

REXX for CICS Transaction Server
1.1

User Guide and Reference

Note

Before using this information and the product it supports, read the information in [“Notices” on page 483](#).

This edition applies to the REXX Development System for CICS®, Version 1 Release 1, program number 5655-086 and to the REXX Runtime Facility for CICS, Version 1 Release 1, program number 5655-087 and to all subsequent releases and modifications until otherwise indicated in new editions.

Contents

About this PDF.....	xiii
Part 1. Developing REXX applications.....	1
Chapter 1. Features and components of REXX.....	3
Chapter 2. Writing and running a REXX application.....	5
Syntax of REXX instructions.....	5
Format of REXX instructions.....	6
Letter case of REXX instructions.....	6
Types of REXX clauses.....	8
Programs using double-byte character set names.....	10
Typing in a program.....	11
Running a program.....	11
Interpreting error messages.....	12
Preventing translation to uppercase.....	13
Passing information to a program.....	14
Getting information from the program stack or terminal input device.....	14
Specifying values when calling a program.....	15
Preventing translation of input to uppercase.....	16
Exercises: using the ARG instruction.....	16
Passing arguments.....	17
Chapter 3. Processing variable data by using variables and expressions.....	19
Variables.....	19
Expressions.....	21
Arithmetic operators.....	21
Comparison operators.....	24
Logical (Boolean) operators.....	27
Concatenation operators.....	28
Priority of operators.....	29
Chapter 4. Controlling the flow within a program.....	33
Conditional instructions.....	33
IF...THEN...ELSE instructions.....	33
Nested IF...THEN...ELSE instructions.....	35
SELECT WHEN...OTHERWISE...END instructions.....	38
Looping instructions.....	41
Repetitive loops.....	41
Conditional loops.....	44
Compound loops.....	48
Interrupt instructions.....	50
EXIT instructions.....	50
CALL and RETURN instructions.....	51
SIGNAL instructions.....	54
Chapter 5. Functions.....	57
Built-In functions.....	58
Subroutines and functions.....	62
Writing subroutines and functions.....	64

Choosing to use internal or external subroutines or functions.....	71
Passing information.....	71
Receiving information from a subroutine or function.....	78
Chapter 6. Manipulating Data.....	81
Using Compound Variables and Stems.....	81
What Is a Compound Variable?.....	81
Using stems.....	82
Exercises - Using Compound Variables and Stems.....	82
Parsing data.....	83
Parsing Instructions.....	83
More about parsing into words.....	85
Parsing with patterns.....	86
Parsing multiple strings as arguments.....	88
Chapter 7. Using commands from a program.....	91
Using quotation marks in commands.....	91
Using variables in commands.....	91
Calling another REXX program as a command.....	91
Issuing commands from a program.....	92
How is a command passed to the host environment?.....	93
Changing the host command environment.....	93
Chapter 8. Diagnosing problems in a program.....	95
Tracing expressions with the TRACE instruction.....	95
Tracing commands with the TRACE instruction.....	97
Using REXX special variables RC and SIGL.....	97
Tracing with the interactive debug facility.....	98
Saving Interactive TRACE Output.....	99
Chapter 9. Using the REXX/CICS help utility.....	101
Chapter 10. Programming Style and Techniques.....	103
Test yourself.....	104
Happy Hour.....	104
Designing a program.....	105
Methods for designing loops.....	106
The conclusion.....	106
What do we have so far?.....	106
Step-wise refinement: an example.....	107
Reconsider the Data.....	107
Correcting your program.....	108
Modifying Your Program.....	108
Tracing your program.....	108
Coding style.....	109
Part 2. Configuring REXX.....	113
Chapter 11. Configuring REXX support.....	115
Create the RFS filepools.....	115
Create resource definitions.....	115
Review LSRPOOL definitions.....	116
Update the CICSTART member.....	116
Modify the CICS initialization JCL.....	117
Format the RFS filepools.....	118
Verify the installation.....	119
Creating the help files.....	119

Configure the REXX Db2 interface.....	120
Chapter 12. REXX/CICS system definition and administration.....	121
Authorized REXX/CICS commands and authorized command options.....	121
System profile exec.....	121
Authorized MVS PDS REXX libraries.....	121
Defining authorized users.....	122
Setting system options.....	122
Defining a REXX file system (RFS) file pool.....	122
Creating a PLT entry for CICSTART.....	122
Security exits.....	122
CICSECX1.....	122
CICSECX2.....	123
Chapter 13. Performance considerations.....	125
Chapter 14. Security.....	127
REXX/CICS supports multiple transaction identifiers.....	127
REXX/CICS file security.....	127
REXX/CICS command level security.....	127
REXX/CICS authorized command support.....	128
Security definitions.....	128
Part 3. REXX for CICS Transaction Server: Reference.....	131
Chapter 15. Overview of product features.....	133
Chapter 16. How to read the syntax diagrams.....	137
Chapter 17. REXX General Concepts.....	139
Structure and General Syntax.....	139
Characters.....	140
Comments.....	140
Tokens.....	141
Implied Semicolons.....	144

About this PDF

This PDF describes REXX/CICS or REXX for CICS Transaction Server. This IBM® program product provides a native REXX-based application development, customization, prototyping, and procedures language environment for REXX/CICS, along with associated runtime facilities.

REXX for CICS Transaction Server (REXX for CICS) is the new name for REXX for CICS/ESA:

- REXX Development System for CICS, Version 1 Release 1 is the new name for REXX Development System for CICS/ESA, Version 1 Release 1.
- REXX Runtime Facility for CICS, Version 1 Release 1 is the new name for REXX Runtime Facility for CICS/ESA, Version 1 Release 1.

The version, release, and product numbers are unchanged. All references in this documentation to REXX for CICS include any earlier versions of this product that are supported for use with CICS and are still called REXX for CICS/ESA.

Who this PDF is for

This PDF is for users who need to refer to REXX for CICS Transaction Server instructions and functions, and for those who need to learn more details about REXX language items such as parsing. It is also intended for anyone who wants to learn how to write REXX programs. The type of users include: application programmers, system programmers, end users, administrators, developers, testers, and support personnel.

Understanding this PDF

This PDF contains both user guide and reference material. The developing REXX applications and configuring REXX support sections will help you become familiar with REXX for CICS Transaction Server. The reference section contains the REXX instructions, functions, and commands. The instructions, functions, and commands are listed alphabetically in their own sections. Also included are details about general concepts you need to know in order to program in REXX.

The programming language described by this book is called the REstructured eXtended eXecutor language (commonly referred to as REXX). This book also describes how the CICS Transaction Server REXX language processor (shortened, hereafter, to the language processor) processes or interprets the REstructured eXtended eXecutor language.

Date of this PDF

This PDF was created on January 31st 2019.

Part 1. Developing REXX applications

This section introduces REXX programs and their syntax, describes the steps involved in writing and running REXX programs, and explains concepts you need to understand to avoid common problems.

A REXX program consists of REXX language instructions that the REXX interpreter interprets directly. A program can also contain commands that the host environment executes, such as CICS commands (see [Chapter 7, “Using commands from a program,” on page 91](#)).

Chapter 1. Features and components of REXX

REXX is a versatile programming language. It can be mixed with commands to host environments, it provides powerful functions, and it has extensive mathematical capabilities.

REXX programs can do many tasks under CICS. These include issuing EXEC CICS commands, SQL statements, as well as commands to the CEDA (Resource Definition Online Transaction) and CEMT (Main Terminal Transaction) utilities.

Features of REXX

Some of the features of REXX are as follows:

Ease of use

The REXX language is easy to read and write because many instructions are meaningful English words. REXX instructions are common words, such as SAY, PULL, IF...THEN...ELSE..., DO...END, and EXIT.

Free format

There are only a few rules about REXX format. You do not need to start an instruction in a particular column. You can skip spaces in a line, or skip entire lines. You can have an instruction span of many lines, or have multiple instructions on one line. You do not need to predefine variables. You can type instructions in upper, lower, or mixed case. See [Syntax of REXX instructions](#).

Built-in functions

REXX supplies built-in functions that perform various processing, searching, and comparison operations for both text and numbers. Other built-in functions provide formatting capabilities and arithmetic calculations.

Debugging capabilities

When a REXX program running in REXX/CICS encounters an error, REXX writes messages describing the error. You can also use the REXX TRACE instruction and the interactive debug facility to locate program errors.

Interpreted language

The REXX/CICS product includes the REXX/CICS interpreter. When a REXX program runs, the interpreter processes each line directly. You do not need to compile or link-edit the program before you can run it.

Extensive parsing capabilities

REXX includes extensive parsing capabilities for character manipulation, so you can set up a pattern to separate characters, numbers, and mixed input.

Components of REXX

REXX is made up of the following components, which make it a powerful tool for programmers:

Clauses

Clauses can be instructions, null clauses, or labels. Instructions can be:

- Keyword instructions
- Assignments
- Commands (REXX/CICS and CICS commands and SQL).

The language processor processes keyword instructions and assignments.

Built-in functions

These functions are built into the language processor and provide convenient processing options.

External functions

REXX/CICS provides these functions that interact with the system to do specific tasks for REXX.

Data stack functions

A data stack can store data for I/O and other types of processing

Prerequisites

REXX/CICS runs under all supported releases of CICS Transaction Server. There are no other prerequisites, other than those required by CICS TS.

Runtime facility

The REXX/CICS MVS Runtime Facility provides a runtime environment for REXX/CICS MVS execs, so that you can run REXX/CICS execs on a CICS region that does not have the REXX/CICS MVS development system installed.

This is especially useful if a company has multiple CICS regions, where only certain regions are available for REXX-based development, but wants the ability to run those execs. You can also use the Runtime Facility to run products that have a REXX prerequisite on other regions, without purchasing a license for the full REXX/CICS MVS development system.

Chapter 2. Writing and running a REXX application

One advantage of the REXX language is its similarity to ordinary English. This similarity makes it easy to read and write a REXX program, as shown in the following examples.

Example of a simple program

To write a line of output, you use the REXX instruction SAY followed by the text you want written.

```
/* Sample REXX Program */  
SAY 'Hello world!'
```

Figure 1. Example: Hello World program

This program starts with a comment line to identify it as a REXX program. A comment begins with /* and ends with */.

When you run the program, the SAY instruction sends the following output to the terminal device:

```
Hello world!
```

Example of a longer program

Even in a longer program, the instructions are similar to ordinary English and are easy to understand. In this example, you call the program ADDTWO, which adds two numbers.

1. From a CICS terminal, clear the screen and enter the following command:

```
REXX addtwo
```

2. Enter two numbers.

Here is the ADDTWO program. The comment in the program code assumes that the first number entered is 42 and the second number is 21.

```
/****** REXX *****/  
/* This program adds two numbers and produces their sum. */  
/****** REXX *****/  
say 'Enter first number.'  
PULL number1 /* Assigns: number1=42 */  
say 'Enter second number.'  
PULL number2 /* Assigns: number2=21 */  
sum = number1 + number2  
SAY 'The sum of the two numbers is' sum.'
```

Figure 2. Example: ADDTWO program

When you run the example program, the first PULL instruction assigns the variable *number1* the value 42. The second PULL instruction assigns the variable *number2* the value 21. The next line contains an assignment. The language processor adds the values in *number1* and *number2* and assigns the result, 63, to *sum*. Finally, the SAY instruction displays the output line:

```
The sum of the two numbers is 63.
```

Syntax of REXX instructions

Some programming languages have rigid rules about how and where you enter characters on each line. For example, assembler statements must begin in a certain column. REXX, on the other hand, has simple syntax rules. You can use upper, or lower, or mixed case. REXX has no restrictions about the columns in which you can type.

An instruction can begin in any column on any line. The following are all valid instructions.

```
SAY 'You can type in any column'
      SAY 'You can type in any column'
            SAY 'You can type in any column'
```

These instructions are sent to the terminal output device:

```
You can type in any column
You can type in any column
You can type in any column
```

Format of REXX instructions

The REXX language has free format. This means you can insert extra spaces between words.

For example, the following all mean the same:

```
total=num1+num2
total =num1+num2
total = num1+num2
total = num1 + num2
```

You can also insert blank lines throughout a program without causing an error.

Letter case of REXX instructions

You can enter a REXX instruction in lowercase, uppercase, or mixed case. The language processor translates alphabetic characters to uppercase, unless you enclose them in single or double quotation marks.

For example, SAY , Say , and say all have the same meaning.

Using quotation marks in an instruction

A series of characters within matching quotation marks is a *literal string* . The following examples contain literal strings.

```
SAY 'This is a REXX literal string.' /* Using single quotation marks */
SAY "This is a REXX literal string." /* Using double quotation marks */
```

Do not enclose a literal string with one each of the two different types of quotation marks. For example, the following is incorrect :

```
SAY 'This is a REXX literal string.'" /* Using mismatched quotation marks */
```

If you omit the quotation marks around a literal string in a SAY instruction, the language processor usually translates the statement to uppercase. For example,

```
SAY This is a REXX string.
```

results in:

```
THIS IS A REXX STRING.
```

(This assumes none of the words is the name of a variable that you have already assigned a value. In REXX, the default value of a variable is its own name in uppercase.)

If a string contains an apostrophe, you can enclose the literal string in double quotation marks.

```
SAY "This isn't difficult!"
```

You can also use two single quotation marks in place of the apostrophe, because a pair of single quotation marks is processed as one.

```
SAY 'This isn't difficult!'
```

Either way, the outcome is the same.

```
This isn't difficult!
```

Ending an instruction

A line usually contains one instruction, except when it contains a semicolon (;) or ends with a comma (,).

The end of the line or a semicolon indicates the end of an instruction. If you put one instruction on a line, the end of the line delineates the end of the instruction. If you put multiple instructions on one line, you must separate adjacent instructions with a semicolon.

```
SAY 'Hi!'; say 'Hi again!'; say 'Hi for the last time!'
```

This example would result in three lines.

```
Hi!  
Hi again!  
Hi for the last time!
```

Continuing an instruction

A comma is the continuation character. It indicates that the instruction continues to the next line. The comma, when used in this manner, also adds a space when the lines are concatenated. Here is how the comma continuation character works when a literal string is being continued on the next line.

```
SAY 'This is an extended',  
    'REXX literal string.'
```

The comma at the end of the first line adds a space (between extended and REXX) when the two lines are concatenated for output. A single line results:

```
This is an extended REXX literal string.
```

The following two instructions are identical and yield the same result:

```
SAY 'This is',  
    'a string.'
```

```
SAY 'This is' 'a string.'
```

The space between the two separate strings is preserved:

```
This is a string.
```

Continuing a literal string without adding a space

If you need to continue an instruction to a second or more lines, but do not want REXX to add spaces in the line, use the concatenation operand (two single OR bars, ||).

```
SAY 'This is an extended literal string that is bro'||,  
    'ken in an awkward place.'
```

This example results in one line and no space in the word "broken":

```
This is an extended literal string that is broken in an  
awkward place.
```

Also note that the following two instructions are identical and yield the same result:

```
SAY 'This is' ||,
'a string.'

SAY 'This is' || 'a string.'
```

These examples result in:

```
This isa string.
```

In both examples, the concatenation operator deletes spaces between the two strings.

The following example demonstrates the free format of REXX.

```
/***** REXX *****/
SAY 'This is a REXX literal string.'
SAY      'This is a REXX literal string.'
      SAY 'This is a REXX literal string.'
SAY,
'This',
'is',
'a',
'REXX',
'literal',
'string.'

SAY 'This is a REXX literal string. '; SAY 'This is a REXX literal string.'
SAY '      This is a REXX literal string.'
```

Figure 3. Example of free format

Running this example results in six lines of identical output, followed by one indented line.

```
This is a REXX literal string.
This is a REXX literal string.
This is a REXX literal string.
This is a REXX literal string.
This is a REXX literal string.
This is a REXX literal string.
      This is a REXX literal string.
```

You can begin an instruction anywhere on a line, you can insert blank lines, and you can insert extra spaces between words in an instruction. The language processor ignores blank lines, and it ignores spaces that are greater than one. This flexibility of format lets you insert blank lines and spaces to make programs easier to read.

Blanks and spaces are only significant during parsing. See [“Parsing data” on page 83](#).

Types of REXX clauses

REXX clauses can be instructions, null clauses, and labels. Instructions can be keyword instructions, assignments, or commands.

The following example shows a program with these types of clauses. A description of each type of clause follows the example.

```
/* QUOTA REXX program. Two car dealerships are competing to */
/* sell the most cars in 30 days. Who will win?                */

store_a=0; store_b=0
DO 30
    CALL sub
END
IF store_a>store_b THEN SAY "Store_a wins!"
ELSE IF store_b>store_a THEN SAY "Store_b wins!"
ELSE SAY "It's a tie!"
EXIT

sub:
store_a=store_a+RANDOM(0,20) /* RANDOM returns a random number in */
store_b=store_b+RANDOM(0,20) /* in specified range, here 0 to 20 */
RETURN
```

Keyword instructions

A keyword instruction tells the language processor to do something. It begins with a REXX keyword that identifies what the language processor is to do. For example, DO can group instructions and execute them repetitively, and IF tests whether a condition is met. SAY writes to the current terminal output device.

IF, THEN and ELSE are three keywords that work together in one instruction. Each keyword forms a clause, which is a subset of an instruction. If the expression that follows the IF keyword is true, the instruction that follows the THEN keyword is processed. Otherwise, the instruction that follows the ELSE keyword is processed. (Note that a semicolon is needed before the ELSE if you are putting an ELSE clause on the same line with a THEN.) If you want to put more than one instruction after a THEN or ELSE, use a DO before the group of instructions and an END after them. More information about the IF instruction appears in [“Conditional instructions” on page 33](#).

The EXIT keyword tells the language processor to end the program. Using EXIT in the preceding example is necessary because, otherwise, the language processor would execute the code in the subroutine after the label sub: . EXIT is not necessary in some programs (such as those without subroutines), but it is good programming practice to include it. More about EXIT appears in [“EXIT instructions” on page 50](#).

Assignment

An assignment gives a value to a variable or changes the current value of a variable. A simple assignment instruction is:

```
number = 4
```

In the preceding program, a simple assignment instruction is: store_a=0. The left side of the assignment (before the equal sign) contains the name of the variable to receive a value from the right side (after the equal sign). The right side can be an actual value (such as 4) or an expression. An expression is something that needs to be evaluated, such as an arithmetic expression. The expression can contain numbers, variables, or both.

```
number = 4 + 4  
number = number + 4
```

In the first example, the value of number is 8. If the second example directly followed the first in a program, the value of number would become 12. More about expressions is in [“Expressions” on page 21](#).

Label

A label, such as sub: , is a symbolic name followed by a colon. A label can contain either single- or double-byte characters or a combination of single- and double-byte characters. (Double-byte characters are valid only if OPTIONS ETMODE is the first instruction in your program.) A label identifies a portion of the program and is commonly used in subroutines and functions, and with the SIGNAL instruction. (Note that you need to include a RETURN instruction at the end of a subroutine to transfer control back to the main program.) More about the use of labels appears in [“Subroutines and functions” on page 62](#) and [“SIGNAL instructions” on page 54](#).

Null clause

A null clause consists of only blanks, or comments, or both. The language processor ignores null clauses, but they make a program easier to read.

Comments

A comment begins with /* and ends with */ . Comments can be on one or more lines, or on part of a line. You can put information in a comment that might not be obvious to a person reading the REXX instructions. Comments at the beginning of a program can describe the overall purpose of the program and, perhaps, list special considerations. A comment next to an individual instruction can clarify its purpose.

Note: REXX/CICS does not require that a REXX program begins with a comment. However, for portability reasons, you may want to start each REXX program with a comment that includes the word REXX. Not every language processor requires this program identifier. However, to run the same exec on MVS TSO and CICS, you should include the `/* REXX */` program identifier to satisfy TSO requirements.

Blank lines

Blank lines separate groups of instructions and aid readability. The more readable a program is, the easier it is to understand and maintain.

Commands

A command is a clause consisting of only an expression. Commands are sent to a previously defined environment for processing. (You should enclose in quotation marks any part of the expression not to be evaluated.) The previous example program did not include any commands. The following example includes a command in an ADDRESS instruction:

```
/* REXX program including a command */
ADDRESS REXXCICS 'DIR'
```

ADDRESS is a keyword instruction. When you specify an environment and a command on an ADDRESS instruction, a single command is sent to the environment you specify. In this case, the environment is REXXCICS. The command is the expression that follows the environment:

```
'DIR'
```

The DIR command lists the files in your current file system directory. For more details about changing the host command environment, see [“Changing the host command environment”](#) on page 93. For more information about issuing commands, see [Chapter 7, “Using commands from a program,”](#) on page 91.

Programs using double-byte character set names

You can use double-byte character set (DBCS) names in your REXX programs for literal strings, symbols, and comments. Such character strings can be single-byte, double-byte, or a combination of both. To use DBCS names, OPTIONS ETMODE must be the first instruction in the program. This specifies that the language processor should check strings containing DBCS characters for validity.

You must enclose DBCS characters within shift-out (SO) and shift-in (SI) delimiters. (The SO character is X'0E', and the SI character is X'0F'). The SO and SI characters are non-printable. In the following example, the less than (<) and greater than (>) symbols represent shift-out (SO) and shift-in (SI), respectively. For example, <.S.Y.M.D> and <.D.B.C.S.R.T.N> represent DBCS symbols in the following example.

Example

The following is an example of a program using a DBCS variable name and a DBCS subroutine label.

```
/* REXX */
OPTIONS 'ETMODE'          /* ETMODE to enable DBCS variable names */
<.S.Y.M.D> = 10           /* Variable with DBCS characters between */
                          /* shift-out (<) and shift-in (>) */
y.<.S.Y.M.D> = JUNK
CALL <.D.B.C.S.R.T.N>      /* Call subroutine with DBCS name */
EXIT
<.D.B.C.S.R.T.N>:         /* Subroutine with DBCS name */
DO i = 1 TO 10
  IF y.i = JUNK THEN       /* Does y.i match the DBCS variable's value? */
    SAY 'Value of the DBCS variable is : ' <.S.Y.M.D>
END
RETURN
```

Typing in a program

About this task

When you type in the following program, use the REXX/CICS editor for files that reside in the REXX File System (RFS). You can also use any editor that lets you save files in MVS partitioned data sets (PDS member). This information assumes that you use the REXX/CICS editor.

The name of the program is HELLO EXEC (for now, assume that the file type is exec).

1. Sign on to a REXX for CICS terminal by entering CESN and supplying your user ID and password when it is requested.
2. Clear the screen.
3. Type:

```
edit hello.exec
```

4. Type in the program, exactly as it is shown in [Figure 4 on page 11](#), beginning with `/* REXX HELLO EXEC */`. Then file it using the EDIT command:

```
====> file
```

Now your program is ready to run.

```
/* REXX HELLO EXEC */  
  
/* A conversation */  
say "Hello! What is your name?"  
pull who  
if who = "" then say "Hello stranger!"  
else say "Hello" who
```

Figure 4. HELLO EXEC

Running a program

About this task

Clear the screen before running an exec. If you want to run a program that has a file type of EXEC, you type in REXX followed by its file name. In this case, type `rexx hello` on the command line and press Enter. Try it!

Suppose your name is Sam. Type `sam` and press Enter. `Hello SAM` is displayed.

```
rexx hello  
Hello! What is your name?  
sam  
Hello SAM
```

Here is what happens:

1. The SAY instruction displays `Hello! What is your name?`
2. The PULL instruction pauses the program, waiting for a reply.
3. You type `sam` on the command line and then press Enter.
4. The PULL instruction puts the word `SAM` into the variable (the place in the computer's storage) called `who`.
5. The IF instruction asks, Is `who` equal to nothing?

```
who = ""
```

This means, " is the value stored in who equal to nothing? " To find out, REXX substitutes that stored value for the variable name. So the question now is: Is SAM equal to nothing?

```
"SAM" = ""
```

6. Not true. The instruction after then is not processed. Instead, REXX processes the instruction after else.
7. The SAY instruction displays "Hello" who , which is evaluated as

```
Hello SAM
```

Now, here is what happens if you press Enter without typing a response first.

```
hello
Hello! What is your name?

Hello stranger!
```

Then again, maybe you did not understand that you had to type in your name. (Perhaps the program should make your part clearer.) Anyhow, if you just press Enter instead of typing a name:

1. The PULL instruction puts "" (nothing) into the place in the computer's storage called who.
2. Again, the IF instruction tests the variable

```
who = ""
```

meaning: Is the value of who equal to nothing? When the value of who is substituted, this scans as:

```
"" = ""
```

And this time, it is true.

3. So the instruction after then is processed, and the instruction after else is not.

Interpreting error messages

When you run a program that contains an error, an error message often includes the line on which the error occurred and gives an explanation of the error. Error messages can result from syntax errors and from computational errors.

Example

The following program has a syntax error.

```
/****** REXX *****/
/* This REXX program contains a deliberate error of not closing */
/* a comment. Without the error, it would pull input to produce */
/* a greeting. */
/******/

PULL who                                /* Get the person's name.
IF who = '' THEN
    SAY 'Hello, stranger'
ELSE
    SAY 'Hello,' who
```

Figure 5. Example of a program with a syntax error

When the program runs, the language processor sends the following lines of output.

```
7 +++ PULL who                                /* Get the person's name.
' ' THEN SAY 'Hello, stranger'ELSE SAY 'Hello,' who
CICREX453E Error 6 running HELLO EXEC, line 7: Unmatched "/" or quote
```

The program runs until the language processor detects the error, the missing `*/` at the end of the comment. The PULL instruction does not use the data from the data stack or terminal because this line contains the syntax error. The program ends, and the language processor sends the error messages.

The first error message begins with the line number of the statement where the language processor detected the error. Three pluses (`+++`) and the contents of the statement follow this.

```
7 +++ PULL who /* Get the person's name. IF who =  
' THEN SAY 'Hello, stranger' ELSE SAY 'Hello,' who
```

The second error message begins with the message number. A message containing the program name, the line where the language processor found the error, and an explanation of the error follow this.

```
CICREX453E Error 6 running HELLO EXEC, line 7: Unmatched  
"/*" or quote
```

To fix the syntax error in this program , add `*/` to the end of the comment on line 7.

```
PULL who /* Get the person's name. */
```

Preventing translation to uppercase

The language processor generally translates alphabetic characters to uppercase before processing them. You can prevent the translation to uppercase.

Characters in a program

To prevent translation of alphabetic characters in a program to uppercase, simply enclose the characters in single or double quotation marks. The language processor does not change numbers and special characters, regardless of whether they are in quotation marks. If you use a SAY instruction with a phrase containing a mixture of alphabetic characters, numbers, and special characters, the language processor changes only the alphabetic characters.

```
SAY The bill for lunch comes to $123.51!
```

results in:

```
THE BILL FOR LUNCH COMES TO $123.51!
```

This example assumes none of the words are the names of variables that have been assigned other values.

Quotation marks ensure that information in a program is processed exactly as typed. This is important in the following situations:

- For output that must be lowercase or a mixture of uppercase and lowercase.
- To ensure that commands are processed correctly. For example, if a variable name in a program is the same as a command name, the program can end in error when the command is issued. It is a good programming practice to avoid using variable names that are the same as commands and to enclose all commands in quotation marks.

Characters input to a program

When reading input or passing input from another program, the language processor also changes alphabetic characters to uppercase before processing them. To prevent translation to uppercase, use the PARSE instruction.

For example, the following program reads input from the terminal and sends this information to the terminal output device.

```
/****** REXX *****/  
/* This REXX program gets the name of an animal from the input */
```

```

/* stream and sends it to the terminal.                                */
/*****/

PULL animal                      /* Get the animal name.*/
SAY animal

```

If the input is tyrannosaurus, the language processor produces the output:

```

TYRANNOSAURUS

```

To cause the language processor to read input exactly as it is presented, use the PARSE PULL instruction instead of the PULL instruction.

```

PARSE PULL animal

```

Now if the input is TyRannOsauRus, the output is:

```

TyRannOsauRus

```

Exercises - running and modifying the example programs

You can write and run the preceding example. Now change the PULL instruction to a PARSE PULL instruction and note the difference.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Passing information to a program

When a program runs, you can pass information to it in several ways.

About this task

- You can use PULL to get information from the program stack or terminal input device and pass it to a program.
- You can specify input when calling the program.

Getting information from the program stack or terminal input device

The PULL instruction is one way for a program to receive input.

About this task

The PULL instruction can extract more than one value at a time from the terminal by separating a line of input.

Example

The following ADDTWO program uses PULL to receive two input numbers:

```

/***** REXX *****/
/* This program adds two numbers and produces their sum.          */
/*****/
PULL number1
PULL number2
sum = number1 + number2
SAY 'The sum of the two numbers is' sum'.'

