended ACL configuration mode
Usage Guide	Run this command to add ACEs in expert extended ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an expert extended ACL in global configuration mode.

Command	access-list <i>acl-id</i> { permit deny } [<i>protocol</i> [<i>ethernet-type</i>] [cos [<i>out</i>] [<i>inner in</i>]]] [[VID [<i>out</i>] [<i>inner in</i>]]] { <i>source source-wildcard</i> host source any } { host source-mac-address any } { <i>destination destination-wildcard</i> host destination any } { host destination-mac-address any } [precedence precedence] [tos tos] [fragment] [range lower upper] [time-range time-range-name]
Parameter Description	acl-id: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 2700-2899. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. protocol: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. ethernet-type: Indicates that L2 packets of the specified Ethernet type are filtered. cos out: Indicates that L2 packets with the specified cos field in the outer tag are filtered. cos inner in: Indicates that L2 packets with the specified cos field in the inner tag are filtered. VID out: Indicates that L2 packets with the specified VLAN ID field in the outer tag are filtered.

	VID inner in: Indicates that L2 packets with the specified VLAN ID field in the inner tag are filtered. source source-wildcard: Indicates that IP packets sent from hosts in the specified IP network segment are filtered. host source: Indicates that IP packets sent from a host with the specified source IP address are filtered. any: Indicates that IP packets sent from any host are filtered. host source-mac-address: Indicates that IP packets sent from a host with the specified source MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. destination destination-wildcard: Indicates that IP packets sent to hosts in a specified IP network segment are filtered. host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. any: Indicates that IP packets sent to any host are filtered. host destination-mac-address: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. any: Indicates that L2 packets sent to any host are filtered. precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered. tos tos: Indicates that IP packets with the specified the TOS field in the header are filtered. dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered. fragment: Indicates that only fragmented IP packets except the first fragments are filtered. time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.
Command Mode	Global configuration mode
Usage Guide	Run this command to add ACEs to a numbered expert extended ACL in global configuration mode. It cannot be used to add ACEs to a named expert extended ACL.

📌 Applying an Expert Extended ACL

Command	expert access-group { <i>acl-id</i> <i>acl-name</i> } { in out }
Parameter Description	● <i>acl-id</i>: Indicates that a numbered expert extended ACL will be applied to the interface. ● <i>acl-name</i>: Indicates that a named expert extended ACL will be applied to the interface. ● in: Indicates that this ACL controls incoming L2 packets of the interface. ● out: Indicates that this ACL controls outgoing L2 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an expert extended ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

 The following configuration example describes only ACL-related configurations.

Configuring an Expert Extended ACL to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)

Scenario Figure 1-5	 The diagram illustrates a network topology where a central switch (SW1) manages three distinct VLANs. The 'Servers' VLAN at the top includes a 'Financial Data Server' (10.1.1.1/24) and a 'Public Server' (10.1.1.2/24). The 'Employees: VLAN 2' at the bottom left has an IP segment of 192.168.1.0/24 and a gateway of 192.168.1.1/24, containing PC1 and PC2. The 'Visitors: VLAN 3' at the bottom right has an IP segment of 192.168.2.0/24 and a gateway of 192.168.2.1/24, also containing PC1 and PC2. SW1's interfaces are Gi 0/1 (connected to Employees), Gi 0/2 (connected to Visitors), Gi 0/3 (connected to Servers), and Gi 0/4 (connected to the Internet).
Configuration Steps	● Configure an expert extended ACL. ● Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2. ● Add an ACE to prevent visitors from accessing the financial data server of the company. ● Add an ACE to permit all packets. ● Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.
SW1	<pre> sw1(config)#expert access-list extended 2700 sw1(config-exp-nacl)#deny ip any any 192.168.1.0 0.0.0.255 any sw1(config-exp-nacl)#deny ip any any host 10.1.1.1 any sw1(config-exp-nacl)#permit any any any any sw1(config-exp-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#expert access-group 2700 in </pre>
Verification	● On a visitor's PC, ping the financial data server. Verify that the ping operation fails. ● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds. ● On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails.

	On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.
SW1	<pre>sw1(config)#show access-lists expert access-list extended 2700 10 deny ip any any 192.168.1.0 0.0.0.255 any 20 deny ip any any host 10.1.1.1 any 30 permit ip any any any any sw1(config)#show access-group expert access-group 2700 in Applied On interface GigabitEthernet 0/2</pre>

1.4.4 Configuring an IPv6 Extended ACL

Configuration Effect

Configure and apply an IPv6 ACL to an interface to control all incoming and outgoing IPv6 packets of this interface. You can permit or deny the entry of specific IPv6 packets to a network to control access of IPv6 users to network resources.

Configuration Steps

📌 Configuring an IPv6 ACL

- (Mandatory) Configure an IP ACL if you want to access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an IPv6 ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv6 packets of the device are denied by default.

📌 Applying an IPv6 ACL

- (Mandatory) Apply an IPv6 ACL to a specified interface on a device if you want this ACL take effect.
- You can apply an IPv6 ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the IPv6 ACL:

- Run the **ping** command to verify that the IPv6 ACL takes effect on the specified interface. For example, if an IPv6 ACL is configured to prohibit a host with a specified IP address or hosts in a specified IPv6 address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access network resources, for example, visit an IPv6 website, to check whether the IPv6 ACL takes effect on the specified interface.

Related Commands

📌 Configuring an IPv6 ACL

Command	ipv6 access-list <i>acl-name</i>
Parameter	<i>acl-name</i> : Indicates the name of a standard or an extended IP ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an IPv6 ACL and enter IPv6 configuration mode.

📌 Adding ACEs to an IPv6 ACL

- To filter TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	[<i>sn</i>] {permit deny } <i>protocol</i> [<i>src-ipv6-prefix/prefix-len</i> host <i>src-ipv6-addr</i> any] [<i>dst-ipv6-pfx/pfx-len</i> host <i>dst-ipv6-addr</i> any] [<i>op dstport</i> range <i>lower upper</i>] [dscp <i>dscp</i>] [flow-label <i>flow-label</i>] [fragment] [time-range <i>tm-rng-name</i>][log]
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. <i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp. <i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered. host <i>src-ipv6-addr</i>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered. any: Indicates that IPv6 packets sent from any host are filtered. <i>dst-ipv6-pfx/pfx-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered. host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are

	filtered. any: Indicates that IPv6 packets sent to any host are filtered. op dstoprt: Indicates that TCP or UDP packets are filtered based on the L4 destination port number. The value of the op parameter can be eq (equal to), neq (not equal to), gt (greater than), or lt (smaller than). range lower upper: Indicates that TCP or UDP packets with the L4 destination port number in the specified range are filtered. dscp dscp: Indicates that IPv6 packets with the specified the dscp field in the header are filtered. flow-label flow-label: Indicates that IPv6 packets with the specified the flow label field in the header are filtered. fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered. time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

- To filter IPv6 packets except for the TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	<pre>[sn] { permit deny } protocol { src-ipv6-prefix/prefix-len host src-ipv6-addr any } { dst-ipv6-pfx/pfx-len host dst-ipv6-addr any } [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name] [log]</pre>
Parameter Description	sn: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. protocol: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp. src-ipv6-prefix/prefix-len: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered. host src-ipv6-addr: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered. any: Indicates that IPv6 packets sent from any host are filtered. dst-ipv6-pfx/pfx-len: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.

	host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered. any: Indicates that IPv6 packets sent to any host are filtered. dscp <i>dscp</i>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered. flow-label <i>flow-label</i>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered. fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered. time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

📌 Applying an IPv6 ACL

Command	ipv6 traffic-filter <i>acl-name</i> { in out }
Parameter Description	<i>acl-name</i>: Indicates the name of an IPv6 ACL. in: Indicates that this ACL controls incoming IPv6 packets of the interface. out: Indicates that this ACL controls outgoing IPv6 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an IPv6 ACL take effect on the incoming or outgoing packets of the specified interface.

Configuration Example

📌 Configuring an IPv6 ACL to Prohibit the R&D Department from Accessing the Video Server

Scenario Figure 1-6	
Configuration	● Configure an IPv6 ACL.

Steps	● Add an ACE to the IPv6 ACL to prevent access to the video server. ● Add an ACE to the IPv6 ACL to permit all IPv6 packets. ● Apply the IPv6 ACL to the incoming direction of the interface connected to the R&D department.
SW1	<pre>sw1(config)#ipv6 access-list dev_deny_ipv6video sw1(config-ipv6-nacl)#deny ipv6 any host 200::1 sw1(config-ipv6-nacl)#permit ipv6 any any sw1(config-ipv6-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6video in</pre>
Verification	● On a PC of the R&D department, ping the video server. Verify that the ping operation fails.
SW1	<pre>sw1(config)#show access-lists ipv6 access-list dev_deny_ipv6video 10 deny ipv6 any host 200::1 20 permit ipv6 any any sw1(config)#show access-group ipv6 traffic-filter dev_deny_ipv6video in Applied On interface GigabitEthernet 0/2</pre>

1.4.5 Configuring an ACL80

Configuration Effect

When the IP ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL with fixed matching fields cannot meet requirements, configure the ACL80 to customize the packet fields that need to be matched.

Configuration Steps

📌 Configuring an Expert Advanced ACL

- (Mandatory) Configure an expert advanced ACL if you want to implement the ACL80 function. For details about how to configure the expert advanced ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert advanced ACL takes effect only on the local device, and does not affect other devices on the network.

➤ Adding ACEs to an Expert Advanced ACL

- (Mandatory) Add ACEs to an expert advanced ACL to customize matching fields. If no ACE is added to the expert advanced ACL, the deny ACEs will drop all packets by default. For details about how to add an ACE to an expert advanced ACL, see the related descriptions.

➤ Applying an Expert Advanced ACL

- (Mandatory) Apply an expert advanced ACL to a specified interface if you want this ACL take effect.
- You can apply an expert advanced ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the expert advanced ACL:
- Run the **ping** command to check whether the configurations take effect.
- Construct packets matching the ACEs to check whether ACEs take effect.

Related Commands

➤ Configuring an Expert Advanced ACL

Command	expert access-list advanced <i>acl-name</i>
Parameter Description	<i>acl-name</i> : Indicates the name of an expert advanced ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an expert advanced ACL and enter expert advanced ACL configuration mode.

➤ Adding ACEs to an Expert Advanced ACL

Command	<i>[sn]</i> { permit deny } <i>hex hex-mask offset</i>
Parameter Description	<i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command. permit: Indicates that the ACE is a permit ACE. deny: Indicates that the ACE is a deny ACE. <i>hex</i>: Indicates the customized matching rule expressed in hexadecimal format, for example, 00d0f800.

	<i>hex-mask</i>: Indicates the matching mask. <i>offset</i>: Indicates the start position of matching. For example, if the matching content is 00d0f800, the matching mask is 00ff0000, and start position is 6, the destination MAC address of each packet is compared. All packets whose second byte of the destination MAC address is d0 match this ACE.
Command Mode	Expert advanced ACL configuration mode
Usage Guide	Run this command to add ACEs in expert advanced ACL configuration mode.

📌 Applying an Expert Advanced ACL

Command	expert access-group <i>acl-n</i> { in out }
Parameter Description	<i>acl-id</i>: Indicates that a numbered expert advanced ACL will be applied to the interface. <i>acl-name</i>: Indicates that a named expert advanced ACL will be applied to the interface. in: Indicates that this ACL controls incoming L2 packets of the interface. out: Indicates that this ACL controls outgoing L2 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an expert advanced ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

 The following configuration example describes only ACL-related configurations.

- 📌 **Configuring an ACL80 to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)**

Scenario
Figure 1-7

Configuration Steps

- Configure an expert advanced ACL.
- Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2.
- Add an ACE to prevent visitors from accessing the financial data server of the company.
- Add an ACE to permit all packets.
- Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.

SW1

```
sw1(config)#expert access-list advanced acl80-guest
sw1(config-exp-dacl)#deny C0A801 FFFFFFFF 42
sw1(config-exp-dacl)#deny 0A010101 FFFFFFFF 42
sw1(config-exp-dacl)#permit 0806 FFFF 24
sw1(config-exp-dacl)#permit 0800 FFFF 24
sw1(config-exp-dacl)#exit
sw1(config)#int gigabitEthernet 0/2
sw1(config-if-GigabitEthernet 0/2)#expert access-group acl80-guest in
```

Verification

- On a visitor's PC, ping the financial data server. Verify that the ping operation fails.
- On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds.
- On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails.
- On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.

SW1

```
sw1(config)#show access-lists
```

```
expert access-list advanced sss

10 deny COA801 FFFFFFFF 42

20 deny 0A010101 FFFFFFFF 42

30 permit 0806 FFFF 24

40 permit 0800 FFFF 24

expert access-group acl80-guest in

Applied On interface GigabitEthernet 0/2
```

1.4.6 Configuring ACL Redirection

Configuration Effect

Configure the ACL redirection function on a specified interface to directly redirect specified packets on the interface to a specified port for further forwarding.

Configuration Steps

📌 Configuring an ACL

- (Mandatory) To implement ACL redirection, you must first configure an ACL, for example, an IP, MAC extended, or expert extended ACL. For details about how to configure an ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, the ACL redirection function is not available. For details about how to add an ACE to an ACL, see the related descriptions.

📌 Configuring ACL Redirection

- (Mandatory) Enable ACL redirection on a specified interface if you want to implement ACL redirection.
- You can configure the ACL redirection function on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Send packets matching ACEs on the port where ACL redirection is enabled, and then use the packet capturing software on the destination port to check whether the ACL redirection function takes effect.

Related Commands

📌 Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

✚ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

✚ Configuring ACL Redirection

Command	redirect destination interface <i>interface-name</i> acl { <i>acl-id</i> <i>acl-name</i> } in
Parameter Description	interface <i>interface-name</i> : Indicates the name of the destination port for redirection. <i>acl-id</i> : Indicates the ID of an ACL. <i>acl-name</i> : Indicates the name of an ACL. in : Indicates that incoming packets of the interface are redirected.
Command Mode	Interface configuration mode
Usage Guide	Run this command to redirect incoming packets of the interface that match ACEs to the destination port for further forwarding.

Configuration Example

i The following configuration example describes only ACL-related configurations.

✚ Enabling ACL Redirection to Redirect Packets Sent from the Host 10.1.1.1 to the Packet Capturing Device for Analysis

Scenario Figure 1-8	
Configuration Steps	- Configures an IP ACL. - Add an ACE to the IP ACL to permit packets sent from the host 10.1.1.1. - Enable ACL redirection on the port Gi 0/1, and set the destination port to Gi 0/2.
SW1	<pre>sw1(config)#ip access-list standard 1</pre>

	<pre>sw1 (config-std-nacl)#permit host 10.1.1.1 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# redirect destination interface gigabitEthernet 0/2 acl 1</pre>
Verification	● Capture packets on PC 2. Ping the video server on PC 1. Verify that ICMP requests sent from PC 1 are captured on PC 2.
SW1	<pre>sw1#show access-lists ip access-list standard 1 10 permit host 10.1.1.1 sw1#show redirect interface gigabitEthernet 0/1 acl redirect configuration on interface gigabitEthernet 0/1 redirect destination interface gigabitEthernet 0/2 acl 1 in</pre>

1.4.7 Configuring a Global Security ACL

Configuration Effect

Configure a global security ACL to prevent internal PCs of a company from accessing illegal websites or prevent virus from attacking the company's internal network. You can also configure exclusive interfaces to allow specified departments of the company to access external websites.

Configuration Steps

📌 Configuring an IP ACL

- (Mandatory) Configure an IP ACL if you want to protect the internal network globally. For details about the configuration method, see the earlier descriptions about the IP ACL.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

📌 Adding ACEs to an IP ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the global security ACL does not exist. For details about how to add an ACE to an ACL, see the related descriptions.

📌 Configuring a Global Security ACL

- (Mandatory) Enable the global security function if you want to make the global security ACL take effect.
- You can configure a global security ACL on an access, an aggregate, or a core device based on the distribution of users.

Verification

On the internal network protected by the global security ACL, ping the website or device that are denied by ACEs to check whether the global security ACL takes effect.

Related Commands

Configuring an IP ACL

For details about the configuration method, see the earlier descriptions about the IP ACL.

Adding ACEs to an IP ACL

For details about the configuration method, see the earlier descriptions about the IP ACL.

Configuring a Global Security ACL

Command	ip access-group <i>acl-id</i> { in out }
Parameter Description	<i>acl-id</i> : Indicates the ID of an IP ACL. in : Filters the incoming packets of the device. out : Filters the outgoing packets of the device.
Command Mode	Global configuration mode
Usage Guide	Run this command to enable the global security ACL so that the ACL takes effect on all L2 interfaces of the device.

 Currently, the global secure ACL takes effect only in the incoming direction of an interface.

Configuring an Exclusive Interface of the Global Security ACL

Command	no global ip access-group
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to invalidate a global security ACL on a specified interface.

Configuration Example

 The following configuration example describes only ACL-related configurations.

Configuring a Global Security ACL to Prevent the R&D Department From Accessing the Server of the Sales Department but Allow the Sales Department to Access This Server

Scenario Figure 1-9	Server of the Sales Dept. 10.1.1.3/24 Gateway: 10.1.1.1/24 SW1: SVI1:10.1.1.1, SVI2:12.1.1.1, SVI3:13.1.1.1 Sales Dept.: VLAN 1 IP Segment:11.1.1.0/24 Gateway:11.1.1.1/24 R&D Dept. 1: VLAN 2 IP Segment:12.1.1.0/24 Gateway:12.1.1.1/24 R&D Dept. 2: VLAN 3 IP Segment:13.1.1.0/24 Gateway:13.1.1.1/24
Configuration Steps	● Configure an extended IP ACL "ip_ext_deny_dst_sale_server". ● Add the ACE that prevents the device to forward packets to the destination host 10.1.1.3/24. ● Configure the ACL "ip_ext_deny_dst_sale_server" as a global security ACL. ● Configure the interface directly connected to the sales department as the exclusive interface of the global security ACL.
SW1	<pre>sw1(config)#ip access-list extended ip_ext_deny_dst_sale_server sw1(config-ext-nacl)# deny ip any host 10.1.1.3 sw1(config-ext-nacl)#exit sw1(config)#ip access-group ip_ext_deny_dst_sale_server in sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# no global ip access-group</pre>
Verification	● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds. ● On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.
	<pre>sw1#show access-lists ip access-list extended ip_ext_deny_dst_sale_server 10 deny ip any host 10.1.1.3 sw1#show running !</pre>

```
ip access-group ip_ext_deny_dst_sale_server in
!
!
!
!
!
!
!
!
!
!
interface GigabitEthernet 0/1
  no global ip access-group
!
.....
```

1.4.8 Configuring a Security Channel

Configuration Effect

Configure a security channel to enable packets meeting the security channel rules to bypass the checks of access control applications. Configure the security channel if an access control application (such as DOT1X) is enabled on an uplink interface of a user, but the user should be allowed to log in to a website to download some resources (for example, downloading the Ruijie SU client) before the DOT1X authentication.

Configuration Steps

📌 Configuring an ACL

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

📌 Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured for an ACL, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

📌 Configuring a Security Channel on a Specified Interface or Globally

- Configure a security channel on an interface if you want this security channel take effect on the interface. Configure a global security channel if you want this security channel take effect globally. You must configure either the interface-based security channel or the global security channel.
- You can configure a security channel on an access, an aggregate, or a core device based on the distribution of users.

📌 Configuring an Exclusive Interface for the Global Security Channel

- (Optional) Configure an interface as the exclusive interface for the global security channel if you do not want the global security channel to take effect on this interface.

📌 Configuring an Access Control Application

- (Optional) You can enable the DOT1X or Web authentication function to verify the security channel function.
- You can configure the access control function on an access, an aggregate, or a core device based on the distribution of users.

Verification

On a PC that is subject to the control of an access control application, ping the resources (devices or servers) that are allowed to bypass the check of the access control application to verify the configuration of the security channel.

Related Commands

📌 Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

📌 Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

📌 Configuring a Security Channel on an Interface

Command	security access-group {<i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure a specified ACL as the security channel on the specified interface.

📌 Configuring a Global Security Channel

Command	security global access-group {<i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel.

	<i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the specified ACL as the global security channel.

✎ Configuring an Exclusive Interface for the Global Security Channel

Command	security uplink enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure the specified interface as the exclusive interface of the global security channel.

Configuration Example

i The following configuration example describes only ACL-related configurations.

✎ Enabling DOT1X Authentication and Configuring a Security Channel to Allow Users to Download the SU Software From the Server Before Authentication

Scenario Figure 1-10	Software Server 10.1.1.2/24 Gateway:10.1.1.1 SW1 SVI:10.1.1.1 Gi 0/4 SVI:11.1.1.1 Gi 0/1 PC1 PC2 Dot1x-enabled Devices: VLAN 1 IP Segment : 11.1.1.0/24 Gateway:11.1.1.1/24
Configuration Steps	● Configure an expert extended ACL "exp_ext_esc". ● Add an ACE to allow forwarding packets to the destination host 10.1.1.2. ● Add an ACE to permit the DHCP packets. ● Add an ACE to permit the ARP packets. ● On the interface where DOT1X authentication is enabled, configure the ACL "exp_ext_esc" as the security channel.
SW1	sw1(config)#expert access-list extended exp_ext_esc

	<pre>swl(config-exp-nacl)# permit ip any any host 10.1.1.2 any swl(config-exp-nacl)# permit 0x0806 any any any any any swl(config-exp-nacl)# permit tcp any any any any eq 67 swl(config-exp-nacl)# permit tcp any any any any eq 68 swl(config)#int gigabitEthernet 0/1 swl(config-if-GigabitEthernet 0/1)# security access-group exp_ext_esc</pre>
Verification	● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds. ● On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.
	<pre>swl#show access-lists expert access-list extended exp_ext_esc 10 permit ip any any host 10.1.1.2 any 20 permit arp any any any any any 30 permit tcp any any any any eq 67 40 permit tcp any any any any eq 68..... swl#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 59 bytes interface GigabitEthernet 0/1 security access-group exp_ext_esc</pre>

1.4.9 Configuring the Time Range-Based ACEs

Configuration Effect

Configure the time range-based ACEs if you want some ACEs to take effect or to become invalid in a specified period of time, for example, in some time ranges during a week.

Configuration Steps

➤ Configuring an ACL

- (Mandatory) Configure an ACL if you want ACEs to take effect in the specified time range. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

➤ Adding an ACE with the Time Range Specified

- (Mandatory) Specify the time range when adding an ACE. For details about how to configure the time range, see the configuration manual related to the time range.

➤ Applying an ACL

- (Mandatory) Apply the ACL to a specified interface if you want to make ACEs take effect in the specified time range.
- You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

In the time range that the configured ACE takes effect or becomes invalid, run the **ping** command or construct packets matching the ACE to check whether the ACE takes effect or becomes invalid.

Related Commands

➤ Configuring an ACL

For details about the ACL configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

➤ Adding an ACE with the Time Range Specified

For details about the ACE configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

➤ Applying an ACL

For details about the command for applying an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuration Example

 The following configuration example describes only ACL-related configurations.

➤ Adding an ACE With the Time Range Specified to Allow the R&D Department to Access the Internet Between 12:00 and 13:30 Every Day

Scenario Figure 1-11	Router Breakout Gateway (NAT) Gi 0/2 IP: 110.1.1.2 Gi 0/1 11.1.1.2 SV2: 11.1.1.1 Gi 0/2 SW1 SV1: 11.1.1.1 Gi 0/1 PC1 PC2 ... R&D Dept.: VLAN 1 IP Segment: 10.1.1.0/24 Gateway: 10.1.1.1
Configuration Steps	● Configure a time range named "access-internet", and add an entry of the time range between 12:00 and 13:30 every day. ● Configure an IP ACL "ip_std_internet_acl". ● Add an ACE to allow packets with the source IP address in the network segment 10.1.1.0/24, and associate this ACE with the time zone "access-internet". ● Add an ACE to deny packets with the source IP address the network segment 10.1.1.0/24. Access to the Internet is not allowed except in the specified time range. ● Add an ACE to permit all packets. ● Apply the ACL to the outgoing direction of the interface connected to the breakout gateway.
SW1	<pre> Ruijie(config)# time-range access-internet Ruijie(config-time-range)# periodic daily 12:00 to 13:30 Ruijie(config-time-range)# exit sw1(config)# ip access-list standard ip_std_internet_acl sw1(config-std-nacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet sw1(config-std-nacl)# deny 10.1.1.0 0.0.0.255 sw1(config-std-nacl)# permit any sw1(config-std-nacl)# exit sw1(config)# int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ip access-group ip_std_internet_acl out </pre>
Verification	● Within the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&D department. Verify that the website can be opened normally. ● Beyond the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&D department. Verify that the website cannot be opened.

SW1	<pre>sw1#show time-range time-range entry: access-internet (inactive) periodic Daily 12:00 to 13:30 sw1#show access-lists ip access-list standard ip_std_internet_acl 10 permit 10.1.1.0 0.0.0.255 time-range access-internet (inactive) 20 deny 10.1.1.0 0.0.0.255 30 permit any sw1#show access-group ip access-group ip_std_internet_acl out Applied On interface GigabitEthernet 0/2</pre>

1.4.10 Configuring Comments for ACLs

Configuration Effect

During network maintenance, if a lot of ACLs are configured without any comments, it is difficult to distinguish these ACLs later on. You can configure comments for ACLs to better understand the intended use of ACLs.

Configuration Steps

📌 Configuring an ACL

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

📌 Configuring Comments for ACLs

- (Optional) Configure comments for ACLs so that it is easy to manage and understand the configured ACLs.

📌 Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

✚ Configuring Comments for ACEs

- (Optional) To facilitate understanding of a configured ACL, you can configure comments for ACEs in addition to comments for the ACL.

Verification

Run the **show access-lists** command on the device to display the comments configured for ACLs.

Related Commands

✚ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

✚ Configuring a Comment for an ACL

Use either of the following two methods to configure a comment for an ACL:

Command	list-remark <i>comment</i>
Parameter Description	comment : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

Command	access-list <i>acl-id</i> list-remark <i>comment</i>
Parameter Description	acl-id : Indicates the ID of an ACL. comment : Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

✚ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

✚ Configuring Comments for ACEs

Use either of the following two methods to configure a comment for an ACE:

Command	remark <i>comment</i>

Parameter Description	comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE.

Command	access-list <i>acl-id</i> remark <i>comment</i>
Parameter Description	acl-id: Indicates the ID of an ACL. comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE.

1.5 Monitoring

Clearing

Description	Command
Clears the ACL packet matching counters.	clear counters access-list [<i>acl-id</i> <i>acl-name</i>]
Clears the counters of packets matching the deny ACEs.	clear access-list counters [<i>acl-id</i> <i>acl-name</i>]

Displaying

Description	Command
Displays the basic ACLs.	show access-lists [<i>acl-id</i> <i>acl-name</i>] [summary]
Displays the redirection ACEs bound to a specified interface. If the interface is not specified, redirection ACEs bound to all interfaces are displayed.	show redirect [interface <i>interface-name</i>]
Displays the ACL configurations applied to an interface.	show access-group [interface <i>interface-name</i>]
Displays the IP ACL configurations applied to an interface.	show ip access-group [interface <i>interface-name</i>]
Displays the MAC extended ACL configurations applied to an interface.	show mac access-group [interface <i>interface-name</i>]
Displays the expert extended ACL configurations applied to an interface.	show expert access-group [interface <i>interface-name</i>]
Displays the IPv6 ACL configurations applied to an interface.	show ipv6 traffic-filter [interface <i>interface-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the ACL running process.	debug acl acld event
Debugs the ACL clients.	debug acl acld client-show
Debugs the ACLs created by all ACL clients.	debug acl acld acl-show

2 Configuring QoS

2.1 Overview

Quality of Service (QoS) indicates that a network can provide a good service capability for specified network communication by using various infrastructure technologies.

When the network bandwidth is sufficient, all data streams can be properly processed; when network congestion occurs, all data streams may be discarded. To meet users' requirements for different applications and different levels of service quality, a network must be able to allocate and schedule resources based on users' requirements and provide different levels of service quality for different data streams. To be specific, the network can process real-time and important data packets in higher priorities, and process non-real-time and common data packets in lower priorities and even discard the data packets upon network congestion.

The "doing the best" forwarding mechanism used by traditional networks cannot meet the requirements any longer and then QoS comes into being. QoS-enabled devices provide transmission QoS quality service. A transmission priority can be assigned to data streams of a type to identify the importance of the data streams. Then, the devices provide forwarding policies for different priorities, congestion mitigation and other mechanisms to provide special transmission services for these data streams. A network environment configured with QoS can provide predictability for network performance, effectively allocate network bandwidth, and reasonably utilize network resources.

2.2 Applications

Application	Description
Interface Rate Limit + Priority Relabeling	Based on different service requirements for a campus network, provide rate control and priority-based processing for outgoing traffic of the teaching building, laboratories and dormitory building.
Priority Relabeling + Queue Scheduling	Provide priority-based processing and bandwidth control for traffic of internal access to servers of an enterprise.

2.2.1 Interface Rate Limit + Priority Relabeling

Scenario

To meet the service requirements of normal teaching, a school puts forwards the following requirements:

- Control the Internet access traffic under 100M and discard packets out of control.
- Control the outgoing traffic of the dormitory building under 50M and discard packets out of control.
- Control the rate of packets with DSCP priority 7 sent from laboratories under 20M, and change the DSCP priorities of these packets whose rates exceed 20M to 16.
- Control the outgoing traffic of the teaching building under 30M and discard packets out of control.

Figure 2-1

Remarks	A school connects GigabitEthernet 0/24 of Switch A to the Internet in the uplink and connects GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A to the teaching building, laboratory and dormitory building in the downlink respectively.

Deployment

- Configure the QoS interface rate limit for the interface G0/24 of Switch A for connecting the Internet. Configure the QoS rate limit for packets sent from the dormitory building on Switch A.
- Set the rate limit for packets with the DSCP priority 7 sent from the laboratory to 20M and relabel the DSCP priority of packets out of the rate limit to 16.
- Configure the QoS rate limit for packets sent from the teaching building on Switch A.

2.2.2 Priority Relabeling + Queue Scheduling

Scenario

Configure priority relabeling and queue scheduling to meet the following requirements:

- When the R&D department and market department access servers, the priorities of the server packets are as follows: mail server > file server > salary query server.
- No matter when the HR management department accesses the Internet or servers, the switch processes the corresponding packets in the highest priority.
- Since network congestion often occurs in switch running, in order to ensure smooth business operation, WRR queue scheduling must be used to schedule IP packets for the R&D and market departments to access the mail database, file database, and salary query database based on the ratio of 6:2:1.

Figure 2-2

Remarks	The R&D, market and HR management departments access the interfaces GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A respectively. The salary query server, mail server and file server are connected to GigabitEthernet 0/23 of Switch A.

Deployment

- Configure the CoS values of data streams for accessing different servers to ensure that the switch processes packets for different servers in different priorities.
- Set the default CoS value of the interface to a specific value to ensure that the switch processes packets sent by the HR management department in the highest priority.
- Configure WRR queue scheduling to ensure that data packets are transmitted in a specific quantity ratio.

2.3 Features

Basic Concept

DiffServ

The Differentiated Services (DiffServ) Mode is an IETF system based on which QoS is implemented in Ruijie products. The DiffServ system classifies all packets transmitted in a network into different types. The classification information is included in layer-2/3 packet headers, including 802.1P, IP and IP DSCP priorities.

In a DiffServ-compliant network, all devices apply the same transmission service policy to packets containing the same classification information and apply different transmission service policies to packets containing different classification information. Classification information of packets is either assigned by hosts or other devices in the network or assigned based on different application policies or different packet contents. Based on the classification information carried by packets, a device may provide different transmission priorities for different packet streams, reserve bandwidth for a kind of packet streams, discard certain packets with lower priorities, or take some other actions.

802.1P(PRI) priority

The 802.1 P priority is located at the header of a layer-2 packet with the 802.1Q header, and is used in scenarios where layer-3 headers do not need to be analyzed and QoS needs to be implemented at layer 2. Figure 2-3 shows the structure of a layer-2 packet.

Figure 2-3

As shown in Figure 2-3, the 4-byte 802.1Q header contains 2-byte Tag Protocol Identifier (TPID) whose value is 0x8100 and 2-byte Tag Control Information (TCI). The first three bits of the TCI indicate the 802.1P priority.

IP priority (IP PRE) and DSCP priority

The priorities of IP packets are identified by the IP PRE and DSCP priority. The Type Of Service (ToS) field of the IPv4 header comprises 8 bits; where the first three bits indicate the IP precedence (IP PRE), ranging from 0 to 7. RFC 2474 redefines the ToS field of the IPv4 header, which is called the Differentiated Services (DS) field. The Differentiated Services Code Point (DSCP) priority is identified by the first 6 bits (bits 0 to 5) of the DS field, and by the first 6 bits of the Traffic Class field in the IPv6 header. Figure 2-4 shows the locations of the IP PRE and DSCP priorities in IPv4/IPv6 packets.

Figure 2-4

CoS

Class of Service (COS). Ruijie products convert packet priorities into CoS values to identify the local priorities of the packets and determine the input queue ID when packets are sent from the output interface.

Overview

Feature	Description
Stream Classification	Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services.
Priority Labeling and Mapping	Label packet priorities with specified values and map the values to corresponding CoS values.
Traffic Supervision	Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of the traffic.
Congestion Management	Determine the sequence of data packets sent from an interface based on the priorities of the data packets and ensure that key services can be processed in time when congestion occurs.
Congestion Mitigation	Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

2.3.1 Stream Classification

Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services. Stream classification rules are used to distinguish different packets in the network and specify different QoS parameters for packets at different service levels.

Working Principle

Stream classification rules can be matching the PRE or DSCP priorities of IP packets or classifying packets by identifying packet content through an ACL. You can define the binding between multiple streams and stream behaviors by using commands to form policies which can be applied to interfaces for stream classification and processing.

📌 QoS policy

A QoS policy comprises three elements: class, stream behavior and policy.

- Class

A class identifies streams and comprises the class name and class rules. You can define the class rules by using commands to classify packets.
- Stream behavior

Stream behaviors define the QoS actions taken for packets, including priority labeling and traffic supervision for packets.
- Policy

A policy binds a specific class and specific stream behaviors and comprises the policy name, names of the classes bound, and stream behaviors. You can bind a specified class and stream behaviors by using a QoS policy and apply the policy to one or more interfaces.

📌 QoS logical interface group

You can specify a series of interfaces as a QoS logical interface group (including both APs and Ethernet interfaces) and associate polices with the logical interface group for QoS processing. Take rate limit for stream behaviors for example. For packets that meet the rate limit conditions, all interfaces in the same logical interface group share the bandwidth specified by the policy.

Related Configuration

➤ Creating a class

No class is defined by default.

You can run the **class-map** command to create a class and enter the class configuration mode.

➤ Matching an ACL

No rules are defined for a class by default.

In the class configuration mode, you can run the **match access-group** command to define a class rule as matching an ACL. You need to create ACL rules first.

➤ Matching PRE priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip precedence** command to define a class rule as matching PRE priorities of IP packets. The value range of IP PRE is 0 to 7.

➤ Matching DSCP priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip dscp** command to define a class rule as matching DSCP priorities of IP packets. The value range of DHCP priorities is 0 to 63.

➤ Creating a policy

No policy is defined by default.

You can run the **policy-map** command to create a policy and enter the policy configuration mode.

➤ Associating a class

A policy is not associated with any class by default.

In the policy configuration mode, you can run the **class** command to associate a class and enter the policy-class configuration mode.

➤ Binding a stream behavior

A class is not bound to any stream behavior by default.

In the policy-class configuration mode, you can run the **set** command to modify the CoS or DSCP values of a specified stream; where, the CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63. You can run the **police** command

to limit the bandwidth and process streams out of the limit for specified streams. The bandwidth limit ranges are determined by products.

📌 Configuring a logical interface group

No logical interface group is defined and an interface is not added to any logical interface group by default.

In the global configuration mode, you can run the **virtual-group** command to create a logical interface group. In the interface configuration mode, you can run the **virtual-group** command to add an interface to a logical interface group. If this logical interface group is not created, you can create the logical interface group and add the interface to the group. You can create 128 logical interface groups, ranging from 1 to 128.

📌 Applying a policy to an interface

No policy is applied to an interface by default.

In the interface configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of the interface.

2.3.2 Priority Labeling and Mapping

Priorities are used to label the scheduling weights of packets or the priorities of the packets in forwarding. Different packet types have different priority types including 802.1P(PRI), IP PRE and DSCP priorities. Priority labeling and mapping refer to labeling packet priorities with specified values and mapping the values to corresponding CoS values.

Working Principle

After data streams of packets enter a device interface, the device assigns priorities to the packets based on the trust mode configured for the interface. The following describes several trust modes:

- When the interface trust mode is untrust, which means not trusting the priority information carried in packets:
Modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
- When the interface trust mode is trusting CoS:
For packets carrying the 802.1Q tag, modify the CoS value according to the PRI value, CoS-DSCP mapping table, and DSCP-CO mapping table, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
For packets not carrying the 802.1Q tag, modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
- When the interface trust mode is trusting DSCP:
For non-IP packets, the processing is the same as that for trusting CoS.

For IP packets, modify the CoS value according to the DSCP value of the packets and the DSCP-CoS mapping table and put the packets into queues based on the final CoS value.

- When the interface trust mode is trusting IP PRE:

For non-IPv4 packets, the processing is the same as that for trusting CoS.

For IPv4 packets, obtain and modify the DSCP priority of the packets according to the IP PRE value of the packets and the IP-PRE-DSCP mapping table, obtain the CoS value according to the DSCP-CoS mapping table, and then put the packets into queues based on the final CoS value.

- When the trust mode and the applied policy of an interface work together:

When the trust mode and the applied policy of an interface work together, the trust mode has a lower priority than the policy and the CoS priority can be obtained according to the DSCP-CoS mapping table.

If a policy is applied to the interface but the policy does not have a configuration for modifying the DSCP and CoS values, the processing will be performed based on the trust mode of the interface.

Related Configuration

📌 Configuring the trust mode of an interface

The default trust mode of an interface is untrust.

In the interface configuration mode, run the **mls qos trust** command to modify the trust mode. The trust mode can be trusting CoS, trusting DSCP or trusting IP PRE.

📌 Configuring the default CoS value of an interface

The default CoS value of an interface is 0.

In the interface configuration mode, run the **mls qos cos** command to modify the default CoS value of the interface, which ranges from 0 to 7.

📌 Labeling the priority of streams

The priorities of streams are not relabeled by default.

In the policy-class configuration mode, run the **set** command to modify the CoS and DSCP values of streams. The CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63.

📌 Configuring CoS-to-DSCP Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map cos-dscp** command to configure the CoS-DSCP mapping. The DSCP value ranges from 0 to 63.

📌 Configuring DSCP-to-CoS Map

By default, DSCP 0 to 7 are mapped to CoS 0, DSCP 8 to 15 mapped to CoS 1, DSCP 16 to 23 mapped to CoS 2, DSCP 24 to 31 mapped to CoS 3, DSCP 32 to 39 mapped to CoS 4, DSCP 40 to 47 mapped to CoS 5, DSCP 48 to 55 mapped to CoS 6, and DSCP 56 to 63 mapped to CoS 7.

Run the **mls qos map dscp-cos** command to configure the DSCP-CoS mapping. The CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63.

Configuring IP-PRE-to-DSCP Map

By default, the IP PRE values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map ip-prec-dscp** command to configure the IP PRE-DSCP mapping. The DSCP value ranges from 0 to 63.

2.3.3 Traffic Supervision

Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of packets. In addition, the total traffic of an interface can be monitored and the traffic out of the limit will be discarded.

Working Principle

Traffic supervision is used to monitor the specification of traffic flowing into a network and conduct preset supervision actions based on different assessment results. These actions can be:

- Forwarding: Normally forward packets within the traffic limit.
- Discarding: discard packets out of the traffic limit.
- Changing the priority and forwarding: modify the priorities of packets out of the traffic limit and then forward the packets.

Directly discard packets out of the total traffic limit of an interface.

Related Configuration

Configuring the action to be conducted for traffic out of limit

No action to be conducted for traffic out of limit is configured by default.

In the policy-class configuration mode, run the **police** command to configure the action to be conducted for traffic out of limit to discarding traffic out of limit, or modifying the CoS value or DSCP value. The traffic limit range is determined by products. When the traffic is out of the limit, you can modify the CoS value in the range of 0 to 7 and the DSCP value in the range of 0 to 63.

Configuring the total traffic limit for an interface

The total traffic limit for an interface is not configured by default.

In the interface configuration mode, run the **rate-limit** command to configure the total traffic limit for an interface in the input and output directions. The traffic limit range is determined by products.

2.3.4 Congestion Management

When the receiving rate of packets exceeds the sending rate of packets, congestion will occur on the sending interface. If no sufficient buffer is provided to store these packets, the packets may be lost. The congestion management mechanism

determines the sequence of data packets to be sent from an interface based on the priorities of the data packets. The congestion management function allows for congestion control by increasing the priorities of important data packets. When congestion occurs, the important data packets are sent in higher priorities to ensure that key services are implemented in time.

Working Principle

A queue scheduling mechanism is used for congestion management and the process is as follows:

- After each packet passes all QoS processing in a switch, the packet will obtain a CoS value finally.
- At the output interface, the device classifies the packets into corresponding sending queues based on the CoS values.
- The output interface selects packets in a queue for sending based on various scheduling policies (SP, WRR, DRR, SP+WRR, SP+DRR).

📌 Scheduling policy

The queue scheduling policies include SP, WRR, DRR, SP+WRR and SP+DRR.

- Strict-Priority (SP) scheduling means scheduling packets strictly following queue IDs. Before sending packets each time, check whether a queue with the first priority has packets to be sent. If yes, the packets in this queue are sent first. If not, check whether a queue with the second priority has packets. Follow the same rules for packets in other queues.
- Weighted Round Robin (WRR) scheduling means scheduling queues in turn to ensure that all queues have certain service time. For example, a 1000 Mbps interface has 8 output queues. The WRR configures a weighted value (5, 5, 10, 20, 20, 10, 20 and 10, which indicate the proportions of obtained resources) for each queue. This scheduling method ensures that a queue with the lowest priority is assigned with at least 50 Mbps bandwidth, which avoids that packets in the queue with the lowest priority are not served for long time when the SP scheduling method is used.
- Deficit Round Robin (DRR) scheduling is similar to the WRR, but applies weight values based on bytes, but not based on time slices.
- SP+WRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the WRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, the packets in WRR queues can be sent.
- SP+WFQ scheduling means configuring the SP scheduling for one or more sending queues and configuring the WFQ scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, the packets in WFQ queues can be sent.

📌 QoS multicast queue

On some products, interface queues are classified into unicast queues and multicast queues. There are 8 unicast queues. All known unicast packets enter corresponding unicast queues for forwarding based on their priorities. There are 1 to 8 multicast queues (depending on products. Certain products do not support multicast queues). Except for known unicast packets, all packets (such as broadcast packets, multicast packets, unknown unicast packets, and mirroring packets) enter corresponding multicast queues for forwarding based on their priorities. Similar to unicast queues, you can configure priority

mappings and scheduling algorithms for multicast queues. The **Cos-to-Mc-Queue** command can be used to configure mapping from priorities to multicast queues. At present, multicast queues support the SP, WRR and SP+WRR scheduling algorithms.

📌 Scheduling policy and round robin weight for output queues on an interface

The scheduling policies and round robin weight for output queues are based on global configurations. Some products support both global configurations and interface-based configurations. Interface-based configurations have higher priorities than global configurations. The global scheduling policy works with the corresponding global round robin weight whereas the interface scheduling policy works with the interface round robin weight. If only the global scheduling policy or interface scheduling policy is configured but no corresponding round robin weights are configured, the default round robin weights will work with the scheduling policy.

📌 Queue bandwidth

Some products allow for configuring the guaranteed minimum bandwidth and the limited maximum bandwidth for a queue. A queue configured with the guaranteed minimum bandwidth ensures that the bandwidth for this queue is not smaller than the configured value. A queue configured with the limited maximum bandwidth ensures that the bandwidth for this queue is not greater than the configured value and packets out of the bandwidth limit will be discarded. The bandwidth limits for unicast and multicast queues are configured together on some products whereas configured separately on some other products. In addition, some products allow for configuring bandwidth only for unicast queues.

Related Configuration

📌 Configuring CoS-to-Queue Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the queues 1, 2, 3, 4, 5, 6, 7 and 8 respectively.

Run the **priority-queue cos-map** command to configure the CoS-to-queue mapping. The CoS value ranges from 0 to 7 and the queue value ranges from 1 to 8.

📌 Configuring the scheduling policy for an output queue

By default, the scheduling policy for a global output queue is WRR and no scheduling policy is configured for an interface.

Run the **mls qos scheduler** command to configure the output scheduling policy for a queue. Configurable scheduling policies include SP, WRR and DRR. You can also run the **priority-queue** command to configure the scheduling policy as SP.

📌 Configuring the round robin weight corresponding to the WRR scheduling policy for an output queue

By default, the weight of a global or interface-based queue is 1:1:1:1:1:1:1:1.

Run the **wrr-queue bandwidth** command to configure the round robin weight corresponding to the WRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means longer output time.

📌 Configuring the round robin weight corresponding to the DRR scheduling policy for an output queue

By default, the weight of a global or interface-based queue is 1:1:1:1:1:1:1:1.

Run the **rrr-queue bandwidth** command to configure the round robin weight corresponding to the DRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

✚ Configuring CoS-to-MC-Queue Map

By default, the CoS-to-multicast queue mapping is determined by products.

Run the **qos mc-queue cos-map** command to configure the CoS-to-multicast queue mapping. The CoS value ranges from 0 to 7 and the multicast queue value range is determined by products.

✚ Configuring the scheduling policy for a multicast output queue

By default, the scheduling policy for a multicast output queue is WRR.

Run the **qos mc-queue scheduler mode** command to configure the output scheduling policy for a multicast queue. The configurable scheduling policies include SP and WRR.

✚ Configuring the round robin weight corresponding to the WRR scheduling policy for a multicast output queue

By default, the weight for each queue is 1:1.

Run the **qos mc-queue scheduler weight** command to configure the round robin weight corresponding to the WRR scheduling policy for a multicast output queue. The configurable weight range is determined by products.

A higher weight means longer output time.

✚ Configuring the bandwidth for a queue

Run the **qos queue** command to configure the guaranteed minimum bandwidth and the limited maximum bandwidth for each queue. The queue value ranges from 1 to 8 and the guaranteed minimum bandwidth and limited maximum bandwidth value ranges are determined by products. Supported queue types (unicast, multicast, or both unicast and multicast) are determined by products.

2.3.5 Congestion Mitigation

Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

Working Principle

Mitigate congestion by effectively monitoring the network traffic and forecasting occurrence of congestion. Packets need to be discarded to mitigate congestion. Discarding policies include Tail-Drop, Random Early Detection (RED), and Weighted Random Early Detection (WRED).

✚ Tail-Drop

Traditional packet loss policies include Tail-Drop. Tail-Drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue will be discarded until the congestion is removed.

✚ RED and WRED

Hosts running TCP will decrease the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. In this way, Tail-Drop may cause TCP Global Synchronization. When a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion mitigation and slow startup state simultaneously, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks may appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest quantity and the highest quantity. When TCP global synchronization occurs, the connection bandwidth cannot be adequately used, which causes bandwidth waste.

To avoid this circumstance, you can use the RED/WRED packet discarding policy. This policy provides a mechanism for discarding packets in random, which avoids TCP global synchronization. When packets of a TCP connection are discarded and sent at a lower rate, packets of other TCP connections are still sent at higher rates. In this way, there are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

When WRED is used, you can set the lower threshold value and maximum discarding probability for a queue. When the queue length is smaller than the lower threshold value (value range: 1 to 100), WRED does not discard packets. When the queue length is between the higher (100) and lower threshold values, WRED discards packets in random (the longer the queue length, the higher probability of packet discarding. There is a maximum discarding probability). When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special example of WRED. When all CoS values of an interface are mapped to the same lower and higher threshold values, WRED becomes RED.

Related Configuration

✚ Enabling the WRED function

The default packet discarding policy is Tail-Drop.

You can run the **queueing wred** command to enable the WRED function.

✚ Configuring the lower threshold value

When 2 groups of lower threshold values are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect min-threshold** command to configure the lower threshold values for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The lower threshold value ranges from 1 to 100.

When the queue length is smaller than the lower threshold value, WRED does not discard packets. When the queue length is between the lower and higher threshold values, WRED discards packets in random.

✚ Configuring the maximum discarding probability

When 2 groups of maximum discarding probabilities are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect probability** command to configure the maximum discarding probabilities for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The maximum discarding probability ranges from 1 to 100.

When the queue length is between the lower and higher threshold values, WRED discards packets in random. The longer the queue, the higher the discarding probability. The maximum discarding probability cannot be exceeded. When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

📌 Configuring the CoS-to-threshold mapping

By default, all CoS values are mapped to the first group of threshold values (the number of threshold groups is determined by products).

In the interface configuration mode, you can run the **wrr-queue cos-map** command to configure the CoS-to-threshold group mapping. The CoS value ranges from 0 to 7 and the number of threshold groups is determined by products. Multiple groups of lower threshold values and maximum discarding probabilities can be configured. By configuring the CoS-to-threshold group mapping, you can select the effective threshold group mapped to a CoS value, for example, CoS 0 mapped to the first threshold group, and CoS 1 mapped to the second threshold group. If the packets of CoS 0 and 1 are added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold values and maximum discarding probabilities in the first group and the packets of CoS 1 are processed based on the lower threshold values and maximum discarding probabilities of the second group.

When all CoS values of an interface are mapped to the same group of threshold values, the enabled WRED becomes RED.

2.4 Configuration

Configuration	Description and Command	
Configuring Stream Classification	⚠️ (Optional) It is used to create stream classification information.	
	class-map	Creates a class.
	match access-group	Matches ACL rules.
	match ip precedence	Matches the PRE priorities of IP packets.
	match ip dscp	Matches the DSCP priorities of IP packets.
	policy-map	Creates a policy.
	class	Associates a class.
	police	Binds the bandwidth limit for streams and the action for processing packets out of the limit.
	set	Binds the behaviors for modifying the CoS, DSCP and VID values of streams.
	virtual-group	Creates a logical interface group and adds interfaces to the logical interface group.
	service-policy	Applies a policy to an interface.
Configuring Priority Labeling and Mapping for Packets	⚠️ (Optional) It is used to configure the trust mode, default CoS value and various mappings for an interface.	
	mls qos trust	Modifies the trust mode of an interface.

Configuration	Description and Command	
	mls qos cos	Modifies the default CoS value of the interface.
	mls qos map cos-dscp	Configures the CoS-to-DSCP mapping.
	mls qos map dscp-cos	Configures the DSCP-to-CoS mapping.
	mls qos map ip-precedence-dscp	Configures the IP PRE-to-DSCP mapping.
Configuring Interface Rate Limit	 (Optional) It is used to configure the rate limit for an interface.	
	rate-limit	Configures the traffic limit for an interface.
Configuring Congestion Management	 (Optional) It is used to configure the CoS-to-queue mapping, queue scheduling policies and round robin weight.	
	priority-queue cos-map	Configures the CoS-to-queue mapping.
	priority-queue	Configures the output scheduling policy for a queue to SP.
	mls qos scheduler	Configures the output scheduling policy for a queue.
	wrr-queue bandwidth	Configures the round robin weight corresponding to the WRR scheduling policy for an output queue.
	drr-queue bandwidth	Configures the round robin weight corresponding to the DRR scheduling policy for an output queue.
	qos mc-queue cos-map	Configures the CoS-to-multicast queue mapping.
	qos mc-queue scheduler mode	Configures the output scheduling policy for a multicast queue.
	qos mc-queue scheduler weight	Configures the round robin weight corresponding to the WRR scheduling policy for a multicast output queue.
	qos queue	Configures the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.
Configuring Congestion Mitigation	 (Optional) It is used to prevent network congestion by setting packet discarding.	
	queueing wred	Enables the WRED function.
	wrr-queue random-detect min-threshold	Configures the lower threshold value for packets discarded by WRED.
	wrr-queue random-detect probability	Configures the maximum discarding probability for packets discarded by WRED.
	wrr-queue cos-map	Configures the threshold-to-CoS mapping.

2.4.1 Configuring Stream Classification

Configuration Effect

- Create a class and match classification rules.
- Create a policy, bind a class and stream behaviors, and associate with an interface.

Notes

- The class and policy names cannot comprise more than 31 characters.
- Interface configurations allow for only AP and Ethernet interface configurations. Certain products support policies applied to SVI interfaces through the **service-policy** command. When both physical interfaces and SVI interfaces are configured with policies, the priority of the physical interfaces is higher than that of the SVI interfaces.

Configuration Steps

📄 Creating a class and matching ACL rules

- Optional.
- Create a class. In the class configuration mode, match ACL, IP PRE or DSCP.

📄 Creating a policy

- Optional.
- Create a policy. In the policy configuration mode, bind the class and stream behaviors.

📄 Creating a logical interface group and adding interfaces to the logical interface group

- Optional.
- Create a logical interface group and add interfaces to the logical interface group.

📄 Applying a policy to an interface

- Optional.
- Associate a configured policy with a specified interface or logical interface group.

Verification

- Run the **show class-map** command to check whether the class is successfully created and whether rules are successfully matched.
- Run the **show policy-map** command to check whether the policy is successfully created and whether the class and stream behaviors are successfully bound.
- Run the **show mls qos interface** command to check whether the interface is associated with the policy.
- Run the **show virtual-group** command to check the interfaces in the logical interface group.

- Run the **show mls qos virtual-group** command to check whether the logical interface group is associated with the policy.

Related Commands

📌 Creating a class

Command	class-map <i>class-map-name</i>
Parameter Description	<i>class-map-name</i> : Indicates the name of a class to be created. The name cannot comprise more than 31 characters.
Command Mode	Global configuration mode
Usage Guide	-

📌 Matching an ACL

Command	match access-group <i>access-list-number</i>
Parameter Description	<i>access-list-number</i> : Indicates the number of the ACL to be matched.
Command Mode	Class configuration mode
Usage Guide	-

📌 Matching PRE of IP packets

Command	match ip precedence <i>precedence-value... [precedence-value...]</i>
Parameter Description	<i>precedence -value</i> : Indicates the IP PRE to be matched, ranging from 0 to 7.
Command Mode	Class configuration mode
Usage Guide	-

📌 Matching DSCP of IP packets

Command	match ip dscp <i>dscp-value... [dscp-value...]</i>
Parameter Description	<i>dscp -value</i> : Indicates the DSCP to be matched, ranging from 0 to 63.
Command Mode	Class configuration mode
Usage Guide	-

📌 Creating a policy

Command	policy-map <i>policy-map-name</i>
Parameter Description	<i>policy-map-name</i> : Indicates the name of a policy to be created. The name cannot comprise more than 31 characters.

Command Mode	Global configuration mode
Usage Guide	-

✚ Associating a class

Command	class <i>class-map-name</i>
Parameter Description	<i>class-map-name</i> : Indicates the name of a class to be associated.
Command Mode	Policy configuration mode
Usage Guide	-

✚ Binding the behaviors for modifying the CoS and DSCP values of streams

Command	set { ip dscp <i>new-dscp</i> cos <i>new-cos</i> [none-tos] }
Parameter Description	ip dscp <i>new-dscp</i> : Changes the DSCP value of streams to <i>new-dscp</i> , ranging from 0 to 63. cos <i>new-cos</i> : Changes the CoS value of streams to <i>new-cos</i> , ranging from 0 to 7. none-tos : Does not change the DSCP value of packets when changing the CoS value of the packets.
Command Mode	Class configuration mode
Usage Guide	-

✚ Binding the bandwidth limit for streams and the action for processing packets out of the limit

Command	police <i>rate-bps burst-byte</i> [exceed-action { drop dscp <i>new-dscp</i> cos <i>new-cos</i> [none-tos] }]
Parameter Description	<i>rate-bps</i> : Indicates the bandwidth limit per second (KBits). The value range is determined by products. <i>burst-byte</i> : Indicates the burst traffic limit (Kbytes). The value range is determined by products. drop : Discards packets out of the bandwidth limit. dscp <i>new-dscp</i> : Changes the DSCP value of packets out of the bandwidth limit to <i>new-dscp</i> , ranging from 0 to 63. cos <i>new-cos</i> : Changes the CoS value of packets out of the bandwidth limit to <i>new-cos</i> , ranging from 0 to 7. none-tos : Does not change the DSCP value of packets when changing the CoS value of the packets.
Command Mode	Class configuration mode
Usage Guide	-

✚ Creating a logical interface group and adding interfaces to the logical interface group

Command	virtual-group <i>virtual-group-number</i>
Parameter Description	<i>virtual-group-number</i> : Indicates the logical interface group number, ranging from 1 to 128.
Command	Create the logical interface group in the global configuration mode, add the interface to the logical interface

Mode	group in the interface configuration mode. If no logical interface group exists, you need to create a logical interface group first and then add interfaces to the logical interface group.
Usage Guide	-

📌 Applying a policy to an interface

Command	service-policy { input output } <i>policy-map-name</i>
Parameter	input: Indicates the input direction of the interface.
Description	output: Indicates the output direction of the interface. <i>policy-map-name</i> : Indicates the name of the policy applied to the interface.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

📌 Creating four stream classes and matching ACL, IP PRE and DSCP

Configuration Steps	● Create ACL rules. ● Create four stream classes and match ACL, IP PRE and DSCP.
	<pre>Ruijie# configure terminal Ruijie(config)# access-list 11 permit host 192.168.23.61</pre>
	<pre>Ruijie(config)# class-map cmap1 Ruijie(config-cmap)# match access-group 11 Ruijie(config-cmap)# exit Ruijie(config)# class-map cmap2 Ruijie(config-cmap)# match ip dscp 21 Ruijie(config-cmap)# exit Ruijie(config)# class-map cmap3 Ruijie(config-cmap)# match ip precedence 5 Ruijie(config-cmap)# exit</pre>
Verification	● Check whether the created ACL rules and stream class rules are successful.
	<pre>Ruijie# show access-lists ip access-list standard 11 10 permit host 192.168.23.61</pre>
	<pre>Ruijie# show class-map</pre>

```

Class Map cmap1

  Match access-group 11

Class Map cmap2

  Match ip dscp 21

Class Map cmap3

  Match ip precedence 5

```

📌 Creating a policy, binding a class and stream behaviors, and associating with an interface

Configuration Steps

- Create the stream class cmap1, and match packets whose DSCP value is 18. Create cmap2 and match packets whose IP PRE is 7.
- Create the policy pmap1, associate the policy with cmap1, and bind the behavior of changing the CoS value of the stream to 6. Associate the policy with cmap2, bind the behavior of changing the DSCP value of the stream to 16, limiting the traffic per second within 10,000 Kbits and trigger traffic within 1024 Kbits per second, and changing the DSCP value for traffic out of limit to 7.
- Apply the policy pmap1 to the output direction of the interface gigabitEthernet 0/0.
- Create virtual logical group 1, add the interfaces gigabitEthernet 0/1 and gigabitEthernet 0/2 to the group, and apply the policy pmap1 to the input interface of the virtual logical group.

```

Ruijie# configure terminal
Ruijie(config)# class-map cmap1
Ruijie(config-cmap)# match ip dscp 18
Ruijie(config-cmap)# exit
Ruijie(config)# class-map cmap2
Ruijie(config-cmap)# match ip precedence 7
Ruijie(config-cmap)# exit

```

```

Ruijie(config)# policy-map pmap1
Ruijie(config-pmap)# class cmap1
Ruijie(config-pmap-c)# set cos 6
Ruijie(config-pmap-c)# exit
Ruijie(config-cmap)# class cmap2
Ruijie(config-pmap-c)# set ip dscp 15
Ruijie(config-pmap-c)# police 10000 1024 exceed-action dscp 7
Ruijie(config-pmap-c)# exit
Ruijie(config-pmap)# exit

```

	<pre> Ruijie(config)# interface gigabitEthernet 0/0 Ruijie(config-if-GigabitEthernet 0/0)# service-policy output pmap1 Ruijie(config-if-GigabitEthernet 0/0)# exit </pre>
	<pre> Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# virtual-group 1 Ruijie(config-if-GigabitEthernet 0/1)# exit Ruijie(config)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# virtual-group 1 Ruijie(config-if-GigabitEthernet 0/2)# exit Ruijie(config)# virtual-group 1 Ruijie(config-VirtualGroup)# service-policy input pmap1 Ruijie(config-VirtualGroup)# exit </pre>
Verification	● Check whether the stream class rules are successfully created. ● Check whether the policy is successfully created, and whether the stream and stream behaviors are successfully bound. ● Check whether the policy is applied to the interface. ● Check whether the logical interface group is successfully created, whether interfaces are successfully associated and whether the policy is successfully applied to the interface.
	<pre> Ruijie# show class-map Class Map cmap1 Match ip dscp 18 Class Map cmap2 Match ip precedence 7 </pre>
	<pre> Ruijie# show policy-map Policy Map pmap1 Class cmap1 set cos 6 Class cmap2 set ip dscp 15 police 10000 1024 exceed-action dscp 7 </pre>
	<pre> Ruijie# show mls qos interface gigabitEthernet 0/0 </pre>

	<pre> Interface: GigabitEthernet 0/0 Ratelimit input: Ratelimit output: Attached input policy-map: Attached output policy-map: pmap1 Default trust: none Default cos: 0 </pre>
	<pre> Ruijie# show virtual-group 1 virtual-group member ----- 1 Gi0/1 Gi0/2 Ruijie# show mls qos virtual-group 1 Virtual-group: 1 Attached input policy-map: pmap1 </pre>

2.4.2 Configuring Priority Labeling and Mapping for Packets

Configuration Effect

- Configure the trust mode and default CoS value of an interface.
- Configure the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

📌 Configuring the trust mode and default CoS value of an interface

- Optional.
- In the interface configuration mode, configure the trust mode and default CoS value of an interface.

📌 Configuring the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings

- Optional.
- Configure various mappings.

Verification

- Run the **show mls qos interface** command to display the trust mode and default CoS value of the interface.

- Run the **show mls qos maps** command to display the CoS-to-DSCP, DSCP-to-CoS and IP-PRE-to-DSCP mappings.

Related Commands

↘ Configuring the trust mode of an interface

Command	mls qos trust { cos ip-precedence dscp }
Parameter	cos: Configures the trust mode of an interface to CoS.
Description	ip-precedence: Configures the trust mode of an interface to IP PRE. dscp: Configures the trust mode of an interface to DSCP.
Command Mode	Interface configuration mode
Usage Guide	-

↘ Configuring the default CoS value of an interface

Command	mls qos cos default-cos
Parameter	default-cos: Configures the default CoS value, ranging from 0 to 7. The default value is 0.
Description	
Command Mode	Interface configuration mode
Usage Guide	-

↘ Configuring CoS-to-DSCP MAP

Command	mls qos map cos-dscp dscp1...dscp8
Parameter	dscp1...dscp8: Indicates the DSCP values mapped to the CoS values. The default CoS values 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Description	
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring DSCP-to-CoS MAP

Command	mls qos map dscp-cos dscp-list to cos
Parameter	dscp-list: Indicates the DSCP list mapped to the CoS values. The default DSCP 0~7 are mapped to CoS 0, DSCP 8~15 mapped to CoS 1, DSCP 16~23 mapped to CoS 2, DSCP 24~31 mapped to CoS 3, DSCP 32~39 mapped to CoS 4, DSCP 40~47 mapped to CoS 5, DSCP 48~55 mapped to CoS 6, and DSCP 56~63 mapped to CoS 7. The DSCP value ranges from 0 to 63.
Description	cos: Indicates the CoS values mapped to the dscp-list, ranging from 0 to 7.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring IP-PRE-to-DSCP MAP

Command	mls qos map ip-prec-dscp dscp1...dscp8
Parameter Description	<i>dscp1...dscp8</i> : Indicates the DSCP values mapped to the IP PRE values. The default IP PRE 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

Configuring the trust mode and default CoS value of an interface

Configuration Steps	- Modify the trust mode of the interface gigabitEthernet 0/0 to DSCP. - Change the default CoS value of the interface gigabitEthernet 0/1 to 7.
	<pre> Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/0 Ruijie(config-if-GigabitEthernet 0/0)# mls qos trust dscp Ruijie(config-if-GigabitEthernet 0/0)# exit Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# mls qos cos 7 Ruijie(config-if-GigabitEthernet 0/1)# exit </pre>
Verification	Check whether the trust mode and default CoS value are successfully configured for the interface.
	<pre> Ruijie# show mls qos interface gigabitEthernet 0/0 Interface: GigabitEthernet 0/0 Ratelimit input: Ratelimit output: Attached input policy-map: Attached output policy-map: Default trust: dscp Default cos: 0 Ruijie# show mls qos interface gigabitEthernet 0/1 Interface: GigabitEthernet 0/1 Ratelimit input: Ratelimit output: Attached input policy-map: </pre>

Attached output policy-map:

Default trust: none

Default cos: 7

📌 Configuring the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings

Configuration Steps	● Configure CoS-to-DSCP to map CoS 0, 1, 2, 3, 4, 5, 6, and 7 to DSCP 7, 14, 21, 28, 35, 42, 49, and 56 respectively. ● Configure DSCP-to-CoS to map DSCP 0, 1, 2, 3, and 4 to CoS 4 and DSCP 11, 12, 13 and 14 to CoS 7. ● Configure IP-PRE-to-DSCP to map IP PRE 0, 1, 2, 3, 4, 5, 6, and 7 to DSCP 31, 26, 21, 15, 19, 45, 47, and 61 respectively.
	<pre>Ruijie# configure terminal Ruijie(config)# mls qos map cos-dscp 7 14 21 28 35 42 49 56</pre>
	<pre>Ruijie(config)# mls qos map dscp-cos 0 1 2 3 4 to 4 Ruijie(config)# mls qos map dscp-cos 11 12 13 14 to 7</pre>
	<pre>Ruijie(config)# mls qos map ip-precedence-dscp 31 26 21 15 19 45 47 61</pre>
Verification	● Check whether all mappings are successfully configured.
	<pre>Ruijie# show mls qos maps cos-dscp cos dscp ---- 0 7 1 14 2 21 3 28 4 35 5 42 6 49 7 56</pre>

2.4.3 Configuring Interface Rate Limit

Configuration Effect

- Configure the traffic limit for an interface.

Notes

- The configuration is supported only by Ethernet interfaces.

Configuration Steps

📌 Configuring the traffic limit for an interface

- Optional.
- Configure the limit on the traffic and burst traffic for an interface.

Verification

- Run the **show mls qos rate-limit** command to display the rate limit information about the interface.

Related Commands

📌 Configuring the traffic limit for an interface

Command	rate-limit { input output } <i>bps</i> <i>burst-size</i>
Parameter Description	input: Indicates the input direction of the interface. output: Indicates the output direction of the interface. <i>bps:</i> Indicates the bandwidth limit per second (Kbits). The value range is determined by products. <i>burst-size:</i> Indicates the burst traffic limit (Kbytes). The value range is determined by products.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

📌 Typical application – Interface rate limit + priority relabeling

Configuration Steps	● For Internet access by using the output interface, configure the output traffic limit on the interface G0/24, and set the bandwidth limit to 102,400 Kbits per second and burst traffic limit to 256 Kbytes per second. ● For the dormitory building, configure the input traffic limit on the interface G0/3, and set the bandwidth limit to 51,200 Kbits per second and burst traffic limit to 256 Kbytes per second. ● For the teaching building, configure the input traffic limit on the interface G0/1, and set the bandwidth limit to 30,720 Kbits per second and burst traffic limit to 256 Kbytes per second. ● For the laboratory, create the class cmap_dscp7 to match DSCP priority 7, create the policy pmap_shiyan to associate with cmap_dscp7, bind the stream behavior of changing the DSCP value for packets whose rates exceed 20M to 16, apply pmap_shiyan to the interface G0/2, and configure the interface to trusting DSCP.
	<pre>Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/24</pre>

	<pre> Ruijie(config-if-GigabitEthernet 0/24# rate-limit output 102400 256 Ruijie(config-if-GigabitEthernet 0/24)# exit Ruijie(config)# interface gigabitEthernet 0/3 Ruijie(config-if-GigabitEthernet 0/3# rate-limit input 51200 256 Ruijie(config-if-GigabitEthernet 0/3)# exit Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1# rate-limit input 30720 256 Ruijie(config-if-GigabitEthernet 0/1)# exit </pre>
	<pre> Ruijie(config)# class-map cmap_dscp7 Ruijie(config-cmap)# match ip dscp 7 Ruijie(config-cmap)# exit Ruijie(config)# policy-map pmap_shiyan Ruijie(config-pmap)# class cmap_dscp7 Ruijie(config-pmap-c)# police 20480 128 exceed-action dscp 16 Ruijie(config-pmap-c)# exit Ruijie(config-pmap)# exit Ruijie(config)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2# service-policy input pmap_shiyan Ruijie(config-if-GigabitEthernet 0/2)# mls qos trust dscp Ruijie(config-if-GigabitEthernet 0/2)# exit </pre>
Verification	● Check whether the interface rate limit is successfully configured. ● Check whether the class and policy are successfully created and successfully applied to the interface.
	<pre> Ruijie# show mls qos rate-limit Interface: GigabitEthernet 0/1 rate limit input Kbps = 30720 burst = 256 Interface: GigabitEthernet 0/3 rate limit input Kbps = 51200 burst = 256 Interface: GigabitEthernet 0/24 rate limit output Kbps = 102400 burst = 256 </pre>
	<pre> Ruijie# show class-map cmap_dscp7 </pre>

```
Class Map cmap_dscp7
  Match ip dscp 7
Ruijie# show policy-map pmap_shiyan

Policy Map pmap_shiyan
  Class cmap_dscp7
    police 20480 128 exceed-action dscp 16
Ruijie# show mls qos interface gigabitEthernet 0/2
Interface: GigabitEthernet 0/2
Ratelimit input:
Ratelimit output:
Attached input  policy-map: pmap_shiyan
Attached output policy-map:
Default trust: dscp
Default cos: 0
```

2.4.4 Configuring Congestion Management

Configuration Effect

- Configure the CoS-to-queue mapping.
- Configure the scheduling policy and round robin weight for an output queue.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

📌 Configuring the CoS-to-unicast and CoS-to-multicast mappings

- Optional.
- Configure the CoS-to-queue mappings. On products supporting multicast queues, you can configure the CoS-to-multicast queue mapping.

📌 Configuring the scheduling policies and round robin weight for unicast and multicast output queues

- Optional.

- Configure the scheduling policy for an output queue and modify the round robin weight. On products supporting multicast queues, you can configure the scheduling policies and round robin weights for multicast queues.

✚ Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

- Optional.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Verification

- Run the **show mls qos queueing** command to display the output queue information.
- Run the **show mls qos scheduler** command to display the scheduling policy for the output queue.
- Run the **show qos mc-queue scheduler** command to display the scheduling policy for the multicast queue.
- Run the **show qos bandwidth** command to display the queue bandwidth.

Related Commands

✚ Configuring CoS-to-Queue MAP

Command	priority-queue cos-map <i>qid</i> <i>cos0</i> [<i>cos1</i> [<i>cos2</i> [<i>cos3</i> [<i>cos4</i> [<i>cos5</i> [<i>cos6</i> [<i>cos7</i>]]]]]]]]
Parameter	<i>qid</i> : Indicates the queue ID to be mapped, ranging from 1 to 8.
Description	<i>cos0~cos7</i> : Indicates the CoS values to be mapped to the qid. The default CoS values 0~7 are mapped to queues 1~8. The value range is 0 to 7.
Command Mode	Global configuration mode
Usage Guide	-

✚ Configuring the scheduling policy for an output queue to SP

Command	priority-queue
Parameter	-
Description	
Command Mode	Global configuration mode
Usage Guide	-

✚ Configuring the scheduling policy for an output queue

Command	mls qos scheduler { sp wrr drr }
Parameter	sp : Sets the scheduling algorithm for an output queue to SP.
Description	wrr : Sets the scheduling algorithm for an output queue to WRR. drr : Sets the scheduling algorithm for an output queue to DRR.
Command Mode	Global/Interface configuration mode

Usage Guide	-

✚ Configuring the scheduling policy and round robin weight for an output queue

Command	{ drr-queue wrr-queue } bandwidth weight1...weight8
Parameter Description	drr-queue: Configures the round robin weight corresponding to the DRR scheduling policy for an output queue. wrr-queue: Configures the round robin weight corresponding to the WRR scheduling policy for an output queue. weight1...weight8: Indicates the weight of queues 1 to 8. The value range is determined by products. The value 0 indicates that the queue uses the SP scheduling algorithm. The default weight for global/interface queues is 1:1.
Command Mode	Global/Interface configuration mode
Usage Guide	-

✚ Configuring CoS-to-Queue MAP for multicast queues

Command	qos mc-queue cos-map cos0-qid...cos7-qid
Parameter Description	cosN-qid: Indicates the queue ID to be mapped by CoS N. The specific number of multicast queues is determined by products. The default value is determined by products.
Command Mode	Global/Interface configuration mode
Usage Guide	-

✚ Configuring the output scheduling policy for a multicast queue

Command	qos mc-queue scheduler mode { sp wrr }
Parameter Description	sp: Sets the scheduling policy for an interface to SP. wrr: Sets the scheduling algorithm for an output queue to WRR.
Command Mode	Global/Interface configuration interface, determined by products.
Usage Guide	-

✚ Configuring the round robin weight corresponding to the WRR scheduling policy for a multicast output queue

Command	qos mc-queue scheduler weight weight1 weight2 [weight3 [weight4 [weight5 [weight6 [weight7 [weight8]]]]]]]]
Parameter Description	weightN: Indicates the specific number of multicast queues, which is determined by products. The maximum value is 8. The value range is determined by products. The value 0 indicates that the queue uses the SP scheduling algorithm. The default weight for all queues is 1:1.
Command Mode	Global/Interface configuration interface, determined by products.
Usage Guide	-

➤ Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

Command	qos queue [ucast mcast] queue-id bandwidth { minimum maximum } bandwidth
Parameter Description	queue [ucast mcast]: queue ucast configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring the unicast queue bandwidth limit; queue mcast configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring the multicast queue bandwidth limit; queue configures the guaranteed minimum bandwidth or limited maximum bandwidth for devices that allow for configuring both the unicast and multicast queue bandwidth limits. queue-id: Indicates the queue ID to be configured, ranging from 1 to 8. minimum bandwidth: Indicates the guaranteed minimum bandwidth Kbps. The value range is determined by products. It is not configured by default. maximum bandwidth: Indicates the limited maximum bandwidth Kbps. The value range is determined by products. It is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

➤ Configuring the CoS-to-queue mapping and modifying the scheduling policy and its round robin weight

Configuration Steps	- Configure the CoS-to-queue mapping to the mapping from the CoS values 0, 1, 2, 3, 4, 5, 6, and 7 to queues 1, 2, 5, 5, 5, 5, 7, and 8. - Configure the output scheduling policy for a queue to DRR and the round robin weight to 2:1:1:1:6:6:6:8.
	<pre> Ruijie# configure terminal Ruijie(config)# priority-queue cos-map 5 2 3 4 5 Ruijie(config)# mls qos scheduler drr Ruijie(config)# drr-queue bandwidth 2 1 1 1 6 6 6 8 </pre>
Verification	Check whether the CoS-to-queue mapping is successfully created, and whether the output scheduling policy and round robin weight are successfully configured for the queue.
	<pre> Ruijie# show mls qos scheduler Global Multi-Layer Switching scheduling Deficit Round Robin Ruijie# show mls qos queueing CoS-to-queue map: cos qid </pre>

✎ Configuring the CoS-to-queue mapping for multicast queues and modifying the scheduling policy and its round robin weight (Assuming that the multicast is supported and the number of multicast queues is 3)

Configuration Steps	- Configure the CoS-to-queue mapping for multicast queues to the mapping from the CoS values 0, 1, 2, 3, 4, 5, 6, and 7 to queues 1, 1, 2, 2, 2, 2, 3, and 3. - For products supporting global multicast queues, configure the output scheduling policy to WRR and the round robin weight to 1:2:2 for global multicast queues. - For products supporting interface multicast queues, configure the output scheduling policy to WRR and the round robin weight to 1:2:4 for the gigabitEthernet 0/1 multicast queues.
	<pre>Ruijie# configure terminal Ruijie(config)# qos mc-queue cos-map 1 1 2 2 2 2 3 3</pre>
	<pre>Ruijie(config)# qos mc-queue scheduler mode wrr Ruijie(config)# qos mc-queue scheduler weight 1 2 2</pre>
	<pre>Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# qos mc-queue scheduler mode wrr Ruijie(config-if-GigabitEthernet 0/1)# qos mc-queue scheduler weight 1 2 4 Ruijie(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	- Check whether the CoS-to-queue is successfully configured for multicast queues. - For products supporting global multicast queues, check whether the scheduling policy and round robin weight are successfully configured for the global output queues. - For products supporting interface multicast queues, check whether the scheduling policy and round robin weight are successfully configured for the interface output queues.
	<pre>Ruijie# show qos mc-queue cos-map Cos to multicast queue map: Cos Queue id ----- - 0 1 1 1 2 2</pre>

	<pre> 3 2 4 2 5 2 6 3 7 3 </pre>

📌 **Taking products that support separate configuration of unicast and multicast queues for example and configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue**

Configuration Steps	Configure the limited maximum bandwidth to 10M and guaranteed minimum bandwidth to 5M for unicast queue 1 on the interface gigabitEthernet 0/1. Configure the guaranteed minimum bandwidth to 2M for unicast queue 2. Configure the limited maximum bandwidth to 5M and guaranteed minimum bandwidth to 1M for multicast queue 1.
	<pre> Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# qos queue ucast 1 bandwidth maximum 10240 Ruijie(config-if-GigabitEthernet 0/1)# qos queue ucast 1 bandwidth minimum 5120 </pre>

	<pre> Ruijie(config-if-GigabitEthernet 0/1)# qos queue ucast 2 bandwidth minimum 2048 Ruijie(config-if-GigabitEthernet 0/1)# qos queue mcast 1 bandwidth maximum 5120 Ruijie(config-if-GigabitEthernet 0/1)# qos queue mcast 1 bandwidth minimum 1024 Ruijie(config-if-GigabitEthernet 0/1)# exit </pre>
Verification	Check whether the guaranteed minimum bandwidth and limited maximum bandwidth are successfully configured for the interface.
	<pre> Ruijie# show qos bandwidth interface gigabitEthernet 0/1 Interface: GigabitEthernet 0/1 ----- uc-queue-id minimum-bandwidth maximum-bandwidth ----- 1 5120 10240 2 0 0 3 0 0 4 0 0 5 0 0 6 0 0 7 0 0 8 0 0 Total ucast-queue minimum-bandwidth: 5120 Total ucast-queue maximum-bandwidth: 10240 Interface: GigabitEthernet 0/1 ----- mc-queue-id minimum-bandwidth maximum-bandwidth ----- 1 1024 5120 2 0 0 3 0 0 </pre>

	4	0	2048

	Total mcast-queue minimum-bandwidth:		1024
	Total mcast-queue maximum-bandwidth:		5120

▢ Typical application – Priority relabeling + queue scheduling

Configuration Steps	● Create ACLs for accessing various servers and create classes for matching these ACLs. ● Create policies for associating with the classes and specify new CoS values for packets accessing various servers. Associate the CoS values with the input interfaces for the R&D and market departments and configure the interfaces to trusting CoS. ● Configure the default CoS value for the HR management department interface to the highest priority 7 to ensure that packets from the HR management department are sent in the highest priority. ● Configure the output scheduling policy to WR and the round robin weight to 1:1:1:2:6:1:1:0 for the queues. This means that the SP scheduling algorithm is used for packets of the HR management department, and the packets of the R&D and market departments for accessing the mail database, file database and salary query database are scheduled based on the ratio of 6:2:1.
	<pre> Ruijie# configure terminal Ruijie(config)# ip access-list extended salary Ruijie(config-ext-nacl)# permit ip any host 192.168.10.1 Ruijie(config-ext-nacl)# exit Ruijie(config)# ip access-list extended mail Ruijie(config-ext-nacl)# permit ip any host 192.168.10.2 Ruijie(config-ext-nacl)# exit Ruijie(config)# ip access-list extended file Ruijie(config-ext-nacl)# permit ip any host 192.168.10.3 Ruijie(config-ext-nacl)# exit </pre>

2.4.5 Configuring Congestion Mitigation

Configuration Effect

- Configure the lower threshold value for WRED. When the length of packets in a queue is smaller than the lower threshold value, WRED does not discard packets.

- Configure the maximum discarding probability. When the length of packets in the queue is between the lower and higher threshold values, WRED discards packets in random. The maximum probability for discarding packets is configured.
- Configure the CoS-to-threshold mapping.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

▾ Enabling the WRED function

- Optional.
- Enable the WRED function if necessary.

▾ Configuring the lower threshold value

- Optional.
- Configure the lower threshold value if necessary.

▾ Configuring the maximum discarding probability

- Optional.
- Configure the maximum discarding probability if necessary.

▾ Configuring the CoS-to-threshold mapping

- Optional.
- Configure the CoS-to-threshold mapping if necessary.

Verification

- Run the **show queueing wred interface** command to display the WRED configuration.

Related Commands

▾ Enabling the WRED function

Command	queueing wred
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

▾ Configuring the lower threshold value

Command	wrr-queue random-detect min-threshold <i>queue_id</i> <i>thr1</i> [<i>thr2</i>]
Parameter	<i>queue_id</i> : Indicates the queue ID for an interface, ranging from 1 to 8.
Description	<i>thrN</i> : Supports 2 groups of lower threshold values, ranging from 1 to 100.
Command Mode	Interface configuration mode
Usage Guide	-

✚ Configuring the maximum discarding probability

Command	wrr-queue random-detect probability <i>queue_id</i> <i>prob1</i> [<i>prob2</i>]
Parameter	<i>queue_id</i> : Indicates the queue ID for an interface, ranging from 1 to 8.
Description	<i>probN</i> : Supports 2 groups of maximum discarding probabilities, ranging from 1 to 100.
Command Mode	Interface configuration mode
Usage Guide	-

✚ Configuring the CoS-to-threshold mapping

Command	wrr-queue cos-map <i>threshold_id</i> <i>cos1</i> [<i>cos2</i> [<i>cos3</i> [<i>cos4</i> [<i>cos5</i> [<i>cos6</i> [<i>cos7</i> [<i>cos8</i>]]]]]]]]
Parameter	<i>threshold_id</i> : Indicates the threshold group ID, ranging from 1 to 2. Two threshold groups are supported.
Description	<i>cos1...cos8</i> : Indicates the CoS values to be mapped to the threshold group, ranging from 0 to 7. By default, all CoS values are mapped to the first threshold group.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

✚ Enabling the WRED function and configuring the lower threshold value, maximum discarding probability, and the CoS-to-threshold mappings (assuming that there are 2 groups of threshold values for a product)

Configuration Steps	● Enable the WRED function. ● Configure the lower threshold values for queue 2 of the interface gigabitEthernet 0/2 to 10 and 20. ● Configure the maximum discarding probabilities for queue 2 of the interface gigabitEthernet 0/2 to 60 and 80. ● Configure the CoS values 0, 1, 2, and 3 on the interface gigabitEthernet 0/2 to use the threshold group 2.
	<pre> Ruijie# configure terminal Ruijie(config)# queueing wred Ruijie(config)# interface gigabitEthernet 0/2 Ruijie(config-if-GigabitEthernet 0/2)# wrr-queue random-detect min-threshold 2 10 20 Ruijie(config-if-GigabitEthernet 0/2)# wrr-queue random-detect probability 2 60 80 </pre>

	Ruijie(config-if-GigabitEthernet 0/2)# wrr-queue cos-map 2 0 1 2 3
Verification	Check whether the WRED function is enabled, whether the threshold values are successfully configured, and whether the CoS-to-threshold mapping is successfully configured.

3 Configuring MMU

3.1 Overview

The Memory Management Unit (MMU) means that the chip buffer is distributed reasonably so that the switching equipment can better deal with all kinds of burst flows.

Flows not steady all the time and various burst flows exist on the network. When the network flow is steady and the bandwidth is sufficient, all the data flows are processed better; when burst flows exist on the network, data flows may be discarded even if the average flow rate does not exceed the bandwidth.

Data packets that enter the switching equipment are stored in the buffer of switching equipment before being forwarded. Normally, data packets stay for a short period of time in the buffer and will be forwarded in microseconds; when there is a burst flow, if the instantaneous rate of burst flow exceeds the processing capacity of the switching equipment, the data packets that cannot be processed in time will be piled up in the switching equipment and packet loss will take place once the buffer is insufficient. In this case, the MMU can be used to reasonably configure the buffer and allocate different buffer sizes to respective services, with a view to optimizing the network.

3.2 Applications

Application	Description
Configuring Large Buffer Application Based on Egress Queue	An enterprise needs a buffer large enough in the SkyDrive service to avoid packet loss for the service flow.
Configuring Large Buffer Application Based on Ingress PG	An enterprise needs to ensure no package loss in RDMA scenario. When the buffer reaches the threshold, PAUSE frame based on PFC mechanism should be generated to ensure no package loss.

3.2.1 Configuring Large Buffer Application Based on Egress Queue

Scenario

An enterprise needs a buffer large enough in the SkyDrive service to avoid packet loss for the service flow.

As shown in the following figure, equipment A is connected to 5 clients and 35 service servers, where 15 service servers virtualize 15 front end servers.

The main service flow is as follows:

- The client server sends a request packet to the front end server.
- The front end server sends the received request packet to the service server.
- After receiving the request packet, the service server sends a response packet to the front end server.
- After receiving the response packet, the front end server sends it to the client server.

- After receiving the response packet, the client indicates that a session is created successfully.

A many-to-one flow transmission mode exists under this service model:

- The request flows of multiple clients are sent to one front end server.
- The request flows of multiple front end servers are sent to one service server.
- The response flows of multiple service servers are sent to one front end server.
- The response flows of multiple front end servers are sent to one client.

These flows are transmitted through equipment A basically, easily leading to network congestion. Such a problem can be fixed by configuring a large buffer on the equipment.

Figure 3-1

Deployment

- In all the service ports (namely, the ports connecting clients to servers), configure the shared buffer of the queue where the service is as 100%.
- In all the service ports, configure the minimum value for the guaranteed buffer of the queue not in use.
- In all the ports not in use, configure the minimum value for the guaranteed buffers of all the queues.

 For the specific configuration, see the configuration examples in "Configuration".

3.2.2 Configuring Large Buffer Application Based on Ingress PG

Scenario

A large enterprise needs to ensure no package loss in the data center. There are three kinds of flow in the data center:

- Storage flow: no package loss.
- High-performance computing flow: low delay.

- Ethernet flow: package loss and delay are allowed.

The traditional data center implements three networks for different flows, as shown below:

As the center scale expands, Ethernet is applied to take three kinds of flow and more mechanism is added so that it can meet different requirements, and storage package will not lose and have no effect on other 2 flows based on PFC (Priority-based Flow Control) of ingress PG.

Deployment

- Map RDMA flow to a PG.
- Enable PFC on the PG to ensure no package loss of the flow.
- Configure xon/xoff threshold on the PG to generate flow control frame.
- For the PG not enabling PFC, the egress threshold should be lower than the ingress threshold. For the PG enabling PFC, the ingress threshold should be lower than the egress threshold.

i For more specific configuration, see Configuration Examples in Configuration.

3.3 Features

Basic Concepts

Cell

Cell is a buffer unit, i.e., the minimum unit for the switching equipment to store packets. The size of each cell varies with the product. One packet can use multiple cells, while one cell can be used by only one packet.

Port group

All the ports physically belonging to one switching chip are collectively called a port group, the buffer of switching equipment is managed in the port group. Take the board card M18000_40XS_CB as an example, this version has two switching chips, so there are two port groups. The first 20 ports belong to Port Group 1, and the back 20 ports belong to Port Group 2.

Egress queue

Port egress queues are classified into unicast queues and multicast queues (the number of queues depends on the product). Logically the switching chip is divided into the ingress (incoming direction) and egress (outgoing direction). The egress queue is in the egress direction. Before packets go out of the egress, the enqueue operation needs to be performed for them at the egress queue. Some of our products implement buffer management based on the egress queue.\

Figure 3-2

Currently there are three types of egress queue models:

- There are 8 unicast queues and 8 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are 8 unicast queues and 4 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are only 8 queues at the egress, without differentiating unicast and multicast.

Overview

Feature	Description
Buffer Adjustment	The buffer is adjusted based on the queue. It is the foundation of MMU.
Buffer Monitoring	Buffer monitoring actually means monitoring on the use of the buffer capacity, which facilitates buffer adjustment.
Queue Counting	The received and sent packets of each queue are counted so that the buffer adjustment result can be displayed easily.

3.3.1 Configuring Buffer Adjustment

Buffer adjustment means that the queue of each service has different buffer sizes through some adjustment of the queue buffer so that each service is treated differently and services at different priorities are served differently.

Working Principle

Working mechanism of caching in hardware

In terms of hardware, the buffer is managed in the input direction and output direction. The processing mechanism is shown below:

Figure 3-3

During buffer management, the input direction is adjusted to the maximum value to prevent packet loss in the input direction and make packet loss take place in the output direction. Therefore, adjustment is not opened for the buffer in the input direction, and CLI provides buffer adjustment in the output direction only, including the queue guaranteed buffer and queue shared buffer. Buffer adjustment configures the guaranteed buffer threshold and shared buffer threshold of queues to allocate different buffer sizes to queues.

Guaranteed buffer

Guaranteed buffer is also called exclusive buffer. This part of buffer is distributed based on each queue. The guaranteed buffer of a queue can be used by this queue only. A fixed guaranteed buffer is allocated to each queue by default. This part of queue enables this queue to forward packets at the normal line rate under the stable flow.

➤ Shared buffer

In the total buffer of port group, the remaining part is the total shared buffer after the guaranteed buffer of each queue is deducted. The shared buffer can be used by all the queues. A shared queue threshold can be set for each queue. This threshold restricts the maximum shared buffer quantity that can be used by this queue. When the shared buffer sum configured for each queue in the port group exceeds the total shared queue of port group, the "First Come First Served" buffer occupancy mechanism is adopted.

3.3.2 Configuring Buffer Monitoring

Buffer monitoring implements monitoring on the use amount of each queue and shared buffer, with a view to providing data support for network optimization and reasonable buffer configuration.

Working Principle

Buffer monitoring adopts the polling mode to read the buffer use amount of each queue and the use situation of total buffer regularly and display the buffer use situation of current equipment in real time.

➤ Port group buffer utilization alarm threshold

When the buffer utilization of port group exceeds this threshold, syslog will be printed to remind the user.

➤ Queue buffer utilization alarm threshold

When the buffer utilization of queue exceeds this threshold, syslog will be printed to remind the user.

➤ Buffer monitoring data sampling interval

Buffered monitoring data is sampled at a certain interval, and the interval can be configured based on user requirements.

3.3.3 Configuring Queue Counting

Queue counting monitors the forwarding and packet loss data of each queue to provide data support for network optimization and reasonable buffer configuration.

Working Principle

The queue adopts the polling mode to read the number of forwarded packets/number of bytes and the number of lost packets/number of bytes of each queue regularly, and then use the data to calculate each kind of statistics of the queue.

➤ Queue packet loss alarm

The device analyzes statistics on discarded packets to judge whether packet loss occurs on a queue. After packet loss occurs on a queue, the device displays a packet loss alarm according to the packet loss alarm configuration.

➤ Queue packet loss alarm frequency

Only N packet loss alarms can be displayed within a certain period of T . You can configure the period (T) and number of alarms (N) to adjust the display of packet loss alarms.

3.4 Configuration

Configuration	Description and Command	
Buffer Adjustment	 (Optional) It is used to configure buffer.	
	mmu queue-guarantee	Configures guaranteed buffer.
	mmu queue-threshold	Configures shared buffer.
	mmu pg-guarantee	Configures the guarantee buffer.
	mmu ingress-threshold	Configures ingress PG shared buffer.
	mmu xoff-threshold	Configures ingress PG flow control threshold.
	mmu xon-threshold-offset	Configures ingress PG flow control recovery threshold.
	mmu headroom-threshold	Configures the PG-based headroom buffer size.
	mmu pg-headroom	Configures the global headroom buffer size.
	mmu guarantee-limit	Configures the global guaranteed buffer size.
	mmu {ingress egress} service-pool	Configures the ingress/egress SP size.
	mmu {priority-group unicast-queue multicast-queue } {id1[id2[idN]]} attach	Configures the mapping relation between ingress PG/egress unicast/egress multicast and SP.
Buffer Monitoring	 (Optional) It is used to configure buffer.	
	mmu usage-warn-limit	Configures the buffer utilization alarm threshold.
	mmu sample-period	Configures the buffer monitoring data sampling interval.
Packet Loss Alarm	mmu queue-loss-warn {unicast multicast}	Configures the queue packet loss alarm.
	mmu queue-loss-warn frequency	Configures the packet loss alarm frequency.

3.4.1 Configuring Buffer Adjustment

Configuration Effect

- Configure guaranteed buffer so that the queue can share this part of buffer exclusively.
- Configure shared buffer so as to control the shared buffer use amount of the queue.

Notes

- Configuration on the interface can be made on the physical port only.

Configuration Steps

📌 Configuring guaranteed buffer

- Optional.
- In the interface mode, use the **mmu queue-guarantee** command to configure guaranteed buffer for each queue and ensure that the buffer configuration range varies with the product.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu queue-guarantee output { unicast multicast } [queue-id1 [queue-id2 [queue-idN]] set value
Parameter Description	output: performs buffer management on the egress queue unicast: performs buffer management on the egress unicast queue multicast: performs buffer management on the egress multicast queue <i>queue-id:</i> queue ID, in the range from 1 to 8 <i>value:</i> number of guaranteed buffers, in cells; the range depends on the product.
Defaults	A fixed number of guaranteed buffers are allocated to each queue by default. The specific configuration depends on the product.
Command Mode	Interface mode
Usage Guide	The effective way of this command varies with the equipment and depends on the product.

📌 Configuring shared buffer

- Optional.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu queue-threshold output { unicast multicast } [queue-id1 [queue-id2 [queue-idN]] set thr%
Parameter Description	output: performs buffer management on the egress queue unicast: performs buffer management on the egress unicast queue multicast: performs buffer management on the egress multicast queue <i>queue-id:</i> queue ID, in the range from 1 to 8 <i>thr%:</i> percentage, in the range from 1 to 100
Defaults	● A shared buffer use threshold is allocated to each queue by default. This threshold is a percentage. The calculation method of the maximum available shared buffer for the queue is as follows: Maximum available shared buffer for the queue = Total number of shared buffers of the port group * Threshold percentage The default value depends on the product.
Command Mode	Interface mode
Usage Guide	The effective way of this command varies with the equipment and depends on the product.

↘ Configuring ingress PG guarantee buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu pg-guarantee pg { <i>priority -id1</i> [<i>priority-id2</i> [<i>priority -idN</i>]] set <i>value</i>
Parameter Description	<i>priority -idN</i> : ingress PG No. <i>Value</i> : guarantee buffer configuration value.
Defaults	The default value depends on the product.
Command Mode	Interface configuration mode
Usage Guide	The effective way of this command varies with the product.

↘ Configuring ingress PG shared buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu ingress-threshold pg [<i>pg-id0</i> [<i>pg-id1</i> [<i>pg-id N</i>]] set <i>thr%</i>
Parameter Description	<i>pg-idN</i> : priority group ID. <i>thr%</i> : Total shared buffer x Threshold percentage = Maximum available buffer for the queue
Defaults	The default value depends on the product.
Command Mode	Interface configuration mode
Usage Guide	1. The effective way of this command varies with the product. 2. The configuration takes effect only when flow control/Priority-based Flow Control (PFC) is not enabled. 3. The user-configured value is displayed when the show run command is executed, even if the user-configured value is the default value.

↘ Configuring ingress PG headroom buffer

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu headroom-threshold pg [<i>pg-id0</i> [<i>pg-id1</i> [<i>pg-id N</i>]] set <i>value</i>
Parameter	<i>pg-idN</i> : priority group ID.

Description	<i>Value</i> : headroom threshold value, in the unit of cell.
Defaults	The default value depends on the product.
Command Mode	Interface configuration mode
Usage Guide	1. The effective way of this command varies with the product. 2. The user-configured value is displayed when the show run command is executed, even if the user-configured value is the default value.

✚ Configuring flow control threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu xoff-threshold pg [<i>pg-id0</i> [<i>pg-id1</i> [<i>pg-id N</i>]] set <i>thr%</i>
Parameter Description	<i>pg-idN</i> : priority group ID. <i>Value</i> : headroom threshold value, in the unit of cell.
Defaults	The default value depends on the product.
Command Mode	Interface configuration mode
Usage Guide	1. The effective way of this command varies with the product. 2. The configuration takes effect only when flow control/PFC is enabled. 3. If flow control/PFC is not enabled, the shared buffer threshold of the PG is according to the value of ingress-threshold. 4. The user-configured value is displayed when the show run command is executed, even if the user-configured value is the default value.

✚ Configuring flow control restoration threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu xon-threshold-offset pg [<i>pg-id0</i> [<i>pg-id1</i> [<i>pg-id N</i>]] set <i>value</i>
Parameter Description	<i>pg-idN</i> : priority group ID. <i>Value</i> : headroom threshold value, in the unit of cell.
Defaults	The default value depends on the product.

Command Mode	Interface configuration mode
Usage Guide	1. The effective way of this command varies with the product. 2. The configuration takes effect only when flow control/PFC is enabled. 3. The user-configured value is displayed when the show run command is executed, even if the user-configured value is the default value.

✚ Configuring global headroom threshold

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu pg-headroom set <i>value</i>
Parameter Description	<i>Value</i> : headroom threshold value, in the unit of cell.
Defaults	The default value depends on the product.
Command Mode	Interface configuration mode
Usage Guide	1. The effective way of this command varies with the product. 2. The configuration takes effect only when flow control/PFC is enabled. 3. The user-configured value is displayed when the show run command is executed, even if the user-configured value is the default value.

✚ Configuring size of shared service pool on the input/output

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command **mmu {ingress|egress} service-pool *sp-id* [*name sp-name*] set *cell***

Parameter Description

ingress: configure the shared service pool on the input

egress: configure the shared service pool on the output

sp-id: ID of the shared service pool

cell: cell quantity of the shared service pool

Defaults The default value depends on the product.

Command Mode Global configuration mode

Usage Guide The effective way of this command varies with the product.

It is recommended to set the same size for shared service pools on the input/output for the same traffic, or packet loss may occur.

✚ Configuring mapping relationship between input PG/output queue and shared service pool

- Optional.
- Use the **no** or **default** form of the command to restore the default value of buffer.

Command	mmu {priority-group unicast-queue multicast-queue} [id1 [id2 [idN]] attach sp-id
Parameter	priority-group unicast-queue multicast-queue: configures the mapping relationship of input PG or output
Description	unicast/multicast queue <i>idN</i> : ID of the priority group or queue sp-id: ID of the shared service pool
Defaults	The default value depends on the product.
Command	Global configuration mode
Mode	
Usage Guide	The effective way of this command varies with the product.

Verification

- Run the **show running** command to check the configuration

Configuration Examples

✚ Configuring size of shared service pool on the input/output

- Configuration**
- In the global configuration mode, configure the size of input and output SP1 as 10000 cells.
- Steps**

```
Ruijie# configure
Ruijie(config)# mmu ingress service-pool 1 set 10000
Ruijie(config)# mmu egress service-pool 1 set 10000
```

- Verification**
- Run the **show run** command to check the configuration.

```
Ruijie#show run
      mmu ingress service-pool 1 set 10000
      mmu egress service-pool 1 set 10000
Ruijie#
```

✚ Configuring mapping relationship between input PG/output queue and shared service pool

- Configuration**
- After the size of shared service pool is configured in the global configuration mode, the mapping relationship between the input PG and input service pool/output queue and output service pool can be

Steps configured.

```
Ruijie# configure
Ruijie(config)# mmu ingress service-pool 1 set 10000
Ruijie(config)# mmu egress service-pool 1 set 10000
Ruijie(config)# mmu egress service-pool 2 set 10000
Ruijie(config)# mmu priority-group 1 attach service-pool 1
Ruijie(config)# mmu unicast-queue 1 attach service-pool 1
Ruijie(config)# mmu multicast-queue 1 attach service-pool rdma
Ruijie(config)#exit
Ruijie#
```

Verification

- Run the **show run** command to check the configuration.

```
Ruijie#show run
      mmu ingress service-pool 1 set 10000
      mmu egress service-pool 1 set 10000
      mmu egress service-pool 2 set 10000
      mmu priority-group 1 attach service-pool 1
      mmu unicast-queue 1 attach service-pool 1
      mmu multicast-queue 1 attach service-pool
Ruijie#
```

📌 Configuring size of global guaranteed buffer

- Configuration** ● In the global configuration mode, configure global guaranteed buffer as 10000 cells.

Steps

```
Ruijie#config
Ruijie(config)# mmu guarantee-limit set 10000
Ruijie(config)#exit
Ruijie#
```

Verification

- Run the **show run** command to check the configuration.

```
Ruijie#show run
      mmu guarantee-limit set 10000
Ruijie#
```

3.4.2 Configuring Buffer Monitoring

Configuration Effect

- Configure the buffer utilization alarm threshold of port group. The log alarm will be printed when the buffer utilization of port group exceeds this configured value.
- Configure the buffer utilization alarm threshold of queue. The log alarm will be printed when the buffer utilization of queue exceeds this configured value.
- Configure the monitoring data sampling interval. The bottom layer samples and reports data according to the configured interval.

Notes

- Configuration on the interface can be made on the physical port only.

Configuration Steps

✚ Configuring the port group buffer utilization alarm threshold

- Optional.
- In the global configuration mode, use the **mmu usage-warn-limit** command to configure the buffer utilization alarm threshold for the port group.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu usage-warn-limit set value
Parameter Description	<i>value</i> : percentage, in the range from 1 to 100
Defaults	The default value is 0, indicating that no alarm is reported.
Command Mode	Global configuration mode
Usage Guide	This configuration takes effect for all the port groups.

✚ Configuring the service pool buffer utilization alarm threshold

- Optional.
- In the interface configuration mode, use the **mmu usage-warn-limit {ingress-service-pool | egress-service-pool}** command to configure the buffer utilization alarm threshold for service pool.
- Use the **no** or **default** command of this command to restore the default settings.

Command	mmu usage-warn-limit {ingress-service-pool egress-service-pool} sp-id set value
Parameter Description	ingress-service-pool : ingress shared service pool egress-service-pool : egress shared service pool <i>sp-id</i> : ID of shared pool <i>value</i> : percentage, in the range from 1 to 100
Defaults	The default value is 0, indicating that no alarm is reported.

Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring the priority group/queue buffer utilization alarm threshold

- Optional.
- In the interface configuration mode, use the **mmu usage-warn-limit {pg-headroom | priority-group | unicast | multicast} [id1 [id2 [idN]] set value** command to configure the buffer utilization alarm threshold for each priority group or queue.
- Use the **no** or **default** command of this command to restore the default settings.

Command	mmu usage-warn-limit { pg-headroom priority-group unicast multicast } [id1 [id2 [idN]] set value
Parameter Description	priority-group : priority group pg-headroom : priority group headroom unicast : performs buffer management on the egress unicast queue multicast : performs buffer management on the egress multicast queue <i>idN</i> : priority group/queue ID <i>value</i> : percentage, in the range from 1 to 100
Defaults	The default value is 0, indicating that no alarm is reported.
Command Mode	Interface configuration mode
Usage Guide	N/A

✚ Configuring the monitoring data sampling interval

- Optional.
- In global configuration mode, use the **mmu sample-period { buffer-counter | queue-counter } value** command to configure the monitoring data sampling interval for each queue.
- Use the **no** or **default** form of the command to restore the default setting.

Command	mmu sample-period { buffer-counter queue-counter } value
Parameter Description	buffer-counter : count of occupied buffer. queue-counter : count of sent and discarded records in a queue. <i>value</i> : sampling interval, in the unit of seconds.
Defaults	The sampling interval is 5 seconds by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Use the **show running** command to check whether the MMU under the corresponding interface is configured successfully.
- Use the **show queue-buffer** command to check whether the configuration succeeds.

Configuration Examples

Configuring the buffer utilization alarm threshold based on port group

Configuration Steps	● On the switch, configure the buffer utilization alarm threshold of port group as 80%.
	<pre>Ruijie# configure terminal Ruijie(config)# mmu usage-warn-limit set 80 Ruijie(config)#</pre>
Verification	● Check whether the created guaranteed buffer has been configured successfully.
	<pre>Ruijie# show run mmu usage-warn-limit set 80</pre>

Configuring the buffer utilization alarm limit based on egress queue

Configuration Steps	● Configure the buffer utilization alarm threshold as 70% at the unicast queues 6 and 8 of port 1/1 on the switch.																																																																						
	<pre>Ruijie# configure terminal Ruijie(config)# int tel/1 Ruijie(config-if)#mmu usage-warn-limit unicast 6 8 set 70</pre>																																																																						
Verification	● Check whether the created guaranteed buffer has been configured successfully.																																																																						
	<pre>Ruijie#show queue-buffer interface gigabitEthernet 0/9</pre> <table><tr><th>Dev/slot</th><th>Port-group</th><th>Total-shared(%)</th><th>Guarantee-used(%)</th><th>Share-used(%)</th><th>Available(%)</th><th>Warn-limit(%)</th></tr><tr><td>1/-</td><td>1</td><td>74.5271</td><td>0.0822</td><td>14.7615</td><td>85.1562</td><td>NA</td></tr></table> <pre>Interface GigabitEthernet 0/9:</pre> <table><tr><th>Type</th><th>Queue</th><th>Admin-shared(%)</th><th>Total-used(%)</th><th>Available(%)</th><th>Warn-limit(%)</th><th>Peak-usage(%)</th><th>Peak-time</th></tr><tr><td>Unicast</td><td>1</td><td>(default)</td><td>7.4836</td><td>0.0103</td><td>NA</td><td>7.5041</td><td>2015/7/14 20:7:14</td></tr><tr><td>Unicast</td><td>2</td><td>(default)</td><td>0.0000</td><td>7.4938</td><td>NA</td><td>0.0000</td><td>NA</td></tr><tr><td>Unicast</td><td>3</td><td>(default)</td><td>0.0000</td><td>7.4938</td><td>NA</td><td>0.0000</td><td>NA</td></tr><tr><td>Unicast</td><td>4</td><td>(default)</td><td>0.0000</td><td>7.4938</td><td>NA</td><td>0.0000</td><td>NA</td></tr><tr><td>Unicast</td><td>5</td><td>(default)</td><td>0.0000</td><td>7.4938</td><td>NA</td><td>0.0000</td><td>NA</td></tr><tr><td>Unicast</td><td>6</td><td>(default)</td><td>0.0000</td><td>7.4938</td><td>70%</td><td>0.0000</td><td>NA</td></tr></table>	Dev/slot	Port-group	Total-shared(%)	Guarantee-used(%)	Share-used(%)	Available(%)	Warn-limit(%)	1/-	1	74.5271	0.0822	14.7615	85.1562	NA	Type	Queue	Admin-shared(%)	Total-used(%)	Available(%)	Warn-limit(%)	Peak-usage(%)	Peak-time	Unicast	1	(default)	7.4836	0.0103	NA	7.5041	2015/7/14 20:7:14	Unicast	2	(default)	0.0000	7.4938	NA	0.0000	NA	Unicast	3	(default)	0.0000	7.4938	NA	0.0000	NA	Unicast	4	(default)	0.0000	7.4938	NA	0.0000	NA	Unicast	5	(default)	0.0000	7.4938	NA	0.0000	NA	Unicast	6	(default)	0.0000	7.4938	70%	0.0000	NA

Configuring the shared buffer pool buffer utilization alarm limit

Configuration Steps	Configure the alarm limit in global configuration mode.
	<pre>Ruijie# configure terminal Ruijie(config)# mmu usage-warn-limit ingress-service-pool 1 set 10 Ruijie(config)# mmu usage-warn-limit egress-service-pool 2 set 20</pre>
Verification	Check whether the alarm limit has been configured successfully. <pre>Ruijie# show run mmu usage-warn-limit ingress-service-pool 1 set 10 mmu usage-warn-limit egress-service-pool 2 set 20</pre>

Configuring the monitoring data sampling interval

Configuration Steps	Configure the monitoring data sampling interval in global configuration mode.
	<pre>Ruijie# configure terminal Ruijie(config)# mmu sample-period buffer-counter 8 Ruijie(config)# mmu sample-period queue-counter 10</pre>
Verification	Check whether the sampling interval has been configured successfully. <pre>Ruijie# show run mmu sample-period buffer-counter 8 mmu sample-period queue-counter 10</pre>

3.4.3 Configuring the Packet Loss Alarm

Configuration Effect

- Enable/Disable the global queue packet loss alarm of all interface queues.
- Enable/Disable the queue packet loss alarm on an interface. The priority of this configuration is higher than the global configuration.
- Configure the packet loss alarm frequency so that only N packet loss alarms are displayed in the period of T .

Notes

- This function can be configured in global configuration mode and interface configuration mode.

Configuration Steps

Configuring the packet loss alarm

- Optional.
- In global or interface configuration mode, run the **mmu queue-loss-warn {unicast | multicast} [qid1 [qid2 [qidN]]] {on | off}** command to enable/disable the packet loss alarm function on queues.
- Use the **no** or **default** form of this command to restore default configuration. The packet loss alarm function is disabled by default.

Command	[no] mmu queue-loss-warn {unicast multicast } [qid1 [qid2 [qidN]]] {on off}
Parameter Description	Unicast: Indicates a unicast queue. multicast : Indicates a multicast queue. <i>qid</i> : Indicates the queue ID. on : Enables the packet loss alarm. off : Disables the packet loss alarm.
Defaults	The packet loss alarm function is disabled by default.
Command Mode	Global configuration mode and interface configuration mode.
Usage Guide	The effective way of this command varies with the product.

Configuring the Packet Loss Alarm Frequency

- Optional.
- In global configuration mode, run the **mmu queue-loss-warn frequency cycle value1 times value2** command to configure the packet loss alarm frequency.
- Use the **no** or **default** form of the command to restore the default configuration.

Command	[no] mmu queue-loss-warn frequency cycle value1 times value2
Parameter Description	<i>value1</i> : Indicates the displaying period of the packet loss alarm. <i>value2</i> : Indicates the number of packet loss alarms that can be displayed in a period.
Defaults	Up to 30 packet loss alarms can be displayed within 60s by default.
Command Mode	Global configuration mode
Usage Guide	The effective way of this command varies with the product.

3.5 Monitoring

Clearing

Running the **clear** command during operation of the equipment may lead to service interruption due to loss of important information.

Description	Command
Clears the queue counter value.	clear queue-counter
Clears the historical peak value of the egress queue buffer	clear mmu queue-buffer peaked
Clears the historical peak value of the ingress PG buffer	clear mmu pg-buffer peaked
Clears the number of times that the occupied buffer exceeds the warning threshold	clear mmu usage-warn-count

Displaying

Description	Command
Displays the buffer use information of panel interface.	show queue-buffer interface
Displays the queue counter information of panel interface.	show queue-counter interface
Displays the buffer use information of the ingress PG	show pg-buffer interface

Reliability Configuration

1. Configuring REUP
2. Configuring RLDP
3. Configuring DLDP
4. Configuring VRRP
5. Configuring VRRP Plus
6. Configuring BFD
7. Configuring IP Event Dampening
8. Configuring VSU
9. Configuring RNS

1 Configuring REUP

1.1 Overview

The Rapid Ethernet Uplink Protection Protocol (REUP) provides a rapid uplink protection function.

In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.

The upstream interfaces of REUP are configured in pairs. If both interfaces are normal, an interface works in the backup state. The interface in the backup state does not forward data packets. When the interface in the forward state is faulty, the backup interface switches to the forward state immediately, and provides data transmission. In addition, REUP also sends address update packets to upstream devices so that the upstream devices can update their MAC addresses immediately. This function of REUP ensures that layer-2 data streams can be restored within 50 ms after a link is faulty.

REUP is mutually exclusive with the Spanning Tree Protocol (STP) based on interfaces. In this case, a device runs STP downward and runs REUP upward to implement backup and fault protection for the upstream link. REUP ensures that basic link redundancy is provided when STP is disabled and that millisecond-level fault recovery faster than STP is also provided.

Protocols and Standards

- REUP is a proprietary protocol of Ruijie Network, and there is no standard and protocol for reference.

1.2 Applications

Application	Description
Communication in Dual Uplink Networking	Forward packets in the dual-uplink networking.

1.2.1 Communication in Dual Uplink Networking

Scenario

For communication in dual uplink networking, the access switch has two uplink paths, as shown in Figure 1-1.

Figure 1-1 Dual uplink networking

Deployment

- Enable REUP on interface1 and interface2 of the access switch D/E to implement fast switching when a link is faulty.
- Enable MAC address update message receiving of REUP on the interfaces connected to switches A/B/C to rapidly clear the MAC addresses on the interfaces when a link is faulty.

1.3 Features

Basic Concepts

REUP Pair

Specify an interface as the backup interface of another interface to configure an REUP pair. One interface is the active interface and the other interface is the backup interface. When the two interfaces are normal, an interface is configured as the forward interface whereas the other interface is configured as the backup interface. You can determine the interface to be configured as the backup interface. See the related information in the section "Configuring the Preemption Mode and Delay Time of REUP".

MAC Address Update Message

MAC address update messages refer to FLUSH packets sent by Ruijie Network to uplink devices through private multicast. When an uplink device of Ruijie Network enables the function for receiving MAC address update messages and receives MAC address update messages, the device updates the MAC addresses of corresponding interfaces.

MAC Address Update Group

Multiple interfaces are added to a group. If one interface in the group receives a MAC address update message, the MAC addresses of other interfaces in the group will be updated. In this case, the group is called MAC address update group.

MAC Address Update Packet

Packets sent to update MAC addresses in order to support uplink devices are called MAC address update packets.

Link Tracking Group

The uplink and downstream interfaces of a device are added to a group. If all upstream interfaces in the group are down, all downstream interfaces in this group are forced down. In this case, this group is called a link tracing group.

Overview

Feature	Description
Dual Link Backup of REUP	When a link is faulty, the other link can rapidly switch to the forward state.
Preemption Mode and Delay Time of REUP	When both links are normal, the preemption mode can be used to determine the link that is used for forwarding data and the delay time that is used to determine the waiting time before switching.
MAC Address Update	During link switching, the MAC address of an interface is updated to make packet convergence faster.
VLAN Load Balance	When the two links are normal, the utilization of link bandwidth can be maximized.
Link State Tracking	When the upstream link is faulty, the downstream link is switched.

1.3.1 Dual Link Backup of REUP

When an active link is faulty, the link in the backup state will rapidly switch to the forward state and start forwarding data, minimizing the service interruption caused by link failure.

Working Principle

Specify an interface as the backup interface of another interface to configure an REUP pair. When the two interfaces are normal, a link is in the forward state (forwarding data packets) and the other link is in the backup state (not forwarding data). When the active link is faulty, the link in the backup state rapidly switches to the forward state and starts forwarding data. When the faulty link is recovered, the link enters the backup state and does not forward data packets. Of course, you can configure the preemption mode to specify whether a link recovered from failure preempts the link that is in the forward state currently.

Figure 1-2 A topology with two normal links

As shown in Figure 1-2, connect interfaces 1 and 2 of switch D (E) to the uplink switches B and C (C and B) and configure REUP on interfaces 1 and 2. When the links are normal, interface 1 is in the forward state and forwards data packets and interface 2 is in the backup state and does not forward data packets.

Figure 1-3 A topology with interface 1 of switch D (E) faulty

Once interface 1 is faulty, interface 2 immediately starts forwarding data packets and recovers the uplink transmission of the switch. In the non-preemption mode, when the link of interface 1 is recovered, interface 1 is in the backup state and does not forward data packets whereas interface 2 continues forwarding data packets.

Related Configuration

📌 Enabling Dual Link Backup on an interface

By default, dual link backup on an interface is disabled.

You can run the **switchport backup interface** command to configure a layer-2 physical interface (or layer-2 AP interface) as a backup interface and enable the dual link backup function of REUP.

You must enable the dual link backup function of REUP on an interface. The function involves the link switching of REUP only when an interface is faulty.

- ❗ REUP, ERPS, and RERP do not share interfaces.
- ❗ Devices enabled with REUP must disable the storm control function of all layer-2 interfaces.

1.3.2 Preemption Mode and Delay Time of REUP

Working Principle

You can determine which link should be used first by configuring the preemption mode of REUP. If the preemption mode is set to bandwidth first, REUP selects a link with a high bandwidth first. You can also set the preemption mode to forced to select a stable and reliable link first forcibly.

To avoid frequent active/backup link switching caused by abnormal faults, REUP provides a preemption delay function. When the two links are recovered, link switching is performed when the faulty link becomes stable after a delay (35s by default).

Related Configuration

Configuring the Preemption Mode and Delay Time of REUP

By default, the preemption mode is disabled and the delay time is 35s.

You can run the **switchport backup interface preemption mode** command to configure the preemption mode.

You can run the **switchport backup interface preemption delay** command to configure the delay time.

A smaller delay means more frequent preemption switching after the faulty link is recovered.

-  REUP uses the value of the **Bandwidth** attribute for an AP interface as the actual bandwidth of the AP interface, which is equal to the value of the **Speed** attribute (the number of link up member interfaces x the number of member interfaces).
-  When an uplink enables STP, the preemption delay time of REUP is greater than 35s.

1.3.3 MAC Address Update

During link switching, the MAC address of an interface is updated to make packet convergence faster.

Working Principle

As shown in Figure 1-2, interface 1 and interface 2 of switch D (E) are enabled with dual link backup of REUP. Interface 1 works as the active interface. During normal communication, switch A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the interfaces connecting to switch B (C).

When interface 1 of switch D (E) is faulty, interface 2 rapidly switches to the forward state and starts forwarding data packets. In this case, switch A does not learn the MAC addresses of users 1 and 2 (users 3 and 4) on the interfaces connecting to switch B (C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to switch C (B) by switch A, causing that the packets from the server to users 1 and 2 (users 3 and 4) are lost.

To avoid the preceding problems, you can enable the MAC address update function on switch D (E). When interface 2 starts forwarding packets, switch D (E) sends a MAC address update message to interface 2. After receiving the MAC address update message, switch A updates the MAC address on the interface of switch A. In this way, switch A forwards the packets sent by the server to the users to the interfaces of switch B (C) to make packet convergence faster.

In addition, import the setting of a MAC address update group, that is, classify multiple interfaces into the same group. When an interface in this group receives a MAC address update message, the MAC addresses on other interfaces in the group are updated to reduce the side effect of flooding caused by MAC address update.

To be compatible with upstream devices not supporting MAC address update messages, switch D (E) will send MAC address update packets for users 1 and 2 (users 3 and 4) upward when interface 2 switches to the forward state. In this way, switch A can update the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding interfaces and recover the downlink data transmission of switch A.

Related Configuration

▾ Enabling Sending of MAC Address Update Messages on an interface

By default, sending of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update transit** command to enable sending of MAC address updates on all interfaces of a device.

If sending of MAC address update messages is not enabled, MAC address update messages will not be sent when dual link backup switching of REUP is performed.

▾ Enabling Receiving of MAC Address Update Messages on an interface

By default, receiving of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update receive** command to enable receiving of MAC address updates on all interfaces of a device.

If receiving of MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during dual link backup switching of REUP and will not update the MAC addresses.

▾ Configuring a VLAN for Sending MAC Address Update Messages

By default, a VLAN for sending MAC address update messages is the default VLAN to which an interface belongs.

You can run the **mac-address-table move update transit vlan** command to configure the VLAN in which interfaces send MAC address update messages.

If the VLAN in which interfaces send MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.

▾ Configuring a VLAN for Receiving MAC Address Update Messages

By default, MAC address update messages are received in all VLANs.

You can run the **no mac-address-table move update receive vlan** command to configure a VLAN in which interfaces do not receive MAC address update messages. MAC address update messages are received in remaining VLANs.

If no VLAN in which interfaces receive MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the remaining VLANs.

▾ Configuring a MAC Address Update Group

By default, there is no MAC address update group.

You can run the **mac-address-table update group** command to add an interface to the MAC address update group. The interface is added to the first update group by default.

If no MAC address update group is configured, MAC address update will not be performed when MAC address update packets are received.

📌 Configuring the Maximum Number of MAC Address Update Packets Sent Per Second

By default, the maximum number of MAC address update packets sent per second is 150.

You can run the **mac-address-table move update max-update-rate** command to configure the maximum number of MAC address update packets sent per second.

The larger the number of packets, the more CPU time used for sending the packets, and the fewer downlink packets are lost.

1.3.4 VLAN Load Balance

Working Principle

The VLAN load balance function allows REUP to forward data packets of mutually exclusive VLANs for two interfaces to make full use of the link bandwidth.

As shown in Figure 1-4, configure dual link backup of REUP and enable VLAN load balance of REUP on interface 1 and interface 2 of switch D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through interface 1 and all the other data of VLAN 2 (instance 2) is transmitted through interface 2. Perform the same processing on switch E.

When an interface is faulty, the other interface takes over the transmission of all VLANs. When the faulty interface is recovered and does not become faulty within the preemption delay, the transmission of VLANs is switched back to the recovered interface.

Figure 1-4 A topology with two normal links of load balance

Related Configuration

▾ Enabling VLAN Load Balance on an interface

By default, the VLAN load balance function on an interface is disabled.

You can run the **switchport backup interface prefer instance** command to enable the VLAN load balance function.

If this function is not enabled, the link bandwidth cannot be fully used when packets are forwarded when the two links are normal. You must enable the VLAN load balance function on a port so that the interface can be involved in VLAN load balance.

i The instance mapping of REUP VLAN load balance is controlled by the MSTP module in a unified manner. For details about how to configure the instances, see the description in the *Configuring MSTP*.

! The VLAN load balance function can be configured only on trunk, uplink or hybrid interfaces.

1.3.5 Link State Tracking

Link tracking means that when the upstream link is faulty, services are switched to the downstream link so that the backup interface can continue forwarding packets.

Working Principle

Link state tracking provides the function of notifying downlink devices for link switching when the upstream link is faulty. You can configure the uplink and downstream interfaces of a link state tracking group and bind the link status of multiple downstream interfaces to the interfaces of multiple upstream links to implement link status synchronization. When all upstream links in a tracking group are faulty, the interfaces of the downstream links are shut down forcibly to ensure that the transmission of the downstream links is switched from the active link to the backup link.

As shown in Figure 1-5, when the upstream link of switch B is faulty, link state tracking rapidly shuts down the downstream interface of switch B so that the uplink transmission of switch D is switched to switch C.

Figure 1-5 A topology where the upstream link of the active link is faulty

Related Configuration

▾ Enabling Link Tracking

Link tracking is disabled by default.

You can run the **link state track [number]** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1).

If link tracking is not enabled, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

Enabling the Downlink Delay Up Function for a Link Tracking Group

By default, the downlink delay for link tracking is 0s.

You can run the **link state track *number* up-delay *timer*** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1). The value of **timer** ranges from 0 to 300s, which is 0s by default.

By enabling the downlink delay up function, you can avoid frequent downlink switching caused by uplink flapping in a link tracking group. That is, when the upstream link becomes up, the downstream link becomes up after a delay.

Adding an interface to a Link Tracking Group

By default, an interface is not added to a link tracking group.

You can run the **link state group [*number*] {upstream | downstream}** command to set upstream interfaces and downstream interfaces of the link tracking group. The value of **number** ranges from 1 to 2. An interface is added to the first link tracking group by default (the default value of **number** is 1).

If an interface is not added to a tracking group, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of REUP	 (Mandatory) It is used to enable dual link backup of REUP.	
	switchport backup interface	Enables dual link backup of REUP.
Configuring the Preemption Mode and Delay Function of REUP	 (Optional) It is used to determine the preemption mode and delay time. The default values are used if they are not configured.	
	switchport backup interface preemption mode	Sets the preemption mode.
	switchport backup interface preemption delay	Sets the delay time for preemption.
Configuring MAC Address Update	 (Optional) It is used to enable rapid update of MAC addresses.	

Configuration	Description and Command	
	mac-address-table update group	Sets the MAC address update group ID of a switch.
	mac-address-table move update transit	Enables sending of MAC address update messages.
	mac-address-table move update transit vlan	Enables sending of the VLAN ID of MAC address update messages.
	mac-address-table move update	Configures the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
	mac-address-table move update receive	Enables receiving of MAC address update messages.
	mac-address-table move update receive vlan	Configures the VLAN range for processing MAC address update messages.
Configuring VLAN Load Balance	 (Optional) It is used to enable VLAN load balance.	
	switchport backup interface prefer instance	Configures the link VLAN load balance of REUP.
Configuring Link Tracking	 (Optional) It is used to enable link tracking.	
	link state track up-delay	Enables the downlink delay up for a link state tracking group.
	link state track	Enables a link state tracking group.
	link state group	Add an interface as an upstream interface or a downstream interface of a specified link state tracking group.

1.4.1 Configuring Basic Functions of REUP

Configuration Effect

- When a link is faulty, the other normal link is switched to the forward state immediately for forwarding packets.

Notes

- An interface belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different interfaces.
- REUP supports layer-2 physical interfaces and AP interfaces, but does not support AP member interfaces.
- The active and backup interfaces may be of different types and have different rates. For example, an AP interface can be used as the active interface whereas a physical interface is configured as the backup interface.
- Interfaces configured with REUP are not involved in STP calculation.

- Each device can be configured with a maximum of 16 REUP pairs.
- Interfaces successfully configured with REUP cannot change interfaces to layer-3 interfaces or be added to an AP.

Configuration Steps

📌 Enabling Dual Link Backup of REUP

- Mandatory.
- If there is no special requirement, dual link backup of REUP should be enabled on an interface of the receiving switch.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether dual link backup of REUP is configured.

Related Commands

📌 Enabling Dual Link Backup of REUP

Command	switchport backup interface <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Indicates the backup interface ID.
Command Mode	Interface configuration mode
Usage Guide	If the interface where the mode resides is the active interface, the interface corresponding to the interface-id parameter is the backup interface. When the active link is faulty, rapidly recover the transmission of the backup link.

Configuration Example

📌 Enabling Dual Link Backup of REUP

Scenario Figure 1-6 Dual uplink networking	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.

Configuration Steps	● Configure dual link backup (the interface Gi0/1 is the active interface and Gi0/2 is the backup interface) of REUP on the access switch D (E).
D	SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit
E	SwitchE> enable SwitchE# configure terminal SwitchE(config)# interface GigabitEthernet 0/1 SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchE(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit
Verification	● Check the dual link backup information configured for switch D (E).
D	SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs:

	Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : off Preemption Delay : 35 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)
E	SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : off Preemption Delay : 35 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)

Common Errors

- Other REUP pairs are configured on a configured interface.
- A configured interface is not a layer-2 physical interface or AP interface.

1.4.2 Configuring the Preemption Mode and Delay Function of REUP

Configuration Effect

- Restrict the preemption mode and preemption delay time for REUP link switching.

Notes

- Dual link backup of REUP must be configured.

Configuration Steps

- Optional.

- If the active link needs to always forward packets or the link bandwidth needs to be used to determine the link for forwarding packets, the corresponding preemption mode and delay time must be configured.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether the preemption mode and delay time are consistent with the configurations.

Related Commands

Configuring the Preemption Mode of REUP

Command	switchport backup interface <i>interface-id</i> preemption mode {forced bandwidth off}
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	mode : Sets the preemption mode: forced : Indicates the forced mode. bandwidth : Indicates the bandwidth mode. off : Indicates that the preemption mode is off.
Command Mode	Interface configuration mode
Usage Guide	The preemption modes include forced, bandwidth and off. In the bandwidth mode, an interface with a high bandwidth is selected first to transmit data; in the forced mode, the active interface is selected first to transmit data; in the off mode, no preemption is performed. The default mode is off.

Configuring the Delay Time of REUP

Command	switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i>
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	<i>delay-time</i> : Indicates the delay time.
Command Mode	Interface configuration mode
Usage Guide	Preemption delay indicates the delay time after a faulty link is recovered to the time when link switching is performed again.

Configuration Example

Configuring the Preemption Mode and Delay Time of REUP

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	● Configure the preemption mode to bandwidth on the access switch D (E) and the delay time to 40s.
D	SwitchD> enable

	<pre>SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
E	<pre>SwitchE> enable SwitchE# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	● Check the dual link backup information configured for switch D (E).
D	<pre>SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : bandwidth Preemption Delay : 40 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>
E	<pre>SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby</pre>

	Interface Pair : Gi0/1, Gi0/2 Preemption Mode : bandwidth Preemption Delay : 40 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.3 Configuring MAC Address Update

Configuration Effect

- Rapidly delete and update MAC addresses of an interface during link switching to make packet convergence faster.

Notes

- Dual link backup of REUP must be configured.
- Each device can be configured with a maximum of 8 address update groups. Each address update group can have a maximum of 8 member interfaces and an interface can belong to multiple address update groups.

Configuration Steps

- Mandatory.
- If there is no special requirement, the MAC address update function should be configured.

Verification

Run the **show mac-address-table update group [detail]** command to view the update group configuration.

Related Commands

📌 Configuring the MAC Address Update Group ID of a Switch

Command	mac-address-table update group [group-num]
Parameter Description	<i>group-num</i> : Indicates the MAC address update group ID.
Command Mode	Interface configuration mode
Usage Guide	In order to reduce large flooding caused by MAC address update which may affect normal data transmission of the switch, we add a setting of a MAC address update group. Only after all interfaces on a switching path are added to the same MAC address update group, transmission of downlink data can be rapidly recovered.

📌 Enabling Sending of MAC Address Update Messages

Command	mac-address-table move update transit
Parameter Description	-
Command Mode	Command Mode
Usage Guide	To reduce link switching and loss of downlink data streams, you need to enable sending of MAC address update messages on a switch that performs switching.

✚ Enabling Sending of the VLAN ID of MAC Address Update Messages

Command	mac-address-table move update transit vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates the VLAN ID for sending MAC address update messages.
Command Mode	Interface configuration mode
Usage Guide	After sending of MAC address update messages is enabled, MAC address update messages can be sent to uplink devices during link switching.

Configure the maximum number of MAC address update packets sent per second.

✚ Configuring the Maximum Number of MAC Address Update Packets Sent Per Second

Command	mac-address-table move update max-update-rate <i>pkts-per-second</i>
Parameter Description	<i>pkts-per-second</i> : Indicates the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
Command Mode	Configuration mode
Usage Guide	During link switching, REUP sends MAC address update packets of a specified quantity to uplink devices per second to recover the downlink data transmission of the uplink device.

✚ Enabling Receiving of MAC Address Update Messages

Command	mac-address-table move update receive
Parameter Description	-
Command Mode	Configuration mode
Usage Guide	During switching of dual link backup, downlink data streams may be lost since the MAC address table of the uplink switch is not updated in real time. In order to reduce loss of layer-2 data streams, you need to update the MAC address table of the uplink switch. In this case, you need to enable receiving of MAC address update messages on the uplink switch.