```

Figure 6. Example of a program that uses PULL

The following variation of the example shows how to use the PULL instruction, by separating a line of input, to extract more than one value at a time from the terminal.

```
/****** REXX ******/
/* This program adds two numbers and says their sum */
/*******/
PULL number1 number2
sum = number1 + number2
SAY 'The sum of the two numbers is' sum'.'
```

Figure 7. Variation of an example that uses PULL

To call the program, issue the following command from the CICS terminal:

```
REXX addtwo 42 21
```

The PULL instruction extracts the numbers 42 and 21 from the terminal.

Specifying values when calling a program

Another way for a program to receive input is through values you specify when you call the program.

For example, to pass the two numbers 42 and 21 to a program named ADD, you could use the CICS command:

```
REXX add 42 21
```

The ADD program uses the ARG instruction to assign the input to variables as shown in the following example.

```
/****** REXX ******/
/* This program receives two numbers as input, adds them, and */
/* produces their sum. */
/*******/
ARG number1 number2
sum = number1 + number2
SAY 'The sum of the two numbers is' sum'.'
```

Figure 8. Example of a program that uses the ARG instruction

ARG assigns the first number, 42, to number1, and the second number, 21, to number2.

If the number of values is fewer or more than the number of variable names after ARG or PULL, errors can occur, as the following sections describe.

Specifying too few values

If you specify fewer values than the number of variables after PULL or ARG, the extra variables are set to the null string. Here is an example in which you pass only one number to the program:

```
REXX add 42
```

The language processor assigns the value 42 to number1, the first variable following ARG. It assigns the null string to number2, the second variable. In this situation, the program ends with an error when it tries to add the two variables. In other situations, the program might not end in error.

Specifying too many values

When you specify more values than the number of variables following PULL or ARG, the last variable gets the remaining values. For example, you pass three numbers to the program ADD:

```
REXX add 42 21 10
```

The language processor assigns the value 42 to number1, the first variable following ARG. It assigns the value 21 10 to number2, the second variable. In this situation, the program ends with an error when it tries to add the two variables. In other situations, the program might not end in error.

To prevent the last variable from getting the remaining values, use a period (.) at the end of the PULL or ARG instruction.

```
ARG number1 number2 .
```

The period acts as a *dummy variable* to collect unwanted extra information. In this case, number1 receives 42, number2 receives 21, and the period ensures the 10 is discarded. If there is no extra information, the period is ignored. You can also use a period as a placeholder within the PULL or ARG instruction, as follows:

```
ARG . number1 number2
```

In this case, the first value, 42, is discarded and number1 and number2 get the next two values, 21 and 10.

Preventing translation of input to uppercase

Like the PULL instruction, the ARG instruction changes alphabetic characters to uppercase. To prevent translation to uppercase, use PARSE ARG.

Example

This example shows how to use PARSE ARG to prevent translation to uppercase.

```

/***** REXX *****/
/* This program receives the last name, first name, and score of */
/* a student and reports the name and score. */
/***** */
PARSE ARG lastname firstname score
SAY firstname lastname 'received a score of' score.'

```

Figure 9. Example of a program that uses PARSE ARG

Exercises: using the ARG instruction

About this task

The left column shows the input values sent to a program. The right column is the ARG instruction within the program that receives the input. What value does each variable receive?

	Input	Variables Receiving Input
1	115 -23 66 5.8	ARG first second third
2	.2 0 569 2E6	ARG first second third fourth
3	13 13 13 13	ARG first second third fourth fifth
4	Weber Joe 91	ARG lastname firstname score
5	Baker Amanda Marie 95	PARSE ARG lastname firstname score
6	Callahan Eunice 88 62	PARSE ARG lastname firstname score .

ANSWERS

1. first = 115, second = -23, third = 66 5.8
2. first = .2, second = 0, third = 569, fourth = 2E6

3. first = 13, second = 13, third = 13, fourth = 13, fifth = *null*
4. lastname = WEBER, firstname = JOE, score = 91
5. lastname = Baker, firstname = Amanda, score = Marie 95
6. lastname = Callahan, firstname = Eunice, score = 88

Passing arguments

Values passed to a program are usually called arguments. An argument can consist of one word, or a string of words. Blanks separate words within an argument from each other. The number of arguments passed depends on how the program is called.

About this task

When you call a REXX program using either the CALL instruction or a REXX function call, you can pass up to 20 arguments to the program. Separate each argument from the next with a comma.

For more information about functions and subroutines, see [“Subroutines and functions” on page 62](#). For more information about arguments, see [“Parsing multiple strings as arguments” on page 88](#).

Chapter 3. Processing variable data by using variables and expressions

One of the most powerful aspects of computer programming is the ability to process variable data to achieve a result.

About this task

Regardless of the complexity of a process, when data is unknown or varies, you substitute a symbol for the data. The symbol, when its value can vary, is called a *variable*. A group of symbols or numbers that must be calculated to be resolved is called an *expression*.

Variables

A variable is a character or group of characters representing a value. A variable can contain single- or double-byte characters, or both.

Double-byte characters are valid only if `OPTIONS ETMODE` is the first instruction of your program. The following variable *big* represents the value one million or 1,000,000.

```
big = 1000000
```

Variables can refer to different values at different times. If you assign a different value to *big*, it gets the value of the new assignment, until it is changed again.

```
big = 999999999
```

Variables can also represent a value that is unknown when the program is written. In the following example, the user's name is unknown, so it is represented by the variable *who*.

```
PARSE PULL who      /* Gets name from current input stream */  
                   /* and puts it in variable "who" */
```

Variable names

A variable name, the part that represents the value, is always on the left of the assignment statement and the value itself is on the right.

In the following example, the variable name is *variable1*.

```
variable1 = 5  
SAY variable1
```

As a result of the earlier assignment statement, the language processor assigns *variable1* the value 5 , and the SAY produces:

```
5
```

Variable names can consist of: the following characters:

A - Z

uppercase alphabetic

a - z

lowercase alphabetic

0 - 9

numbers

? ! . _

special characters

X'41' - X'FE'

double-byte character set (DBCS) characters

Note: Double-byte characters are valid only if `OPTIONS ETMODE` is the first instruction of your program.

The following restrictions apply to variable names:

- The first character cannot be 0 through 9 or a period (.)
- The variable name cannot exceed 250 bytes. For names containing DBCS characters, count each DBCS character as 2 bytes, and count the shift-out (SO) and shift-in (SI) as 1 byte each.
- SO (X'0E') and SI (X'0F') must delimit DBCS characters within a DBCS name. Also:
 - SO and SI cannot be contiguous.
 - Nesting of SO / SI is not permitted.
 - A DBCS name cannot contain a DBCS blank (X'4040').
- The variable name should not be RC, SIGL, or RESULT, which are REXX special variables. See [Special variables](#).

The following names are examples of acceptable variable names:

```
ANSWER ?98B A Word3 number the_ultimate_value
```

Also, if `OPTIONS ETMODE` is the first instruction in your program, the following are valid DBCS variable names, where < represents shift-out, > represents shift-in, X, Y, and Z represent DBCS characters, and lowercase letters and numbers represent themselves.

```
<.X.Y.Z> number_<.X.Y.Z> <.X.Y>1234<.Z>
```

Variable values

The value of the variable, which is the value the variable name represents, might be categorized as follows:

- A **constant**, which is a number that is expressed as:

An integer (12)

A decimal (12.5)

A floating point number (1.25E2)

A signed number (-12)

A string constant (' 12')

- A **string**, which is one or more words that may or may not be within quotation marks, such as:

```
This value can be a string.  
'This value is a literal string.'
```

- The **value from another variable**, such as:

```
variable1 = variable2
```

In the preceding example, *variable1* changes to the value of *variable2*, but *variable2* remains the same.

- An **expression**, which is something that needs to be calculated, such as:

```
variable2 = 12 + 12 - .6      /* variable2 becomes 23.4 */
```

Before a variable is assigned a value, its value is the value of its own name translated to uppercase. For example, if the variable *new* has not been assigned a value, then

```
SAY new
```

produces

```
NEW
```

Exercises: identifying valid variable names

Which of the following are valid REXX variable names?

1. 8eight
2. \$25.00
3. MixedCase
4. nine_to_five
5. result

ANSWERS

1. Incorrect, because the first character is a number.
2. Incorrect, because the first character is a currency symbol (\$).
3. Valid
4. Valid
5. Valid, but it is a special variable name that you should use only to receive results from a subroutine.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Expressions

An expression is something that needs to be evaluated and consists of numbers, variables, or strings, and zero or more operators. The operators determine the kind of evaluation to do on the numbers, variables, and strings. There are four types of operators: arithmetic, comparison, logical, and concatenation.

Arithmetic operators

Arithmetic operators work on valid numeric constants or on variables that represent valid numeric constants.

Types of numeric constants

12

A **whole number** has no decimal point or commas. Results of arithmetic operations with whole numbers can contain a maximum of nine digits unless you override this default by using the `NUMERIC DIGITS` instruction. For information about the `NUMERIC DIGITS` instruction, see [NUMERIC](#). Examples of whole numbers are:

```
123456789 0 91221 999
```

12.5

A **decimal number** includes a decimal point. Results of arithmetic operations with decimal numbers are limited to a total maximum of nine digits (`NUMERIC DIGITS` default) before **and** after the decimal. Examples of decimal numbers are:

```
123456.789 0.888888888
```

1.25E2

A **floating point number** in exponential notation, is said to be in scientific notation. The number after the E represents the number of places the decimal point moves. Thus 1.25E2 (also written as 1.25E+2) moves the decimal point to the right two places and results in 125. When an E is followed by a minus (-), the decimal point moves to the left. For example, 1.25E-2 is .0125.

You can use floating point numbers to represent very large or very small numbers. For more information about scientific notation (floating point numbers), see [Exponential Notation](#).

-12

A **signed number** with a minus (-) next to the number represents a negative value. A signed number with a plus (+) next to the number represents a positive value. When a number has no sign, it is processed as if it has a positive value.

Arithmetic operators

Operator

Meaning

+

Add

-

Subtract

*

Multiply

/

Divide

%

Divide and return a whole number without a remainder

//

Divide and return the remainder only

**

Raise a number to a whole number power

- **number**

(Prefix -) Same as the subtraction 0 - number

+**number**

(Prefix +) Same as the addition 0 + number

Using numeric constants and arithmetic operators, you can write arithmetic expressions such as:

```
7 + 2      /* result is 9 */
7 - 2      /* result is 5 */
7 * 2      /* result is 14 */
7 ** 2     /* result is 49 */
7 ** 2.5   /* result is an error */
```

Division

Notice that three operators represent division. Each operator computes the result of a division expression in a different way.

/

Divide and express the answer possibly as a decimal number. For example:

```
7 / 2      /* result is 3.5 */
6 / 2      /* result is 3 */
```

%

Divide and express the answer as a whole number. The remainder is ignored. For example:

```
7 % 2      /* result is 3 */
```

```
//
```

Divide and express the answer as the remainder only. For example:

```
7 // 2      /* result is 1 */
```

Order of evaluation

When you have more than one operator in an arithmetic expression, the order of numbers and operators can be critical. For example, in the following expression, which operation does the language processor perform first?

```
7 + 2 * (9 / 3) - 1
```

Proceeding from left to right, the language processor evaluates the expression as follows:

- First it evaluates expressions within parentheses.
- Then it evaluates expressions with operators of higher priority before expressions with operators of lower priority.

Arithmetic operator priority is as follows, with the highest first:

Table 1. Arithmetic Operator Priority	
Operator symbol	Operator description
- +	Prefix operators
**	Power® (exponential)
* / % //	Multiplication and division
+ -	Addition and subtraction

Thus, the preceding example would be evaluated in the following order:

1. Expression in parentheses

```
7 + 2 * (9 / 3) - 1
          \_--_/
           3
```

2. Multiplication

```
7 + 2 * 3 - 1
    \_--/
     6
```

3. Addition and subtraction from left to right

```
7 + 6 - 1 = 12
```

Using arithmetic expressions

You can use arithmetic expressions in a program many different ways. The following example uses several arithmetic operators to round and remove extra decimal places from a dollar and cents value.

```

/***** REXX *****/
/* This program computes the total price of an item including sales */
/* tax, rounded to two decimal places. The cost and percent of the */
/* tax (expressed as a decimal number) are passed to the program */
/* when you run it. */
/*****/

PARSE ARG cost percent_tax

total = cost + (cost * percent_tax)      /* Add tax to cost. */
price = ((total * 100 + .5) % 1) / 100    /* Round and remove extra */
                                         /* decimal places. */
SAY 'Your total cost is $'price'.'

```

Figure 10. Example Using Arithmetic Expressions

Exercises: calculating arithmetic expressions

What line of output does the following program produce?

```

/***** REXX *****/
pa = 1
ma = 1
kids = 3
SAY "There are" pa + ma + kids "people in this family."

```

What is the value of:

1. $6 - 4 + 1$
2. $6 - (4 + 1)$
3. $6 * 4 + 2$
4. $6 * (4 + 2)$
5. $24 \% 5 / 2$

ANSWERS

1. There are 5 people in this family.
2. The values are as follows:
 - a. 3
 - b. 1
 - c. 26
 - d. 36
 - e. 2

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Comparison operators

Comparison operators can compare numbers or strings and perform evaluations. Expressions that use comparison operators do not return a number value as do arithmetic expressions. Comparison expressions return either 1, which represents true, or 0, which represents false.

These are typical comparisons:

- Are the terms equal? ($A = Z$)
- Is the first term greater than the second? ($A > Z$)
- Is the first term less than the second? ($A < Z$)

For example, if $A = 4$ and $Z = 3$, then the results of the previous comparison questions are:

- $(A = Z)$ Does $4 = 3$? 0 (False)
- $(A > Z)$ Is $4 > 3$? 1 (True)
- $(A < Z)$ Is $4 < 3$? 0 (False)

Commonly used comparison operators

Operator

Meaning

=	Equal
==	Strictly Equal
\=	Not equal
\==	Not strictly equal
>	Greater than
<	Less than
> <	Greater than or less than (same as not equal)
> =	Greater than or equal to
\<	Not less than
< =	Less than or equal to
\>	Not greater than

Note: The NOT character (\neg) is synonymous with the backslash (\backslash). You can use the two characters interchangeably according to availability and personal preference. This information uses the backslash (\backslash) character.

The strictly equal and equal operators

When two expressions are **strictly equal**, everything including the blanks and case (when the expressions are characters) is exactly the same.

When two expressions are **equal**, they are resolved to be the same. The following expressions are all true.

```
'WORD' = word      /* returns 1 */
'word' \== word    /* returns 1 */
'word' == 'word'   /* returns 1 */
4e2 \== 400        /* returns 1 */
4e2 \= 100         /* returns 1 */
```

Using comparison expressions

You often use a comparison expression in an IF...THEN...ELSE instruction. The following example uses an IF...THEN...ELSE instruction to compare two values. For more information about this instruction, see [“IF...THEN...ELSE instructions” on page 33](#).

```

/***** REXX *****/
/* This program compares what you paid for lunch for two */
/* days in a row and then comments on the comparison. */
/*****

PARSE PULL yesterday /* Gets yesterday's price from input stream */
PARSE PULL today /* Gets today's price */
IF today > yesterday THEN /* lunch cost increased */
    SAY "Today's lunch cost more than yesterday's."
ELSE /* lunch cost remained the same or decreased */
    SAY "Today's lunch cost the same or less than yesterday's."

```

Figure 11. Example Using a Comparison Expression

Exercises: using comparison expressions

Based on the preceding example of using a comparison expression, what result does the language processor produce from the following lunch costs?

Yesterday's Lunch

Today's Lunch

4.42

3.75

3.50

3.50

3.75

4.42

What is the result (0 or 1) of the following expressions?

1. "Apples" = "Oranges"
2. "Apples" = "Apples"
3. " Apples" == "Apples"
4. 100 = 1E2
5. 100 \= 1E2
6. 100 \== 1E2

ANSWERS

1. The language processor produces the following sentences:
 - a. Today's lunch cost the same or less than yesterday's.
 - b. Today's lunch cost the same or less than yesterday's.
 - c. Today's lunch cost more than yesterday's.
2. The expressions result in the following. Remember 0 is false and 1 is true.
 - a. 0
 - b. 1
 - c. 0 (The first " Apples" has a space.)
 - d. 1
 - e. 0
 - f. 1

Logical (Boolean) operators

Logical expressions, like comparison expressions, return 1 (true) or 0 (false) when processed. Logical operators combine two comparisons and return 1 or 0 depending on the results of the comparisons.

Logical operators

Operator
Meaning

&

AND

Returns 1 if both comparisons are true. For example:

```
(4 > 2) & (a = a) /* true, so result is 1 */  
(2 > 4) & (a = a) /* false, so result is 0 */
```

|

Inclusive OR

Returns 1 if at least one comparison is true. For example:

```
(4 > 2) | (5 = 3) /* at least one is true, so result is 1 */  
(2 > 4) | (5 = 3) /* neither one is true, so result is 0 */
```

&&

Exclusive OR

Returns 1 if only one comparison (but not both) is true. For example:

```
(4 > 2) && (5 = 3) /* only one is true, so result is 1 */  
(4 > 2) && (5 = 5) /* both are true, so result is 0 */  
(2 > 4) && (5 = 3) /* neither one is true, so result is 0  
*/
```

Prefix \,~

Logical NOT

Negates—returning the opposite response. For example:

```
\ 0 /* opposite of 0, so result is 1 */  
\ (4 > 2) /* opposite of true, so result is 0 */
```

Using logical expressions

You can use logical expressions in complex conditional instructions and as checkpoints to screen unwanted conditions. When you have a series of logical expressions, for clarification, use one or more sets of parentheses to enclose each expression.

```
IF ((A < B) | (J < D)) & ((M = Q) | (M = D)) THEN ....
```

The following example uses logical operators to make a decision.

Figure 12. Example Using Logical Expressions

```
IF ((season = 'WINTER') | (snowing = 'YES')) & (broken_leg = 'NO') THEN
    \      \      \
    false  true   true
    \      \      /
    \      true  /
    \      \    /
    \      true /
```

Go skiing.

```
IF (inexpensive | scholarship) & (reputable | nearby) THEN
  SAY "I'll consider it."
ELSE
  SAY "Forget it!"
```

IF (inexpensive | scholarship) & (reputable | nearby) THEN ...

```

graph TD
    Root[IF (inexpensive | scholarship) & (reputable | nearby) THEN ...]
    Root -->|true| Node1[ ]
    Root -->|false| Node2[ ]
    Node1 -->|true| Node3[ ]
    Node1 -->|false| Node4[ ]
    Node2 -->|true| Node5[ ]
    Node2 -->|false| Node6[ ]
    Node5 -->|true| Node7[ ]
    Node5 -->|false| Node8[ ]
    Node6 --> X((X))
    Node7 --> O((O))
  
```

28 REXX for CICS Transaction Server: User Guide and Reference

```
SAY true blue /* result is TRUE BLUE */
```

||

Concatenates terms with no blanks between them. For example:

```
(8 / 2)|| (3 * 3) /* result is 49 */
```

abuttal

Concatenates terms with no blanks between them. For example:

```
per_cent '%' /* if per_cent = 50, result  
is 50% */
```

You can use abuttal only with terms that are of different types, such as a literal string and a symbol, or when only a comment separates two terms.

Using concatenation operators

One way to format output is to use variables and concatenation operators as in the following example.

```
/****** REXX ******/  
/* This program formats data into columns for output. */  
/*******/  
sport = 'base'  
equipment = 'ball'  
column = ''  
cost = 5  
  
SAY sport||equipment column '$'  
cost
```

Figure 13. Example Using Concatenation Operators

The result of this example is:

```
baseball      $5
```

A more sophisticated way to format information is with parsing and templates. See [“Parsing data” on page 83](#).

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Priority of operators

When more than one type of operator appears in an expression, the language processor follows an overall priority that includes all operators.

The priority of operators is as follows with the highest first.

Table 2. Overall operator priority	
Operator symbol	Operator description
\ or ~ - +	Prefix operators
**	Power (exponential)
* / % //	Multiply and divide
+ -	Add and subtract
blank abuttal	Concatenation operators
== = > < and so on	Comparison operators

Table 2. Overall operator priority (continued)	
Operator symbol	Operator description
&	Logical AND
&&	Inclusive OR and exclusive OR

Example

The following expression contains more than one type of operator:

```
IF (A > 7**B) & (B < 3)
```

Given the following values

A = 8

B = 2

C = 10

the language processor would evaluate this example as follows:

1. Evaluate what is inside the first set of parentheses.
 - a. Evaluate A to 8.
 - b. Evaluate B to 2.
 - c. Evaluate 7**2.
 - d. Evaluate 8 > 49 is false (0).
2. Evaluate what is inside the next set of parentheses.
 - a. Evaluate B to 2.
 - b. Evaluate 2 < 3 is true (1).
3. Evaluate 0 & 1 is 0

Exercises: priority of operators

1. What are the answers to the following examples?
 - a. 22 + (12 * 1)
 - b. -6 / -2 > (45 % 7 / 2) - 1
 - c. 10 * 2 - (5 + 1) // 5 * 2 + 15 - 1
2. In the example of the student and the college from the previous exercise in “Logical (Boolean) operators” on page 27, if the parentheses were removed from the student's formula, what would be the outcome for the college?

```
IF inexpensive | scholarship & reputable | nearby THEN
  SAY "I'll consider it."
ELSE
  SAY "Forget it!"
```

Remember the college is inexpensive, did not offer a scholarship, is reputable, but is 1000 miles away.

ANSWERS

1. The results are as follows:
 - a. 34 (22 + 12 = 34)
 - b. 1 (true) (3 > 3 - 1)
 - c. 32 (20 - 2 + 15 - 1)
2. I'll consider it.

The & operator has priority, as follows, but the outcome is the same as the previous version with the parentheses.

Chapter 4. Controlling the flow within a program

Generally, when a program runs, one instruction after another executes, starting with the first and ending with the last. The language processor, unless told otherwise, executes instructions sequentially. You can change the order of execution within a program by using REXX instructions that cause the language processor to skip some instructions, repeat others, or transfer control to another part of the program.

About this task

The REXX instructions that alter the sequential execution of a REXX program can be classified as follows:

Conditional instructions

Conditional instructions set up at least one condition in the form of an expression. If the condition is true, the language processor selects the path following that condition. Otherwise the language processor selects another path. The REXX conditional instructions are:

```
IF expression THEN...ELSE
SELECT WHEN expression ...OTHERWISE...END
```

Looping instructions

Looping instructions tell the language processor to repeat a set of instructions. A loop can repeat a specified number of times or it can use a condition to control repeating. REXX looping instructions are:

```
DO repetitor ...END
DO WHILE expression ...END
DO UNTIL expression ...END
```

Interrupt instructions

Interrupt instructions tell the language processor to leave the program entirely or leave one part of the program and go to another part, either permanently or temporarily. The REXX interrupt instructions are:

```
EXIT
SIGNAL label
CALL label ...RETURN
```

Conditional instructions

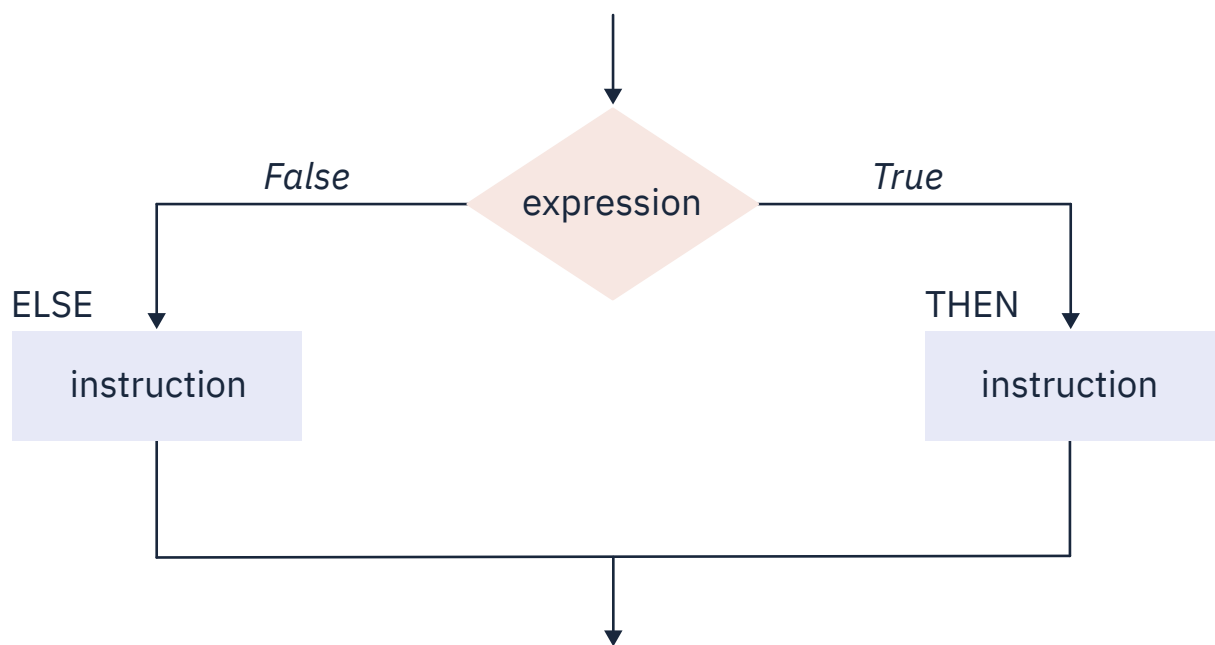

There are two types of conditional instructions.

- IF...THEN...ELSE can direct the execution of a program to one of two options.
- SELECT WHEN...OTHERWISE...END can direct the execution to one of many options.

IF...THEN...ELSE instructions

Code examples help you learn how to specify IF...THEN...ELSE instructions.

The following flowchart illustrates IF...THEN...ELSE instructions.

As a REXX instruction, the code looks like:

```
IF expression THEN instruction
    ELSE instruction
```

You can also arrange the clauses in one of the following ways to enhance readability:

```
IF expression THEN
    instruction
ELSE
    instruction
```

or

```
IF expression
    THEN
        instruction
    ELSE
        instruction
```

When you put the entire instruction on one line, you must use a semicolon before the ELSE to separate the THEN clause from the ELSE clause.

```
IF expression THEN instruction; ELSE instruction
```

Generally, at least one instruction should follow the THEN and ELSE clauses. When either clause has no instructions, it is good programming practice to include NOP (no operation) next to the clause.

```
IF expression THEN
    instruction
ELSE NOP
```

If you have more than one instruction for a condition, begin the set of instructions with a DO and end them with an END.

```
IF weather = rainy THEN
    SAY 'Find a good book.'
ELSE
    DO
        PULL playgolf /* Gets data from input stream */
        If playgolf='YES' THEN SAY 'Fore!'
    END
```

Without the enclosing DO and END, the language processor assumes only one instruction for the ELSE clause.

Nested IF...THEN...ELSE instructions

Code examples help you learn how to specify IF...THEN...ELSE instructions.

Sometimes it is necessary to have one or more IF...THEN...ELSE instructions within other IF...THEN...ELSE instructions. Having one type of instruction within another is called nesting. With nested IF instructions, it is important to match each IF with an ELSE and each DO with an END.

```
IF weather = fine THEN
    DO
        SAY 'What a lovely day!'
        IF tenniscourt = free THEN
            SAY 'Let's play tennis!'
        ELSE NOP
    END
ELSE
    SAY 'We should take our raincoats!'
```

Not matching nested IFs to ELSEs and DOs to ENDS can have some surprising results. If you eliminate the DOs and ENDS and the ELSE NOP, as in the following example, what is the outcome?

```

/***** REXX *****/
/* This program demonstrates what can happen when you do not include */
/* DOs, ENDS, and ELSEs in nested IF...THEN...ELSE instructions.    */
/*****
weather = 'fine'
tenniscourt = 'occupied'

IF weather = 'fine' THEN
    SAY 'What a lovely day!'
    IF tenniscourt = 'free' THEN
        SAY 'Let's play tennis!'
ELSE
    SAY 'We should take our raincoats!'