✚ Configuring the VLAN Range for Processing MAC Address Update Messages

Command	mac-address-table move update receive vlan <i>vlan-range</i>

Parameter Description	<i>vlan-range</i> : Indicates the VLAN range for processing MAC address update messages.
Command Mode	Configuration mode
Usage Guide	This command is used to disable the function for processing MAC address update messages on certain VLANs. For a VLAN disabled with the function for processing MAC address update messages, MAC address update packets can be used to recover the downlink transmission of uplink devices; however, the convergence performance for link faults will be decreased.

Configuration Example

Configuring MAC Address Update

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	● Enable sending of MAC address update messages on the access switch D (E). ● Enable receiving of MAC address update packets on switch B (C). ● Add all interfaces on the REUP switching path to the same MAC address update group. ● In the environment, Gi0/1 and Gi0/3 of switch B are the interfaces on the switching path of switch D's uplink, and Gi0/3 and Gi0/2 are the interfaces on the switching path of switch E's uplink. You can add interfaces Gi0/1, Gi0/2 and Gi0/3 to the same address update group. Similarly, you can obtain the configuration of switch C. ● Enable receiving of MAC address update packets on switch A. ● Add all interfaces on the REUP switching path of switch A to the same MAC address update group.
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# mac-address-table move update transit SwitchD(config)# exit</pre>
E	<pre>SwitchE> enable SwitchE# configure terminal SwitchE((config)# mac-address-table move update transit SwitchE(config)# exit</pre>

B	<pre>SwitchB# configure terminal SwitchB(config)# mac-address-table move update receive SwitchB(config)# interface range gigabitEthernet 0/1 -3 SwitchB(config-if-range)#switchport mode trunk SwitchB(config-if-range)# mac-address-table update group 1 SwitchB(config-if-range)# end</pre>
C	<pre>SwitchB# configure terminal SwitchB(config)# mac-address-table move update receive SwitchB(config)# interface range gigabitEthernet 0/1 -3 SwitchB(config-if-range)#switchport mode trunk SwitchB(config-if-range)# mac-address-table update group 1 SwitchB(config-if-range)# end</pre>
A	<pre>SwitchA# configure terminal SwitchA(config)# mac-address-table move update receive SwitchA(config)# interface range gigabitEthernet 0/1 -2 SwitchA(config-if-range)# switchport mode trunk SwitchA(config-if-range)# mac-address-table update group 1 SwitchA(config-if-range)# end</pre>
Verification	Check the information about the address update groups on switches D, E, C, B and A.

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.4 Configuring VLAN Load Balance

Configuration Effect

- Maximize the utilization of link bandwidth.

Notes

- Dual link backup of REUP must be configured.
- The Access interface cannot be shared by VLAN load balance and STP.

- For interfaces successfully configured with VLAN load balance, you cannot modify the attributes of the interfaces but can modify the VLAN attributes of the interfaces.

Configuration Steps

- If maximizing bandwidth utilization is not required, this configuration is optional.
- If there is a requirement for VLAN load balance, corresponding configuration must be performed.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether VLAN load balance is configured.

Related Commands

Configuring VLAN Load Balance

Command	switchport backup interface <i>interface-id</i> prefer instance <i>instance-range</i>
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	<i>instance-range</i> : Indicates the load instance range of the backup interface.
Command Mode	Interface configuration mode
Usage Guide	You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.

Configuration Example

Configuring VLAN Load Balance

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	● Configure instance mappings on switch D (E) to map VLAN 1 to instance 1, VLAN 2 to instance 2, VLAN 3 to instance 3, and VLAN 4 to instance 4. For details, see the <i>MSTP Configuration Guide</i>. ● Configure the VLAN load balance function on switch D (E).
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)# switchport backup interface gi0/2 prefer instance 2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
E	<pre>SwitchE> enable</pre>

	<pre>SwitchE# configure terminal SwitchE(config)# interface GigabitEthernet 0/1 SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi0/2 prefer instance 4 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	Check the dual link backup information configured for switch D (E).
D	<pre>SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Up Instances Preferred on Active Interface: Instance 0-1,3-64 Mapping VLAN 1,3-4094 Instances Preferred on Backup Interface: Instance 2 Mapping VLAN 2 Interface Pair : Gi0/1, Gi0/2 Preemption Mode : balance Preemption Delay : 35 seconds Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)</pre>
E	<pre>SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Up</pre>

	<pre>Instances Preferred on Active Interface: Instance 0-3, 5-64 Mapping VLAN 1-3, 5-4094 Instances Preferred on Backup Interface: Instance 4 Mapping VLAN 4 Interface Pair : Gi0/1, Gi0/2 Preemption Mode : balance Preemption Delay : 35 seconds Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)</pre>

Common Errors

- The mappings between VLAN IDs and instances are not configured.

1.4.5 Configuring Link Tracking

Configuration Effect

- After detecting that the upstream link is disconnected, forcibly disconnect the downstream link so that link switching can be performed.

Notes

- Dual link backup of REUP must be configured.
- For the link state tracking function, each interface belongs to only one link state tracking group and each device can be configured with up to 2 link state tracking groups. Each link state tracking group can have 8 upstream interfaces and 256 downstream interfaces.

Configuration Steps

- Mandatory.
- If there is no special requirement, the uplink tracking function should be configured.

Verification

Run the **show link state group** command to view the configured link tracking information.

Related Commands

📄 Enabling a Link State Tracking Group

Command	link state track [<i>num</i>]
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	
Command Mode	Configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

✚ Enabling the Downlink Delay Up for a Link State Tracking Group

Command	link state track <i>num</i> up-delay <i>timer</i>
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	<i>timer</i> : Indicates the downlink delay up time, which is 0s by default.
Command Mode	Global configuration mode
Usage Guide	You must enable the delay function so that the downstream link can be up after the delay.

✚ Adding an interface to a Link Tracking Group

Command	ink stategroup <i>num</i> {upstream downstream}
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	upstream : Adds the interface as an upstream interface of the tracking group. downstream : Adds the interface as a downstream interface of the tracking group.
Command Mode	Interface configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

Configuration Example

✚ Configuring a Link Tracking Group

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	- Create link tracking group 1 on switch B (C). - On switch B (C), add the interfaces Gi0/1 and Gi0/2 as downstream interfaces of the link tracking group and add the interface Gi0/3 as an upstream interface of the link tracking group.

B	<pre> SwitchB> enable SwitchB# configure terminal SwitchB(config)# link state track 1 SwitchB(config)# interface GigabitEthernet 0/1 SwitchB(config-if-GigabitEthernet 0/1)#link state group 1 downstreamSwitchB(config-if-GigabitEthernet 0/1)#exit SwitchB(config)# interface GigabitEthernet 0/2 SwitchB(config-if-GigabitEthernet 0/2)# link state group 1 downstream SwitchB(config-if-GigabitEthernet 0/2)#exit SwitchB(config)# interface GigabitEthernet 0/3 SwitchB(config-if-GigabitEthernet 0/3)#link state group 1 upstream SwitchB(config-if-GigabitEthernet 0/3)#exit </pre>
C	<pre> SwitchC> enable SwitchC# configure terminal SwitchC(config)# link state track 1 SwitchC(config)# interface GigabitEthernet 0/1 SwitchC(config-if-GigabitEthernet 0/1)#link state group 1 downstreamSwitchC(config-if-GigabitEthernet 0/1)#exit SwitchC(config)# interface GigabitEthernet 0/2 SwitchC(config-if-GigabitEthernet 0/2)# link state group 1 downstream SwitchC(config-if-GigabitEthernet 0/2)#exit SwitchC(config)# interface GigabitEthernet 0/3 SwitchC(config-if-GigabitEthernet 0/3)#link state group 1 upstream SwitchC(config-if-GigabitEthernet 0/3)#exit </pre>
Verification	Check the link tracking group information configured for switch B (C).
B	<pre> SwitchB#show link state group Link State Group:1 Status: enabled, Down Upstream Interfaces :Gi0/3(Down) </pre>

	Downstream Interfaces : Gi0/2(Down)

Common Errors

- Interfaces are added to a link tracking group when the link tracking group is not enabled.

1.5 Monitoring

Displaying

Description	Command
Displays the dual link backup information of REUP.	show interfaces [<i>interface-id</i>] switchport backup [detail]
Displays the configurations of an MAC address update group.	show mac-address-table update group [detail]
Displays the REUP statistics about sent MAC address update messages.	show mac-address-table move update
Displays the information about a link state tracking group.	show link state group

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables all REUP debugging.	debug reup all
Debugs the normal running process of REUP.	debug reup process
Debugs MAC address update messages of REUP.	debug reup packet
Debugs MAC address update packets of REUP.	debug reup macupdt
Debugs hot backup.	debug reup ha
Debugs errors occurring in REUP running.	debug reup error
Debugs received events.	debug reup evnet
Debugs statistics when show operations are performed.	debug reup status

2 Configuring RLDP

2.1 Overview

The Rapid Link Detection Protocol (RLDP) achieves rapid detection of unidirectional link failures, directional forwarding failures and downlink loop failures of an Ethernet. When a failure is found, relevant ports will be closed automatically according to failure treatment configuration or the user will be notified to manually close the ports to avoid wrong flow forwarding or an Ethernet layer-2 loop.

2.2 Applications

Application	Description
Unidirectional Link Detection	Detect a unidirectional link failure.
Bidirectional Forwarding Detection	Detect a bidirectional link failure.
Downlink Loop Detection	Detect a link loop.

2.2.1 Unidirectional Link Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber. The two lines are the Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If any of the Tx of Port A, Rx of Port B, Tx of Port B and Rx of Port A fails, a unidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-1

Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.

Deployment

- Global RLDP is enabled.

- Configure unidirectional link detection under Port A and Port B and define a method for failure treatment.

2.2.2 Bidirectional Forwarding Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber, and the two lines are Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If the Tx of Port A, Rx of Port B, Rx of Port A and Tx of Port B all fail, a bidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-2

Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.

Deployment

- Global RLDP is enabled.
- Configure BFD under Port A and Port B and define a method for failure treatment.

2.2.3 Downlink Loop Detection

Scenario

As shown in the following figure, A, B and C are connect into a loop. Downlink loop detection is enabled on A, and a loop is detected and treated.

Figure 2-3

Remarks	A, B and C are layer-2 or layer-3 switches. A, B and C are interconnected via exchange ports.

Deployment

- Global RLDP is enabled on A.
- Configure downlink loop detection on the Gi 2/0/1 and Gi 2/0/9 ports of A, and define a method for failure treatment.

2.3 Features

Most Ethernet link detection mechanisms detect link connectivity through automatic physical-layer negotiation. However, in some cases devices are connected on the physical layer and operate normally but layer-2 link communication is disabled or abnormal. The RLDP recognizes a neighbor device and detects a link failure through exchanging Prob packets, Echo packets or Loop packets with the device.

Basic Concepts

↘ Unidirectional Link Failure

A unidirectional link failure occurs in case of a cross-connected optical fiber, a disconnected optical fiber, an open-circuit optical fiber, one open-circuit line in a twisted-pair cable, or unidirectional open circuit of an intermediate device between two devices. In such cases, one end of a link is connected and the other disconnected so that flow is forwarded wrongly or a loop guard protocol (for example, the STP) fails.

↘ Bidirectional Link Failure

A bidirectional link failure occurs in case of two optical fibers, two open-circuit lines in a twisted-pair cable, or bidirectional open circuit of an intermediate device between two devices. In such cases, the both ends of a link are disconnected so that flow is forwarded wrongly.

↘ Loop Failure

A downlink device is wrongly connected to form a loop, resulting in a broadcast storm.

↘ RLDP Packet

The RLDP defines three types of packets: Prob packets, Echo packets and Loop packets.

- Prob packets are layer-2 multicast packets for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Echo packets are layer-2 unicast packets as response to Prob packets and used for unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.

- Loop packets are layer-2 multicast packets for downlink loop detection. They can only be received. The default encapsulation format is SNAP.

↘ RLDP Detection Interval and Maximum Detection Times

A detection interval and the maximum detection times can be configured for the RLDP. A detection interval determines the period of sending Prob packets and Loop packets. When a device receives a Prob packet, it replies with an Echo packet immediately. A detection interval and the maximum detection times determine the maximum detection time (equal to a detection interval × the maximum detection times + 1) for unidirectional or bidirectional link detection. If neither Prob nor Echo packet from a neighbor can be received within the maximum detection time, the treatment of unidirectional or bidirectional failure will be triggered.

↘ RLDP Neighbor Negotiation

When configured with unidirectional or bidirectional link detection, a port can learn a peer-end device as its neighbor. One port may learn one neighbor, which is variable. If negotiation is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation, which succeeds when a port receives a Prob packet from the neighbor. However, if the RLDP is enabled under a failure, the port cannot learn a neighbor so that detection cannot start. In this case, recover the link state before enabling the RLDP.

↘ Treatment for Failed Port under RLDP

- Warning: Only print Syslog to indicate a failed port and a failure type.
- Shutdown SVI: Print Syslog, and then inquire an SVI according to the Access VLAN or Native VLAN of a port and shut down the SVI if the port is a physical exchange port or layer-2 AP member port.
- Port violation: Print Syslog, and configure a failed port as in violation state, and the port will enter Linkdown state physically.
- Block: Print Syslog, and configure the forward state of a port as Block, and the port will not forward packets.

↘ Recovery of Failed Port under RLDP

- Manual reset: Manually reset all failed ports to initialized state and restart link detection.
- Manual or automatic errdisable recovery: Recover all failed ports to initialized state manually or regularly (30s by default and configurable) and restart link detection.
- Automatic recovery: Under unidirectional or bidirectional link detection, if the treatment for failed ports is not specified as port violation, recover ports to initialized state based on Prob packets and restart link detection.

↘ Port State under RLDP

- normal: Indicates the state of a port after link detection is enabled.
- error: Indicates the state of a port after a unidirectional or bidirectional link failure or a loop failure is detected.

↘ Overview

Feature	Description
Deploying RLDP Detection	Enable unidirectional or bidirectional link detection or downlink loop detection for failures and implement treatment.

2.3.1 Deploying RLDP Detection

The RLDP provides unidirectional link detection, bidirectional forwarding detection and downlink loop detection.

Working Principle

↘ Unidirectional Link Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives Prob packets but no Echo packets, or none of them, treatment for a unidirectional failure will be triggered and detection will stop.

↘ Bidirectional Forwarding Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives neither Prob packets nor Echo packets from a neighbor, treatment for a bidirectional failure will be triggered and detection will stop.

↘ Downlink Loop Detection

When this function is enabled, a port sends Loop packets regularly. In the following cases, a loop failure will be triggered after the same port or a different port receives the packets: in one case, the egress and ingress ports are the same routed port or layer-3 AP member port; in another case, the egress and ingress ports are exchange ports or layer-2 AP member ports in a same default VLAN and in Forward state. Treatment for the failure will be implemented and detection will stop.

Related Configuration

● Configuring RLDP Detection

By default, RLDP detection is disabled.

You may run the global command **rldp enable** or the interface command **rldp port** to enable RLDP detection and specify a detection type and treatment.

You may run the **rldp neighbor-negotiation** command to neighbor negotiation, the **rldp detect-interval** to specify a detection interval, the **rldp detect-max** to specify detection times, or the **rldp reset** to recover a failed port.

2.4 Configuration

Configuration	Description and Command

[Configuring Basic RLDLP Functions](#)

 (Mandatory) It is used to enable RLDLP detection under global configuration mode.	
rldp enable	Enables global RLDLP detection on all ports.
 (Mandatory)It is used to specify under interface configuration mode a detection type and failure treatment for an interface.	
rldp port	Enables RLDLP detection on a port and specifies a detection type and failure treatment.
 (Optional)It is used to configure a detection interval, detection times and neighbor negotiation under global configuration mode.	
rldp detect-interval	Modifies global RLDLP parameters on all ports, such as the detection interval, maximum detection times and neighbor negotiation.
rldp detect-max	
rldp neighbor-negotiation	
 (Optional) It is used under privileged mode.	
rldp reset	Recovers all ports.

2.4.1 Configuring Basic RLDLP Functions

Configuration Effect

- Enable RLDLP unidirectional link detection, bidirectional forwarding detection, or downlink loop detection to discover failures.

Notes

- Loop detection is effective to all member ports of an AP when configured on one of the ports. Unidirectional link detection and bidirectional forwarding detection are effective only on an AP member port.
- The loop detection on a physical port added to an AP shall be configured the same as that of the other member ports. There are three cases. First, if loop detection is not configured on a newly-added port but on the existing member ports, the new port adopts the configuration and detection results of the existing ports. Second, if a newly-added port and the existing member ports have different loop detection configuration, the new port adopts the configuration and detection results of the existing ports.
- When configuring the RLDLP on an AP port, you may configure failure treatment only as "shutdown-port", to which other configurations will be modified.
- When "shutdown-port" is configured on a port, RLDLP detection cannot be restored in case of a failure. After troubleshooting, you may run the **rldp reset** or **errdisable recovery** command to restore the port and resume detection. For configuration of the **errdisable recovery** command, please refer to the *SWITCH-INTF-SCG.doc*.

Configuration Steps

↘ Enabling RLDP

- Mandatory.
- Enable RLDP detection on all ports under global configuration mode.

↘ Enabling Neighbor Negotiation

- Optional.
- Enable the function under global configuration mode, and port detection will be started under successful neighbor negotiation.

↘ Configuring Detection Interval

- Optional.
- Specify a detection interval under global configuration mode.

↘ Configuring Maximum Detection Times

- Optional.
- Specify the maximum detection times under global configuration mode.

↘ Configuring Detection under Port

- Mandatory.
- Configure unidirectional RLDP detection, bidirectional RLDP detection or downlink loop detection under interface configuration mode, and specify failure treatment.

↘ Restoring All Failed Ports

- Optional.
- Enable this function under privileged mode to restore all failed ports and resume detection.

Verification

- Display the information of global RLDP, port and neighbor.

Related Commands

↘ Enabling Global RLDP Detection

Command	rldp enable
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	Enable global RLDP detection.

✚ Enabling RLDP Detection on Interface

Command	rldp port { unidirection-detect bidirection-detect loop-detect } { warning shutdown-svi shutdown-port block }
Parameter Description	unidirection-detect : Indicates unidirectional link detection. bidirection-detect : Indicates bidirectional forwarding detection. loop-detect : Indicates downlink loop detection. warning : Indicate the failure treatment is warning. shutdown-svi : Indicate the failure treatment is closing the SVI that the interface is on. shutdown-port : Indicates the failure treatment is port violation. block : Indicates the failure treatment is disabling learning and forwarding of a port.
Command Mode	Interface configuration mode
Usage Guide	The interfaces include layer-2 switch ports, layer-3 routed ports, layer-2 AP member ports, and layer-3 AP member ports.

✚ Modifying Global RLDP Detection Parameters

Command	rldp {detect-interval <i>interval</i> detect-max <i>num</i> neighbor-negotiation }
Parameter Description	detect-interval <i>interval</i> : Indicates a detection interval. detect-max <i>num</i> : Indicates detection times. neighbor-negotiation : Indicates neighbor negotiation.
Command Mode	Global configuration mode
Usage Guide	Modify all RLDP parameters on all ports when necessary.

✚ Recovering Failed Port

Command	rldp reset
Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	Recover all failed ports to initialized state and resume detection.

✚ Displaying RLDP State Information

Command	show rldp [interface <i>interface-name</i>]

Parameter	<i>interface-name</i> : Indicates the interface to display information of.
Description	
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	Display RLDP state information.

Configuration Example

▾ Enabling RLDP Detection in Ring Topology

Scenario Figure 2-4	As shown in the following figure, the aggregation and access sections are in a ring topology. The STP is enabled on all devices to prevent loop and provide redundancy protection. To avoid a unidirectional or bidirectional link failure resulting in STP failure, RLDP unidirectional and bidirectional link detection is enabled between aggregation devices as well as between an aggregation device and the access device. To avoid loop due to wrong downlink connection of the aggregation devices, enable RLDP downlink loop detection on the downlink ports of the aggregation devices and of the access device. To avoid loop due to wrong downlink connection of the access device, enable RLDP downlink loop detection on the downlink ports of the access device. 
Configuration Steps	- SW A and SW B are aggregation devices, and SW C is an access device. Users connected to SW C. SW A, SW B and SW C are structured in a ring topology, and the STP is enabled on each of them. For STP configuration, refer to relevant configuration guide. - Enable the RLDP on SW A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port. - Enable the RLDP on SW B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port. - Enable the RLDP on SW C, enable unidirectional and bidirectional link detection on the two uplink ports, and enable loop detection on the two downlink ports.
A	<pre>A#configure terminal A(config)#rldp enable A(config)#interface GigabitEthernet 2/0/1</pre>

	<pre> A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)# exit A(config)#interface GigabitEthernet 2/0/9 A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#rldp port loop-detect shutdown-port A(config-if-GigabitEthernet 2/0/1)#exit </pre>
B	Apply the configuration on SW A.
C	<pre> C#configure terminal C(config)#rldp enable C(config)#interface GigabitEthernet 0/49 C(config-if-GigabitEthernet 0/49)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)# exit C(config)#interface GigabitEthernet 0/50 C(config-if-GigabitEthernet 0/50)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#exit C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/1)#exit C(config)#interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/2)#exit </pre>
Verification	● Check the RLDP information on SW A, SW B and SW C. Take SW A for example.
A	<pre> A#show rldp rldp state : enable rldp hello interval: 3 rldp max hello : 2 rldp local bridge : 00d0.f822.33aa </pre>

```
-----

bidirection detect information:  
    action: shutdown-port  
    state : normal  
loop detect information:  
    action: shutdown-port  
    state : normal
```

Common Errors

- RLDP functions and private multicast address authentication or TPP are enabled at the same time.
- Neighbor negotiation is not enabled when configuring unidirectional or bidirectional link detection. The RLDP should be enabled on a neighbor device, or otherwise a unidirectional or bidirectional failure will be detected.
- If RLDP detection is configured to be implemented after neighbor negotiation while configuring unidirectional or bidirectional link detection, detection cannot be implemented as no neighbor can be learned due to a link failure. In this situation, you are suggested to recover the link state first.

- You are suggested not to specify the failure treatment as Shutdown SVI under a routed port.
- You are suggested not to specify the failure treatment as Block for a port, on which a loop protection protocol is enabled, for example, the STP.

Displaying

Description	Command
Displays RLDP state.	show rldp [interface <i>interface-name</i>]

3 Configuring DLDP

3.1 Overview

The Data Link Detection Protocol (DLDP) is a protocol used to quickly detect faulty Ethernet links.

A typical Ethernet link detection mechanism detects physical link connectivity through autonegotiation at the physical layer. Such a mechanism has limitations when detecting Layer-3 data communication exceptions despite normal physical connections.

DLDP provides reliable Layer-3 link detection information. After detecting a faulty link, DLDP shuts down the logical state of Layer-3 ports to realize fast Layer-3 protocol convergence.

3.2 Applications

Application	Description
Intra-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in the same network segment.
Inter-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in different network segments.

3.2.1 Intra-Network Segment DLDP Detection

Scenario

This section describes the basic DLDP application scenario where the source IP address of the detected port and the detected IP address are in the same network segment.

In Figure 3-1, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/2 Layer-3 port on Switch C are in the same network segment. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/2, enable DLDP on Gi 0/1 or Gi 0/2.

Figure 3-1

Remarks	Device A and Device C are switches. Gi 0/1 and Gi 0/2 are Layer-3 ports in the same network segment. B is a network in the same network segment as Gi 0/1 and Gi 0/2.

Deployment

- Enable DLDP on Gi 0/1 or Gi 0/2.

3.2.2 Inter-Network Segment DLDP Detection

Scenario

This section describes the DLDP application scenario where the source IP address of the detected port and the detected IP address are in different network segments.

In Figure 3-2 the Gi 0/1 Layer-3 port on Switch A and the Gi 0/4 Layer-3 port on Switch D are in different network segments. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/4, enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address (IP address of the Gi 0/2 port on Switch B).

Figure 3-2

Remarks	Device A, Device B, and Device D are switches. Gi 0/1 and Gi 0/4 are Layer-3 ports in different network segments.

Deployment

- Enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address.

3.3 Features

Basic Concepts

DLDP Detection Interval and Retransmission Times

Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.

Retransmission times: Indicate the maximum times DLDP detection packets can be retransmitted in the case of a DLDP detection failure.

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the retransmission times, the device determines that a Layer-3 link failure occurs and shuts down the logical state of its Layer-3 port (despite the normal physical link connection). When Layer-3 link connectivity is recovered, the device restores its Layer-3 port to Up logical state.

DLDP Detection Modes

Active mode and passive mode are two DLDP detection modes.

Active mode (default): ICMP detection packets are sent actively.

Passive mode: ICMP detection packets are received passively.

DLDP Next Hop

Next hop: Indicates the next node connected to the detected IP address in inter-network segment DLDP detection.

In some cases, DLDP needs to detect IP reachability in non-directly connected network segments. You need to configure the next-hop IP address for the detected port to allow DLDP to obtain the next-hop MAC address through an ARP packet before sending a correct ICMP packet.

In this situation, you need to avoid the return of the reply packet from another link; otherwise, DLDP will misjudge that the detected port does not receive an ICMP reply.

DLDP Recovery Times

Recovery times: Indicate the times DLDP needs to receive consecutive reply packets (ICMP reply) before it can determine link failure recovery.

In some cases, link detection may be unstable. For example, a link is only intermittently pingable. In this case, DLDP repeatedly changes the link status between Up and Down, which may further destabilize the ring network.

Recovery times indicate the times DLDP needs to receive consecutive reply packets before DLDP can set the link in Down state to Up. The default recovery times are three times, indicating that the link needs to be successfully pinged three times before it is set to Up. The recovery times setting reduces link detection sensitivity but increases stability. Related parameters are adjustable according to the network condition.

DLDP Bound MAC Address

Bound MAC address: Indicates the MAC address bound to the detected IP address.

In a complex network environment, DLDP may obtain an invalid MAC address if the detected link has abnormal ARP packets transmitted (causing ARP spoofing), which will make DLDP detection abnormal.

To address this problem, you can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Overview

Feature	Description
DLDP Detection	Detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.
MAC Address Binding	Binds the detected IP address to the MAC address of the detected device to avoid DLDP exceptions otherwise caused by ARP spoofing.
Passive DLDP Detection	When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

3.3.1 DLDP Detection

DLDP detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the corresponding Layer-3 port.

Working Principle

After DLDP detection is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specific period, DLDP determines that the link is abnormal and sets the Layer-3 port to Down.

Related Configuration

- Enabling DLDP Detection

By default, DLDP detection is disabled on ports.

Run the **dlldp** command with the detected IP address specified to enable DLDP detection.

You can configure the next-hop IP address, MAC address of the detected device, transmission interval, retransmission times, and recovery times based on the actual environment.

3.3.2 MAC Address Binding

The MAC address binding feature is used to bind the detected IP address (or next-hop IP address) to the MAC address of the detected device (or next-hop device) to avoid DLDP exceptions otherwise caused by ARP spoofing

Working Principle

You can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Related Configuration

By default, no MAC address is bound in DLDP detection.

Bind the MAC address of the detected device when you run the **dlldp** command to enable DLDP detection. If the next-hop IP address is specified, bind the MAC address of the next-hop device.

After DLDP detection is enabled, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address. If the source IP address and MAC address in the received packet do not match the bound IP address and MAC address, DLDP will not process the packet.

3.3.3 Passive DLDP Detection

When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

Working Principle

After the device at the local end sends an ICMP echo packet, the peer device determines link connectivity according to the packet reception time by using specific detection parameters, which are the same as those at the local end, thus saving bandwidth and CPU resources.

Related Configuration

By default, passive DLDP detection is disabled.

Run the **dldp passive** command to enable passive DLDP detection.

After passive DLDP detection is enabled, DLDP will return an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. If DLDP does not receive an ICMP echo packet within a specific period, it determines that the link to the peer port is abnormal.

3.4 Configuration

Configuration	Description and Command	
Enabling DLDP Detection	 (Mandatory) It is used to enable DLDP detection in interface configuration mode.	
	dldp	Enables DLDP detection.
	 (Mandatory) It is used to enable passive DLDP detection in interface configuration mode.	
	dldp passive	Enables passive DLDP detection.
	 (Optional) It is used to configure the detection interval, retransmission times, and recovery times of DLDP detection in global configuration mode.	
	dldp interval	Modifies the DLDP parameters globally to apply the modifications to DLDP detection on all ports.
	dldp retry	
	dldp resume	

3.4.1 Enabling DLDP Detection

Configuration Effect

- Detect Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.

Notes

- DLDP supports the configuration of multiple IP addresses on a Layer-3 port. DLDP sets the port to Down when none of the IP addresses receives an ICMP reply. If one IP address resumes communication, DLDP sets the port to Up again.
- DLDP uses the first IP address of the Layer-3 port as the source IP address of detection packets.

Configuration Steps

▾ Enabling DLDP Detection

- Mandatory.
- When you enable DLDP detection in interface configuration mode, you can configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment.

▾ Configuring a DLDP Detection Mode

- Optional.
- You can configure active or passive DLDP detection in interface configuration mode based on the actual environment.
- If DLDP detection needs to be enabled at both ends of a Layer-3 link, you can configure passive DLDP detection at one end to save bandwidth and CPU resources.

▾ Configuring DLDP Parameters Globally

- Optional.
- You can modify the parameters of DLDP detection on all ports in global configuration mode based on requirements. The parameters include the packet transmission interval, packet retransmission times, and recovery times.

Verification

- Display the device DLDP information, including the status and statistics of DLDP detection on all ports.

Related Commands

▾ Enabling DLDP Detection

Command	dldp <i>ip-address</i> [<i>next-hop-ip</i>] [mac-address <i>mac-addr</i>] [interval <i>tick</i>] [retry <i>retry-num</i>] [resume <i>resume-num</i>]
Parameter Description	<i>ip-address</i> : Indicates the detected IP address. <i>next-hop-ip</i> : Indicates the next-hop IP address. <i>mac-addr</i> : Indicates the MAC address of the detected device to be bound. If the next-hop IP address is specified, bind the MAC address of the next-hop device. <i>tick</i> : Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s). <i>retry-num</i> : The value ranges from 1 to 3,600. The default value is 4. <i>resume-num</i> : Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
Command Mode	Interface configuration mode
Usage Guide	The port to be enabled with DLDP detection must be a Layer-3 port, such as a router port, L3AP port, and SVI port.

▾ Configuring a DLDP Detection Mode

Command	dldp passive
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	You need to enable DLDP detection before configuring a DLDP detection mode.

✎ Modifying DLDP Detection Parameters Globally

Command	dldp { interval <i>tick</i> retry <i>retry-num</i> resume <i>resume-num</i> }
Parameter Description	<i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s). <i>retry-num</i>: Indicates the interval at which detection packets are retransmitted. The value ranges from 1 to 3,600. The default value is 4. <i>resume-num</i>: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.
Command Mode	Global configuration mode
Usage Guide	Use this command to quickly modify the parameters of DLDP detection on all ports when the actual environment is changed.

✎ Displaying the DLDP Status

Command	show dldp statistic [interface <i>interface-name</i>]
Parameter Description	<i>interface-name</i> : Indicates the Layer-3 port on which the DLDP status will be displayed.
Command Mode	Privileged mode, global configuration mode, and interface configuration mode
Usage Guide	Use this command to display the DLDP status on a specific port. You can also use this command to display the DLDP status on all ports.

Configuration Example

✎ Enabling DLDP Detection on Layer-3 Ports on Device A and Device B in a Layer-3 Network

Scenario Figure 3-3	

Verification	● Enable DLDAP detection on the Gi 0/1 and Gi 0/2 router ports on Device A to detect the Layer-3 link connectivity between Device A and Device B and that between Device A and Device D. ● To control the Gi 0/2 router port of Device B, enable passive DLDAP detection on the port.																								
A	<pre>A#configure terminal A(config)#interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#dldap 192.168.1.2 A(config-if-GigabitEthernet 0/1)# exit A(config)#interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/1)#dldap 192.168.3.4 192.168.2.3</pre>																								
B	<pre>B#configure terminal B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/1)#dldap 192.168.1.1 B(config-if-GigabitEthernet 0/1)#dldap passive</pre>																								
Verification	● Display the DLDAP status on Device A and Device B to check whether DLDAP detection is enabled and works normally.																								
A	<pre>A# show dldap</pre> <table><thead><tr><th>Interface</th><th>Type</th><th>Ip</th><th>Next-hop</th><th>Interval</th><th>Retry</th><th>Resume</th><th>State</th></tr></thead><tbody><tr><td>Gi0/1</td><td>Active</td><td>192.168.1.2</td><td></td><td>100</td><td>4</td><td>3</td><td>Up</td></tr><tr><td>Gi0/1</td><td>Active</td><td>192.168.3.4</td><td>192.168.2.3</td><td>100</td><td>4</td><td>3</td><td>Up</td></tr></tbody></table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/1	Active	192.168.1.2		100	4	3	Up	Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/1	Active	192.168.1.2		100	4	3	Up																		
Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up																		
B	<pre>B# show dldap</pre> <table><thead><tr><th>Interface</th><th>Type</th><th>Ip</th><th>Next-hop</th><th>Interval</th><th>Retry</th><th>Resume</th><th>State</th></tr></thead><tbody><tr><td>Gi0/2</td><td>Passive</td><td>192.168.1.1</td><td></td><td>100</td><td>4</td><td>3</td><td>Up</td></tr></tbody></table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/2	Passive	192.168.1.1		100	4	3	Up								
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/2	Passive	192.168.1.1		100	4	3	Up																		

Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDAP detection failure.
- DLDAP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured in inter-network segment DLDAP detection.

3.5 Monitoring

Clearing

Description	Command
Clears DLDAP statistics.	clear dldap [interface <i>interface-name</i> [<i>ip-address</i>]]

Displaying

Description	Command
Displays the DLDAP status.	show dldap [interface <i>interface-name</i>]
Displays the DLDAP statistics on the Up/Down port sates.	show dldap statistic

4 Configuring VRRP

4.1 Overview

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol.

VRRP adopts the master-backup design to ensure migration of functions from a Master router to a Backup one when the Master failed, without influencing internal and external data communication or modifying Local Area Network (LAN) configuration. A VRRP group maps multiple routers into a virtual router. VRRP ensures only one router at a moment on behalf of a virtual router transfers packets, which is the elected Master. If the Master fails, one of the Backup routers will replace it. Under VRRP, it seems that a host in a LAN uses only one router, and the routing remains functional even when the first-hop router fails.

- VRRP is applicable to LAN scenarios which require the redundancy of routing egresses.

Protocols and Standards

- RFC2338: Virtual Router Redundancy Protocol
- RFC3768: Virtual Router Redundancy Protocol (VRRP)
- RFC5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

4.2 Applications

Application	Description
Routing Redundancy	Configure routers in a LAN as one VRRP group to achieve simple routing redundancy.
Load Balancing	Configure routers in a LAN as multiple VRRP groups to achieve traffic load balancing.

4.2.1 Routing Redundancy

Scenario

Configure routers in a LAN as one VRRP group, where hosts take the virtual IP address of this group as the default gateway address.

- Packets from Host 1, Host 2 and Host 3 to other networks are forwarded by the elected Master router (Router A in Figure 4-1).
- If Router A fails, the Master will be re-elected between Router B and Router C to forward packets, achieving simple routing redundancy.

Figure 4-1

Deployment

- Router A, Router B and Router C are connected to the LAN via Ethernet interfaces.
- On Router A, Router B and Router C, VRRP is configured on the Ethernet interfaces connected to the LAN.
- These Ethernet interfaces are in the same VRRP group whose virtual IP address is 192.168.12.1.
- The gateway address for Host 1, Host 2 and Host 3 is the IP address of the VRRP group, namely 192.168.12.1.

4.2.2 Load Balancing

Scenario

Configure routers in a LAN as multiple VRRP groups. Hosts in the LAN take virtual IP addresses of the groups as their gateways, and each router backs up for other routers in different group.

- Packets from Host 1 and Host 2 to other networks with the default gateway address as the virtual IP address of virtual router 1 are forwarded by the Master of virtual router 1 (Router A in Figure 4-2).
- Packets from Host 3 and Host 4 to other networks with the default gateway address as the virtual IP address of virtual router 2 are forwarded by the Master of virtual router 2 (Router B in Figure 4-2).
- Routing redundancy is achieved on Router A and Router B, and the LAN traffic is shared to achieve load balancing.

Figure 4-2

Deployment

- Router A and Router B are connected to the LAN via Ethernet interfaces.
- On Router A and Router B, two virtual routers are configured on the Ethernet interfaces connected to the LAN.

Router A takes the IP address 192.168.12.1 of Ethernet interface Gi0/0 as the IP address of virtual router 1. Thus for virtual router 1, Router A becomes the Master and Router B becomes the Backup.

- Router B takes the IP address 192.168.12.2 of Ethernet interface Gi0/0 as the IP address of virtual router 2. Thus for virtual router 2, Router B becomes the Master and Router A becomes the Backup.
- In the LAN, Host 1 and Host 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while Host 3 and Host 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address.

4.3 Features

Basic Concepts

Virtual Router

A virtual router, also called a VRRP group, is regarded as a default gateway for hosts in a LAN. A VRRP group contains a Virtual Router Identifier (VRID) and a set of virtual IP addresses.

Virtual IP Address

Indicates the IP address of a virtual router. A virtual router can be configured with one or multiple IP addresses.

IP Address Owner

If a VRRP group has the virtual IP address as that of an Ethernet interface on one real router, the router is regarded as the virtual IP address owner. In such case, the router priority is 255. If the owned Ethernet interface is available, the VRRP group will be in Master state automatically. The IP address owner receives and processes the packets with the destination IP address as that of the virtual router.

Virtual MAC Address

The virtual MAC address of a VRRP group is an IEEE 802 MAC address, formatted as **00-00-5E-00-01-{VRID}** with the first five octets assigned and the last two as a group VRID. A VRRP group responds to an Address Resolution Protocol (ARP) request with its virtual MAC address instead of a real MAC address.

Master Router

In a VRRP group, only the Master router answers ARP requests and forwards IP packets. If a real router is the IP Address Owner, it becomes the Master router.

Backup Router

In a VRRP group, Backup routers only monitor the state of the Master but do not respond to ARP requests or forward IP packets. When the Master fails, Backup routers will take the chance to compete for the position.

Preemption Mode

If a VRRP group runs in Preemption mode, a higher priority Backup router will replace the lower priority Master router.

Overview

Feature	Description
VRRP	VRRP achieves redundancy for the default gateways of terminals on a multi-access media (for example, Ethernet). It enables a Backup router to forward packets when the Master router is down, providing transparent routing switch and promoting network service quality.

4.3.1 VRRP

In case that the Master router is faulty, VRRP achieves migration of functions from the Master router to a Backup one without influencing internal and external data communication or modifying LAN configuration.

Working Principle

Figure 4-3 Working Principle of VRRP

Working Mode of VRRP

The RFC2338, RFC3768 and RFC5798 protocols define the format and operating mechanism of VRRP packets. Multicast VRRP packets are sent periodically with specified destination addresses by the Master router to advertise normal operation or for Master election. VRRP allows a router in a LAN to automatically replace the Master who forwards IP packets when the latter fails. This helps achieve hot backup and fault tolerance of IP-based routing as well as ensure communication continuity and reliability for hosts in the LAN. A VRRP group achieves redundancy through multiple real routers. However, only one router acts as the Master to forward packets while the others are Backup routers. Router switching in a VRRP group is completely transparent to hosts in a LAN.

📌 Master Election Process

The RFC standards stipulate the master election process as follows:

- VRRP provides a simple mechanism for Master election. First, compare the VRRP priorities configured on the interfaces of the routers in a VRRP group. The router with the highest priority is elected as the Master. If these priorities are equal, compare the primary IP addresses of these routers. The router with the biggest IP address is elected as the Master.
- After the Master router is elected, the other routers become Backup routers (and enter the **Backup** state) and monitor the state of the master router through the VRRP packets the master router sends. If the master router is operational, it regularly sends VRRP multicast packets known as Advertisement packets to notify the Backup routers of its status. If the Backup routers do not receive such packets within a set period, all of them will enter the Master state. In such case, the previous step of Master election is repeated. In this way, a router with the highest priority will be elected as a new master, achieving VRRP backup.

Once the Master router of a VRRP group is elected, it is responsible to forward packets for hosts in a LAN.

📌 Communication Process

The VRRP communication process can be explained by Figure 4-3. The routers R1 and R2 are connected to the LAN segment 192.168.12.0/24 via the VRRP-enabled Ethernet interfaces Gi0/0. Hosts in the LAN take the virtual IP address of the VRRP group as the default gateway address. Only the virtual router is recognized by the hosts. The Master router in the group, however, is unknown. For example, when PC 1 plan to communicate with PC 2, PC 1 sends packets to the default gateway with the virtual IP address; The Master router in the group receives the packets and forwards them to PC 2. In this process, PC 1 only senses the virtual router instead of R1 or R2. The Master router in the group is elected between R1 and R2. When the Master fails, it will be replaced automatically by the other router.

Related Configuration

📌 Enabling VRRP

By default, VRRP is disabled on an interface.

In the interface configuration mode, run the **vrrp group ip ipaddress [secondary]** or **vrrp group ipv6 ipv6-address** command to set the VRID and virtual IP address to enable VRRP.

VRRP must be enabled on an interface.

📌 Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode.

Run the **vrrp group authentication *string*** command to set an authentication string in MD5 authentication mode or a plain text password in plain text mode for an IPv4 VRRP group. In the plain text authentication mode, a password contains 8 bytes at most.

Members of a VRRP group can communicate with each other only when they are in the same authentication mode. In the plain text authentication mode, all routers in a VRRP group should have the same authentication password. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations.

✚ Configuring the VRRP Advertisement Interval

By default, the advertisement interval of the Master router is 1 second.

Run the **vrrp [ipv6] group timers advertise { advertise-interval | csec centisecond-interval }** command to change the interval.

When VRRP learning timer is not configured, the same advertisement interval should be set for a VRRP group, otherwise routers in **Backup** state will discard received VRRP packets.

✚ Configuring the VRRP Preemption Mode

By default, a VRRP group operates in the Preemption mode.

To enable the Preemption mode for a VRRP group, run the **vrrp [ipv6] group preempt [delay seconds]** command. The optional parameter **delay seconds** is 0 by default.

If a VRRP group operates in the Preemption mode, a router will become the Master of the group when it finds that its priority is higher than that of the current Master. If a VRRP group operates in Non-preemption mode, a router will not become the Master even when it finds that its priority is higher than that of the current Master. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group. The optional parameter **Delay Seconds** defines the delay before a backup VRRP router declares its Master identity.

✚ Enabling the IPv6 VRRP Accept Mode

By default, the Accept mode is disabled for an IPv6 VRRP group.

To enable the Accept mode, run the **vrrp ipv6 group accept_mode** command.

After the Accept mode is enabled, an IPv6 VRRP virtual router in **Master** state receives and processes packets with the virtual router IP address as the destination; when the Accept mode is disabled, the virtual router discards such packets except Neighbor Advertisement (NA) packets and Neighbor Solicitation (NS) packets. Besides, an IPv6 VRRP master virtual router in **Owner** state receives and processes packets with the virtual router IP address as the destination by default no matter whether the Accept mode is configured or not.

✚ Configuring the VRRP Router Priority

By default, the router priorities in a VRRP group are all 100.

To adjust the priority, run the **vrrp [ipv6] group priority level** command.

If a router in the Preemption mode owns the group's virtual IP address and the highest priority, it becomes the group Master, while the other routers with lower priorities in the group become Backup (or monitoring) routers.

📌 Configuring the VRRP Tracked Interface

By default, no interface is tracked by a VRRP group.

To configure such an interface, run the **vrrp group track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* } [*priority*] or **vrrp ipv6 group track** *interface-type interface-number* [*priority*] command.

After an interface is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the interface state. Once the interface becomes unavailable, the priority of the router in the group will be reduced by a set value, and another functional and higher priority router in this group will become the Master.

📌 Configuring the VRRP Tracked IP Address

By default, no IP address is tracked by a VRRP group.

To configure such an address, run the **vrrp group track** *ip-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] or **vrrp ipv6 group track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] command.

After an IP address is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the address accessibility. Once the address is inaccessible (the **ping** command fails), the priority of the router in the group will be reduced by a set value, and another higher priority router in this group will become the Master.

📌 Configuring the VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group.

To enable it, run the **vrrp [ipv6] group timers learn** command.

After the learning timer is configured, a VRRP Backup router learns the advertisement interval of NA packets from the Master. Based on this instead of a locally set interval, the Backup router calculates the interval for determining a failure of the Master. This command achieves the synchronization of advertisement intervals between Backup routers and the Master.

📌 Configuring the VRRP Group Description

By default, no description is configured for a VRRP group.

To configure such a string, run the **vrrp [ipv6] group description** *text* command.

A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

📌 Configuring the VRRP Delay

By default, no delay is configured for a VRRP group.

To enable it, run the **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* } command. The two types of delay range from 0 to 60 seconds.

The command configures the delay of starting a VRRP group on an interface. There are two types of VRRP delay: the delay after system startup and the delay after an interface resumes. You may configure them respectively or simultaneously. After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

✎ Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard.

To specify the version for IPv4 VRRP, run the **vrrp group version { 2 | 3 }** command.

When the parameter value is set to 2, VRRPv2 is adopted; when the parameter value is set to 3, VRRPv3 is adopted.

✎ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

By default, IPv4 VRRP packets are sent to the first **Up** Sub VLAN interface of a Super VLAN.

To specify the first Sub VLAN in Up state of a Super VLAN to receive IPv4 VRRP packets, run the **vrrp detection-vlan first-subvlan** command; to specify a Sub VLAN, run the **vrrp detection-vlan subvlan-id** command. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN.

Both the above configurations reduce VRRP packets and avoids influencing router performance and occupying network bandwidth. Yet the routers constituting an IPv4 VRRP group should be interconnected within the first UP Sub VLAN interface or a specified Sub VLAN of the Super VLAN.

✎ Configuring the BFD Support for IPv4 VRRP on an Interface

By default, the Bidirectional Forwarding Detection (BFD) protocol support for VRRP is not enabled on an interface.

To enable it, run the **vrrp group bfd ip-address** command.

For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

After the BFD support is enabled for a specified IPv4 VRRP group, when the Master fails, a Backup router may detect it within one second.

✎ Configuring Global IPv4 VRRP BFD

By default, the VRRP does not adopt the global IPv4 VRRP BFD mode in detecting the state of the Master.

To enable global IPv4 VRRP BFD, run the **vrrp bfd interface-type interface-number ip-address** command.

After global IPv4 VRRP BFD is enabled, multiple IPv4 VRRP groups may share BFD sessions, achieving fast detection and master-backup failover.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

4.4 Configuration

Configuration	Description and Command	
Configuring IPv4 VRRP	 (Mandatory) It is used to enable IPv4 VRRP.	
	vrrp group ip <i>ipaddress</i> [secondary]	Enables IPv4 VRRP.
	 (Optional) It is used to configure IPv4 VRRP parameters.	
	vrrp group authentication <i>string</i>	Configures the IPv4 VRRP authentication string.
	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }	Configures the IPv4 VRRP advertisement interval.
	vrrp group preempt [delay <i>seconds</i>]	Configures the IPv4 VRRP Preemption mode.
	vrrp group priority <i>level</i>	Configures the IPv4 VRRP router priority.
	vrrp group track { <i>interface-type</i> <i>interface-number</i> bfd <i>interface-type</i> <i>interface-number</i> <i>ipv4-address</i> } [<i>priority</i>]	Configures the IPv4 VRRP tracked interface.
	vrrp group track ip-address [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]	Configures the IPv4 VRRP tracked IP address.
	vrrp group timers learn	Configures the IPv4 VRRP learning timer.
	vrrp group description <i>text</i>	Configures the IPv4 VRRP group description.
	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }	Configures the IPv4 VRRP delay.
	vrrp group version { 2 3 }	Configures the IPv4 VRRP version.
	vrrp detection-vlan { <i>first-subvlan</i> <i>subvlan-id</i> }	Specifies a sub VLAN of a super VLAN to receive the IPv4 VRRP packets.
	vrrp group bfd <i>ip-address</i>	Configures the BFD support for IPv4 VRRP on an Interface.
	vrrp bfd <i>interface-type</i> <i>interface-number</i> <i>ip-address</i>	Configures global IPv4 VRRP BFD.
Configuring IPv6 VRRP	 (Mandatory) It is used to enable IPv6 VRRP.	
	vrrp group ipv6 <i>ipv6-address</i>	Enables IPv6 VRRP on the interface.
	 (Optional) It is used to configure IPv6 VRRP parameters.	

Configuration	Description and Command	
	vrrp ipv6 group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }	Configures the IPv6 advertisement interval.
	vrrp ipv6 group preempt [delay <i>seconds</i>]	Configures the IPv6 VRRP Preemption mode.
	vrrp ipv6 group accept_mode	Enables the Accept mode for an IPv6 VRRP group.
	vrrp ipv6 group priority <i>level</i>	Configures the IPv6 VRRP router priority.
	vrrp ipv6 group track <i>interface-type</i> <i>interface-number</i> [<i>interface-priority</i>]	Configures the IPv6 VRRP tracked interface.
	vrrp ipv6 group track { <i>ipv6-global-address</i> { <i>ipv6-linklocal-address</i> <i>interface-type</i> <i>interface-number</i> } } [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]	Configures the IPv6 VRRP tracked IP address.
	vrrp ipv6 group timers learn	Configures the IPv6 VRRP learning timer.
	vrrp ipv6 group description <i>text</i>	Configures the IPv6 VRRP group description.
	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }	Configures the IPv6 VRRP delay.
Configuring VRRP-MSTP	 The configuration is the same as IPv4 VRRP configuration.	

4.4.1 Configuring IPv4 VRRP

Configuration Effect

- Configure a VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IP address.
- Configure multiple VRRP groups on an interface to achieve load balancing and offer more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv4 address.
- To achieve mutual backup between multiple IPv4 VRRP groups, configure multiple IPv4 VRRP groups with identical VRRP configuration on different interface and configure different priorities for them so that they act as the master and backup groups mutually.
- Enable VRRP on Layer-3 interfaces.

Configuration Steps

➤ Enabling IPv4 VRRP

- By default, IPv4 VRRP is disabled on an interface. You can enable it based on your demand.

➤ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in non-authentication mode. You can enable plain text authentication mode based on your demand.

➤ Configuring the IPv4 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

➤ Configuring the IPv4 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

➤ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

➤ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface and the value of priority change is 10. To achieve fault monitoring through interface monitoring, please configure this item.

➤ Configuring the IPv4 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

➤ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

➤ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

➤ Configuring the IPv4 VRRP Version

- By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

➤ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first **UP** Sub VLAN interface of a Super VLAN, but you may configure a specific Sub VLAN.

➤ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the BFD support is not configured on an interface. To configure it, use the corresponding command.

✚ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not enabled. To implement it, use the corresponding command.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

✚ Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [<i>secondary</i>]
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipaddress</i> : Indicates the IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

✚ Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3. Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

✚ Configuring the IPv4 VRRP Advertisement Interval

Command	vrrp group timers advertise { <i>advertise-interval</i> <i>csec centisecond-interval</i> }
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.

Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information. According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.

✚ Configuring the IPv4 VRRP Preemption Mode

Command	vrrp group preempt [delay seconds]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. delay seconds: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.

✚ Configuring the IPv4 VRRP Router Priority

Command	vrrp group priority level
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>level</i>: Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

✚ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { interface-type interface-number bfd interface-type interface-number ipv4-address } [priority]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>interface-type interface-number</i>: Indicates the interface to be tracked. bfd interface-type interface-number ipv4-address: A specified adjacent IP address tracked through BFD. <i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface,

	a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

📌 Configuring the IPv4 VRRP Tracked IP Address

Command	vrrp group track <i>ipv4-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>ipv4-address</i>: Indicates the IPv4 address to be tracked. interval <i>interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default. timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. <i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

📌 Configuring the IPv4 VRRP Learning Timer

Command	vrrp group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

📌 Configuring the IPv4 VRRP Group Description

Command	vrrp group description <i>text</i>
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>text</i>: Indicates the description of a VRRP group.

Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

✚ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter Description	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes. reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

✚ Configuring the IPv4 VRRP Version

Command	vrrp group version { 2 3 }
Parameter Description	2 : Indicates VRRPv2. 3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

✚ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

Command	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }
Parameter Description	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN. <i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

✚ Configuring the BFD Support for IPv4 VRRP on an Interface

Command	<code>vrrp group bfd ip-address</code>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Interface configuration mode
Usage Guide	For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator. If global IPv4 VRRP BFD is configured, this configuration cannot be performed. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

📌 Configuring Global IPv4 VRRP BFD

Command	<code>vrrp bfd interface-type interface-number ip-address</code>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address..
Command Mode	Global configuration mode
Usage Guide	If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface. A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.

Configuration Example

📌 Configuring an IPv4 VRRP Group and Tracked Interface

Scenario
Figure 4-4

Configuration Steps

- The cluster of Work Station A and Work Station B (192.168.201.0/24) uses the virtual IP address 192.168.201.1 of the VRRP group constituted by the routers R1 and R2 as the gateway address to communicate with Work Station B (192.168.12.0 /24).
- GigabitEthernet 2/1 on R1 is configured as the tracked interface.
- No VRRP but an ordinary routing function is configured on R3.

R3

```
R3#configure terminal
R3(config)#interface GigabitEthernet 0/0
// The command "no switchport" is only required for a switch.
R3(config-if-GigabitEthernet 0/0)#no switchport
R3(config-if-GigabitEthernet 0/0)#ip address 192. 168. 12. 217 255. 255. 255. 0
R3(config-if-GigabitEthernet 0/0)#exit
R3(config)#interface GigabitEthernet 1/1
// The command "no switchport" is only required for a switch.
R3(config-if-GigabitEthernet 1/1)#no switchport
R3(config-if-GigabitEthernet 1/1)#ip address 60. 154. 101. 5 255. 255. 255. 0
R3(config-if-GigabitEthernet 1/1)#exit
R3(config)#interface GigabitEthernet 2/1
// The command "no switchport" is only required for a switch.
```

	<pre> R3(config-if-GigabitEthernet 2/1)#no switchport R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 2/1)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10 </pre>
R1	<pre> R1#configure terminal R1(config)#interface GigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120 R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/0)#vrrp 1 track GigabitEthernet 2/1 30 R1(config-if-GigabitEthernet 0/0)#exit R1(config)#interface GigabitEthernet 2/1 R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 2/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
R2	<pre> R2#configure terminal R2(config)#interface GigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#exit R2(config)#interface GigabitEthernet 1/1 // The command “no switchport” is only required for a switch. R2(config-if-GigabitEthernet 1/1)#no switchport R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 </pre>

	<pre> R2(config-if-GigabitEthernet 1/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
Verification	Run the show vrrp command to verify the configuration. ● Check whether R1, which acts as the Master, reduces its VRRP priority from 120 to 90 when GigabitEthernet2/1 connected to the Wide Area Network (WAN) is unavailable. If yes, R2 becomes the Master. ● Check whether R1 resumes its VRRP priority from 30 to 120 when GigabitEthernet 2/1 connected to the WAN recovers. If yes, R1 is re-elected as the Master.
R1	<pre> R1#show vrrp GigabitEthernet 0/0 - Group 1 State is Master Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 2/1 priority decrement=30 </pre>
R2	<pre> R2#show vrrp GigabitEthernet 0/0 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec </pre>

	Priority is 100 Master Router is 192.168.201.217 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec

Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

Configuration Example

Configuring Multiple IPv4 VRRP Groups

Scenario Figure 4-5	The diagram illustrates a network topology with three routers (R1, R2, R3) connected to a central cloud labeled 'Internet'. R1 and R2 are connected to a local network (192.168.201.0/24) via their Gi0/0 interfaces. R3 is connected to a local network (192.168.12.0/24) via its Gi0/0 interface. The diagram also shows WorkStation A (192.168.201.221/24), WorkStation B (192.168.12.216/24), and WorkStation C (192.168.201.227/24). The routers are configured with various IP addresses and interfaces, including Virtual Gateway 1 (192.168.201.1) and Virtual Gateway 2 (192.168.201.2).
Configuration	● The user workstation cluster (192.168.201.0/24) uses the backup group constituted by the routers R1

Steps	and R2. The gateway for partial workstations (A for example) points to the virtual IP address 192.168.201.1 of the backup group 1, while that for other partial workstations (C for example) points to the virtual IP address 192.168.201.2 of the backup group 2. IPv4 multicast routing is enabled on all the routers. ● R1 acts as the master router in the group 2 and as a backup router in the group 1. ● R2 acts as a backup router in the group 2 and as a master router in the group 1.
R3	<pre> R3#configure terminal R3(config)#interface GigabitEthernet 0/0 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 0/0)#no switchport R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0 R3(config-if-GigabitEthernet 0/0)#exit R3(config)#interface GigabitEthernet 1/1 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 1/1)#no switchport R3(config-if-GigabitEthernet 1/1)#ip address 60.154.101.5 255.255.255.0 R3(config-if-GigabitEthernet 1/1)#exit R3(config)#interface GigabitEthernet 2/1 // The command “no switchport” is only required for a switch. R3(config-if-GigabitEthernet 2/1)#no switchport R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 2/1)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10 </pre>
R1	<pre> R1#configure terminal R1(config)#interface GigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 </pre>

	<pre> R1(config-if-GigabitEthernet 0/0)#vrrp 2 priority 120 R1(config-if-GigabitEthernet 0/0)#vrrp 2 timers advertise 3 R1(config-if-GigabitEthernet 0/0)#vrrp 2 ip 192.168.201.2 R1(config-if-GigabitEthernet 0/0)#vrrp 2 track GigabitEthernet 2/1 30 R1(config-if-GigabitEthernet 0/0)#exit R1(config)#interface GigabitEthernet 2/1 R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 2/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
R2	<pre> R2#configure terminal R2(config)#interface GigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120 R2(config-if-GigabitEthernet 0/0)#vrrp 2 ip 192.168.201.2 R2(config-if-GigabitEthernet 0/0)#vrrp 2 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#exit R2(config)#interface GigabitEthernet 1/1 R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 1/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10 </pre>
Verification	Run the show vrrp command to verify the configuration. ● Check whether R1, which acts as a master router in the group 2, reduces its VRRP group priority from 30 to 90 when it finds that the interface GigabitEthernet 2/1 connected to a WAN is unavailable. If yes, R2 in the group 2 becomes a master router. ● Check whether R1 increases its VRRP group priority from 30 to 120 when it finds the interface GigabitEthernet 2/1 connected to a WAN becomes available again. If yes, R1 becomes a master router

	again in the group 2.
R1	<pre> R1#show vrrp GigabitEthernet 0/0 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 100 Master Router is 192.168.201.213 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec GigabitEthernet 0/0 - Group 2 State is Master Virtual IP address is 192.168.201.2 configured Virtual MAC address is 0000.5e00.0102 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 2/1 priority decrement=30 </pre>
R2	<pre> R2#show vrrp GigabitEthernet 0/0 - Group 1 State is Master Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 </pre>

```
Advertisement interval is 3 sec

Preemption is enabled
    min delay is 0 sec

Priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.82 sec
```

4.4.2 Configuring IPv6 VRRP

Configuration Effect

- Configure an IPv6 VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IPv6 address.
- Configure multiple IPv6 VRRP groups on an interface to achieve load balance and achieve more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv6 address.
- To achieve mutual backup for multiple IPv6 VRRP backup groups, you need to configure multiple IPv6 VRRP groups with identical VRRP configuration on an interface and configure different priorities for them to make routers master and backup mutually.
- VRRP must be enabled on Layer-3 interfaces.

Configuration Steps

✚ Enabling IPv6 VRRP

- By default, IPv6 VRRP is not enabled on an interface. You can enable it based on your demand.

✚ Configuring the IPv6 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

✚ Configuring the IPv6 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

✚ Enabling the Accept Mode for an IPv6 VRRP Group

- By default, the Accept mode is disabled for an IPv6 VRRP group. To require an IPv6 VRRP VRRP group in Master state to receive and process packets with the destination IP address as that of the virtual router, enable Accept mode.

✚ Configuring the IPv6 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

✚ Configuring the IPv6 VRRP Tracked Interface

- By default, no tracked interface is configured. You can modify the interval based on your demand.

✚ Configuring the IPv6 VRRP Tracked IP Address

- By default, no tracked IPv6 address is configured and the value of priority change is 10. You can configure this function based on your demand.

✚ Configures the IPv6 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

✚ Configuring the IPv6 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

✚ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

▾ Enabling IPv6 VRRP

Command	vrrp group ipv6 ipv6-address
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipv6-address</i> : Indicates the IPv6 address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	IPv6 VRRP groups and IPv4 VRRP groups share a VRID range from 1 to 255. One VRID is applicable to an IPv4 VRRP group and an IPv6 VRRP group at the same time. The first configured address should be a link-local address, which can be deleted only after other virtual addresses.

▾ Configuring the IPv6 VRRP Advertisement Interval

Command	vrrp ipv6 group timers advertise { advertise-interval csec centisecond-interval }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). <i>csec centisecond-interval</i> : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information. According to the RFC standards, if an IPv6 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.

▾ Configuring the Preemption Mode

Command	vrrp ipv6 group preempt [delay seconds]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	delay seconds : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.

▾ Enabling the Accept Mode for an IPv6 VRRP Group

Command	vrrp ipv6 group accept_mode

Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	By default, an IPv6 VRRP group in Master state is not permitted to receive packets with the destination IPv6 address as that of the VRRP group. However, it receives NA and NS packets no matter whether Accept mode is configured. Besides, the IP Address Owner in Master state receives and processes the packets with the destination IPv6 address as that of the VRRP group no matter whether Accept mode is configured or not.

📌 Configuring the IPv6 VRRP Router Priority

Command	vrrip ipv6 group priority level
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>level</i> : Indicates the priority of a VRRP router.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

📌 Configuring the IPv6 VRRP Tracked Interface

Command	vrrip ipv6 group track interface-type interface-number [priority]
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>interface-type interface-number</i> : Indicates the interface to be tracked. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

📌 Configuring the IPv6 VRRP Tracked IP Address

Command	vrrip ipv6 group track { ipv6-global-address ipv6-linklocal-address interface-type interface-number } [interval interval-value] [timeout timeout-value] [retry retry-value] [priority]
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>ipv6-global-address</i> : Indicates the IPv6 global unicast address. <i>ipv6-linklocal-address</i> : Indicates the IPv6 link-local address. <i>interface-type interface-number</i> : Indicates the interface to be tracked. interval interval-value : Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.

	timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. priority: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv6 address for an IPv6 VRRP group. If the host IP address being tracked is a link-local address, specify a network interface. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

✚ Configures the IPv6 VRRP Learning Timer

Command	vrrp ipv6 group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

✚ Configuring the IPv6 VRRP Group Description

Command	vrrp ipv6 group description text
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>text</i>: Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

✚ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter Description	minimum <i>min-seconds</i>: Indicates the VRRP delay after an interface state changes. reload <i>reload-seconds</i>: Indicates the VRRP delay after the system starts.
Command	Interface configuration mode

Mode	
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

Configuration Example

Configuring an IPv6 VRRP Group and Tracked Interface

Scenario Figure 4-6	The diagram illustrates a network setup where two Ruijie routers, Ruijie A and Ruijie B, are connected to the Internet through their GigabitEthernet 0/2 interfaces. They share a common Virtual Gateway on their GigabitEthernet 0/1 interfaces, with virtual addresses FE80::1/64 and 2000::1/64. Host A and Host B are connected to this Virtual Gateway. Ruijie A has a physical IP address of 2000::2/64 on GigabitEthernet 0/1, and Ruijie B has a physical IP address of 2000::3/64 on GigabitEthernet 0/1.
Configuration Steps	- Host A and Host B access the Internet resources through the default gateway 2000::1/64. - Ruijie A and Ruijie B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. - Ruijie A tracks the interface GigabitEthernet 0/2 connected to the Internet. When GigabitEthernet 0/2 is unavailable, Ruijie A reduces its priority and Ruijie B acts as a gateway.
RuijieA	<pre> RuijieA#configure terminal RuijieA(config)#interface GigabitEthernet 0/1 RuijieA(config-if-GigabitEthernet 0/1)#no switchport RuijieA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 track GigabitEthernet 0/2 50 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode </pre>
RuijieB	<pre> RuijieB#configure terminal </pre>

	<pre> RuijieB(config)#interface GigabitEthernet 0/1 RuijieB(config-if-GigabitEthernet 0/1)#no switchport RuijieB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode </pre>
Verification	Run the show vrrp command to verify the configuration. ● Check whether Ruijie A, which acts as the Master router, reduces its VRRP group priority from 120 to 70 when it finds that the interface GigabitEthernet 0/2 connected to WAN is unavailable. If yes, Ruijie B becomes the Master. ● Check whether Ruijie A increases its VRRP group priority from 50 to 120 when it finds the interface GigabitEthernet 0/2 connected to WAN becomes available again. If yes, Ruijie A becomes the Master again.
RuijieA	<pre> RuijieA#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/2 priority decrement=50 </pre>

RuijieB	<pre>RuijieB#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::1234, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec</pre>

Configuration Example

Multiple VRRP Backup Groups (under IPv6)

Scenario Figure 4-7	The diagram illustrates a VRRP configuration for IPv6. Two Ruijie routers, Ruijie A and Ruijie B, are connected to the Internet via their GigabitEthernet 0/2 interfaces. They are also connected to Host A and Host B via their GigabitEthernet 0/1 interfaces. Host A is connected to Virtual Gateway 1 (FE80::1/64, 2000::1/64) and Host B is connected to Virtual Gateway 2 (FE80::100/64, 2000::100/64). The routers have IP addresses 2000::2/64 and 2000::3/64 respectively.
Configuration Steps	● Host A and Host B access the Internet resources through the gateways 2000::1/64 and 2000::100/64 respectively. ● Ruijie A and Ruijie B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively.