```

Figure 14. Example of Missing Instructions

Looking at the program, you might assume the ELSE belongs to the first IF. However, the language processor associates an ELSE with the nearest unpaired IF. The outcome is as follows:

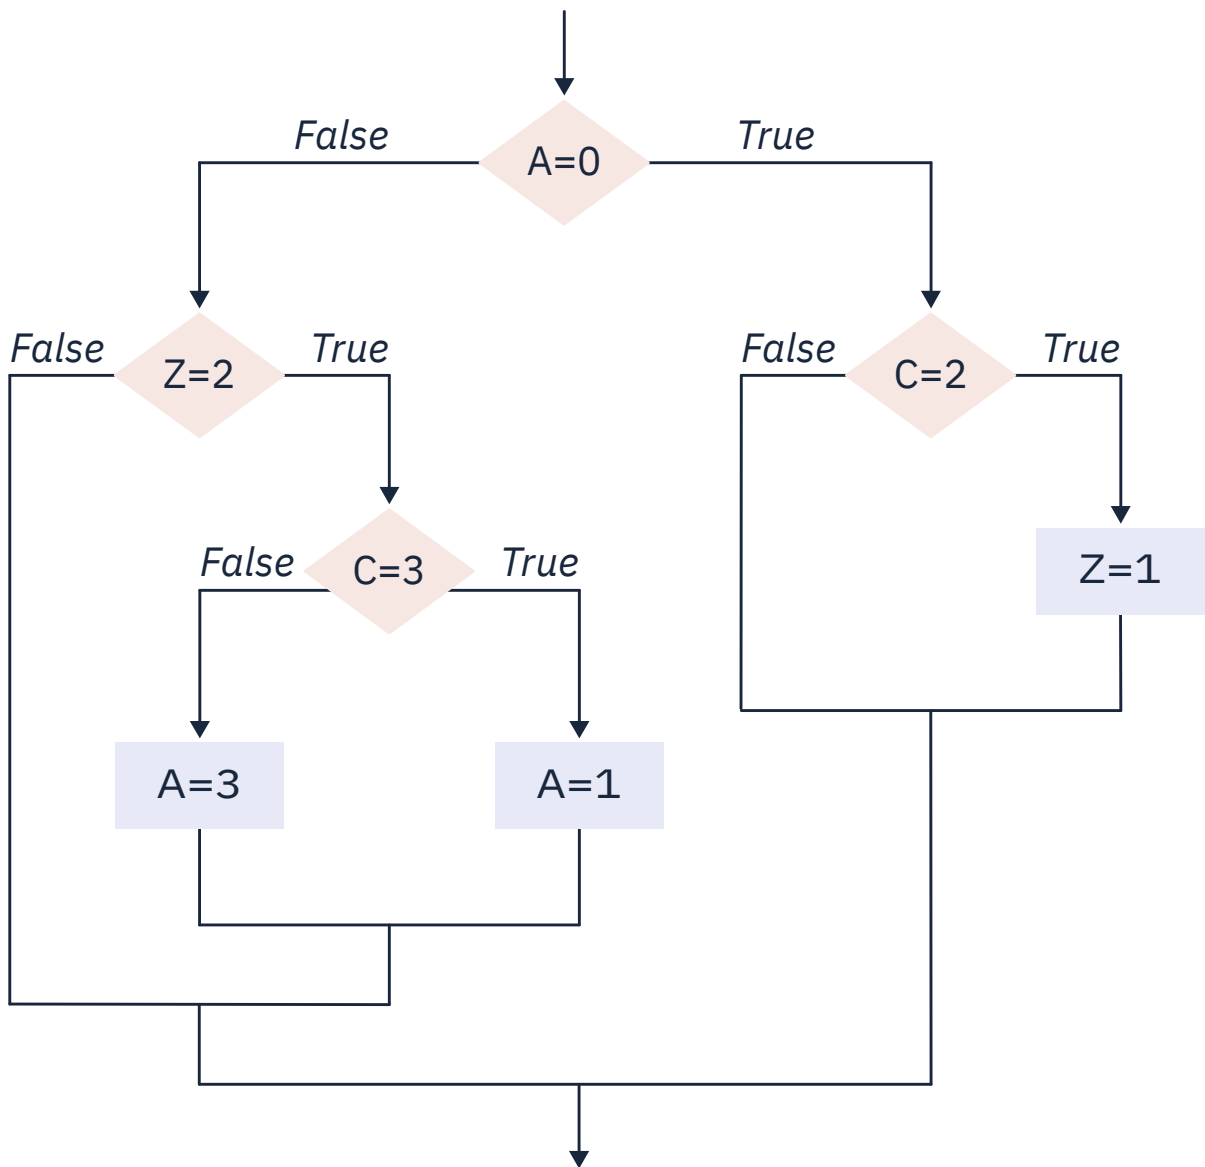

```

What a lovely day!
We should take our raincoats!

```

Exercise: using the IF...THEN...ELSE instruction

Write the REXX instructions for the following flowchart:

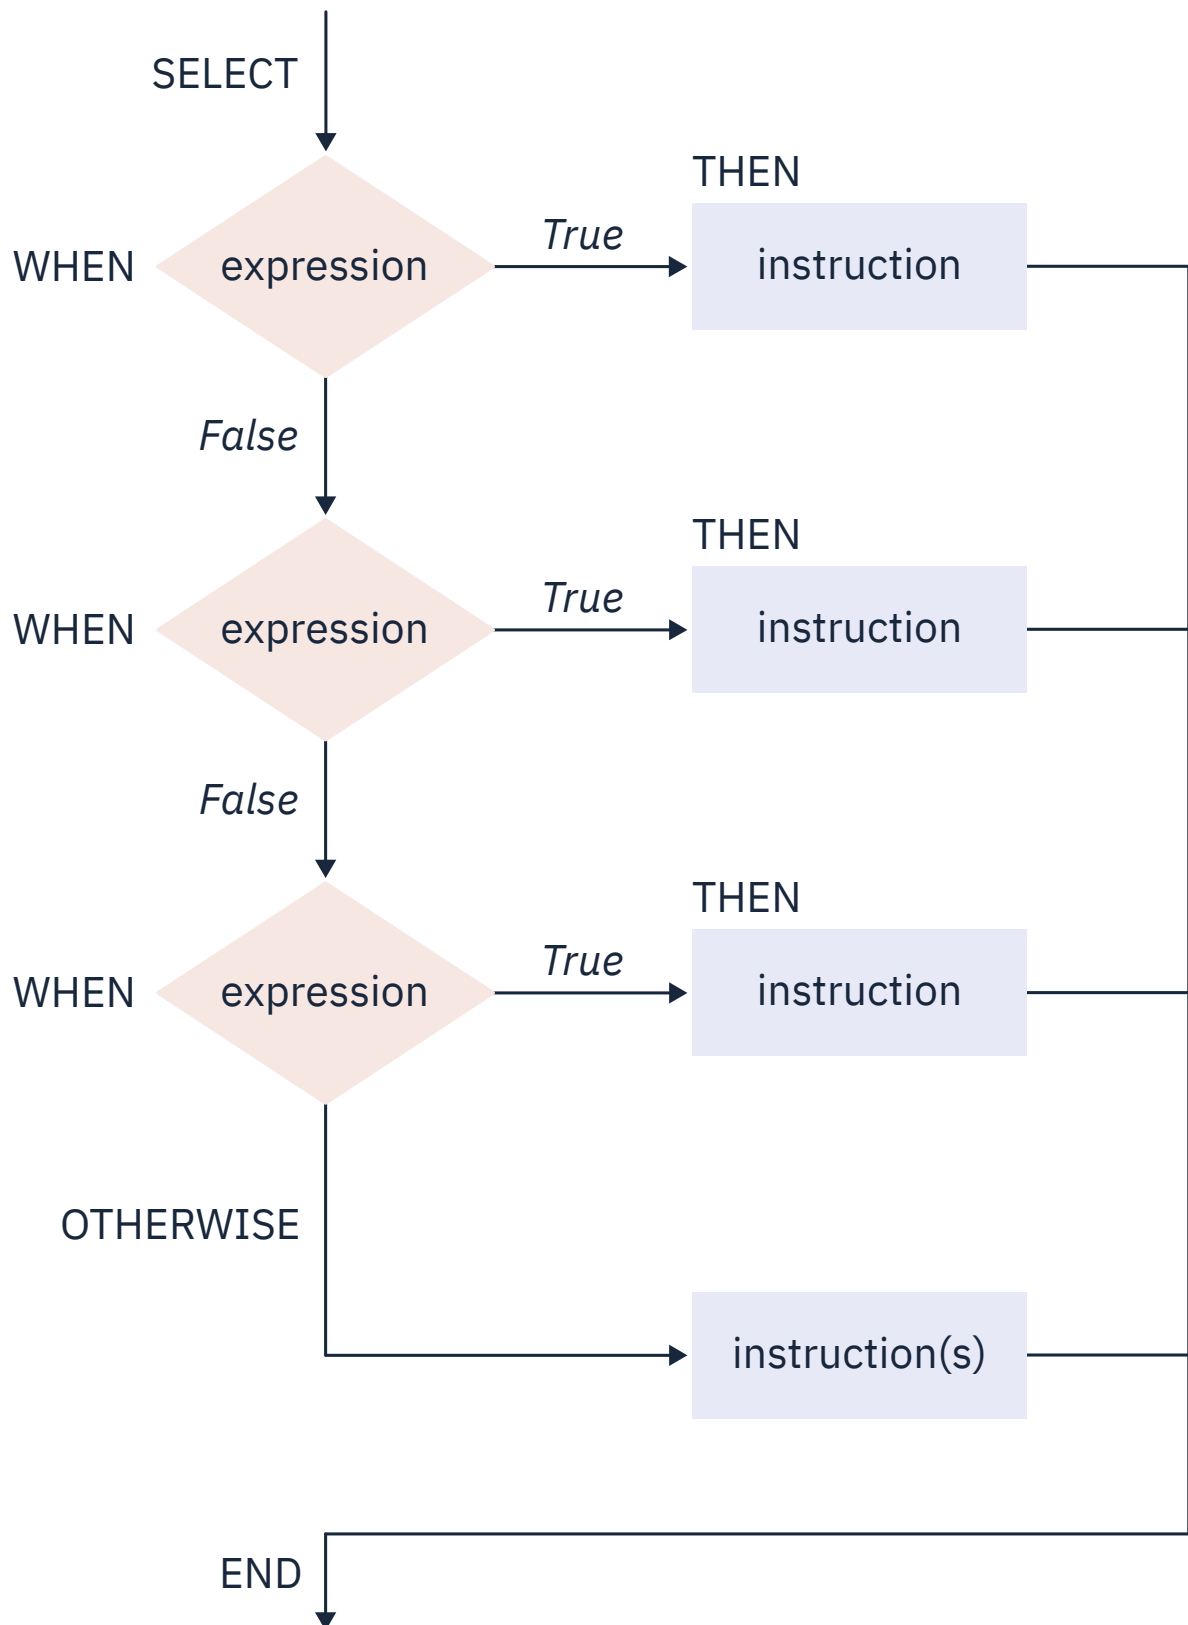

ANSWER

```
IF a = 0 THEN
  IF c = 2 THEN
    z = 1
  ELSE NOP
ELSE
  IF z = 2 THEN
    IF c = 3 THEN
      a = 1
    ELSE
      a = 3
  ELSE NOP
```

SELECT WHEN...OTHERWISE...END instructions

Code examples help you learn how to specify SELECT WHEN...OTHERWISE...END instructions.

To select one of any number of choices, use the SELECT WHEN...OTHERWISE...END instruction. In a flowchart it appears as follows:

As a REXX instruction, the flowchart example looks like:

```

SELECT
  WHEN expression THEN instruction
  WHEN expression THEN instruction
  WHEN expression THEN instruction
  :
  :
  OTHERWISE
    instruction(s)
END

```

The language processor scans the WHEN clauses starting at the beginning until it finds a true expression. After it finds a true expression, it ignores all other possibilities, even though they might also be true. If no WHEN expressions are true, it processes the instructions following the OTHERWISE clause.

As with IF...THEN...ELSE, when you have more than one instruction for a possible path, begin the set of instructions with a DO and end them with an END. However, if more than one instruction follows the OTHERWISE keyword, DO and END are not necessary.

```

/***** REXX *****/
/* This program receives input with a person's age and sex. In */
/* reply, it produces a person's status as follows:           */
/* BABIES - under 5                                           */
/* GIRLS - female 5 to 12                                     */
/* BOYS - male 5 to 12                                         */
/* TEENAGERS - 13 through 19                                   */
/* WOMEN - female 20 and up                                    */
/* MEN - male 20 and up                                         */
/*****/
PARSE ARG age sex .

SELECT
  WHEN age < 5 THEN /* person younger than 5 */
    status = 'BABY'
  WHEN age < 13 THEN /* person between 5 and 12 */
    DO
      IF sex = 'M' THEN /* boy between 5 and 12 */
        status = 'BOY'
      ELSE /* girl between 5 and 12 */
        status = 'GIRL'
    END
  WHEN age < 20 THEN /* person between 13 and 19 */
    status = 'TEENAGER'
  OTHERWISE
    IF sex = 'M' THEN /* man 20 or older */
      status = 'MAN'
    ELSE /* woman 20 or older */
      status = 'WOMAN'
END

SAY 'This person should be counted as a' status'.'

```

Figure 15. Example Using SELECT WHEN...OTHERWISE...END

Each SELECT must end with an END. Indenting each WHEN makes a program easier to read.

Exercises: using SELECT WHEN...OTHERWISE...END

"Thirty days hath September, April, June, and November; all the rest have thirty-one, save February alone ..."

Write a program that uses the input of a number from 1 to 12, representing the month, and produces the number of days in that month. Assume the user specifies the month number as an argument when calling the program. (Include in the program an ARG instruction to assign the month number into the variable month). Then have the program produce the number of days. For month 2 , this can be 28 or 29.

ANSWER

```

/***** REXX *****/
/* This program uses the input of a whole number from 1 to 12 that */
/* represents a month. It produces the number of days in that      */
/* month.                                                           */
/*****

ARG month

SELECT
  WHEN month = 9 THEN
    days = 30
  WHEN month = 4 THEN
    days = 30
  WHEN month = 6 THEN
    days = 30
  WHEN month = 11 THEN
    days = 30
  WHEN month = 2 THEN
    days = '28 or 29'
  OTHERWISE
    days = 31
END

SAY 'There are' days 'days in Month' month'.'

```

Figure 16. Possible Solution

Looping instructions

There are two types of looping instructions: *repetitive loops* and *conditional loops*. All loops, regardless of the type, begin with the DO keyword and end with the END keyword.

Repetitive loops let you repeat instructions a certain number of times. Conditional loops use a condition to control repeating. There are two types of conditional loops, DO WHILE and DO UNTIL.

Repetitive loops

The simplest repetitive loop tells the language processor to repeat a group of instructions a specific number of times. It uses a constant after the keyword DO.

When you run the following example, it produces five lines of Hello!:

```

DO 5
SAY 'Hello!'
END

```

```

Hello!
Hello!
Hello!
Hello!
Hello!

```

You can also use a variable in place of a constant, as in the following example, which gives you the same results.

```

number = 5
DO number
  SAY 'Hello!'
END

```

A variable that controls the number of times a loop repeats is called a *control variable*. Unless you specify otherwise, the control variable increases by 1 each time the loop repeats.

```

DO number = 1 TO 5
  SAY 'Loop' number
  SAY 'Hello!'
END
SAY 'Dropped out of the loop when number reached' number

```

This example results in five lines of Hello! preceded by the number of the loop. The number increases at the bottom of the loop and is tested at the top.

```
Loop 1
Hello!
Loop 2
Hello!
Loop 3
Hello!
Loop 4
Hello!
Loop 5
Hello!
Dropped out of the loop when number reached 6
```

You can change the increment of the control variable with the keyword BY as follows:

```
DO number = 1 TO 10 BY 2
  SAY 'Loop' number
  SAY 'Hello!'
END
  SAY 'Dropped out of the loop when number reached' number
```

This example has results similar to the previous example except the loops are numbered in increments of two.

```
Loop 1
Hello!
Loop 3
Hello!
Loop 5
Hello!
Loop 7
Hello!
Loop 9
Hello!
Dropped out of the loop when number reached 11
```

Infinite loops

What happens when the control variable of a loop cannot attain the last number? For example, in the following program segment, count does not increase beyond 1.

```
DO count = 1 to 10
  SAY 'Number' count
  count = count - 1
END
```

The result is called an infinite loop because count alternates between 1 and 0, producing an endless number of lines saying Number 1.

If your program is in an infinite loop, contact the operator to cancel it. An authorized user can issue the **CEMT SET TASK PURGE** command to halt an exec.

DO FOREVER loops

Sometimes you might want to write an infinite loop purposely; for instance, in a program that reads records from a file until it reaches the end of the file. You can use the EXIT instruction to end an infinite loop when a condition is met, as in the following example. For more about the EXIT instruction, see [“EXIT instructions” on page 50](#).

```

/***** REXX *****/
/* This program processes strings until the value of a string is */
/* a null string. */
/***** REXX *****/
DO FOREVER
  PULL string /* Gets string from input stream */
  IF string = '' THEN
    PULL file_name
    IF file_name = '' THEN
      EXIT
    ELSE
      DO
        result = process(string) /* Calls a user-written function */
        /* to do processing on string. */
        IF result = 0 THEN SAY "Processing complete for string:" string
        ELSE SAY "Processing failed for string:" string
      END
    END
  END
END

```

Figure 17. Example Using a DO FOREVER Loop

This example sends strings to a user-written function for processing and then issues a message that the processing completed successfully or failed. When the input string is a blank, the loop ends and so does the program. You can also end the loop without ending the program by using the LEAVE instruction.

LEAVE instruction

The LEAVE instruction causes an immediate exit from a repetitive loop. Control goes to the instruction following the END keyword of the loop. An example of using the LEAVE instruction follows:

```

/***** REXX *****/
/* This program uses the LEAVE instruction to exit from a DO */
/* FOREVER loop. */
/***** REXX *****/
DO FOREVER
  PULL string /* Gets string from input stream */
  IF string = 'QUIT' then
    LEAVE
  ELSE
    DO
      result = process(string) /* Calls a user-written function */
      /* to do processing on string. */
      IF result = 0 THEN SAY "Processing complete for string:" string
      ELSE SAY "Processing failed for string:" string
    END
  END
END
SAY 'Program run complete.'

```

Figure 18. Example Using the LEAVE Instruction

ITERATE instruction

The ITERATE instruction stops execution from within the loop and passes control to the DO instruction at the top of the loop. Depending on the type of DO instruction, the language processor increases and tests a control variable or tests a condition to determine whether to repeat the loop. Like LEAVE, ITERATE is used within the loop.

```

DO count = 1 TO 10
  IF count = 8
    THEN
      ITERATE
  ELSE
    SAY 'Number' count
  END
END

```

This example results in a list of numbers from 1 to 10 with the exception of number 8.

```

Number 1
Number 2
Number 3
Number 4

```

```
Number 5  
Number 6  
Number 7  
Number 9  
Number 10
```

Exercises: using loops

What are the results of the following loops?

```
DO digit = 1 TO 3  
  SAY digit  
END  
SAY 'Digit is now' digit
```

```
DO count = 10 BY -2 TO 6  
  SAY count  
END  
SAY 'Count is now' count
```

```
DO index = 10 TO 8  
  SAY 'Hup! Hup! Hup!'  
END  
SAY 'Index is now' index
```

Sometimes an infinite loop can occur when input to end the loop does not match what is expected. For instance, in the example of using the LEAVE instruction, what happens when the input is Quit and a PARSE PULL instruction replaces the PULL instruction?

```
PARSE PULL file_name
```

ANSWERS

1. The results of the repetitive loops are as follows:

a. 1
2
3
Digit is now 4

b. 10
8
6
Count is now 4

c. Index is now 10

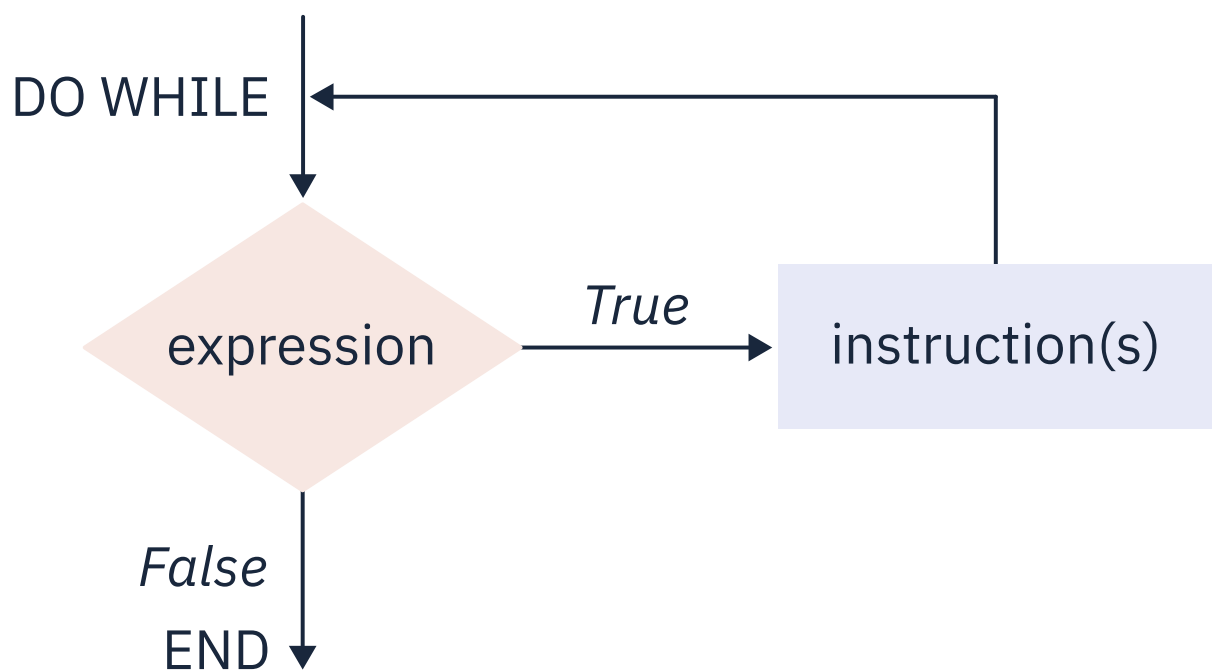

2. The program would be unable to leave the loop because Quit is not equal to QUIT. In this case, omitting the PARSE keyword is preferred because regardless of whether the input is quit, QUIT, or Quit, the language processor translates the input to uppercase before comparing it to QUIT.

Conditional loops

There are two types of conditional loops: DO WHILE and DO UNTIL. One or more expressions control both types of loops. However, DO WHILE loops test the expression before the loop executes the first time and repeat only when the expression is true. DO UNTIL loops test the expression after the loop executes at least once and repeat only when the expression is false.

DO WHILE loops

DO WHILE loops in a flowchart appear as follows:

As REXX instructions, the flowchart example looks like:

```
DO WHILE expression /* expression must be true */
  instruction(s)
END
```

Use a DO WHILE loop when you want to execute the loop while a condition is true. DO WHILE tests the condition at the top of the loop. If the condition is initially false, the language processor never executes the loop.

You can use a DO WHILE loop instead of the DO FOREVER loop in the example of using the LEAVE instruction in “Repetitive loops” on page 41. However, you need to initialize the loop with a first case so the condition can be tested before you get into the loop. Notice the first case initialization in the first PULL of the following example.

```
/****** REXX ******/
/* This progra uses a DO WHILE loop to send a string to a */
/* user-written function for processing. */
/*******/
PULL string /* Gets string from input stream */
DO WHILE string \= 'QUIT'
  result = process(string) /* Calls a user-written function */
                          /* to do processing on string. */
  IF result = 0 THEN SAY "Processing complete for string:" string
  ELSE SAY "Processing failed for string:" string
  PULL string
END
SAY 'Program run complete.'
```

Figure 19. Example Using DO WHILE

Exercise: using a DO WHILE loop

Write a program with a DO WHILE loop that uses as input a list of responses about whether passengers on a commuter airline want a window seat. The flight has 8 passengers and 4 window seats. Discontinue the loop when all the window seats are taken. After the loop ends, produce the number of window seats taken and the number of responses processed.

ANSWER

```
/****** REXX ******/
/* This program uses a DO WHILE loop to keep track of window seats */
/* in an 8-seat commuter airline. */
/*******/

window_seats = 0 /* Initialize window seats to 0 */
passenger = 0 /* Initialize passengers to 0 */

DO WHILE (passenger < 8) & (window_seats \= 4)

/*******/
/* Continue while the program has not yet read the responses of */
/* all 8 passengers and while all the window seats are not taken. */
/*******/

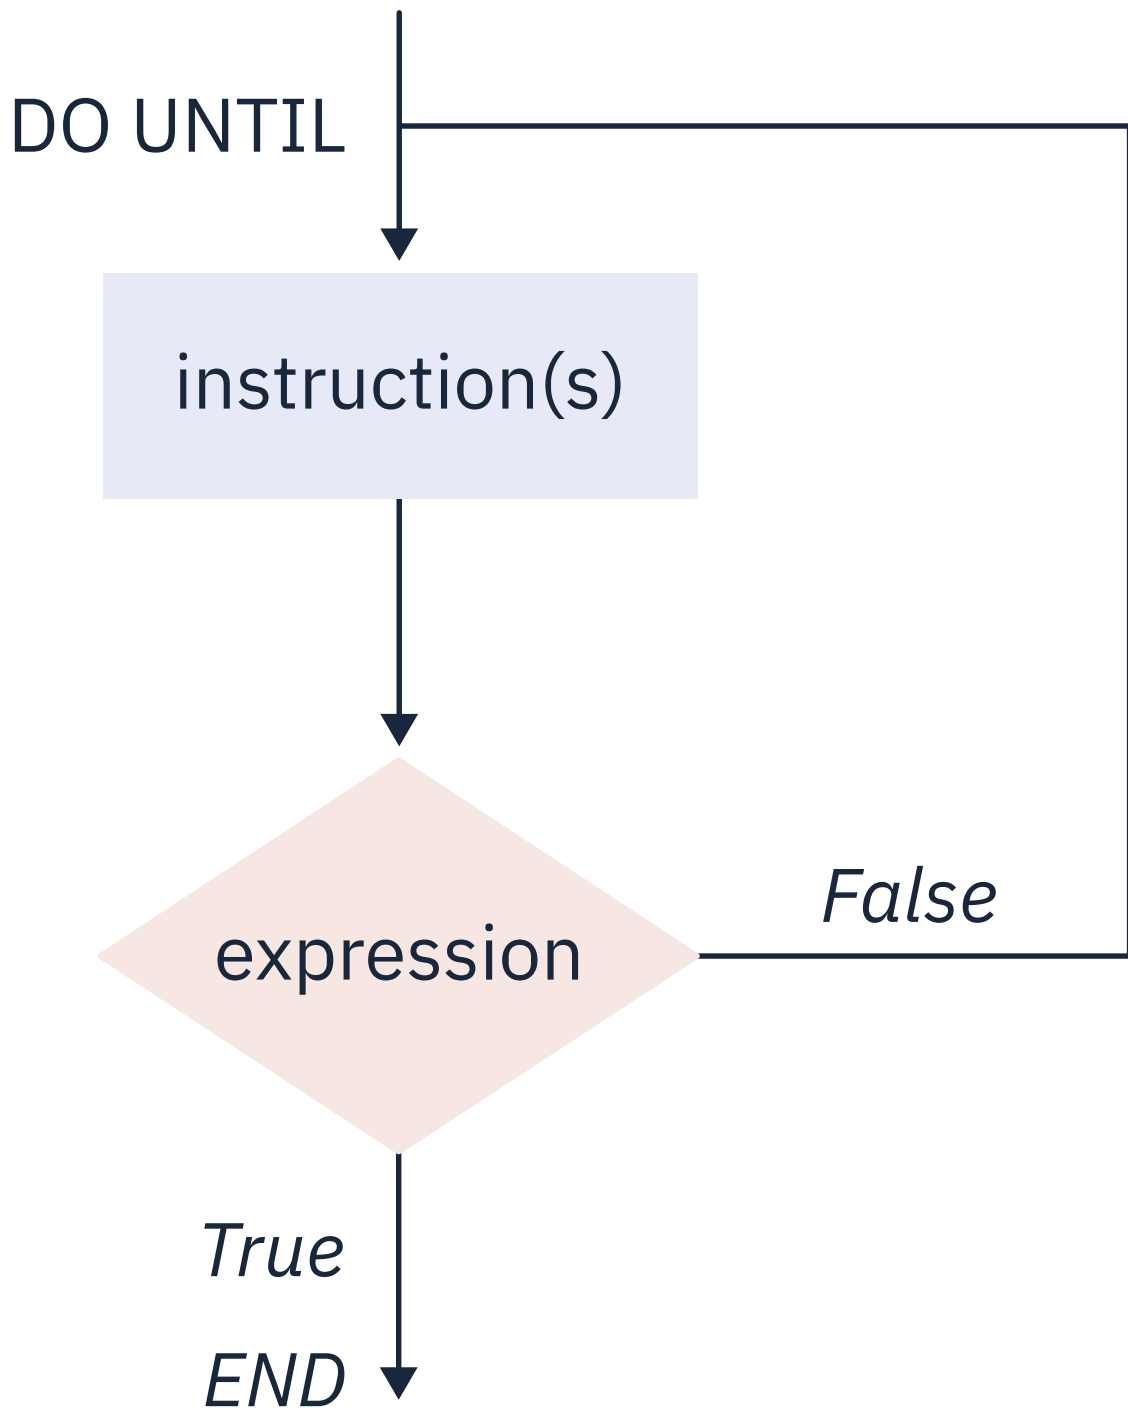

PULL window /* Gets "Y" or "N" from input stream */
passenger = passenger + 1 /* Increase number of passengers by 1 */
IF window = 'Y' THEN
  window_seats = window_seats + 1 /* Increase window seats by 1 */
ELSE NOP
END

SAY window_seats 'window seats were assigned.'
SAY passenger 'passengers were questioned.'
```

Figure 20. Possible solution

DO UNTIL loops

DO UNTIL loops in a flowchart appear as follows:

As REXX instructions, the flowchart example looks like:

```
DO UNTIL expression /* expression must be false */
    instruction(s)
END
```

Use DO UNTIL loops when a condition is not true and you want to execute the loop until the condition is true. The DO UNTIL loop tests the condition at the end of the loop and repeats only when the condition is false. Otherwise, the loop executes once and ends. For example:

```
/****** REXX ******/
/* This program uses a DO UNTIL loop to ask for a password. If the */
/* password is incorrect three times, the loop ends. */
/*******/
password = 'abracadabra'
time = 0
DO UNTIL (answer = password) | (time = 3)
    PULL answer /* Gets ANSWER from input stream */
    time = time + 1
END
```

Figure 21. Example using DO UNTIL

Exercise: using a DO UNTIL loop

Change the program in the previous exercise from a DO WHILE to a DO UNTIL loop and achieve the same results. Remember that DO WHILE loops check for true expressions and DO UNTIL loops check for false expressions, which means their logical operators are often reversed.