	● Ruijie A and Ruijie B belong to the backup group 2 of a virtual IPv6 router, and their virtual addresses are 2000::100/64 and FE80::100 respectively. ● Ruijie A and Ruijie B act as gateways and forward flows, being a backup router to each other.
RuijieA	<pre> RuijieA#configure terminal RuijieA(config)#interface GigabitEthernet 0/1 RuijieA(config-if-GigabitEthernet 0/1)#no switchport RuijieA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode RuijieA(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 RuijieA(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 100 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 RuijieA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>
RuijieB	<pre> RuijieB#configure terminal RuijieB(config)#interface GigabitEthernet 0/1 RuijieB(config-if-GigabitEthernet 0/1)#no switchport RuijieB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode RuijieB(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 RuijieB(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 120 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 RuijieB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>

Verification	Run the show vrrp command to verify the configuration.
RuijieA	<pre>RuijieA#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec GigabitEthernet 0/1 - Group 2 State is Backup Virtual IPv6 address is as follows: FE80::100 2000::100 Virtual MAC address is 0000.5e00.0202 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::5678, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec</pre>
RuijieB	<pre>RuijieB#show ipv6 vrrp</pre>

```
GigabitEthernet 0/1 - Group 1

State is Backup

Virtual IPv6 address is as follow:

    FE80::1

    2000::1

Virtual MAC address is 0000.5e00.0201

Advertisement interval is 3 sec

Accept_Mode is enabled

Preemption is enabled

    min delay is 0 sec

Priority is 100

Master Router is FE80::1234, priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.82 sec

GigabitEthernet 0/1 - Group 2

State is Master

Virtual IPv6 address is as follows:

    FE80::100

    2000::100

Virtual MAC address is 0000.5e00.0202

Advertisement interval is 3 sec

Accept_Mode is enabled

Preemption is enabled

    min delay is 0 sec

Priority is 120

Master Router is FE80::5678(local), priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.59 sec
```

4.4.3 Configuring VRRP-MSTP

Configuration Effect

- Link-level and gateway-level backup are achieved and network robustness is improved greatly when MTSP and VRRP are applied simultaneously.

Notes

- configure the routers in a VRRP backup group with the same virtual IPv4 address.
- Enabled VRRP on a Layer 3 interface.

Configuration Steps

▾ Enabling IPv4 VRRP

- By default, IPv4 VRRP is not enabled on an interface. To enable IPv4 VRRP, please configure this item.

▾ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in a non-authentication mode. To enable plain text password authentication for VRRP, please configure this item.

▾ Configuring the IPv4 VRRP Advertisement Interval

- By default, a master router sends VRRP GWADV packets at an interface of one second. To manually set a value, please configure this item.

▾ Configuring the IPv4 VRRP Preemption Mode

- By default, VRRP groups work in the preemption mode with zero-second delay.

▾ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

▾ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface. To achieve fault monitoring through monitoring an interface, please configure this item.

▾ Configuring the IPv4 VRRP Learning Timer

- By default, timed learning is not enabled for a VRRP backup group. To enable backup routers to learn the VRRP GWADV packets from a master router, please configure this item.

▾ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups conveniently, please configure this item.

▾ Configuring the IPv4 VRRP Delay

- By default, the VRRP delay for a VRRP group is not configured. Configure the delay to guarantee a stable transition from Non-preemption mode to Preemption mode.

✚ Configuring the IPv4 VRRP Version

- By default, the VRRPv2 standard is adopted for IPv4 VRRP packets. To modify it manually, please configure this item.

✚ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first UP Sub VLAN interface in a Super VLAN, but you may configure a specific Sub VLAN interface to send such packets.

✚ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the linkage between an IPv4 VRRP and BFD is not configured on an interface. To enable such linkage, please configure this item.

✚ Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not used to detect whether a master router is active. To enable this, please configure this item.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

✚ Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [<i>secondary</i>]
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models. <i>ipaddress</i> : The IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

✚ Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3.

Authentication is abolished for VRRPv3 packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

✚ Configuring the IPv4 VRRP Advertisement Interval

Command	vrrip group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>advertise-interval</i>: Indicates the advertisement interval of a VRRP group (unit: second). csec <i>centisecond-interval</i>: An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information. According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.

✚ Configuring the IPv4 VRRP Preemption Mode

Command	vrrip group preempt [<i>delay seconds</i>]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. delay seconds: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.

✚ Configuring the IPv4 VRRP Router Priority

Command	vrrip group priority <i>level</i>
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>level</i>: Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the priority of a VRRP group.

✚ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { <i>interface-type interface-number</i> bfd <i>interface-type interface-number ipv4-address</i> } [<i>priority</i>]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>interface-type interface-number</i>: Indicates the interface to be tracked. bfd <i>interface-type interface-number ipv4-address</i>: A specified adjacent IP address tracked through BFD. <i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface). The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

📌 Configuring the IPv4 VRRP Tracked IP Address

Command	vrrp group track <i>ipv4-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]
Parameter Description	<i>group</i>: Indicates the VRID of a VRRP group. <i>ipv4-address</i>: Indicates the IPv4 address to be tracked. interval <i>interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default. timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default. retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default. <i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

📌 Configuring the IPv4 VRRP Learning Timer

Command	vrrp group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode

Mode	
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

✚ Configuring the IPv4 VRRP Group Description

Command	vrrp group description text
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>text</i> : Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

✚ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum min-seconds reload reload-seconds }
Parameter	minimum min-seconds : Indicates the VRRP delay after an interface state changes.
Description	reload reload-seconds : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

✚ Configuring the IPv4 VRRP Version

Command	vrrp group version { 2 3 }
Parameter	2 : Indicates VRRPv2.
Description	3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

✚ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

Command	vrrp detection-vlan {first-subvlan subvlan-id}
Parameter	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.

Description	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If both VRRP and VRRP PLUS are enabled on a Super VLAN interface, VRRP packets are sent to all the UP Sub VLAN interfaces of the Super VLAN interface. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

✚ Configuring the BFD Support for IPv4 VRRP on an Interface

Command	vrrp group bfd <i>ip-address</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Interface configuration mode
Usage Guide	For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator. If global IPv4 VRRP BFD is configured, this configuration cannot be performed. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

✚ Configuring Global IPv4 VRRP BFD

Command	vrrp bfd <i>interface-type interface-number ip-address</i>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Global configuration mode
Usage Guide	If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted. To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface. A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.

Configuration Example

✚ Configuring VRRP+MSTP

Scenario
Figure 4-8

Configuration Steps

- Enable MSTP on routers (switches A, B, C, D, E and F in this example). Configure VLAN-Instance mapping (mapping VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0), and configure gateways (Switch A and Switch B in this example) as the root bridges of corresponding instances.
- Add the SVIs of all VLANs to corresponding VRRP backup groups, and configure gateways as the master and backup routers for corresponding backup groups. See configuration details in the following table.

Gateway	VLAN ID	SVI	Backup Group	Virtual IP Address	State
Switch A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Configure the uplink port (port Gi 0/1 of Switch A and Switch B) of master routers as a monitored interface of master router.
- Step 1: Create VLAN. Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 respectively on Switch A and Switch B.
- Step 2: Configure MST regions. Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.
- Step 3: Configure Switch A as the root bridge for MST 0 and MST 1, and Switch B as the root bridge for

	MST 2. ● Step 4: Enable MSTP. ● Step 5: Configure SVIs of all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the groups. See configuration in the above table. ● Step 6: Configure master routers and backup routers for all the groups. ● Step 7: Configure the uplink ports of master routers as monitored ports of VRRP groups. Caution: Monitored ports should be Layer 3 ports. Step 8: Configure the Internet interfaces of the core routers as AP interfaces.
SwitchA	<pre>//Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 on Switch A. SwitchA#configure terminal Enter configuration commands, one per line. End with CNTL/Z. SwitchA(config)#vlan range 10,20,30,40 SwitchA(config-vlan-range)#exit //Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0. Debugs VRRP status.	debug [ipv6] vrrp state

5 Configuring VRRP Plus

5.1 Overview

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway backup and load balancing in the IEEE 802.3 local area network (LAN).

A disadvantage of VRRP is that the router in backup state cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue.

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This greatly reduces the workload of the network administrator.

5.2 Applications

Application	Description
Enabling Load Balancing Within a VRRP Group	Implement load balancing within a VRRP group without configuring multiple groups or configuring different default gateways for hosts.

5.2.1 Enabling Load Balancing Within a VRRP Group

Scenario

Enable load balancing within a VRRP group without configuring without configuring multiple VRRP groups or configuring different default gateways for hosts.

As shown in Figure 5-1, configure data as follows:

- Configure a VRRP group that consists of Router A and Router B, and enable the VRRP Plus function.
- Configure the default gateway of each host as the master virtual IP address of the VRRP group.

Figure 5-1 Application topology of IPv4 VRRP Plus

1. Two layer-3 (L3) devices, Router A and Router B, form a VRRP Plus group, and the virtual IP address of the group is 192.168.12.1. Router A is the master device of VRRP and functions as a balancing virtual gateway (BVG). Router B is the backup device of VRRP and functions as a balancing virtual forwarder (BVF).
2. Host 1 to Host 4 are hosts in the LAN with the network segment 192.168.12.0/24. Their default gateway addresses are set to the virtual IP address 192.168.12.1 of the VRRP Plus group.
3. The load balancing policy is configured on the device to respond to the ARP requests sent from different hosts. For example, when Host 1 and Host 2 request the gateway ARP, the MAC address 0000.5e00.0101 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the gateway ARP, the MAC address 001A.A916.0201 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.

Figure 5-2 Application topology of IPv6 VRRP Plus

Remarks	1. Two L3 devices, Router A and Router B, form an IPv6 VRRP Plus group, and the virtual IPv6 addresses are fe80::8 and 2000::8. Router A is the master device of IPv6 VRRP and functions as a BVG. Router B is the backup device of IPv6 VRRP and functions as a BVF. 2. Host 1 to Host 4 are hosts in the LAN, and all their IPv6 gateway addresses are set to 2000::8. 3. When Host 1 and Host 2 request the neighbor discovery (ND) of the gateway, the MAC address 0000.5e00.0201 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the ND of the gateway, the MAC address 1414.4B72.7701 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.

Deployment

- Deploy VRRP Plus on Router A and Router B to implement load balancing on the local host.

5.3 Features

Basic Concepts

➤ BVG

The BVG allocates virtual MAC addresses to members of the VRRP Plus group. It responds to the gateway ARP/ND requests in the LAN, and forwards packets of hosts in the LAN.

➤ BVF

The BVF forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

Overview

Feature	Description
VRRP Plus	Extend VRRP and use VRRP to implement gateway backup and load balancing in the IEEE 802.3 LAN.

5.3.1 VRRP Plus

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to the virtual IP addresses of different VRRP groups.

Basic Principles

Hosts in a LAN use the unified gateway IP address (that is, virtual IP address of the VRRP group). When different hosts request the gateway ARP, the BVG responds with different virtual MAC addresses. In this way, traffic of different hosts are distributed to different members of the VRRP Plus group, thereby implementing load balancing.

Relationship Between VRRP Plus and VRRP

VRRP Plus relies on VRRP, and runs in the following way:

A master device in VRRP corresponds to a BVG in VRRP Plus, and a backup device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in the LAN are set to the virtual IP address of VRRP.

MAC Address Allocation Rules of the BVG and BVF

The BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01-{VRID}, where VRID is the VRRP group number. The virtual MAC address used by a BVF is 00-1A-A9-16-{MemberID}-{VRID}, where MemberID is the member ID of the BVF in the VRRP Plus group. Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04. For an IPv6 VRRP Plus group, the BVG directly uses the virtual MAC address of IPv6 VRRP to ensure compatibility between IPv6 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-02-{VRID}, where VRID is the IPv6 VRRP group number. The virtual MAC address used by a BVF is 14-14-4B-72-{76 + MemberID}-{VRID}, where MemberID ranges from 01 to 03.

Load Balancing Policy of VRRP Plus

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. Based on the specific load balancing policy, the BVG responds hosts with different virtual MAC addresses. There are three types of load balancing policies:

- Host-dependent policy: A specified virtual MAC address is used to respond to the requests sent by aspecified host.

- Round-robin policy: Virtual MAC addresses in the backup group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- Weighted policy: The ARP/NA requests are responded based on the forwarding capability of each device.

If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the polling response mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode regardless of the earlier responses of the device. If the weighted policy is used, and the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded.

Proxy of the Virtual MAC Address

When a device with a virtual MAC address becomes faulty in the backup group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted.

The BVG in the VRRP Plus backup group can quickly detect the fault, and automatically allocates the virtual MAC address of the faulty BVF to another device in the backup group. The new device acts as the proxy of the faulty device to forward packets of the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in the backup group can be called master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called proxy virtual MAC address.

Redirection Time and Timeout of the Proxy Virtual MAC Address

VRRP Plus provides the proxy function for the virtual MAC address so that another device can take the place of a faulty device with a virtual MAC address to forward packets. If the BVF is recovered from the fault, its forwarding role is recovered and the BVF continues to forward packets of the virtual MAC address allocated to this BVF. If the faulty BVF is not recovered, the backup group stops redirecting traffic to this virtual MAC address. That is, when ARP requests are received again, this virtual MAC address is no longer responded. After a sufficient long period of time, it is believed that hosts that use the MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. At this time, this virtual MAC address can be deleted, and packets sent to this virtual MAC address are dropped.

VRRP Plus supports configuration of the redirection time and timeout of the backup group. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address and stops using this virtual MAC address for proxy forwarding. Figure 1-3 shows the changes to the role of the virtual MAC address within the redirection time and timeout.

Figure 5-3 Changes to the Role of the Virtual MAC Address Within the Redirection Time and Timeout

Weight-based Forwarding

VRRP Plus supports the weight configuration of the backup group. Different weights are configured for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices. When the weight of a BVF in the backup group is smaller than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies for the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.

Association of VRRP Plus with BFD

VRRP Plus supports association with bidirectional forwarding detection (BFD) to adjust the weight based on the link status. Each device in a backup group can associate its weight with the link status. When a link is abnormal or interrupted, the device automatically decreases its weight. When the weight is too low, the device automatically exits from the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the associated link recovers, the device can automatically restore its original weight and the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the recovered weight. IPv6 VRRP Plus currently does not support association with BFD.

Weight-based Forwarding Seizure

VRRP Plus supports the function of seizing the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus backup group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the status of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding will take the place of the faulty device to forward packets. Assume that a VRRP Plus backup group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or the original forwarding role encounters a link failure and consequently degradation of forwarding performance. In this case, if the

seizure mode is enabled, the fifth device can seize the forwarding role from a device with a smaller weight (that is, with lower forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This can minimize the waste of resources.

The BVG in a backup group is responsible for allocation of virtual MAC addresses. Therefore, the BVG role cannot be seized, and only the forwarding role of a BVF can be seized. If the BVG device is faulty, VRRP re-elects a new master device, which assumes the BVG role.

Factors Affecting the Forwarding Policy

1. After VRRP Plus is configured, the ARP/NS requests are received from hosts can be responded based on different load balancing policies to implement load balancing among these hosts. However, load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before configuration of VRRP Plus. Therefore, if VRRP Plus is configured after the VRRP state is changed to Master, real load balancing cannot be implemented before aging of the ARP/NDs learned by hosts. Load balancing is implemented only after the gateway ARP/NDs recorded by the hosts age and the hosts request for new gateway addresses.
2. Periodical sending of gratuitous ARPs on an interface also affect the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARPs of VRRP virtual IP addresses will be disabled. When an virtual IP address overlaps with an actual IP address, gratuitous ARPs of this address are no longer sent.
3. When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict of the VRRP Plus virtual address occurs, sending gratuitous ARP/NA packet will result re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

5.4 Configuration

Configuration Item	Description and Command	
Configuring VRRP Plus	 (Mandatory) It is used to enable the VRRP Plus function.	
	vrrp balance	Enables the VRRP Plus function of a VRRP backup group with the specified group ID in interface configuration mode.
	 (Optional) It is used to configure parameters of a VRRP Plus backup group.	
	vrrp load-balancing	Configures the load balancing policy of VRRP Plus in interface configuration mode.
	vrrp timers redirect	Configures the redirection time and timeout of the proxy virtual MAC address in a VRRP Plus backup group in interface configuration mode.

Configuration Item	Description and Command	
	vrrp weighting	Configures the weight and upper and lower thresholds of a VRRP Plus backup group in interface configuration mode.
	vrrp forwarder preempt	Configures the forwarding seizure function of a VRRP Plus backup group in interface configuration mode.
	vrrpweighting track	Configures a weight tracking object of a VRRP Plus backup group in interface configuration mode.

5.4.1 Configure VRRP Plus

Configuration Effect

- Enable the VRRP Plus function. (By default, this function is disabled.)
- Configure a weight tracking object of a VRRP Plus backup group.

Notes

- To enable the VRRP Plus function, you must configure the VRRP virtual IP address for the corresponding backup group.

Configuration Steps

➤ Enabling VRRP Plus on an Interface

- By default, VRRP Plus is enabled. Perform this configuration if VRRP Plus is required.

➤ Configuring the Load Balancing Policy of VRRP Plus

- After VRRP Plus is enabled, the host-dependent load balancing policy is used by default.

➤ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

- After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default.

➤ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the weight of the backup group is set to 100, the lower threshold to 1, and the upper threshold to 100 by default.

➤ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the forwarding seizure function is enabled by default.

➤ Configuring the Weight Tracking Object of a VRRP Plus Backup Group

- The weight tracking object of a VRRP Plus backup group is disabled by default. Perform this configuration if the tracking function is required.

Verification

- Run the **show [ipv6]group vrrp balance** command to display the VRRP backup group configuration. If the backup group has the packet forwarding tasks, "local" is displayed in the **forwarders** column, and the virtual MAC address allocated to this backup group is also displayed.

Related Commands

▾ Enabling VRRP Plus on an Interface

Command	vrrp [ipv6]group balance
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. group: Indicates the ID of the VRRP group. The value range of the group ID varies according to the product model.
Command Mode	Interface configuration mode
Usage Guide	VRRP Plus can be enabled only after a VRRP group is configured.

▾ Configuring the Load Balancing Policy of a VRRP Plus Backup Group

Command	vrrp [ipv6]group load-balancing{host-dependent round-robin weighted }
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. group: Indicates the ID of the VRRP group. host-dependent: Indicates the host-dependent load balancing policy. round-robin: Indicates the round-robin load balancing policy. weighted: Indicates the weighted load balancing policy.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the host-dependent load balancing policy is used by default. The load balancing policy of the entire backup group is determined by the policy configured on the BVG. If you wish to use the same load balancing policy after the role of the BVG device changes, configure the same policy on all devices in the backup group.

▾ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

Command	vrrp [ipv6]group timers redirectredirecttimeout
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. group: Indicates the ID of the VRRP group. redirect: Indicates the redirection time. The value ranges from 0 to 3,600s. The default value is 300s, that is, 5 minutes. timeout: Indicates the timeout time. The value ranges from (redirect + 600) to 64,800s. The default value is 14400, that is, 4 hours.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another

	device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address.

✚ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

Command	vrrip [ipv6]group weightingmaximum [lowerlower] [upperupper]
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. maximum: Indicates the weight of the backup group. The value ranges from 2 to 254. The default value is 100. lowerlower: Indicates the lower threshold of the backup group. The value ranges from 1 to (maximum - 1). The default value is 1. upperupper: Indicates the upper threshold of the backup group. The value ranges from lower to maximum. The default value is 100.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the weight and upper and lower thresholds of a VRRP Plus backup group are configured by default. You can use this command to configure different weights for different devices so that more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight. When the weight of a BVF in the backup group is lower than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is higher than the upper threshold, the forwarding role of the BVF is automatically restored.

✚ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

Command	vrrip[ipv6]group forwarder preempt
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. group: Indicates the ID of the VRRP group.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the forwarding seizure function is enabled by default. VRRP Plus supports configuration of the forwarding seizure function of a backup group. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state.

✚ Configuring the Weight Tracking Object of a VRRP Plus Backup Group

Command	vrrip [ipv6] group weighting track object-number [decrement value]
Parameter Description	ipv6: Indicates that this configuration applies to IPv6. By default, the configuration applies to IPv4. group: Indicates the ID of the VRRP group. object-number: Indicates the number of the tracking object. The value ranges from 1 to 700.

	decrement value: Indicates the decrement weight when the tracking object is down. The decrement value ranges from 1 to 255. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, no tracking object is configured by default. After the tracking object is configured, the decrement value is 10 by default.

Configuration Example

Enabling Load Balancing Within an IPv4 VRRP Group

Scenario Figure 5-4	
Configuration Steps	- Configure a tracking object respectively on Router A and Router B to track the status of the local GigabitEthernet 0/14 interface. - Configure a VRRP group and enable VRRP Plus respectively on Router A and Router B. Configure the local IP addresses so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device. - Configure the weighted load balancing policy. Configure the weight tracking object, and set the decrement value to 100. - Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding seizure of the backup group. - Set the default gateway addresses of Host 1 to Host 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.
Router A	<pre> RuijieA#config RuijieA(config)#track 1 interface GigabitEthernet0/14 line-protocol RuijieA(config)#interface GigabitEthernet0/0 // 'no switchport' is used on the switch. </pre>

	<pre> RuijieA(config-if-GigabitEthernet 0/0)#no switchport RuijieA(config-if-GigabitEthernet 0/0)#ip address 192.168.12.3 255.255.255.0 RuijieA(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1 RuijieA(config-if-GigabitEthernet 0/0)#vrrp 1 balance RuijieA(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted RuijieA(config-if-GigabitEthernet 0/0)#vrrp 1 weighting track 1 decrement 100 </pre>
Router B	<pre> RuijieB#config RuijieB(config)#track 1 interface GigabitEthernet0/14 line-protocol RuijieB(config)#interface GigabitEthernet0/0 RuijieB(config-if-GigabitEthernet 0/0)#no switchport RuijieB(config-if-GigabitEthernet 0/0)#ip address 192.168.12.2 255.255.255.0 RuijieB(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1 RuijieB(config-if-GigabitEthernet 0/0)#vrrp 1 balance RuijieB(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted RuijieB(config-if-GigabitEthernet 0/0)#vrrp 1 weighting track 1 decrement 100 </pre>
Verification	Run the show vrrp balance command to display the configuration of the VRRP Plus group. If the backup group has the packet forwarding tasks, "local" is displayed in the forwarders column, and the virtual MAC address allocated to this backup group is also displayed.
Router A	<pre> RuijieA# show vrrp balance interface GigabitEthernet0/0 State is BVG Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 Track object 1, state: up, decrement weight: 100 There are 2 forwarders Forwarder 1 (local) MAC address: 0000.5e00.0101 Owner ID is 0000.0001.0006 </pre>

	Preemption disabled (BVG cannot be preempted) Forwarder 2 MAC address: 001a.a916.0201 Owner ID is 00d0.f822.33a3 Preemption enabled
Router B	RuijieB# show vrrp balance interface GigabitEthernet0/0 State is BVF Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 Track object 1, state: up, decrement weight: 100 There are 2 forwarders Forwarder 1 MAC address: 0000.5e00.0101 Owner ID is 0000.0001.0006 Preemption disabled (BVG cannot be preempted) Forwarder 2 (local) MAC address: 001a.a916.0201 Owner ID is 00d0.f822.33a3 Preemption enabled

 Enabling Load Balancing Within an IPv6 VRRP Group

Scenario
Figure 5-5

Configuration Steps

- Configure an IPv6 VRRP group and enable IPv6 VRRP Plus respectively on Router A and Router B. Configure the priorities so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device.
- Configure the weighted load balancing policy for the IPv6 VRRP Plus backup group.
- Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding seizure of the backup group.
- Set the default gateway addresses of Host 1 to Host 4 in the LAN to 2000::8.

Router A

```
RouterA#config
RouterA(config)#interface GigabitEthernet0/0
// 'no switchport' is used on the switch.
RouterA(config-if-GigabitEthernet 0/0)#no switchport
RouterA(config-if-GigabitEthernet 0/0)#ipv6 address 2000::6/64
RouterA(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 fe80::8
RouterA(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 2000::8
RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 priority 120
RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 load-balancing weighted
RouterA(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 balance
```

Router B

```
RouterB#config
RouterB(config)#interface GigabitEthernet0/0
RouterB(config-if-GigabitEthernet 0/0)#no switchport
RouterB(config-if-GigabitEthernet 0/0)# ipv6 address 2000::7/64
RouterB(config-if-GigabitEthernet 0/0)#vrrp 1 ipv6 fe80::8
```

	<pre>RouterB(config-if-GigabitEthernet 0/0)#vrrp 1 ipv62000::8 RouterB(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 load-balancing weighted RouterB(config-if-GigabitEthernet 0/0)#vrrp ipv6 1 balance</pre>
Verification	Run the show ipv6 vrrp balance command to display the configuration of the VRRP Plus group. If the backup group has the packet forwarding tasks, "local" is displayed in the forwarders column, and the virtual MAC address allocated to this backup group is also displayed.
Router A	<pre>RouterA# show ipv6 vrrp balance interface GigabitEthernet0/0 GigabitEthernet 0/0 - Group 1 State is BVG Virtual IPv6 address is as follows: FE80::8 2000::8 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 There are 2 forwarders Forwarder 1 (local) MAC address: 0000.5e00.0201 Owner ID is 00d0.f8fb.96f3 Preemption disabled (BVG cannot be preempted) Forwarder 2 MAC address: 1414.4b72.7701 Owner ID is 00d0.f8fb.6c42 Preemption enabled</pre>
Router B	<pre>RouterB# show ipv6 vrrp balance interface GigabitEthernet0/0 GigabitEthernet 0/0 - Group 1 State is BVF Virtual IPv6 address is as follows:</pre>

```

FE80::8

2000::8

Hello time 1 sec, hold time 3 sec

Redirect time 300 sec, forwarder time-out 14400 sec

Weighting 150 (configured 150), thresholds: lower 1, upper 100

There are 2 forwarders

Forwarder 1

  MAC address:

    0000.5e00.0201

  Owner ID is 00d0.f8fb.96f3

  Preemption disabled (BVG cannot be preempted)

Forwarder 2 (local)

  MAC address:

    1414.4b72.7701

  Owner ID is 00d0.f8fb.6c42

  Preemption enabled

```

Common Errors

- VRRP Plus does not take effect because the VRRP virtual IP address is not configured for the related group.

5.5 Monitoring

Displaying

Description	Command
Displays the brief or detailed configuration of VRRP Plus.	show [ipv6] vrrp balance
Displays the actions of the VRRP Plus group on a specified interface.	show [ipv6] vrrp balance interface

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command

Description	Command
Debugs the VRRP Plus function.	debug[ipv6] vrrp balance
Debugs errors.	debug[ipv6] vrrp balance error
Debugs events of the VRRP Plus group.	debug [ipv6]vrrp balance event
Debugs the messages between the VRRP module and the track module.	debug[ipv6] vrrp balance messages
Debugs the VRRP Plus packets.	debug[ipv6]vrrp balance packets
Debugs the VRRP Plus group status.	debug [ipv6] vrrp balance state
Debugs the timers of the VRRP Plus group.	debug vrrp balance timer

6 Configuring BFD

6.1 Overview

Communication failures will interrupt networking and thus affect services. Therefore, it is essential to rapidly locate communication failures on links with adjacent devices to ensure a timely action and service availability. Bidirectional Forwarding Detection (BFD) provides a method of rapidly detecting connectivity of the forwarding path between two adjacent routers in an underloaded way. It can quickly spot faults on the bidirectional forwarding path between two routers for upper-layer protocols such as routing protocols and Multi-Protocol Label Switching (MPLS). As a result, a standby forwarding path is adopted to maintain the performance of the existing network.

Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multi-hop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

6.2 Applications

Application	Description
BFD Support for OSPF	OSPF utilizes BFD to rapidly detect the neighbor status.
BFD Support for Static Routing	Static routing utilizes BFD to rapidly detect the next-hop reachability of a route.

6.2.1 BFD Support for OSPF

Scenario

The Open Shortest Path First (OSPF) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, a BFD session is established with the neighbor in the full adjacency to detect the neighbor status. When the neighbor fails, OSPF immediately performs network convergence. The convergence time can be shortened from 120 seconds (by default, on a non-broadcast network, OSPF hello packets are transmitted at an interval of 30 seconds and the neighbor failure time is four times the interval, that is, 120 seconds) to 1 second.

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, OSPF is configured on the routers to establish routes, and BFD support for OSPF is enabled on the interfaces of Router A and Router B. When

the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to OSPF, so as to trigger fast OSPF convergence.

Figure 6-1

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Run OSPF on Router A and Router B.
- Set BFD parameters on interconnected interfaces of Router A and Router B.
- Enable BFD support for OSPF on Router A and Router B.

6.2.2 BFD Support for Static Routing

Scenario

BFD support for static routing prevents routers from selecting a faulty static route as the forwarding path and enables rapid routing failover by using an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the neighbor discovery (ND) mechanism. When BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session status. If a BFD session fails, the next hop of a static route is thought unreachable and will not be added to the routing information base (RIB).

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, static routing is configured on the routers to establish forwarding paths, and BFD support for static routing is enabled on the interfaces of Router A and Router B. When the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to static routing, so as to trigger the system to delete the static route from the RIB, thereby preventing routing errors.

Figure 6-2

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Configure static routing on Router A and Router B.
- Set BFD parameters for interconnected interfaces of Router A and Router B.
- Enable BFD support for static routing on Router A and Router B.

6.3 Features

Basic Concepts

Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into control packets and echo packets. Echo packets concern only the local system of a BFD session. Therefore, their formats are not specified. BFD specifies the format of only control packets. Currently, there are two versions (version 0 and version 1) for the format of control packets. Version 1 is adopted by default for establishing a BFD session. If a device receives packets of version 0 from the peer system, the device automatically switches to version 0.

Figure 6-3

Field	Description
Vers	Indicates the BFD protocol version number, which is 1 currently.
Diag	Indicates the cause for the local system's last change in session state, including: 0 -- No Diagnostic. 1 -- Control Detection Time Expired 2 -- Echo Function Failed

Field	Description
	3 -- Neighbor Signaled Session Down 4 -- Forwarding Plane Reset 5 --Path Down 6 -- Concatenated Path Down 7 --Administratively Down
Sta	Indicates the BFD local session state, including: 0 -- AdminDown. 1 -- Down. 2 -- Init. 3 -- Up.
P	Indicates that the transmitter in a BFD session adds this bit in a verification request upon parameter changes, waiting for the peer response.
F	Indicates the bit that must be set in the response packet for responding to the P bit.
C	Indicates the control plane independent. If set, changes of the control plane do not affect BFD detection. For example, if the control plane is OSPF, when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link status.
A	Indicates the authentication present. If set, a session is to be authenticated.
D	Indicates the demand request. If set, the transmitter desires to detect links in Demand mode.
M	Indicates the multipoint bit to be used in point-to-multipoint extensions. It must be set to 0 currently.
Detect Mult	Indicates the detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Indicates the packet length.
My Discriminator	Indicates the discriminator of the local end connected by a BFD session.
Your Discriminator	Indicates the discriminator of the remote end connected by a BFD session.
Desired Min Tx Interval	Indicates the minimum interval of transmitting BFD packets supported by the local end.
Required Min RX Interval	Indicates the minimum interval of receiving BFD packets supported by the local end.
Required Min Echo RX Interval	Indicates the minimum interval of receiving echo packets supported by the local end. It is set to 0 if the local end does not support the echo function.
Auth Type	(Optional) Indicates the authentication type, including: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Indicates the authentication data length.
Authentication Data	Indicates the authentication data area.

A BFD session can be in any of the four basic states: Down, Init, Up, and AdminDown.

1. Down: Indicates that a session is in the Down state or is established just now.
2. Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the Up state.
3. Up: Indicates that a session has been negotiated successfully.
4. AdminDown: Indicates that a session is in the AdminDown state.

BFD migrates the state machine based on the local session state and received BFD packets from the peer end.

A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the status change.

Transmission Interval and Detection Time

Both ends negotiate BFD parameters during the establishment of a BFD session, to determine the transmission interval and detection time.

After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

Overview

Feature	Description
BFD Session Establishment	Establishes a BFD session.
BFD Session Detection	Rapidly detects a bidirectional forwarding path.
BFD Support for Applications	Rapidly advertises the BFD detection result.
BFD Protection	Protects BFD from attacks for stability.
BFD Flapping Dampening	Protects stability of associated applications in the case of line instability.

6.3.1 BFD Session Establishment

BFD detection starts from the establishment of a BFD session.

Working Principle

Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify a neighbor to establish a session.

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-4

BFD session establishment process:

1. OSPF discovers a neighbor and establishes a connection with the neighbor.
2. OSPF instructs BFD to establish a session with the neighbor.
3. BFD establishes a session with the neighbor.

📌 BFD Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- **Active mode**
Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.
- **Passive mode**
BFD does not actively transmit a control packet for establishing a BFD session before a session is established but wait till it receives a control packet for establishing a BFD session from the peer end.

i The passive mode is not supported currently.

📌 Negotiation of BFD Session Parameters

Both ends negotiate BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

1. BFD session parameters (including **Desired Min Tx Interval**, **Required Min RX Interval**, and **Detect Mult**) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established.
2. Interfaces at both ends negotiate BFD session parameters and detect the session based on the parameters during the establishment of a BFD session.
3. After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

6.3.2 BFD Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is Down and notifies the associated application to accelerate the convergence.

Working Principle

↘ Detection Process

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-5

Handling procedure after a BFD session is Down:

1. The link between Router A and Switch fails.
2. The BFD session between Router A and Router B is Down.
3. BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
4. OSPF processes the neighbor Down situation. If a backup forwarding path is available, it starts protocol convergence to enable the alternative forwarding path.

↘ Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is Down.

- Query mode

In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If a system fails to receive a returned packet within the detection time, it advertises that the session is Down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several consecutive echo packets within the detection time, it advertises that the session is Down. The echo function can be used together the preceding two detection modes. The echo packet detection function does not require the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. The enabling of the echo function in asynchronous mode can greatly

reduce transmission of control packets because the detection is accomplished by the echo function. The enabling of the echo function in query mode can thoroughly cancel transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

-
-  The query mode is not supported and cannot be configured at present.
 -  Only BFD session version 1 supports the BFD echo mode.
 -  The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.
-

6.3.3 BFD Support for Applications

By BFD support, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened within 1 second.

Working Principle

After BFD support for a certain application is enabled, a BFD session is established based on the BFD configuration. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process, thereby improving its convergence. Currently, BFD supports the following applications:

- BFD support for RIP

After BFD support for the Routing Information Protocol (RIP) is enabled, RIP can utilize the BFD fault detection, which is faster than the ND mechanism of RIP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for RIP, see *Configuring RIP*.
-

- BFD support for OSPF

After BFD support for OSPF is enabled, OSPF can utilize the BFD fault detection, which is faster than the ND mechanism of OSPF, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPF, see *Configuring OSPF*.
-

- BFD support for OSPFv3

After BFD support for OSPFv3 is enabled, OSPFv3 can utilize the BFD fault detection, which is faster than the ND mechanism of OSPFv3, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPFv3, see *Configuring OSPFv3*.
-

- BFD support for BGP

After BFD support for the Border Gateway Protocol (BGP) is enabled, BGP can utilize the BFD fault detection, which is faster than the ND mechanism of BGP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

 For more details about BFD support for BGP, see *Configuring BGP*.

- BFD support for IS-IS

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, IS-IS uses BFD to establish a BFD session with a neighbor that is in the Up state and detect the neighbor status. When a BFD neighbor fails, IS-IS immediately performs network convergence. The convergence time can be shortened from 30 seconds (by default, on a point-to-point network, IS-IS hello packets are transmitted at an interval of 10 seconds and the neighbor failure time is triple the interval, that is, 30 seconds) to 1 second.

 For more details about BFD support for IS-IS, see *Configuring IS-IS*.

- BFD support for static routing

After BFD support for static routing is enabled, BFD prevents routers from selecting an unavailable static route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the ND mechanism. Therefore, after BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session state. If a BFD session detects a fault, the next hop of a static route is unreachable and the static route is not added to the RIB.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the forwarding behavior of static routing is not affected.

 For more details about BFD support for static routing, see *Configuring NSM*.

- BFD support for PBR

After BFD support for PBR is configured, BFD prevents routers from selecting an unavailable policy route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

BFD support for PBR is equivalent to that for static routing. BFD tracks and detects the forwarding path to a specified neighbor. When a BFD session fails, BFD notifies the PBR that the next hop is unreachable. Then, the policy route to the next hop does not take effect.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the PBR forwarding behavior is not affected.

 For more details about BFD support for PBR, see *Configuring PBR*.

- BFD support for VRRP

The BFD support for the Virtual Router Redundancy Protocol (VRRP) can replace the ND mechanism of VRRP to rapidly detect the running status of the active and standby routers. When a fault occurs, it accelerates the active/standby router switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP can also utilize BFD to track a specified neighbor. If the forwarding path to the neighbor fails during a BFD session, it automatically lowers the VRRP priority to a certain extent to trigger active/standby router switching. This

configuration takes effect only when the dynamic routing protocol or other applications notify BFD to establish a session with a neighbor.

 For more details about BFD support for VRRP, see *Configuring VRRP*.

- BFD support for VRRP Plus

The BFD support for VRRP Plus can replace the BVF detection conducted by the balancing virtual gateway (BVG) of VRRP Plus to rapidly detect the running status of balancing virtual functions (BVs). When a fault occurs, it accelerates the forwarding entity switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

 For more details about BFD support for VRRP Plus, see *Configuring VRRP Plus*.

- BFD support for MPLS

The BFD support for Multiple protocol Label Switching (MPLS) refers that label switched paths (LSPs) use BFD to rapidly detect the neighbor status. The following detection modes are supported:

1. BFD detects static LSPs.
2. BFD detects LSPs generated by the Label Distribution Protocol (LDP).
3. BFD can detect reverse links of LSPs by using the IP protocols.

 For more details about BFD support for MPLS, see *Configuring MPLS*.

- BFD support for Layer-3 interfaces

BFD supports changing status of Layer-3 interfaces. In interface configuration mode, use the **bfd bind peer-ip** command to detect the direct address of a specified Layer-3 interface. After this CLI command is executed, a BFD session is created and the status of a Layer-3 interface can be changed based on the detection result of the BFD session, for example, BFD Down or BFD Up. This function is often used in various types of fast reroute (FRR), which uses BFD to detect the interface status to implement fast FRR switching.

 Only LDP FRR switching is supported in BFD support for Layer-3 interfaces.

- BFD support for L3AP member ports

After BFD support for Layer-3 access point (L3AP) member ports is enabled, BFD can rapidly detect a fault occurring on a member port link so that traffic on this link is rapidly distributed to other effective member links. In general, the fault detection time can be shortened within 1 second.

 For more details about BFD support for L3AP member ports, see *Configuring AP*.

6.3.4 BFD Protection

The BFD protection is used to protect BFD against session flapping caused by attacks (for example, a large number of ping packets attack devices).

Working Principle

The BFD protocol is very sensitive. If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD sessions flap, the BFD protection can be configured to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.

6.3.5 BFD Flapping Dampening

A BFD session may frequently switch over between Down and Up due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths and the running services are affected. The BFD flapping dampening can solve this problem.

Working Principle

A BFD session may frequently switch over between Down and Up. This function allows users to set the delay for status change advertisement. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies an associated application of BFD Down.

6.4 Configuration

Configuration	Description and Command	
Configuring BFD Basic Functions	 (Mandatory) It is used to establish a BFD session.	
	bfd interval	Sets BFD parameters.
	N/A	Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides.
	 (Optional) It is used to configure the BFD detection mode, slow timer, and BDF support for Layer-3 interfaces.	
	bfd echo	Configures the BFD echo mode.
	bfd slow-timer	Configures the BFD slow timer.
	bfd bind peer-ip	Configures the BFD support for Layer-3 interfaces.
Configuring BFD Protection	 (Optional) It is used to protect BFD against attacks.	
	bfd cpp	Enables BFD protection.
Configuring BFD Flapping Dampening	 (Optional) It is used to protect associated protocols against BFD flapping.	
	bfd up-dampening	Configures BFD flapping dampening.

6.4.1 Configuring BFD Basic Functions

Configuration Effect

- Configure BFD support for applications.
- Establish a BFD session.
- A BFD session detects link faults.

Notes

- Pay attention to the following points when setting BFD session parameters:
 1. It is recommended that parameter settings be consistent at both ends of a BFD session, to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding due to different dampening time at both ends.
 2. Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.
- Pay attention to the following points when configuring BFD support for applications:
 1. Ensure that it is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application requires BFD to establish a session with a neighbor, the BFD session can also be established.
 2. If the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established.
- Pay attention to the following points when configuring the BFD detection mode:
 1. In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, configure Quality of Service (QoS) policies to ensure that echo packets are processed preferentially or disable the echo function.
 2. The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hops.
 3. The echo mode takes effect only after this mode is enabled at both ends of a BFD session.
 4. Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the **no ip deny land** command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

Configuration Steps

📄 Setting BFD Parameters

- Mandatory.

- BFD parameters need to be set at BFD session egresses of routers at both ends detected by BFD if no special requirements are raised.
- Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.

Command	bfd interval <i>milliseconds</i> min_rx <i>milliseconds</i> multiplier <i>interval-multiplier</i>
Parameter Description	interval <i>milliseconds</i> : Indicates the minimum TX interval, with the unit of milliseconds. min_rx <i>milliseconds</i> : Indicates the minimum RX interval, with the unit of milliseconds. multiplier <i>interval-multiplier</i> : Indicates the detection timeout multiplier.
Defaults	No BFD session parameter is configured.
Command Mode	Interface configuration mode
Usage Guide	The fast forwarding function must be enabled before the BFD function is enabled on routers.

📌 Enabling the BFD Echo Mode

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured.
- Complete the configuration on ports of switches or routers.
- A session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode.

Command	bfd echo
Parameter Description	N/A
Defaults	The BFD echo mode is disabled.
Command Mode	Interface configuration mode
Usage Guide	This command cannot be configured on AP interfaces. By default, when BFD session parameters are set, the system automatically enables the echo mode. The minimum TX interval and minimum RX interval of echo packets adopt the Interval milliseconds and min_rx milliseconds parameters of a session. Before enabling the echo mode of BFD, run the no ip redirects command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the no ip deny land command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

📌 Configuring the BFD Slow Timer

- (Optional) The default slow timer is 3,000 milliseconds. The value can be changed as required.
- Configure this function in global configuration mode of switches or routers.

- In BFD echo mode or session building, the slow timer is used to control packets. If the value increases, the required time for negotiating and establishing a BFD session becomes longer, and the time required for transmitting slow BFD packets in echo mode is longer.

Command	bfd slow-timer [<i>milliseconds</i>]
Parameter Description	<i>milliseconds</i> : Indicates the BFD slow timer, with the unit of milliseconds. The value ranges from 1,000 to 30,000 and the default value 3,000 is adopted if it is not set.
Defaults	The transmission interval of slow control packets is 3,000 milliseconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the slow timer in echo mode.

📌 Configuring the BFD Support for Layer-3 Interfaces

- (Optional) Currently, this function is used only when MPLS LDP is used for FRR.
- Configure this function on interfaces of switches or routers.

Command	bfd bind peer-ip <i>src-address</i> [<i>source-ip dst-address</i>] process-pst
Parameter Description	<i>src-address</i> : Indicates the peer IP address of an interface. <i>dst-address</i> : Indicates the local IP address of an interface.
Defaults	BFD support for Layer-3 interfaces is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	This command is used to enable BFD support for Layer-3 interfaces so as to rapidly detect connectivity of Layer-3 interfaces.

📌 Configuring the BFD Support for Applications

- Mandatory.
- This function is disabled by default.
- The configuration command varies with the associated applications. For details, see their configuration guides.
- This function must be configured at both ends so that a BFD session can be established.
- In RIP routing configuration mode, run the **bfd all interfaces** command to enable BFD support for RIP on all interfaces. For details, see *Configuring RIP*.
- In OSPF routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPF on all interfaces. For details, see *Configuring OSPF*.
- In OSPFv3 routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPFv3 on all interfaces. For details, see *Configuring OSPFv3*.
- In BGP routing configuration mode, run the **neighbor address fall-over bfd** command to enable BFD support for BGP. For details, see *Configuring BGP*.

- In IS-IS routing configuration mode, run the **bfd all interfaces** command to enable BFD support for IS-IS on all interfaces. For details, see *Configuring IS-IS*.
- In global configuration mode, run the **ip route static bfd [vrf vrf-name] interface-type interface-number gateway [source ip-address]** command to enable BFD support for static routing. For details, see *Configuring NSM*.
- In global configuration mode, run the **ipv6 route static bfd [vrf vrf-name] interface-type interface-number gateway [source ip-address]** command to enable BFD support for IPv6 static routing. For details, see *Configuring NSM*.
- Run the **set ip next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for PBR. For details, see *Configuring PBR*.
- Run the **set ipv6 next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for IPv6 PBR. For details, see *Configuring PBR*.
- Run the **vrrp bfd interface-type interface-number ip-address** command to enable BFD support for VRRP. For details, see *Configuring VRRP*.
- VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus. Only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

Verification

- The verification command varies with the associated applications. For details, see their configuration guides.

Configuration Example

Configuring BFD support for OSPF

Scenario Figure 6-6	
Configuration Steps	● Configure IP addresses for interconnected interfaces of Router A and Router B. ● Run OSPF on Router A and Router B. ● Set BFD parameters for interconnected interfaces of Router A and Router B. ● Enable BFD support for OSPF on Router A and Router B.
A	<pre> A#configure terminal A(config)#interface GigabitEthernet2/1 A(config-if-GigabitEthernet2/1)# no switchport //The configuration is not required on routers. Common Errors

- BFD parameters are not set for device interfaces at one end.
- The BFD support for applications is disabled.
- The BFD support for applications is enabled only at one end.

6.4.2 Configuring BFD Protection

Configuration Effect

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD session flaps accordingly, the BFD protection can be enabled to provide protection.

Notes

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.
- This function and limitations are applicable only to switches.

Configuration Steps

📌 Enabling BFD Protection

- Optional.
- Configure this function in global configuration mode on switches or routers.
- The BFD protection function raises the processing priority of BFD packets and ensures normal running of BFD services in a scenario in which devices are attacked.

Command	bfd cpp
Parameter	N/A
Description	
Defaults	The BFD protection function is enabled by default.
Command Mode	Global configuration mode
Usage Guide	Enable the BFD protection function to provide protection if a device encounters BFD flapping due to attacks.

Verification

Run the **show running-config** command to verify the configuration on an interface.

Configuration Example

📌 Enabling BFD Protection

Configuration Steps	● Configure this function on a switch on a network where attacks exist. ● Configure the BFD protection function.
	<pre>Ruijie#configure terminal Ruijie(config)# bfd cpp Ruijie(config)# end</pre>
Verification	N/A

6.4.3 Configuring BFD Flapping Dampening

Configuration Effect

- A BFD session may frequently switch over between Down and Up due to link instability. As a result, a relevant application (such as static routing) may frequently switch forwarding paths and the running services are affected.
- Users can set the delay for status change advertisement, after which BFD notifies an associated application of BFD Up. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies it of BFD Down. The purpose is to reduce flapping of associated protocols caused by instable links.

Notes

- The BFD basic functions must be configured.
- If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

Configuration Steps

📌 Configuring BFD Flapping Dampening

- (Optional) The BFD flapping dampening is disabled on ports by default. If a BFD session frequently switches over between Down and Up, it is advised to enable this function.
- Configure this function on ports of switches or routers.
- With BFD flapping dampening enabled, it is relieved that associated applications, such as route re-calculation, process quantities of advertisements because of frequent status BFD change. The larger the configured time is, the longer the required BFD stability time is. BFD notifies an application module of BFD Up only after the stability time reaches the configured time.

Command	bfd up-dampening[<i>milliseconds</i>]
Parameter	<i>milliseconds</i> : Indicates the delay for status change advertisement, after which BFD notifies an associated

Description	application of BFD Up, with the unit of milliseconds. The value ranges from 0 to 300,000. The value 0 indicates that BFD notifies the application layer immediately when a session switches over from Down to Up and the default value is 0.
Defaults	The BFD flapping dampening function is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This function needs to be enabled only when the link is instable. If a BFD session does not frequently switch over between Down and Up, the enabling of BFD flapping dampening will delay notifying an associated application of BFD Up.

Verification

Run the **show running-config** command to verify the configuration on an interface.

Configuration Example

Configuring BFD Flapping Dampening with the Advertisement Delay as 60,000 Milliseconds

Configuration Steps	- Configure this function in an environment where BFD frequent flaps due to link instability. - Set the delay for status change advertisement to 60,000 milliseconds.
	<pre>Ruijie#configure terminal Ruijie(config)# interface fastEthernet 0/2 Ruijie(config)# bfd up-dampening 60000 Ruijie(config)# end</pre>
Verification	N/A

6.5 Monitoring

Displaying

Description	Command

7 Configuring IP Event Dampening

7.1 Overview

When the Layer-3 port on a Layer-3 device frequently goes Up and Down due to manual enabling/disabling or other external causes, the routing table on the device will flap repeatedly. If a routing protocol is configured, the protocol may propagate the flap to the entire network, causing repeated updates and recalculation of neighboring routes, which wastes network bandwidths and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, which affects the normal running of customer networks.

IP Event Dampening detects abnormal Up/Down flapping and automatically suppresses frequent port state changes, which prevents the propagation of single-point link failures by a routing protocol. When the port is restored, it will be automatically unsuppressed, thus reducing network flaps and CPU resource consumption while improving network stability.

Protocols and Standards

- RFC2439: BGP Route Flap Dampening

 At its core, the suppression algorithm used by IP Event Dampening is the same as that used by BGP Route Flap Dampening.

7.2 Applications

Application	Description
Routed Port Flap Dampening	Monitors the state change of the Layer-3 port on a router, and suppresses frequent port flapping.

7.2.1 Routed Port Flap Dampening

Scenario

In a network that runs a routing protocol, when a port on a router connected to another router frequently goes Up and Down, neighboring routes will be repeatedly updated and recalculated. The routing protocol may propagate the flap to the entire network, causing a network flap. IP Event Dampening can be enabled on the connected routers to monitor port state changes and suppress frequent port flapping, thus reducing network flaps and CPU resource consumption while improving network stability.

Figure 7-1

Remarks	A and B are routers.

Deployment

Configure IP Event Dampening on portGE0/1 on Router A and portGE0/1 on Router B respectively.

 The subinterfaces and the virtual templates of interfaces on routers do not support the dampening feature.

7.3 Features

Basic Concepts

Penalty

A port that goes Up or Down gets a penalty for each state change, but the penalty decays exponentially when the port is stable. In this way, port behaviors can be sensed and controlled intelligently.

Suppress Threshold

When the cumulative penalty of a port exceeds a suppress threshold, the port is considered to flap and will be suppressed.

Half-Life Period

The half-life period is the period required for the penalty to decrease to half of the original value when the port is stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the port is detected to be stable, but the flap detection sensitivity is reduced.

Reuse Threshold

When the port no long flaps and its penalty decays to a certain degree (below the suppress threshold), the port is considered to be stable and is unsuppressed.

Maximum Suppress Time

When a port keeps flapping and reaches a very large penalty, the port will not be usable for a long time. To avoid this problem, the maximum suppress time is defined to always maintain the port suppression duration below a certain value no matter how long the port has flapped.

Overview

Feature	Description
Port Flap Suppression	Configure the criteria and parameters of flap suppression on ports to enable switches to identify and suppress frequently flapping ports, which ensures route stability and avoids route flap propagation.

7.3.1 Port Flap Suppression

Working Principle

A port configured with IP Event Dampening is assigned a penalty. The port gets a penalty of 1,000 each time when it goes Down, but the penalty decreases with time. If the port goes Down again, the penalty increases accordingly. When the cumulative penalty exceeds the suppress threshold, the port will be suppressed. For the affected upper-layer protocol, the suppressed port is always Down no matter what the actual port state is. When the penalty decreases to the reuse threshold, the port will be unsuppressed, and the upper-layer protocol can sense the actual port state.

If a Layer-3 port is not configured with IP Event Dampening, or is not suppressed by it, the routing protocol or other protocol concerned about the port status still work normally. When the port is suppressed, the upper-layer protocol considers the port to be Down. Any state change of the port before the port is unsuppressed does not affect the routing table and the route calculation and advertisement performed by the upper-layer routing protocol.

Related Configuration

Configuring IP Event Dampening

- By default, IP Event Dampening is disabled on Layer-3 ports.
- Run the **dampening** [*half-life-period* [*reuse-threshold suppress-threshold max-suppress* [**restart** [*restart-penalty*]]]] command to enable or disable IP Event Dampening on Layer-3 ports.

7.4 Configuration

Configuration	Description and Command	
Enabling IP Event Dampening	 (Mandatory) It is used to suppress Layer-3 port flapping.	
	dampening	Configures IP Event Dampening.

7.4.1 Enabling IP Event Dampening

Configuration Effect

When a port configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the port is set to Down.

Notes

- When a Layer-3 port on a switch is converted to a Layer-2 port (for example, from a routed port to a switch port), the IP Event Dampening configuration on the port will be deleted.

Configuration Steps

Configuring IP Event Dampening

- Mandatory.
- Perform the configuration in Layer-3 interface configuration mode.
- You can specify the half-life period, reuse threshold, suppress threshold, maximum suppress time, and initial penalty. If you do not set these parameters, their default values will be used.

Verification

Use any one of the following commands to check whether the configuration takes effect:

- **show running-config**
- **show interfaces** [*interface-id*] **dampening**, which is used to check the IP Event Dampening configuration on a specified port

Related Commands

Enabling IP Event Dampening on a Port

Command	dampening [<i>half-life-period</i> [<i>reuse-threshold</i> <i>suppress-threshold</i> <i>max-suppress</i> [restart [<i>restart-penalty</i>]]]]
Parameter Description	<i>half-life-period</i>: Indicates the half-life period. Value range: <1–30>; default value: 5s. <i>reuse-threshold</i>: Indicates the reuse threshold. Value range: <1–20,000>; default value: 1,000. <i>suppress-threshold</i>: Indicates the suppress threshold. Value range: <1–20,000>; default value: 2,000. <i>max-suppress</i>: Indicates the maximum suppress time. Value range: <1–255>; default value: four times the half-life period. restart <i>restart-penalty</i>: Indicates the initial penalty. Value range: <1–20,000>; default value: 2,000.
Command Mode	Interface configuration mode
Usage Guide	IP Event Dampening can affect direct routes, host routes, static routes, dynamic routes, and VRRP. When a port is suppressed based on the configured criteria, the affected modules determine that the port is Down and therefore delete corresponding routes. No data packet will be transmitted through the port. When the dampening command is rerun on a port configured with IP Event Dampening, the dampening information on the port will be cleared, but the flap count is retained, unless you use the clear counters command to clear the counters on the port. If the max-suppress parameter is set to a very small value, making the maximum penalty smaller than the suppress threshold, the port will never be suppressed. When such a configuration error occurs, the following message indicating a configuration failure will be printed: <pre>% Maximum penalty (10) is less than suppress penalty (2000). Increase maximum suppress time</pre>

If the available system memory is insufficient to run the **dampening** command, the following message indicating a configuration failure will be printed:

```
% No memory, configure dampening fail!
```

Configuration Example

Configuring IP Event Dampening on Layer-3 Ports

Scenario Figure 7-2	
Configuration Steps	Enable IP Event Dampening on port GigabitEthernet 0/1 on Router A and on port GigabitEthernet 0/1 on Router B respectively, and set half-time-period to 30s, reuse-threshold to 1,500, suppress-threshold to 10,000, and max-suppress to 120s.
A	<pre>Ruijie(config)#interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#dampening 30 1500 10000 100</pre>
B	<pre>Ruijie(config)#interface GigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)#dampening 30 1500 10000 100</pre>
Verification	Run the show interfaces dampening command to check the IP Event Dampening configuration on the corresponding ports.
	<pre>Ruijie#show interfaces dampening GigabitEthernet 0/1 Flaps Penalty Supp ReuseTm HalfL ReuseV SuppV MaxSTm MaxP Restart 0 0 FALSE 0 30 1500 1000 100 15119 0</pre>

Common Errors

- The port on a Layer-3 switch is not converted to a routed port by using the **no swithport** command before IP Event Dampening is configured.

7.5 Monitoring

Clearing

Description	Command
Clears the interface counters.	clear counters

For details about the **clear counter** command, see the related chapter for the "Interface" command.

Displaying

Description	Command
Displays the counters on suppressed ports.	show dampening interface
Displays the IP Event Dampening configuration on ports.	show interfaces dampening

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables debugging of IP Event Dampening.	debug dampening interface

8 Configuring VSU

8.1 Overview

In order to improve the reliability of networks, the two devices at core layer and convergence layer of traditional networks are configured with two cores to provide redundancy. Access and convergence devices are respectively connected to the cores through two links. The following figure shows a typical traditional network architecture. Redundant network architecture increases the complexity of network design and operation. At the same time, a large number of redundant links reduce the utilization of network resources and return on investment.

Figure 8-1 Traditional network architecture

Virtual Switching Unit (VSU) is a kind of network system virtualization technology that supports combining multiple devices into a single virtualized device. As shown in Figure 8-2, access, convergence and core layer devices can respectively form VSUs, and then these VSUs connect to one another to form an end-to-end VSU network. Compared with traditional network, this networking can:

- Simplify the network topology.
- Reduce the costs of network management and maintenance.
- Shorten application recovery time and service interruption time.
- Enhance the utilization of network resources.

Figure 8-2 End-to-End VSU Networking

8.2 Applications

Application	Description
Managing Multiple Devices in a Unified Manner	Uses multiple physical devices as a logical device for unified management.
Simplifying Networking Topology	Uses a VSU as a logical device to simplify the networking topology.

8.2.1 Managing Multiple Devices in a Unified Manner

Scenario

When multiple physical devices form a VSU system, the physical devices can be viewed as a logical device. All configurations are managed on the global master device.

As shown in Figure 8-3, four devices (numbered as 1, 2, 3, and 4 from left to right) form a VSU system. Device 1 is the global master device, device 2 is the global slave device, and devices 3 and 4 are the global candidate devices.

- All devices are configured simply on the global master device.

Figure 8-3

Remarks	The devices from left to right in Figure 1-3 are Device 1, Device 2, Device 3 and Device 4. For details on VSL, see the description in section 1.3.1.

Device 1 is the global master device. Device 2 is the global slave device. Devices 3 and 4 are the global candidate devices.

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.
- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when faulty.
- The global candidate devices are involved in data forwarding and do not run control-plane protocols. When the global slave device is faulty, a global candidate device can take over the work of the global slave device. In this case, when the global master and slave devices are faulty, the VSU system will restart.

8.2.2 Simplifying Networking Topology

Scenario

In traditional networks as shown in Figure 8-4, redundant devices and lines need to be added to increase the networking reliability; however, many algorithms also need to be introduced to prevent loops, which make the networking more complex. In the VSU system, all devices are viewed as a logical device. Different devices back up each other, and no loop prevention algorithm needs to be introduced, which can simplify the network.

- Two aggregate switches form a VSU system. It is unnecessary to configure a loop prevention algorithm. The two switches are redundant mutually.
- The access switch is connected to the aggregate switches through the uplink AP.
- When a switch in the VSU system is faulty, the other link still works.

Figure 8-4

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.

- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when the global master device is faulty.
- The access switch is oriented to users and allows access by users' devices.

8.3 Features

Basic Concepts

VSU System

VSU system is a single logical entity consisting of two or multiple devices in traditional network architecture. For example, the convergence layer VSU system as shown in the following figure can be seen as a single device that interacts with the core layer and access layer.

Figure 8-5 Convergence layer VSU

In the above VSU network structure, the member devices form a logical entity through internal links and the access layer devices are connected to the VSU through aggregated links. In this way, there is no layer 2 loop between the access and convergence layers.

Figure 8-6 Access layer VSU

Except the core and convergence layer devices, the access layer devices can also form a VSU system. A server that requires high availability can adopt multiple network cards to form an Aggregate Port (AP) to connect access layer devices. Since AP can only connect to the same access device, the risk of single device fault increases. In this case, VSU can be used to solve the problem. In the VSU mode, a server adopts multiple network cards and binds them into an AP to connect

different member devices in the same VSU group. This way can prevent single point failure and network interruption caused by single link failure.

📌 VSU Domain ID

A VSU domain has only one ID. Only the devices with the same domain IDs can form a VSU system.

📌 Member Device ID

Every member device in a VSU system has a unique ID, namely, Switch ID. Switch IDs can be used in device management or configuring interfaces on member devices. You need to configure an ID for a device when adding the device to a VSU system and ensure that the ID is unique in the same VSU system. If an ID conflict occurs, the VSU system will reserve one device according to priority.

📌 Member Device Role

A VSU system consists of several devices. When establishing a VSU system, you need to select a global master device and a global slave device. All other devices are global candidate devices. A global master device is elected from multiple devices based on an election protocol. All other devices are global slave devices in the 1: N hot standby mode. When the 1:1 hot standby mode is supported, one device is the global master device, one device is the global slave device, and all other devices are global candidate devices.

The global master device is responsible for controlling the entire VSU system, running control plane protocols and participating in data forwarding. Other devices, including the global slave devices and candidate devices, participate in data forwarding but do not run control plane protocols. All received control plane data flows are forwarded to the global master device for processing.

The global slave device also receives the statuses of the global master device in real-time and provide 1:1 or 1:N redundancy with the global master device. If the global master device becomes faulty, the global slave device will take over services from the master device and manage the entire VSU system.

❓ The following is the method for selecting the master device of a VSU system:

1. Rules for selecting the master device of a VSU system include (Continue with the next rule if the previous rule does not help in selecting the master device): a) Select the currently running host as the master device with the highest priority (All devices are not master devices during startup). b) Select the device with the highest priority as the master device. c) Select the device with the lowest device No. as the host. d) Select the device with the smallest MAC address as the master device.
2. In the 1:N hot standby mode, select the device that has the most familiar configurations with the master device as the slave device to prevent dual active devices. The selection order is: the nearest/the highest priority/the smallest MAC address.
3. VSU system supports hot adding a support device. Even the hot added device has a higher priority than the master device has, the VSU system does not perform active/standby switch.
4. The startup order of member device may affect the election of master device. A member device may not join in the VSU system because it starts up too slowly. In this case, the device will be hot added to the VSU system. Even the device has a higher priority than the master device, the VSU system does not perform active/standby switchover.

Overview

Feature	Description
Virtual Switching Link (VSL)	In a VSU system, a virtual link is used to connect all devices.
Topology	Describes the internal topology of a VSU system.
Dual-Active Detection (DAD)	Avoids that dual master switches coexist in a VSU domain.
System Management	Describes possible connections between external devices and VSU devices.
Quick Blinking Location	Manages devices in the VSU system.

8.3.1 Virtual Switching Link (VSL)

Working Principle

➤ VSL

The VSU system is a network entity that consists of multiple devices. These devices need to share control information and part of data streams. The VSL is a special link used for transmission of control information and data streams among devices of the VSU system. For example, the VSL can be established between two devices through 10 Gigabit Ethernet interfaces. Figure 8-7 shows the position of the VSL in the VSU system.

Figure 8-7 VSL

The VSL exists in the form of AP groups. The data streams transmitted through the VSL balance load among the aggregation port members according to the traffic balancing algorithm.

➤ VSL Traffic

The control streams transmitted through the VSL between devices include:

1. The protocol packets received by the member devices: These protocol packets need to be forwarded through the VSL to the global master device for processing.
2. The protocol packets processed by the global master device: These protocol packets need to be forwarded through the VSL to the interfaces of other member devices and then sent to the peer devices by these interfaces.

The data streams transmitted through the VSL between devices include:

1. The data stream flooded on the VLAN
2. The data streams that need to be forwarded across devices and transmitted through the VSL

Furthermore, the internal management packets of the VSU system are also transmitted through the VSL. The management packets include the protocol information switched by the hot backup and configuration information delivered by the host to other member devices.

? In terms of the switched port analyzer (SPAN) function, the interface associated with the VSL cannot be regarded as the source port or destination port of the SPAN.

📌 VSL Failure

If a certain member link connected to the VSL AP group fails to work, the VSU will adjust the configurations of the VSL aggregation port automatically to prevent the traffic from being transmitted through the faulty member link.

If all member links are disconnected to the VSL AP group, the VSU topology will change. If the original VSU topology is a ring topology, the ring will convert into a line. For details, see topology ring and line conversion in the section of *Topology Changes*.

📌 Detecting Error Frames on a VSL Interface

When a large number of consecutive error frames are detected on a VSL interface, the interface must be disabled and switched to another VSL interface. The detection method is as follows:

If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interface every 5 seconds by default. If the number of error frames is greater than the value of *num* as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for the value of *times*, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Different user scenarios have different requirements for *num* and *times*. The default value of *num* is 3 and that of *times* is 10. If users have strict requirements on the scenarios, select smaller values for *num* and *times*; if reverse, select greater values.

8.3.2 Topology

The VSU system supports line topology and ring topology. Devices are connected through a VSL to form a line that is called the line topology.

Working Principle

📌 Topology

The line topology is simple. It uses a very few ports and cables. Two devices are connected with a communication link only. Therefore, the VSL has low reliability.

Figure 8-8 Line topology

Except for the line topology, devices can also form a ring topology, as shown in Figure 8-9. In the ring topology, the two communication links between devices can back up for each other and perform link redundancy to improve the reliability of the VSU system.

Figure 8-9 Ring Topology

- ? You are advised to select the ring topology for the VSU system, thus the normal operation of the whole VSU system will not be affected by any single faulty device or VSL.
- ? Besides selecting the ring topology networking, you are advised to configure multiple VSLs for every VSL member to improve the reliability of a single VSL. At least two links are recommended and a maximum of four links can be configured. A reasonable configuration comprises more than two VSLs crossing different cards.