ANSWER

```
/****** REXX ******/
/* This program uses a DO UNTIL loop to keep track of window seats */
/* in an 8-seat commuter airline. */
/*******/

window_seats = 0 /* Initialize window seats to 0 */
passenger = 0 /* Initialize passengers to 0 */

DO UNTIL (passenger >= 8) | (window_seats = 4)

    /*******/
    /* Continue while the program has not yet read the responses of */
    /* all 8 passengers and while all the window seats are not taken. */
    /*******/

    PULL window /* Gets "Y" or "N" from input stream */
    passenger = passenger + 1 /* Increase number of passengers by 1 */
    IF window = 'Y' THEN
        window_seats = window_seats + 1 /* Increase window seats by 1 */
    ELSE NOP
END
SAY window_seats 'window seats were assigned.'
SAY passenger 'passengers were questioned.'
```

Figure 22. Possible solution

Compound loops

You can combine repetitive and conditional loops to create a compound loop.

The following loop is set to repeat 10 times while the quantity is less than 50, at which point it stops.

```
quantity = 20
DO number = 1 TO 10 WHILE quantity < 50
    quantity = quantity + number
    SAY 'Quantity = 'quantity ' (Loop 'number')'
END
```

The result of this example is as follows:

```
Quantity = 21 (Loop 1)
Quantity = 23 (Loop 2)
Quantity = 26 (Loop 3)
```

```
Quantity = 30 (Loop 4)
Quantity = 35 (Loop 5)
Quantity = 41 (Loop 6)
Quantity = 48 (Loop 7)
Quantity = 56 (Loop 8)
```

You can substitute a DO UNTIL loop, change the comparison operator from < to > , and get the same results.

```
quantity = 20
DO number = 1 TO 10 UNTIL quantity > 50
    quantity = quantity + number
    SAY 'Quantity = 'quantity ' (Loop 'number')'
END
```

Nested DO loops

Like nested IF...THEN...ELSE instructions, DO loops can contain other DO loops.

A simple example follows:

```
DO outer = 1 TO 2
    DO inner = 1 TO 2
        SAY 'HIP'
    END
    SAY 'HURRAH'
END
```

The output from this example is:

```
HIP
HIP
HURRAH
HIP
HIP
HURRAH
```

If you need to leave a loop when a certain condition arises, use the LEAVE instruction followed by the name of the control variable of the loop. If the LEAVE instruction is for the inner loop, processing leaves the inner loop and goes to the outer loop. If the LEAVE instruction is for the outer loop, processing leaves both loops.

To leave the inner loop in the preceding example, add an IF...THEN...ELSE instruction that includes a LEAVE instruction after the IF instruction.

```
DO outer = 1 TO 2
    DO inner = 1 TO 2
        IF inner > 1 THEN
            LEAVE inner
        ELSE
            SAY 'HIP'
        END IF
    END
    SAY 'HURRAH'
END
```

The result is as follows:

```
HIP
HURRAH
HIP
HURRAH
```

Exercises: combining loops

1. What happens when the following program runs?

```
DO outer = 1 TO 3
    SAY /* Produces a blank line */
    DO inner = 1 TO 3
        SAY 'Outer' outer 'Inner' inner
```

```
END
END
```

2. Now what happens when the LEAVE instruction is added?

```
DO outer = 1 TO 3
  SAY /* Produces a blank line */
  DO inner = 1 TO 3
    IF inner = 2 THEN
      LEAVE inner
    ELSE
      SAY 'Outer' outer 'Inner' inner
    END
  END
END
```

ANSWERS

1. When this example runs, it produces the following:

```
Outer 1 Inner 1
Outer 1 Inner 2
Outer 1 Inner 3

Outer 2 Inner 1
Outer 2 Inner 2
Outer 2 Inner 3

Outer 3 Inner 1
Outer 3 Inner 2
Outer 3 Inner 3
```

2. The result is one line of output for each of the inner loops.

```
Outer 1 Inner 1

Outer 2 Inner 1

Outer 3 Inner 1
```

Interrupt instructions

Interrupt instructions include EXIT, SIGNAL, CALL, and RETURN.

Instructions that interrupt the flow of a program can cause the program to:

- End (EXIT)
- Skip to another part of the program marked by a label (SIGNAL)
- Go temporarily to a subroutine either within the program or outside the program (CALL or RETURN).

EXIT instructions

The EXIT instruction causes a REXX program to unconditionally end and return to where the program was called. If another program called the REXX program, EXIT returns to that calling program.

Besides ending a program, EXIT can also return a value to the caller of the program. If the program was called as a subroutine from another REXX program, the value is received in the REXX special variable RESULT. If the program was called as a function, the value is received in the original expression at the point where the function was called. Otherwise, the value is received in the REXX special variable RC. The value can represent a return code and can be in the form of a constant or an expression that is computed.

```

/***** REXX *****/
/* This program uses the EXIT instruction to end the program and */
/* return a value indicating whether a job applicant gets the   */
/* job. A value of 0 means the applicant does not qualify for   */
/* the job, but a value of 1 means the applicant gets the job.  */
/* The value is placed in the REXX special variable RESULT.     */
/***** */
PULL months_experience      /* Gets number from input stream */
PULL references             /* Gets "Y" or "N" from input stream */
PULL start_tomorrow        /* Gets "Y" or "N" from input stream */

IF (months_experience > 24) & (references = 'Y') & (start_tomorrow= 'Y')
THEN job = 1                /* person gets the job */
ELSE job = 0                /* person does not get the job */

EXIT job

```

Figure 23. Example Using the EXIT Instruction

For more information about calling external routines, see “Subroutines and functions” on page 62. For more detailed information on the EXIT instruction, see [EXIT](#).

CALL and RETURN instructions

The CALL instruction interrupts the flow of a program by passing control to an internal or external subroutine. An internal subroutine is part of the calling program. An external subroutine is another program. The RETURN instruction returns control from a subroutine back to the calling program and optionally returns a value.

When calling an internal subroutine, CALL passes control to a label specified after the CALL keyword. When the subroutine ends with the RETURN instruction, the instructions following CALL are processed.

instruction(s)

CALL sub1

instruction(s)

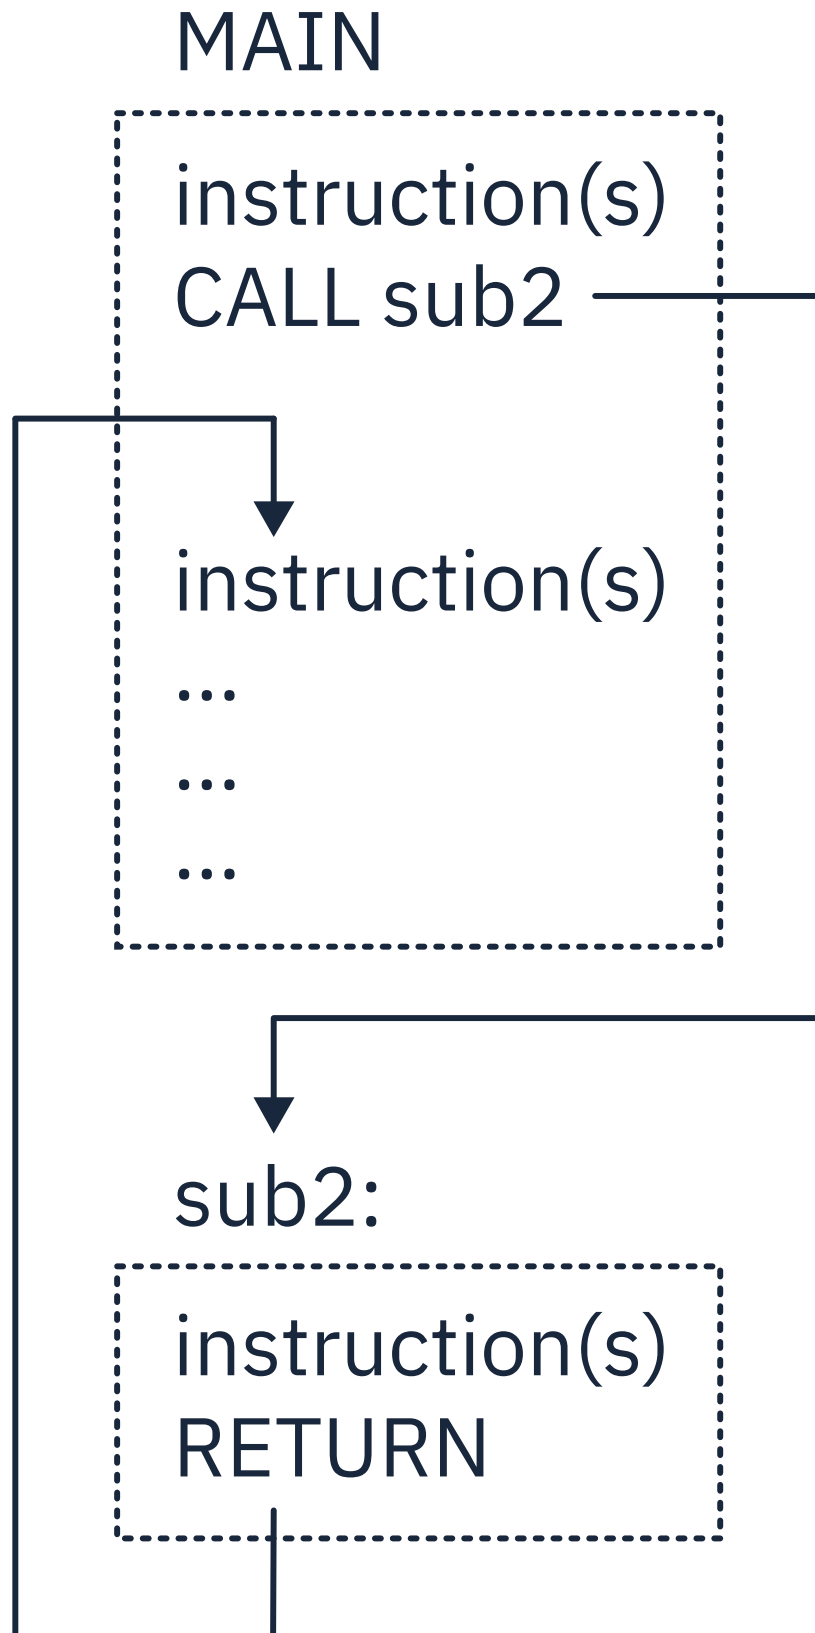

EXIT

sub1:

instruction(s)

RETURN

When calling an external subroutine, CALL passes control to the program name that is specified after the CALL keyword. When the external subroutine completes, you can use the RETURN instruction to return to where you left off in the calling program.

For more information about calling subroutines, see [“Subroutines and functions” on page 62](#).

You can use the CALL instruction with the **ON** parameter to implement a routine that receives control when REXX detects an exception condition, for example an error or failure condition. See [Conditions and condition traps](#).

For more details about the CALL and RETURN instructions, see [CALL](#) and [RETURN](#).

SIGNAL instructions

The SIGNAL instruction, like CALL, interrupts the usual flow of a program and causes control to pass to a specified label. The label to which control passes can be before or after the SIGNAL instruction. Unlike CALL, SIGNAL does not return to a specific instruction to resume execution.

When you use SIGNAL from within a loop, the loop automatically ends. When you use SIGNAL from an internal routine, the internal routine does not return to its caller.

SIGNAL is useful for testing programs or providing an emergency course of action. It should not be used as a convenient way to move from one place in a program to another. SIGNAL does not provide a way to return as does the [CALL](#) instruction.

You can use the SIGNAL instruction with the **ON** parameter to implement a routine that receives control when REXX detects an exception condition, for example an error or failure condition. See [Conditions and condition traps](#).

For more information about the SIGNAL instruction, see [“Using REXX special variables RC and SIGL” on page 97](#) and [SIGNAL](#).

Example

In the following example, if the expression is true, then the language processor goes to the label `Emergency:` and skips all instructions in between.

IF expression THEN
 SIGNAL Emergency
ELSE
 instruction(s)

Emergency:
instruction(s)

Chapter 5. Functions

A *function* is a sequence of instructions that can receive data, process it, and return a value. In REXX, there are several kinds of functions.

- Built-in functions are built into the language processor. For more information, see [“Built-In functions” on page 58](#).
- User-written functions are those an individual user writes or an installation supplies. These can be internal or external. An *internal function* is part of the current program that starts at a label. An *external function* is a self-contained program or program outside the calling program. For information about user-written functions, see [“Writing subroutines and functions” on page 64](#).

Regardless of the kind of function, all functions return a value to the program that issued the function call. To call a function, type the function name immediately followed by parentheses enclosing arguments to the function (if any). **There can be no space between the function name and the left parenthesis.**

```
function(arguments)
```

A function call can contain up to 20 arguments separated by commas. Arguments can be:

- Constant

```
function(55)
```

- Symbol

```
function(symbol_name)
```

- Option that the function recognizes

```
function(option)
```

- Literal string

```
function('With a literal string')
```

- Unspecified or omitted

```
function()
```

- Another function

```
function(function(arguments))
```

- Combination of argument types

```
function('With literal string', 55, option)
function('With literal string',, option) /* Second argument
omitted */
```

All functions must return values. When the function returns a value, the value replaces the function call. In the following example, the language processor adds the value the function returns to 7 and produces the sum.

```
SAY 7 + function(arguments)
```

A function call generally appears in an expression. Therefore a function call, like an expression, does not usually appear in an instruction by itself.

Example of a function

Calculations that functions represent often require many instructions. For example, the simple calculation for finding the highest number in a group of three numbers, might be written as follows:

```
/****** REXX ******/
/* This program receives three numbers as arguments and analyzes */
/* which number is the greatest. */
/*******/

PARSE ARG number1, number2, number3 .

IF number1 > number2 THEN
  IF number1 > number3 THEN
    greatest = number1
  ELSE
    greatest = number3
ELSE
  IF number2 > number3 THEN
    greatest = number2
  ELSE
    greatest = number3

RETURN greatest
```

Figure 24. Finding a Maximum Number

Rather than writing multiple instructions every time you want to find the maximum of a group of three numbers, you can use a built-in function that does the calculation for you and returns the maximum number. The function is called MAX, and you can use it as follows:

```
MAX(number1,number2,number3,...)
```

To find the maximum of 45, -2, *number*, and 199 and put the maximum into the symbol *biggest*, write the following instruction:

```
biggest = MAX(45,-2,number,199)
```

Built-In functions

More than 50 functions are built into the language processor.

The built-in functions fall into the following categories:

Arithmetic functions

Evaluate numbers from the argument and return a particular value.

Comparison functions

Compare numbers, or strings, or both and return a value.

Conversion functions

Convert one type of data representation to another type of data representation.

Formatting functions

Manipulate the characters and spacing in strings supplied in the argument.

String manipulating functions

Analyze a string supplied in the argument (or a variable representing a string) and return a particular value.

Other functions

Do not clearly fit into any of the other categories.

The following tables briefly describe the functions in each category. For a complete description of these functions, see [Functions](#).

Arithmetic functions

Function	Description
ABS	Returns the absolute value of the input number.
DIGITS	Returns the current setting of NUMERIC DIGITS.
FORM	Returns the current setting of NUMERIC FORM.
FUZZ	Returns the current setting of NUMERIC FUZZ.
MAX	Returns the largest number from the list specified, formatted according to the current NUMERIC settings.
MIN	Returns the smallest number from the list specified, formatted according to the current NUMERIC settings.
RANDOM	Returns a quasi-random, non-negative whole number in the range specified.
SIGN	Returns a number that indicates the sign of the input number.
TRUNC	Returns the integer part of the input number and optionally a specified number of decimal places.

Comparison functions

Function	Description
COMPARE	Returns 0 if the two input strings are identical. Otherwise, returns the position of the first character that does not match.
DATATYPE	Returns a string indicating the input string is a particular data type, such as a number or character.
SYMBOL	Returns VAR , LIT , or BAD to indicate the state of the symbol (variable, literal, or bad).

Conversion functions

Function	Description
B2X	Returns the hexadecimal representation of the input binary string. (Binary to Hexadecimal).
C2D	Returns the decimal representation of the input character string. (Character to Decimal).
C2X	Returns the hexadecimal representation of the input character string. (Character to Hexadecimal).
D2C	Returns the character representation of the input decimal string. (Decimal to Character).
D2X	Returns the hexadecimal representation of the input decimal string. (Decimal to Hexadecimal).
X2B	Returns the binary representation of the input hexadecimal string. (Hexadecimal to Binary).
X2C	Returns the character representation of the input hexadecimal string. (Hexadecimal to Character).
X2D	Returns the decimal representation of the input hexadecimal string. (Hexadecimal to Decimal).

Formatting functions

Function	Description
CENTER or CENTRE	Returns a string of a specified length with the input string centered in it, with pad characters added as necessary to make up the length.
COPIES	Returns the specified number of concatenated copies of the input string.
FORMAT	Returns the input number, rounded and formatted.
JUSTIFY ¹	Returns a specified string formatted by adding pad characters between words to justify to both margins.
LEFT	Returns a string of the specified length, truncated or padded on the right as needed.
RIGHT	Returns a string of the specified length, truncated or padded on the left as needed.
SPACE	Returns the words in the input string with a specified number of pad characters between each word.

1. Is a non-SAA built-in function REXX/CICS provides.

String manipulating functions

Function	Description
ABBREV	Returns a string indicating if one string is equal to the specified number of leading characters of another string.
DELSTR	Returns a string after deleting a specified number of characters, starting at a specified point in the input string.
DELWORD	Returns a string after deleting a specified number of words, starting at a specified word in the input string.
FIND ¹	Returns the word number of the first word of a specified phrase found within the input string.
INDEX ¹	Returns the character position of the first character of a specified string found in the input string.
INSERT	Returns a character string after inserting another input string into it from a specified character position.
LASTPOS	Returns the starting character position of the last occurrence of one string in another.
LENGTH	Returns the length of the input string.
OVERLAY	Returns a string that is the target string overlaid by a second input string.
POS	Returns the character position of one string in another.
REVERSE	Returns a character string that is the reverse of the original.
STRIP	Returns a character string after removing leading or trailing characters or both from the input string.
SUBSTR	Returns a portion of the input string beginning at a specified character position.
SUBWORD	Returns a portion of the input string starting at a specified word number.
TRANSLATE	Returns a character string with each character of the input string translated to another character or unchanged.

Function	Description
VERIFY	Returns a number indicating whether an input string is composed only of characters from another input string or returns the character position of the first unmatched character.
WORD	Returns a word from an input string as a specified number indicates.
WORDINDEX	Returns the character position in an input string of the first character in the specified word.
WORDLENGTH	Returns the length of a specified word in the input string.
WORDPOS	Returns the word number of the first word of a specified phrase in the input string.
WORDS	Returns the number of words in the input string.

1. Is a non-SAA built-in function REXX/CICS provides.

Other functions

Function	Description
ADDRESS	Returns the name of the environment to which commands are currently being sent.
ARG	Returns an argument string or information about the argument strings to a program or internal routine.
BITAND	Returns a string composed of the two input strings logically ANDed together, bit by bit.
BITOR	Returns a string composed of the two input strings logically ORed together, bit by bit.
BITXOR	Returns a string composed of the two input strings eXclusive ORed together, bit by bit.
CONDITION	Returns the condition information, such as name and status, associated with the current trapped condition.
DATE	Returns the date in the default format (dd mon yyyy) or in one of various optional formats.
ERRORTXT	Returns the error message associated with the specified error number.
EXTERNALS ¹	This function always returns a 0.
LINESIZE ¹	Returns the width of the current output device.
QUEUED	Returns the number of lines remaining in the external data queue at the time when the function is called.
SOURCELINE	Returns either the line number of the last line in the source file or the source line a number specifies.
TIME	Returns the local time in the default 24-hour clock format (hh:mm:ss) or in one of various optional formats.
TRACE	Returns the trace actions currently in effect.
USERID ¹	Returns the current user ID. This is the last user ID specified on the SETUID command, the user ID of the calling REXX program if one program calls another, the user ID under which the job is running, or the job name.
VALUE	Returns the value of a specified symbol and optionally assigns it a new value.
XRANGE	Returns a string of all 1-byte codes (in ascending order) between and including specified starting and ending values.

1. Is a non-SAA built-in function REXX/CICS provides.

Testing input with built-in functions

Some of the built-in functions provide a convenient way to test input. When a program uses input, the user might provide input that is not valid. For instance, in the example of using comparison expressions in “Comparison operators” on page 24, the program uses a dollar amount in the following instruction.

```
PARSE PULL yesterday /* Gets yesterday's price from input stream */
```

If the program pulls only a number, the program processes that information correctly. However, if the program pulls a number preceded by a dollar sign or pulls a word, such as nothing, the program returns an error. To avoid getting an error, you can check the input with the DATATYPE function as follows.

```
IF DATATYPE(yesterday) \= 'NUM'
THEN DO
  SAY 'The input amount was in the wrong format.'
  EXIT
END
```

Other useful built-in functions to test input are WORDS, VERIFY, LENGTH, and SIGN.

Exercise: writing a program with built-in functions

Write a program that checks a file name for a length of 8 characters. If the name is longer than 8 characters, the program truncates it to 8 and sends a message indicating the shortened name. Use the built-in functions [LENGTH function](#) and [SUBSTR \(Substring\) function](#).

ANSWER

```
/****** REXX ******/
/* This program tests the length of a file name. */
/* If the name is longer than 8 characters, the program truncates */
/* extra characters and sends a message indicating the shortened */
/* name. */
/*******/
PULL name /* Gets name from input stream */

IF LENGTH(name) > 8 THEN /* Name is longer than 8 characters */
DO
  name = SUBSTR(name,1,8) /* Shorten name to first 8 characters */
  SAY 'The name you specified was too long.'
  SAY name 'will be used.'
END
ELSE NOP
```

Figure 25. Possible Solution

Subroutines and functions

Subroutines and functions are routines made up of a sequence of instructions that can receive data, process it, and return a value.

The routines can be:

Internal

The routine is within the current program, marked by a label, and only that program uses the routine.

External

A REXX subroutine that exists as a separate file.

In many aspects, subroutines and functions are the same. However, they are different in a few major aspects, such as how to call them and the way they return values.

- Calling a subroutine

To call a subroutine, use the CALL instruction followed by the subroutine name (label or program member name). You can optionally follow this with up to 20 arguments separated by commas. The subroutine call is an entire instruction.

```
CALL subroutine_name argument1, argument2,...
```

- Calling a function

To call a function, use the function name (label or program member name) immediately followed by parentheses that can contain arguments. There can be no space between the function name and the left parentheses. The function call is part of an instruction, for example, an assignment instruction.

```
z = function(argument1, argument2,...)
```

- Returning a value from a subroutine

A subroutine does not have to return a value, but when it does, it sends back the value with the RETURN instruction.

```
RETURN value
```

The calling program receives the value in the REXX special variable named RESULT.

```
SAY 'The answer is' RESULT
```

- Returning a value from a function

A function **must** return a value. When the function is a REXX program, the value is returned with either the RETURN or EXIT instruction.

```
RETURN value
```

The calling program receives the value at the function call. The value replaces the function call, so that in the following example, z = value.

```
z = function(argument1, argument2,...)
```

When to write subroutines instead of functions

The actual instructions that make up a subroutine or a function can be identical. It is the way you want to use them in a program that turns them into either a subroutine or a function. For example, you can call the built-in function SUBSTR as either a function or a subroutine. This is how to call SUBSTR as a function to shorten a word to its first eight characters:

```
a = SUBSTR('verylongword',1,8) /* a is set to 'verylong' */
```

You get the same results if you call SUBSTR as a subroutine.

```
CALL SUBSTR 'verylongword', 1, 8  
a = RESULT /* a is set to 'verylong' */
```

When deciding whether to write a subroutine or a function, ask yourself the following questions:

- Is a returned value optional? If so, write a subroutine.
- Do I need a value returned as an expression within an instruction? If so, write a function.

Subroutines and functions: similarities and differences

Subroutines and functions have the following similarities:

- They can be internal or external.
 - Internal

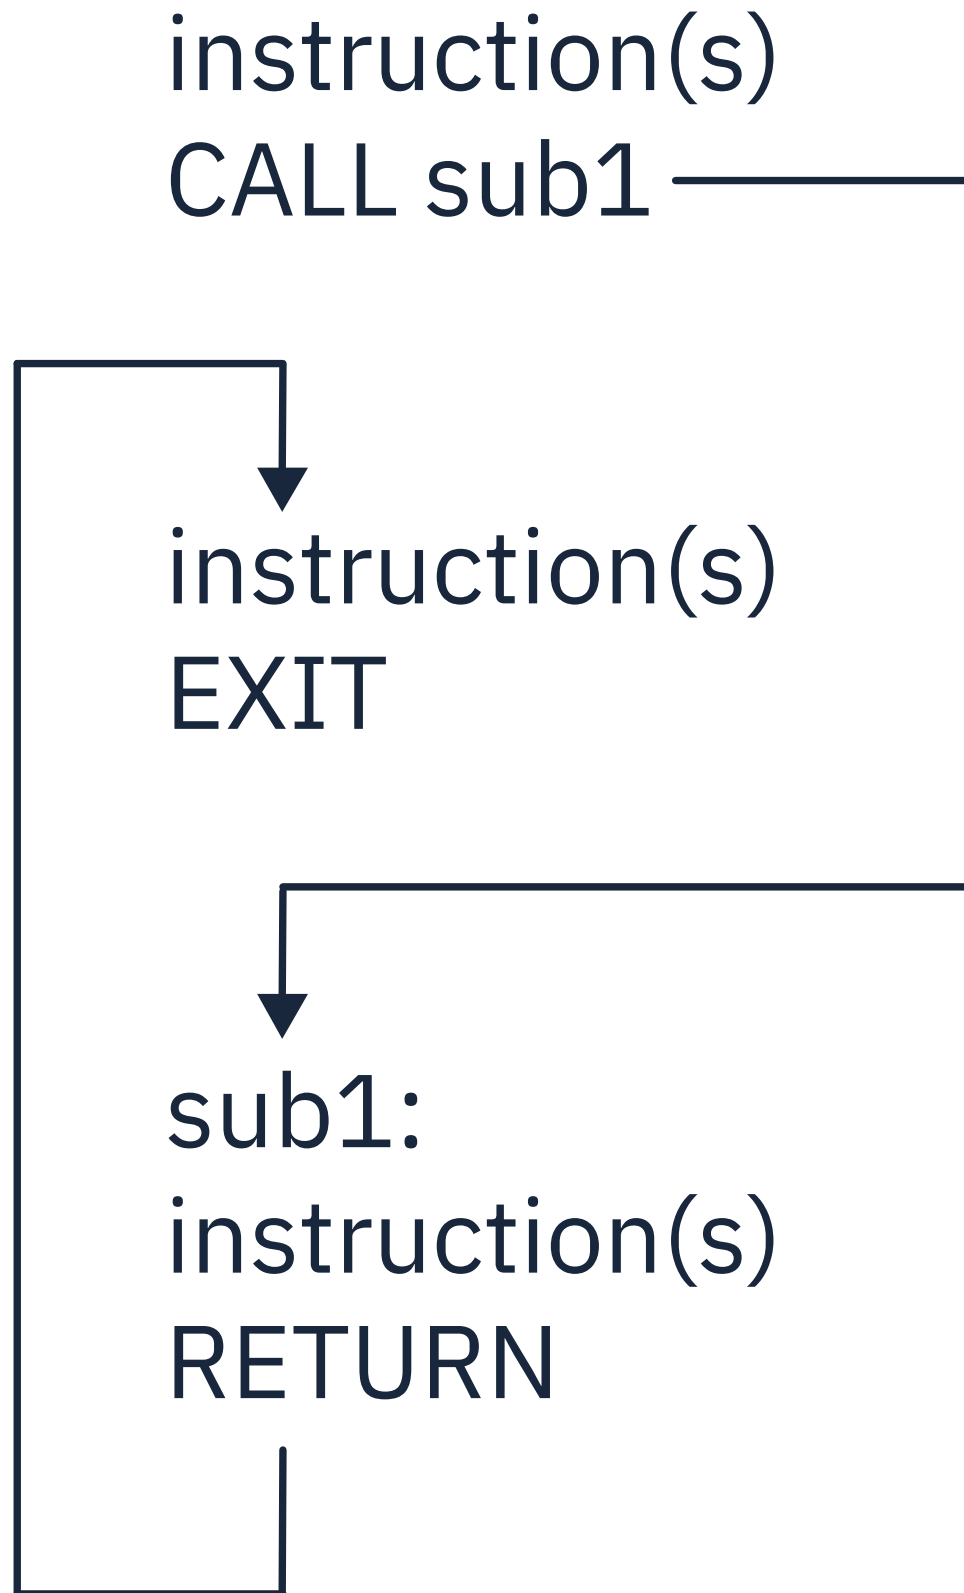

- Can pass information by using common variables
- Can protect variables with the PROCEDURE instruction
- Can pass information by using arguments.
- External
 - Must pass information by using arguments
 - Can use the ARG instruction or the ARG built-in function to receive arguments.
- They use the RETURN instruction to return to the caller.