Topology Convergence

Before the establishment of the VSU, the member devices need to discover neighbors through topology discovery protocols and check devices in the VSU system to confirm the range of the management domain. Then a global master device is selected to manage the whole VSU system and a global slave device is selected for backup of the master device. Then the whole VSU topology is converged. As the start up time differs for different devices, the first convergence time of the topology is also different.

Topology ring and Line Conversion

In a ring topology, if a VSL link is disconnected, the ring topology will convert into a line topology. The whole VSU system will still run normally without network disconnection. To prevent other VSL links and nodes from being faulty, you are advised to locate the VSL failures and recover the availability of the VSL. After the VSL link is recovered, the line topology will convert into the ring topology.

Figure 8-10 Ring-to-line and line-to-ring

Topology Splitting

In the line topology, if the VSL link is disconnected, the line topology will be split, as shown in Figure 8-11. A VSU group is split into two groups. In this condition, two devices with the absolutely same configurations may exist on the network, which will cause abnormal operation of the network. Therefore, the multi-active detection (MAD) function needs to be deployed to solve the problem of topology splitting.

Figure 8-11 Topology splitting

Topology Combining

If the two VSU groups are connected through the VSL link, the line topology will be combined. During the topology combining, restart one VSU group and then hot add the other VSU group.

The principle of topology combining: Minimizing influences on the services during topology combining. The rules are as follows (Judge from the first item. If you cannot select the optimal topology, continue to judge the next item):

- Use the device priority as the first criteria for judging topology combining. Reserve the VSU group containing a device with the highest priority.

- If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
- If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the global master switches).

Figure 8-12 Topology combining

- During topology combining of two VSU groups, the two VSU groups need to be elected. The VSU group that fails the election will restart automatically and hot add to the other VSU group.

8.3.3 Dual-Active Detection (DAD)

Working Principle

When the VSL is disconnected, the slave device switches to the master device. If the original master device is still running, a series of problems including IP address conflict on the LAN will be caused due to there are two master devices and their configurations are the same completely. In this condition, the VSU system must detect the two devices and take recovery measures. The VSU system provides two methods to perform MAD as follows:

- Bidirectional forwarding detection (BFD)
- AP-based detection

➤ MAD Rules

1. Select the VSU group with the highest priority.
2. If the previous item cannot help make a judgment, select the VSU group with more physical devices.
3. If the previous item cannot help make a judgment, select the VSU group with a higher health. (Health: total bandwidth of all physical interfaces (except for management and VSL interfaces) in the UP state in the topology.)
4. If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
5. If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the two global master switches).

6. If the previous item cannot help make a judgment, reserve the VSU group with a greater startup time (that of the global master switches).

↘ BFD

The VSU system supports the BFD to detect multiple master devices. Figure 8-13 shows the topology. A link is added for the two devices on the edges for MAD specially. When the VSL link is disconnected between the global master and slave devices, two master devices exist concurrently. If the BFD function is set, the two master devices will send the BFD packets to each other through the BFD link. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules and enter the recovery state to avoid network abnormality.

Figure 8-13 BFD

- ⚠ When there is a pair of BFD links, you are advised to deploy the detection links at the two ends of the topology.
- ⚠ You need to adopt the extension BFD and you cannot configure the dual-active detection port by using the existing BFD configurations and commands.

↘ MAD

The VSU system also supports the MAD dual-active detection mechanism. Figure 8-14 shows the topology. The VSU system and the upstream device both need to support the MAD function. When the VSL link is disconnected, two master devices exist concurrently. The two master devices respectively send the MAD packets to the member ports of the MAD-APs and then the MAD packets are forwarded to each other through the upstream device. As shown in Figure 8-14, the MAD-AP has four member ports. Each member port is connected to a different device of the VSU system. When the topology splitting occurs, the four member ports all send and receive the MAD packets. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules and enter the recovery state to avoid network abnormality.

Figure 8-14 MAD based on upstream and downstream devices

✓ In the topology above, the upstream device must be Ruijie device and support the MAD packet forwarding function.

8.3.4 VSU Traffic Forwarding

Working Principle

↘ Cross-device AP Group

An AP binds multiple physical links together to form a logical link. The VSU system supports the AP across the member devices.

As shown in Figure 8-15, two devices form a VSU group. The external access device Switch A is connected to the VSU in the form of the AP. In terms of Switch A, there is no difference between the AP in Figure 8-15 and the common AP group.

Figure 8-15 Cross-device aggregation port

↘ Troubleshooting

You are advised to configure the cross-device AP with the physical link between the peripheral device and each VSU device. On the one hand, the VSL bandwidth can be reserved (prioritize the AP member of the same chassis as the egress to transmitted the cross-chassis AP traffic and prevent unnecessary traffic from being transmitted through the VSL link). On the other hand, the network reliability can be improved (if a certain chassis is faulty, the member ports of normal devices can work normally).

The follows sections describe the possible faults of the cross-device AP and the consequences.

- Single link failure

If a single link of the cross-device AP is faulty but other links still work normally, the cross-device AP will reallocate the traffic for the remaining normal links.

- Link failure of all cross-device AP member ports on the global master device

If the links of all cross-device AP member ports on the global master device fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the global master device, the system will forward the data stream to the corresponding egress on the global master device through the VSL link.

The control plane protocols are still running on the global master device. Therefore, the protocol packets that enter the VSU system need to be forwarded to the global master device through the VSL link for protocol computing.

- Failure of all links of other member devices

If all links of the cross-device AP and a single device A fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the member device A, the system will forward the data stream to the corresponding egress on the member device A through the VSL.

- Global master device fault

If the global master device is faulty, the hot backup switching is performed to switch the original slave device to the master device. Meanwhile, the member ports on other member devices continue working. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream to normal links.

- Member device fault

If a member device is faulty, the AP member link connected to this member device is disconnected. However, other member links still work normally. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream forwarding paths to normal links.

📌 Traffic Balancing

In a VSU system, traffic may have multiple egresses. The AP and ECMP have their own traffic balancing algorithms, for example, using destination or source MAC addresses. For details, see the *Configuring Aggregate Port*. The local forwarding first (LFF) can be configured detailed in this configuration manual. Packets received by a device are forwarded on this device first. In this way, packets can be forwarded to other devices without using a VSL.

8.3.5 System Management

Working Principle

📌 Access to the Console

The master device console of VSU system manages multiple devices on the system simultaneously. The consoles of the slave and candidate devices do not support command line input. However, you can configure the VSU system on the master device for a specified member device and log in to the master device console through the serial port of the slave device. A session can be used to redirect to the master console of a device.

📌 Slot Naming

In terms of the chassis device, in the VSU mode, the slot is named with the device number (Switch ID). Therefore, the slot number turns from one-dimensional into two-dimensional. For example, cable clip 1/1 indicates the slot numbered 1 of the slot 1 on a member device.

📌 Interface Naming

In the VSU working mode, a slot number may occur in multiple devices. Therefore, the interface is named with the device number (Switch ID).

For example, interface gigabitEthernet 1/0/1 indicates the Gigabit port 1 on the slot 0 of the device whose ID is 1; interface gigabitEthernet 2/0/2 indicates the Gigabit port 2 on the slot 0 of the device whose ID is 2.

Access to the File System

In the VSU working mode, you can access to the file system on other member devices from the master device. The detailed access method is the same to that of the local file system. The unique difference is that different URL prefixes are used.

System Upgrade

Generally the VSU system requires version consistency of the main program version numbers of the member devices. However, there are so many member devices that it takes too much time and energy to perform upgrade one by one in the standalone mode and it is also easy to make mistakes. Ruijie switches provide consummate system upgrade solution to help you with system upgrade by adopting the two methods as follows:

- When the VSU system is being established: the system will automatically align the main program version numbers of all member devices. Once the main program versions are discovered inconsistency, the main program of the master device will be selected to be synchronized to all member devices.
- After the VSU system is established: the main program version will be synchronized to all member devices automatically by using the file that is downloaded by the TFTP.

SYSLOG

All member devices of the VSU system can display the SYSLOG. The SYSLOG generated by the master device is displayed on the master device console with the same format to that in the standalone mode. The SYSLOG generated by other member devices is also displayed on the master device console, but the message format is different from that in the standalone mode because the device number information is added.

For example, the SYSLOG information generated in the standalone state is "%VSU-5-DTM_TOPO_CVG:Node discovery done. Topology converged." The SYSLOG information generated by the member device numbered 3 is "%VSU-5-DTM_TOPO_CVG:(3) Node discovery done. Topology converged."

8.3.6 Quick Blinking Location

In a network cabling environment, the equipment room where switches are located and the operation console are often at different places. If there are many devices in the environment, network administrators cannot easily locate the locations of specific devices.

Quick blinking location provides network administrators with a method for locating devices by means of quick blinking. By enable this function for a device on the console, you can easily find the corresponding device in the equipment room.

When quick blinking location is enabled, the status LED cannot show original status until the quick blinking location is disabled.

8.3.7 Device Recovery in Recovery Mode

By default, a device in recovery mode automatically restarts and is added to the VSU topology again after the VSL link recovers.

The **no recovery auto-restart enable** command is provided to disable the automatic restart and recovery function in recovery mode. After the VSL link recovers, the administrator can enable the automatic restart and recovery function in recovery mode again or manually enter the restart command for devices in recovery mode.

- After the automatic restart and recovery function in recovery mode is disabled, the device stays in recovery mode until the administrator enables the function again or manually resets the device.

8.3.8 Automatic Recovery Without Restart for a Device in Recovery Mode upon Master Device Abnormality

Figure 8-16 Automatic Recovery Without Restart in Recovery Mode

By default, a device in recovery mode does not perform any operation when the master device is abnormal. The device stays in recovery mode until the VSL link recovers.

A configuration command is provided for the administrator to enable the automatic recovery without restart function in recovery mode. In this case, a device in recovery mode can automatically become the master device without being restarted and take over services of the original master device.

- After the automatic recovery without restart function in recovery mode is enabled, a device in recovery mode becomes the master device when a master device abnormality is detected.

8.3.9 MGMT Interface Configuration in VSU Mode

By default, a device creates one MGMT interface for each chassis when the device is started in VSU mode.

The **mgmt_mode unique** command also allows administrators to configure a device to create only one MGMT interface for the system in VSU mode. In this way, the MGMT interface occupies only one IP address.

- After this command is configured, run the **write** command to save the configuration. The configuration takes effect only in VSU mode and only after the device is restarted.

8.4 Configuration

Configuration		Configuration and Command	
Configuring VSU in the Standalone Mode		 (Mandatory) It is used to configure VSU in the standalone mode.	
		switch virtual domain	Configures the domain ID.
		switch	Configures the switch ID.
		switch priority	Configures the switch priority.
		vsl-port	Enters the VSL interface configuration mode.
		port-member interface	Configures the VSL member interface.
		switch convert mode virtual	Changes the standalone mode to the VSU mode.
		 (Optional) It is used to configure the device attributes in the VSU mode.	
		switch description	Configures the device description.
		switch crc	Configures error frame check.
Configuring VSU in the VSU Mode	Configuring VSU Attributes	 (Optional) It is used to configure the device attributes in the VSU mode.	
		switch domain	Changes the domain ID.
		switch renumber	Changes the switch ID.
		switch description	Configures the device description.
		switch crc	Configures error frame check.
	Configuring the VSL	 (Optional) It is used to configure a VSL.	
		vsl-port	Enters the VSL interface configuration mode.
		port-member interface	Configures a VSL member interface.
	Configuring Dual-Active Detection	 (Mandatory) It is used to configure DAD.	
		dual-active detection	Configures DAD.
		dual-active bfd interface	Configures the BFD DAD interface.
		dual-active interface	Configures an AP as a DAD interface.
		dual-active exclude interface	Configures an excluded interface.
	Configuring Traffic Balancing	 (Optional) It is used to configure traffic balancing in the VSU mode.	
		switch virtual aggregateport-lff enable	Configures the AP LFF mode.
		switch virtual ecmp-lff enable	Configures the ECMP LFF mode.
	Configuring the Device Recovery Method in Recovery Mode	 (Optional) It is used to configure the device recovery in recovery mode.	
		no recovery auto-restart enable	Disables the automatic restart and recovery function in recovery mode.

Configuration		Configuration and Command	
	Configuring Automatic Recovery Without Restart in Recovery Mode	 (Optional) It is used to configure the automatic recovery without restart function in recovery mode.	
		dual-active enable	auto-recovery Enables the automatic recovery without restart function in recovery mode.
	Changing the VSU Mode to the Standalone Mode	 (Optional) It is used to change the VSU mode to the standalone mode.	
		switch convert mode standalone	Changes the VSU mode to the standalone mode.
Quick Blinking Location		 (Optional) It is used to quickly locate a device.	
		led-blink	Enables quick blinking location.
Configuring the MGMT Interface		 (Optional) It is used to configure a device to create one MGMT interface for each chassis or create only one MGMT interface in VSU mode.	
		mgmt_mode unique	Configures the system to create only one MGMT interface in VSU mode.
		no mgmt_mode	Configures the system to create one MGMT interface for each chassis in VSU mode.

8.4.1 Configuring VSU in the Standalone Mode

Configuration Effect

Start up the switch in the standalone mode to set relevant VSU parameters to establish the VSU system.

Configuration Steps

📌 Configuring VSU Attributes

- A switch starts in the standalone mode by default. You need to set the same domain ID on the two chassis of the established VSU system. The domain ID must be unique within the local area network (LAN). Furthermore, you need to set the ID of each chassis in the VSU.
- Run the **switch virtual domain** *domain_id* command to configure the domain ID. This command is mandatory.
- Run the **switch** *switch_id* command to configure the device ID in the VSU. This command is mandatory. For devices with the same priorities in the VSU system, a device with the smallest device ID is selected as the global master device.
- Run the **switch** *switch_id* **priority** *priority_num* command to configure the device priority. This command is mandatory.
- The value ranges from 1 to 255. A larger value means a higher priority.

- Run the **switch** *switch_id* **description** *switch1* command to configure the device alias. This command is optional. The default name is Ruijie. For easy identification of devices in the network environment, this item can be selected to set the device alias.
- A maximum of 32 characters are allowed.

Command	switch virtual domain <i>number</i>
Parameter Description	<i>number</i> : Indicates domain ID of the VSU
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU. The domain ID must be unique within the LAN.

Command	switch <i>switch_id</i>
Parameter Description	<i>switch_id</i> : indicates the switch ID in the VSU system. The value varies with products.
Defaults	The default device ID is 1.
Command Mode	Domain configuration mode
Usage Guide	The device ID identifies each virtual device member. In VSU mode, the interface name format changes to "switch/slot/port" from "slot/port", in which "switch" is the device ID. If either chassis are active or if the role of the just started chassis is uncertain and both have the same priority, the chassis with a smaller ID is elected as the active one. This command can be only used to modify the device ID in standalone mode. In VSU mode, run the switch renumber command to modify the device ID. The modified device ID takes effect only after you restart the device, regardless of in standalone mode or in VSU mode.

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter Description	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured. <i>priority_num</i> : Indicates the switch priority, ranging from 1 to 255.
Defaults	The default device priority is 100.
Command Mode	Domain configuration mode
Usage Guide	A larger value means a higher priority. A device with the highest priority is chosen as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device. This command is not used to modify the value of <i>switch_id</i>. In the standalone mode, if <i>switch_id</i> is set to 1, running the switch 2 priority 200 command does not work. You can first set <i>switch_id</i> to 2 and then run the switch 2 priority 200 command. In the VSU mode, <i>switch_id</i> indicates the ID of the currently running

	switch. If the ID does not exist, the configuration does not take effect.

Command	switch <i>switch_id</i> description <i>dev-name</i>
Parameter	<i>switch_id</i> : Indicates the device ID.
Description	<i>dev-name</i> : Indicates the device description, no greater than 32 characters.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	This command is configured on a device in whether standalone or VSU mode and takes effect immediately after configuration.

Configuring the VSL

- To establish the VSU system, you need to decide which ports are configured as the VSL member ports.
- Run the **vsl-port** command to enter the VSL interface configuration mode. This command is mandatory.
- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is mandatory.

When the device enters the VSL interface configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter	N/A
Description	
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter	<i>interface-name</i> : Indicates a two-dimensional interface name, such as Tengigabitethernet 1/1 and Tengigabitethernet 1/3.
Description	copper : Indicates the copper interface attribute. fiber : Indicates the optical interface attribute.
Command Mode	VSL interface configuration mode
Usage Guide	Add a member interface of the VSL link. <i>interface-name</i> indicates the two-dimensional interface name in the standalone mode. The two-dimensional interface can be the 10 Gigabit interface or Gigabit interface. (The Gigabit interface can be an opto-copper interface. If the media type is not specified, the Gigabit copper interface is adopted by default.) For an opto-copper interface, you must specify its optical or copper interface attribute. A VSL interface for a chassis device must be a 10 Gigabit interface.

You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

In the standalone mode, the VSL configurations cannot take effect immediately unless the device shifts into the VSU mode and restart.

Configuring Error Frame Check

- Run the **switch crc** command to configure error frame check. This command is optional. Run this command to modify the default method for checking error frames.
- If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Command	switch crc errors <i>error_num</i> times <i>time_num</i>
Parameter Description	<i>error_num</i>: Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once. <i>time_num</i>: Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
Defaults	The default value of errors is 3; the default value of times is 10.
Command Mode	Domain configuration mode
Usage Guide	The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. The default action for an abnormal interface is displaying a log prompt. You can set the action to disabling the interface. If the interface is disabled, you must recover it by unplugging and plugging it.

Different products have different requirements for error frame check and different processing for VSL interfaces. In version 11.0, error frame check is configurable.

Changing the Standalone Mode to the VSU Mode

- Use the **switch convert mode virtual** command to change the standalone mode to the VSU Mode.
- In the standalone mode, the software will take the following actions after you run the **switch convert mode virtual** command.

Back up the global configuration file *config.text* in the standalone mode as *standalone.text* for subsequent use.

Clear the contents of the configuration file *config.text*.

Write the relevant VSU configurations to the special configuration file *config_vsu.dat*.

- If there is a *virtual_switch.text* file on the switch, the system will prompt you whether to overwrite the contents of the file *virtual_switch.text* to the file *config.text* (the file *virtual_switch.text* is a backup file for the file *config.text* when the switch shifts from the VSU mode to the standalone mode). Then you can click **Yes** or **No**. Finally the switch restarts in the VSU mode and reads VSU parameters in the file *config_vsu.dat*.

Command	switch convert mode virtual
Parameter Description	N/A
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	Change the standalone mode to the VSU mode.

Verification

Run the **show switch virtual config** [*switch_id*] command to check the VSU configuration of the current switch in the standalone mode.

Command	show switch virtual config [<i>switch_id</i>]
Parameter Description	<i>switch_id</i> : Indicates the switch ID. After this parameter is specified, only the VSU configuration of the specified device is displayed.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the VSU configuration in the standalone or VSU mode.

 The relevant VSU configurations are set for a single physical switch and the configurations are stored in the special configuration file *config_vsu.dat*. Therefore, you can view the current VSU configurations by running the **show switch virtual config** command rather than the **show running config** command.

In the standalone mode, the VSU running information is null. When you enter commands such as **show switch virtual**, the system will prompt you that the switch is in the standalone mode and there is no VSU running information.

Configuration Example

Configuring VSU in the Standalone Mode

Scenario Figure 8-16	 Switch 1 and Switch 2 form a VSU system. The domain ID is 100. The chassis on the left side is configured as Chassis 1, with the priority of 200, alias of Switch 1, and the VSL interfaces of 1/1 and 1/2. The chassis on the right side is configured as Chassis 2, with the priority of 100, alias of Switch 2, and the VSL interfaces of 1/1 and 1/2.

Configuration Steps	5. Perform the following configuration on the Switch 1: ● Configure VSU attributes and VSL interfaces. ● Change the standalone mode to the VSU mode. 6. Perform the following configuration on the Switch 2: ● Configure VSU attributes and VSL interfaces. ● Change the standalone mode to the VSU mode.
Switch-1	<pre> Ruijie# configure terminal Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)#switch 1 Ruijie(config-vs-domain)#switch 1 priority 200 Ruijie(config-vs-domain)#switch 1 description switch-1 Ruijie(config-vs-domain)# switch crc errors 10 times 20 Ruijie(config-vs-domain))#exit Ruijie(config)#vsl-port Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/1 Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/2 Ruijie(config)#exit Ruijie#switch convert mode virtual </pre>
Switch-2	<pre> Ruijie# configure terminal Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch 2 Ruijie(config-vs-domain)# switch 2 priority 200 Ruijie(config-vs-domain)# switch 2 description switch-2 Ruijie(config-vs-domain)# switch crc errors 10 times 20 Ruijie(config-vs-domain))#exit Ruijie(config)#vsl-port Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/1 Ruijie(config-vsl-port)#port-member interface Tengigabitethernet 1/2 Ruijie(config-vsl-port)#exit Ruijie#switch convert mode virtual </pre>
Verification	● Run the show switch virtual config command to view the VSU attributes of Switch 1 and Switch 2.

Switch-1	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 ! switch crc errors 10 times 20 !</pre>
Switch-2	<pre>Ruijie#show switch virtual config switch_id: 2 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 2 switch 2 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 !</pre>

	<pre>switch crc errors 10 times 20 !</pre>

Common Errors

- ✔ A VSL interface of a chassis device must be 10 Gigabit or higher.

8.4.2 Configuring VSU in the VSU Mode

8.4.2.1 Configuring VSU Attributes

Configuration Effect

During the VSU system running, you can modify the parameters, such as domain ID, switch ID, and priority of the master device or the slave device. However, you can only log in to the VSU master device console to modify these parameters, but cannot enter the global configuration mode from the slave device console.

Notes

- Among the commands above, the all configuration commands take effect only after the switch restarts except the **switch sw_id description switch1** command that can take effect immediately.

Configuration Steps

↘ Entering the Domain Configuration Mode

- Optional.
- Run this command in the VSU mode to enter the domain configuration mode. Switches with the same domain ID form a VSU system. You can modify or configure the domain ID, switch priority, and switch ID only after entering the domain configuration mode in the VSU mode.

Command	switch virtual domain <i>domain_id</i>
Parameter Description	<i>domain_id</i> : Indicates the virtual domain ID of the VSU system.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

↘ Changing the Domain ID

- Optional.

- To modify the value of *domain_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> domain <i>new_domain_id</i>
Parameter Description	<i>switch_id</i> : Indicates the ID of the currently running switch in the VSU mode, ranging from 1 to 8. <i>new_domain_id</i> : Indicates the modified domain ID, ranging from 1 to 255.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

↘ Changing the Switch ID

- Optional.
- To modify the value of *switch_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> renumber <i>new_switch_id</i> [force]
Parameter Description	<i>switch_id</i> : Indicates the ID of a switch. In a VSU system, the switch ID ranges from 1 to 16 for box switches. <i>new_switch_id</i> : Indicates the modified switch ID. force : (Optional) Indicates whether the ID of a device needs to be forcibly modified. After this parameter is added, the VSU configuration is saved immediately and the device is restarted.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

↘ Changing the Switch Priority

- Optional.
- To modify the priority of a device, you can configure this item on the master device console of the VSU system.
- A larger value means a higher priority. Select the device with the highest priority as the master device.

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter Description	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured. <i>priority_num</i> : Indicates the switch priority, ranging from 1 to -255 for box switches.
Defaults	The default priority is 100.
Command Mode	Domain configuration mode
Usage Guide	A larger value means a higher priority. Select the device with the highest priority as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you

	restart the device. This command is not used to modify the value of switch_id. In the standalone mode, if switch_id is set to 1, running the switch 2 priority 200 command does not work. You can first set switch_id to 2 and then run the switch 2 priority 200 command. In the VSU mode, switch_id indicates the ID of the currently running switch. If the ID does not exist, the configuration does not take effect.

📌 Configuring the Device Description

- Optional.
- To configure the description for a device, you can configure this item on the master device console of the VSU system.
- Run the **switch switch_id description switch1** command to configure the device description. A maximum of 32 characters are allowed.

Command	switch switch_id description dev-name
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>dev_name</i> : Indicates the device name.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	You can run this command in the standalone or VSU mode. The configuration takes effect immediately in the VSU mode.

📌 Configuring Error Frame Check

- Optional.
- Run the **switch crc errors error_num times time_num** command to configure the conditions for triggering error frame check.

Command	switch crc errors error_num times time_num
Parameter	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once.
Description	<i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
Defaults	The default value of errors is 3 ; the default value of times is 10 .
Command Mode	Domain configuration mode
Default Level	14
Usage Guide	N/A

Verification

Use the **show switch virtual [topology | config]** command to display the current VSU running information, topology or configuration parameters.

Command	show switch virtual [topology config]
Parameter	topology: Indicates topology information.
Description	config: Indicates the VSU configurations.
Command Mode	Privileged EXEC mode
Usage Guide	View the domain ID, and the device ID, status and role of each device.

Configuration Example

Configuring VSU Attributes

Scenario Figure 8-17	 Switch 1 and Switch 2 form a VSU system. Modify the chassis ID of Switch 2 to 3 and its priority to 150. Assume that Switch 1 is the global master switch and perform the configuration on the global master switch.
Configuration Steps	Modify the configurations of Switch 2.
Switch-1	<pre>Ruijie#config Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch 2 renumber 3 Ruijie(config-vs-domain)# switch 2 priority 150 Ruijie(config-vs-domain)# switch 2 description switch-3</pre>
Verification	Run the show switch virtual config command for verification.
Switch-1	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual !</pre>

```
port-member interface Tengigabitethernet 1/1
!  
port-member interface Tengigabitethernet 1/2
!
```

```
switch_id: 3 (mac: 0x1201aeda0E)
!  
switch virtual domain 100
!  
switch 3
switch 3 priority 150
!  
switch convert mode virtual
!  
port-member interface Tengigabitethernet 1/1
!  
port-member interface Tengigabitethernet 1/2
!  
switch 3 description switch-3
!
```

8.4.2.2 Configuring the VSL

Configuration Effect

When switches form a VSU system or when the VSU system is running, you can shift between common interfaces and VSL interfaces. However, you can only log in to the master device console of the VSU system for modification, but cannot enter the global configuration mode from the slave device console.

Notes

- You can log in to the console of the VSU system by using a serial port or telnet, in order to add or delete the configurations of VSL member interfaces.
- To prevent incorrect connections in actual scenarios, the VSL AP uses dynamic negotiation. You need to configure the VSL interface pool first, and then add the VSL interface pool to the same AP after successful negotiation. Interfaces connecting to the same device are within the same AP.

Configuration Steps

📌 Entering the VSL Interface Configuration mode

- Run the **vsl-port** command to enter the VSL-PORT configuration mode. This command is optional.
- When the device enters the VSL-PORT configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

📌 Configuring a VSL Member Interface

- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is optional.
- Run the **port-member interface** command to configure a VSL member interface.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter Description	<i>interface-name</i> : Indicates a two-dimensional interface name, such as GigabitEthernet 0/1 and GigabitEthernet 0/3. copper : Indicates the copper interface attribute. fiber : Indicates the optical interface attribute.
Defaults	N/A
Command Mode	VSL interface configuration mode
Usage Guide	You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

During the VSU system running, the configured VSL member links take effect immediately. VSL interfaces need to be configured for all devices.

For box devices, VSL interfaces can be optical and copper interfaces of Gigabit or higher.

40G one-to-four interfaces cannot be configured as VSL interfaces.

-
- ⚠ For a 40G port (no matter whether splitting is performed for the interface), its member interfaces (namely, four 10G interfaces) cannot be shifted to VSL member interfaces.
 - ❗ If an interface has been configured as an NLB reflex interface, this interface can be shifted to a VSL member interface only after the NLB reflex interface configuration is deleted.
 - ⚠ To prevent a loop that may occur when a VSL member interface exits from the VSL AP, the system automatically sets the member interface to the shutdown state when the command is executed to make the VSL member interface exit from the VSL AP. After the VSL member interface exits from the VSL AP, you can reconnect the link and run the **no shutdown** command to enable this interface again. When you configure a VSL interface, the system will shut it down

first. If the configuration fails and you want to use it as a common interface, you can run the **no shutdown** command to enable this interface again. Add a member interface number that must be a three-dimensional interface number. For example, in the VSL-PORT configuration mode, if you run the **port-member interface** `Tengigabitethernet 1/1/1` command, it indicates that you configure the global three-dimensional interface 1/1/1 as a VSL interface.

! If VSU topology splitting occurs when you change a VSL interface to a common interface, the VSL interface cannot be deleted. You can disconnect the physical interface first and then delete the VSL interface.

Verification

- Use the `show switch virtual link [ port ]` to display the current VSL link running information in the VSU mode.

Command	<code>show switch virtual link [port]</code>
Parameter Description	port : Displays the status information of the VSL member interfaces.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the VSL

Scenario Figure 8-18	
Configuration Steps	● Add interface 1/1/3 as the VSL interface for Switch 1 and delete interface 1/1/2 from the VSL interface.
Switch-1	<pre>Ruijie#config Ruijie(config)# vsl-port Ruijie(config-vsl-port)# port-member interface Tengigabitethernet 1/1/3 Ruijie(config-vsl-port)# no port-member interface Tengigabitethernet 1/1/2</pre>
Verification	● Run the show switch virtual config command to view the VSL. Assume that Switch 1 is the global master switch and run the command on the global master switch.
Switch-1	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) !</pre>

	<pre>switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>
	<pre>switch_id: 3 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 3 switch 3 priority 150 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 ! switch 3 description switch-3 !</pre>

8.4.2.3 Configuring Dual-Active Detection

Configuration Effect

Configure the relevant detection mechanism to prevent the dual-active is being generated.

Notes

- The DAD can be configured only in the VSU mode. You are not allowed to configure the DAD mechanism in the standalone mode.
- All DAD configurations will take effect immediately after being configured on the master or slave devices in global configuration mode by running the **show running-config** command.
- The BFD-detected configuration information can be displayed only by running the dual-active detection display command rather than the BFD display command.

Configuration Steps

📌 Configuring the BFD DAD

- The BFD DAD requires establishing a directly connected link between two switches. The interfaces on the two ends must be physical routing interfaces. The following configuration must be performed on both chassis.
- Enter the interface configuration mode of the DAD interface and configure the DAD interface as a routing interface.
- After exiting from the interface configuration mode, run the **switch virtual domain *domain_id*** command to enter the domain configuration mode.
- In the domain mode, run the **dual-active detection bfd** command to enable BFD. This command is optional and can be used when BFD DAD needs to be configured.
- In the domain configuration mode, run the **dual-active bfd interface *interface-name*** command to configure the BFD DAD interface. This command is optional and can be used to configure the BFD DAD interface when BFD DAD is configured.
- Delete the BFD DAD interface. If no BFD DAD interface is available, BFD detection cannot be used.

Command	switch virtual domain <i>domain_id</i>
Parameter Description	<i>domain_id</i> : Indicates the domain ID.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

Command	dual-active detection { aggregateport bfd }
Parameter Description	aggregateport : Specifies the AP detection mode. bfd : Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode.

Command	dual-active bfd interface <i>interface-name</i>
Parameter	<i>interface-name</i> : Indicates the interface type and ID.
Description	
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	A BFD DAD interface must be a routing interface and on different switches.

The BFD detection interfaces must be directly connected physical routing ports. The two ports must be on different devices.

The interface type is not limited. The dual-active detection link is only used to transmit BFD packets with a small amount of traffic. Therefore, you are advised to adopt the Gigabit interface or 100 M interface as the dual-active detection interface.

After the layer 3 routing interface that is configured with two master devices is converted into a layer 2 switch interface (run the switchport command under this interface), the BFD dual-active detection will be cleared automatically.

You are advised to directly connect BFD detection interfaces only to the master and slave devices.

-
-  When the VSU system detects dual-active conflict and brings another VSU group to the recovery state, you can resolve the problem only by rectifying the VSL fault, but not directly restoring the VSU group in the recovery state; otherwise, dual-active conflict may be caused on the network.
-

Configuring the AP-based DAD

- To configure the AP-based DAD, you must configure an aggregate port (AP) first and then specify the AP port as the DAD interface.
- Run the **port-group** *ap-num* command to add a physical member interface to the AP.
- After entering the domain configuration mode, run the **dual-active detection aggregateport** command to enable AP detection mode. This command is optional. You can run this command when AP detection needs to be configured.
- Run the **dual-active interface** *interface-name* [**vlan** *vlan-id*] command to configure the AP as the DAD interface. This command is optional. You can run this command to configure the AP as the DAD interface when AP detection needs to be configured. When the AP is a trunk port and the native VLAN is beyond the allowable VLAN range of the AP-based DAD interface, a detection VLAN needs to be configured for the AP-based DAD interface. The configured VLAN must be within the allowable VLAN range of the trunk port, and has been correctly created on the device.
- Run the **dad relay enable** command to enable dual-active detection packet relay for upstream and downstream interfaces. This command is optional. You can run this command to relay DAD packets (dual-active detection packets) when AP-based DAD is configured.
- Disabling AP-based DAD will inactivate DAD.
- Delete the detected interface. If no AP-based DAD interface is available, AP-based DAD cannot be used.
- If the AP is a trunk port and VLAN limits have been configured for it, **vlan** *vlan-id* (applicable to the configured limited VLANs) must be configured and the permitted VLANs must be configured on the device. Otherwise, the AP-based DAD function is unavailable.
- The AP-based DAD packet relay is disabled by default.

Command	dual-active detection { aggregateport bfd }
Parameter	aggregateport : Specifies the AP detection mode.
Description	bfd : Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode.

Command	dual-active interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates the interface type and interface ID. An AP-based DAD interface must be specified.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Only one AP-based DAD interface can be configured. This interface must be created before you configure an AP as a DAD interface. Subsequently configured DAD interfaces will overwrite the previous ones.

Command	dad relay enable
Parameter Description	N/A
Defaults	The AP-based DAD packet relay is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command can only be executed on the AP.

You are advised to distribute the physical interfaces that are added to the AP-based detection interface to different devices.

If the AP is a trunk port and VLAN limits have been configured, **vlan** *vlan-id* (applicable to configured limited VLANs) must be configured and the permitted VLANs must be configured on the device.

The excluded interface must be routing rather than VSL.

After the excluded interface is converted from a routing one into a switch interface (run the **switchport** command under this interface), the configurations of the excluded interface that is associated with this interface will be cleared automatically.

Verification

Use the **show switch virtual dual-active { aggregateport | bfd | summary }** to display the current DAD configuration.

Command	show switch virtual dual-active { aggregateport bfd summary }
Parameter	aggregateport : Displays DAD information on the AP.

Description	bfd: Displays BFD-based DAD information. summary: Displays DAD summary.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the BFD DAD

Scenario Figure 8-19

- Switch 1 and Switch 2 form a VSU (The domain ID is 1) system. The priorities of Switch 1 and Switch 2 are 200 and 150 respectively. The links between Te1/3/1 and Te1/3/2 of Switch 1 and Te2/3/1 and Te2/3/2 of Switch 2 are established respectively to form a VSL between Switch 1 and Switch 2. The G0/1, G0/2, G0/3 and G0/4 interfaces of Switch A are connected to G1/1/1 and G1/2/1 of Switch 1 and G2/1/1 and G2/2/1 of Switch 2 to form an AP group including four member links. The ID of the AP group is 1. All members of AP group 1 are Gigabit optical interfaces. G1/1/2 and G2/1/2 are routing interfaces.
- G1/1/2 and G2/1/2 are a pair of BFD DAD interfaces.

Configuration Steps

- Configure G1/1/2 and G2/1/2 as routing interfaces.
- Enable the BFD DAD.
- Configure G1/1/2 and G2/1/2 as BFD DAD interfaces.

Since Switch 1 and Switch 2 are in a VSU system, the preceding configuration can be performed on either Switch 1 or Switch 2. on the following example configures the functions on Switch 1.

Switch 1

```
Ruijie(config)# interface GigabitEthernet 1/1/2
Ruijie(config-if-GigabitEthernet 1/1/2)# no switchport
Ruijie(config)# interface GigabitEthernet 2/1/2
Ruijie(config-if-GigabitEthernet 2/1/2)# no switchport
Ruijie(config-if)# switch virtual domain 1
```

	<pre> Ruijie(c config-vs-domain)# dual-active detection bfd Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 1/1/2 Ruijie(config-vs-domain)# dual-active bfd interface GigabitEthernet 2/1/2 </pre>
Switch A	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# interface aggregateport 1 Ruijie(config-if-aggregateport 1)# interface range GigabitEthernet 0/1-4 Ruijie(config-if-aggregateport 1)# port-group 1 Ruijie(config)# interface vlan 1 Ruijie(config-if-vlan 1)#ip address 1.1.1.2 255.255.255.0 Ruijie(config-if-vlan 1)#exit Ruijie(config)#interface aggregateport 1 Ruijie(config-if-AggregatePort 1)# dad relay enable Ruijie(config-if-AggregatePort 1)# exit </pre>
Verification	● View the DAD configuration. ● View the BFD DAD configuration.
Switch 1	<pre> Ruijie# show switch virtual dual-active summary BFD dual-active detection enabled: No Aggregateport dual-active detection enabled: Yes Interfaces excluded from shutdown in recovery mode: In dual-active recovery mode: NO Ruijie# show switch virtual dual-active bfd BFD dual-active detection enabled: Yes BFD dual-active interface configured: GigabitEthernet 1/1/2: UP GigabitEthernet 2/1/2: UP </pre>

Common Errors

- A BFD DAD interface is not a routing interface.
- Neither BFD DAD nor AP-based DAD are enabled and activated.

8.4.2.4 Configuring Traffic Balancing

Configuration Effect

In the VSU system, if egresses are distributed on multiple devices, the Local Forward First (LFF) can be configured.

Notes

The default configuration is LFF.

Configuration Steps

📌 Configuring the AP LFF mode

- In the domain configuration mode, run the **switch virtual aggregateport-lff enable** command to enable the AP LFF mode. This command is optional.
- The member ports of AP can be distributed on two chassis of the VSU system. You can configure whether the AP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the AP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual aggregateport-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode
Usage Guide	Enable the AP LFF in the VSU mode.

📌 Configuring the ECMP LFF mode

- In the domain configuration mode, run the **switch virtual ecmp-lff enable** command to enable the ECMP LFF mode. This command is optional.
- The Equal-Cost MultiPath (ECMP) routing egress can be distributed on two chassis of the VSU system. You can configure whether the ECMP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the ECMP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual ecmp-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode

Usage Guide	Enable the ECMP LFF in the VSU mode.

-  In the VSU mode, the across-chassis AP LFF mode and the ECMP LFF mode are disabled by default.
-  To deploy a VSU system for layer-3 switches, you are advised to configure the IP-based AP load balancing (src-ip, dst-ip abd src-dst-ip).

Verification

Use the **show switch virtual balance** command to display the current traffic balancing mode of the VSU system.

Command	show switch virtual balance
Parameter	N/A
Description	
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the configuration of the traffic balancing mode in the VSU mode.

Configuration Example

Configuring the LFF

Scenario Figure 8-20	
	In Figure, Switch 1 and Switch 2 form a VSU system. It is assumed that Switch 1 is the global master switch and configuration is performed on Switch 1.
Configuration Steps	Configure the AP LFF.
Switch-1	<pre>Ruijie#config Ruijie(config)# switch virtual domain 100 Ruijie(config-vs-domain)# switch virtual aggregateport-lff enable</pre>
Verification	Run the show switch virtual balance command for verification.
Switch-1	<pre>Ruijie#show switch virtual balance Aggregate port LFF: enable Ecmp lff enable</pre>

8.4.2.5 Changing the VSU Mode to the Standalone Mode

Configuration Effect

Dismiss the VSU system into individual devices that can operate in the standalone mode.

Configuration Steps

- Run the **switch convert mode standalone** [*switch_id*] command to change the VSU mode to the standalone mode. This command is optional.
- After you run this command, the system will prompt you as follows: Whether to restore the configuration file to standalone text? If **yes**, the configuration file will be restored; if **no**, the configuration of virtual device mode will be cleared.

Command	switch convert mode standalone [<i>switch_id</i>]
Parameter Description	<i>switch_id</i> : Indicates the switch ID.
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	After you run the switch convert mode standalone command, the master switch backs up the global configuration files of all VSDs in the VSU mode as <i>vsd.virtual_switch.text.vsd</i> ID. Then, the master switch clears the global configuration files <i>config.text</i> of all VSDs in the VSU mode, and asks you whether to overwrite the global configuration files <i>config.text</i> with <i>vsd.standalone.text.vsd</i> ID. If you select yes, the content of <i>vsd.standalone.text.vsd</i> ID will overwrite the global configuration file <i>config.text</i> of all VSDs; otherwise, the master switch does not recover <i>config.text</i>. Finally, restart the switch. This command can be used in the standalone mode or VSU mode. If the command is executed in the standalone mode, the mode switching is performed on the current switch. If the command contains the <i>sw_id</i> parameter and is executed in the VSU mode, the mode switching is performed on the switch with the ID specified by <i>sw_id</i>. If the command does not contain the <i>sw_id</i> parameter, the mode switching is performed on the master switch. You are advised to switch the mode of the slave switch and then that of the master switch.

Configuration Example

Changing the VSU Mode to the Standalone Mode

Scenario Figure 8-21	 In Figure 8-21, it is assumed that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master switch.
Configuration Steps	● Change the mode of Switch 1 to the standalone mode. ● Change the mode of Switch 2 to the standalone mode.

Switch-1	<pre>Ruijie# switch convert mode standalone 1 Ruijie# switch convert mode standalone 2</pre>
Verification	Run the show switch virtual config command to display the switch status.
Switch-1	<pre>Ruijie#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode standalone ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>
	<pre>switch_id: 2 (mac: 0x1201aeda0E) ! switch virtual domain 100 ! switch 2 switch 2 priority 150 ! switch convert mode standalone ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/2 !</pre>

```
switch 2 description switch-2
!
```

8.4.3 Configuring Quick Blinking Location

Configuration Effect

- Enable quick blinking location of a switch to make the status LED of the switch quickly blink.

Notes

If you do not disable quick blinking location, the system automatically disables the function 30 minutes after it is enabled.

Configuration Steps

✚ Enabling/Disabling quick blinking location

- Mandatory. Use this function on a switch that needs to be located.
- In the privileged EXEC mode, run the **led-blink** command to enable quick blinking location.

Command	led-blink { enable disable } [device <i>device_id</i>]
Parameter	enable: Enables quick blinking location.
Description	disable: Disables quick blinking location. <i>device_id</i> : Indicates the device ID.
Defaults	Quick blinking location is disabled by default.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command without the <i>device_id</i> parameter to enable or disable the quick blinking search in the standalone mode. In the VSU mode, you can set the <i>device_id</i> parameter to enable or disable this function for a specified device. If you ignore the device_id parameter, you can enable or disable this function for all devices in the VSU system. If you do not disable this function, the system automatically disables the function 30 minutes after it is enabled. This configuration cannot be saved. Quick blinking location will be disabled upon restart or failover.

Verification

- Check whether the status LED of a switch quickly blinks.

Configuration Example

✚ Enabling quick blinking location for the two VSU devices

Scenario	Assume that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master device.

Configuration Steps	- Enter the led-blink enable device 2 command on the Switch 1 console to enable quick blinking location. - Enter the led-blink enable device 2 command on the Switch 1 console to disable quick blinking location.
Verification	When quick blinking location is enabled, check whether the status LED of Switch 2 quickly blinks.

8.4.4 Configuring the MGMT Interface

Configuration Effect

- Configure a device to create one MGMT interface for each chassis or create only one MGMT interface for the system in VSU mode.

Notes

After this command is configured, run the **write** command to save the configuration. The configuration takes effect only in VSU mode and only after the device is restarted.

Configuration Steps

📌 Configuring a Device to Create Only One MGMT Interface for the System in VSU Mode

- Optional. Configure this function only when a device needs to create only one MGMT interface for the system. One MGMT interface is created for each chassis by default.
- In global configuration mode, run the **mgmt_mode** command to configure the MGMT interface.

Command	mgmt_mode unique
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	In VSU mode, set the system to create only one MGMT interface. The configuration needs to be saved, and takes effect only after the device is restarted.

📌 Configuring a Device to Create One MGMT Interface for Each Chassis

- Optional. After a device has been configured to create only one MGMT interface, use this command to restore default configuration, that is, to create one MGMT interface for each chassis.

Command	no mgmt_mode
Parameter Description	N/A
Defaults	N/A
Command	Global configuration mode

Mode	
Usage Guide	In VSU mode, set the system to create one MGMT interface for each chassis. The configuration needs to be saved, and takes effect only after the device is restarted.

Verification

After configuration, run the **write** command to save the configuration. After running the **reload** command to restart the device, run the **show interface** command to display the number of MGMT interfaces.

Configuration Example

Configuring a Device to Create Only One MGMT Interface for the System in VSU Mode

Scenario Figure 8-1	 Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device.
Configuration Steps	Run the command to configure a device to create only one MGMT interface for the system, run the write command to save the configuration, and run the reload command to restart the device for the configuration to take effect.
	<pre>Ruijie(config)#mgmt_mode unique Please write and reload system to take config effect! Ruijie(config)#exit Ruijie#write Building configuration... [OK] Ruijie#reload Reload system?(Y/N)y</pre>
Verification	After the device is restarted, run the show interfaces inc mgmt command. The system creates only one MGMT interface even if there are multiple chassis in the VSU mode. <pre>Ruijie#show interfaces inc Mgmt ===== Mgmt 0 ===== Mgmt 0 is UP , line protocol is UP Hardware is Mgmt, address is 1414.3344.5519 (bia 1414.3344.5519)</pre>

8.4.5 Configuring the Device Recovery in Recovery Mode

Configuration Effect

Disable the automatic restart and recovery function in recovery mode.

Notes

If the automatic restart and recovery function is disabled, the function needs to be enabled again or the devices need to be manually restart for devices in recovery mode.

Configuration Steps

📌 Enabling/Disabling the Automatic Restart Function in Recovery Mode

- Mandatory. Enable or disable the function on a device as required.
- In config-vs-domain configuration mode, run the **[no] recovery auto-restart enable** command to enable or disable automatic restart function.

Command	recovery auto-restart enable
Parameter	N/A
Description	
Defaults	The automatic restart and recovery function in recovery mode is enabled by default.
Command Mode	config-vs-domain configuration mode
Usage Guide	This command can be executed only in VSU mode. After the command is configured, the configuration needs to be saved for the configuration to take effect immediately.

Verification

Run the **show run** command to display the configurations.

Configuration Example

📌 Disabling Automatic Restart and Recovery in Recovery Mode in VSU Mode

Scenario	Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device. The dual-active detection function is enabled.
Configuration Steps	● Run the switch virtual domain 100 command on Switch-1 to enter the config-vs-domain configuration mode. ● Run the no recovery auto-restart enable command on Switch-1 to disable the automatic restart and recovery function.

Verification	Disconnect the VSL link. After dual-active detection is completed, Switch-2 enters the recovery mode. Re-connect the VSL link. Switch-2 does not restart. Run the recovery auto-restart enable command on Switch-2 to enable the automatic restart and recovery function. Switch-2 automatically resets.

8.4.6 Configuring Automatic Recovery Without Restart in Recovery Mode

Configuration Effect

Enable the automatic recovery without restart function in recovery mode.

Configuration Steps

📌 Enabling/Disabling the Automatic Recovery Without Restart Function in Recovery Mode

- Mandatory. Enable or disable the function on a device as required.
- In config-vs-domain configuration mode, run the **[no] dual-active auto-recovery enable** command to enable or disable the automatic recovery without restart function.

Command	dual-active auto-recovery enable
Parameter Description	N/A
Defaults	The automatic recovery without restart function in recovery mode is disabled by default.
Command Mode	config-vs-domain configuration mode
Usage Guide	This command can be executed only in VSU mode. After the command is configured, the configuration needs to be saved for immediate validation.

Verification

Run the **show run** command to display the configurations.

Configuration Example

📌 Enabling Automatic Recovery Without Restart in Recovery Mode in VSU Mode

Scenario Figure 8-2	 Switch-1 and Switch-2 form a VSU, and Switch-1 is the global active device. The DAD function is enabled.

Configuration Steps	● Run the switch virtual domain 100 command on Switch-1 to enter the config-vs-domain configuration mode. ● Ru the dual-active auto-recovery enable command on Switch-1 to enable the automatic recovery without restart function in recovery mode.
Verification	Disconnect all VSL links. After DAD is completed, Switch-2 enters the recovery mode. Power off Switch-1. Verify that Switch-2 automatically becomes the master device without restart.

8.5 Monitoring and Maintenance

Displaying

Description	Command
Displays the current VSU operation, topology or configuration.	show switch virtual [topology config role]
Displays the current dual-active configuration.	show switch virtual dual-active { bfd aggregateport summary }
Displays the current VSL running information in the VSU mode.	show switch virtual link [port]
Redirects to the console of the master switch or any switch.	session { device <i>switch_id</i> master }
Displays the current switch ID.	show switch id

9 Configuring RNS

9.1 Overview

The reliable network service (RNS) tests specific services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. Using the RNS test results, you can:

- Learn the network performance in time and take measures accordingly to handle related network performance problems.
- Diagnose and locate network faults.

9.2 Applications

9.2.1 Testing and Evaluating Service Performance

Scenario

As shown in the following figure, a company is going to deploy a video conference system between the headquarters and branches, and has completed the related quality of service (QoS) configurations. Before formal deployment, it must be checked whether the services can be provisioned normally under the existing service pressure of the company. The video conference system is sensitive to the User Datagram Protocol (UDP) delay and UDP transmission jitter of the network. The traditional ping tool can test the Internet Control Message Protocol (ICMP) performance, but cannot effectively evaluate the UDP transmission performance and cannot meet the requirement for jitter measurement.

Remarks	A, B, and C are switches.

Deployment

- Configure RNS on the egress switching device or switch of each branch to test the UDP jitter and delay.

- On Switch A, specify the IP address and UDP port of the egress switching device or switch in the headquarters, and then UDP packets can be automatically sent. Based on the configurations, the egress switching device or switch in the headquarters can automatically respond to the UDP packets. The egress switching device or switch of the branch processes the sent and received packets, and calculates the UDP jitter. To learn the performance in different periods of time, you also need to configure scheduling functions, such as periodically start/stop and repeated running, for the RNS.

9.2.2 Locating Network Faults

Scenario

On the campus network as shown in Figure 9-1, Student 1 reports a Web server access failure, Student 3 reports an Internet access failure, and Student 6 reports an email sending/receiving failure.

Figure 9-1

Deployment

- The administrator directly enables the DNS function on the access switch of the dormitories to test whether the domain name service (DNS) server is faulty. If DNS fails, an ICMP echo packet is automatically triggered to test whether the Web server is reachable.
- When a fault occurs, the administrator only needs to start a test, and the subsequent tests can be automatically triggered. Then, the administrator can check the test results to locate the fault, which greatly reduces the workload for the administrator.

9.3 Features

Basic Concepts

📌 RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure the RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

Feature	Description
RNS Instance	Use an RNS instance to conduct a functional test.
Track Support for the RNS	Track the test results and notify the related module of the results.

9.3.1 RNS Instance

Use an RNS instance to conduct a functional test, for example, testing whether the DNS function of the device is normal. Currently, the RNS supports the following types of tests: ICMP echo and DNS.

Working Principle

📌 ICMP Echo Test

ICMP echo is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

The RNS client sends an ICMP echo request to the destination IP address based on the preset test time and frequency. On receiving the ICMP echo request, the destination address responds with an ICMP echo reply. Based on the information related to the received ICMP echo reply, for example, the packet receiving time and number of packets, the RNS client calculates the response time and packet loss rate of the destination IP address to reflect the current network performance and network status. The ICMP echo test results and historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

⚠ The precondition of a successful ICMP echo test is that the destination device can correctly respond to the ICMP echo request.

📌 DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

📌 Procedure for Configuring an RNS Instance Test

1. Create a test group, and configure the test parameters based on the test type.
2. Start an RNS test.
3. Use the RNS client to construct a packet of the specified test type, and send the packet to the peer end.
4. On receiving the test packet, the peer end returns a reply packet containing the timestamp.
5. The RNS client calculates the packet loss rate and round-trip time based on availability of the received reply packet and the timestamp in the reply packet.
6. Use the show or debug command to check the test result.

 The preceding configuration procedure is a general test procedure of an RNS instance. For details about the specific configuration procedures for the three types of tests, see the configuration descriptions provided later.

Related Configuration

📄 Configuring the Test Repeat Interval

By default, the test repeat interval is 60s.

Run the **frequency** *millisecond* command to configure the repeat interval of an instance.

Perform this configuration in IP RNS configuration mode to perform the test periodically. You can run the **frequency** command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test:

$$(\text{frequency milliseconds}) > (\text{timeout milliseconds}) \geq (\text{threshold milliseconds})$$

📄 Configuring the Test Timeout

The default timeout varies according to the test type. You can run the **show ip rns configuration** command to display the timeout of a specific test type.

Run the **timeout** *milliseconds* command to configure the timeout of an instance.

Perform this configuration in IP RNS configuration mode. The value of **timeout** must be equal to or greater than the value of **threshold**. For the relationship between **timeout**, **frequency**, and **threshold**, see "Usage Guide" of the **frequency** command.

📄 Configuring the Test Threshold

By default, the test threshold is 5,000 ms.

Run the **threshold** *milliseconds* command to configure the threshold of an instance.

Perform this configuration in IP RNS configuration mode. The value of **threshold** must be equal to or smaller than the value of **timeout**. For the relationship between **timeout**, **frequency**, and **threshold**, see "Usage Guide" of the **frequency** command.

📄 Configuring a Tag for the Test

No default configuration is available.

Run the **tag text** command to configure a test tag.

Perform this configuration in IP RNS configuration mode. The **tag** command can specify a tag for a test, which is generally used to identify the function of this test.

📌 Configuring the Protocol Payload Size

The default protocol payload size varies according to the test type. By default, the protocol payload size of a test type is the minimum or appropriate size for the test.

Run the **request-data-sizebytes** command to configure the protocol payload size.

Perform this configuration in IP RNS configuration mode.

📌 Configuring the TOS of the Test Packet

By default, the TOS is 0.

Run the **tos number** command to configure the TOS field in the IPv4 packet used for the IP RNS test.

Perform this configuration in IP RNS configuration mode.

📌 Configuring the VRF

No default configuration is available.

Run the **vrf vrf-name** command to configure the virtual routing and forwarding (VRF) of the IP RNS test.

Perform this configuration in IP RNS configuration mode.

9.3.2 Track Support for the RNS

Objects that can be tracked include: test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of the related module (such as DNS) is triggered.

Working Principle

The test result of an RNS instance is tracked as follows:

- Configure a track object for tracking the test result of an RNS instance.
- When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.
- On receiving this message, the track module locates the track object based on the RNS instance ID. After the preset delay time elapses, if the status of the RNS instance still changes, the status of the track module is modified, and the module of the track object is notified of the modification. If the status of the RNS instance recovers within the preset delay time, the track status is not modified and the related module is not notified.

Related Configuration

📌 Configuring a Track Object for Tracking the Link Status of An Interface

By default, the function of tracking the link status of an interface is disabled.

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

If the link status of the interface is UP, the status of the track object is UP. If the link status of the interface is DOWN, the status of the track object is also DOWN.

📌 Configuring a Track Object for Tracking the Test Result of an RNS Instance

By default, the function of tracking the test result of an RNS instance is disabled.

Run the **track rns** command to configure a track object, which is used to track the test result of an RNS instance. The RNS instance ID ranges from 1 to 500.

If the test result of the RNS instance is successful, the status of the track object is UP. If the test result of the RNS instance is unsuccessful, the status of the track object is also DOWN.

📌 Configuring a Track Object for Tracking the Test Result of an RNS List

By default, the function of tracking the test result of an RNS list is disabled.

Run the **track rns-list** command to configure a track object, which is used to track the test result of an RNS list. The RNS instance ID ranges from 1 to 500.

The result can be the AND or OR operation result of all member status. If the result of this track object is set to the OR operation result of all member status, and the OR result of the status of all the tracked RNS objects is UP, the status of this track object is UP. If the OR result of the status of all the tracked RNS objects is DOWN, the status of this track object is also DOWN. If the result of this track object is set to the AND operation result of all member status, and the AND result of the status of all the tracked RNS objects is UP, the status of this track object is UP. If the AND result of the status of all the tracked RNS objects is DOWN, the status of this track object is also DOWN.

📌 Configuring a Track Object for Tracking the Status of a Track List

By default, the function of tracking the status of a track list is disabled.

Run the **track list** command to configure a track object, which is used to track the status of a track list. The result can be the AND or OR operation result of all member status.

If the result of this track object is set to the OR operation result of all member status, and the OR result of the status of all members is UP, the status of this track object is UP. If the OR result of the status of all members is DOWN, the status of this track object is also DOWN. If the result of this track object is set to the AND operation result of all member status, and the AND result of the status of all members is UP, the status of the track object is UP. If the AND result of the status of all members is DOWN, the status of this track object is also DOWN.

📌 Configuring a Track List Member

By default, no member is configured for the track list.

Run the **object** command to configure a track list member. The status of a track list member meeting conditions can be set to UP or DOWN.

Assume that the status of a member meeting conditions is set to UP. If the status of a track list member is UP, the member meets conditions. If the status of a track list member is DOWN, the member does not meet conditions.

Adjusting the Delay for Notifying the Status Change of a Track Object

By default, the delay for notifying the status change of a track object is 0.

Run the **delay** command to adjust the delay for track notification, including the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. The delay ranges from 0 to 180. The unit is second.

A longer delay indicates that it takes more time before the module that is concerned with the track object is notified of the status. A shorter delay indicates that it takes less time before the module that is concerned with the track object is notified of the status.

9.4 Configuration

Configuration Item	Description and Command	
Configuring RNS Basic Functions	 (Mandatory) It is used to configure basic function parameters of the RNS.	
	ip rns	Supports detailed configuration and brief configuration. - Detailed configuration: An IP RNS operation object is defined, and used as the configuration ID for subsequent tests and parameters. - Brief configuration: Subsequent configuration of the test type is not required. Currently, one-step startup of the ICMP, DNS, and TCP connect tests is supported.
	ip rns reaction-configuration	Configures the proactive threshold monitoring and triggering mechanism of the IP RNS test.
	ip rns reaction-trigger	Triggers another type of the IP RNS test in pending state when the monitoring threshold exceeds the expectation during an IP RNS test.
	ip rns schedule	Configures the scheduling method, start time, and life time of an IP RNS test.
	ip rns restart	Restarts an IP RNS test.
	ip rns reset	Clears all the IP RNS configurations.
Configuring the ICMP Echo Test	 (Optional) It is used to implement the ICMP echo test.	
	icmp-echo	Creates an RNS test, the type of which is ICMP echo.
	request-data-size	Configures the protocol payload size.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.

Configuration Item	Description and Command	
	threshold	Configures the test threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the header of the IPv4 test packet.
	vrf	Configure the VRF of a test.
Configuring the DNS Test	 (Optional) It is used to implement the DNS test.	
	dns	Creates an RNS test, the type of which is DNS.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the header of the IPv4 test packet.
	vrf	Configure the VRF of a test.
Configuring the Track Support for the RNS	 (Optional) It is used to configure the track support for other test modules.	
	track rns	Configures a track object for tracking the test result of an RNS instance.
	track interface line-protocol	Configures a track object for tracking the link status of an interface.
	track list	Configures a track object for tracking the status of a track list.
	object	Configures a member object for a track list object.
	delay	Configures the delay for notifying the status change of a track object.

9.4.1 Configuring RNS Basic Functions

Configuration Effect

- Detailed configuration: Configures an RNS instance to complete basic configuration of the RNS test.
- Brief configuration: Configure and start an RNS instance at a time. (Optional)

Notes

- In the case of detailed configuration, if you do not further configure the test type after entering ip-ms mode, the RNS object cannot be created.
- In the case of detailed configuration, you must run the command to configure the startup policy after an IP RNS test is configured; otherwise, the test is not conducted.

Configuration Steps

➤ Defining an IP RNS Operation Object

- Mandatory.
- Perform this configuration on every switching device unless otherwise required.
- Brief configuration is optional.

➤ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

- Perform this configuration if it is required to configure the proactive threshold monitoring and triggering mechanism for the test.
- Perform this configuration on every switching device unless otherwise required.

➤ Enabling an RNS Test to Trigger Another RNS Test

- Perform this configuration if it is required to trigger another type of the IP RNS test in pending state when the monitoring threshold exceeds the expectation during an IP RNS test.
- Perform this configuration on every switching device unless otherwise required.

➤ Configuring the Schedule Parameters of an RNS Test

- Configure the scheduling method, start time, and life time if it is required to trigger an IP RNS test.
- Perform this configuration on every switching device unless otherwise required.
- In the case of brief configuration, this command is already configured using the default values, and manual configuration is not required.

➤ Restarting an IP RNS Test

- Perform this configuration, or directly run the **ip rns schedule X start-time now** command if it is required to restart an IP RNS instance in pending state.

➤ Clearing Configurations of All the IP RNS Instances

- Perform this configuration if it is required to clear configurations of all the IP RNS instances, for example, when a lot of instances are configured but configurations are found incorrect.

➤ Starting the IP RNS Server to Provide Server Functions

- Perform this configuration on every switching device unless otherwise required.

Verification ---

- Run the **show ip rns configuration** command to display configurations of RNS instances.

Related Commands ---

➤ Defining an IP RNS Operation Object

Command	ip rns operation-number
Parameter Description	<i>operation-number</i> : Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Currently, the IP RNS supports only IPv4-related tests, but not IPv6-related tests. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporarily disabled to ensure normal operation of core services, such as route forwarding. Detailed configuration (mandatory items of ip rns operation-number): Run this command and enter ip-rns mode. In ip-rns mode, you can define various test types. If the test type is not configured, the RNS object is not created. After configuring an IP RNS test, you must run the ip rns schedule command to configure its scheduling parameter; otherwise, the test cannot be conducted. After configuring an IP RNS test, you can run the ip rns command to directly enter the mode of the related test type. To modify a type of the IP RNS test object that is currently conducted, you must first delete this IP RNS test by running the no ip rns command in global configuration mode.

📌 Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

Command	ip rns reaction-configuration operation-number react monitored-element[action-type option][threshold-type {average [number-of-measurements] consecutive [occurrences] immediate never xofy[x-value y-value] }] [threshold-value upper-threshold lower-threshold]
Parameter Description	<i>operation-number</i>: Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500. <i>monitored-element</i>: Specifies the monitored element. action-type option: Indicates the action taken after the test is triggered. average [number-of-measurements]: Indicates that the subsequent associated actions are triggered if the average of <i>number-of-measurements</i> of the monitored element exceeds the threshold. consecutive [occurrences]: Indicates that the test is triggered if the consecutive number of <i>occurrences</i> of the monitored element exceeds the threshold. The default value of <i>occurrences</i> is 5. The value ranges from 1 to 16. immediate: Indicates that the test is triggered immediately after the monitored element exceeds the threshold. never: Indicates that the test is never triggered. xofy [x-value y-value]: Indicates that results of X tests exceed the threshold in the last Y tests. The default values of X and Y are 5. The value of X or Y ranges from 1 to 16. threshold-value upper-threshold lower-threshold: Indicate the upper and lower thresholds. - When <i>monitored-element</i> is rtt, the thresholds are the time. For default values, see "Usage Guide". The value ranges from 0 to 60,000 ms. - Note that you do not need to configure threshold-value when react is set to timeout.
Command	Global configuration mode

Mode

Usage Guide

For the same IP RNS object, you can configure multiple thresholds to monitor different elements. The following table provides the mapping between test types and monitored elements.

monitored-element	icmp-echo	dns
timeout	✓	✓
rtt	✓	✓

The following table lists the default thresholds of each monitored element.

Monitored Element	Upper Threshold	Lower Threshold
timeout	-	-
rtt	5000ms	0ms

📌 Enabling an RNS Test to Trigger Another RNS Test

Command	ip rns reaction-trigger <i>operation-number target-operation</i>
Parameter Description	<i>operation-number</i>: Indicates the number of the source operation that triggers the action. The value ranges from 1 to 500. <i>target-operation</i>: Indicates the number of the target operation that is triggered. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	The trigger function is generally used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

📌 Configuring the Schedule Parameters of an RNS Test

Command	ip rns schedule <i>operation-number</i> [life { forever seconds}] [start-time { <i>hh:mm[:ss]</i> [<i>month</i> <i>day</i> <i>daymonth</i>] }] [pending now after <i>hh:mm:ss</i>] [recurring]
Parameter Description	<i>operation-number</i>: Indicates the number of the RNS operation. The value ranges from 1 to 500. lifeforever: Indicates that the RNS operation life time is valid forever. lifeseconds: Indicates the life time of the RNS in second. <i>hh:mm[:ss]</i>: Accurately indicates the start time of the operation. The 24-hour format is used. <i>month</i>: Indicates the start month of the operation. The default value is the current month. <i>day</i>: Indicates the start date of the operation. The default value is the current date. pending: Indicates that the operation start time is not defined yet. This is the default value. now: Indicates that the operation start time is now, that is, the operation starts now. after<i>hh:mm:ss</i>: Indicates that the operation starts after a delay of <i>hh:mm:ss</i>.

	recurring: Indicates whether the operation automatically starts every day at the same time.
Command Mode	Global configuration mode
Usage Guide	If the scheduling parameter of an IP RNS test is already configured by running the ip rns schedule command, its test parameters cannot be modified. To modify the configuration, you must run the no ip rns schedule command to delete the scheduling policy configuration. life{seconds} indicates the lifecycle of the IP RNS test, that is, after the test is started according to the configured start time, the test stops after a period of time specified by <i>seconds</i>.