<i>Table 3. Differences between subroutines and functions</i>		
	Subroutines	Functions
Calling	Call by using the CALL instruction, followed by the subroutine name and, optionally, up to 20 arguments.	Call by specifying the function's name, immediately followed by parentheses that optionally contain up to 20 arguments.
Returning a Value	<i>Might</i> return a value to the caller. If you include a value on the RETURN instruction, the language processor assigns this value to the REXX special variable RESULT.	<i>Must</i> return a value. Specify a value on the RETURN instruction; the language processor replaces the function call with this value.

Writing subroutines and functions

A subroutine is a series of instructions that a program calls to perform a specific task. The instruction that calls the subroutine is the CALL instruction. You can use the CALL instruction several times in a program to call the same subroutine.

When the subroutine ends, it can return control to the instruction that directly follows the subroutine call. The instruction that returns control is the RETURN instruction.

A function is a series of instructions that a program calls to perform a specific task and return a value. As [Chapter 5, “Functions,”](#) on page 57 describes, a function can be built-in or user-written. Call a user-

written function the same way as a built-in function: specify the function name immediately followed by parentheses that can contain arguments. There can be no blanks between the function name and the left parenthesis. The parentheses can contain up to 20 arguments or no arguments at all.

```
function(argument1, argument2,...)
```

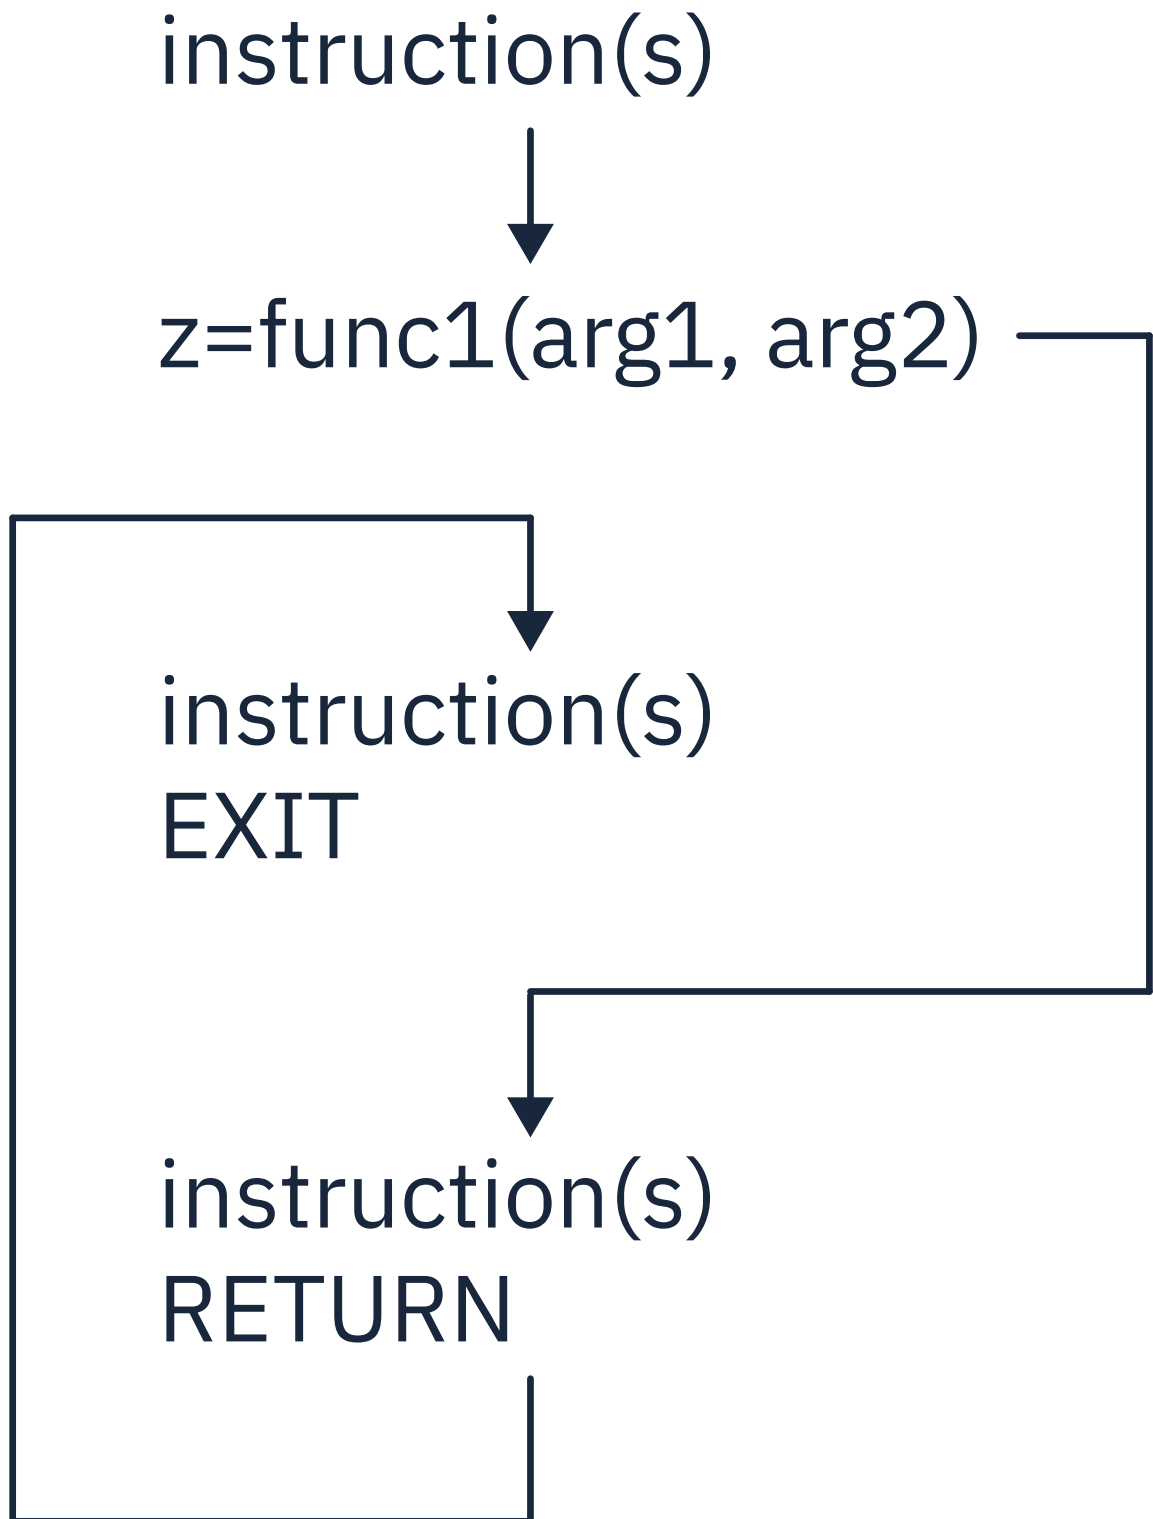

or

```
function()
```

A function requires a return value because the function call generally appears in an expression.

```
z = function(arguments1, argument2,...)
```

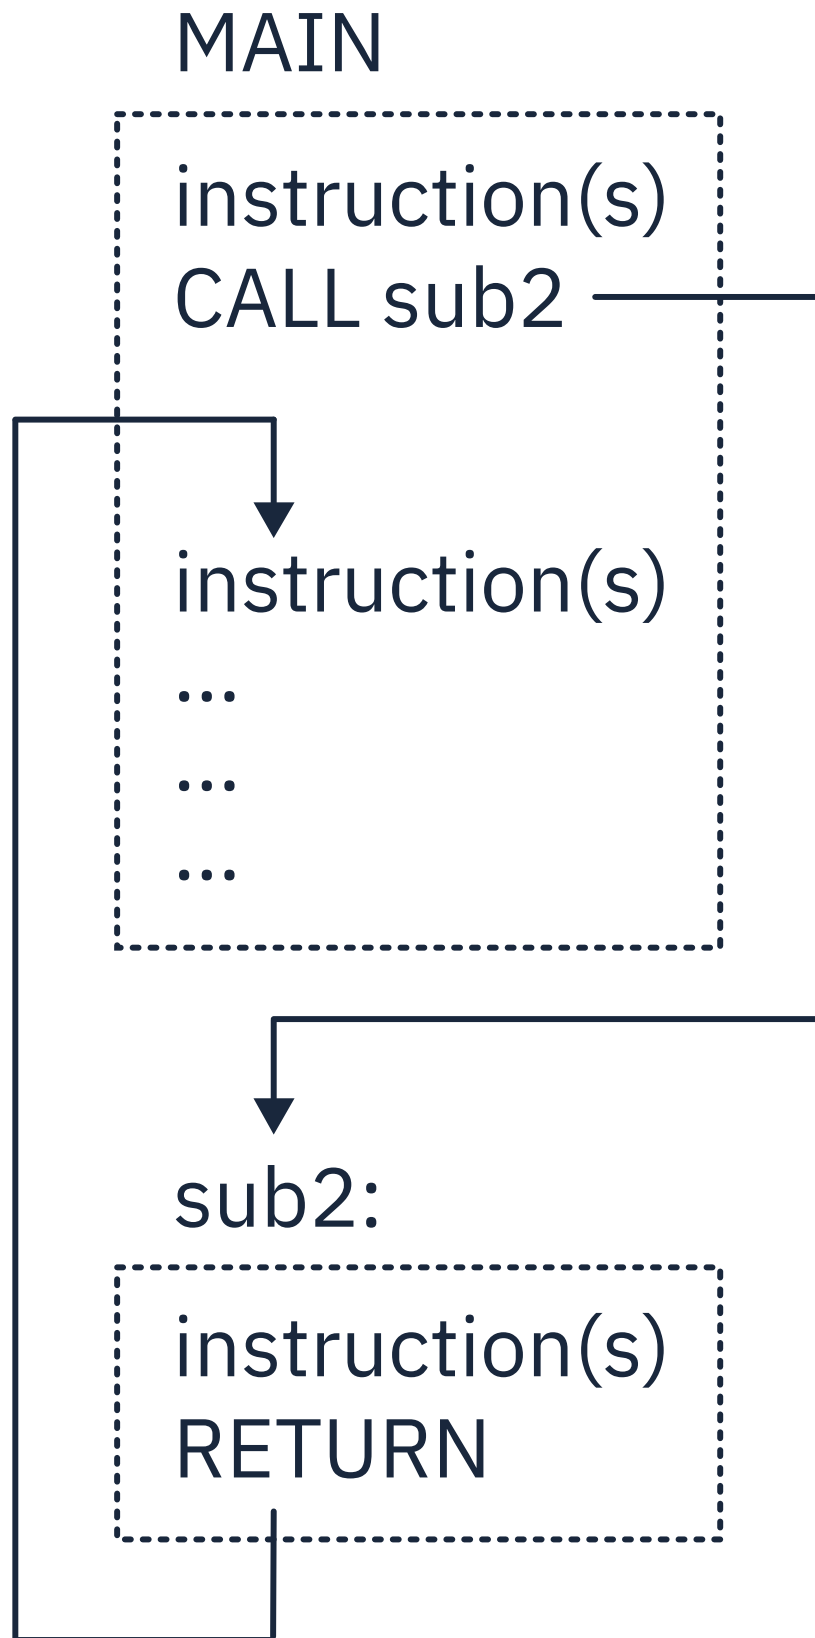

When the function ends, it can use the RETURN instruction to send back a value to replace the function call.

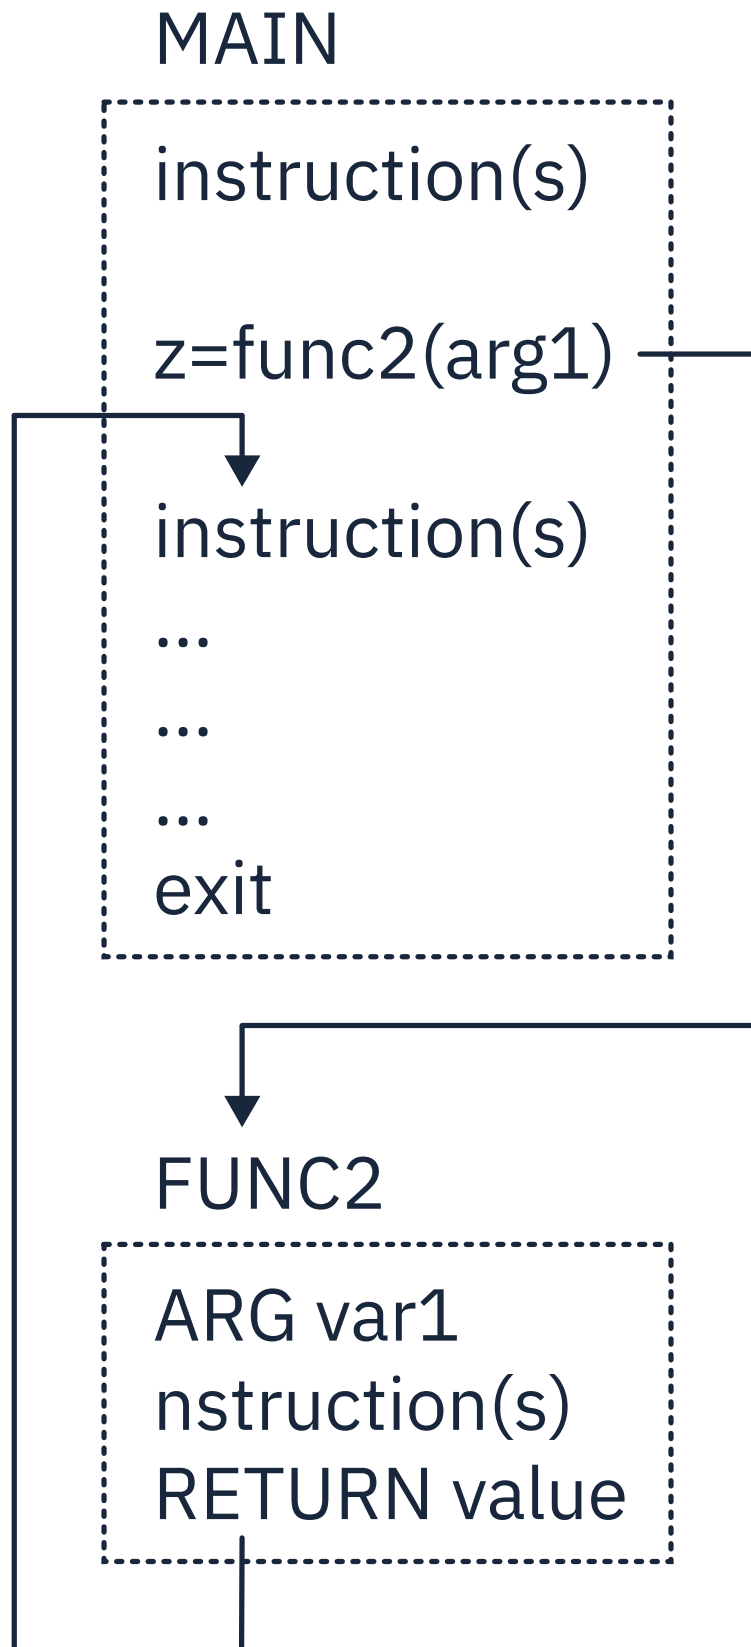

Both subroutines and functions can be *internal* (a label designates these) or *external* (a REXX File System or partitioned dataset member name that contains the subroutine or function designates these). The two preceding examples illustrate an internal subroutine named sub1 and an internal function named func1.

Important: Because internal subroutines and functions generally appear after the main part of the program, when you have an internal subroutine or function, it is important to end the main part of the program with the EXIT instruction.

The following illustrates an external subroutine named sub2.

The following illustrates an external function named `func2`.

Choosing to use internal or external subroutines or functions

To determine whether to make a subroutine or function internal or external, you might consider factors, such as:

- Size of the subroutine or function. Very large subroutines and functions often are external, whereas small ones fit easily within the calling program.
- How you want to pass information. It is quicker to pass information through variables in an internal subroutine or function. The next topic describes passing information this way.
- Whether the subroutine or function might be of value to more than one program or user. If so, an external subroutine or function is preferable.
- Performance. For functions, the language processor searches for an internal function before it searches for an external function. For the complete search order of functions, see [Functions and subroutines](#).

Passing information

A program and its internal subroutine or function can share the same variables. Therefore, you can use commonly shared variables to pass information between caller and internal subroutine or function. You can also use arguments to pass information to and from an internal subroutine or an internal function.

External subroutines, however, cannot share variables with the caller. To pass information to them, you need to use arguments or some other external way, such as the data stack. (Remember: An internal function does not need to pass arguments within the parentheses that follow the function call. However, all functions, both internal and external, must return a value.)

Passing information with variables

When a program and its internal subroutine or function share the same variables, the value of a variable is what was last assigned. This is regardless of whether the assignment was in the main part of the program or in the subroutine or function.

The following example shows passing information to a subroutine. The variables `number1`, `number2`, and `answer` are shared. The value of `answer` is assigned in the subroutine and used in the main part of the program.

```
/****** REXX ******/
/* This program receives a calculated value from an internal */
/* subroutine and uses that value in a SAY instruction.      */
/*******/

number1 = 5
number2 = 10
CALL subroutine
SAY answer                /* Produces 15 */
EXIT

subroutine:
answer = number1 + number2
RETURN
```

Figure 26. Example of Passing Information in a Variable Using a Subroutine

The next example is the same, except it passes information to a function rather than a subroutine. The subroutine includes the variable `answer` on the `RETURN` instruction. The language processor replaces the function call with the value in `answer`.

```

/***** REXX *****/
/* This program receives a calculated value from an internal */
/* function and uses SAY to produce that value. */
/*****

number1 = 5
number2 = 10
SAY add()          /* Produces 15 */
SAY answer          /* Also produces 15 */
EXIT

add:
answer = number1 + number2
RETURN answer

```

Figure 27. Example of Passing Information in a Variable Using a Function

Using the same variables in a program and its internal subroutine or function can sometimes create problems. In the next example, the main part of the program and the subroutine use the same control variable, *i*, for their DO loops. As a result, the DO loop runs only once in the main program because the subroutine returns to the main program with *i* = 6.

```

/***** REXX *****/
/* NOTE: This program contains an error. */
/* It uses a DO loop to call an internal subroutine, and the */
/* subroutine uses a DO loop with the same control variable as the */
/* main program. The DO loop in the main program runs only once. */
/*****

number1 = 5
number2 = 10
DO i = 1 TO 5
  CALL subroutine
  SAY answer          /* Produces 105 */
END
EXIT

subroutine:
DO i = 1 TO 5
  answer = number1 + number2
  number1 = number2
  number2 = answer
END
RETURN

```

Figure 28. Example of a Problem Caused by Passing Information in a Variable Using a Subroutine

The next example is the same, except it passes information using a function instead of a subroutine.

```

/***** REXX *****/
/* NOTE: This program contains an error. */
/* It uses a DO loop to call an internal function, and the */
/* function uses a DO loop with the same control variable as the */
/* main program. The DO loop in the main program runs only once. */
/*****

number1 = 5
number2 = 10
DO i = 1 TO 5
  SAY add()          /* Produces 105 */
END
EXIT

add:
DO i = 1 TO 5
  answer = number1 + number2
  number1 = number2
  number2 = answer
END
RETURN answer

```

Figure 29. Example of a Problem Caused by Passing Information in a Variable Using a Function

To avoid this kind of problem in an internal subroutine or function, you can use:

- The PROCEDURE instruction, as described in the next section.
- Different variable names in a subroutine or function than in the main part of the program . For a subroutine, you can pass arguments on the CALL instruction. See [“Passing information with arguments” on page 74.](#)

Protecting variables with the PROCEDURE instruction

When you use the PROCEDURE instruction immediately after the subroutine or function label, all variables in the subroutine or function become local to the subroutine or function; they are shielded from the main part of the program. You can also use the PROCEDURE EXPOSE instruction to protect all but a few specified variables.

The following examples show how results differ when a subroutine or function uses or does not use PROCEDURE.

```
/****** REXX ******/
/* This program uses a PROCEDURE instruction to protect the */
/* variables within its subroutine.                          */
/*******/
number1 = 10
CALL subroutine
SAY number1 number2          /* Produces 10 NUMBER2 */
EXIT

subroutine: PROCEDURE
number1 = 7
number2 = 5
RETURN
```

Figure 30. Example of Subroutine Using the PROCEDURE Instruction

```
/****** REXX ******/
/* This program does not use a PROCEDURE instruction to protect the */
/* variables within its subroutine.                          */
/*******/
number1 = 10
CALL subroutine
SAY number1 number2          /* Produces 7 5 */
EXIT

subroutine:
number1 = 7
number2 = 5
RETURN
```

Figure 31. Example of Subroutine without the PROCEDURE Instruction

The next two examples are the same, except they use functions rather than subroutines.

```
/****** REXX ******/
/* This program uses a PROCEDURE instruction to protect the */
/* variables within its function.                            */
/*******/
number1 = 10
SAY pass() number2          /* Produces 7 NUMBER2 */
EXIT

pass: PROCEDURE
number1 = 7
number2 = 5
RETURN number1
```

Figure 32. Example of Function Using the PROCEDURE Instruction

```

/***** REXX *****/
/* This program does not use a PROCEDURE instruction to protect the */
/* variables within its function. */
/*****
number1 = 10
SAY pass() number2          /* Produces 7 5 */
EXIT

pass:
number1 = 7
number2 = 5
RETURN number1

```

Figure 33. Example of Function without the PROCEDURE Instruction

Exposing variables with PROCEDURE EXPOSE

To protect all but specific variables, use the EXPOSE option with the PROCEDURE instruction, followed by the variables that are to remain exposed to the subroutine or function.

The next example uses PROCEDURE EXPOSE in a subroutine.

```

/***** REXX *****/
/* This program uses a PROCEDURE instruction with the EXPOSE option */
/* to expose one variable, number1, in its subroutine. The other */
/* variable, number2, is set to null and the SAY instruction */
/* produces this name in uppercase. */
/*****
number1 = 10
CALL subroutine
SAY number1 number2          /* produces 7 NUMBER2 */
EXIT

subroutine: PROCEDURE EXPOSE number1
number1 = 7
number2 = 5
RETURN

```

Figure 34. Example Using PROCEDURE EXPOSE in Subroutine

The next example is the same except PROCEDURE EXPOSE is in a function instead of a subroutine.

```

/***** REXX *****/
/* This program uses a PROCEDURE instruction with the EXPOSE option */
/* to expose one variable, number1, in its function. */
/*****
number1 = 10
SAY pass() number1          /* Produces 5 7 */
EXIT

pass: PROCEDURE EXPOSE number1
number1 = 7
number2 = 5
RETURN number2

```

Figure 35. Example Using PROCEDURE EXPOSE in a Function

For more information about the PROCEDURE instruction, see [PROCEDURE](#).

Passing information with arguments

A way to pass information to internal or external subroutines, or functions, is through arguments. When calling a subroutine, you can pass up to 20 arguments separated by commas on the CALL instruction as follows:

```
CALL subroutine_name argument1, argument2, argument3,...
```

In a function call, you can pass up to 20 arguments separated by commas.

```
function(argument1,argument2,argument3,...)
```

Using the ARG instruction

A subroutine or function can receive the arguments with the ARG instruction. In the ARG instruction, commas also separate arguments.

```
ARG arg1, arg2, arg3, ...
```

The names of the arguments that are passed do not have to be the same as those on the ARG instruction because information is passed by position rather than by argument name. The first argument sent is the first argument received and so forth. You can also set up a template in the CALL instruction or function call. The language processor then uses this template in the corresponding ARG instruction. For information about parsing with templates, see [“Parsing data” on page 83](#).

In the following example, the main routine sends information to a subroutine that computes the perimeter of a rectangle. The subroutine returns a value in the variable `perim` by specifying the value in the RETURN instruction. The main program receives the value in the special variable `RESULT`.

```
PARSE ARG long wide  
CALL perimeter long, wide  
SAY 'The perimeter is' RESULT 'inches.'  
EXIT
```

```
perimeter:  
  ARG length, width  
  perim = 2 * length + 2 * width  
  RETURN perim
```

Figure 36. Example of Passing Arguments on the CALL Instruction

The next example is the same except it uses ARG in a function instead of a subroutine.

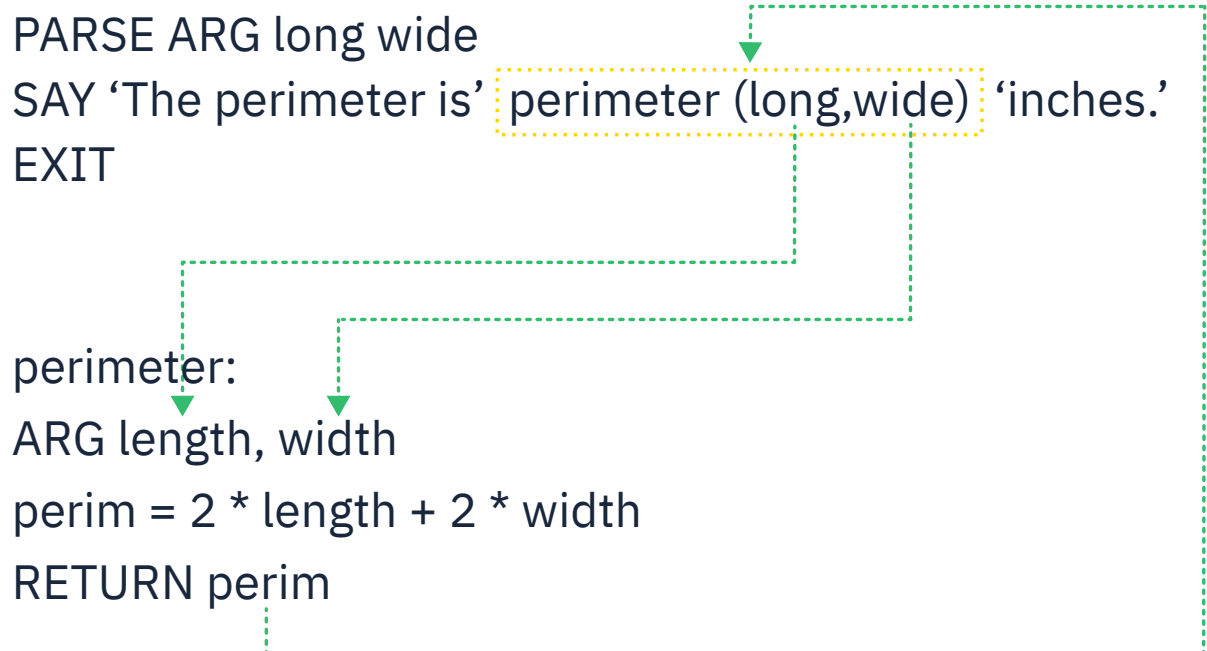

Figure 37. Example of Passing Arguments on the Call to an Internal Routine

In the two preceding examples, notice the positional relationships between `long` and `length`, and `wide` and `width`. Also notice how information is received from variable `perim`. Both programs include `perim` on a `RETURN` instruction. For the program with a subroutine, the language processor assigns the value in `perim` to the special variable `RESULT`. For the program using a function, the language processor replaces the function call `perimeter(long,wide)` with the value in `perim`.

Using the ARG built-in function

Another way for a subroutine or function to receive arguments is with the `ARG` built-in function. This function returns the value of a particular argument. A number represents the argument position.

For instance, in the previous example, instead of the `ARG` instruction:

```
ARG length, width
```

you can use the `ARG` function as follows:

```
length = ARG(1) /* puts the first argument into length */
width = ARG(2)  /* puts the second argument into width */
```

For more information about the `ARG` function see [ARG](#).

Receiving information from a subroutine or function

Although a subroutine or function can receive up to 20 arguments, it can specify only one expression on the `RETURN` instruction.

That expression can be:

- A number

```
RETURN 55
```

- One or more variables whose values are substituted (or their names if no values have been assigned).

```
RETURN value1 value2 value3
```

- A literal string

```
RETURN 'Work complete.'
```

- An arithmetic, comparison, or logical expression whose value is substituted.

```
RETURN 5 * number
```

Exercise: writing an internal and an external subroutine

Write a program that plays a simulated coin toss game and produces the accumulated scores.

There should be four possible inputs:

- 'HEADS'
- 'TAILS'
- '' (Null - to quit the game)
- None of these three (incorrect response).

Write an internal subroutine without arguments to check for valid input. Send valid input to an external subroutine that uses the `RANDOM` built-in function to generate random outcomes. Assume `HEADS` = 0 and `TAILS` = 1, and use `RANDOM` as follows:

```
RANDOM(0,1)
```

Compare the valid input with the value from RANDOM. If they are the same, the user wins one point; if they are different, the computer wins one point. Return the result to the main program where results are tallied.

ANSWER

```

/***** REXX *****/
/* This program plays a simulated coin toss game. */
/* The input can be heads, tails, or null (") to quit the game. */
/* First an internal subroutine checks input for validity. */
/* An external subroutine uses the RANDOM built-in function to */
/* obtain a simulation of a throw of dice and compares the user */
/* input to the random outcome. The main program receives */
/* notification of who won the round. It maintains and produces */
/* scores after each round. */
/***** REXX *****/
PULL flip /* Gets "HEADS", "TAILS", or "" */
/* from input stream. */
computer = 0; user = 0 /* Initializes scores to zero */
CALL check /* Calls internal subroutine, check */
DO FOREVER
    CALL throw flip /* Calls external subroutine, throw */

    IF RESULT = 'machine' THEN /* The computer won */
        computer = computer + 1 /* Increase the computer score */
    ELSE /* The user won */
        user = user + 1 /* Increase the user score */

    SAY 'Computer score = ' computer ' Your score = ' user
    PULL flip
    CALL check /* Call internal subroutine, check */
END
EXIT

```

Figure 38. Possible Solution (Main program)

```

/***** REXX *****/
/* This internal subroutine checks for valid input of "HEADS", */
/* "TAILS", or "" (to quit). If the input is anything else, the */
/* subroutine says the input is not valid and gets the next input. */
/* The subroutine keeps repeating until the input is valid. */
/* Commonly used variables return information to the main program */
/***** REXX *****/
check:
DO UNTIL outcome = 'correct'
    SELECT
        WHEN flip = 'HEADS' THEN
            outcome = 'correct'
        WHEN flip = 'TAILS' THEN
            outcome = 'correct'
        WHEN flip = '' THEN
            EXIT
        OTHERWISE
            outcome = 'incorrect'
            say 'Incorrect input, reply "HEADS", "TAILS" or blank'
            PULL flip
    END
END
RETURN

```

Figure 39. Possible Solution (Internal Subroutine Named CHECK)

```

/***** REXX *****/
/* This external subroutine receives the valid input, analyzes it, */
/* gets a random "flip" from the computer, and compares the two. */
/* If they are the same, the user wins. If they are different, */
/* the computer wins. The routine returns the outcome to the */
/* calling program. */
/*****

throw:
  ARG input
  IF input = 'HEADS' THEN
    userthrow = 0          /* heads = 0 */
  ELSE
    userthrow = 1          /* tails = 1 */

  compthrow = RANDOM(0,1)  /* choose a random number */
                          /* between 0 and 1 */
  IF compthrow = userthrow THEN
    outcome = 'human'      /* user chose correctly */
  ELSE
    outcome = 'machine'    /* user chose incorrectly */

  RETURN outcome

```

Figure 40. Possible Solution (External Subroutine named THROW)

Exercise: writing a function

Write a function named AVG that receives a list of numbers separated by blanks and computes their average. The final answer can be a decimal number. To call this function, you would use:

```
AVG(number1 number2 number3...)
```

Use the WORDS (see [WORDS function](#)) and WORD (see [WORD function](#)) built-in functions.

ANSWER

```

/***** REXX *****/
/* This function receives a list of numbers, adds them, computes */
/* their average, and returns the average to the calling program. */
/*****

ARG numlist          /* receive the numbers in a single variable */

sum = 0              /* initialize sum to zero */

DO n = 1 TO WORDS(numlist) /* Repeat for as many times as there */
                          /* are numbers */

  number = WORD(numlist,n) /* Word #n goes to number */
  sum = sum + number       /* Sum increases by number */
END

average = sum / WORDS(numlist) /* Compute the average */

RETURN average

```

Figure 41. Possible solution

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Chapter 6. Manipulating Data

This section describes how to use compound variables and stems to access data and how to use parsing.

Using Compound Variables and Stems

Sometimes it is useful to store groups of related data in a way that makes data retrieval easy. For example, you could store a list of employee names in an array and retrieve them by number. An array is an arrangement of elements in one or more dimensions, identified by a single name. An array called `employee` could contain names as follows:

```
EMPLOYEE
(1) Adams, Joe
(2) Crandall, Amy
(3) Devon, David
(4) Garrison, Donna
(5) Leone, Mary
(6) Sebastian, Isaac
```

In some computer languages, you use the number of the element to access an element in an array. For example, `employee(1)` would retrieve Adams, Joe. In REXX, you use compound variables.

What Is a Compound Variable?

You can use compound variables to create an array or a list of variables in REXX. A *compound variable*, for example: `employee.1`, consists of a stem and a tail.

A *stem* is a symbol with a period at the end. Here are some examples of stems:

```
FRED.
Array.
employee.
```

A *tail* is similar to a subscript. It follows the stem and consists of additional parts of the name that can be constant symbols (as in `employee.1`), simple symbols (as in `employee.n`), or null. Thus, in REXX, subscripts need not necessarily be numeric. A compound variable contains at least one period with characters on both sides of it. Here are some more examples of compound variables:

```
FRED.5
Array.Row.Col
employee.name.phone
```

You cannot do any substitution for the name of the stem but you can use substitution for the tail. For example:

```
employee.7='Amy Martin'
new=7
employee.new='May Davis'
say employee.7           /* Produces: May Davis */
```

As with other REXX variables, if you have not previously assigned a value to a variable in a tail, it takes on the value of its own name in uppercase.

```
first = 'Fred'
last = 'Higgins'
name = first.last           /* NAME is assigned FIRST.Higgins */
                             /* The value FIRST appears because the */
                             /* variable FIRST is a stem, which */
                             /* cannot change. */
SAY name.first.middle.last  /* Produces NAME.Fred.MIDDLE.Higgins */
```

You can use a DO loop to initialize a group of compound variables and set up an array.

```
DO i = 1 TO 6
  PARSE PULL employee.i
END
```

If you use the same names used in the example of the employee array, you have a group of compound variables as follows:

```
employee.1 = 'Adams, Joe'
employee.2 = 'Crandall, Amy'
employee.3 = 'Devon, David'
employee.4 = 'Garrison, Donna'
employee.5 = 'Leone, Mary'
employee.6 = 'Sebastian, Isaac'
```

After the names are in the group of compound variables, you can easily access a name by its number or by a variable that represents its number.

```
name = 3
SAY employee.name      /* Produces 'Devon, David' */
```

For more information about compound variables, see [Compound symbols](#).

Using stems

When working with compound variables, it is often useful to initialize an entire collection of variables to the same value. You can do this easily by using an assignment that includes a stem. For example, `number. = 0` initializes all array elements in the array named `number.` to 0.

You can change the values of all compound variables in an array the same way. For example, to change all employee names to Nobody, use the following assignment instruction:

```
employee. = 'Nobody'
```

As a result, all compound variables beginning with the stem `employee.`, previously assigned or not, have the value Nobody. After a stem assignment, you can assign individual compound variables new values.

```
employee. = 'Nobody'
SAY employee.5           /* Produces 'Nobody' */
SAY employee.10          /* Produces 'Nobody' */
SAY employee.oldest      /* Produces 'Nobody' */

employee.new = 'Clark, Evans'
SAY employee.new         /* Produces 'Clark, Evans' */
```

You can use stems with the EXECIO and RFS commands when reading to and writing from a file. See [EXECIO](#) and [RFS](#). RFS is the preferred I/O method under CICS.

Exercises - Using Compound Variables and Stems

1. After these assignment instructions, what do the following SAY instructions produce?

```
a = 3           /* assigns '3' to variable 'A' */
d = 4           /* '4' to 'D' */
c = 'last'      /* 'last' to 'C' */
a.d = 2        /* '2' to 'A.4' */
a.c = 5        /* '5' to 'A.last' */
z.a.d = 'cv3d' /* 'cv3d' to 'Z.3.4' */
```

- SAY a
- SAY D
- SAY c
- SAY a.a
- SAY A.D
- SAY d.c

- g. SAY c.a
 - h. SAY a.first
 - i. SAY z.a.4
2. After these assignment instructions, what output do the SAY instructions produce?

```
hole.1 = 'full'
hole. = 'empty'
hole.s = 'full'
```

- a. SAY hole.1
- b. SAY hole.s
- c. SAY hole.mouse

ANSWERS

- 1. a. 3
- b. 4
- c. last
- d. A.3
- e. 2
- f. D.last
- g. C.3
- h. A.FIRST
- i. cv3d
- 2. a. empty
- b. full
- c. empty

Parsing data

Parsing is separating data and assigning parts of it into one or more variables. Parsing can assign each word in the data into a variable or can divide the data into smaller parts. Parsing is also useful to format data into columns.

The variables to receive data are named in a template. A template is a model telling how to split the data. It can be as simple as a list of variables to receive data. More complex templates can contain patterns; see [“Parsing with patterns”](#) on page 86.

Parsing Instructions

The REXX parsing instructions are PULL, ARG, and PARSE. (PARSE has several variants.)

PULL instruction

PULL is an instruction that reads input and assigns it to one or more variables. If the program stack contains information, the PULL instruction takes information from the program stack. When the program stack is empty, PULL takes information from the current terminal input device. See [“Getting information from the program stack or terminal input device”](#) on page 14 for information about the data stack.

```
/* This REXX program parses the string "Knowledge is power." */
PULL word1 word2 word3
/* word1 contains 'KNOWLEDGE' */
/* word2 contains 'IS' */
/* word3 contains 'POWER.' */
```

PULL translates character information to uppercase before assigning it into variables. If you do not want uppercase translation, use the PARSE PULL instruction.

```
/* This REXX program parses the string: "Knowledge is power." */
PARSE PULL word1 word2 word3
/* word1 contains 'Knowledge' */
/* word2 contains 'is' */
/* word3 contains 'power.' */
```

You can include the optional keyword UPPER on any variant of the PARSE instruction. This causes the language processor to translate character information to uppercase before assigning it into variables. For example, using PARSE UPPER PULL gives the same result as using PULL.

ARG instruction

The ARG instruction takes information passed as arguments to a program, function, or subroutine, and puts it into one or more variables. To pass the three arguments Knowledge is power. to a REXX program named sample :

1. Call the program and pass the arguments as a string following the exec name:

```
REXX sample Knowledge is power.
```

2. Use the ARG instruction to receive the three arguments into variables.

```
/* SAMPLE -- A REXX program using ARG */
ARG word1 word2 word3
/* word1 contains 'KNOWLEDGE' */
/* word2 contains 'IS' */
/* word3 contains 'POWER.' */
```

ARG translates character information to uppercase before assigning the arguments into variables.

If you do not want uppercase translation, use the PARSE ARG instruction instead of ARG.

```
/* REXX program using PARSE ARG */
PARSE ARG word1 word2 word3
/* word1 contains 'Knowledge' */
/* word2 contains 'is' */
/* word3 contains 'power.' */
```

PARSE UPPER ARG has the same result as ARG. It translates character information to uppercase before assigning it into variables.

PARSE VALUE ... WITH instruction

The PARSE VALUE...WITH instruction parses a specified expression, such as a literal string, into one or more variables whose names follow the WITH subkeyword.

```
PARSE VALUE 'Knowledge is power.' WITH word1 word2 word3
/* word1 contains 'Knowledge' */
/* word2 contains 'is' */
/* word3 contains 'power.' */
```

PARSE VALUE does not translate character information to uppercase before assigning it into variables. If you want uppercase translation, use PARSE UPPER VALUE. You could use a variable instead of a string in PARSE VALUE (you would first assign the variable the value):

```
string='Knowledge is power.'
PARSE VALUE string WITH word1 word2 word3
/* word1 contains 'Knowledge' */
/* word2 contains 'is' */
/* word3 contains 'power.' */
```

Or you can use PARSE VAR to parse a variable.

PARSE VAR instruction

The PARSE VAR instruction parses a specified variable into one or more variables.

```
quote = 'Knowledge is power.'
PARSE VAR quote word1 word2 word3
/* word1 contains 'Knowledge' */
/* word2 contains 'is' */
/* word3 contains 'power.' */
```

PARSE VAR does not translate character information to uppercase before assigning it into variables. If you want uppercase translation, use PARSE UPPER VAR.

More about parsing into words

The behavior when the number of words in the data to parse is not the same as the number of variables in the template is described.

In the examples in the previous topic, the number of words in the data to parse is always the same as the number of variables in the template. Parsing always assigns new values to all variables named in the template. If there are more variable names than words in the data to parse, the leftover variables receive null (empty) values. If there are more words in the data to parse than variable names in the template, each variable gets one word of data in sequence except the last variable, which gets the remainder of the data.

In the next example, there are more variable names in the template than words of data; the leftover variable receives a null value.

```
PARSE VALUE 'Extra variables' WITH word1 word2 word3
/* word1 contains 'Extra' */
/* word2 contains 'variables' */
/* word3 contains '' */
```

In the next example there are more words in the data than variable names in the template; the last variable gets the remainder of the data. The last variable name can contain several words and possibly leading and trailing blanks.

```
PARSE VALUE 'More words in data' WITH var1 var2 var3
/* var1 contains 'More' */
/* var2 contains 'words' */
/* var3 contains ' in data' */
```

Parsing into words generally removes leading and trailing blanks from each word before putting it into a variable. However, when putting data into the last variable, parsing removes one word-separator blank but retains any extra leading or trailing blanks. There are two leading blanks before words. Parsing removes both the word-separator blank and the extra leading blank before putting 'words' into var2. There are four leading blanks before in. Because var3 is the last variable, parsing removes the word-separator blank but keeps the extra leading blanks. Thus, var3 receives ' in data' (with three leading blanks).

A period in a template acts as a placeholder. It receives no data. You can use a period as a "dummy variable" within a group of variables, or at the end of a template to collect unwanted information.

```
string='Example of using placeholders to discard junk'
PARSE VAR string var1 . var2 var3 .
/* var1 contains 'Example' */
/* var2 contains 'using' */
/* var3 contains 'placeholders' */
/* The periods collect the words 'of' and 'to discard junk' */
```

For more information about parsing instructions, see [PARSE](#).

Parsing with patterns

The simplest template is a group of blank-separated variable names. This parses data into blank-delimited words. Templates can also contain patterns. A pattern can be a string, a number, or a variable representing either of these.

String

If you use a string in a template, parsing checks the input data for a matching string. When assigning data into variables, parsing generally skips over the part of the input string that matches the string in the template.

```
phrase = 'To be, or not to be?'      /* phrase containing comma */
PARSE VAR phrase part1 ',' part2    /* template containing comma */
                                   /* as string separator      */
/* part1 contains 'To be'          */
/* part2 contains ' or not to be?' */
```

In this example, notice that the comma is not included with 'To be' because the comma is the string separator. (Notice also that part2 contains a value that begins with a blank. Parsing splits the input string at the matching text. It puts data up to the start of the match in one variable and data starting after the match in the next variable.

Variable

When you do not know in advance what string to specify as separator in a template, you can use a variable enclosed in parentheses.

```
separator = ','
phrase = 'To be, or not to be?'
PARSE VAR phrase part1 (separator) part2
/* part1 contains 'To be' */
/* part2 contains ' or not to be?' */
```

Again, in this example, notice that the comma is not included with 'To be' because the comma is the string separator.

Number

You can use numbers in a template to indicate the column at which to separate data. An unsigned integer indicates an absolute column position. A signed integer indicates a relative column position.

An unsigned integer or an integer with the prefix of an equal sign (=) separates the data according to *absolute column position*. The first segment starts at column 1 and goes up to, but does not include, the information in the column number specified. Subsequent segments start at the column numbers specified.

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2
PARSE VAR quote part1 5 part2
/* part1 contains 'Igno' */
/* part2 contains 'rance is bliss.' */
```

The following code has the same result:

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2
PARSE VAR quote 1 part1 =5 part2
/* part1 contains 'Igno' */
/* part2 contains 'rance is bliss.' */
```

Specifying the numeric pattern 1 is optional. If you do not use a numeric pattern to indicate a starting point for parsing, this defaults to 1. The example also shows that the numeric pattern 5 is the same as =5.

If a template has several numeric patterns and a later one is lower than a preceding one, parsing loops back to the column the lower number specifies.

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2

PARSE VAR quote part1 5 part2 10 part3 1 part4
/* part1 contains 'Igno' */
/* part2 contains 'rance' */
/* part3 contains ' is bliss.' */
/* part4 contains 'Ignorance is bliss.' */
```

When each variable in a template has column numbers both before and after it, the two numbers indicate the beginning and the end of the data for the variable.

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2

PARSE VAR quote 1 part1 10 11 part2 13 14 part3 19 1 part4 20
/* part1 contains 'Ignorance' */
/* part2 contains 'is' */
/* part3 contains 'bliss' */
/* part4 contains 'Ignorance is bliss.' */
```

Thus, you could use numeric patterns to skip over part of the data:

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2

PARSE VAR quote 2 var1 3 5 var2 7 8 var3 var 4 var5
SAY var1||var2||var3 var4 var5 /* || means concatenate */
/* Says: grace is bliss. */
```

A signed integer in a template separates the data according to *relative column position*. The plus or minus sign indicates movement right or left, respectively, from the starting position. In the next example, remember that part1 starts at column 1 (by default because there is no number to indicate a starting point).

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2

PARSE VAR quote part1 +5 part2 +5 part3 +5 part4
/* part1 contains 'Ignor' */
/* part2 contains 'ance ' */
/* part3 contains 'is bl' */
/* part4 contains 'iss.' */
```

+5 part2 means parsing puts into part2 data starting in column 6 (1+5=6). +5 part3 means data put into part3 starts with column 11 (6+5=11), and so on. The use of the minus sign is similar to the use of the plus sign. It identifies a relative position in the data string. The minus sign "backs up" (moves to the left) in the data string.

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2
PARSE VAR quote part1 +10 part2 +3 part3 -3 part4
/* part1 contains 'Ignorance ' */
/* part2 contains 'is ' */
/* part3 contains 'bliss.' */
/* part4 contains 'is bliss.' */
```

In this example, part1 receives characters starting at column 1 (by default). +10 part2 receives characters starting in column 11 (1+10=11). +3 part3 receives characters starting in column 14 (11+3=14). -3 part4 receives characters starting in column 11 (14-3=11).

To provide more flexibility, you can define and use *variable numeric patterns* in a parsing instruction. To do this, first define the variable as an unsigned integer before the parsing instruction. Then, in the parsing instruction, enclose the variable in parentheses and specify one of the following before the left parenthesis:

- A plus sign (+) to indicate column movement to the right
- A minus sign (-) to indicate column movement to the left
- An equal sign (=) to indicate an absolute column position.

(Without + , - , or = before the left parenthesis, the language processor would consider the variable to be a string pattern.) The following example uses the variable numeric pattern movex.

```
quote = 'Ignorance is bliss.'
      ....+....1....+....2

movex = 3
PARSE VAR quote part5 +10 part6 +3 part7 -(movex) part8
/* part5 contains 'Ignorance ' */
/* part6 contains 'is ' */
/* part7 contains 'bliss.' */
/* part8 contains 'is bliss.' */
```

For more information about parsing, see [Parsing](#).

Parsing multiple strings as arguments

When passing arguments to a function or a subroutine, you can specify multiple strings to be parsed. The ARG, PARSE ARG, and PARSE UPPER ARG instructions parse arguments. These are the only parsing instructions that work on multiple strings.

To pass multiple strings, use commas to separate adjacent strings.

The next example passes three arguments to an internal subroutine.

```
CALL sub2 'String One', 'String Two', 'String Three'
:
:
EXIT

sub2:
PARSE ARG word1 word2 word3, string2, string3
/* word1 contains 'String' */
/* word2 contains 'One' */
/* word3 contains '' */
/* string2 contains 'String Two' */
/* string3 contains 'String Three' */
```

The first argument is two words String One to parse into three variable names, word1, word2, and word3. The third variable, word3, is set to null because there is no third word. The second and third arguments are parsed entirely into variable names string2 and string3.

For more information about parsing multiple arguments that have been passed to a program or subroutine, see [Parsing multiple strings](#).

Exercise - practise with parsing

What are the results of the following parsing examples?

1.

```
quote = 'Experience is the best teacher.'
PARSE VAR quote word1 word2 word3
```

 - a) word1 =
 - b) word2 =
 - c) word3 =
2.

```
quote = 'Experience is the best teacher.'
PARSE VAR quote word1 word2 word3 word4 word5 word6
```

 - a) word1 =
 - b) word2 =
 - c) word3 =

- d) word4 =
e) word5 =
f) word6 =
3. `PARSE VALUE 'Experience is the best teacher.' WITH word1 word2 . . word3`
- a) word1 =
b) word2 =
c) word3 =
4. `PARSE VALUE 'Experience is the best teacher.' WITH v1 5 v2
.....1.....2.....3.`
- a) v1 =
b) v2 =
5. `quote = 'Experience is the best teacher.'
.....1.....2.....3.`
`PARSE VAR quote v1 v2 15 v3 3 v4`
- a) v1 =
b) v2 =
c) v3 =
d) v4 =
6. `quote = 'Experience is the best teacher.'
.....1.....2.....3.`
`PARSE UPPER VAR quote 15 v1 +16 =12 v2 +2 1 v3 +10`
- a) v1 =
b) v2 =
c) v3 =
7. `quote = 'Experience is the best teacher.'
.....1.....2.....3.`
`PARSE VAR quote 1 v1 +11 v2 +6 v3 -4 v4`
- a) v1 =
b) v2 =
c) v3 =
d) v4 =
8. `first = 7
quote = 'Experience is the best teacher.'
.....1.....2.....3.`
`PARSE VAR quote 1 v1 =(first) v2 +6 v3`
- a) v1 =
b) v2 =
c) v3 =
9. `quote1 = 'Knowledge is power.'
quote2 = 'Ignorance is bliss.'
quote3 = 'Experience is the best teacher.'
CALL sub1 quote1, quote2, quote3
EXIT`

`sub1:
PARSE ARG word1 . . , word2 . . , word3 .`

- a) word1 =
- b) word2 =
- c) word3 =

ANSWERS

1.
 - a) word1 = Experience
 - b) word2 = is
 - c) word3 = the best teacher.
2.
 - a) word1 = Experience
 - b) word2 = is
 - c) word3 = the
 - d) word4 = best
 - e) word5 = teacher.
 - f) word6 = "
3.
 - a) word1 = Experience
 - b) word2 = is
 - c) word3 = teacher.
4.
 - a) v1 = Expe
 - b) v2 = rience is the best teacher.
5.
 - a) v1 = Experience
 - b) v2 = is (Note that v2 contains 'is ' .)
 - c) v3 = the best teacher.
 - d) v4 = perience is the best teacher.
6.
 - a) v1 = THE BEST TEACHER
 - b) v2 = IS
 - c) v3 = EXPERIENCE
7.
 - a) v1 = 'Experience '
 - b) v2 = 'is the'
 - c) v3 = ' best teacher.'
 - d) v4 = ' the best teacher.'
8.
 - a) v1 = 'Experi'
 - b) v2 = 'ence i'
 - c) v3 = 's the best teacher.'
9.
 - a) word1 = Knowledge
 - b) word2 = Ignorance
 - c) word3 = Experience

Chapter 7. Using commands from a program

This section describes the use of commands in a REXX program.

The main categories of commands are:

REXX/CICS commands

These commands provide access to miscellaneous REXX/CICS facilities. See [REXX/CICS Commands](#).

CICS commands

These commands implement the EXEC CICS commands that application programs use to access CICS services. See [CICS command summary](#).

Be aware that if restricted commands and keywords are defined in CICS TS 5.5 or later, those restrictions do not apply to EXEC CICS commands called from a REXX program. For details, see [Controlling the use of specific CICS API and SPI commands](#).

SQL statements

These statements are prepared and executed dynamically. See [REXX/CICS DB2 interface](#).

EDIT commands

These commands invoke the editor facilities from the REXX/CICS macros. See [REXX/CICS text editor](#).

RFS commands

These commands are for the REXX File System (RFS). See [REXX/CICS File System](#).

RLS commands

These commands are for the REXX List System (RLS). See [REXX/CICS List System](#).

When a program issues a command, the REXX special variable RC is set to the return code. A program can use the return code to determine a course of action within the program. Every time a command is issued, RC is set. Therefore, RC contains the return code from the most recently issued command.

Using quotation marks in commands

Generally, to differentiate commands from other types of instructions, you enclose the command within single or double quotation marks. If the command is not enclosed within quotation marks, it is processed as an expression and might end in error. For example, the language processor treats an asterisk (`*`) as a multiplication operator.

Many CICS commands use single quotation marks within the command. For this reason, it is recommended that, as a matter of course, you enclose CICS commands within double quotation marks.

The following example places the word `test` in the temporary storage queue `ABC`.

```
"CICS WRITEQ TS QUEUE('ABC') FROM('test')"
```

Using variables in commands

When a command contains a variable, the value of the variable is not substituted if the variable is within quotation marks. The language processor uses the value of a variable only for variables outside quotation marks.

Calling another REXX program as a command

You can call another program as an external routine, or you can call a program from another program explicitly with the EXEC command.

“Subroutines and functions” on page 62 discussed how to call another program as an external routine. You can also call a program from another program explicitly with the EXEC command. Like an external routine, a program called explicitly or implicitly can return a value to the caller with the RETURN or EXIT

instruction. Unlike an external routine, which passes a value to the special variable RESULT, the program that is called passes a value to the REXX special variable RC.

To explicitly call another program from within a program, use the EXEC command as you would any other REXX/CICS command. The called program should end with a RETURN or EXIT instruction, ensuring that control returns to the caller. The REXX special variable RC is set to the return code from the EXEC command. You can optionally return a value to the caller on the RETURN or EXIT instruction. When control passes back to the caller, the REXX special variable RC is set to the value of the expression returned on the RETURN or EXIT instruction.

For example, to call a program named CALC and pass it an argument of four numbers, you could include the following instructions:

```
"EXEC calc 24 55 12 38"  
SAY 'The result is' RC
```

CALC might contain the following instructions:

```
ARG number1 number2 number3 number4  
answer = number1 * (number2 + number3) - number4  
RETURN answer
```

Issuing commands from a program

Discover what a host command environment is, how commands are passed to host command environments, and how to change the host command environment.

About this task

An environment for executing commands is called a *host command environment*. Before a program runs, an active host command environment is defined to handle the commands. When the language processor encounters a command, it passes the command to the host command environment for processing.

When a REXX program runs on a host system, there is at least one default environment available for executing commands.

The host command environment are as follows:

REXXCICS

This is the default REXX/CICS command environment. All REXX/CICS, SQL, EDIT, RFS, or RLS commands can be issued from this environment. However, CICS commands must be prefixed with CICS, SQL statements with EXECSQL, EDIT commands with EDITSVR, RFS commands with RFS, and RLS commands with RLS.

CICS

This is an optional environment that only issues CICS commands. The first word of the host command string is the command name (for example: SEND, RECEIVE).

EXECSQL

This is an optional environment that issues SQL statements (SELECT) to the CICS/Db2® interface.

EDITSVR

This is an optional environment that creates the edit session.

FLTSVR

This is an optional environment that executes commands for the File List Utility.

RFS

This is an optional environment that executes commands for the REXX File System.

RLS

This is an optional environment that executes commands for the REXX List System.

Note: It is recommended that the default environment of REXXCICS is used for all commands (that is, the ADDRESS instruction should not be specified).

How is a command passed to the host environment?

The language processor evaluates each expression in a REXX program. This evaluation results in a character string (which may be the null string). The character string is prepared appropriately and submitted to the host command environment. The environment processes the string as a command, and, after processing is complete, returns control to the language processor. If the string is not a valid command for the current host command environment, a failure occurs and the special variable RC contains the return code from the host command environment.

Changing the host command environment

You can change the host command environment from the default environment (REXXCICS) or from whatever environment was previously established.

To change the host command environment, use the ADDRESS instruction followed by the name of an environment.

The ADDRESS instruction has two forms; one affects only a single command, and one affects all commands issued after the instruction.

- Single command

When an ADDRESS instruction includes both the name of the host command environment and a command, only that command is sent to the specified environment. After the command is complete the former host command environment becomes active again.

- All commands

When an ADDRESS instruction includes only the name of the host command environment, all commands issued afterward within that host command environment are processed as that environment's commands.

This ADDRESS instruction affects only the host command environment of the program that uses the instruction. If a program calls an external routine, the host command environment is the default environment regardless of the host command environment of the calling program. Upon return to the original program, the host command environment that the ADDRESS instruction previously established is resumed.

Determining the active host command environment

To find out which host command environment is currently active, use the ADDRESS built-in function. For example:

```
cu:env = ADDRESS()
```

In this example, cu:env is set to the active host command environment, for example, REXXCICS.

Chapter 8. Diagnosing problems in a program

When you encounter an error in a program, there are several ways to locate the error.

- The TRACE instruction shows how the language processor evaluates each operation. For information about using the TRACE instruction to evaluate expressions, see [“Tracing expressions with the TRACE instruction” on page 95](#). For information about using the TRACE instruction to evaluate host commands, see [“Tracing commands with the TRACE instruction” on page 97](#).
- REXX/CICS sets the special variables RC and SIGL as follows:

RC

Indicates the return code from a command.

SIGL

Indicates the line number from which there was a transfer of control because of a function call, a SIGNAL instruction, or a CALL instruction.

Tracing expressions with the TRACE instruction

You can use the TRACE instruction to show how the language processor evaluates each operation of an expression as it reads it, or to show the final result of an expression. These two types of tracing are useful for debugging programs.

Tracing operations

To trace operations within an expression, use the TRACE I (TRACE Intermediates) form of the TRACE instruction. The language processor breaks down all expressions that follow the instruction and analyzes them as:

>V> Variable value

The data traced is the contents of a variable.

>L> Literal value

The data traced is a literal (string, uninitialized variable, or constant).

>O> Operation result

The data traced is the result of an operation on two terms.

The following example uses the TRACE I instruction. (The line numbers are not part of the program. They facilitate the discussion of the example that follows it.)