↘ Restarting an IP RNS Test

Command	ip rns restart <i>operation-number</i>
Parameter Description	<i>operation-number</i> : Indicates the ID of the IP RNS operation object. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	This command restarts an IP RNS test for which the scheduling policy is configured and is in pending state. This command is invalid for an IP RNS test for which the scheduling policy is not configured.

↘ Clearing Configurations of All the IP RNS Instances

Command	ip rns reset
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command clears configurations of all the IP RNS instances. It is used only in extreme cases, for example, when a lot of RNS tests are configured but the configurations are found incorrect.

Configuration Example

↘ Configuring RNS Basic Functions

Scenario Figure 9-2	 <pre> graph LR A((Switch A)) --- 10.1.1.1/16 ISP((ISP)) ISP --- 10.2.2.2/16 B((Switch B)) subgraph Client [RNS Client] A end subgraph Server [RNS Server] B end </pre>
Configuration Steps	● Configure instance 1 on Switch A. ● Configure the scheduling method, start time, and life time of instance 1.

	● Configure the proactive threshold monitoring and triggering mechanism of instance 1. ● Trigger instance 2 in pending state when the monitoring threshold of instance 1 exceeds the expectation.
Switch A	<pre> A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.1.1.1 A(config-ip-rns-icmp-echo)#exit A(config)ip rns schedule 1 start-time now life forever A(config)ip rns reaction-configuration 1 react timeout threshold-type immediate action-type trigger A(config)ip rns reaction-trigger 1 2 </pre>
Verification	Run the show ip rns configuration command to display the instance configurations. <pre> Router#show ip rns configuration 1 Entry number: 1 Tag: ruijie555 Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): 3500 Next Scheduled Start Time:Start Time already passed Target address/Source address: 2.2.2.3/0.0.0.0 Request size (ARR data portion): 36 </pre>

9.4.2 Configuring the ICMP Echo Test

Configuration Effect

Create an IP RNS test of the ICMP echo type.

Notes

- The RNS basic functions must be configured.

Configuration Steps

↘ Creating an IP RNS Test of the ICMP Echo Type

- Mandatory.
- Perform this configuration on every switching device unless otherwise required.

↘ Configuring Common Optional Parameters of the Test

- Perform this configuration if it is required to change common optional parameters of the test, such as the repeat interval, tag, time threshold, timeout, and TOS.
- Perform this configuration on every switching device unless otherwise required.

↘ Configuring the Protocol Payload Size

- Perform this configuration if it is required to change the protocol payload size of the test.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

↘ Creating an IP RNS Test of the ICMP Echo Type

Command	<code>icmp-echo { oob { destination-ip-address destination-hostname [name-server ip-address] } [source-ipaddr ip-address] via type num next-hop ip-address } { { destination-ip-address destination-hostname [name-server ip-address] } [source-ipaddr ip-address] [out-interface type num [next-hop ip-address]] }</code>
Parameter Description	oob: Indicates the test on the MGMT interface. <i>destination-ip-address</i>: Indicates the destination IP address. <i>destination-hostname</i>: Indicates the destination host name. name-server ip-address: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by using the ipname-server command is used for address resolution. source-ipaddr ip-address: Indicates the source IP address. out-interface type num: Specifies the outgoing interface (non-MGMT interface) of the test packet. via type num: Specifies the MGMT interface as the outgoing interface of the test packet. next-hop ip-address: Indicates the IP address of the next hop.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After this command is configured, the IP RNS object starts to send the ICMP echo packet, and the destination IP address is the IP address configured by the user. By default, the payload size of an ICMP echo packet is 36 bytes. You can run the request-data-size command to change the packet size. You must first configure the type of the IP RNS test (such as the ICMP echo test), and then configure

parameters of the test type. To modify the test type of an IP RNS test, you must first delete this IP RNS test by running the **no ip rns** command in global configuration mode.

✚ Configuring the Protocol Payload Size of the IP RNS Test

Command	request-data-size <i>bytes</i>
Parameter Description	<i>bytes</i> : Indicates the bytes of the test packet. The minimum/maximum bytes vary according to the test type. You need to configure this item based on the command prompt in configuration mode of a specific test.
Command Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command is used to stuff some bytes in the test packet so that large packets can be used for the test.

✚ Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Tests are conducted periodically in an IP RNS test lifecycle. You can run the frequency command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test: (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

✚ Configuring a Tag for an IP RNS Test

Command	tag <i>text</i>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

✚ Configuring the Time Threshold of an IP RNS Test

Command	threshold <i>milliseconds</i>
Parameter	<i>milliseconds</i> : Indicates the time threshold of the test. The value ranges from 0 to 60,000. The unit is ms. The

Description	default value is 5,000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The value of threshold must be equal to or smaller than the value of timeout . For the relationship between timeout , frequency , and threshold , see "Usage Guide" of the frequency command.

↘ Configuring the Timeout of an IP RNS Test

Command	timeout <i>millisecond</i>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The value of timeout must be equal to or greater than the value of threshold . For the relationship between timeout , frequency , and threshold , see "Usage Guide" of the frequency command.

↘ Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

Command	tos <i>number</i>
Parameter Description	<i>number</i> : Sets the TOS field in the IPv4 test packet. The value ranges from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

↘ Configuring the VRF of an IP RNS Test

Command	vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Figure 9-3	
	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.2.2.2 A(config-ip-rns-icmp-echo)#exit A(config)#ip rns schedule 1 start-time now life forever</pre>
	Run the show ip rns configuration command to display the instance configurations.
Switch A	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): foerver Next Scheduled Start Time:Start Time already passed Target address/Source address: 10.2.2.2/0.0.0.0 Request size (ARR data portion): 36</pre>

9.4.3 Configuring the DNS Test

Configuration Effect

Create an IP RNS test of the DNS type and implement the DNS test.

Notes

- The RNS basic functions must be configured.

Configuration Steps

Creating an IP RNS Test of the DNS Type

- Mandatory.
- Perform this configuration on every switching device unless otherwise required.

Configuring Common Optional Parameters of the Test

- Perform this configuration if it is required to change common optional parameters of the test, such as the repeat interval, tag, time threshold, timeout, and TOS.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

📌 Creating an IP RNS Test of the DNS Type

Command	dns { oob <i>destination-hostname</i> name-server <i>ip-address</i> }
Parameter Description	oob : Indicates the test on the MGMT interface. <i>destination-hostname</i> : Indicates the destination host name. name-server <i>ip-address</i> : Indicates the IP address of the DNS server.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	You must first configure the type of the IP RNS test (such as the ICMP echo test), and then configure parameters of the test type. To modify the test type of an IP RNS test, you must first delete this IP RNS test by running the no ip rns command in global configuration mode.

📌 Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Tests are conducted periodically in an IP RNS test lifecycle. You can run the frequency command to specify the repeat interval. The configured frequency must meet the requirement of the following formula to ensure calculation correctness of the test: (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

📌 Configuring a Tag for an IP RNS Test

Command	tag <i>text</i>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command	IP RNS DNS configuration mode (config-ip-rns-dns)

Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

✚ Configuring the Upper Threshold of an RNS Test

Command	threshold <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the upper threshold of the test. The value ranges from 0 to 60,000. The unit is ms. The default value is 5,000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The value of threshold must be equal to or smaller than the value of timeout . For the relationship between timeout , frequency , and threshold , see "Usage Guide" of the frequency command. The value of threshold must be smaller than the value of timeout .

✚ Configuring the Timeout of an IP RNS Test

Command	timeout <i>millisecond</i>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The value of timeout must be equal to or greater than the value of threshold . For the relationship between timeout , frequency , and threshold , see "Usage Guide" of the frequency command.

✚ Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

Command	tos <i>number</i>
Parameter Description	<i>number</i> : Sets the TOS field in the IPv4 test packet. The value ranges from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

✚ Configuring the VRF of an IP RNS Test

Command	vrf <i>vrf-name</i>

Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Scenario Figure 9-4	 The diagram illustrates a network topology for RNS configuration. On the left, a device labeled 'RNS Client' (Switch A) is connected to a central cloud labeled 'ISP'. The IP address for the RNS Client is 10.1.1.1/16. On the right, a device labeled 'Dns server' is connected to the same 'ISP' cloud. The IP address for the Dns server is 10.2.2.2/16.
Configuration Steps	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre> A# configure terminal A(config)# ip rns 1 A(config-ip-rns)# dns www.ruijie.com.cn name-server 10.2.2.2 A(config-ip-rns-dns)#exit A(config)# ip rns schedule 1 start-time now life forever </pre>
Verification	Run the show ip rns configuration command to display the instance configurations.
Switch A	<pre> A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: dns Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): forever Next Scheduled Start Time:Start Time already passed Target host name: www.ruijie.com.cn Name Server: 10.2.2.2 </pre>

Common Errors

- The IP address of the server is incorrect.

9.4.4 Configuring the Track Support for the RNS

Configuration Effect

- Configure the track function to track the test result of an RNS instance.
- Configure the track function to track the link status of an interface.
- Configure the track function to track the status of a track list.
- Configure the track function to track the status of an RNS list.

Notes

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.

Configuration Steps

📌 Configuring a Track Object

- Perform this operation if it is required to create a track object.
- The following four methods are available to create a track object:
 - Create a track object for tracking the test result of an RNS instance: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the link status of an interface: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of a track list: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of an RNS list: Perform this configuration on every switching device unless otherwise required.

📌 Configuring the Notification Delay of a Track Object

- Perform this configuration if it is required to delay notification of the status change of a track object.
- Delay for notifying the status change of a track object includes the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. You can configure either delay or both of delays.

- Perform this configuration on every switching device unless otherwise required.

📌 Configuring a Track Member

- Perform this configuration if it is required to configure a track object for tracking the status of a track list.
- When configuring a track member, you can set the status of a member meeting conditions to UP or DOWN.
- Perform this configuration on every switching device unless otherwise required.

Verification

Observe the status of a track object when the status of the track object (such as test results of an RNS instance, link status of an interface, or status of a track list) changes.

- After the preset delay, run the **show track** command to check whether the current track status changes.

Related Commands

📌 Configuring a Track Object for Tracking the Link Status of An Interface

Command	track <i>object-number</i> interface <i>interface-type interface-number</i> line-protocol
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	<i>Interface-type interface-number</i> : Indicates the interface type and interface number.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is UP, the status of the corresponding track object is UP.

📌 Configuring a Track Object for Tracking the Test Result of an RNS Instance

Command	track <i>object-number</i> rns <i>entry-number</i>
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	<i>entry-number</i> : Indicates the number of an RNS object. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the test result of an RNS instance. When the test result of the RNS instance is successful, the status of the corresponding track object is UP.

📌 Configuring a Track Object for Tracking the Status of a Track List

Command	track <i>object-number</i> listboolean { and or }
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of all member status.

📌 Configuring a Track Member

Command	object <i>object-number</i> [not]
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Command Mode	Track configuration mode
Usage Guide	Run this command to configure a member for a track list. The number of track list members that can be configured is restricted only by the capacity of track objects.

📌 Configuring a Track Object for Tracking the Status of an RNS List

Command	track <i>object-number</i> rns-list <i>men-list</i> { and or }
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. <i>men-list</i> : Indicates the RNS list that is tracked. mem-list can be an RNS instance or a series of RNS instances. If mem-list is a series of RNS instances, the format is as follows: Smallest RNS ID–Greatest RNS ID, for example, 10–20. The RNS ID ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of an RNS list. The result can be the AND or OR operation result of all member status.

Configuring the Notification Delay of a Track Object

Command	delay { upseconds [downseconds] [upseconds] downseconds }
Parameter Description	up seconds : Specifies the delay for notifying the status change of a track object from DOWN to UP. The value ranges from 0 to 180. The unit is second. The default value is 0. downseconds : Specifies the delay for notifying the status change of a track object from UP to DOWN. The value ranges from 0 to 180. The unit is second. The default value is 0.
Command Mode	Track configuration mode
Usage Guide	When the status of a track object frequently changes, the status of the client that use this track object will frequently change as well. Using this command can delay notification of the status change of a track object. For example, if the status of a track object changes from UP to DOWN, and delay down 10 is configured, the DOWN status of the track object is notified 10s later. If the status of the track objects changes to UP again within this period of time, no notification is sent. For the client that uses this track object, the status of the track object is always UP.

📌 Displaying the Track Object Statistics

Command	showtrack [<i>object-number</i>]
Parameter Description	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700. The default is all track objects.

Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display statistics of track objects.

Configuration Example

Configuring Track Object3 for Tracking the Link Status of the Interface FastEthernet 1/0

Configuration Steps	- Configure a track object for tracking the link status of an interface. - Configure the delay for notifying the status change from UP to DOWN.
	<pre>Ruijie# configure terminal Ruijie(config)# track 3 interface FastEthernet 1/0 line-protocol Ruijie(config-track)# delay down 10 Ruijie(config-track)# exit</pre>
Verification	Change the link status of the interface FastEthernet 1/0 to DOWN. - Immediately check the status of the track object, and verify that the status is still UP. - Check the status of the track object 10s later, and verify that the status changes to DOWN.
	<pre>Ruijie# show track 3 Track 3 Interface FastEthernet 1/0 The state is Up, delayed Down (5 secs remaining) 1 change, current state last: 300 secs Delay up 0 secs, down 10 secs</pre>

Configuring Track Object 3 (When the status of track object 1 is UP, and the status of track object 2 is DOWN, the status of track object 3 is UP.)

Configuration Steps	- Configuring track object 1 and track object 2. - Configure track object 3, and its members include track object 1 and track object 2.

	<pre> Ruijie # config Ruijie(config)#track 1 interface gigabitEthernet 0/0 line-protocol Ruijie(config-track)#delay up 20 down 40 Ruijie(config-track)#exit Ruijie(config)# Ruijie(config)#track 2 interface gigabitEthernet 0/1 line-protocol Ruijie(config-track)#delay down 30 Ruijie(config-track)#exit Ruijie(config)# track 3 list Boolean and Ruijie(config-track)#object 1 Ruijie(config-track)#object 2 not Ruijie(config-track)# exit </pre>
Verification	When the status of track objects 1 and 2 change, check the status of track object 3. - When the status of track object 1 changes from DOWN to UP, and the status of track object 2 remains DOWN, verify that the status of track object 3 changes from DOWN to UP. - When the status of track object 1 remains UP, and the status of track object 2 changes from DOWN to UP, verify that the status of track object 3 changes from UP to DOWN.
	<pre> Ruijie# show track 3 Track 3 List boolean and Object 1 Object 2 not The state is Down 1 change, current state last:10 secs Delay up 0 secs, down 0 secs </pre>

Configuring Track Object 5 for Tracking the Test Result of RNS Instance 7

Configuration Steps	- Configure an RNS instance. - Configure a track object for tracking the test result of an RNS instance. - Configure the delay for notifying the test result change from successful to unsuccessful, and the delay for notifying the test result change from unsuccessful to successful.

	<pre> Ruijie# configure terminal Ruijie (config)#ip rns 7 Ruijie (config-ip-rns)#icmp-echo 2.2.2.2 Ruijie (config-ip-rns-icmp-echo)#exit Ruijie (config)#ip rns schedule 7 start-time now life forever Ruijie(config)# track 5 rns 7 Ruijie (config-track)# delay up 20 down 30 Ruijie (config-track)# exit </pre>
Verification	Let the test result of RNS instance 7 change from successful to unsuccessful. - When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP. - Check the status of the track object 30s later, and verify that the status changes to DOWN.
	<pre> Ruijie# show track 5 Track 5 Reliable Network Service 7 The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs </pre>

Configuring Track Object 5 for Tracking the Test Results of an RNS List (consisting of RNS Instances 1, 2–5, and 8)

Configuration Steps	- Configure and start the RNS. - Configure a track object for tracking the test result of an RNS list. - Configure the delay for notifying the test result change from UP to DOWN, and the delay for notifying the test result change from DOWN to UP.
	<pre> Ruijie(config)# track 5 rns-list 1,2-5,8 and Ruijie (config-track)# delay up 20 down 30 Ruijie (config-track)# exit </pre>
Verification	Let the test result of one of the RNS instances 1, 2-5, and 8 changes from successful to unsuccessful. - When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still UP. - Check the status of the track object 30s later, and verify that the status changes to DOWN.

```
Ruijie# show track 5

Track 5

  rns-list 1,2-5,8 and

  The state is Down

    2 change, current state last: 10 secs
  Delay up 20 secs, down 30 secs
```

Common Errors

- The track object for tracking an RNS instance is configured, but the corresponding RNS instance is not configured.
- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.
- The track object for tracking the status of a track list, but no member of the RNS list is configured.
- The track object for tracking the status of an RNS list is configured, but the corresponding RNS instance is not configured.

9.5 Monitoring

Displaying

Description	Command
Displays configurations of one or more RNS instances.	show ip rns configuration [<i>operation-number</i>]
Displays detailed statistics of one or more RNS instances.	show ip rns collection-statistics [<i>operation-number</i>]
Displays the current RNS status.	show ip rns operational-state [<i>operation-number</i>]
Displays the proactive threshold monitoring information of one or more RNS instances.	show ip rns reaction-configuration [<i>operation-number</i>]
Displays information about the test triggered by one or more RNS instances.	show ip rns reaction-trigger [<i>operation-number</i>]
Displays the brief statistics of one or more RNS instances.	show ip rns statistics [<i>operation-number</i>]
Displays the brief statistics of one or more track objects.	show track [<i>object-number</i>]
Displays the brief statistics of a track client.	show track client

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the track module.	debug track { all proc-event rdnd-event client }
Debugs the RNS module.	debug rns { all interface lib rdnd-event restart rns_id [0, 500] }

10 Configuring PCAP

10.1 Overview

Packet Capture (PCAP) is a maintenance function commonly used in network devices.

Similar to the packet capture software running on a personal computer, the PCAP function can capture, save, or display the packets sent from and received by the network device.

10.2 Applications

Application	Description
Capturing Packets	During routine maintenance, if you find packet sending or receiving failures in the network, specify the capture point and capture direction, enter the packet feature, and start the packet capture to check whether the packets arrives at the device or are sent from the device.

10.2.1 Capturing Packets

Scenario

During routine maintenance, if you find packet sending or receiving failures in the network, specify the capture point and capture direction, enter the packet feature, and start the packet capture to check whether the packets arrives at the device or are sent from the device.

Deployment

Perform packet capture as follows:

- Create a capture feature rule and name it.
- Create a capture point and specify the capture point name, capture location (physical port, VLAN, and control plane), capture direction, and capture feature.
- Specify the name of the file to be saved.
- Enable packet capture at the capture point.
- Wait until the capture ends.
- Upload the file to the PC.
- Enable the capture software on the PC to check the captured packets.

10.3 Features

Overview

Feature	Description
Capturing Packets on Control Plane	Clients can define the capture point and specify the capture location and direction, matching rule information, number of captured packets, and file name; and then enable the capture procedure.
Capturing Packets on Forwarding Plane	Users can specify rules of matching between ACL IDs and physical ports (ACL IDs are mandatory and physical ports are optional), number of to-be-captured packets, name of the file for storing captured packets, and other information, and then start the packet capture.

10.3.1 Capturing Packets on Control Plane

Clients can define the capture point and specify the capture location and direction, matching rule information, number of captured packets, and file name; and then enable the capture procedure.

Working Principle

Clients can define the capture rules by defining capture points. To capture multiple types of packets at the same time, a client is allowed to define multiple capture points and distinguish them by their names. The capture rules are as follows:

- 1) The capture location can be selected from the certain physical port, VLAN port, and system control plane. Each capture point can only have one capture location.
- 2) The available capture directions can be the outgoing direction, incoming direction, and bidirectional.
- 3) The 7-tuple information can match the source MAC address, destination MAC address, layer-2 protocol type, source IP address, destination IP address, layer-3 protocol type, and TCP/UDP port information.
- 4) The number of captured packets or size of the captured packet can be specified.
- 5) The file name can be specified. The captured packet will be saved in PCAP file format.

A client enables capture via commands after the rules are configured. The capture will automatically stop when the number of captured packets or the file size reaches the specified value, or when timeout happens. The client can also stop the capture after commands are entered manually.

10.3.2 Capturing Packets on Forwarding Plane

Users can specify rules of matching between ACL IDs and physical ports (ACL IDs are mandatory and physical ports are optional), number of to-be-captured packets, name of the file for storing captured packets, and other information, and then start the packet capture.

Working Principle

1. The rule of matching between ACL IDs and physical ports can be specified for packet capture and physical ports are optional.

- Multiple rules of matching between ACL IDs and physical ports can be configured for packet capture.
- Packet capture at the ingress is supported.
- No packet capture point needs to be specified and 7-tuple matching information is not supported.
- The number of to-be-captured packets or the size of the file for storing captured packets can be defined.
- Captured packets are stored in a specified file in the PCAP file format. Users can run commands to start packet capture after configuring rules. The capture automatically stops when the number of captured packets or the file size reaches the specified value or when timeout occurs. Users can also run commands to manually stop packet capture.

10.4 Configuration

Configuration	Description and Command	
Capturing Packets on Control Plane	packet capture rule rule-name filter [src-mac smac] [dst-mac dmac] [etype type ip arp] [ipv4-sip sip sip-mask] [ipv4-dip dip dip-mask] [ipv6-sip sipv6 sipv6-prefix] [ipv6_dip dipv6 dipv6-prefix] [v6_protocol protocol tcp udp] [ipv6_sport sport] [ipv6_dport dport] [v4_protocol protocol tcp udp] [ipv4_sport sport] [ipv4_dport dport]	Defines capture matching rule.
	packet capture point capture-point-name rule rule-name location{interfaceinterface-name control-plane} {in out both}	Creates the capture point and specifies the capture location, matching rule, and capture direction.
	packet capture file filename [buffer-size buf-size] [packet-numpkt-num] [timeouttimeout]	Specifies the name of the file to be saved.
	packet capture {start stop}	Starts/Stops packet capture.
Capturing Packets on Forwarding Plane	packet capture rule rule-name filter acl aclid aclname [interfaceinterface-name]	Defines capture matching rule.
	packet capture file filename [buffer-size buf-size][packet-numpkt-num] [timeouttimeout]	Specifies the name of the file to be saved.
	packet capture {start stop}	Starts/Stops packet capture.

10.4.1 Capturing Packets on Control Plane

Configuration Effect

- Define the capture matching rule.

- Create the capture point.
- Specify the name of the file to be saved.
- Start packet capture.
- Stop packet capture.

Configuration Steps

📌 Defining Capture Matching Rule

- (Mandatory) Run this command to define the packet capture rule.

Command	packet capture rule <i>rule-name</i> filter [src-mac <i>smac</i>] [dst-mac <i>dmac</i>] [etype <i>type</i> ip arp] [ipv4_sip <i>sip sip-mask</i>] [ipv4_dip <i>dip dip-mask</i>] [ipv6_sip <i>sipv6 sipv6-prefix</i>] [ipv6_dip <i>dipv6 dipv6-prefix</i>] [v6_protocol <i>protocol</i> tcp udp] [ipv6_sport <i>sport</i>] [dst-port <i>dport</i>] [v4_protocol <i>protocol</i> tcp udp] [ipv4_sport <i>sport</i>] [dst-port <i>dport</i>]
Parameter Description	<i>rule-name</i> : Indicates the matching rule name. <i>smac</i> : Indicates the source MAC address. <i>dmac</i> : Indicates the destination MAC address. <i>type</i> ip arp : Indicates the layer-2 protocol type. <i>sip</i> : Indicates the source IP address. <i>sip-mask</i> : Indicates the source IP address mask. <i>dip</i> : Indicates the destination IP address. <i>dip-mask</i> : Indicates the destination IP address mask. <i>sipv6</i> : Indicates the source IPv6 address. <i>sipv6-prefix</i> : Indicates the source IPv6 prefix. <i>dipv6</i> : Indicates the destination IPv6 address. <i>sipv6-prefix</i> : Indicates the destination IPv6 prefix. <i>protocol</i> tcp udp : Indicates the layer-3 protocol type. <i>sport</i> : Indicates the TCP/UDP protocol source port. <i>dport</i> : Indicates the TCP/UDP protocol destination port.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The user can define multiple capture rules and distinguish them by different names. After a rule is defined, the rule needs to be referenced by the packet capture point to actually take effect. 2. Before deleting the capture rule, all the packet capture points referencing the rule need to be deleted.

📌 Creating Capture Point

- (Mandatory) Run this command to create the capture point.

Command	packet capture point <i>capture-point-name</i> rule <i>rule-name</i> location { interface <i>interface-name</i> control-plane } { in out both }
Parameter	<i>capture-point-name</i> : Indicates the capture point name.

Description	<i>rule-name</i>: Indicates the matching rule name, which is defined by running the packet capture rule command. <i>interface-name</i>: Indicates the name of the port on which packets are captured. <i>vlan-id</i>: Indicates the ID of the VLAN in which packets are captured. control-plane: Indicates the control plane on which packets are captured. in out both: Indicates the capture direction (incoming, outgoing, or bidirectional).
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The user can define multiple capture points at the same location as required to match different capture rules or packet directions. The capture points can work simultaneously without affecting each other. 2. If the capture point is modified during packet capture, the modification will not take effect immediately and will take effect next time when packet capture is enabled.

📌 Specifying Name of File to Be Saved

- (Optional) Run this command to specify the name of the file to be saved.

Command	packet capture file filename [buffer-size buf-size] [packet-num pkt-num] [timeout timeout]
Parameter Description	<i>filename</i>: Indicates the name of the file to be saved. <i>buf-size</i>: Indicates the buffer size. The buffer size is 2 MB by default if not specified. Packet capture automatically stops when the buffer is full. Up to 200M buffer is supported. <i>pkt-num</i>: Indicates the number of captured packets. Packet capture automatically stops when the number of captured packets reaches the specified number. 1024 packets will be captured continually by default unless otherwise specified. <i>timeout</i>: Indicates packet capture timeout. Packet capture automatically stops when the time of captured packets reaches the specified number. The default packet capture time is 10 minutes unless otherwise specified. The longest continually packet capture time is 120 minutes.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The file name setting takes effect next time packet capture is enabled.

📌 Starting/Stopping Packet Capture

- (Mandatory) Enter this command to start or stop packet capture.

Command	packet capture { start stop}
Parameter Description	start stop : Starts/Stops packet capture.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. If the packet capture stop command is not entered after packet capture starts, the packet capture

automatically stops at the capture point when the number of captured packets reaches the specified number. If the packet capture stop condition is not met, run this command to immediately stop the packet capture.

2. Run the packet capture start command to capture packets at all packet capture points simultaneously.

Verification

Run the **show packet capture status** command to display packet capture information.

Command	show packet capture status
Parameter	N/A
Description	
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display the packet capture status.
Command Presentation	<pre>Ruijie#show packet capture status Capture rules: Capture rules tcp: etype: 0x0800 source MAC: 2222.2222.2222 destination MAC: 1111.1111.1111 protocol: 0x6 source IP: 10.10.10.3 destination IP: 10.10.10.10 source port: 5 destination port: 10 Capture points: Capture point controlplane: Capture rules: tcp location: control-plane direction: all Capture file:</pre>

```
Filename: /tmp/tcp.pcap

Buffer size: 2(MB)

Capture Statistic:

Status: stop

Stop reason: Normal

Start time: 2017-5-20 9:24:19

End time: 2017-5-20 9:28:19

Timeout: 10(minutes)

Packets limit: 1024

Packet capture cnts:10

Ruijie#
```

Configuration Example

📌 Capturing Packets

Scenario	In the client environment, the TCP connection of a certain application on a device connected to Port 0/1 fails, TCP packets need to be captured on this port for analysis.
Configuration Steps	Run the packet capture command to capture and save TCP packets to the file tcp.pcap and upload the file to a PC to display the captured data.
	<pre>Ruijie# packet capture rule tcp etype ip protocol tcp Ruijie# packet capture point tcppoint rule tcp location interface gi0/1 both Ruijie# packet capture file usb0:tcp.pcap packet-num 1500 Ruijie# packet capture start</pre>
Verification	<pre>Ruijie#show packet capture status Capture rules: Capture rules tcp: etype: 0x0800 protocol: 0x6 Capture points: Capture point tcppoint: Capture rules: tcp location: Gi0/1 direction: all Capture file: Filename: /mnt/usb0/tcp.pcap Buffer size: 2 (MB) Capture Statistic: Status: running Timeout: 10 (minutes) Packets limit: 1500 Packet capture cnts:10</pre>

10.4.2 Capturing Packets on Forwarding Plane

Configuration Effect

- Define the capture matching rule.
- Specify the name of the file to be saved.
- Start packet capture.
- Stop packet capture.

Configuration Steps

📌 Defining Capture Matching Rule

- (Mandatory) Run this command to define the packet capture rule.

Command	packet capture rule <i>rule-name</i> filter acl <i>aclid</i> [interface <i>interface-name</i>]
Parameter	<i>rule-name</i> : Indicates the matching rule name.
Description	<i>aclid</i> : Indicates the ACL ID or name. <i>interface-name</i> : Indicates the interface.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	The user can define multiple capture rules and distinguish them by different names. After a rule is defined, the rule needs to be referenced by the packet capture point to actually take effect.

📌 Specifying Name of File to Be Saved

- (Optional) Run this command to specify the name of the file to be saved.

Command	packet capture file <i>filename</i> [buffer-size <i>buf-size</i>] [packet-num <i>pkt-num</i>] [timeout <i>timeout</i>]
Parameter	<i>filename</i> : Indicates the name of the file to be saved.
Description	<i>buf-size</i> : Indicates the buffer size. The buffer size is 2 MB by default if not specified. Packet capture automatically stops when the buffer is full. Up to 200 MB buffer is supported. <i>pkt-num</i> : Indicates the number of captured packets. Packet capture automatically stops when the number of captured packets reaches the specified number. 1024 packets will be captured continually by default unless otherwise specified. <i>timeout</i> : Indicates packet capture timeout. Packet capture automatically stops when the time of captured packets reaches the specified number. The default packet capture time is 10 minutes unless otherwise specified. The longest continually packet capture time is 120 minutes.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	1. The file name setting takes effect next time packet capture is enabled.

📌 Starting/Stopping Packet Capture

- (Mandatory) Enter this command to start or stop packet capture.

Command	packet capture { start stop }
Parameter Description	start stop: Starts/Stops packet capture.
Defaults	-
Command Mode	Privileged EXEC mode
Usage Guide	If the packet capture stop command is not entered after packet capture starts, the packet capture automatically stops at the capture point when the number of captured packets reaches the specified number. If the packet capture stop condition is not met, run this command to immediately stop the packet capture.

Verification

Run the **show packet capture status** command to display packet capture information.

Command	show packet capture status
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display the packet capture status.
Command Presentation	<pre>Ruijie#show packet capture status Capture rules: Capture rules rule1: acl_id: 1 Capture file: Filename: /tmp/vsd/0/test.pcap Buffer size: 2 (MB) Capture Statistic: Status: stopped Stopped reason: Normal Timeout: 10 (minutes) Packets limit: 1024</pre>

```
Write file packet count: 0
Ruijie#
```

Configuration Example

📌 Capturing Packets

Scenario	In the client environment, a traffic error occurs to interface 0/1. Traffic may not reach the device. Therefore, packets need to be captured on this port for analysis.
Configuration Steps	Run the packet capture command to capture and save TCP packets to the file tcp.pcap and upload the file to a PC to display the captured data.
	<pre>Ruijie(config)#access-list 100 permit tcp host 1.1.1.1 any Ruijie(config)#exit Ruijie#packet capture rule rule1 filter acl 100 interface tenGigabitEthernet 0/1 Ruijie# packet capture file usb0:tcp.pcap packet-num 1500 Ruijie# packet capture start</pre>
Verification	<pre>Ruijie#show packet capture status</pre> Capture rules: <pre>Capture rules rule1: acl_id: 100 acl_ifx: TenGigabitEthernet 0/1</pre> Capture file: <pre>Filename: /tmp/vsd/0/test.pcap Buffer size: 2 (MB)</pre> Capture Statistic: <pre>Status: running Start time: 2018-6-4 16:34:55 Timeout: 10 (minutes) Packets limit: 1024 Write file packet count: 4</pre>

10.5 Monitoring

Displaying

Description	Command
Displays the packet capture status.	show packet capture status

Network Management & Monitoring Configuration

1. Configuring SNMP
2. Configuring RMON
3. Configuring NTP
4. Configuring SNTP
5. Configuring SPAN-RSPAN
6. Configuring ERSPAN
7. Configuring sFlow
8. Configuring NETCONF

1 Configuring SNMP

1.1 Overview

Simple Network Management Protocol (SNMP) became a network management standard RFC1157 in August 1988. At present, because many vendors support SNMP, SNMP has in fact become a network management standard and is applicable to the environment where systems of multiple vendors are interconnected. By using SNMP, the network administrator can implement basic functions such as information query for network nodes, network configuration, fault locating, capacity planning, and network monitoring and management.

📄 SNMP Versions

Currently, the following SNMP versions are supported:

- SNMPv1: The first official version of SNMP, which is defined in RFC1157.
- SNMPv2C: Community-based SNMPv2 management architecture, which is defined in RFC1901.
- SNMPv3: SNMPv3 provides the following security features by identifying and encrypting data.
 1. Ensuring that data is not tampered during transmission.
 2. Ensuring that data is transmitted from legal data sources.
 3. Encrypting packets and ensuring data confidentiality.

Protocols and Standards

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)
- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

1.2 Applications

Application	Description
Managing Network Devices Based on SNMP	Network devices are managed and monitored based on SNMP.

1.2.1 Managing Network Devices Based on SNMP

Scenario

Take the following figure as an example. Network device A is managed and monitored based on SNMP network manager.

Figure 1-1

Remarks	A is a network device that needs to be managed. PC is a network management station.

Deployment

The network management station is connected to the managed network devices. On the network management station, users access the Management Information Base (MIB) on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

1.3 Features

Basic Concepts

SNMP is an application layer protocol that works in C/S mode. It consists of three parts:

- SNMP network manager
- SNMP agent
- MIB

Figure 1-2 shows the relationship between the network management system (NMS) and the network management agent.

SNMP Network Manager

The SNMP network manager is a system that controls and monitors the network based on SNMP and is also called the NMS.

SNMP Agent

The SNMP agent (hereinafter referred to as the agent) is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

MIB

The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits may be used to uniquely identify a management unit system among network devices. The MIB is a collection of unit identifiers of network devices.

Figure 1-3 Tree Hierarchical Structure

Operation Types

Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

- Get-request: The NMS extracts one or more parameter values from the agent.
- Get-next-request: The NMS extracts the parameter value next to one or more parameters from the agent.
- Get-bulk: The NMS extracts a batch of parameter values from the agent.
- Set-request: The NMS sets one or more parameter values of the agent.
- Get-response: The agent returns one or more parameter values, which are the operations in response to the three operations performed by the agent on the NMS.
- Trap: The agent actively sends a message to notify the NMS of something that happens.

The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. (Note: SNMPv1 does not support the Get-bulk operation.) Figure 1-4 describes the operations.

Figure 1-4 SNMP Packet Types

The three operations performed by the NMS on the agent and the response operations of the agent are based on UDP port 161. The trap operation performed by the agent is based on UDP port 162.

Overview

Feature	Description
Basic SNMP Functions	The SNMP agent is configured on network devices to implement basic functions such as information query for network nodes, network configuration, fault locating, and capacity planning.
SNMPv1 and SNMPv2C	SNMPv1 and SNMPv2C adopt the community-based security architecture, including authentication name and access permission.

SNMPv3	SNMPv3 redefines the SNMP architecture, namely, it enhances security functions, including the security model based on users and access control model based on views. The SNMPv3 architecture already includes all functions of SNMPv1 and SNMPv2C.

1.3.1 Basic SNMP Functions

Working Principle

📌 Working Process

SNMP protocol interaction is response interaction (for exchange of packets, see Figure 1-4). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and returns a Get-response. Sometimes, the agent actively sends a trap message and an Inform message to the NMS. The NMS does not need to respond to the trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

Related Configuration

📌 Shielding or Disabling the SNMP Agent

By default, the SNMP function is enabled.

The **no snmp-server** command is used to disable the SNMP agent.

The **no enable service snmp-agent** command is used to directly disable all SNMP services.

📌 Setting Basic SNMP Parameters

By default, the system contact mode, system location, and device Network Element (NE) information are empty. The default serial number is 60FF60, the default maximum packet length is 1,572 bytes, and the default UDP port ID of the SNMP service is 161.

The **snmp-server contact** command is used to configure or delete the system contact mode.

The **snmp-server location** command is used to configure or delete the system location.

The **snmp-server chassis-id** command is used to configure the system serial number or restore the default value.

The **snmp-server packetsize** command is used to configure the maximum packet length of the agent or restore the default value.

The **snmp-server net-id** command is used to configure or delete the device NE information.

The **snmp-server udp-port** command is used to set the UDP port ID of the SNMP service or restore the default value.

📌 Configuring the SNMP Host Address

By default, no SNMP host is configured.

The **snmp-server host** command is used to configure the NMS host address to which the agent actively sends messages or to delete the specified SNMP host address. In the messages sent to the host, the SNMP version, receiving port,

authentication name, or user can be bound. This command is used with the **snmp-server enable traps** command to actively send trap messages to the NMS.

📌 Setting Trap Message Parameters

By default, SNMP is not allowed to actively send a trap message to the NMS, the function of sending a Link Trap message on an interface is enabled, the function of sending a system reboot trap message is disabled, and a trap message does not carry any private field.

By default, the IP address of the interface where SNMP packets are sent is used as the source address.

By default, the length of a trap message queue is 10 and the interval for sending a trap message is 30s.

The **snmp-server enable traps** command is used to enable or disable the agent to actively send a trap message to the NMS.

The **snmp trap link-status** command is used to enable or disable the function of sending a Link Trap message on an interface.

The **snmp-server trap-source** command is used to specify the source address for sending messages or to restore the default value.

The **snmp-server queue-length** command is used to set the length of a trap message queue or to restore the default value.

The **snmp-server trap-timeout** command is used to set the interval for sending a trap message or to restore the default value.

The **snmp-server trap-format private** command is used to set or disable the function of carrying private fields in a trap message when the message is sent.

The **snmp-server system-shutdown** command is used to enable or disable the function of sending a system reboot trap message.

1.3.2 SNMPv1 and SNMPv2C

SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

Working Principle

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. The authentication name of the NMS must be the same as an authentication name defined in devices.

SNMPv2C adds the Get-bulk operation mechanism and can return more detailed error message types to the management workstation. The Get-bulk operation is performed to obtain all information from a table or obtain lots of data at a time, so as to reduce the number of request responses. The enhanced error handling capabilities of SNMPv2C include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for errors. Now, errors can be differentiated based on error codes. Because management workstations supporting SNMPv1 and SNMPv2C may exist on the network, the SNMP agent must be able to identify SNMPv1 and SNMPv2C packets and return packets of the corresponding versions.

Security

One authentication name has the following attributes:

- Read-only: Provides the read permission of all MIB variables for authorized management workstations.
- Read-write: Provide the read/write permission of all MIB variables for authorized management workstations.

Related Configuration

Setting Authentication Names and Access Permissions

The default access permission of all authentication names is read-only.

The **snmp-server community** command is used to configure or delete an authentication name and access permission.

This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.

1.3.3 SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2 into the SNMPv3 system.

Working Principle

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the User-based Security Model (USM). The security level of the NMS user must be the same as that of an SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the discover and report operation mechanisms. When the NMS does not know agent engine IDs, the NMS may first send a discover message to the agent and the agent returns a report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

Security

- SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include: SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

SNMPv1 and SNMPv2C Security Models and Security Levels

Security Model	Security Level	Authentication	Encryption	Description
SNMPv1	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.

SNMPv2c	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.

SNMPv3 Security Model and Security Level

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	User name.	N/A	Data validity is confirmed through user name.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and data encryption mechanism based on CBC-DES are provided.

📌 Engine ID

An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, one SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must has a unique engine ID, that is, `SnpEngineID`.

An engine ID is an octet string that consists of 5 to 32 bytes. RFC3411 defines the format of an engine ID:

- The first four bytes indicate the private enterprise ID (allocated by IANA) of a vendor, which is expressed in hexadecimal.
- The fifth byte indicates remaining bytes:
- 0: Reserved.
- 1: The later four bytes indicate an IPv4 address.
- 2: The later 16 bytes indicate an IPv6 address.
- 3: The later six bytes indicate a MAC address.
- 4: Text consisting of 27 bytes, which is defined by the vendor.
- 5: Hexadecimal value consisting of 27 bytes, which is defined by the vendor.
- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

Related Configuration

📌 Configuring an MIB View and a Group

By default, one view is configured and all MIB objects can be accessed.

By default, no user group is configured.

The **snmp-server view** command is used to configure or delete a view and the **snmp-server group** command is used to configure or delete a user group.

One or more instructions can be configured to specify different community names so that network devices can be managed by NMSs of different permissions.

📌 Configuring an SNMP User

By default, no user is configured.

The **snmp-server user** command is used to configure or delete a user.

The NMS can communicate with the agent by using only legal users.

An SNMPv3 user can specify the security level (whether authentication and encryption are required), authentication algorithm (MD5 or SHA), authentication password, encryption password (only DES is available currently), and encryption password.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic SNMP Functions	 (Mandatory) It is used to enable users to access the agent through the NMS.	
	enable service snmp-agent	Enables the agent function.
	snmp-server community	Sets an authentication name and access permission.
	snmp-server user	Configures an SNMP user.
	snmp-server view	Configures an SNMP view.
	snmp-server group	Configures an SNMP user group.
	snmp-server authentication	Configures the SNMP attack protection and detection function.
	snmp-server enable secret-dictionary-check	Configures password dictionary check for communities and users.
Enabling the Trap Function	 (Optional) It is used to enable the agent to actively send a trap message to the NMS.	
	snmp-server host	Configures the NMS host address.
	snmp-server enable traps	Enables the agent to actively send a trap message to the NMS.
	snmp trap link-status	Enables the function of sending a Link Trap message on an interface.
	snmp-server system-shutdown	Enables the function of sending a system reboot trap message.
	snmp-server trap-source	Specifies the source address for sending a trap message.

Configuration	Description and Command	
	snmp-server trap-format private	Enables a trap message to carry private fields when the message is sent.
Shielding the Agent Function	 (Optional) It is used to shield the agent function when the agent service is not required.	
	no snmp-server	Shields the agent function.
Setting SNMP Control Parameters	 (Optional) It is used to set or modify SNMP control parameters.	
	snmp-server contact	Sets the device contact mode.
	snmp-server location	Sets the device location.
	snmp-server chassis-id	Sets the serial number of the device.
	snmp-server net-id	Sets NE information about the device.
	snmp-server packetsize	Modifies the maximum packet length.
	snmp-server udp-port	Modifies the UDP port ID of the SNMP service.
	snmp-server queue-length	Modifies the length of a trap message queue.
	snmp-server trap-timeout	Modifies the interval for sending a trap message.

1.4.1 Configuring Basic SNMP Functions

[Configuration Effect](#)

Enable users to access the agent through the NMS.

[Notes](#)

- By default, no authentication name is set on network devices and SNMPv1 or SNMPv2C cannot be used to access the MIB of network devices. When an authentication name is set, if no access permission is specified, the default access permission is read-only.

[Configuration Steps](#)

📌 [Configuring an SNMP View](#)

- Optional
- An SNMP view needs to be configured when the View-based Access Control Model (VACM) is used.

📌 [Configuring an SNMP User Group](#)

- Optional
- An SNMP user group needs to be configured when the VACM is used.

📌 [Configuring an Authentication Name and Access Permission](#)

- Mandatory

- An authentication name must be set on the agent when SNMPv1 and SNMPv2C are used to manage network devices.

✚ Configuring an SNMP User

- Mandatory
- A user must be set when SNMPv3 is used to manage network devices.

✚ Enabling the Agent Function

- Optional
- By default, the agent function is enabled. When the agent function needs to be enabled again after it is disabled, this command must be used.

Verification

Run the **show snmp** command to check the SNMP function on devices.

Related Commands

✚ Configuring an SNMP View

Command	snmp-server view <i>view-name oid-tree</i> { include exclude }
Parameter Description	<i>view-name</i> : View name <i>oid-tree</i> : MIB objects associated with a view, which are displayed as an MIB subtree. include : Indicates that the MIB object subtree is included in the view. exclude : Indicates that the MIB object subtree is not included in the view.
Command Mode	Global configuration mode
Usage Guide	Specify a view name and use it for view-based management.

✚ Configuring an SNMP User Group

Command	snmp-server group <i>groupname</i> { v1 v2c v3 { auth noauth priv } } [read <i>readview</i>] [write <i>writeview</i>] [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter Description	v1 v2c v3 : Specifies the SNMP version. auth : Messages sent by users in the group need to be verified but data confidentiality is not required. This configuration is valid for SNMPv3 only. noauth : Messages sent by users in the group do not need to be verified and data confidentiality is not required. This configuration is valid for SNMPv3 only. priv : Messages sent by users in the group need to be verified and confidentiality of transmitted data is required. This configuration is valid for SNMPv3 only. <i>readview</i> : Associates one read-only view. <i>writeview</i> : Associates one read/write view. <i>aclnum</i> : ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.

	<i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>ipv6-aclname</i>: IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
Command Mode	Global configuration mode
Usage Guide	Associate certain users with a group and associate the group with a view. Users in a group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.

📌 Configuring an Authentication Name and Access Permission

Command	snmp-server community [0 7] <i>string</i> [view <i>view-name</i>] [[ro rw] [host <i>ipaddr</i>]] [ipv6 <i>ipv6-aclname</i>] [<i>aclnum</i> <i>aclname</i>]
Parameter Description	0: Indicates that the input community string is a plaintext string. 7: Indicates that the input community string is a ciphertext string. <i>string</i>: Community string, which is equivalent to the communication password between the NMS and the SNMP agent. <i>view-name</i>: Specifies a view name for view-based management. ro: Indicates that the NMS can only read variables of the MIB. rw: The NMS can read and write variables of the MIB. <i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. <i>ipv6-aclname</i>: ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified. <i>ipaddr</i>: Associates NMS addresses and specifies NMS addresses for accessing the MIB.
Command Mode	Global configuration mode
Usage Guide	This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed. To disable the SNMP agent function, run the no snmp-server command.

📌 Configuring an SNMP User

Command	snmp-server user <i>username</i> <i>groupname</i> { v1 v2c v3 [encrypted] [auth { md5 sha } <i>auth-password</i>] [priv des56 <i>priv-password</i>] } [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter Description	<i>username</i>: User name. <i>groupname</i>: Specifies the group name for a user. v1 v2c v3: Specifies the SNMP version. Only SNMPv3 supports later security parameters. encrypted: The specified password input mode is ciphertext input. Otherwise, plaintext is used for input. If ciphertext input is selected, enter a key consisting of continuous hexadecimal digits. An MD5 protocol

	authentication key consists of 16 bytes and an SHA authentication protocol key consists of 20 bytes. Two characters stand for one byte. Encrypted keys are valid for this engine only. auth: Specifies whether authentication is used. md5: Specifies the MD5 authentication protocol. sha specifies the SHA authentication protocol. auth-password: Configures a password string (not more than 32 characters) used by the authentication protocol. The system converts the passwords into the corresponding authentication keys. priv: Specifies whether confidentiality is used. des56 specifies the use of the 56-bit DES encryption protocol. priv-password: Configures a password string (not more than 32 characters) used for encryption. The system converts the password into the corresponding encryption key. aclnum: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. aclname: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. ipv6-aclname: IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
Command Mode	Global configuration mode
Usage Guide	Configure user information so that the NMS can communicate with the agent by using a valid user. For an SNMPv3 user, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (at present, only DES is available), and encryption password.

📌 Enabling the Agent Function

Command	enable service snmp-agent
Parameter Description	
Configuration mode	Privileged mode.
Usage Guide	This command is used to enable the SNMP agent function of a device.

📌 Displaying the SNMP Status Information

Command	show snmp [mib user view group host process-mib-time]
Parameter Description	mib: Displays information about the SNMP MIB supported in the system. user: Displays information about an SNMP user. view: Displays information about an SNMP view. group: Displays information about an SNMP user group. host: Displays information about user configuration. process-mib-time: Displays the MIB node with the longest processing time.
Configuration mode	Privileged mode.

Usage Guide	N/A

Configuration Example Configuring SNMP v1/2c

Scenario Figure 1-5	 - The NMS is connected to an agent through the Ethernet. The IP address of the agent is 192.168.3.1/24, and the IP address of the NMS is 192.168.3.2/24. - The NMS monitors and manages the agent through SNMP v1 or SNMP v2c.
	When the agent is faulty or an error occurs, the agent can actively reports the related information to the NMS.
Configuration Steps	- Configure the SNMP basic information, including the version and community name. - Allow the NMS (192.168.3.2/24) to send Trap messages. - Configure the IP address of the agent, and set the IP address of the Gi0/1 interface to 192.168.3.1/24.
Agent	<pre>Ruijie(config)#snmp-server community public rw Ruijie(config)#snmp-server host 192.168.3.2 traps version 2c public Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
Verification	- Run the show running-config command to display configuration information of the device. - Run the show snmp host command to display the host information configured by the user.
NMS	On the NMS that uses the SNMP v1/v2c, configure the read/write community name, timeout time, and retry times. You can use the NMS to query and configure the device.  Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.

Configuring SNMP v3 (Default View)

Scenario Figure 1-6	<pre> graph LR Agent[Agent] --- Gi0/1[Gi0/1] --- NMS[NMS] Agent_IP[IP:192.168.3.1/24] --- Agent NMS_IP[IP:192.168.3.2/24] --- NMS </pre> ● The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password. ● You can access all MIB nodes. ("read default write default" indicates that all MIB nodes can be accessed.) ● Network devices can actively send authentication and encryption messages to the NMS.
Configuration Steps	● Configure an MIB group. Create a group "g1", select the version "v3", set the security level to the authentication and encryption mode "priv", and configure permissions to read and write the view "default". "Default" indicates that all MIB nodes can be accessed. ● Configure an SNMP user. Create a user named "user1" under group "g1", select "v3" as the version, and set the authentication mode to "md5", authentication password to "123", encryption mode to "DES56", and encryption password to "321". ● Configure the SNMP host address. Set the host address to 192.168.3.2, select "3" as the version, set the security level to the authentication and encryption mode "priv", and associate the user name "user1". Enable the agent to actively send a trap message to the NMS. ● Configure the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
Agent	<pre> Ruijie(config)#snmp-server group g1 v3 priv read default write default Ruijie(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321 Ruijie(config)#snmp-server host 192.168.3.2 traps version 3 priv user1 Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit </pre>
Verification	● Run the show running-config command to display configuration information of the device. ● Run the show snmp user command to display the SNMP user. ● Run the show snmp view command to display the SNMP view. ● Run the show snmp group command to display the SNMP group. ● Run the show snmp host command to display the host information configured by the user. ● Install MIB-Browser.

NMS

SNMP v3 adopts the authentication and encryption security mechanisms. On the NMS, configure the user name, and select a security level. Based on the selected security level, configure the authentication mode, authentication password, encryption mode, and encryption password. In addition, configure the timeout time and retry times. You can use the NMS to query and configure the device. For details about the configuration, see Figure 1-7.

⚠

Configurations on the NMS must be consistent with those on the device; otherwise, related operations cannot be performed.

➤ Configuring SNMPv3 Configuration (Specified View)

Scenario

Figure 1-7

Agent

IP:192.168.3.1/24

NMS

IP:192.168.3.2/24

Diagram showing the connection between the Agent (IP:192.168.3.1/24) and the NMS (IP:192.168.3.2/24) via the Gi0/1 interface.

- The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password.
- Network devices can control the operation permission of users to access MIB objects. For example, the user named user1 can read MIB objects under the system node (1.3.6.1.2.1.1) and can only write

	MIB objects under the SysContact node (1.3.6.1.2.1.1.4.0). ● Network devices can actively send authentication and encryption messages to the NMS.
Configuration Steps	● Configure a MIB view and a MIB group. Create a MIB view “view1”, which includes the associated MIB object (1.3.6.1.2.1.1); then create a MIB view “view2”, which includes the associated MIB object (1.3.6.1.2.1.1.4.0). Create a group “g1”, select the version “v3”, set the security level to the authentication and encryption mode “priv”, and configure permissions to read the view “view1” and write the view “view2”. ● Configure an SNMP user. Create a user named “user1” under group “g1”, select “v3” as the version, and set the authentication mode to “md5”, authentication password to “123”, encryption mode to “DES56”, and encryption password to “321”. ● Configure the SNMP host address. Set the host address to 192.168.3.2, select “3” as the version, set the security level to the authentication and encryption mode “priv”, and associate the user name “user1”. Enable the agent to actively send a trap message to the NMS. ● Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
Agent	<pre> Ruijie(config)#snmp-server view view1 1.3.6.1.2.1.1 include Ruijie(config)#snmp-server view view2 1.3.6.1.2.1.1.4.0 include Ruijie(config)#snmp-server group g1 v3 priv read view1 write view2 Ruijie(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321 Ruijie(config)#snmp-server host 192.168.3.2 traps version 3 priv user1 Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit </pre>
Verification	1. Run the show running-config command to display configuration information of the device. 2. Run the show snmp user command to display the SNMP user. 3. Run the show snmp view command to display the SNMP view. 4. Run the show snmp group command to display the SNMP group. 5. Run the show snmp host command to display the host information configured by the user. 6. Install MIB-Browser.

Install MIB-Browser, enter IP address **192.168.3.1** in **IP Address** and **user1** in **UserName**, select **AuthPriv** for **Security Level**, enter **123** in **AuthPassWord**, select **MD5** for **AuthProtocol**, and enter **321** in **PrivPassWord**. Click **Add Item** and select a management unit for which the MIB needs to be queried, for example, **System** in the following figure. Click **Start**. The MIB is queried for network devices. The lowest pane in the following figure shows query results.

Common Errors

1.4.2 Enabling the Trap Function

Configuration Effect

Enable the agent to actively send a trap message to the NMS.

Notes

N/A

Configuration Steps

✚ Configuring the SNMP Host Address

- Optional
- Configure the host address of the NMS when the agent is required to actively send messages.

✚ Enabling the Agent to Actively Send a Trap Message to the NMS

- Optional
- Configure this item on the agent when the agent is required to actively send a trap message to the NMS.

✚ Enabling the Function of Sending a Link Trap Message on an Interface

- Optional
- Configure this item on the agent when a link trap message needs to be sent on an interface.

✚ Enabling the Function of Sending a System Reboot Trap Message

- Optional
- Configure this item on the agent when the RGOS system is required to send a trap message to the NMS to notify system reboot before reloading or reboot of the device.

✚ Specifying the Source Address for Sending a Trap Message

- Optional
- Configure this item on the agent when it is required to permanently use a local IP address as the source SNMP address to facilitate management.

✚ Enabling a Trap Message to Carry Private Fields when the Message Is Sent

- Optional
- Configure this item on the agent when private fields need to be carried in a trap message.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

✚ Setting the NMS Host Address

Command	snmp-server host [oob] { <i>host-addr</i> ipv6 <i>ipv6-addr</i> } [vrf <i>vrfname</i>] [traps inrorms] [version { 1 2c 3 } { auth noauth priv }] <i>community-string</i> [udp-port <i>port-num</i>] [<i>notification-type</i>]
Parameter Description	oob: Configures Out-Of-Band (OOB) communication for the alarm server (that is, information is sent to the alarm server through the MGMT interface). <i>host-addr:</i> Address of the SNMP host. <i>ipv6-addr:</i> (IPv6) address of the SNMP host.

	<i>Vrfname</i>: Configures a VRF forwarding table name. traps informs: Configures the host to send a trap message or an inform message. version: SNMP version, which can be set to V1, V2C, or V3. auth noauth priv: Sets the security level of V3 users. <i>community-string</i>: Community string or user name (V3). <i>port-num</i>: Configures the port ID of the SNMP host. <i>notification-type</i>: Type of trap messages that are actively sent, for example, snmp.  If no trap type is specified, all trap messages are sent.
Command Mode	Global configuration mode
Usage Guide	This command is used with the snmp-server enable traps command to actively send trap messages to the NMS. You can configure different SNMP hosts to receive trap messages. A host can support different traps, ports, and VRF forwarding tables. If the same host is configured (the port and VRF configuration are the same), the last configuration is combined with the previous configurations, that is, to send different trap messages to the same host, configure one type of trap messages each time. These configurations are finally combined.  In this command, the via parameter can be specified only when the oob parameter is enabled. In addition, the vrf parameter cannot be used.

📌 Enabling the Agent to Actively Send a Trap Message to the NMS

Command	snmp-server enable traps [<i>notification-type</i>]
Parameter Description	<i>notification-type</i>: Enables trap notification for the corresponding events, including the following types: snmp: Enables trap notification for SNMP events. bgp: Enables trap notification for BGP events. bridge: Enables trap notification for bridge events. isis: Enables trap notification for ISIS events. mac-notification: Enables trap notification for MAC events. ospf: Enables trap notification for OSPF events. urpf: Enables trap notification for URPF events. vrrp: Enables trap notification for VRRP events. web-auth: Enables trap notification for Web authentication events.
Command Mode	Global configuration mode
Usage Guide	This command must be used with the snmp-server host command to so that trap messages can be actively sent.

📌 Enabling the Function of Sending a Link Trap Message on an Interface

Command	snmp trap link-status

Parameter Description	-
Configuration mode	Interface configuration mode
Usage Guide	For interfaces (Ethernet interface, AP interface, and SVI interface), when this function is enabled, the SNMP sends a Link Trap message if the link status on the interfaces changes. Otherwise, the SNMP does not send the message.

✚ Enabling the Function of Sending a System Reboot Trap Message

Command	snmp-server system-shutdown
Parameter Description	-
Configuration mode	Global configuration mode
Usage Guide	When the function of notification upon SNMP system reboot is enabled, a trap message is sent to the NMS to notify system reboot before reloading or reboot of the device.

✚ Specifying the Source Address for Sending a Trap Message

Command	snmp-server trap-source <i>interface</i>
Parameter Description	<i>interface</i> : Used as the interface for the SNMP source address.
Configuration mode	Global configuration mode
Usage Guide	By default, the IP address of the interface where SNMP packets are sent is used as the source address. To facilitate management and identification, this command can be run to permanently use one local IP address as the source SNMP address.

✚ Enabling a Trap message to Carry Private Fields when the Message Is Sent

Command	snmp-server trap-format private
Parameter Description	-
Configuration mode	Global configuration mode
Usage Guide	This command can be used to enable a trap message to carry private fields when the message is sent. At present, supported private fields include the alarm generation time. For the specific data types and data ranges of the fields, see RUIJIE-TRAP-FORMAT-MIB.mib.

Configuration Example

✚ Enabling the Trap Function

Scenario Figure 1-8	 The NMS manages network devices (agents) based on the community authentication mode, and network devices can actively send messages to the NMS.
Configuration Steps	- Perform configuration to enable the agent to actively send messages to the NMS. Set the SNMP host address to 192.168.3.2, the message format to Version2c, and the authentication name to user1. Enable the agent to actively send trap messages. - Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
Agent	<pre>Ruijie(config)#snmp-server host 192.168.3.2 traps version 2c user1 Ruijie(config)#snmp-server enable traps Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
Verification	- Run the show running-config command to display configuration information of the device. - Run the show snmp command to display the SNMP status.
Agent	<pre>Ruijie# show running-config ip access-list standard a1 10 permit host 192.168.3.2 interface gigabitEthernet 0/1 no ip proxy-arp ip address 192.168.3.1 255.255.255.0 snmp-server view v1 1.3.6.1.2.1.1 include snmp-server location fuzhou snmp-server host 192.168.3.2 traps version 2c user1 snmp-server enable traps snmp-server contact ruijie.com.cn snmp-server community user1 view v1 rw a1 snmp-server chassis-id 1234567890</pre>

```
Ruijie#show snmp

Chassis: 1234567890

0 SNMP packets input
    0 Bad SNMP version errors
    0 Unknown community name
    0 Illegal operation for community name supplied
    0 Encoding errors
    0 Number of requested variables
    0 Number of altered variables
    0 Get-request PDUs
    0 Get-next PDUs
    0 Set-request PDUs

0 SNMP packets output
    0 Too big errors (Maximum packet size 1472)
    0 No such name errors
    0 Bad values errors
    0 General errors

    0 Trap PDUs

SNMP global trap: enabled
SNMP logging: disabled
SNMP agent: enabled
```

Common Errors

N/A

1.4.3 Shielding the Agent Function

Configuration Effect

Shield the agent function when the agent service is not required.

Notes

- Run the **no snmp-server** command to shield the SNMP agent function when the agent service is not required.

- Different from the shielding command, after the **no enable service snmp-agent** command is run, all SNMP services are directly disabled (that is, the SNMP agent function is disabled, no packet is received, and no response packet or trap packet is sent), but configuration information of the agent is not shielded.

Configuration Steps

Shielding the SNMP Agent Function for the Device

- Optional
- To shield the configuration of all SNMP agent services, use this configuration.

Disabling the SNMP Agent Function for the Device

- Optional
- To directly disable all services, use this configuration.

Verification

Run the **show services** command to check whether SNMP services are enabled or disabled.

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

Shielding the SNMP Agent Function for the Device

Command	no snmp-server
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	By default, the SNMP agent function is disabled. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are set, the SNMP agent service is automatically enabled. The enable service snmp-agent command must also be run at the same time so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the enable service snmp-agent command is not run, the SNMP agent service does not take effect. Run the no snmp-server command to disable SNMP agent services of all versions supported by the device. After this command is run, all SNMP agent service configurations are shielded (that is, after the show running-config command is run, no configuration is displayed. Configurations are restored after the SNMP agent service is enabled again). After the enable service snmp-agent command is run, the SNMP agent configurations are not shielded.

Disabling the SNMP Agent Function for the Device

Command	no enable service snmp-agent

Parameter	N/A
Description	
Configuration mode	Global configuration mode
Usage Guide	This command can be used to disable the SNMP service, but it will not shield SNMP agent parameters.

Configuration Example

Enabling the SNMP Service

Scenario Figure 1-1	 After the SNMP service is enabled and the SNMP agent server is set, the NMS can access devices based on SNMP.
Configuration Steps	1. Enable the SNMP service. 2. Set parameters for the SNMP agent server to make the SNMP service take effect.
A gent	<pre>Ruijie(config)#enable service snmp-agent</pre>
Verification	1. Run the show services command to check whether the SNMP service is enabled or disabled.
Agent	<pre>Ruijie#show service web-server : disabled web-server(https): disabled snmp-agent : enabled ssh-server : disabled telnet-server : enabled</pre>

Common Errors

N/A

1.4.4 Setting SNMP Control Parameters

Configuration Effect

Set basic parameters of the SNMP agent, including the device contact mode, device location, serial number, and parameters for sending a trap message. By accessing the parameters, the NMS can obtain the contact person of the device and physical location of the device.

Notes

N/A

Configuration Steps

📄 Setting the System Contact Mode

- Optional
- When the contact mode of the system needs to be modified, configure this item on the agent.

📄 Setting the System Location

- Optional
- When the system location needs to be modified, configure this item on the agent.

📄 Setting the System Serial Number

- Optional
- When the system serial number needs to be modified, configure this item on the agent.

📄 Setting NE Information about the Device

- Optional
- When the NE code needs to be modified, configure this item on the agent.

📄 Setting the Maximum Packet Length of the SNMP Agent

- Optional
- When the maximum packet length of the SNMP agent needs to be modified, configure this item on the agent.

📄 Setting the UDP Port ID of the SNMP Service

- Optional
- When the UDP port ID of the SNMP service needs to be modified, configure this item on the agent.

📄 Setting the Queue Length of Trap Messages

- Optional
- When the size of the message queue needs to be adjusted to control the message sending speed, configure this item on the agent.

📄 Setting the Interval for Sending a Trap Message

- Optional
- When the interval for sending a trap message needs to be modified, configure this item on the agent.

📌 Configuring SNMP Flow Control

- Optional
- If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

📌 Setting the System Contact Mode

Command	snmp-server contact <i>text</i>
Parameter Description	<i>text</i> : String that describes the system contact mode.
Command Mode	Global configuration mode
Usage Guide	N/A

📌 Setting the System Location

Command	snmp-server location <i>text</i>
Parameter Description	<i>text</i> : String that describes system information.
Configuration mode	Global configuration mode
Usage Guide	N/A

📌 Setting the System Serial Number

Command	snmp-server chassis-id <i>text</i>
Parameter Description	<i>text</i> : Text of the system serial number, which may be digits or characters.
Configuration mode	Global configuration mode
Usage Guide	In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

📌 Setting NE Information about the Device

Command	snmp-server net-id <i>text</i>
Parameter Description	<i>text</i> : Text that is used to set the device NE code. The text is a string that consists of 1 to 255 characters that are case-sensitive and may include spaces.
Configuration mode	Global mode.
Usage Guide	Set the NE code of the device.

📌 Setting the Maximum Packet Length of the SNMP Agent

Command	snmp-server packet-size <i>byte-count</i>
Parameter Description	<i>byte-count</i> : Packet size, ranging from 484 bytes to 17,876 bytes.
Configuration mode	Global mode.
Usage Guide	N/A

📌 Setting the UDP Port ID of the SNMP Service

Command	snmp-server udp-port <i>port-num</i>
Parameter Description	<i>port-num</i> : Specifies the UDP port ID of the SNMP service, that is, the ID of the protocol port that receives SNMP packets.
Configuration mode	Global mode.
Usage Guide	Specify the protocol port ID for receiving SNMP packets.

📌 Setting the Length of a Trap Message Queue

Command	snmp-server queue-length <i>length</i>
Parameter Description	<i>length</i> : Queue length, ranging from 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the size of the message queue to control the message sending speed.

📌 Setting the Interval for Sending a Trap Message

Command	snmp-server trap-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Interval (unit: second). The value range is 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the interval for sending a message to control the message sending speed.