```
1 /***** REXX *****/
2 /* This program uses the TRACE instruction to show how */
3 /* an expression is evaluated, operation by operation. */
4 /*****/
5 a = 9
6 y = 2
7 TRACE I
8
9 IF a + 1 > 5 * y THEN
10     SAY 'a is big enough.'
11 ELSE NOP /* No operation on the ELSE path */
```

Figure 42. TRACE Shows How REXX Evaluates an Expression

When you run the example, the SAY instruction produces:

```
9 *- IF a + 1 > 5 * y
>V> "9"
>L> "1"
>O> "10"
>L> "5"
>V> "2"
```

```
>0> "10"
>0> "0"
```

The 9 is the line number. The *-* indicates that what follows is the data from the program, IF a + 1 < 5 * y . The remaining lines break down all the expressions.

Tracing results

To trace only the final result of an expression, use the TRACE R (TRACE Results) form of the TRACE instruction. The language processor analyzes all expressions that follow the instruction as follows:

```
>>> Final result of an expression
```

If you changed the TRACE instruction operand in the previous example from an I to an R, you would see the following results.

```
9 *-* IF a + 1 > 5 * y
>>> "0"
```

In addition to tracing operations and results, the TRACE instruction offers other types of tracing. See [TRACE](#).

Exercises: using the TRACE instruction

Write a program with a complex expression, such as:

```
IF (a > z) | (c < 2 * d) THEN ....
```

Define *a* , *z* , *c* , and *d* in the program and use the TRACE I instruction.

ANSWER

```

/***** REXX *****/
/* This program uses the TRACE instruction to show how the language */
/* processor evaluates an expression, operation by operation.      */
/***** */
a = 1
z = 2
c = 3
d = 4

TRACE I

IF (a > z) | (c < 2 * d) THEN
  SAY 'At least one expression was true.'
ELSE
  SAY 'Neither expression was true.'
```

Figure 43. Possible solution

When you run this program, it produces:

```

12 *-* IF (a > z) | (c < 2 * d)
  >V> "1"
  >V> "2"
  >0> "0"
  >V> "3"
  >L> "2"
  >V> "4"
  >0> "8"
  >0> "1"
  >0> "1"
  *-* THEN
13 *-* SAY 'At least one expression was true.'
  >L> "At least one expression was true."
At least one expression was true.
```

Tracing commands with the TRACE instruction

The TRACE instruction has many options for various types of tracing, including C for commands and E for errors.

TRACE C

After TRACE C, the language processor traces each command before execution, then executes it and sends the return code from the command to the current terminal output device. For more information on specifying the current terminal output device, refer to the SET TERMOUT command. See [SET](#).

TRACE E

When you specify TRACE E in a program, the language processor traces any host command that results in a nonzero return code after execution and sends the return code from the command to the terminal.

If a program includes TRACE E and issues an incorrect command, the program sends error messages, the line number, the command, and the return code from the command to the output stream.

For more information about the TRACE instruction, see [TRACE](#).

Using REXX special variables RC and SIGL

The REXX language has three special variables: RC, SIGL, and RESULT. REXX/CICS sets these variables during particular situations and you can use them in an expression at any time.

If REXX/CICS did not set a value, a special variable has the value of its own name in uppercase, as do other variables in REXX. You can use two special variables, RC and SIGL, to help diagnose problems in programs.

RC

RC stands for return code. The language processor sets RC every time a program issues a command. When a command ends without error, RC is usually 0. When a command ends in error, RC is whatever return code is assigned to that error.

The RC variable can be especially useful in an IF instruction to determine which path a program should take.

Note: Every command sets a value for RC, so it does not remain the same for the duration of a program. When using RC, make sure it contains the return code of the command you want to test.

SIGL

The language processor sets the SIGL special variable in connection with a transfer of control within a program because of a function, a SIGNAL or a CALL instruction. When the language processor transfers control to another routine or another part of the program, it sets the SIGL special variable to the line number from which the transfer occurred. (The line numbers in the following example are to aid in discussion after the example. They are not part of the program.)

```
1 /* REXX */
2 :
3 CALL routine
4 :
5
6 routine:
7 SAY 'We came here from line' SIGL      /* SIGL is set to 3 */
8 RETURN
```

If the called routine itself calls another routine, SIGL is reset to the line number from which the most recent transfer occurred.

SIGL and the SIGNAL ON ERROR instruction can help determine which command caused an error and what the error was. When SIGNAL ON ERROR is in a program, any host command that returns a nonzero return code causes a transfer of control to a routine named `error`. The error routine runs regardless of other actions that would usually take place, such as the transmission of error messages.

For more information about the SIGNAL instruction, see [SIGNAL](#).

Tracing with the interactive debug facility

The interactive debug facility lets a user control the execution of a program. The language processor reads from the terminal, and writes output to the terminal.

Starting interactive debug

To start interactive debug, specify `?` before the option of a TRACE instruction, for example: `TRACE ?A`. There can be no blank(s) between the question mark and the option. Interactive debug is not carried over into external routines that are called but is resumed when the routines return to the traced program.

Options in interactive debug

After interactive debug starts, you can provide one of the following during each pause or each time the language processor reads from the input stream.

- A null line, which continues tracing. The language processor continues execution until the next pause or read from the input stream. Repeated input of a null line, therefore, steps from pause point to pause point until the program ends.
- An equal sign (=), which re-executes the last instruction traced. The language processor re-executes the previously traced instruction with values possibly modified by instructions read from the input stream. (The input can also be an assignment, which changes the value of a variable.)
- Additional instructions. This input can be any REXX instruction, including a command or call to another program. This input is processed before the next instruction in the program is traced. For example, the input could be a TRACE instruction that alters the type of tracing:

```
TRACE L /* Makes the language processor pause at labels only */
```

The input could be an assignment instruction. This could change the flow of a program, by changing the value of a variable to force the execution of a particular branch in an IF THEN ELSE instruction. In the following example, RC is set by a previous command.

```
IF RC = 0 THEN
  DO
    instruction1
    instruction2
  END
ELSE
  instructionA
```

If the command ends with a nonzero return code, the ELSE path is taken. To force taking the first path, the input during interactive debug could be:

```
RC = 0
```

Ending interactive debug

You can end interactive debug in one of the following ways:

- Use the TRACE OFF instruction as input. The TRACE OFF instruction ends tracing, as stated in the message at the beginning of interactive debug:

```
+++ Interactive trace. TRACE OFF to end debug, ENTER to continue. +++
```

- Use the TRACE ? instruction as input.

The question mark prefix before a TRACE option can end interactive debug as well as beginning it. The question mark reverses the previous setting (on or off) for interactive debug. Thus you can use TRACE ?R within a program to start interactive debug, and provide input of another TRACE instruction with ? before the option to end interactive debug but continue tracing with the specified option.

- Use TRACE with no options as input. If you specify TRACE with no options in the input stream, this turns off interactive debug but continues tracing with TRACE Normal in effect. (TRACE Normal traces only failing commands after execution.)
- Let the program run until it ends. Interactive debug automatically ends when the program that started tracing ends. You can end the program prematurely using as input an EXIT instruction. The EXIT instruction ends both the program and interactive debug.

Saving Interactive TRACE Output

REXX/CICS provides the ability to route trace output to a file.

The REXX command SET TERMOUT routes linemode output (such as SAY and TRACE output) to a file instead of, or in addition to, the current terminal device. See [SET](#).

Chapter 9. Using the REXX/CICS help utility

REXX/CICS includes an online help utility that you can use to search for and display the product documentation that is supplied with REXX/CICS.

About this task

The help utility provides a table of contents, help topics, and a search results panel.

It is advisable to check the REXX for CICS Transaction Server product documentation that is supplied with the latest release of the [CICS Transaction Server for z/OS® product information](#) for any updates that are more recent than the online product documentation.

Procedure

Accessing help

- You can access help in the following ways:
 - From the CICS environment, enter REXX CICHELP. The help table of contents is displayed.
 - From the REXX/CICS interactive environment (you previously entered the CICS transaction REXX with no parameters), enter HELP. The help table of contents is displayed.
 - From the REXX/CICS text editor, enter HELP or press F1 (HELP). Help about that editor is displayed.
 - From the File List Utility, enter HELP or press F1 (HELP). Help about that utility is displayed.

Accessing a help topic

- You can access a help topic in the following ways:
 - From the REXX/CICS interactive environment, enter HELP followed by a search string for a topic title, for example HELP TRANSLATE. The first help topic with the search string, in upper-case, in its title is displayed.

This method can be useful to find help for specific REXX commands, functions, or keywords.
 - Access the help table of contents, as described earlier, then select a topic from the list. Either position the cursor on the line for the topic you want to select, or enter the line number for the topic in the input field, then press Enter. The selected topic is displayed.
 - Access the help table of contents, as described earlier, then enter a search string. All topics that contain the search string are listed in a search results panel. The search is not case-sensitive. In most cases, the search results panel shows both the topic name and the parent topic. For example, if you search for ADDRESS, the result is shown as follows:

```
Keyword instructions > ADDRESS
```

To select a topic from the list, either position the cursor on the line for the topic you want to select, or enter the line number for the topic in the input field, then press Enter. The selected topic is displayed.

To display all the topics that are listed in the search results panel, enter ALL in the input field.

Scrolling through the table of contents, help topics, or the search results panel

- To scroll forward to the next screen, press F8 (FORWARD).

If you are at the end of the current help topic, the following message is displayed:

```
End of topic -- press F8 for next topic
```

If you are at the end of the table of contents or the search results panel, the following message is displayed:

Already at the bottom

- To scroll forward by part of a screen, position the cursor on a line in the help screen, then press F8 (FORWARD).

The selected line becomes the first line that is displayed on the help screen.

- To scroll backward to the previous screen, press F7 (BACKWARD).

If you are at the start of the current help topic, the following message is displayed:

Start of topic -- press F7 for previous topic

If you are at the start of the table of contents or the search results panel, the following message is displayed:

Already at the top

- To scroll backward by part of a screen, position the cursor on a line in the help screen, then press F7 (BACKWARD).

The selected line becomes the last line that is displayed on the help screen.

Exiting from help, a help topic, or a search results panel

- To exit from help, a help topic, or a search results panel, press F3 (END function). You return to the previous screen that you used.

For example, if the table of contents is displayed and you press F3, you might return to the CICS environment or the REXX/CICS environment, depending on how you accessed help. If a topic is displayed and you press F3, you might return to a search results panel or the help table of contents, depending on how you accessed the help topic.

Chapter 10. Programming Style and Techniques

The method you use for constructing your programs is just as important as the language you use to write them.

Consider the data

When you are faced with the task of writing a program, the first thing to consider is the data you are required to process. Make a list of the input data. What are the items and what are the possible values of each? If the items have a kind of structure or pattern, draw a diagram to illustrate it. Then do the same for the output data. Study your two diagrams and try to see if they fit together. If they do, you are well on the way to designing your program.

Next, write the specification that the user will use. This might be a written specification, a HELP file or both.

Last of all, write your program.

Here is an example:

You are required to write an interactive program that invites the user to play "Heads or tails". The game can be played as long as the user likes. To end the game the user should reply `Quit` in answer to the question "Heads or tails?" The program is arranged so that the computer always wins.

Think about how you would write this program.

The computer starts off with:

```
Let's play a game! Type "Heads", "Tails",  
or "Quit"  
and press ENTER.
```

This means that there are four possible inputs:

- HEADS
- TAILS
- QUIT
- None of these three.

And so the corresponding outputs should be:

- Sorry. It was TAILS. Hard luck!
- Sorry. It was HEADS. Hard luck!
- That's not a valid answer. Try again!

And this sequence must be repeated indefinitely, ending with the return to CICS.

Now that you understand the specification, the input data and the output data, you are ready to write the program.

If you had started by writing down some instructions without considering the data, it would have taken you longer.

Test yourself

Write the program. If you are careful, it should run the first time!

```
/* CON EXEC */

/* Tossing a coin. The machine is lucky, not the user */

do forever
  say "Let's play a game! Type 'Heads', 'Tails',
    "or 'Quit' and press ENTER."
  pull answer

  select
    when answer = "HEADS"
      then say "Sorry! It was TAILS. Hard luck!"
    when answer = "TAILS"
      then say "Sorry! It was HEADS. Hard luck!"
    when answer = "QUIT"
      then exit
    otherwise
      say "That's not a valid answer. Try again!"
  end
end
say
end
```

Happy Hour

Here is a chance to have some fun. This is a very simple arcade game.

Type it in and play it with your friends. Later, you may want to improve it.

CATMOUSE

```
/* CATMOUSE */

/* The user says where the mouse is to go. But where */
/* will the cat jump? */

say "This is the mouse -----> @"
say "These are the cat's paws ---> ( )"
say "This is the mousehole -----> 0"
say "This is a wall -----> |"
say
say "You are the mouse. You win if you reach",
  "the mousehole. You cannot go past"
say "the cat. Wait for him to jump over you.",
  "If you bump into him you're caught!"
say
say "The cat always jumps towards you, but he's not",
  "very good at judging distances."
say "If either player hits the wall he misses a turn."
say
say "Enter a number between 0 and 2 to say how far to",
  "the right you want to run."
say "Be careful, if you enter a number greater than 2 then",
  "the mouse will freeze and the cat will move!"
say
```

```
/*-----*/
/* Parameters that can be changed to make a different */
/* game */
/*-----*/
len = 14          /* length of corridor */
hole = 14         /* position of hole */
spring = 5       /* maximum distance cat can jump */
mouse = 1        /* mouse starts on left */
cat = len        /* cat starts on right */
/*-----*/
/* Main program */
/*-----*/
do forever
  call display
/*-----*/
```

```

/* Mouse's turn */
/*-----*/
pull move
if datatype(move,whole) & move >= 0 & move <= 2
then select
    when mouse + move > len then nop /* hits wall */
    when cat > mouse,
        & mouse + move >= cat /* hits cat */
    then mouse = cat
    otherwise /* moves */
        mouse = mouse + move
end
if mouse = hole then leave /* reaches hole */
if mouse = cat then leave /* hits cat */
/*-----*/
/* Cat's turn */
/*-----*/
jump = random(1, spring)
if cat > mouse then do /* cat tries to jump left */
    Temp = cat - jump
    if Temp < 1 then nop /* hits wall */
    else cat = Temp
end
else do /* cat tries to jump right */
    if cat + jump > len then nop /* hits wall */
    else cat = cat + jump
end
if cat = mouse then leave
end
/*-----*/
/* Conclusion */
/*-----*/
call display
if cat = mouse then say "Cat wins"
else say "Mouse wins"
exit

```

```

/*-----*/
/* Subroutine to display the state of play */
/* */
/* Input: CAT and MOUSE */
/* */
/* Design note: each position in the corridor occupies */
/* three character positions on the screen. */
/*-----*/
display:
corridor = copies(" ", 3*len) /* corridor */
corridor = overlay("0", corridor, 3*hole-1) /* hole */

if mouse = len /* mouse in hole? */
then corridor = overlay("@", corridor, 3*mouse-1) /* mouse */

corridor = overlay("(", corridor, 3*cat-2) /* cat */
corridor = overlay(")", corridor, 3*cat)
say " | "corridor|" "
return

```

Good job! Now, take a while to put your new skills into action, or continue reading.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ €. See also [Conventions and terminology used in the CICS documentation](#).

Designing a program

Still thinking about method, which is just as important as language, let us take another look at CATMOUSE.

The program is about a cat and a mouse and their positions in a corridor. At some stage their positions will have to be pictured on the screen. The whole thing is too complicated to think about all at once; the first step is to break it down into:

- **Main program** : calculate their positions
- **Display subroutine** : display their positions.

Now let us look at main program. The user (who plays the mouse) will want to see where everybody is before making a move. The cat will not. The next step is to break the main program down further, into:

```
Do forever
  call Display
  Mouse's move
  Cat's move
end
Conclusion
```

Methods for designing loops

The method for designing loops is to ask two questions: will it always end, and whenever it terminates, will the data meet the conditions required?

In the CATMOUSE example, the loop terminates (and the game ends) when:

1. The mouse runs to the hole.
2. The mouse runs into the cat.
3. The cat catches the mouse.

The conclusion

At the end of the program, the user must be told what happened.

```
call display
say who won
```

What do we have so far?

Putting all this together, we have:

```
/*-----*/
/* Main program                                */
/*-----*/
do forever
  call display
  /*-----*/
  /* Mouse's turn                              */
  /*-----*/
  ...

  if mouse = hole then leave                    /* reaches hole */
  if mouse = cat then leave                     /* hits cat   */
  /*-----*/
  /* Cat's turn */
  /*-----*/
  ...

  if cat = mouse then leave
end

/*-----*/
/* Conclusion                                  */
/*-----*/
call display
if cat = mouse then say "Cat wins"
else say "Mouse wins"
exit

/*-----*/
/* Subroutine to display the state of play      */
/*-----*/
/* Input: CAT and MOUSE                        */
/*-----*/
display:
...
```

The method that we have just discussed is sometimes called *stepwise refinement*. You start with a specification (which may be incomplete). Then you divide the proposed program into routines, such that

each routine will be easier to code than the program as a whole. Then you repeat the process for each of these routines until you reach routines that you are sure you can code correctly at the first attempt.

While you are doing this, keep asking yourself two questions:

- What data does this routine handle?
- Is the specification complete?

Step-wise refinement: an example

Breaking a job down into simpler jobs is called *step-wise refinement*.

Your grandmother is going to knit you a warm woolen garment to wear when you go sailing. This is what she might do.

1. Knit front
2. Knit back
3. Knit left arm
4. Knit right arm
5. Sew pieces together.

Each of these jobs is simpler to describe than the job of knitting a pullover. In computer jargon, breaking a job down into simpler jobs is called *step-wise refinement*.

At this stage, look at the specification again. A sailor might need to put on the pullover in the dark, quickly, without worrying about the front or back. Therefore, the front should be the same as the back; and the two sleeves should also be the same. This could be programmed:

```
do 2
  CALL Knit_body_panel
end

do 2
  CALL Knit_sleeve
end
CALL sew_pieces_together
```

In programming, the best method is to go on refining your program, working from the top, until you get down to something that is easy to code.

Top down is the best approach.

Reconsider the Data

When you are refining your program, your objective is to make each piece simpler.

This almost certainly means:

- Simpler input data for each segment or routine
- Simpler output data for each segment or routine
- Simpler processing
- And, therefore, simpler code.

If your pieces really are simpler, they will probably have simpler names, too. For instance:

- Knit cuff

rather than

- Make ribbing for cuffs and waistband.

Correcting your program

You can use various techniques to correct your program.

If you cannot understand why your program gives the wrong results:

- You can modify your program so that it indicates what it is doing.
- You can use the REXX interactive trace facilities. See [Interactive Debugging of Programs](#).

You can evaluate which technique you prefer to use.

Modifying Your Program

You can modify your program and put in extra instructions so that it tells you what is happening.

You can put extra instructions into your program, such as:

```
...  
say "Checkpoint A. x =" x  
...  
say "End of first routine"  
...
```

Tracing your program

You can use the REXX interactive trace facilities to understand what is happening in your program.

For details about the TRACE instruction, see [TRACE](#).

- To find out where your program is going, use TRACE Labels. The example shows a program and the trace it gives on the screen.

```
/* ROTATE */  
  
/* Example: two iterations of wheel, six iterations */  
/* of cog. On the first three iterations, "x < 2" */  
/* is true. On the next three, it is false.      */  
trace L  
do x = 1 to 2  
wheel:  
  do 3  
  cog:  
    if x < 2 then do  
true:  
    end  
    else do  
false:  
    end  
  end  
end  
done:
```

Figure 44. ROTATE

This gives the following trace:

```
rotate  
6 *- wheel:  
8 *- cog:  
10 *- true:  
8 *- cog:  
10 *- true:  
8 *- cog:  
10 *- true:  
6 *- wheel:  
8 *- cog:  
13 *- false:  
8 *- cog:  
13 *- false:  
8 *- cog:  
13 *- false:  
17 *- done:
```

- To see how the language processor is computing expressions, use TRACE Intermediates.
- To find out whether you are passing the right data to a command or subroutine, use TRACE Results.
- To make sure that you get to see nonzero return codes from commands, use TRACE Errors.

Coding style

A program must be easy to read to ensure that you can read it and find out whether it is correct.

"Easy to read" means different things to different programmers. Here, we give examples of different styles; you can choose the style you prefer. A very good way to check your program is to ask a colleague to read it, so use a coding style that your colleagues find easy to read.

The following program fragment, from the example program in ["Happy Hour" on page 104](#), is difficult to read for most people.

```

/*****
/* SAMPLE #1: A portion of CATMOUSE          */
/* not divided into segments and written with no      */
/* indentation, and no comments. This style is not    */
/* recommended.                                     */
*****/

do forever
call display
pull move
if datatype(move,whole) & move >= 0 & move <=2
then select
when mouse+move > len then nop
when cat > mouse,
& mouse+move >= cat,
then mouse = cat
otherwise
mouse = mouse + move
end
if mouse = hole then leave
if mouse = cat then leave
jump = random(1, spring)
if cat > mouse then do
if cat-jump < 1 then nop
else cat = cat-jump
end
else do
if cat+jump > len then nop
else cat = cat+jump
end
if cat = mouse then leave
end
call display
if cat = mouse then say "Cat wins"
else say "Mouse wins"
exit

```

This next example is easier to read. It is divided into segments, each with its own heading. The comments on the right are sometimes called *remarks*. They can help the reader get a general idea of what is going on.

```

/*****
/* SAMPLE #2: A portion of CATMOUSE
/* divided into segments and written with 'some'
/* indentation and 'some' comments.
*****/

/*****
/* Main program
*****/
do forever
  call display
  /*****
  /* Mouse's turn
  *****/
  pull move
  if datatype(move,whole) & move >= 0 & move <=2
  then select
    when mouse+move > len then nop      /* hits wall */
    when cat > mouse,
      & mouse + move >= cat,          /* hits cat */
    then mouse = cat
    otherwise                          /* moves */
      mouse = mouse + move
  end
  if mouse = hole then leave           /* reaches hole */
  if mouse = cat then leave            /* hits cat */
  /*****
  /* Cat's turn */
  *****/
  jump = random(1,spring)
  if cat > mouse then do               /* cat tries to jump left */
    if cat - jump < 1 then nop         /* hits wall */
    else cat = cat - jump
  end
  else do                             /* cat tries to jump right */
    if cat + jump > len then nop       /* hits wall */
    else cat = cat + jump
  end
  if cat = mouse then leave
end
/*****
/* Conclusion
*****/
call display
if cat = mouse then say "Cat wins"
else say "Mouse wins"
exit

```

This next example has additional features that are popular with some programmers. Keywords written in uppercase and a different indentation style highlight the structure of the code; the abundant comments recall the detail of the specification.