Configuring SNMP Flow Control

Command	snmp-server flow-control pps [count]
Parameter Description	<i>count</i> : Number of SNMP request packets processed per second. The value range is 50 to 65,535.
Command Mode	Global configuration mode
Usage Guide	If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Configuration Example

Setting SNMP Control Parameters

Scenario Figure 1-2	 The diagram illustrates a network setup where an Agent (Ruijie switch) is connected to an NMS (Network Management System, represented by a laptop) via a Gi0/1 interface. The Agent's IP address is 192.168.3.1/24, and the NMS's IP address is 192.168.3.2/24. The NMS manages network devices (agents) based on the community authentication mode and can obtain basic system information about the devices, for example, system contact mode, location, and serial number.
Configuration Steps	- Set SNMP agent parameters. Set the system location, contact mode, and serial number. - Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.
Agent	<pre>Ruijie(config)#snmp-server location fuzhou Ruijie(config)#snmp-server contact ruijie.com.cn Ruijie(config)#snmp-server chassis-id 1234567890 Ruijie(config)#interface gigabitEthernet 0/1 Ruijie(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0 Ruijie(config-if-gigabitEthernet 0/1)#exit</pre>
Verification	- Check the configuration information of the device. - Check the SNMP view and group information.
Agent	<pre>Ruijie# show running-config ip access-list standard al 10 permit host 192.168.3.2</pre>

	<pre>interface gigabitEthernet 0/1 no ip proxy-arp ip address 192.168.3.1 255.255.255.0 snmp-server view v1 1.3.6.1.2.1.1 include snmp-server location fuzhou snmp-server host 192.168.3.2 traps version 2c user1 snmp-server enable traps snmp-server contact ruijie.com.cn snmp-server community user1 view v1 rw al snmp-server chassis-id 1234567890</pre>

Displays the SNMP status.	show snmp [mib user view group host]

2 Configuring RMON

2.1 Overview

The Remote Network Monitoring (RMON) aims at resolving problems of managing local area networks (LANs) and remote sites by using one central point. In RMON, network monitoring data consists of a group of statistics and performance indicators, which can be used for monitoring the network utilization, so as to facilitate network planning, performance optimization, and network error diagnosis.

RMON is mainly used by a managing device to remotely monitor and manage managed devices.

Protocols and Standards

STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base

RFC4502: Remote Network Monitoring Management Information Base Version 2

RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)

RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules

RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms

RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions

RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services

RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks

RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros

RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

2.2 Applications

Application	Description
Collecting Statistics on Information of a Monitored Interface	Applies four functions of RMON to an interface to monitor the network communication of the interface.

2.2.1 Collecting Statistics on Information of a Monitored Interface

Scenario

The RMON Ethernet statistics function is used to monitor accumulated information of an interface, the history statistics function is used to monitor the packet count of an interface within each monitoring interval, and the alarm function is used to immediately acquire packet count exceptions of an interface. The following figure shows the networking topology.

Figure 2-1

Deployment

The interface is monitored to accumulatively collect statistics on the packet count of the interface and collect statistics on the packet count and bandwidth utilization of the interface within the monitoring interval. If a packet count exception occurs on the interface, an alarm is reported to the network management system (NMS). The configuration key points are as follows:

- Configure the RMON Ethernet statistics function on the interface.
- Configure the RMON history statistics function on the interface.
- Configure the RMON alarm table and define RMON event processing actions in configuration mode. Monitored objects of alarms are the object identifier (OID) values of specific fields in the RMON Ethernet statistical table configured for the interface.

2.3 Features

Basic Concepts

RMON defines multiple RMON groups. Ruijie products support the statistics group, history group, alarm group, and event group, which are described as follows:

Statistics Group

The statistics group is used to monitor and collect statistics on Ethernet interface traffic information, which is accumulated from the entry creation time to the current time. The statistical items include discarded data packets, broadcast data packets, cyclic redundancy check (CRC) errors, large and small blocks, and collisions. Statistical results are stored in the Ethernet statistical table.

History Group

The history group is used to periodically collect network traffic information. It records accumulated values of network traffic information and the bandwidth utilization within each interval, and saves them in the history control table. It includes two small groups:

- The HistoryControl group is used to set the sampling interval, sampling data source, and other control information.
- The EthernetHistory group provides administrators with historical data, including statistics on network segment traffic, error packets, broadcast packets, utilization, and number of collisions.

Alarm Group

The alarm group is used to monitor a specified Management Information Base (MIB) object. When the value of a MIB object exceeds the preset upper limit or is lower than the preset lower limit, an alarm is triggered and the alarm is processed as an event.

Event Group

The event group is used to define the event processing mode. When a monitored MIB object meets alarm conditions, an event is triggered. An event can be processed in any of the following modes:

- none: No action is taken.
- log: Event-relevant information is recorded in the log record table so that administrators can view it at any time.
- snmp-trap: A trap message is transmitted to the NMS to notify the NMS of the event occurrence.
- log-and-trap: Event-relevant information is recorded in the log record table and a trap message is transmitted to the NMS.

Working Principle

RMON supports multiple monitors and two data collection methods. Method 1: A dedicated RMON probe is used to collect data and the NMS can directly acquire all information about the RMON MIB from the RMON probe. Method 2: RMON agents are built into network devices so that the devices have the RMON probe function. The NMS uses basic commands of the Simple Network Management Protocol (SNMP) to exchange data with the RMON agents and collect network management information. This method, however, is limited by device resources and information of only four groups rather than all data of the RMON MIB is acquired.

The following figure shows an example of communication between the NMS and RMON agents. The NMS, through the RMON agents running on devices, can acquire information about overall traffic, error statistics, and performance statistics of the network segment where a managed network device interface is, thereby implementing remote management of network devices.

Figure 2-2

Overview

Feature	Description
RMON Ethernet Statistics	Collects statistics on the packet count, byte count, and other data of a monitored Ethernet interface accumulatively.
RMON History Statistics	Records the counts of packets, bytes, and other data communicated by an Ethernet interface within the configured interval and calculates the bandwidth utilization within the interval.
RMON Alarm	Samples values of monitored variables at intervals. The alarm table is used in combination with the event table. When the upper or lower limit is reached, a relevant event table is triggered to perform event processing or no processing is performed.

2.3.1 RMON Ethernet Statistics

Working Principle

The RMON Ethernet statistics function accumulatively collects statistics on network traffic information of an Ethernet interface from the entry creation time to the current time.

Related Configuration

📌 Configuring RMON Statistical Entries

- The RMON Ethernet statistics function is disabled by default.
- Run the **rmon collection stats** command to create Ethernet statistical entries on a specified Ethernet interface.
- After statistical entries are successfully created on a specified interface, the statistics group collects statistics on the traffic information of the current interface. The statistical items are variables defined in the RMON Ethernet statistical table, and recorded information is the accumulated values of variables from the creation time of the RMON statistical table to the current time.

2.3.2 RMON History Statistics

Working Principle

The RMON history statistics function records accumulated statistics on traffic information of an Ethernet interface within each interval.

Related Configuration

📌 Configuring RMON Historical Control Entries

- The RMON history statistics function is disabled by default.
- Run the **rmon collection history** command to create historical control entries on an Ethernet interface.
- The RMON history group collects statistics on variables defined in the RMON history table and records accumulated values of variables within each interval.

2.3.3 RMON Alarm

Working Principle

The RMON alarm function periodically monitors value changes of alarm variables. If the value of an alarm variable reaches the specified upper threshold or lower threshold, a corresponding event is triggered for processing, for example, a trap message is transmitted or one logTable entry record is generated. If a lower threshold or upper threshold is reached multiple times consecutively, only one corresponding event is triggered and another event is triggered till a reverse threshold is reached.

Related Configuration

Configuring the Event Table

- The RMON event group function is disabled by default.
- Run the **rmon event** command to configure the event table.

Configuring Alarm Entries

- The RMON alarm group function is disabled by default.
- Run the **rmon event** command to configure the event table and run the **rmon alarm** command to configure the RMON alarm table.
- The RMON alarm function is implemented by the alarm table and event table jointly. If a trap message needs to be transmitted to a managing device in the case of an alarm event, the SNMP agent must be correctly configured first. For the configuration of the SNMP agent, see the *Configuring SNMP*.
- If a configured alarm object is a field node in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function need to be configured on a monitored Ethernet interface first.

2.4 Configuration

Configuration	Description and Command	
Configuring RMON Ethernet Statistics	 (Mandatory) It is used to accumulatively collect statistics on traffic information of an Ethernet interface.	
	rmon collection stats	Configures Ethernet statistical entries.
Configuring RMON History Statistics	 (Mandatory) It is used to collect, at intervals, statistics on traffic information of an Ethernet interface and the bandwidth utilization within the interval.	
	rmon collection history	Configures historical control entries.
Configuring RMON Alarm	 (Mandatory) It is used to monitor whether data changes of a variable is within the valid range.	
	rmon event	Configures event entries.

Configuration	Description and Command	
	rmon alarm	Configures alarm entries.

2.4.1 Configuring RMON Ethernet Statistics

Configuration Effect

Acquire accumulated statistics on traffic information of a monitored Ethernet interface from the entry creation time to the current time.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

📌 Configuring RMON Statistical Entries

- Mandatory.
- If statistics and monitoring are required for a specified interface, Ethernet statistical entries must be configured on this interface.

Verification

Run the **show rmon stats** command to display Ethernet statistics.

Related Commands

📌 Configuring RMON Statistical Entries

Command	rmon collection stats <i>index</i> [owner <i>ownername</i>]
Parameter	<i>index</i> : Indicates the index number of a statistical entry, with the value ranging from 1 to 65,535.
Description	owner <i>ownername</i> : Indicates the entry creator, that is, <i>ownername</i> , which is a case-sensitive string of 1-63 characters.
Command Mode	Interface configuration mode
Usage Guide	The values of statistical entry parameters cannot be changed.

Configuration Example

📌 Configuring RMON Ethernet Statistics

Scenario Figure 2-3	
	As shown in the preceding figure, the RMON agent is connected to the server, and the NMS requires the RMON statistics group to conduct performance statistics on received packets of interface Gi0/1. Administrators can view the statistics at any time to understand data about received packets of an interface and take measures in a timely manner to handle network exceptions.
Configuration Steps	● Configure a statistical table instance on interface GigabitEthernet 0/1 to collect statistics on the traffic of this interface.
Agent	<pre>Ruijie# configure terminal Ruijie (config)# interface gigabitEthernet 0/1 Ruijie (config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin</pre>
Verification	Run the show rmon stats command to display Ethernet statistics.
Agent	<pre>Ruijie# show rmon stats ether statistic table: index = 1 interface = GigabitEthernet 0/1 owner = admin status = 1 dropEvents = 0 octets = 25696 pkts = 293 broadcastPkts = 3 multiPkts = 0 crcAlignErrors = 0 underSizePkts = 0 overSizePkts = 0 fragments = 0</pre>

```

jabbers = 0

collisions = 0

packets640ctets = 3815

packets65To1270ctets = 1695

packets128To2550ctets = 365

packets256To5110ctets = 2542

packets512To10230ctets = 152

packets1024To15180ctets = 685

```

Common Errors

Statistical table entries are re-configured or configured statistical table entries are modified.

2.4.2 Configuring RMON History Statistics

Configuration Effect

Acquire accumulated statistics on the traffic of a monitored Ethernet interface and the bandwidth utilization within each interval.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

- Mandatory.
- If network statistics on a specified interface need to be collected, RMON historical control entries must be configured on the interface.

Verification

Run the **show rmon history** command to display history group statistics.

Related Commands

Configuring RMON Historical Control Entries

Command	rmon collection history <i>index</i> [owner <i>ownername</i>] [buckets <i>bucket-number</i>] [interval <i>seconds</i>]
Parameter	<i>index</i> : Indicates the index number of a history statistical entry, with the value ranging from 1 to 65,535.
Description	owner <i>ownername</i> : Indicates the entry creator, that is, <i>ownername</i> , which is a case-sensitive string of 1-63 characters. buckets <i>bucket-number</i> : Sets the capacity of the history table in which a history statistical entry exists, that is, sets the maximum number of records (<i>bucket-number</i>) that can be accommodated in the history table.

	The value of <i>bucket-number</i> ranges from 1 to 65,535 and the default value is 10. interval seconds: Sets the statistical interval, with the unit of seconds. The value ranges from 1 second to 3,600 seconds and the default value is 1,800 seconds.
Command Mode	Interface configuration mode
Usage Guide	The values of history statistical entry parameters cannot be changed.

Configuration Example

Configuring RMON History Statistics

Scenario Figure 2-4	 <pre> graph LR Server[Server] --- Gi0/1 Agent[Agent] Agent --- Console[Console] --- Terminal[Terminal] Agent --- Network((Network)) </pre>
	As shown in the preceding figure, the RMON agent is connected to the server, and the NMS needs to collect statistics on received packets of interface Gi0/1 through the RMON history group at an interval of 60 seconds, in an effort to monitor the network and understand emergency data.
Configuration Steps	Configure the history control table on interface GigabitEthernet 0/1 to periodically collect statistics on the traffic of this interface.
Agent	<pre> Ruijie# configure terminal Ruijie(config)# interface gigabitEthernet 0/1 Ruijie(config-if-GigabitEthernet 0/1)# rmon collection history 1 buckets 5 interval 300 owner admin </pre>
Verification	Run the show rmon history command to display history group statistics.
Agent	<pre> Ruijie# show rmon history rmon history control table: index = 1 interface = GigabitEthernet 0/1 bucketsRequested = 5 bucketsGranted = 5 interval = 60 owner = admin </pre>

Common Errors

History control table entries are re-configured or configured history control table entries are modified.

2.4.3 Configuring RMON Alarm

Configuration Effect

Periodically monitor whether value changes of alarm variables are within the specified valid range.

Notes

If a trap message needs to be transmitted to a managing device when an alarm event is triggered, the SNMP agent must be correctly configured. For the configuration of the SNMP agent, see the *Configuring SNMP*.

If an alarm variable is a MIB variable defined in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function must be configured on the monitored Ethernet interface. Otherwise, an alarm table fails to be created.

Configuration Steps

Configuring Event Entries

- Mandatory.
- Complete the configuration in global configuration mode.

Configuring Alarm Entries

- Mandatory.
- Complete the configuration in global configuration mode.

Verification

- Run the **show rmon event** command to display the event table.
- Run the **show rmon alarm** command to display the alarm table.

Related Commands

Configuring the Event Table

Command	rmon event <i>number</i> [log] [trap <i>community</i>] [description <i>description-string</i>] [owner <i>ownername</i>]
Parameter Description	<i>number</i>: Indicates the index number of an event table, with the value ranging from 1 to 65,535. log: Indicates a log event. The system logs a triggered event. trap <i>community</i>: Indicates a trap event. When an event is triggered, the system transmits a trap message with the community name of <i>community</i>. description <i>description-string</i>: Sets the description information about an event, that is, <i>description-string</i>. The value is a string of 1-127 characters. owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.
Command Mode	Global configuration mode
Usage Guide	The values of configured event entry parameters can be changed, including the event type, trap community name, event description, and event creator.

Configuring the RMON Alarm Group

Command	rmon alarm <i>number</i> <i>variable</i> <i>interval</i> { absolute delta } rising-threshold <i>value</i> [<i>event-number</i>] falling-threshold <i>value</i> [<i>event-number</i>] [owner <i>ownername</i>]
Parameter Description	<i>number</i>: Indicates the index number of an alarm entry, with the value ranging from 1 to 65,535. <i>variable</i>: Indicates an alarm variable, which is a string of 1-255 characters and is represented in dotted format using the node OID (format: entry.integer.instance; example: 1.3.6.1.2.1.2.1.10.1). <i>Interval</i>: Indicates the sampling interval, with the unit of seconds and the value ranging from 1 to 2,147,483,647. absolute: Indicates that the sampling type is absolute value sampling, that is, variable values are directly

	extracted when the sampling time is up. delta: Indicates that the sampling type is changing value sampling, that is, changes in the variable values within the sampling interval are extracted when the sampling time is up. rising-threshold value: Sets the upper limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647. event-number: Indicates that an event with the event number of <i>event-number</i> is triggered when the upper limit or lower limit is reached. falling-threshold value: Sets the lower limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647. owner ownername: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.
Command Mode	Global configuration mode
Usage Guide	Values of configured alarm entry parameters can be changed, including alarm variables, sampling type, entry creator, sampling interval, upper/lower limit of the sampling quantity, and relevant trigger events.

Configuration Example

Configuring RMON Alarm

Scenario
Figure 2-5

Assume that SNMPv1 runs on the NMS, the community name used for accessing the settings is public, with the attribute of read-write, and the IP address used by the NMS to receive trap messages is 3.3.3.3.

Assume that the OID value of unknown protocol packets received by monitored interface GigabitEthernet0/1 is 1.3.6.1.2.1.2.2.1.15.3, the sampling mode is relative sampling, and the sampling interval is 60 seconds. When the relative sampling value is larger than 100 or lower than 10, event 1 and event 2 are triggered respectively. In event 1, a trap message is transmitted and the event is logged. In event 2, the event is only logged.

The configuration of the RMON agent is completed on the terminal. The RMON agent is connected to the NMS and is connected to the server through interface Gi0/1. The RMON agent needs to monitor the count of unknown protocol packets received by interface Gi0/1. The sampling interval is 60 seconds. When the absolute sampling value is smaller than 10, the event is only logged. When the absolute sampling value is larger than 100, the event is logged and a trap message is transmitted to the NMS.

Configuration Steps	● Configure the host address for receiving trap messages. ● Configure an event group to process alarm trigger. ● Configure the alarm function.
Agent	<pre> Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# snmp-server community public rw Ruijie(config)# snmp-server host 3.3.3.3 trap public Ruijie(config)# rmon event 1 description rising-threshold-event log trap public owner admin Ruijie(config)# rmon event 2 description falling-threshold-event log owner admin Ruijie(config)# rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2 owner admin </pre>
Verification	● Run the show rmon event command to display the event table. ● Run the show rmon alarm command to display the alarm table.
Agent	<pre> Ruijie# show rmon event rmon event table: index = 1 description = rising-threshold-event type = 4 community = public lastTimeSent = 0d:0h:0m:0s owner = admin status = 1 index = 2 description = falling-threshold-event type = 2 community = lastTimeSent = 6d:19h:21m:48s owner = admin </pre>

	<pre> status = 1 rmon log table: eventIndex = 2 index = 1 logTime = 6d:19h:21m:48s logDescription = falling-threshold-event Ruijie# show rmon alarm rmon alarm table: index: 1, interval: 60, oid = 1.3.6.1.2.1.2.2.1.15.3 sampleType: 2, alarmValue: 0, startupAlarm: 3, risingThreshold: 100, fallingThreshold: 10, risingEventIndex: 1, fallingEventIndex: 2, owner: admin, stauts: 1 </pre>

Common Errors

- The entered OID of a monitored object is incorrect, the variable corresponding to the OID does not exist, or the type is not an integer or unsigned integer.
- The upper threshold is smaller than or equal to the lower threshold.

2.5 Monitoring

Displaying

Description	Command
Displays all RMON configuration information.	show rmon

Description	Command
Displays the Ethernet statistical table.	show rmon stats
Displays the history control table.	show rmon history
Displays the alarm table.	show rmon alarm
Displays the event table.	show rmon event

3 Configuring NTP

3.1 Overview

The Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment.

Currently, Ruijie devices can be used both as NTP clients and NTP servers. In other words, a Ruijie device can synchronize time with a time server, and be used as a time server to provide time synchronization for other devices. When a Ruijie device is used as a server, it supports only the unicast server mode.

Protocols and Standards

- RFC 1305 : Network Time Protocol (Version 3)

3.2 Applications

Application	Description
Synchronizing Time Based on an External Reference Clock Source	A device is used as a client that synchronizes time with an external clock source. After successful synchronization, it is used as a server to provide time synchronization for other devices.
Synchronizing Time Based on a Local Reference Clock Source	A device uses a local clock as a reliable NTP reference clock source and is also used as a server to provide time synchronization for other devices.

3.2.1 Synchronizing Time Based on an External Reference Clock Source

Scenario

As shown in Figure 3-1

- DEVICE-A is used as a reliable reference clock source to provide time synchronization for external devices.
- DEVICE-B specifies DEVICE-A as the NTP server and synchronizes time with DEVICE-A.
- After successful synchronization, DEVICE-B provides time synchronization for DEVICE-C.

Figure 3-1

Deployment

Configure DEVICE-B to the NTP external reference clock mode.

3.2.2 Synchronizing Time Based on a Local Reference Clock Source

Scenario

As shown in Figure 3-2, DEVICE-B uses a local clock as the NTP reference clock source and provides time synchronization for DEVICE-C.

Figure 3-2

Deployment

Configure DEVICE-B to the NTP local reference clock mode.

3.3 Features

Basic Concepts

📄 NTP Packet

As defined in RFC1305, NTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 3-3 shows the format of an NTP time synchronization packet.

Figure 3-3 Format of an NTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

i 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.

- Version Number(VN): indicates a 3-bit NTP version number. The current version number is 3.
- Mode: indicates a 3-bit NTP working mode.

i 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.

- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master reference clock source; other values: indicate slave reference clock sources.
- Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
- Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.
- Root Delay: indicates the round-trip time to the master reference clock source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

↘ NTP Server

A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

↘ NTP Client

A device is used as an NTP client that synchronizes time with an NTP server in the network.

↘ Stratum

In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratum values have higher clock precisions.

↘ Hardware Clock

A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

Overview

Feature	Description
NTP Time Synchronization	Network devices synchronize time with their servers or reliable clock sources to implement high-precision time correction.
NTP Security Authentication	The NTP packet encryption authentication is used to prevent unreliable clock sources from time synchronization interference on a device.
NTP Access Control	An Access Control List (ACL) is used to filter sources of received NTP packets.

3.3.1 NTP Time Synchronization

Working Principle

NTP time synchronization is implemented by interaction of NTP packets between a client and a server:

- The client sends a time synchronization packet to all servers every 64 seconds. After receiving response packets from the servers, the client filters and selects the response packets from all servers, and synchronizes time with an optimum server.
- After receiving the time synchronization request packet, a server uses the local clock as the reference source, and fills the local time information into the response packet to be sent to the client based on the protocol requirement.

Figure 3-4 shows the format of an NTP time synchronization packet.

Figure 3-4 Working Principle of NTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an NTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

📌 NTP Working Mode

- External clock reference mode

In this mode, a device is used as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server first and provide time synchronization for the clients after successful synchronization.

- Local clock reference mode

In this mode, a device uses the default local clock as the reliable clock source and provides time synchronization directly for other clients.

Related Configuration

📌 Configuring an NTP Server

- The NTP function is disabled by default.
- Run the **ntp server** command to specify an NTP server (external clock reference source), which can enable NTP.
- After the configuration, the device works in the external clock reference mode.

↘ Real-time Synchronization

- A device performs time synchronization every 64 seconds by default.

↘ Updating a Hardware Clock

- By default, a device does not update synchronized time to the hardware clock.
- Run the **ntp update-calendar** command to enable a device to automatically update the hardware clock after successfully synchronizing time each time.

↘ Configuring the NTP Master Clock

- By default, a device works in the external clock reference mode.
- Run the **ntp master** command to configure a device to the local clock reference mode.

3.3.2 NTP Security Authentication

To prevent malicious damage on an NTP server, NTP uses the authentication mechanism to check whether the time synchronization information is really from the announced server and check the information return path to provide an anti-interference protection mechanism.

Working Principle

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

Related Configuration

↘ Configuring a Global Security Authentication Mechanism for NTP

- By default, no NTP security authentication mechanism is enabled.
- Run the **ntp authenticate** command to enable the NTP security authentication mechanism.

↘ Configuring a Global Authentication Key for NTP

- By default, no global authentication key is configured.
- Run the **ntp authentication-key** command to enable an NTP global authentication key.

↘ Configuring a Globally Trusted Key ID for NTP

- By default, no globally trusted key is configured.
- Run the **ntp trusted-key** command to configure a device as the reference clock source to provide a trusted key for time synchronization externally.

↘ Configuring a Trusted Key ID for an External Reference Clock Source

- Run the **ntp server** command to specify an external reference source and the trusted key of this clock source as well.

3.3.3 NTP Access Control

Working Principle

Provide a minimum security measure by using an ACL.

Related Configuration

📌 Configuring the Access Control Rights for NTP Services

- By default, there is no access control right for NTP.
- Run the **ntp access-group** command to configure the access control rights for NTP.

3.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of NTP	 (Mandatory) It is used to enable NTP. After NTP is enabled, a device works in the external clock reference mode.	
	ntp server	Configures an NTP server.
	ntp update-calendar	Automatically updates a hardware clock.
	 (Optional) It is used to configure a device to the local clock reference mode.	
	ntp master	Configures the NTP master clock.
	 (Optional) It is used to disable NTP.	
	no ntp	Disables all functions of NTP and clears all NTP configurations.
	ntp disable	Disables receiving of NTP packets from a specified interface.
Configuring NTP Security Authentication	ntp service disable	Disables the NTP time synchronization service.
	 (Optional) It is used to prevent unreliable clock sources from performing time synchronization interference on a device.	
	ntp authenticate	Enables a security authentication mechanism.
	ntp authentication-key	Configures a global authentication key.
	ntp trusted-key	Configures a trusted key for time synchronization.

	ntp server	Configures a trusted key for an external reference clock source.
Configuring NTP Access Control	 (Optional) It is used to filter the sources of received NTP packets.	
	ntp access-group	Configures the access control rights for NTP.

3.4.1 Configuring Basic Functions of NTP

Configuration Effect

External Clock Reference Mode

- Use a device as a client to synchronize time from an external reference clock source to the local clock.
- After the time synchronization is successful, use the device as a time synchronization server to provide time synchronization.

Local Clock Reference Mode

- Use the local clock of a device as the NTP reference clock source to provide time synchronization.

Notes

- In the client/server mode, a device can be used as a time synchronization server to provide time synchronization only after successfully synchronizing time with a reliable external clock source.
- Once the local clock reference mode is configured, the system will not synchronize time with a clock source with a higher stratum.
- Configuring a local clock as the master clock (especially when specifying a lower stratum) may overwrite an effective clock source. If this command is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the system time configuration section in the configuration guide.

Configuration Steps

Configuring an NTP Server

- (Mandatory) At least one external reference clock source must be specified (A maximum of 20 different external reference clock sources can be configured).
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server.

Automatically Updating a Hardware Clock

- Optional.
- By default, the system updates only the system clock, but not the hardware clock after successful time synchronization.
- After this command is configured, the system automatically updates the hardware clock after successful time synchronization.

✚ Configuring the NTP Master Clock

- To switch a device to the local clock reference mode, run this command.

✚ Disabling NTP

- To disable NTP and clear NTP configurations, run the **no ntp** command.
- By default, all interfaces can receive NTP packets after NTP is enabled. To disable NTP for a specified interface, run the **ntp disable** command.

✚ Disabling the NTP Time Synchronization Service

- NTP works in client/server mode. After the NTP device synchronizes time from an external reliable clock source, it serves as the time server to provide the time synchronization service. If the device just needs to be served as an NTP client, configure the **ntp service disable** command to disable the NTP time synchronization service.

Verification

- Run the **show ntp status** command to display the NTP configuration.
- Run the **show clock** command to check whether time synchronization is completed.

Related Commands

✚ Configuring an NTP Server

Command	ntp server [oob vrf <i>vrf-name</i>]{ <i>ip-addr</i> <i>domain</i> ip <i>domain</i> ipv6 <i>domain</i> }[version <i>version</i>] [source <i>if-name</i>] [key <i>keyid</i>][prefer] [via <i>mgmt-name</i>]
Parameter Description	oob: Indicates whether a reference clock source is bound to the MGMT interface. vrf-name: Indicates the name of the VRF that is bound to the reference clock source. ip-addr: Indicates the IPv4/IPv6 address of the reference clock source. domain: Indicates the IPv4/IPv6 domain name of the reference clock source. version: Indicates the NTP version number, ranging from 1 to 3. if-name: Indicates the interface type, including AggregatePort, Dialer GigabitEthernet, Loopback, Multilink, Null, Tunnel, Virtual-ppp, Virtual-template and VLAN. keyid: Indicates the key used for communicating with the reference clock source, ranging from 1 to 4294967295. prefer: Indicates whether the reference clock source has a high priority. mgmt-name: Specifies the egress management interface for packets in the oob mode.
Command Mode	Global configuration mode

Usage Guide	By default, no NTP server is configured. Ruijie client system supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.
	 If it is necessary to configure an authentication key, you must configure NTP security authentication before configuring an NTP server.
	The default version of NTP for communicating with a server is NTP version 3. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.

✚ Updating a Hardware Clock

Command	ntp update-calendar
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring a Local Reference Clock Source

Command	ntp master[<i>stratum</i>]
Parameter Description	<i>stratum</i> : specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Disabling NTP

Command	no ntp
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command can be used to fast disable all functions of NTP and clear all NTP configurations.

✚ Disabling Receiving of NTP Packets on an Interface

Command	ntp disable
Parameter Description	N/A
Command Mode	Interface configuration mode

Usage Guide	N/A

Disabling the Time Synchronization Service Provided by NTP

Command	ntp service disable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command disables the NTP time synchronization service. After this command is configured, external devices cannot be synchronized time from the NTP device (this command is supported only in some versions).

Configuration Example

External Clock Reference Mode of NTP

Scenario Figure 3-5	
	● DEVICE-B is configured to the NTP external clock reference mode. ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● DEVICE-A configures the local clock as the NTP reference clock source. ● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-A	<pre>A#configure terminal A(config)# ntp master A(config)#exit</pre>
DEVICE-B	<pre>B#configure terminal B(config)# ntp server 192.168.1.1 B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>

Verification	● Run the show ntp status command on DEVICE-B to display the NTP configuration. ● DEVICE-B sends a time synchronization packet to 192.168.1.1 in order to synchronize time with DEVICE-A. ● After successfully synchronizing time with DEVICE-A, DEVICE-B can respond to the time synchronization request from DEVICE-C. ● Run the show clock command on DEVICE-B and DEVICE-C to check whether the time synchronization is successful.

Local Clock Reference Mode of NTP

Scenario Figure 3-6	
	● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<pre>B#configure terminal B(config)# ntp master B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
Verification	● Run the show clock command on DEVICE-C to check whether the time synchronization is successful.

3.4.2 Configuring NTP Security Authentication

Configuration Effect

Synchronizing Time from a Trusted Reference Clock Source

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.

Providing Time Synchronization for a Trusted Device

Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

Notes

The authentication keys of the client and server must be the same.

Configuration Steps

✚ Configuring a Global Security Authentication Mechanism for NTP

- Mandatory.
- By default, a device disables the security authentication mechanism.

✚ Configuring a Global Authentication Key for NTP

- Mandatory.
- By default, a device is not configured with an authentication key.

✚ Configuring a Globally Trusted Key ID for NTP

- Optional.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID.
- Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.

✚ Configuring an Authentication Key ID for an External Reference Clock Source

- Optional.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID.
- Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.

Verification

- Run the **show run** command to verify the NTP configuration.
- Run the **show clock** command to check whether time is synchronized only with a trusted device.

Related Commands

✚ Enabling a Security Authentication Mechanism

Command	ntp authenticate
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, a client does not use a global security authentication mechanism. If no security authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication

between the client and server.

Configuring a Global Authentication Key

Command	ntp authentication-key <i>key-id</i> md5 <i>key-string</i> [<i>enc-type</i>]
Parameter Description	<i>key-id</i> : indicates the ID of a global authentication key, ranging from 1 to 4294967295. <i>key-string</i> : indicates a key string. <i>enc-type</i> : (optional) indicates whether an entered key is encrypted. 0 indicates no encryption, and 7 indicates simple encryption. The default setting is no encryption.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Trusted Key for NTP

Command	ntp trusted-key <i>key-id</i>
Parameter Description	<i>key-id</i> : Indicates the ID of a trusted key, ranging from 1 to 4294967295.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Trusted Key for an External Reference Clock Source

Refer to the section "Related Commands".

Configuration Example

Security Authentication

Scenario Figure 3-7	
	● DEVICE-B is configured to the NTP client/server mode and provides NTP services requiring security authentication for DEVICE-C. The authentication key is "abcd". ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<pre> B#configure terminal B(config)# ntp authentication-key 1 md5 abcd B(config)# ntp trusted-key 1 </pre>

	<pre>B(config)# ntp server 192.168.1.1 B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp authentication-key 1 md5 abcd C(config)# ntp server 192.168.2.1 key 1 C(config)# exit</pre>
Verification	● DEVICE-B sends a time synchronization packet that carries authentication information to 192.168.1.1 in order to synchronize time with DEVICE-A. ● Run the show clock command on DEVICE-B to check whether the time synchronization is successful.

3.4.3 Configuring NTP Access Control

Configuration Effect

Access control for NTP services provides a minimum security measure. A more secure method is to use an NTP authentication mechanism.

Notes

- Currently, the system does not support control query (used to control NTP servers by using network management devices, such as setting the leap second indicator or monitoring its working status). Though rule matching is implemented in the preceding sequence, no request related to control query is supported.
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.

Related Configuration

📌 Configuring the Access Control Rights for NTP

- Optional.
- Run the **ntp access-group** command to configure the access control rights and a corresponding ACL for NTP.

Verification

Run the **show run** command to verify the NTP configuration.

Related Commands

📌 Configuring the Access Control Rights for NTP Services

Command	ntp access-group { peer serve serve-only query-only }access-list-number access-list-name
Parameter	peer: allows time request and control query for local NTP services, and allows a local device to synchronize

Description	time with a remote system (full access rights). serve: allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system. serve-only: allows only time request for local NTP services. query-only: allows only control query for local NTP services. <i>access-list-number</i>: indicates the number of an IP ACL, ranging from 1 to 99 and from 1300 to 1999. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>. <i>access-list-name</i>: indicates the name of an IP ACL. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.
Command Mode	Global configuration mode
Usage Guide	Configure NTP access control rights. When an access request arrives, the NTP service matches rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is peer, serve, serve-only, and query-only.

Configuration Example

Configuring NTP Access Control Rights

Configuration Steps	Allow only the device with the IP address of 192.168.1.1 to send a time synchronization request to a local device.
	<pre>Ruijie(config)# access-list 1 permit 192.168.1.1 Ruijie(config)# ntp access-group serve-only 1</pre>

3.5 Monitoring

Displaying

Description	Command
show ntp status	Displays the current NTP information.

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
debug ntp	Enables debugging.
no debug ntp	Disables debugging.

4 Configuring SNTP

4.1 Overview

The Simple Network Time Protocol (SNTP) is a simplified version of Network Time Protocol (NTP), which is used to synchronize the clocks of computers on the Internet. SNTP is applied in scenarios where it is unnecessary to use all NTP functions.

NTP uses a complex algorithm and has higher requirements for the system whereas SNTP uses a simpler algorithm and provides higher performance. Generally, SNTP precision can reach about 1s, which meets the basic requirements of most scenarios. Since SNTP packets are the same as NTP packets, the SNTP client implemented on a device is fully compatible with an NTP server.

Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

4.2 Applications

Application	Description
Synchronizing Time with an NTP Server	A device is used as a client to synchronize time with an NTP server.

4.2.1 Synchronizing Time with an NTP Server

Scenario

As shown in Figure 4-1, DEVICE-B uses a local clock as the NTP clock reference source and provides time synchronization for DEVICE-C.

DEVICE-C is used as an SNTP client to synchronize time with DEVICE-B.

Figure 4-1

Deployment

- Specify DEVICE-B as the SNTP server of DEVICE-C.
- Enable SNTP for DEVICE-C.

4.3 Features

Basic Concepts

SNTP Packet

SNTPV4 is developed from NTP, which is intended to simplify the functions of NTP. It does not change the NTP specifications and the original implementation of NTP. The message format of SNTPV4 is the same as that of NTP defined in RFC1305, with only some data fields initialized into preset values.

As defined in RFC1305, SNTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 4-2 shows the format of an SNTP time synchronization packet.

Figure 4-2 Format of an SNTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.
-
- 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.
-
- Version Number(VN): indicates a 3-bit NTP/SNTP version number. The current version number is 3.
 - Mode: indicates a 3-bit SNTP/NTP working mode.
-
- 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.
-
- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master clock reference source; other values: indicate slave clock reference sources.
 - Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
 - Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.

- Root Delay: indicates the round-trip time to the master clock reference source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

Overview

Feature	Description
SNTP Time Synchronization	Synchronizes time from an SNTP/NTP server to a local device.

4.3.1 SNTP Time Synchronization

Working Principle

SNTP time synchronization is implemented by interaction of SNTP/NTP packets between a client and a server. The client sends a time synchronization packet to the server at intervals (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

Figure 4-3 shows the format of an SNTP time synchronization packet.

Figure 4-3 Working Principle of SNTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an SNTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

Related Configuration

↘ Enabling SNTP

- SNTP is disabled by default.
- Run the **sntp enable** command to enable SNTP.

↘ Configuring an SNTP Server

- By default, no SNTP server is configured.
- Run the **sntp server** command to specify an SNTP server.

↘ Configuring the SNTP Time Synchronization Interval

- By default, the SNTP time synchronization interval is 1,800s.
- Run the **sntp interval** command to specify the time synchronization interval.

4.4 Configuration

Configuration	Description and Command	
Configuring SNTP	 (Mandatory) It is used to enable SNTP.	
	sntp enable	Enables SNTP.
	sntp server	Configures the IP address of an SNTP server.
	 (Optional) It is used to configure the SNTP time synchronization interval.	

Configuration	Description and Command	
	sntp interval	Configures the SNTP time synchronization interval.

4.4.1 Configuring SNTP

Configuration Effect

An SNTP client accesses an NTP server at fixed intervals to correct the clock regularly.

Notes

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

Configuration Steps

➤ Enabling SNTP

- (Mandatory) SNTP is disabled by default.

➤ Configuring the IP address of an SNTP Server

- (Mandatory) No SNTP/NTP server is configured by default.

➤ Configuring the SNTP Time Synchronization Interval

- Optional.
- By default, a device synchronizes time every half an hour.

Verification

Run the **show sntp** command to display SNTP-related parameters.

Related Commands

➤ Enabling SNTP

Command	sntp enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	SNTP is disabled by default. Run the no sntp enable global configuration command to disable SNTP.

➤ Configuring the IP address of an SNTP Server

Command	sntp server [oob] ip-address [via mgmt-name]

Parameter Description	<i>ip-address</i> : indicates the IP address of an NTP/SNTP server. No NTP/SNTP server is configured by default.
	oob : indicates that the NTP/SNTP server supports an out-band management interface (interface of mgmt). <i>mgmt-name</i> : Specifies the egress management interface for packets in the oob mode.
Command Mode	Global configuration mode
Usage Guide	Since SNTP is fully compatible with NTP, the server can be configured as a public NTP server on the Internet. Since SNTP packets are the same as NTP packets, the SNTP client is fully compatible with the NTP server. There are many NTP servers on the Internet. You can select an NTP server with a shorter delay as the SNTP server on your device.

📌 Configuring the SNTP Time Synchronization Interval

Command	sntp interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the time synchronization interval, ranging from 60s to 65,535s. The default value is 1,800s.
Command Mode	Global configuration mode
Usage Guide	Run this command to set the interval for an SNTP client to synchronize time with an NTP/SNTP server. ⚠ The interval configured here does not take effect immediately. To make it take effect immediately, run the sntp enable command.

Configuration Example

📌 SNTP Time Synchronization

Scenario Figure 4-4	
	● DEVICE-B indicates an NTP server on the Internet. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	Enable SNTP for DEVICE-C and configure DEVICE-B as an NTP server.
DEVICE-C	<pre>C#configure terminal C(config)# sntp server 192.168.2.1 C(config)# sntp enable C(config)# exit</pre>
Verification	● Run the show clock command on DEVICE-C to check whether the time synchronization is successful.

- Run the **show sntp** command on DEVICE-C to display the SNTP status and check whether the server is successfully configured.

4.5 Monitoring

Displaying

Description	Command
show sntp	Displays SNTP-related parameters.

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
debug sntp	Enables debugging.

5 Configuring SPAN-RSPAN

5.1 Overview

The Switched Port Analyzer (SPAN) is to copy packets of a specified port to another switch port that is connected to a network monitoring device, so as to achieve network monitoring and troubleshooting.

All input and output packets of a source port can be monitored through SPAN. For example, as shown in the following figure, all packets on Port 5 are mapped to Port 10, and the network analyzer connected to Port 10 receives all packets that pass through Port 5.

Figure 5-1 SPAN Configuration Instance

The SPAN function is mainly applied in network monitoring and troubleshooting scenarios, to monitor network information and rectify network faults.

The Remote SPAN (RSPAN), an extension to SPAN, is capable of remotely monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port. Users can observe data packets of the remote mirrored port by using an analyzer in the central equipment room.

The application scenarios of RSPAN are similar to those of SPAN. RSPAN allows users to conduct real-time data monitoring without staying in the equipment room, providing great convenience for users.

VLAN SPAN (VSPAN) considers data streams of some VLANs as data sources and mirrors them to a destination port. The configuration is similar to that of the port-based SPAN. VSPAN has the following features:

- A VLAN that is not a remote VLAN can be specified as the data source of VSPAN.
- Some VLANs that are not remote VLANs can be specified as the data sources of VSPAN.
- When a VLAN is configured as a data source, packets only in the Rx direction can be mirrored.

5.2 Applications

Application	Description
Stream-based SPAN	Data streams with certain characteristics need to be monitored, for example, data streams using a specified access control list (ACL) policy need to be monitored.
One-to-Many RSPAN	Multiple users need to monitor data of the same port.
RSPAN Basic Applications	Packets on the mirroring source device need to be mirrored to the destination device for monitoring.

5.2.1 Stream-based SPAN

Scenario

As shown in the following figure, the network analyzer can be configured to can monitor all data streams forwarded by Switch A to Switch B and specific data streams of Switch B (for example, data streams from PC1 and PC2).

Figure 5-2 SPAN Simple Application Topology

Remarks 0000.0000.0001 is the MAC address of PC1.
0000.0000.0002 is the MAC address of PC2.

Deployment

- In the preceding figure, configure the SPAN function on Switch A connected to the network analyzer, set port Gi 0/1 connected to Switch B as the SPAN source port, and set port Gi 0/2 that is directly connected to the network analyzer as the SPAN destination port.
- Configure stream-based SPAN (only data streams of PC1 and PC2 are allowed) for the source port Gi 0/1 of SPAN.

5.2.2 One-to-Many RSPAN

Scenario

As shown in the following figure, one-to-many RSPAN can be implemented on a single device, that is, both PC 1 and PC 2 can be configured to monitor the transmitted and received traffic of the port connected to the server. Users can make proper configuration (for example, remote VLAN and port MAC loopback) to monitor data streams that pass through port Gi 4/1 on PC 1 and PC 2, thereby monitoring data streams of the server.

Figure 5-3 Application Topology of One-to-Many RSPAN

Deployment

- Create a remote VLAN on Switch A.
 - Configure Switch A as the source device of RSPAN and configure the port Gi 4/1 that is directly connected to the server as the RSPAN source port. Select a port that is in the Down state, Gi 4/2 in this example, as the RSPAN output port, add this port to the remote VLAN, and configure MAC loopback (run the **mac-loopback** command in interface configuration mode).
 - Add ports that are directly connected to PC 1 and PC 2 to the remote VLAN.
-
- i** If the inner VLAN tag needs to be removed from the input direction of the loopback port, configure the **mac-loopback remove-itag** command.
-

5.2.3 RSPAN Basic Applications

Scenario

As shown in the following figure, the RSPAN function enables the network analyzer to monitor the STA connected to the source device Switch A from the destination device Switch C through the intermediate device Switch B. The devices can normally exchange data with each other.

Figure 5-4 Basic Application Topology of RSPAN

Deployment

- Configure a remote VLAN on Switch A, Switch B, and Switch C.
- On Switch A, configure port Gi 0/1 directly connected to the STA as the source port, configure port Gi 0/2 connected to Switch B as the output port, and configure the switching function for the output port.
- On Switch B, configure port Gi 0/1 connected to Switch A and port Gi 0/2 connected to Switch C as common ports.
- On Switch C, configure port Gi0/1 connected to Switch B as a common source port, configure port Gi 0/2 connected to the network analyzer as the RSPAN destination port, and configure the switching function for the RSPAN destination port.

5.3 Features

Basic Concepts

SPAN Session

A SPAN session is data streams between the SPAN source port and the destination port, which can be used to monitor the packets of one or more ports in the input, output, or both directions. Switched ports, routed ports, and aggregate ports (APs) can be configured as source ports or destination ports of SPAN sessions. Normal operations on a switch are not affected after ports of the switch are added to a SPAN session.

Users can configure a SPAN session on a disabled port but the SPAN session is inactive. A SPAN session is in the active state only after the port on which the SPAN session is configured is enabled. In addition, a SPAN session does not take effect after a switch is powered on. It is active only after the destination port is in the operational state. Users can run the **show monitor [session session-num]** command to display the operation status of a SPAN session.

SPAN Data Streams

A SPAN session covers data streams in three directions:

- Input data streams: All packets received by a source port are copied to the destination port. Users can monitor input packets of one or more source ports in a SPAN session. Some input packets of a source port may be discarded for some reasons (for example, for the sake of port security). It does not affect the SPAN function and such packets are still mirrored to the destination port.

- **Output data streams:** All packets transmitted by a source port are copied to the destination port. Users can monitor output packets of one or more source ports in a SPAN session. Packets transmitted from other ports to a source port may be discarded for some reasons and such packets will not be transmitted to the destination port. The format of output packets of a source port may be changed for some reasons. For example, after routing, packets transmitted from the source port are changed in source MAC addresses, destination MAC addresses, VLAN IDs, and TTLs, and their formats are also changed after copied to the destination port.
- **Bidirectional data streams:** Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

📌 Source Port

A source port is called a monitored port. In a SPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single SPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not restricted.

A source port has the following features:

- A source port can be a switched port, routed port, or AP.
- A source port cannot be used as a destination port simultaneously.
- A source port and a destination port can belong to the same VLAN or different VLANs.

📌 Destination Port

A SPAN session has one destination port (called a monitoring port) for receiving packets copied from a source port.

A destination port has the following features:

- A destination port can be a switched port, routed port, or AP.
- A destination port cannot be used as a source port simultaneously.

Overview

Feature	Description
SPAN	Configures mirroring of ports on the same device.
RSPAN	Configures mirroring of ports on different devices.

5.3.1 SPAN

SPAN is used to monitor data streams on switches. It copies frames on one port to another switch port that is connected to a network analyzer or RMON analyzer so as to analyze the communication of the port.

Working Principle

When a port transmits or receive packets, SPAN, after checking that the port is configured as a SPAN source port, copies the packets transmitted and received by the port to the destination port.

📌 Configuring a SPAN Source Port

Users need to specify a SPAN session ID and source port ID to configure a SPAN source port, and set the optional SPAN direction item to determine the direction of SPAN data streams or specify an ACL policy to mirror specific data streams.

📌 Configuring a SPAN Destination Port

Users need to specify a SPAN session ID and destination port ID to configure a SPAN destination port, and set the optional switching function item to determine whether to enable the switching function and tag removal function on the SPAN destination port.

Related Configuration

The SPAN function is disabled by default. It is enabled only after a session is created, and the SPAN source and destination ports are configured. A SPAN session can be created when a SPAN source port or destination port is configured.

📌 Configuring a SPAN Source Port

A SPAN session does not have a SPAN source port by default. Users can run the following command to configure a SPAN source port:

```
monitor session session-num source interface interface-id [ both | rx | tx ] [ acl name ]
```

In the preceding command:

session-num: Indicates the SPAN session ID. The number of supported SPAN sessions varies with products.

interface-id: Indicates the SPAN source port to be configured.

rx: Indicates that only packets received by the source port are monitored after **rx** is configured.

tx: Indicates that only packets transmitted by the source port are monitored after **tx** is configured.

both: Indicates that packets transmitted and received by the source port are copied to the destination port for monitoring after **both** is configured, that is, **both** includes **rx** and **tx**. If none of **rx**, **tx**, and **both** is selected, **both** is enabled by default.

acl: Specifies an ACL policy. After this option is configured, packets allowed by the ACL policy on the source port are monitored. This function is disabled by default.

📌 Configuring a SPAN Destination Port

A SPAN session does not have a SPAN destination port by default. Users can run the following command to configure a SPAN destination port:

```
monitor session session-num destination interface interface-id [switch ]
```

In the preceding command:

switch: Indicates that the SPAN destination port only receives packets mirrored from the SPAN source port and discards other packets if this option is disabled, and receives both packets mirrored from the SPAN source port and packets from non-source ports if this option is enabled, that is, the communication between this destination port and other devices is not affected.

When the SPAN destination port is configured, the relevant function is disabled by default if **switch** is not configured.

📌 Configuring Stream-based SPAN

This function is disabled by default. Users can run the **monitor session session-num source interface interface-id rx acl acl-name** command to configure stream-based SPAN.

- ⚠ Pay attention to the following points when using SPAN:
- ⚠ The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.
- ⚠ SPAN is unavailable if a source port or destination port is disabled.
- ⚠ If a VLAN (or VLAN list) is used as a SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the VLAN (or VLAN list).
- ⚠ Not all products support all options of the preceding commands because of product differences.

5.3.2 RSPAN

RSPAN is capable of monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port.

Working Principle

A remote VLAN is created for the source device, intermediate device, and destination device, all ports involved in an RSPAN session need to be added to the remote VLAN. Mirrored packets are broadcasted in the remote VLAN so that they are transmitted from the source port of the source switch to the destination port of the destination switch.

📌 Configuring a Remote VLAN

Packets from an RSPAN source port are broadcasted in a remote VLAN so as to be copied from the local switch to the remote switch. The RSPAN source port, output port, reflection port, transparent transmission ports of the intermediate device (packet input port and output port of the intermediate device), destination port and input port of the destination port must be added to the remote VLAN. The RSPAN function requires configuring a VLAN as a remote VLAN in VLAN mode.

📌 Configuring an RSPAN Session

The configuration of the RSPAN source port and destination port are similar to that of the SPAN source port and destination port, but the mirroring session ID specified during configuration must be the ID of an RSPAN session.

📌 Configuring an RSPAN Source Port

The configuration of an RSPAN source port is the same as that of a SPAN source port, but the specified mirroring session ID must be the ID of an RSPAN session.

📌 Configuring an RSPAN Output Port

The output port is located on the source device and must be added to a remote VLAN. Mirrored packets of a source port are broadcasted in this remote VLAN. The source device transmits packets to the intermediate switch or destination switch through the output port.

📌 Configuring an RSPAN Destination Port

When an RSPAN destination port is configured, an RSPAN session ID, remote VLAN, and port name must be specified so that packets from the source port are copied to the destination port through the remote VLAN.

📌 Configuring Stream-based RSPAN

RSPAN is an extension to SPAN and also supports stream-based mirroring. The configuration is the same as that of stream-based SPAN. Stream-based RSPAN does not affect normal communication.

Users can configure an ACL in the input direction of a source port on an RSPAN source device. Standard ACLs, extended ACLs, MAC ACLs, and user-defined ACLs are supported.

Users can configure a port ACL in the input direction of a source port on an RSPAN source device, and configure a port ACL in the output direction of the destination port on the RSPAN destination device. Users can also configure an ACL in the output direction of a remote VLAN on an RSPAN source switch and configure an ACL in the input direction of the remote VLAN on the RSPAN destination switch.

📌 Configuring One-to-Many RSPAN

If data streams of one source port need to be mirrored to multiple destination ports, users can configure an RSPAN session, configure the source port of the RSPAN session as a one-to-many mirroring source port and select another Ethernet port as the forwarding port (output port on the source device). In addition, the MAC loopback function needs to be configured on the RSPAN forwarding port in interface configuration mode, the expected RSPAN output port and RSPAN forwarding port need to be added to the remote VLAN. Then, mirrored packets are looped back on the RSPAN forwarding port and then broadcasted in the remote VLAN, thereby implementing one-to-many RSPAN.

Related Configuration

The RSPAN function is disabled by default. It is enabled only after an RSPAN session is created, and a remote VLAN, RSPAN source port, and RSPAN destination port are configured.

📌 Configuring a Remote VLAN

No remote VLAN is specified for RSPAN by default. Users can run the **remote-span** command in VLAN mode to configure a VLAN as a remote VLAN. One remote VLAN corresponds to one RSPAN session.

📌 Configuring an RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num remote-source** command in global configuration mode to configure a device as the remote source device of a specified RSPAN session.

📌 Configuring an RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num remote-destination** command in global configuration mode to configure a device as the remote destination device of a specified RSPAN session.

📌 Configuring an RSPAN Source Port

A source port of an RSPAN session is configured on the source device. The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified. This function is disabled by default.

📌 Configuring an Output Port on the RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure an output port on the RSPAN source device. If the option **switch** is configured, the output port can participate in normal data packet switching. It is not configured by default. The output port must be added to a remote VLAN.

📌 Configuring a Destination Port on the RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure a destination port on the RSPAN destination device. If the option **switch** is configured, the destination port can participate in normal data packet switching. It is not configured by default. The destination port must be added to a remote VLAN.

-
- ⚠ Pay attention to the following points when using RSPAN:
 - ⚠ A remote VLAN must be configured on each device, their VLAN IDs must be consistent, and all ports that participate in a session must be added to the VLAN.
 - ⚠ It is not recommended that common ports be added to a remote VLAN.
 - ⚠ Do not configure a port that is connected to an intermediate switch or destination switch as an RSPAN source port. Otherwise, traffic on the network may be in chaos.
-

5.4 Configuration

Configuration	Description and Command	
Configuring SPAN Basic Functions	⚠ (Mandatory) It is used to create SPAN.	
	monitor session session-num source interface interface-id [both rx tx]	Configures a SPAN source port.
	monitor session session-num destination interface interface-id [switch]	Configures a SPAN destination port.
	monitor session session-num source interface interface-id rx acl acl-name	Configures stream-based SPAN.
	monitor session session-num source vlan vlan-id [rx]	Specifies a VLAN as the data source of SPAN.
	monitor session session-num source filter vlan vlan-id-list	Specifies some VLANs as the data sources of SPAN.
Configuring	⚠ (Mandatory) It is used to create RSPAN.	

RSPAN Basic Functions	monitor session <i>session-num</i> remote-source	Configures an RSPAN session ID and specifies a source device.
	monitor session <i>session-num</i> remote-destination	Configures an RSPAN session ID and specifies a destination device.
	remote-span	Configures a remote VLAN.
	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]	Configures an RSPAN source port.
	monitor session <i>session-num</i> destination remote vlan <i>remote-vlan-id</i> interface <i>interface-id</i> [switch]	Configures an output port on the RSPAN source device or a destination port on the RSPAN destination device.

5.4.1 Configuring SPAN Basic Functions

Configuration Effect

- Configure a source and destination ports for a SPAN session.
- Configure a destination port to monitor any packets transmitted and received by a source port.

Notes

- If the switch function is disabled on a SPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.

Configuration Steps

📌 Configuring a SPAN Session

- Global configuration mode. Mandatory.
- You can configure a SPAN session when configuring a SPAN source port or destination port, or when configuring a specified VLAN or some VLANs as a data source or data sources of SPAN.

📌 Configuring a SPAN Source Port

- Global configuration mode. Mandatory.
- You can select the SPAN direction when configuring a SPAN source port. The **both** direction is configured by default, that is, both transmitted and received packets are monitored.

📌 Configuring a SPAN Destination Port

Global configuration mode. Mandatory.

A SPAN session is active only when a SPAN source port is configured (or a VLAN is specified as the data source of SPAN) and a SPAN destination port is configured.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. Alternatively, conduct packet capture analysis on the SPAN destination port and check whether the SPAN function takes effect according to the captured packets.

Related Commands

📌 Configuring a SPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

📌 Configuring a SPAN Destination Port

Command	monitor session <i>session-num</i> destination interface <i>interface-id</i> [switch]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>interface-id</i> : Indicates the interface ID. switch : Indicates that the switching function is enabled on the SPAN destination port. It is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

📌 Configuring Stream-based SPAN

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> rx acl <i>acl-name</i>
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session.

	<i>interface-id</i> : Indicates the interface ID. <i>acl-name</i> : Indicates an ACL name.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Specifying a VLAN as the Data Source of SPAN

Command	monitor session <i>session-num</i> source vlan <i>vlan-id</i> [rx]
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>vlan-id</i> : Indicates a specified VLAN ID. rx : Indicates that packets in the input direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Specifying Some VLANs as the Data Sources of SPAN

Command	monitor session <i>session-num</i> source filter vlan <i>vlan-id-list</i>
Parameter Description	<i>session-num</i> : Indicates the ID of a SPAN session. <i>vlan-id-list</i> : Indicates some specified VLAN IDs.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ The following uses SPAN as an example.

Scenario Figure 5-5	
Configuration Steps	- As shown in Figure 5-5, add ports Gi 0/1 and Gi 0/2 of Device A to VLAN 1. - Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24. - Set IP addresses of PC 1 and PC 2 to 10.10.10.1/24 and 10.10.10.2/24 respectively.

	Configure SPAN for Device A and configure ports Gi 0/1 and Gi 0/2 as the source port and destination port of SPAN respectively.
A	<pre> Ruijie# configure Ruijie(config)# vlan 1 Ruijie(config-vlan)# exit Ruijie(config)# interface vlan 1 Ruijie(config-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0 Ruijie(config-if-VLAN 1)# exit Ruijie(config)# monitor session 1 source interface gigabitEthernet 0/1 Ruijie(config)# monitor session 1 destination interface gigabitEthernet 0/2 </pre>
Verification	Run the show monitor command to check whether SPAN is configured correctly. After successful configuration, PC 1 sends ping packets to SVI 1 and PC 2 conducts monitoring by using the packet capture tool.
A	<pre> Ruijie# show monitor sess-num: 1 span-type: LOCAL_SPAN src-intf: GigabitEthernet 0/1 frame-type Both dest-intf: GigabitEthernet 0/2 </pre>

Common Errors

- The session ID specified during configuration of the SPAN source port is inconsistent with that specified during configuration of the SPAN destination port.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.

5.4.2 Configuring RSPAN Basic Functions

Configuration Effect

- Configure a source port and destination port on the source device of an RSPAN session and configure the destination port on the destination device.
- Configure the destination port on the RSPAN destination device to monitor any packets that are transmitted or received by the source port.

Notes

- If the switch function is disabled on an RSPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.
- All ports involved in RSPAN must be added to a remote VLAN.
- A remote VLAN must be created on an intermediate device and transparent transmission ports must be added to the remote VLAN.

Configuration Steps

📌 Configuring an RSPAN Session

- Global configuration mode. Mandatory.
- The same session ID needs to be configured on the RSPAN source device and RSPAN destination device.

📌 Configuring an RSPAN Source Device

- Global configuration mode. Mandatory.
- It is used to specify a device to be monitored by RSPAN.

📌 Configuring an RSPAN Destination Device

- Global configuration mode. Mandatory.
- It is used to specify the destination device for outputting RSPAN packets.

📌 Configuring an RSPAN Source Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, RSPAN monitoring can be conducted on packets of the RSPAN source port. You can specify RSPAN to monitor remote VLAN packets in the input direction, output direction, or both directions of the RSPAN source port.

📌 Configuring an RSPAN Output Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, mirrored packets received by the ports added to the remote VLAN can be transmitted to the RSPAN destination device through the loopback port and output port.

📌 Configuring an RSPAN Destination Port

- Global configuration mode. Mandatory.
- Complete the configuration on the RSPAN destination device. After configuration, the RSPAN destination device forwards mirrored packets received by the ports added to the remote VLAN to the monitoring device through the destination port.

Verification

- Run the **show monitor** command or the **show running** command to check whether RSPAN is successfully configured on each device, or conduct packet capture on the destination mirroring port on the RSPAN destination device to check whether packets mirrored from the source port of the RSPAN source device are captured.

Related Commands

↘ Configuring an RSPAN Source Device

Command	monitor session <i>session-num</i> remote-source
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	
Command Mode	Global configuration mode

↘ Configuring an RSPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx][acl <i>acl-name</i>]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored. <i>acl-name</i> : Indicates an ACL name.
Command	Global configuration mode

Mode	
Usage Guide	The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified.

✚ Configuring an Output Port on the RSPAN Source Device

Command	monitor session session-num destination remote vlan remote-vlan interface interface-id [switch]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>remote-vlan</i> : Indicates a remote VLAN. <i>interface-id</i> : Indicates the interface ID. switch : Indicates whether the port participates in packet switching.
Command Mode	Global configuration mode
Usage Guide	N/A

✚ Configuring a Destination Port on the RSPAN Destination Device

Command	monitor session session-num destination remote vlan remote-vlan interface interface-id [switch]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>remote-vlan</i> : Indicates a remote VLAN. <i>interface-id</i> : Indicates the interface ID. switch : Indicates whether the port participates in packet switching.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ Configuring One-to-Many RSPAN

Scenario Figure 5-6	The diagram illustrates a one-to-many RSPAN configuration. A central Source Device, Switch A, is connected to a Server via its Source Port Fa0/1. Switch A also has a MAC Loopback Port Fa0/2. Two Destination Devices, Switch B and another switch, are connected to Switch A via ports Fa0/3 and Fa0/4 respectively. Each Destination Device has a Destination Port Fa0/2 connected to a PC (PC 1 and PC 2 respectively).

Configuration Steps	● As shown in the preceding figure, configure a remote VLAN on Switch A, Switch B, and Switch C. ● Configure the source port, output port and loopback port on Switch A. ● Configure the destination port on Switch B and Switch C.
A	<pre> Ruijie# configure Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-source Ruijie(config)# monitor session 1 source interface fa 0/1 both Ruijie(config)# monitor session 1 destination remote vlan 7 interface fa 0/2 switch Ruijie(config)# interface fa0/2 Ruijie(config-if)# mac-loopback Ruijie(config-if)# switchport access vlan 7 Ruijie(config-if)# exit Ruijie(config)# interface range fa0/3-4 Ruijie(config-if-range)# switchport mode trunk </pre>
B, C	<pre> Ruijie(config)# vlan 7 Ruijie(config-vlan)# remote-span Ruijie(config-vlan)# exit Ruijie(config)# monitor session 1 remote-destination Ruijie(config)# monitor session 1 destination remote vlan 7 interface fa 0/2 Ruijie(config)# interface fa0/1 Ruijie(config-if)#switchport mode trunk </pre>
Verification	Run the show monitor command or the show running command on Switch A, Switch B, and Switch C to check whether RSPAN is configured successfully.
A	<pre> Ruijie# show monitor sess-num: 1 span-type: SOURCE_SPAN src-intf: FastEthernet 0/1 frame-type Both </pre>

	<pre> dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on </pre>
B	<pre> Ruijie# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on </pre>
C	<pre> Ruijie# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on </pre>

Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.
- Multiple output ports need to be configured to implement one-to-many RSPAN.

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	debug span

6 Configuring ERSPAN

6.1 Overview

Encapsulated Remote Switched Port Analyzer (ERSPAN) is an extension to Remote Switched Port Analyzer (RSPAN). SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

An ERSPAN encapsulates all SPAN packets into IP packets through a generic routing encapsulation (GRE) tunnel, and routes them to the destination port of an RSPAN device. The following figure shows the topology of a typical application:

Figure 6-1 Topology of a Typical ERSPAN Application

There are two kinds of roles played by the devices in the figure:

- **Source switch:** A source switch refers to the switch where the ERSPAN source port resides. It copies the packets on the source port, outputs the copies from the output port, encapsulates them into IP packets, and forwards the IP packets to the destination switch.
- **Destination switch:** A destination switch refers to the switch where the ERSPAN destination port resides. It puts the received SPAN packets through the SPAN destination port, decapsulates them into GRE packets, and then forwards the GRE packets to the monitoring device.

To implement ERSPAN, the GRE-encapsulate IP packets must be able to be normally routed to the destination SPAN device.

6.2 Applications

Application	Description
Basic ERSPAN Applications	Packets on the SPAN source device need to be mirrored to the destination device for monitoring.

6.3 Basic ERSPAN Applications

Scenario

As shown in the following figure, ERSPAN enables the network analyzer to monitor the users connected to the source device Switch A. The devices can normally exchange data with each other.

Figure 6-2 Topology of Basic ERSPAN Applications

Deployment

- On Switch A, configure the port directly connected to users (Gi 0/1) as a source port, and configure the port connected to Switch B (Gi 0/2) as an output port.
- On Switch B, the ports connected to Switch A and Switch C (Gi 0/1 and Gi 0/2) are respectively member interfaces of switch virtual interface (SVI) interfaces of two network segments, ensuring interworking between the two IP network segments.

6.4 Features

Basic Concepts

↳ ERSPAN Session

SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, ERSPAN mirroring allows SPAN packets to be transmitted between routing networks. An ERSPAN encapsulates all SPAN packets into IP packets through a GRE tunnel, and routes them to the destination port of an RSPAN device. An ERSPAN can monitor input, output, and bidirectional packets of one or more ports. Ports such as a switched port, routed port

and aggregate port (AP) can be configured as a source port for an ERSPAN session. The switch is not affected after the port is added to an ERSPAN session.

Source Port

A source port is also called a monitored port. In an ERSPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single ERSPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not limited. A source port has the following features:

- A source port can be a switched port, routed port, or an AP.
- It supports mirroring of multiple source ports on the source device to the designated output ports.
- The source port and output port cannot be on the same port; when the SPAN source port is a Layer-3 interface, both Layer-2 and Layer-3 packets are monitored.
- When multiple ports are bidirectionally monitored, a packet is input from a port and output from the other. Such monitoring is considered correct if only one packet is monitored.
- When the status of enabled Spanning Tree Protocol (STP) port is in block state, the input and output packets on the port can be monitored;
- Source port and destination port can belong to the same VLAN or different VLANs.

Overview

Feature	Description
ERSPAN	Configures SPAN on different Internet ports.

6.4.1 ERSPAN

Encapsulated ERSPAN is an extension of RSPAN. SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

Working Principle

All the mirrored packets are encapsulated into IP packets through a GRE tunnel, and routed to the destination port of an RSPAN device.

Configuring an ERSPAN Session

Configure ERSPAN of the switch, and distinguish between attributes of ERSPAN switch of the device. You need to designate an ERSPAN session ID, and enter the ERSPAN configuration mode after configuration succeeds.

Configuring a Source Port

After entering the ERSPAN configuration mode, you need to name the source port to configure the SPAN source port, and determine the direction of SPAN data streams according to optional configurations of SPAN direction.

Enabling an ERSAN Session

By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

✚ Encapsulating the Origin IP Address

Encapsulating an origin IP address aims to configure the origin IP address of an encapsulated GRE packet.

✚ Encapsulating the Destination IP Address

Encapsulating a destination IP address aims to configure the destination IP address of an encapsulated GRE packet and ensure normal routing of SPAN packets on the network.

✚ Encapsulating IP TTL/DSCP

Encapsulate Time to Live (TTL) and Differentiated Services Code Point (DSCP) values of IP packets.

✚ `vrf vrf-name`

It indicates the name of virtual routing. Different virtual routing values might obtain different egresses for the same destination IP.

Related Configuration

By default, an SPAN is disabled. It is enabled only after a session is created, and source SPAN port, origin IP and destination IP addresses are configured.

✚ Configuring an ERSPAN Session

```
Ruijie(config)# monitor session session_num erspan-source
```

Wherein,

session-num: Indicates that the number of SPAN sessions supported by SPAN. Session number varies with products.

✚ Configuring a Source Port

```
Ruijie(config-mon-erspan-src)# source interface single_interface {[rx | tx | both]}
```

Wherein,

single_interface: Indicates the SPAN source port to be configured.

rx: Indicates that only the packets received by the source port are monitored after **rx** is configured.

tx: Indicates that only the packets sent from the source port are monitored after **tx** is configured.

both: Indicates that after **both** is configured, the packets sent and received by the source port are transmitted to the destination port to be monitored; that is to say, **both** includes **rx** and **tx**. If none of **rx**, **tx**, or **both** is configured, **both** is enabled by default.

✚ Configuring Stream-based SPAN

The function is disabled by default. Run the `Ruijie(config-mon-erspan-src)# source interface interface-id rx acl acl-name` command to configure stream-based SPANs.

↘ Enabling an ERSAN Session

Ruijie(config-mon-erspan-src)# **shutdown**

This command is used to disable ERSPAN mirroring. (By default) Run the **no shutdown** command to enable ERSPAN mirroring.

↘ Encapsulating the Destination IP Address

Ruijie(config-mon-erspan-src)# **destination ip address** *ip-address*

Wherein,

ip-address: Encapsulates the destination IP address.

↘ Encapsulating the Origin IP Address

Ruijie(config-mon-erspan-src)# **origin ip address** *ip-address*

Wherein,

ip-address: Encapsulates the origin IP address.

↘ Encapsulating IP TTL

Ruijie(config-mon-erspan-src)# **ip ttl** *tll_value*

Wherein,

tll_value: Configures the TTL value of an encapsulated IP address. The TTL value ranges from 0 to 255, and the default value is 64.

↘ Encapsulating IP DSCP

Ruijie(config-mon-erspan-src)# **ip dscp** *dscp_value*

Wherein,

dscp_value: Configures the DSCP value of an encapsulated IP address. The DSCP value ranges from 0 to 63, and the default value is 0. The function takes effect only after trusting DSCP is configured on the SPAN source port.

↘ Encapsulating vrf *vrf-name*

Ruijie(config-mon-erspan-src)# **vrf** *vrf-name*

Wherein,

vrf-name: Indicates the name of VPN Routing & Forwarding Instance (VRF).

Pay attention to the following issues during use:

- Confirm the Layer-3 routing connectivity from source switch to destination switch.
- ERSPAN is unavailable if a source port is disabled.
- If a source port or destination port is added to an AP, the source port or destination port egresses an ERSPAN session.
- As a result of product differences, not all products support all options of the above-mentioned commands.

6.5 Configuration

Configuration	Description and Command	
Configuring Basic ERSPAN Functions	 (Mandatory) It is used to create ERSPAN mirroring.	
	monitor session <i>erspan_source_session_number</i> erspan-source	Configures an ERSPAN session ID, and enters the configuration mode of the source ERSPAN device.
	source interface <i>single_interface</i> {[rx tx both]}	Associates the source ERSPAN port, and selects an SPAN direction.
	source interface <i>single_interface</i> rx acl <i>acl-name</i>	Configures the stream-based SPAN source for ERSPAN.
	shutdown	Disables ERSPAN mirroring.
	destination ip address <i>ip_address</i>	Configures the destination IP address for an ERSPAN stream. The address must be the interface address of the destination device.
	original ip address <i>ip_address</i>	Configures the encapsulated origin IP address for ERSPAN.
	ip ttl <i>tth_value</i>	(Optional) Configures the TTL value of an encapsulated IP address for ERSPAN.
	ip dscp <i>dscp_value</i>	(Optional) Configures the DSCP field value of an encapsulated IP address for ERSPAN.
	vrf <i>vrf_name</i>	(Optional) Configures the VRF name.

6.5.1 Configuring Basic ERSPAN Functions

Configuration Effect

- RSPAN enables a network analyzer to monitor users.
- Devices can normally exchange data with each other.

Notes

- If a source port is added to an AP, the source port egresses an ERSPAN session.
- The Layer-3 routing connectivity from source switch to destination switch must be ensured.

Configuration Steps

- **ERSPAN Session**
- Global configuration mode. Mandatory.
- The session ID configured with local SPAN or RSPAN cannot be used for an ERSPAN session. Enter the ERSPAN mode after configuration.

↘ Source Port

- Global configuration mode. Mandatory.
- An SPAN direction can be selected during configuration of the SPAN source port. The direction is **both** by default; that is, both reception and transmission of packets are monitored.

↘ Enabling an ERSPAN Session

- ERSPAN configuration mode. Mandatory.
- By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

↘ Encapsulating the Origin IP Address

- ERSPAN configuration mode. Mandatory.
- It is used to encapsulate origin IP addresses of SPAN packets.

↘ Encapsulating the Destination IP Address

- ERSPAN configuration mode. Mandatory.
- It is used to encapsulate destination IP addresses of SPAN packets.

↘ Encapsulating IP TTL/DSCP

- ERSPAN configuration mode. Optional.
- It is used to encapsulate DSCP values of SPAN IP packets.

↘ vrf vrf-name

- Global configuration mode. Optional.
- It indicates the name of VRF. VRF must exist.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. You can also conduct packet capture analysis on the SPAN destination port and check whether SPAN takes effect according to the captured packets.

✚ Enabling an ERSAN Session

Command	shutdown
Parameter Description	
Command Mode	ERSPAN session mode
Usage Guide	N/A

✚ Encapsulating the Origin IP Address

Command	original ip address <i>ip_address</i>
Parameter Description	<i>ip_address</i> : Indicates the origin IP address to be encapsulated.
Command Mode	ERSPAN session mode
Usage Guide	

✚ Encapsulates the Destination IP Address

Command	destination ip address <i>ip_address</i>
Parameter Description	<i>ip_address</i> : Indicates the destination IP address to be encapsulated.
Command Mode	ERSPAN session mode

↘ Encapsulating IP TTL

Command	ip ttl <i>ttl_value</i>
Parameter Description	<i>ttl_value</i> : Configures the TTL value of an encapsulated IP address for ERSPAN. The value ranges from 1 to 255.
Command Mode	ERSPAN session mode
Usage Guide	-

↘ Encapsulating DSCP

Command	ip dscp <i>dscp_value</i>
Parameter Description	<i>dscp_value</i> : Configures the DSCP field value of an encapsulated IP address for ERSPAN. The value ranges from 0 to 64.
Command Mode	ERSPAN session mode
Usage Guide	-

↘ Configuring VRF *vrf-name*

Command	vrf <i>vrf_name</i>
Parameter Description	<i>vrf_name</i> : Indicates the VRF name.
Command Mode	ERSPAN session mode
Usage Guide	-

Configuration Example

↘ The following uses a SPAN as an example.

Scenario
Figure 6-3

Configuration Steps

- As shown in Figure 6-3, on Switch A, create ERSPAN Session 1 and configure it as the source device, and configure Gi 0/1 as the source port.

```
SwitchA(config)#monitor session 1 erspan-source
SwitchA(config-mon-erspan-src)#source interface gigabitEthernet 0/1 both
SwitchA(config-mon-erspan-src)#origin ip address 10.1.1.2
SwitchA(config-mon-erspan-src)#destination ip address 12.1.1.2
SwitchA(config-mon-erspan-src)#vrf vrf-name
```

Verification

Step 1: Check the configuration of the device.

```
SwitchA#show running-config
!
monitor session 1 erspan-src
source interface GigabitEthernet 0/1 both
origin ip address 10.1.1.2
destination ip address 12.1.1.2
vrf vrf-name
```

Step 2: Check the ERSPAN information of the device.

```
SwitchA#show monitor

sess-num: 1                               //ERSPAN Session
span-type: ERSPAN_SOURCE                  //ERSPAN source device
src-intf:                                 //ERSPAN source port information
GigabitEthernet 0/1      frame-type Both  TX status: Inactive  RX status: Inactive
dest-intf:                               //ERSPAN output port information
GigabitEthernet 0/2
origin ip address 10.1.1.2
destination ip address 12.1.1.2
ip ttl 64
ip dscp 0
vrf vrf-name
```

Common Errors

- The session ID used to configure ERSPAN mirroring is configured with RSPAN or LOCAL SPAN.
- Layer-3 routing interworking between source switch and destination switch fails.

6.6 Monitoring

Displaying

Description	Command
Displays all SPAN sessions in the system.	show monitor
Displays specific SPAN sessions.	show monitor session <i>session-id</i>

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	debug span

7 Configuring sFlow

7.1 Overview

sFlow is a network monitoring technology jointly developed by InMon, HP, and FoundryNetworks in 2001. This technology has been standardized. It can provide complete traffic flows of Layer 2 to Layer 4, and it is applicable to traffic analysis in the extra-large network. This technology helps users analyze the performance, trend, and existence of network traffic flows in a detailed manner in real time.

sFlow has the following advantages:

- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

Protocol Specification

- sFlow Version 5
- RFC 1014

7.2 Applications

Typical Application	Scenario
Monitoring the LAN Traffic	Regard the device as an sFlow Agent, perform sampling of interface traffic in the LAN, and send the sFlow datagrams to an sFlow Collector for traffic analysis, thereby achieving the purpose of network monitoring.

7.2.1 Monitoring the LAN Traffic

Application Scenario

As shown in Figure 7-1, start switch A that serves as an sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling data into sFlow datagrams at regular intervals or when the buffer is full, and sent the sFlow data to the sFlow Collector for traffic analysis.

Figure 7-1

Function Deployment

- Configure the addresses of sFlow Agent and sFlow Collector on switch A.
- Enable flow sampling and counter sampling on port Te 0/1 of switch A.

i Lots of server software supports sFlow. You can obtain software supporting sFlow at <http://www.sflow.org/products/collectors.php>. The software sflowtrend is free of charge.

7.3 Features

Basic Concepts

📌 sFlow Agent

sFlow Agent is embedded in a network device. Generally, one network device can serve as an sFlow Agent. sFlow Agent can perform flow sampling and counter sampling, encapsulate sampled data into sFlow datagrams, and send the sFlow datagrams to the sFlow Collector.

sFlow datagrams are encapsulated in UDP. Figure 7-2 shows the sFlow datagram format.

Figure 7-2 sFlow Datagram Format

One sFlow datagram may contain one or multiple flow samples and counter samples.

Figure 7-3 sFlow Header

sFlow Geader Description:

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, Ruijie supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub-agent ID
Datagram sequence number	Serial number of the sFlow datagram

Switch uptime	Duration from the startup time of the switch to the current time
n samples in datagram	The number of samples in the an sFlow datagram. One sFlow datagram may contain one or multiple flow samples and counter samples.

↘ sFlow Collector

sFlow Collector receives and analyzes the sFlow datagram sent from the sFlow Agent. sFlow Collector may be a PC or server. A PC or server installed with the application software for sFlow datagram analysis can be regarded as an sFlow Collector.

↘ Flow Sampling

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet.

Figure 7-4 Flow Sample Header

1	8	32
int data format sample data (20 bit enterprise & 12 bit format) (standard enterprise 0, formats 1)		
int sample length byte		
int sample sequence number		
int source id type (0=ifIndex 1=smonVlanDataSource 2=entPhysicalEntry)	int source id index value	
int sampling rate		
int sample pool (total number of packets that could have been sampled)		
int drops (packets dropped due to a lack of resources)		
int input (SNMP ifIndex of input interface, 0 if not known)		
int output (SNMP ifIndex of output interface, 0 if not known) broadcast or multicast are handled as follows: the first bit indicates multiple destinations, the lower order bits number of interfaces		
int n * flow records		

Counter Sampling

In counter sampling, an sFlow Agent periodically obtains the statistics and CPU usage on a specified interface. The statistics on the interface include the number of packets input through the interface and the number of packets output through the interface.

Figure 7-5 Counter Sample Header

Functions and Features

Feature	Description
Flow Sampling	Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.
Counter Sampling	Periodically send the statistics on the interface to the sFlow Collector for analysis.

7.3.1 Flow Sampling

Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.

Working Principle

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet. Then, the sFlow Agent encapsulates the flow sampling data into an sFlow datagram and sends the datagram to the sFlow Collector for analysis.

7.3.2 Counter Sampling

Periodically send the statistics on the interface to the sFlow Collector for analysis.

Working Principle

The sFlow Agent performs interface polling on a regular basis. For an interface whose counter sampling interval expires, the sFlow Agent obtains the statistics on this interface, encapsulates the statistics into an sFlow datagram, and sends the datagram to the sFlow Collector for analysis.

7.4 Configuration

Configuration Item	Suggestion & Related Command	
Configuring Basic Functions of sFlow	 Mandatory configuration. Establish communication connections between sFlow Agent and sFlow Collector.	
	sflow agent { address interface }	Configures the sFlow Agent address.
	sflow collector <i>collector-id</i> destination	Configures the sFlow Collector address.
	 Mandatory configuration. Enable flow sampling and counter sampling.	
	sflow counter collector	Enables the sFlow Agent to send counter samples to the sFlow Collector.
	sflow flow collector	Enables the sFlow Agent to send flow samples to the sFlow Collector .
	sflow enable	Enables sFlow sampling for the configuration interface, that is, enables counter sampling and flow sampling.
Configuring Optional Parameters of sFlow	 Optional configuration. Sets the optional parameter attributes of sFlow.	
	sflow collector <i>collector-id</i> max-datagram-size	Configures the maximum length of the sFlow datagram.
	sflow counter interval	Configures the counter sampling interval.
	sflow flow max-header	Configures the maximum length of the packet header copied during flow sampling.
	sflow sampling-rate	Configures the sampling rate of flow sampling.
	sflow source {address interface}	Configures the sFlow source address.

7.4.1 Configuring Basic Functions of sFlow

Configuration Effect

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

Notes

- Flow sampling can be configured on only physical interfaces.
- To enable the sFlow Collector to analyze the flow sampling results, the IP address of the sFlow Collector on the sFlow Agent device is required.

Configuration Method

📌 Configuring sFlow Agent Address

- Mandatory configuration.
- Use the **sflow agent address** command to configure the address of the sFlow Agent.
- The sFlow Agent address must be a valid address. That is, the sFlow Agent address must not be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.

Command Syntax	sflow agent { address { <i>ip-address</i> ipv6 <i>ipv6-address</i> } } { interface { <i>interface-name</i> ipv6 <i>interface-name</i> } }
Parameter Description	address: Configures the IP address of the sFlow agent. <i>ip-address</i> : sFlow Agent IPv4 address ipv6 <i>ipv6-address</i>: sFlow Agent IPv6 address interface: Configures the interface of the sFlow agent. <i>interface-name</i> : Interface of IPv4 address. ipv6 <i>interface-name</i>: Interface of IPv6 address.
Defaults	No sFlow Agent address is configured by default
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the Agent IP address field in the output sFlow datagram. The datagram not configured with this field cannot be output. The sFlow Agent address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Agent address, a message indicating configuration failure is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

📌 Configuring sFlow Collector Address

- Mandatory configuration.
- Use the **sflow collector** command to configure the address of the sFlow Collector.
- The sFlow Collector address must be a valid address. That is, the sFlow Collector address must not be a multicast or broadcast address. sFlow Collector must exist, and the route to it must be reachable.

Command Syntax	sflow collector <i>collector-id</i> destination { <i>ip-address</i> ipv6 <i>ipv6_address</i> } udp-port [[vrf <i>vrf-name</i>] [oob] [via mgmt <i>mgmt-name</i>]]] [[description <i>collector-name</i>]]
Parameter	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.

Description	<i>ip-address</i>: sFlow Agent IPv4 address. It is not configured by default ipv6 <i>ipv6-address</i>: sFlow Agent IPv6 address. It is not configured by default <i>udp-port</i>: sFlow Collector listening port number vrf <i>vrf-name</i>: VRF instance name. It is not configured by default oob: The sampled traffics are output through the management interface. By default, this parameter is not configured. via mgmt <i>mgmt-name</i>: Management port. It is not configured by default. description <i>collector-name</i>: Description of the sFlow Connector. It is not configured by default.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the sFlow Collector address. The sFlow Collector address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Collector address, a message indicating configuration failure is displayed. The sFlow Collector monitors the sFlow datagram on the specified port. When the vrf parameter is configured, the corresponding VRF instance must exist. When you remove the a VRF instance, the sFlow Collector address will be removed if this VRF instance is also configured for an sFlow Collector address. When the oob parameter is configured, a datagram is sent to the sFlow Collector through the management interface.

↘ Enabling sFlow Samples Output to the sFlow Collector

- Mandatory configuration.
- You can use the **sflow flow collector** command to enable the sFlow Agent to send flow samples to the sFlow Collector.
- This function must be enabled on the interface to send flow samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command Syntax	sflow flow collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending the flow samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

↘ Enabling Counter Samples Output to the sFlow Collector

- Mandatory configuration.
- You can use the **sflow counter collector** command to enable the sFlow Agent to send counter samples to the sFlow Collector.
- This must be enabled on the interface to send counter samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command Syntax	sflow counter collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending counter samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

Enabling Counter Sampling and Flow Sampling

- Mandatory configuration.
- You can use the **sflow enable** command to enable the flow sampling and counter sampling on an interface.
- The forwarding performance of an interface may be affected after flow sampling is enabled.

Command Syntax	sflow enable [ingress egress]
Parameter Description	ingress : Enables sFlow sampling in ingress direction. egress : Enables sFlow sampling in egress direction.
Defaults	The sFlow sampling function on an interface is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used to enable counter sampling and flow sampling for physical ports, SVI ports, sub routed ports and aggregate ports. If the direction parameter is not specified, sampling on both directions are enabled. The SVI ports and sub routed ports support only the ingress parameter.

Verification

- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

Configuring Flow Sampling and Counter Sampling for sFlow Agent

Network Environment Figure 7-6	The diagram illustrates a network setup for sFlow. A central switch, labeled 'Switch A', is connected to three different network segments. The left segment is represented by a cloud and connected to Switch A's Te 0/1 interface (IP 192.168.1.1). The right segment is also a cloud connected to Te 0/2 (IP 192.168.2.1). The top segment connects Switch A's Te 0/3 interface (IP 192.168.3.1) to an sFlow Collector (IP 192.168.3.100).
	As shown in Figure 7-6, start switch A that serves as the sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling traffic into sFlow datagrams at regular intervals or when the buffer is full, and send the sFlow datagrams to the sFlow Collector for traffic analysis.
Configuration Method	● Configure 192.168.1.1 as the sFlow Agent address. ● Configure 192.168.3.100 as the address of sFlow Collector 1, and 6343 as the port number. ● Configure interface TenGigabitEthernet 0/1 to output flow samples and counter samples to sFlow Collector 1, and enable the sFlow sampling function on this interface.
Switch A	<pre> Ruijie# configure terminal Ruijie(config)# sflow agent address 192.168.1.1 Ruijie(config)# sflow collector 1 destination 192.168.3.100 6343 Ruijie(config)# interface TenGigabitEthernet 0/1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow flow collector 1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow counter collector 1 Ruijie(config-if-TenGigabitEthernet 0/1)# sflow enable Ruijie(config-if-TenGigabitEthernet 0/1)# end </pre>
Check Method	Use the show sflow command to check whether the command output is consistent with the configuration.
	<pre> Ruijie# show sflow sFlow datagram version 5 Global information: Agent IP: 192.168.1.1 sflow counter interval:30 sflow flow max-header:64 sflow sampling-rate:8192 </pre>

Collector information:

ID	IP	Port	Size	VPN
1	192.168.3.100	6343	1400	
2	NULL	0	1400	

Port information

Interface	CID	FID	Enable
TenGigabitEthernet 0/1	1	1	Y

Information displayed on the sFlowTrend software:

The preceding figure shows the Top N page of the sFlowTrend software. This page displays the flow sampling results and displays the top 5 source IP addresses that involve the largest traffic. The total incoming traffic is about 450 Kpps and the total outgoing traffic is 450 Kpps, which are consistent with the actual traffic.

7.4.2 Configuring Optional Parameters of sFlow

Configuration Effect

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

Notes

- The forwarding performance may be affected when the sampling rate is too low.

Configuration Method

Configuring the Maximum Length of the Output sFlow Datagram

- Optional configuration.
- You can use the **sflow collector** command to configure the length of the sFlow datagram, excluding the Ethernet header, IP header, and UDP header. An sFlow datagram may contain one or multiple flow samples and counter samples. Configuration of the output sFlow datagram's maximum length may lead to the result that the number of sFlow datagrams output during processing of a certain number of flow samples differs from the number of sFlow datagrams output during processing of the same number of counter packets. If the maximum length is greater than MTU, the output sFlow datagrams will be segmented.

Command Syntax	sflow collector <i>collector-id</i> max-datagram-size <i>datagram-size</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2 max-datagram-size <i>datagram-size</i> : maximum length of the output sFlow datagram. The range is from 200 to 9,000.
Defaults	The default value is 1,400.
Command Mode	Global configuration mode
Configuration Usage	-

✚ Configuring the Flow Sampling Rate

- Optional configuration.
- You can use the **sflow sampling-rate** command to configure the global flow sampling rate.
- Configuration of flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate means a higher accuracy and larger CPU consumption. Therefore, the forwarding performance of the interface may be affected when the sampling rate is low.

Command Syntax	sflow sampling-rate <i>rate</i>
Parameter Description	<i>rate</i> : Sampling rate of sFlow sampling. One packet is sampled from every <i>n</i> packets (<i>n</i> equals the value of rate). The range is from 4,096 to 65535.
Defaults	The default global flow sampling rate is 8,192.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sampling rate of sFlow flow sampling, and sFlow flow sampling of all interfaces uses this sampling rate.

✚ Configuring the Maximum Length of the Packet Header Copied During Flow Sampling

- Optional configuration.
- You can use the **sflow flow max-header** command to configure the length of the packet header copied during flow sampling globally.
- Users can use this command to modify the datagram information to be sent to the sFlow Collector. For example, if a user concerns about the IP header, this user can configure the length to 56 bytes. During encapsulation of flow samples, the first 56 bytes of the sample packet are copied to the sFlow datagram.

Command Syntax	sflow flow max-header <i>length</i>
Parameter Description	<i>length</i> : maximum length of the packet header to be copied. The range is from 18 to 256.
Defaults	The default length of the packet header to be copied during global flow sampling is 64 bytes.

Command Mode	Global configuration mode
Configuration Usage	Configure the maximum number of bytes of the packet content copied from the header of the original packet. The copied content is recorded in the generated sample.

✚ Configuring the Sampling Interval

- Optional configuration.
- You can use the **sflow counter interval** command to configure the global counter sampling interval.
- Enable the counter sampling interface to send the statistics on it to the sFlow Collector at the sampling interval.

Command Syntax	sflow counter interval <i>seconds</i>
Parameter Description	<i>seconds</i> : time interval. The range is from 3 to 2,147,483,647. The unit is second.
Defaults	The default global counter sampling interval is 30 seconds.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sFlow counter sampling interval, and sFlow Counter sampling of all interfaces uses this sampling interval.

✚ Configuring the sFlow Source Address

- Optional configuration.
- You can use the **sflow source { address | interface }** command to configure the sFlow Source address of the output packets.

Command	sflow source { address { <i>ip-address</i> ipv6 <i>ipv6-address</i> } } { interface { <i>interface-name</i> ipv6 <i>interface-name</i> } }
Parameter Description	address : Configures the source IP address of sFlow output packets. <i>ip-address</i> : sFlow Source IPv4 address ipv6 <i>ipv6-address</i> : sFlow Source IPv6 address. interface : Configures the source interface of sFlow output packets <i>interface-name</i> : sFlow Source interface (configured with an IPv4 address) ipv6 <i>interface-name</i> : sFlow Source interface (configured with an IPv6 address)
Defaults	The default sFlow Source address is the local device IP address which is used to ping the destination IP.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the source IP address of the output packets. If a source interface is specified, the primary address of the interface will be the source IP address of the outputs packets. If the

	source interface is not specified or the IP address of the source interface is unreachable, for example, the interface is shutdown, the default source address will be used.

Verification

- Check whether an sFlow datagram with the flow samples is received on the sFlow Collector.
- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

Configuring Optional Parameters of sFlow

Network Environment	See Figure 7-6.
	● Set the flow sampling rate to 4,096 in global configuration mode. ● Configure the length of the packet header copied during flow sampling to 128 bytes in global configuration mode. ● Set the sampling interval to 10 in global configuration mode.
Configuration Method	<pre>Ruijie# configure terminal Ruijie(config)# sflow sampling-rate 4096 Ruijie(config)# sflow flow max-header 128 Ruijie(config)# sflow counter interval 10</pre>
	Make traffic pass through interface TenGigabitEthernet 0/1. ● Check whether there is traffic on interface TenGigabitEthernet 0/1 on sFlow Collector 1. ● Use the show sflow command to check whether the command output is consistent with the configuration.

Check Method	<pre>Ruijie# show sflow sFlow datagram version 5 Global information: Agent IP: 10.10.10.10 sflow counter interval:10 sflow flow max-header:128 sflow sampling-rate:4096 Collector information: ID IP Port Size VPN 1 192.168.2.100 6343 1400 2 NULL 0 1400 Port information Interface CID FID Enable TenGigabitEthernet 0/1 0 1 Y</pre>

8 Configuring NETCONF

8.1 Overview

The Network Configuration Protocol (NETCONF) is a brand new Extensible Markup Language (XML)–based protocol proposed by the NETCONF working group of the Internet Engineering Task Force (IETF) in 2003. It can be used for device configuration, parameter retrieval, and monitoring and management. This protocol adopts the client/server communication mode, in which the protocol server program runs on the device while the protocol client program runs on clients. The XML format is used in packets of this protocol, including all configuration data and protocol messages. The NETCONF protocol consists of four layers: content layer, operation layer, Remote Procedure Call (RPC) layer, and transport layer. The content layer is a collection of managed data objects and configuration data of devices is stored at this layer. The operation layer is the basic primitive operation set applied to RPCs, such as <get>, <get-config>, <edit-config>, and <delete-config>. The RPC layer provides a simple mechanism unrelated to transport protocols, and the mechanism specifies elements of some error feedback messages. The transport layer provides a secure transport channel. The NETCONF protocol supports Secure Shell (SSH) (mandatory), Simple Object Access Protocol (SOAP), and Blocks Extensible Exchange Protocol (BEEP).

Protocols and Standards

- RFC4741: NETCONF Configuration Protocol
- RFC4742: Using the NETCONF Configuration Protocol over Secure Shell (SSH)
- RFC4743: Using NETCONF over the Simple Object Access Protocol (SOAP)
- RFC4744: Using the NETCONF Protocol over the Blocks Extensible Exchange Protocol (BEEP)
- RFC5277: NETCONF Event Notifications
- RFC5381: Experience of Implementing NETCONF over SOAP
- RFC5539: NETCONF Over Transport Layer Security (TLS)
- RFC5717: Partial Lock RPC for NETCONF
- RFC6022: NETCONF Monitoring Schema
- RFC6241: Network Configuration Protocol
- RFC6242: Using the Network Configuration Protocol over Secure Shell
- RFC6243: With-defaults capability for NETCONF
- RFC6470: NETCONF Notification Events
- RFC6536: NETCONF Access Control Model (NACM)
- RFC4741 and RFC4742 are replaced by RFC6241 and RFC6242 respectively.

8.2 Applications

Application	Description
NETCONF Network Device Management	Users send NETCONF configuration packets in the XML format to devices through network management software installed on a NETCONF client, to configure and manage the devices.

8.2.1 NETCONF Network Device Management

Scenario

As shown in the figure below, users can utilize the NETCONF network management software to manage and monitor network devices.

Figure 8-1

Deployment

The network management station and managed network devices are connected via networks. The SSH protocol needs to run on both the network management software and the devices. On the network management station, by using the NETCONF network management software, users can access the configuration databases and state databases on network devices, receive event notifications sent from the network devices, and manages and monitors the network devices.

8.3 Features

Basic Concepts

Common Terms

- RFC: Remote Procedure Call
- DM: Data Model

Protocol Structure

The figure below shows the structure of the NETCONF protocol.

Figure 8-2 Structure of the NETCONF Protocol

Session Connection

- NETCONF over SSH

The server listens to Port 830. An SSH channel needs to be established before the NETCONF protocol is used. The establishment of the SSH channel (SSH subsystem, named netconf) requires user authentication and negotiation of a range of transmission algorithms (including negotiation of keys, a compression algorithm, a hash algorithm, an encryption algorithm, and a signature algorithm).

Figure 8-3 Packets Exchanged in a NETCONF Session

Capability Set Exchange

Capability sets need to be exchanged after a channel is established. Both the server and client provide their implemented capability sets and ignore capabilities that are not understood or not implemented. Each peer must support at least the basic protocol capability (`urn:ietf:params:netconf:base:1.1`). If the NETCONF protocol is compatible with an earlier protocol version, each peer should support the basic capability (`urn:ietf:params:netconf:base:1.0`) of this earlier version.

Protocol Operations

Nine basic operation methods are defined for the operation layer of NETCONF and the operation methods are as follows: `<get>` and `<get-config>` are value acquisition operations, `<edit-config>`, `<copy-config>`, and `<delete-config>` are configuration operations, `<lock>` and `<unlock>` are lock protection operations provided in the case of concurrent operations on critical device resources (configuration files), and `<close-session>` and `<kill-session>` are session termination operations.

- `get`: Obtains the status and configuration data of a device.
- `get-config`: Obtains configuration data based on the filtering node in an RPC request.

- **edit-config:** Configures a device based on the provided data model definition and operation attributes. One important attribute operation can be set to merge, replace, create, delete, or remove, and the default value is merge.
- **copy-config:** Copies a configuration file, for example, copies a candidate configuration into a configuration file, copies a startup configuration into the running configuration, and writes a running configuration into the startup configuration. These copy operations need the target files to support the write capability.
- **delete-config:** Deletes a configuration file of a device. The running configuration file of a device cannot be deleted.
- **lock:** Provides lock protection for configuration data files. When a client is accessing (or modifying) a configuration data file of a device, other clients or non-NETCONF clients (such as SNMP or CLI clients) cannot access (or modify) the configuration data file.
- **unlock:** Unlocks a configuration data file.
- **close-session:** Closes the current session, including resource release, lock release, and disconnection. When this operation is performed, it must be ensured that the handling of the current service is complete and no new request is being handled.
- **kill-session:** forcibly terminates a session (the current session cannot be terminated), including resource release, lock release, and disconnection. When this operation is performed, an ongoing service must be terminated and uncompleted services must be rolled back to the state prior to service handling.

Overview

Feature	Description
Capability Set Exchange	The NETCONF server and client mutually send capability sets to each other. The server (device) supports NETCONF 1.0 and NETCONF 1.1.
get	The client obtains configuration or state data of the device.
get-config	The client obtains configuration data of the device.
edit-config	The client modifies configuration data of the device.
copy-config	The client copies a configuration file on the device into another configuration file.
delete-config	The client deletes a configuration file on the device.
close-session	The client actively closes the current NETCONF session with the device.
lock	The client locks configuration files of the device.
unlock	The client unlocks the configuration files of the device.

8.3.1 Capability Set Exchange

The NETCONF client and NETCONF server exchange their capability sets immediately after establishing a connection. They can perform subsequent data operations only when they support the same NETCONF protocol version. The format of sent packets is as follows:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
      urn:ietf:params:netconf:base:1.1
```

```

    </capability>
    <capability>
      Capability set 1
    </capability>
    <capability>
      Capability set 2
    </capability>
  </capabilities>
  <session-id>Session ID</session-id>
</hello>

```

The capability exchange packet sent from the client to the server cannot contain the session ID (<session-id>) node.

Example of capability set exchange on the server:

```

<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
    <capability>urn:ietf:params:netconf:base:1.1</capability>
    <capability>urn:ietf:params:netconf:capability:writable-running:1.0</capability>

    <capability>urn:ietf:params:xml:ns:yang:ietf-yang-types?module=ietf-yang-types&revision=2013-07-15</capability>

    <capability>urn:rg:params:xml:ns:yang:rg-tacacs?module=rg-tacacs&revision=2016-10-25</capability>

    <capability>urn:rg:params:xml:ns:yang:rg-interfaces?module=rg-interfaces&revision=2016-10-25</capability>

    <capability>urn:ietf:params:xml:ns:yang:ietf-inet-types?module=ietf-inet-types&revision=2010-09-24</capability>

    <capability>urn:rg:params:xml:ns:yang:rg-openflow?module=rg-openflow&revision=2016-09-26</capability>
  </capabilities>
  <session-id>28</session-id>
</hello>

```

Example of capability set exchange on the client:

```

<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">

```

```
<capabilities>
  <capability>urn:ietf:params:netconf:base:1.0</capability>
</capabilities>
</hello>
```

8.3.2 get

This operation is used to obtain the configuration or state data of the device.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <filter type="subtree">
      Configuration data (or state data) filtering rule
    </filter>
  </get-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    Acquired configuration data (or state data)
  </data>
</rpc-reply>
```

If none of the subsets of state data on the device matches a filtering rule, the device returns a blank data node shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

8.3.3 get-config

This operation is used to acquire configuration data of the device. It acquires configuration data subsets based on various subtree filtering rules but cannot obtain the state data of the device.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
```

```
</source>
<filter type="subtree">
  Protocol filtering rules
</filter>
</get-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    Acquired configuration data
  </data>
</rpc-reply>
```

If none of the subsets of configuration data on the device matches filtering rules, the device returns a blank data node shown below:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

8.3.4 edit-config

This operation is used to edit the configuration based on the provided data model definition and operation attributes. The edit-config packets contain five operation attributes, which are specified in the operation attribute description of the configuration node in the delivered XML packets. The five attributes are as follows:

merge: Merges configuration data in edit-config packets that contain this attribute into a specified device configuration file (or database). If the configuration data does not exist, it is created based on delivered content.

replace: Uses configuration data in the edit-config packets that contain this attribute to replace a related configuration data node in a specified device configuration file (or database). If the configuration data does not exist, it is created based on delivered content. Ruijie devices do not support this operation temporarily. If such an attribute is delivered, it is treated as the merge attribute.

create: Creates, in a specified configuration data file (or database), the configuration data in the edit-config packets that contain this attribute. If the configuration data does not exist, it is created based on delivered content. If the configuration data already exists, an rpc-error packet is returned and error-tag indicates that the data already exists.

delete: Deletes configuration data in the edit-config packets that contain this attribute from a specified configuration data file (or database). If the configuration data already exists, it is deleted directly. If the configuration data does not exist, an rpc-error packet is returned and error-tag indicates that the data is missing.

remove: Removes configuration data in the edit-config packets that contain this attribute from a specified configuration data file (or database). If the configuration data already exists, it is removed directly. If the configuration data does not exist, this operation is ignored and an OK response is returned.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target> <running/> </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      Configuration data
    </config>
  </edit-config>
</rpc>
```

If a packet does not carry the error-option node, the value of this node is **stop-on-error** by default, indicating that once the configuration of a node in a packet is incorrect, subsequent configuration in the same packet is stopped and rpc-error is returned. If a packet does not carry the test-option node, the value of this node is **test-then-set** by default. If a packet does not carry the default-operation node, the value of this node is **merge** by default.

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="message ID" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

If a packet carries the error-option node, the format is generally as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target> <running/> </target>
    <error-option>behavior option in the case of a configuration error</error-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      Configuration data
    </config>
  </edit-config>
</rpc>
```

The error-option node is a node of the enumeration type. It can be set to either of the following values:

stop-on-error: Stops the current edit-config operation immediately when the first error occurs. It is the default value of error-option. The configuration data before the error in the current configuration packet already takes effect.

continue-on-error: Continues processing configuration data even if an error occurs. Errors are recorded, and an error message is returned after all processing is completed (that is, rpc-error is returned for all configuration errors).

8.3.5 copy-config

This operation is used to synchronize startup configuration to running configuration.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <startup/>
    </target>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.3.6 delete-config

This operation is used to delete the startup configuration of the device. The running configuration cannot be deleted.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
    <target>
      <startup/>
    </target>
  </delete-config>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.3.7 close-session

This operation is used to close the current session, release resources and locks, and break the connection.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <close-session/>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.3.8 lock

According to RFC6241, this operation is used to lock the configuration database (configuration files) and prevent multiple sources (such as the CLI, SNMP, and multiple concurrent NETCONF sessions) from modifying configuration files of the device concurrently, so as to avoid unnecessary configuration modifications. The device simplifies this operation, and can only prevent concurrent modifications (running configuration) from multiple NETCONF sessions and ensures modification security of configuration data.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <lock>
    <target>
      <running/>
    </target>
  </lock>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.3.9 unlock

This operation is used to unlock the configuration database (configuration files; running configuration on the device here).

<lock> and <unlock> are an operation pair.

The format of packets sent by the client is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <unlock>
    <target>
      <running/>
    </target>
  </unlock>
</rpc>
```

The format of packets returned by the server is as follows:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

8.4 Configuration

Configure parameters related to SSH channel authentication before using NETCONF. For the SSH configuration, see *Configuring SSH*.

Configuration	Description and Command	
Configuring the Candidate Capability of NETCONF	 (Optional) It is used to configure the NETCONF server to feed back the candidate capability to the client when exchanging capabilities with the client.	
	netconf capability candidate	Enables the candidate and confirmed-commit capabilities of NETCONF.
Configuring the Rollback Capability of NETCONF	 (Optional) It is used to configure the NETCONF server to feed back the rollback-on-error capability to the client when exchanging capabilities with the client.	
	netconf capability rollback	Enables the rollback-on-error capability of NETCONF.
Configuring the Validate Capability of NETCONF	 (Optional) It is used to configure the NETCONF server to feed back the validate capability to the client when exchanging capabilities with the client.	
	netconf capability validate	Enables the validate capability of NETCONF.
Configuring the Feature Function of the YANG Module	 (Optional) It is used to configure the NETCONF server not to feed back the feature attribute to the client when exchanging capabilities with the client.	

	netconf feature-disable	Disables the feature function of the NETCONF.
Configuring the Maximum Number of the Returned Nodes from NETCONF Session	 (Optional) It is used to configure the server to advertise all versions of all supported YANG modules to the client when exchanging capabilities with the client.

8.4.2 Configuring the Candidate Capability of NETCONF

Configuration Effect

The NETCONF server returns the candidate and confirmed-commit capabilities when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

Configuration Steps

✚ Enabling the Candidate and Confirmed-Commit Capabilities of NETCONF

Command	netconf capability candidate
Parameter	N/A
Description	
Defaults	The candidate and confirmed-commit capabilities of NETCONF are enabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ Enabling the Candidate and Confirmed-Commit Capabilities of NETCONF

Scenario Figure 8-4	NETCONF server  NETCONF client
Configuration Steps	● Enable the candidate and confirmed-commit capabilities of NETCONF.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf capability candidate Ruijie(config)#</pre>
Verification	N/A

8.4.3 Configuring the Rollback Capability of NETCONF

Configuration Effect

The NETCONF server returns the rollback capability when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

Configuration Steps

✚ Enabling the Rollback Capability of NETCONF

Command	netconf capability rollback
Parameter	N/A
Description	
Defaults	The rollback capability of NETCONF is enabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

✚ Enabling the Rollback Capability of NETCONF

Scenario Figure 8-5	NETCONF server  NETCONF client
Configuration Steps	● Enable the rollback capability of NETCONF.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf capability rollback Ruijie(config)#</pre>
Verification	N/A

8.4.4 Configuring the Validate Capability of NETCONF

Configuration Effect

The NETCONF server returns the validate capability when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

Configuration Steps

✚ Enabling the Validate Capability of NETCONF

Command	netconf capability validate
Parameter	N/A
Description	
Defaults	The validate capability of NETCONF is enabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Enabling the Validate Capability of NETCONF

Scenario Figure 8-6	NETCONF server NETCONF client 
Configuration Steps	● Enable the validate capability of NETCONF.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf capability validate Ruijie(config)#</pre>
Verification	N/A

8.4.5 Configuring the Feature Function of the YANG Module

Configuration Effect

The NETCONF server does not return the feature attribute of the YANG module when exchanging capabilities with the NETCONF client (via Hello packets and capabilities packets).

Configuration Steps

▾ Disabling the Feature Attribute of NETCONF

Command	netconf feature-disable
Parameter	N/A
Description	
Defaults	The feature attribute of NETCONF is disabled by default.
Command	Global configuration mode

Mode	
Usage	N/A
Guide	

Configuration Example

Disabling the Feature Attribute of NETCONF

Scenario Figure 8-7	NETCONF server  NETCONF client
Configuration Steps	Disable the feature attribute of the YANG module.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf feature-disable Ruijie(config)#</pre>
Verification	N/A

8.4.6 Configuring the Maximum Number of the Returned Nodes from NETCONF Session

Configuration Effect

The NETCONF client can only return the supported maximum number of XML nodes, or else, the client returns error.

Notes

This configuration takes effect only on the search result whose target is running.

Configuration Steps

Configuring the Maximum Number of the Returned Nodes from the NETCONF Session

Command	netconf filter nodes-limit <i>num</i>
Parameter Description	<i>num</i> : indicates the maximum number of the returned nodes. The default value is 100000, and the value ranges from 100 to 2147483647.
Defaults	The maximum number of the returned nodes is 100000.
Command Mode	Global configuration mode
Usage	N/A

Guide	

Configuration Example

Configuring the Maximum Number of the Returned Nodes from the NETCONF Session

Scenario Figure 8-8	NETCONF server  NETCONF client
Configuration Steps	Configure the maximum number of the returned nodes from the NETCONF session.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf filter nodes-limit 101 Ruijie(config)#</pre>
Verification	<pre>Ruijie (config)# show running-config in filter nodes-limit netconf filter nodes-limit 101</pre>

8.4.7 Configuring the Maximum Number of the NETCONF Session

Configuration Effect

The NETCONF client can only support the specified number of sessions.

Configuration Steps

Configuring the Maximum Number of the NETCONF Session

Command	netconf max-sessions <i>num</i>
Parameter Description	<i>num</i> : indicates the maximum number of the NETCONF session. The default value is 5, and the value ranges from 1 to 36.
Defaults	The maximum number of the NETCONF session is 5.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Maximum Number of the NETCONF Session

Scenario Figure 8-9	NETCONF server  NETCONF client
Configuration Steps	Configure the maximum number of the NETCONF session.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf max-sessions 15 Ruijie(config)#</pre>
Verification	<pre>Ruijie (config)#show running-config in max-sessions netconf max-sessions 15</pre>

8.4.8 Configuring the YANG Module Multi-version Notification

Configuration Effect

The NETCONF server advertises all versions of all supported YANG modules on the device when exchanging capabilities with the NETCONF client (via Hello packets).

Notes

- The **netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised.
- The **no netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised and one YANG module can advertise only its current latest version in the capability notification packet.

Configuration Steps

Configuring the YANG Module Multi-version Notification

- Optional.
- This configuration must be completed before the NETCONF server advertises the capability packet (Hello packet).

Command	netconf yang multi-revision
Parameter	N/A
Description	
Defaults	The YANG module multi-version notification is enabled by default.
Command Mode	Global configuration mode

Usage Guide	N/A

Configuration Example

Configuring the YANG Module Multi-version Notification

Scenario Figure 8-10	NETCONF server NETCONF client 
Configuration Steps	Configure the YANG module multi-version notification.
NETCONF	<pre>Ruijie# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Ruijie(config)# netconf yang multi-revision Ruijie(config)#</pre>
Verification	N/A

8.5 Monitoring

Data Center Configuration

1. Configuring DCB

1 Configuring DCB

1.1 Overview

A data center (DC) mainly processes the following three traffic types:

- Storage traffic: The requirement of packet integrity must be met.
- High-performance computing traffic: The requirement of low delay must be met.
- Ethernet traffic: Certain degree of packet loss and delay are allowed.

Due to the different requirements for the three traffic types, traditional DC bears the traffic on three types of networks, as shown in Figure 1-1.

Figure 1-1 Three types of DC networks

This topology configuration is feasible for a small-sized DC. If the DC grows, running the three types of networks becomes costly. An alternative method is to bear the three traffic types on Ethernet and define additional mechanisms, so that the Ethernet can meet the requirements of the three types of networks. The following definitions are formulated in IEEE to implement the method:

- Priority-based Flow Control (PFC): a mechanism that avoids packet loss in storage traffic and impact on other traffic types if the three traffic types coexist on Ethernet.
- Data Center Bridging Capability Exchange Protocol (DCBX): a protocol that is defined by IEEE 802.1Qaz for negotiating the data center bridge (DCB) capability. With the Link Layer Discovery Protocol (LLDP), DCBX discovers devices and exchanges DCB capability.

Protocols and Standards

- IEEE Std 802.1Qaz
- IEEE 802.1Qbb

- IEEE 802.1Qau
- IEEE 802.3bd
- <http://www.ieee802.org/1/files/public/docs2008/az-wadekar-dcbx-capability-exchange-discovery-protocol-1108-v1.01.pdf>

1.2 Applications

Application	Description
Configuring DC Network	The Ethernet of a DC bears three types of data traffic.

1.2.1 Configuring DC Network

Scenario

The DC Ethernet bearing three types of data traffic must meet the following requirements:

- Storage traffic: The requirement of packet integrity must be met.
- High-performance computing traffic: The requirement of low delay must be met.
- Ethernet traffic: Certain degree of packet loss and delay are allowed.

Figure 1-2

Deployment

- Enable PFC for storage traffic to meet the requirement of packet integrity.
- Map the packet priority of high-performance computing traffic to the traffic class (TC) which boasts strict priority (SP) algorithm.
- Allocate bandwidth to the TC of Ethernet traffic.

1.3 Features

Basic Concepts

802.1p (Cos)

In 802.1p, the L2 header Virtual Local Area Network (VLAN) tag field falls into 8 priorities, ranging from 0 to 7.

16bit	3bit	1bit	12bit
Tag Protocol ID (0x8100)	priority	CFI	VLAN ID

Traffic with priorities in the range 0~2 indicates common Ethernet traffic that is transmitted with maximum capability; traffic with priority 3 indicates Fiber Channel Over Ethernet (FCoE) Storage Area Network (SAN) traffic; traffic with priorities 4 and 5 indicates delay-sensitive voice traffic; and traffic with priorities 6 and 7 indicates delay-sensitive main traffic. Traffic with priority 7 indicates network control packets.

Trust edge and application priority identification

By default, Ethernet ports are untrusted ports and need to be set to trust mode, so that packets carrying 802.1p value tags can be mapped to corresponding TC. The priority of untagged packets is 0 by default and can be modified.

The identified priority of FCoE packets is 3 by default and can be modified. The priority identification function must be enabled on a network interface card (NIC) which supports DCBX. If the NIC does not support DCBX, the priority identification function will be ignored.

If NICs do not support DCBX or users require more detailed priority identification function, configure Quality of Service (QoS) policies on ports to map an access control list (ACL) and identify application priority; or modify the FCoE packet priority on the servers directly connected to switches.

Queue and TC

A switch port has 3~8 queues for caching packets. A traffic class (TC) can be a single queue caching packets with different priorities or composed of multiple queues, with each queue caching packets of specified priority. The SP algorithm can be performed for a TC.

For example, TC 1 contains queue 1 only, and queue 1 caches packets with priorities 0~2; or TC 1 contains queues 0~2, where, queue 0 caches packets with priority 0, queue 1 caches packets with priority 1, and queue 2 caches packets with priority 2. Meanwhile, the SP algorithm may be enabled for queues 0~2 to ensure that packets with priority 2 are transmitted first.

Mapping list

Packets are mapped to a TC in the mapping list according to identified priority and then allocated to a specific queue of the TC.

- A TC is composed of multiple queues.

Each packet with a priority is mapped to a specific queue of the TC. The following table lists the mapping relationship between priorities and queues.

Cos	0	1	2	3	4	5	6	7

Queue	0	1	2	3	4	5	6	7

Queues in a TC are associated with the priorities mapped. According to the mapping list, users can modify queues contained in a TC. For example, users can map priorities 0~2 to TC 1, then TC 1 contains queues 0~2 that are associative with priorities 0~2.

- A TC contains a single queue.

A TC is associative with a specific queue. The following table lists the mapping relationship between queues and TCs.

Queue	0	1	2	3	4	5	6	7
TC	0	1	2	3	4	5	6	7

According to the mapping list, the mapping relationship between priorities and TCs is the mapping relationship between priorities and queues. For example, if priority 3 is mapped to TC 1, packets with priority 3 will be mapping to queue 1 of TC 1.

Overview

Feature	Description
PFC	Implements PFC on packets based on 802.1p value. If traffic of specified priority becomes congested, stops forwarding packets of this priority and instructs the transmitting device to stop sending such packets. With this function, packet integrity of Ethernet can be ensured.
DCBX	The DCB device on the edge access layer instructs the servers connected to automatically synchronize with the DCB device.

1.3.1 Configuring PFC

With PFC, packet integrity of the storage traffic can be ensured and impact on other traffic types can be avoided if the three traffic types, storage traffic, high-performance computing traffic, and Ethernet traffic, coexists on Ethernet. An 802.1p value is allocated to the storage traffic, and the PFC function is enabled for the priority. Other 802.1p values are allocated to the high-performance computing traffic and Ethernet traffic and the PFC function is disabled.

Working Principle

PFC is an enhanced version of the flow control function. Generally, if a receiver is unable to process received packets, the receiver instructs the packet sender to stop sending packets, which avoids packet loss. The flow control function is implemented by receiving or sending PAUSE frames via ports.

Figure 1-3 Flow control

As shown in Figure 1-3, when ports Gi 0/1 and Gi 0/2 forward packets at 1 Gbps, port Fa 0/1 will be congested. To avoid packet loss, enable the flow control function on ports Gi 0/1 and Gi 0/2.

- If port Fa 0/1 is congested in the course of forwarding packets, switch B will cache the packets. When the traffic exceeds the forwarding capability of switch B, packets will be lost. In this case, port Gi 0/2 will send a PAUSE frame to port Gi 0/1, instructing port Gi 0/1 to stop forwarding packets.
- Upon receiving the PAUSE frame, port Gi 0/1 stops forwarding packets to port Gi 0/2. The pause time is subject to the information carried in the PAUSE frame. If the congestion problem persists after the pause time is up, the preceding procedure will repeat until the congestion problem is cleared.

As described above, the flow control function can avoid packet loss, but it will result in link stop as well. That is, the entire link is stopped. The PFC function, however, allows eight virtual links to be created over an Ethernet link and specifies an 802.1p value for each virtual link. Any virtual link can be paused or restarted independently, without causing traffic interruption to other virtual links.

Figure 1-4 PFC

As shown in the preceding figure, enable the PFC function on ports Gi 0/1 and Gi 0/2 for priority 3.

- If port Fa 0/1 is congested in the course of forwarding packets with priority 3, switch B will cache the packets. When the traffic exceeds the forwarding capability of switch B, port Gi 0/2 will send a PFC PAUSE frame to port Gi 0/1, instructing port Gi 0/1 to stop forwarding packets with 802.1p value 3.
- Upon receiving the PFC PAUSE frame, port Gi 0/1 stops forwarding packets to port Gi 0/2. The pause time is subject to the information carried in the PFC PAUSE frame. If the congestion problem persists after the pause time is up, the preceding procedure will repeat until the congestion problem is cleared. As shown in the preceding figure, stopping forwarding packets with priority 3 will not have impact on packet transmission of other links between Gi 0/1 and Gi 0/2.

Related Configuration

📌 Enabling the PFC Function

The PFC function is disabled for any priority by default.

Run the **priority-flow-control nodrop** *cos-value-list* {**off** | **on**} command to enable the PFC function for a specified priority. *cos-value-list* indicates a priority list (range: 0~7); **on** indicates that the PFC function is enabled; and **off** indicates that the PFC function is disabled.

📌 Configuring Flow Rate Warning for Pause Frames for a Priority of an Interface

By default, no warning is generated when a device interface sends or receives Pause frames.

Run the **priority-flow-control early-warning cos-value-list { output pps rate-num } | input pps rate-num** command to configure the flow rate warning thresholds for Pause frames in the input and output directions for a specified PFC priority of an interface. *cos-value-list* indicates the configured priority list, and a priority ranges from **0** to **7**. **output pps rate-num** indicates the threshold of Pause frames in the output direction while **input pps rate-num** indicates the threshold of Pause frames in the input direction.

If the rate for an interface at a specified priority to send/receive Pause frames exceeds the configured threshold (packets per second), a warning is generated and logged.

1.3.2 Configuring DCBX

Working Principle

▾ DCBX version

Currently, market products support the following DCBX versions:

- CIN-DCBX: indicates the first-generation of DCBX designed by Cisco, Intel, and Nuova that is compatible with the converged network adapter (CNA).
- CEE-DCBX: indicates the second-generation of DCBX that is compatible with the CAN.
- IEEE-DCBX: indicates a standard DCBX that is defined by IEEE 802.1Qaz.

▾ Negotiating DCB capability

DCBX encapsulates each DCB capability into an LLDP type/length/value (TLV). Based on the LLDP TLV, peer devices discover the DCB capabilities of neighboring devices and then negotiate with the neighboring devices according to the discovered DCB capabilities. By the negotiation, DCB configuration can be synchronized and error detection can be implemented at both ends.

DCB capabilities that need to be negotiated include PFC, and APP. The Willing field is contained in corresponding TLV of the capabilities. When the Willing field is 1, peer DCB configuration is acceptable; when the Willing field is 0, peer DCB configuration is unacceptable. DCB capabilities are negotiated based on the Willing field. The following table lists the values of the Willing field at both ends and negotiation results.

Local Willing Field	Peer Willing Field	Negotiation Result
1	1	DCB configuration of the device with smaller media access control (MAC) address is selected as a common DCB configuration.
1	0	Peer DCB configuration is selected.
0	1	Local DCB configuration is selected.
0	0	If DCB configuration at both ends is the same, negotiation succeeds; otherwise, negotiation fails.

Related Configuration

The DCBX function is enabled by default, so DCB capability configuration can be performed without additional configuration.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of the PFC	✔ (Mandatory) It is used to enable the PFC capability.	
	priority-flow-control nodrop <i>cos-value-list</i> { off on }	Configures the PFC function for specified priorities.
Configuring Basic Functions of the DCBX	✔ (Mandatory) It is used to discover, detect, and negotiate peer DCB capabilities.	
	dcbx enable	Enables the global and interface DCBX function.
	dcbx mode { auto cee ieee }	Configures the DCBX mode of interfaces.
	dcbx { pfc app-proto } advertise	Configures the DCBX TLV type that can be released on ports.
	dcbx { pfc app-proto } willing enable	Enables DCB capability synchronization for ports.

- Remark: Configuration commands vary with specific products. For details about the commands, refer to DCB Commands.

1.4.1 Configuring Basic Functions of the PFC

Configuration Effect

- Implement PFC for port data traffic based on 802.1p values.

Notes

- PFC is applicable to point-to-point (P2P) full-duplex links only.
- The PFC function conflicts with ordinary flow control function.
- If the priorities with PFC enabled and the priorities with PFC disabled are mapped to a queue, packets with the latter priorities will be suppressed. Generally, it is not recommended to map such priorities to a same queue.
- The PFC function is not applicable to packets sent by a CPU.
- The PFC function can take effect after a port trusts the CoS values.

Configuration Steps

📌 Enabling the PFC function

- The PFC function is disabled for packets with any priority by default. To implement PFC on specified priority, configure PFC.

Verification

- Check the display result.

Related Commands

▾ Enabling the PFC function

Command	priority-flow-control nodrop <i>cos-value-list</i> { off on }
Parameter	<i>cos-value-list</i> : Indicates a priority list (range: 0~7).
Description	on : Enables the PFC function of a priority. off : Disables the PFC function of a priority.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	priority-flow-control nodrop <i>cos-value-list</i> { off on }
Parameter	<i>cos-value-list</i> : Indicates a priority list (range: 0~7).
Description	on : Enables the PFC function of a priority. off : Disables the PFC function of a priority.
Command Mode	Interface configuration mode
Usage Guide	The PFC function can be automatically negotiated and configured based on DCBX. After the PFC function is configured on the CLI, configuration results fall into the following scenarios: 1) The PFC function is automatically negotiated and configured based on DCBX. The automatic configuration takes effect. 2) The PFC function is not automatically negotiated and configured based on DCBX. The configuration on the CLI takes effect.

▾ Configuring Flow Rate Warning for a Priority of an Interface

Command	priority-flow-control early-warning <i>cos-value-list</i> { output pps <i>rate-num</i>] input pps <i>rate-num</i> }
Parameter	<i>cos-value-list</i> : Indicates the configured priority list. The priority ranges from 0 to 7 .
Description	<i>rate-num</i> : Indicates the flow rate warning value. The value ranges from 1 to 148809523 .
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the Global PFC Statistics Collection Interval

Command	priority-flow-control counting-interval <i>number</i>
Parameter	<i>number</i> : Indicates the statistics collection interval in seconds. The value ranges from 1 to 20 .
Description	
Command Mode	Global configuration mode

Usage Guide	N/A

Configuration Example

Enabling PFC for 802.1p value 3

Scenario Figure 1-5	 <pre> graph LR SA[Server A] --- Gi 0/1 S[SwitchA] S --- Fa 0/2 SB[Server B] </pre>
Configuration Steps	- Specify PFC IEEE 802.1p value 3 on a server. - Specify PFC IEEE 802.1p value 3 on a switch.
A	<pre>Ruijie(config)# priority-flow-control nodrop 3 on</pre>
Verification	Check the display result.

Common Errors

- The common flow control function is not disabled. As a result, PFC fails to be enabled.
- A port is not set to trust the CoS values.
- Priorities with the PFC function enabled are mapped to a TC that contains any other priorities (including priorities with the PFC function enabled).

1.4.2 Configuring Basic Functions of the DCBX

Configuration Effect

- Discover peer DCB capabilities.
- Check whether DCB capabilities configured for both ends are the same.
- Automatically negotiate and configure DCB.

Notes

- The DCB capability negotiation function can take effect on interfaces only after the following requirements are met: the LLDP function is enabled in global configuration mode and interface configuration mode; the LLDP working mode of the interfaces is set to txrx; the TLV of corresponding DCB capability can be released; and corresponding DCB capability is supported. If the requirements are not met, the DCBX function will not take effect even if it is enabled on the interfaces.
- When configuring AP ports, make sure that the LLDP of different AP member ports is set to the same value, the AP port topology is correctly set, and the DCBX TLV released for different AP member ports is the same. Otherwise, abnormalities occur when DCB capabilities are negotiated on the AP ports at both ends.

Configuration Steps

📌 Enabling DCBX

- The global and interface DCBX function is enabled by default.
- Enable DCBX in global or interface configuration mode to launch the DCB capability negotiation of the interface. Disabling the global DCBX function will disable the DCB capability negotiation of all interfaces. The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

📌 Configuring a DCBX mode

- (Mandatory) Interfaces work in the automatic switch mode by default.
- (Interface configuration mode) The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

📌 Configuring DCBX TLV types that can be released

- (Mandatory) All types of DCBX TLV can be released on interfaces by default.
- (Interface configuration mode) The DCBX function runs on physical ports or AP ports, and it is not applicable to stacking ports or VSL ports.

✚ Configuring synchronization willingness

- Local end is unwilling to receive peer configuration by default. That is, the Willing parameter is not set.
- During negotiation of DCB capability synchronization, specify the Willing parameter for local ports to receive peer configuration. If local end is willing to receive peer configuration, configure the Willing parameter.

Verification

- Check the display result.

Related Commands

✚ Enabling DCBX

Command	dcbx enable
Parameter	N/A
Description	
Command mode	Global configuration mode/Interface configuration mode
Usage Guide	Disabling the global DCBX function will disable the DCB capability negotiation of all interfaces. AP ports negotiate DCB capabilities based on AP member ports.

✚ Configuring a DCBX mode

Command	dcbx mode { auto cee ieee }
Parameter	Interfaces work in the automatic switch mode by default.
Description	auto: Allows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in the automatic switch mode and the default mode is CEE-DCBX. cee: Disallows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in CEE-DCBX mode. ieee: Disallows an interface to automatically switch a DCBX mode based on the received DCBX TLV type if an interface works in IEEE-DCBX mode.
Command mode	Interface configuration mode
Usage Guide	AP ports negotiate DCB capabilities based on AP member ports.

✚ Configuring DCBX TLV types that can be released

Command	dcbx { pfc app-proto } advertise
Parameter	All types of DCBX TLV can be released on interfaces by default.
Description	pfc: Enables the DCBX TLV release function corresponding to the PFC capability. app-proto: Enables the DCBX TLV release function corresponding to the APP capability.

Command mode	Interface configuration mode
Usage Guide	AP ports negotiate DCB capabilities based on AP member ports. Types of DCBX TLV that can be released on AP ports will be applied to different AP member ports.

📌 Configuring synchronization willingness

Command	dcbx { pfc app-proto } willing enable
Parameter Description	pfc : Enables PFC capability synchronization willingness. app-proto : Enables APP capability synchronization willingness.
Command mode	Interface configuration mode
Usage Guide	AP ports negotiate DCB capabilities based on AP member ports. If the Willing parameter is set to the same value at both ends and the local and peer ports are willing to receive peer configuration, the configuration on the port with a smaller MAC address prevails. If the local and peer ports are unwilling to receive peer configuration, the same value of the Willing parameter indicates negotiation success; otherwise, it indicates negotiation failure. If DCB capabilities support only global configuration mode, they cannot be negotiated over DCBX. In this case, local configuration prevails. For example, if the PFC function supports only global configuration mode, even though the local PFC Willing bit is set to 1, the local port will not receive peer configuration. That is, the PFC capability cannot be negotiated, and local PFC configuration prevails.

Configuration Example

📌 Automatically configuring DCB

Scenario Figure 1-6	 The diagram illustrates a network connection between a Server and a SwitchA. A horizontal line connects the two devices, with the label 'Gi 0/1' positioned above the line. The Server is represented by a blue server icon on the left, and SwitchA is represented by a blue switch icon on the right.
Configuration Steps	● Enable LLDP in global configuration mode and interface configuration mode (default configuration). ● Set the LLDP mode of an interface to txrx (default configuration). ● Enable DCBX of an interface (default configuration). ● Allow all types of DCBX TLV to be released on an interface (default configuration).
A	By default, switch A can instruct the server to automatically configure DCB, free users of manually configuring DCB.
Verification	Check the display result.
A	<pre>Ruijie#show dcbx status interface GigabitEthernet 0/1 ----- Port [GigabitEthernet 0/1] -----</pre>

Local managing configuration information and port link state:	
Port status of DCBX	: Enable
Port mode of DCBX	: AUTO mode
Port active of DCBX	: CEE active
PFC is allowed to advertise	: Yes
APP is allowed to advertise	: Yes
PFC is willing to accept peer configuration	: No
APP is willing to accept peer configuration	: No
Port link state	: UP
Negotiated configuration information:	
PFC negotiated result	: using local configuraiton
APP negotiated result	: using local configuration

Common Errors

- The LLDP function is not enabled in global configuration mode or interface configuration mode.
- The LLDP mode of an interface is not set to txrx.

1.5 Monitoring

Clearing

- ✔ Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears statistical information of PFC.	clear priority-flow-control statistics [interface <i>interface-name</i>]

Displaying

Description	Command
Displays global PFC configuration information.	show priority-flow-control status
Displays PFC configuration and status information of a port.	show priority-flow-control status [interface <i>interface-name</i>]
Displays statistical information of PFC.	show priority-flow-control statistics [interface <i>interface-name</i>]
Displays DCBX configuration information and negotiation status of an interface.	show dcbx status [interface <i>interface-name</i>]
Displays DCB configuration information and capability negotiation status at both ends.	show dcbx information { pfc app-proto } [interface <i>interface-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs the PFC details.	debug pfc detail
Debugs the PFC error.	debug pfc error
Debugs the PFC event.	debug pfc event
Debugs the PFC statistics.	debug pfc statistics
Debugs DCBX events.	debug dcbx event
Debugs DCBX and DCB capability submodule interaction.	debug dcbx detail
Debugs error information during DCBX running.	debug dcbx error
Debugs packet transmission and receiving of DCBX.	debug dcbx pkt
Debugs change of the DCBX status machine.	debug dcbx stm
Debugs hot standby information of DCBX.	debug dcbx ha
Debugs the DCB library.	debug dcb-lib