```

/*****
/* SAMPLE #3: A portion of CATMOUSE
/* divided into segments and written with 'more'
/* indentation and 'more' comments.
/* Note commands in uppercase (to highlight logic)
*****/

/*****
/* Main program
*****/
DO FOREVER
  CALL display
  /*****
  /* Mouse's turn
  *****/
  PULL move
  IF datatype(move,whole) & move >= 0 & move <=2
    THEN SELECT
      WHEN mouse+move > len /* mouse hits wall */
      THEN nop /* and loses turn */
      WHEN cat > mouse,
        & mouse+move >= cat, /* mouse hits cat */
      THEN mouse = cat /* and loses game */
      OTHERWISE mouse = mouse + move /* mouse ... */
    END /* moves to new location */
  IF mouse = hole THEN LEAVE /* mouse is home safely */
  IF mouse = cat THEN LEAVE /* mouse hits cat (ouch) */
  /*****
  /* Cat's turn
  *****/
  jump = RANDOM(1,spring) /* determine cat's move */
  IF cat > mouse /* cat must jump left */
    THEN DO
      IF cat-jump < 1 /* cat hits wall */
      THEN nop /* misses turn */
      ELSE cat = cat-jump /* cat jumps left */
    END
  ELSE DO /* cat must jump right */
    IF cat+jump > len /* cat hits wall */
    THEN nop /* misses turn */
    ELSE cat = cat+jump /* cat jumps right */
  END
  IF cat = mouse THEN LEAVE /* cat catches mouse */
END
/*****
/* Conclusion
*****/
CALL display /* on final display */
IF cat = mouse /* who won? */
  THEN say "Cat wins" /* ... the cat */
  ELSE say "Mouse wins" /* ... the mouse */
EXIT

```

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Part 2. Configuring REXX

This section introduces aspects of configuring and administering REXX.

Chapter 11. Configuring REXX support

Before you can run a REXX program, you must configure the REXX support.

Create the RFS filepools

The REXX Filing System (RFS) uses two or more filepools to store data.

These are implemented as sets of VSAM clusters. The supplied member, CICVSAM, in CICSTS61.REXX.SCICJCL, creates the VSAM data sets for two RFS filepools. Change this job to reflect your own environment as required. For example, you might change the data set names to match your installation standards. After you complete the changes, run the job to define the filepools.

If you change any filepool names or add filepool components in the resource definitions, you must make corresponding changes to the filepool definitions in your CICSTART member. See [“Create resource definitions” on page 115](#) and [“Update the CICSTART member” on page 116](#).

Ensure that the following definitions are consistent:

- The filepool definitions in CICSTART
- The resource definitions in CICRDOD (for the for Development System) or CICRDOR (for the Runtime Facility)
- The VSAM cluster definitions in CICVSAM

Create resource definitions

Definitions for profile, program, transaction, and file resources for REXX are in group CICREXX, which is in the supplied or upgraded CSD.

The CICRDOR job, for the Runtime Facility, or the CICRDOD job, for the Development System, in the CICSTS61.REXX.SCICJCL data set adds the entries that the product requires, including REXX/CICS profiles, VSAM files, programs, transactions, and transient data queues.

The transient data queues are used for REXX/CICS IMPORT and EXPORT commands. The jobs also contain the definitions for the REXX/CICS SQL interface that authorize the transactions to the Db2 plan.

Edit the JCL, ensuring that you uncomment the entries as explained in comments at the beginning of the JCL, and run the job.

Modifying TD queues for IMPORT and EXPORT commands

The REXX/CICS environment uses dynamic allocation to IMPORT members from a partitioned data set or to EXPORT RFS files to a partitioned data set.

The CICRDOD or CICRDOR member in the CICSTS61.REXX.SCICJCL data set defines three transient data entries used as input for IMPORT and three transient data entries for output for EXPORT, so that three users can concurrently IMPORT and three users can concurrently EXPORT from and to partitioned data sets.

Modify the number of TDQ entries to suit your requirements, but allow for at least one input and one output entry. The TDQUEUE NAME must begin with REX and be suffixed with a valid character. Do not have other applications using TDQUEUE names that begin with REX, because IMPORT and EXPORT use them and can cause files to become corrupted.

Review LSRPOOL definitions

Because the RFS files have a maximum key length of 252, and the supplied VSAM definitions use a control interval size of 18K, it is important to check that the LSRPOOL used for the RFS supports these values.

If you fail to do this, you might get an OPEN error on the system console. For more information, see [LSRPOOL resources](#) and [Local shared resources \(LSR\) or nonshared resources \(NSR\)](#).

Update the CICSTART member

The CICSTART member, in the *hlq.CICSTS61.REXX.SCICEXEC* data set, contains default definitions for the REXX/CICS environment. **CICSTART** runs when the first transaction that uses the CICS/REXX program is issued, after the CICS system starts.

CICSTART holds the permanent configuration for the environment. Either edit the supplied CICSTART member, or use it as a model for your own **CICSTART** exec.

- Initialization

Use the initialization statements that set pseudo-conversational mode off (PSEUDO OFF) and check an RLS directory (RLS CKDIR) exactly as shown at the start of the supplied CICSTART member.

- Define RFS filepools

The supplied CICSTART member defines two filepools:

```
'FILEPOOL DEFINE POOL1 RFSDIR1 RFSP00L1 (USER'
  IF RC -> 0 THEN EXIT RC
'FILEPOOL DEFINE POOL2 RFSDIR2 RFSP00L2 (USER'
  IF RC -> 0 THEN EXIT RC
```

If you changed any filepool names or added any filepools during the step [“Create the RFS filepools” on page 115](#), make corresponding changes to the filepool definitions in your **CICSTART** exec.

- Authorize user IDs

The supplied CICSTART member authorizes the user ID RCUSER. Ensure that your **CICSTART** exec includes commands to authorize the users in your organization who require it.

Include any users who need access to format the file pools; otherwise, the FILEPOOL FORMAT command will fail with return code of -4.

For a region where CICS security is turned off (that is, the SIT parameter SEC=NO), include an AUTHUSER command in **CICSTART** for the CICS default user ID. For example, if the default user ID for the region is SYSA, include the following command:

```
'AUTHUSER SYSA'
```

- Associate CICS transaction IDs with REXX execs as required

CICSTART must include DEFTRNID statements that associate CICS transaction IDs, as defined by CICS **DEFINE TRANSACTION** commands, with the REXX execs they are intended to invoke. The supplied CICSTART member associates the REXX, EDIT, and FLST transactions with **CICRXTRY**, **CICEDIT**, and **CICFLST** execs, respectively. These CICS transactions are defined in the CICRDOR and CICRDOD JCL files. See [“Create resource definitions” on page 115](#).

Your **CICSTART** exec must include DEFTRNID statements for any CICS transactions that you define to run REXX/CICS transactions.

- Set defaults for running REXX execs

Include SETSYS commands that you require for the environment. For example, you can set the language, the retrieve PF key, and the pseudo-conversational setting for running REXX/CICS execs in your installation.

By default, pseudo-conversational mode is on (although the **CICSTART** exec itself must run in conversational mode). For more information about pseudo-conversational mode, see [PSEUDO](#) and [Processing dialogs with users](#).

- Define the help paths

The supplied CICSTART member defines the help path HELPPTH2 for the current help utility, and, for compatibility, the help path HELPPTH for the previous help facility:

```
HELPPATH = 'POOL2:\BOOK'  
'RLS VARPUT HELPPATH \SYSTEM\DEFAULTS'  
IF RC ^= 0 THEN EXIT  
HELPPTH2 = 'POOL2:\HELP'  
'RLS VARPUT HELPPTH2 \SYSTEM\DEFAULTS'  
IF RC ^= 0 THEN EXIT RC
```

For a new installation, where the previous help facility is not installed, you can remove the three statements that define HELPPTH.

- Use EXECLOAD to preload execs as required

You can include EXECLOAD statements to preload execs. When execs are preloaded, performance can improve because the exec does not need to be loaded for each user, and less storage is required because all concurrent users can share the same copy.

You can use the list of **EXECLOAD** commands in the supplied CICSTART member, or include **EXECLOAD** commands for the execs that you require.

The supplied CICSTART member contains **EXECLOAD** commands for the **CICEDIT**, **CICESVR**, and **CICEPROF** execs. These execs are components of the REXX/CICS text editor, which you can use when developing your own REXX programs, and that is part of the REXX Development System only. If your installation uses the REXX/CICS text editor, you can include these **EXECLOAD** commands.

For more information, see [EXECLOAD](#).

Modify the CICS initialization JCL

Add DD statements to your CICS startup job and the DFHRPL concatenation.

Add the following DD statements to your CICS startup job:

```
//CICAUTH DD DSN=CICSTS61.REXX.SCICCMDS,DISP=SHR  
//CICEXEC DD DSN=CICSTS61.REXX.SCICEXEC,DISP=SHR  
//CICUSER DD DSN=CICSTS61.REXX.SCICUSER,DISP=SHR
```

Add a DD statement for the REXX data sets to the DFHRPL concatenation:

```
//DFHRPL DD DSN=CICSTS61.REXX.SCICLOAD,DISP=SHR
```

The REXX/CICS environment uses three data set concatenations that do not have resource definitions in CICS; the CICCMDS, CICEXEC, and CICUSER DD names. These data sets are partitioned data sets and are accessed by using MVS facilities.

CICCMDS

The CICCMDS DD name concatenation starts by referencing the CICSTS61.REXX.SCICCMDS data set. This data set contains the execs that implement REXX/CICS environment authorized commands. Only authorized users, or execs authorized to use authorized commands, can access these execs. If you extend the REXX/CICS environment with your own authorized commands, concatenate your data set to this DD name concatenation.

CICEXEC

The CICEXEC DD name concatenation starts by referencing the CICSTS61.REXX.SCICEXEC data set. This data set contains the execs that are supplied by the REXX/CICS environment that use authorized commands. If you extend the REXX/CICS environment with your own execs that use authorized commands, concatenate your data set to this DD name concatenation.

CICUSER

The CICUSER DD name concatenation starts by referencing the CICSTS61.REXX.SCICUSER data set. This data set contains the execs that are supplied by the REXX/CICS environment that do not use authorized commands. If you extend the REXX/CICS environment with your own execs that do not use authorized commands, concatenate your data set to this DD name concatenation.

The facilities used to access these data set concatenations use CICS WAIT EXTERNAL capabilities to avoid placing the CICS region into a wait.

Format the RFS filepools

You must format every REXX Filing System (RFS) filepool that is defined in **CICSTART**.

1. Ensure that all required configuration tasks are complete, and if necessary restart CICS.
2. Sign on with a userid defined as an authorized user in **CICSTART**.
3. Enter REXX (which is the default transaction id associated with the **CICRXTRY** exec).

This action invokes the REXXTRY utility, which provides the interactive environment where you can execute REXX and REXX/CICS commands interactively. The following line is displayed at the top of the screen, a READ is displayed in the lower right corner, and the cursor is in the lower left corner:

Enter a REXX command or EXIT to quit

4. Prepare the filepools for use by entering the following command for every filepool that is defined in **CICSTART**:

```
'FILEPOOL FORMAT poolname'
```

poolname is the filepool name that you specified in the **CICSTART** exec (the defaults are POOL1 and POOL2).

It is advisable to use either single or double quotes to delimit the REXX command.

The interactive environment echoes each command at the next available line on the screen and displays any requested output.

The **FILEPOOL FORMAT** command does not display any information to indicate that it has successfully completed, but the word READ is displayed in the lower right corner of the screen.

5. To determine whether the **FILEPOOL FORMAT** command was successful, enter SAY RC (without apostrophes). A 0 displayed on the next available line indicates that the command succeeded.

Attempting to re-format a filepool gives the following message:

```
Subcommand return code = 1836
```

6. Continue this process until all RFS filepools are formatted. You format the filepool only when a new filepool is defined, or if you delete and redefine the clusters for an existing filepool.

If you fill the screen while formatting the filepools, or interactively executing REXX or REXX/CICS commands and instructions, a MORE indicator is displayed at the bottom right corner. To clear the screen, press the Enter key. You can press the Clear key any time you want to clear the screen of data. Press the PF3 key to exit from the interactive environment; this action simulates entering the EXIT instruction. You can also enter the EXIT instruction yourself (without apostrophes).

In the interactive environment, you can press the RETRIEVE key to recall previously entered commands. The default system setting for this key is PF12. The RETRIEVE key re-displays the previously entered line at the input location. You can then modify this area and execute the instruction again by pressing Enter. Pressing the RETRIEVE key multiple times continues to bring the preceding previously entered command to the input area.

Verify the installation

An exec is supplied to verify that the installation is successful.

1. Under the REXX/CICS REXXTRY utility, enter CALL CICIVP1 to run the installation verification program. Output from the exec is as follows (remember to press Enter when the screen displays MORE):

```
EXEC CICIVP1
***-----***
*** This is a test REXX program running under CICS-TS ***
*** It was loaded from CICUSER-CICIVP1 ***
***-----***

What is your name?
```

2. Type a name and press Enter. Output is as follows:

```
Welcome to REXX/CICS for CICS-TS , xxxx

Invoking nested exec CICIVP2 (which has tracing on)
  20 *-* say 'You entered CICIVP2 exec'
    >>> "You entered CICIVP2 exec"
You entered CICIVP2 exec
  21 *-* call CICIVP3
You entered CICIVP3 exec which has tracing off
  22 *-* exit
Back to CICIVP1 exec

      This is fullscreen output to terminal xxxx
      Now input some data and press ENTER or a PF key

The AID key that was pressed = ENTER
The cursor was at (Row Col): 24 7
The data that was entered (Row Col Data): 24 1 <DATA>
Example of more than one screen
1000 assignment statements have been executed
2000 assignment statements have been executed
3000 assignment statements have been executed
4000 assignment statements have been executed
5000 assignment statements have been executed
6000 assignment statements have been executed
7000 assignment statements have been executed
8000 assignment statements have been executed

19000 assignment statements have been executed
20000 assignment statements have been executed
Today's date is dd mmm yyyy
The time is hh:mm:ss
REXX/CICS CICIVP1 is now finished
```

Creating the help files

REXX/CICS includes an online help utility that you can use to search for and display the product documentation that is supplied with REXX/CICS.

About this task

As part of installation, you must load the information from the CICS TS product delivery data sets into the REXX/CICS file system.

Procedure

1. Define the REXX Filing System (RFS) filepools and set the help paths for the help utility.

The supplied CICSTART member, in the *hlq.CICSTS61.REXX.SCICEXEC* data set, includes statements to define RFS filepools and to set help paths for REXX help. Check and, if necessary, change these statements to meet your requirements. For details, see [“Update the CICSTART member” on page 116](#).

The supplied CICSTART member defines the help path HELPPTH2 for the current help utility. For compatibility, it also defines the help path HELPPTH for the previous help facility. You do not need HELPPTH unless the previous help facility is installed and you want to use it until these installation steps are complete.

2. Ensure that the user ID that will load the help information in step “3” on page 120 is authorized to import the relevant data sets from the CICS TS product delivery libraries to the REXX Filing System.

The **CICHLLOAD** exec in the *hlq.CICSTS61.REXX.SCICEXEC* data set imports help information from the supplied *hlq.CICSTS61.REXX.SCICDOC* and *hlq.CICSTS61.REXX.SCICPNL* data sets. It uses the information to build files in the RFS that REXX help uses.

One way to ensure this authorization is to create copies of *hlq.CICSTS61.REXX.SCICDOC* and *hlq.CICSTS61.REXX.SCICPNL* with the relevant user ID as the high-level qualifier.

3. Start REXX/CICS and issue the **EXEC CICHLLOAD** command.

CICHLLOAD imports help information and panel definitions from MVS libraries. When the following messages are displayed, provide the data set names that you set in the previous step:

Please enter the MVS dataset name of the help package library
Example: *hlq.CICSTS55.REXX.SCICDOC*

Please enter the MVS dataset name of the panels library
Example: *hlq.CICSTS55.REXX.SCICPNL*

The supplied *CICSTS61.REXX.SCICDOC* data set contains the *CICRXHLP* member, which contains online help information. The *CICHLLOAD* program processes this to create the files that the online help utility uses. Files are created in the help path HELPPTH2 that you specified.

Any *CICR3270* or *CICR3820* members in this data set are superseded by the *CICRXHLP* member and a PDF that is supplied with the [CICS Transaction Server for z/OS product information](#).

It is advisable to check the REXX for CICS Transaction Server product documentation that is supplied with the latest release of the [CICS Transaction Server for z/OS product information](#) for any updates that are more recent than the online product documentation.

Configure the REXX Db2 interface

This step is required only if the REXX EXEC SQL command environment is enabled for Db2 support. Db2 must be fully installed before you can perform this step.

The *CICRDOD* or *CICRDOR* member in the *CICSTS61.REXX.SCICJCL* data set authorizes the REXX transactions to use the Db2 plan.

If you modify the supplied transactions for the REXX/CICS environment, or implement new transactions that use the Db2 interface code, you must also modify or add the Db2 entry definitions.

Binding the CICS SQL program to your Db2 plan

The *CICBIND* job in the *CICSTS61.REXX.SCICJCL* data set binds CICS SQL to the correct Db2 package. Edit and run the job.

You might receive condition code 4 for the job, depending on the level of Db2 being used.

Chapter 12. REXX/CICS system definition and administration

System definition, customization, and administration of REXX/CICS is described.

Authorized REXX/CICS commands and authorized command options

Several REXX/CICS commands, or command options, are identified as being authorized.

See [REXX/CICS Commands](#). An authorized REXX/CICS command can be executed only if:

- The user ID issuing the exec is an authorized REXX/CICS user. Authorized users are defined by the AUTHUSER command.
- The exec was loaded from a REXX/CICS authorized sublibrary. An authorized library is an MVS partitioned dataset allocated (in the CICS startup procedure/JCL) to ddname CICAUTH or CICEXEC.

These rules apply regardless of whether the exec attempting the command was issued by an authorized exec.

System profile exec

A system profile exec, named **CICSTART**, is issued before the first user exec is run after a CICS system restart.

Usually, the system profile exec contains system customization commands, authorized sublibrary definitions, authorized user definitions, and authorized command definitions that must reside in an authorized MVS PDS REXX library allocated to ddname CICAUTH or CICEXEC.

The system user profile exec, named **CICSPROF**, is issued when you enter REXX/CICS for the first time since the CICS system restart. The exec contains any setup instructions that need to be executed by every user. CICSPROF also invokes the user profile.

The user profile is a user created and maintained exec. It allows you to customize your REXX/CICS environment (for example: set path, change the retrieve key, invoke other execs). This profile should reside in your personal RFS directory.

Related reference

“Update the CICSTART member” on page 116

The CICSTART member, in the *hlq.CICSTS61.REXX.SCICEXEC* data set, contains default definitions for the REXX/CICS environment. **CICSTART** runs when the first transaction that uses the CICS/REXX program is issued, after the CICS system starts.

Authorized MVS PDS REXX libraries

All MVS partitioned data sets allocated to ddnames CICAUTH and CICEXEC are considered REXX/CICS authorized libraries.

If multiple data sets are concatenated together, they are searched in the order of concatenation. The **CICSTART** exec resides in CICEXEC.

- Users can cause dynamic allocation of their own non-authorized libraries by using the REXX/CICS PATH command.
- Any user can run an exec from CICEXEC data sets and any exec loaded from CICEXEC can use REXX/CICS authorized commands.
- Data sets at the CICEXEC JCL DD statement must be variable blocked.

Defining authorized users

Users can be specified as authorized by using the **AUTHUSER** command.

It is advisable to place all **AUTHUSER** commands in the **CICSTART** exec, or in an exec issued from the **CICSTART** exec. See [“Update the CICSTART member” on page 116](#).

Setting system options

System options are specified by using the REXX/CICS **SETSYS** command.

It is advisable to place system-wide **SETSYS** commands in the **CICSTART** exec. See [“Update the CICSTART member” on page 116](#).

Defining a REXX file system (RFS) file pool

Use FILEPOOL commands to define, initialize, and add files to an RFS file pool. Use the RFS AUTH command for RFS file sharing authorization.

- Use the FILEPOOL DEFINE command to define an RFS file pool.
- Use the FILEPOOL FORMAT command to initialize the first file in each file pool.
- Use the FILEPOOL ADD command to add a VSAM file to an RFS file pool.

RFS file sharing authorization

Use the RFS AUTH command to specify file sharing permission.

Normally, you can allow sharing of resources that you own. As an authorized REXX/CICS user, you can specify permission for the sharing of any RFS directories that you have created.

Creating a PLT entry for CICSTART

The **CICSTART** exec can be issued immediately after CICS system initialization by creating a CICS program load table (PLT) entry to invoke the CICREXD or CICREXR program.

Otherwise, the first REXX/CICS user after region startup will cause the **CICSTART** exec to be run.

Security exits

Replaceable security exits CICSECX1 and CICSECX2 are described. IBM provides sample assembler exits that you can customize or replace.

This section contains Product-sensitive Programming Interface information.

Note: These exits must reside in the same region as REXX/CICS (for example: the use of distributed program link is not allowed).

CICSECX1

CICSECX1 is an MVS dataset access security exit. This exit is called by an EXEC CICS LINK and the parameters are passed in the COMMAREA.

Parameters

Attention: This topic contains Product-sensitive Programming Interface and Associated Guidance Information.

The COMMAREA contains the following on input to the exit.

Parameter	Number of Bytes	Datatype	Description
1	4	fullword	Return code
2	8	character	CICS sign on ID
3	4	character	Function requested
4	3		Reserved for IBM use
5	44	character	MVS Data set

Return codes

0

Function request allowed

4

Function request rejected

Function IDs

Update

Chapter 13. Performance considerations

Client/server support is a REXX feature that provides a substantial performance advantage. With this facility, a server REXX exec can often be used instead of a nested REXX exec to provide application function. The performance characteristics of such a server can be better managed. The advantage of a server exec over a nested exec is that a server exec can be started and can process multiple client requests before ending. This has a shorter path length, provides better response time, and often uses less system resource. For more information, see [High-level, natural, transparent REXX client interface](#).

Unlike typical CICS application programming, you do not need to issue EXEC CICS SUSPEND commands because REXX/CICS handles this by suspending your program automatically at intervals.

REXX/CICS execs can reside in either VSAM-based REXX file system files or MVS partitioned data sets. CICS allocates certain MVS partitioned data sets at CICS region startup time. The REXX PATH (only when a dataset name is specified), IMPORT, EXPORT, and ALLOC commands can allocate MVS partitioned data sets dynamically by using SVC 99. Excessive use of SVC 99 might cause performance degradation of the CICS region.

Chapter 14. Security

The REXX transaction can be controlled using CICS transaction security. The REXX transaction might be made widely available, or might be limited to a few individuals, depending upon the nature of the CICS region it is running in.

REXX/CICS can be viewed as a more sophisticated version of the CICS-supplied Command Level Interpreter Transaction (CECI). The REXX transaction (used to issue REXX execs), much like the CECI transaction, can be controlled using CICS transaction security.

Note: The REXX transaction is not required to execute existing REXX execs, but is required if users or programmers want the ability to create or modify REXX execs, and then test them.

REXX/CICS supports multiple transaction identifiers

REXX/CICS supports the ability to associate transaction identifiers (TRANIDs), other than REXX, with the REXX/CICS support program.

In this case, the name of the REXX exec that is issued is determined by a previous DEFTRNID command. This gives you the ability to still use transaction security with REXX on an exec by exec basis.

REXX/CICS file security

Access at the RFS directory level is controlled with the RFS AUTH command and the RFS replaceable security exit.

Access to authorized execs accessed by the CICAUTH ddname is controlled by the AUTH parameter on the DEFCMD and DEFSCMD commands.

Access to dynamically allocated data sets is controlled by the dataset replaceable security exit.

REXX/CICS command level security

Command level security can be used to control access to CICS (and other product or system) facilities.

In some situations, current software practices limit the effectiveness of relying on CICS resource security alone. For additional security control, REXX/CICS was designed with the concept of command level security. Because most facilities under REXX/CICS are accessed as commands, command level security can be used to control access to CICS (and other product or system) facilities. For example, VSAM file access is accomplished through the READ, WRITE, and REWRITE commands.

REXX/command level security is controlled by the DEFSCMD and DEFCMD AUTH parameter and by the provision of authorized REXX/CICS library support.

Command execution security controls the use of certain REXX/CICS commands, or command keywords. In general, this is accomplished by the designation of certain commands (or command options) as authorized. Such command designation is accomplished by the DEFCMD and DEFSCMD commands. For authorized commands to execute properly, one of the following conditions must apply:

1. The command must be executed from an exec loaded from an MVS PDS allocated to ddnames CICAUTH or CICEXEC in the CICS startup JCL procedure.
2. The command must be executed by an authorized user. A user can be authorized by the AUTHUSER command.

REXX/CICS authorized command support

Any REXX/CICS command can be identified as authorized by a REXX/CICS systems administrator. Authorized commands can be successfully executed only in an exec that is issued by an authorized REXX/CICS user or that was loaded from an authorized REXX/CICS library.

Only authorized REXX/CICS users have access to the CICAUTH authorized exec library. All users have the ability to run execs in the CICEXEC authorized library. All users can run execs in the unauthorized CICUSER library. Authorized users can be defined by any existing authorized user or in an authorized exec. The REXX/CICS **CICSTART** exec that is called at REXX/CICS initialization (at the first REXX/CICS transaction after a CICS restart) is automatically authorized. This is the logical place to define authorized users and libraries.

Because access to REXX/CICS libraries can easily be controlled, this is the logical counterpart to controlling access to CICS production program libraries. Any commands that a site feels are sensitive (such as READ, WRITE, and DELETE) could be defined as authorized in the production region. This would mean that only authorized users could create execs that issue authorized commands and decide whether all users could invoke these execs that contain authorized commands or only other authorized users.

Note: You can control the ability of REXX/CICS execs to access external APIs by redefining the CICS START, LINK, and XCTL commands as REXX/CICS authorized commands.

Security definitions

Security definitions for REXX/CICS such as general users, authorized users, authorized commands, authorized exec, and system libraries are described.

REXX/CICS general users

REXX/CICS users that are not defined as authorized by the AUTHUSER command cannot use REXX/CICS authorized commands. However, these users can define, write, alter, and use user commands (defined using the DEFCMD command) and execs. Users can also use (but not define, create, or alter) REXX/CICS authorized execs that reside in the CICEXEC library.

Individual user's information is maintained by the REXX/CICS environment by the user ID designation. Each user must be uniquely identified and each user must be signed on to the REXX/CICS environment only once. Two users with the same user ID operating at the same time can create unusual results.

REXX/CICS authorized users

Authorized users are defined by the AUTHUSER command, and are allowed to use authorized REXX/CICS commands (commands defined using the DEFCMD or DEFSCMD command with the AUTH option specified).

REXX/CICS authorized commands

Authorized commands are REXX/CICS commands that can be used only by authorized users or from authorized execs. Authorized commands are defined using the DEFCMD or DEFSCMD command with the AUTH option specified.

REXX/CICS authorized execs

Authorized execs are programs (execs) that were loaded from ddname CICEXEC or CICAUTH and are considered authorized. That is, these programs are allowed to use authorized REXX/CICS commands. All REXX/CICS users have access to CICEXEC authorized programs, but only authorized users have access to CICAUTH authorized programs.

REXX/CICS system libraries

All authorized commands written in the REXX language must be loaded from an MVS partitioned dataset concatenated to ddname CICAUTH. These can be both IBM and customer (or vendor) supplied.

All authorized execs must be loaded from an MVS partitioned dataset concatenated to ddname CICEXEC or CICAUTH. These can be both IBM and customer (or vendor) supplied.

User execs that are not authorized but are being shared by all REXX/CICS users can be placed in an MVS partitioned dataset allocated or concatenated to ddname CICUSER.

Note:

1. The AUTH option of the DEFCMD or DEFSCMD is itself an authorized command option. That is, AUTH can be used only if the user issuing it is an authorized user or if it was issued from an exec loaded from an authorized library.
2. The EXECLOAD and EXECDROP commands are authorized. Therefore, only an authorized user or exec can EXECLOAD an exec from an authorized sublibrary.

Part 3. REXX for CICS Transaction Server: Reference

REXX/CICS or REXX for CICS Transaction Server provides a native REXX-based language environment for application development, customization, prototyping and procedures, along with associated runtime features.

REXX/CICS runs under all supported releases of CICS Transaction Server.

This reference describes the REXX for CICS Interpreter (referred to from now on as the interpreter or language processor) and the REstructured eXtended eXecutor (called REXX) language. This reference is intended for experienced programmers, particularly those who have used a block-structured, high-level language (for example, PL/I, Algol, or Pascal).

Descriptions include the use and syntax of the language and how the language processor "interprets" the language while a program is running under the REXX/CICS interpreter. The reference also describes:

- Programming services that let you interface with REXX and the language processor.
- Customizing services that let you customize REXX processing and how the language processor accesses and uses system services, such as storage and I/O requests.

Chapter 15. Overview of product features

Product features of REXX/CICS are described.

The following product features are described:

- [“SAA Level 2 REXX language support under REXX/CICS” on page 133](#)
- [“Support for the interpretive execution of REXX execs” on page 133](#)
- [“CICS-based text editor for REXX execs and data” on page 133](#)
- [“VSAM-based file system for REXX execs and data” on page 133](#)
- [“Dynamic support for EXEC CICS commands” on page 134](#)
- [“REXX interface to CEDA and CEMT transaction programs” on page 134](#)
- [“High-level client/server support” on page 134](#)
- [“Support for commands written in REXX” on page 134](#)
- [“Command definition of REXX commands” on page 134](#)
- [“Support for system- and user-profile execs” on page 134](#)
- [“Shared execs in virtual storage” on page 134](#)
- [“Db2/SQL interface” on page 135](#)

SAA Level 2 REXX language support under REXX/CICS

REXX/CICS is currently at REXX language level 3.48 and provides all Systems Application Architecture® (SAA) REXX Level 2 capability except for stream I/O and REXX language processor exits.

Support for the interpretive execution of REXX execs

Interpretive execution of REXX execs provides the ability to create and run REXX execs without first compiling them. The use of the interpreter provides a very productive development, customization, prototyping, and command list (CLIST) processing environment. This is because it provides a fast development cycle, source level interactive debug, and a native CICS-based development environment, in one integrated package.

Note: REXX execs can freely invoke CICS programs and transactions written in any CICS supported language.

CICS-based text editor for REXX execs and data

A native CICS text editor, similar to the TSO ISPF/PDF and VM/CMS XEDIT editors, is provided as part of REXX/CICS, so execs (and other data) can be created and modified directly under CICS, and from CICS-based application platforms. Edit support is provided for files residing in the provided VSAM-based REXX File System (RFS), and for files existing in traditional Multiple Virtual Storage (MVS) partitioned data sets.

Note: SVC 99 is used to dynamically allocate partitioned data sets specified in the PATH, IMPORT, EXPORT, ALLOC, and editor GETPDS commands. Other partitioned data sets (those concatenated to ddnames CICAUTH, CICEXEC, and CICUSER) are allocated at region startup. It is advisable to use this technique mainly for file migration purposes, to minimize the impact on system performance.

VSAM-based file system for REXX execs and data

REXX/CICS includes the REXX File System (RFS), a high-level file system that is hierarchically structured and is similar to the Advanced Interactive Executive (AIX®), and the VM Shared File systems. The RFS automatically provides each REXX user with a file system to store execs and data. The file list utility supports working with this file system, the text editor supports editing members of this file system, and

execs to be run are loaded from this file system. This file system is VSAM based for performance, security, and portability reasons.

Dynamic support for EXEC CICS commands

Support for most EXEC CICS application programming commands is included in REXX/CICS. This is a dynamic interface (no EXEC CICS command translation preprocessing step is needed). This support is provided through the addition of an ADDRESS CICS command environment.

REXX interface to CEDA and CEMT transaction programs

With this interface, CEDA and CEMT commands can be easily issued from REXX execs, with any subsequent output placed into a REXX variable, instead of being displayed at the terminal. This facilitates the automation of many CICS administration and operation activities, and helps programmers.

High-level client/server support

REXX/CICS provides integrated client/server support to REXX execs by providing facilities to allow REXX execs to act as clients (which make requests to REXX/CICS servers) and by providing facilities to allow REXX execs to act as servers (with the ability to wait for and process requests from REXX/CICS clients).

REXX/CICS facilities are provided which allow REXX/CICS servers to wait on requests from clients (WAITREQ), and to retrieve (C2S) and set (S2C) the contents of client REXX variables.

Note: Servers do not execute as nested execs of clients, but rather execute as parallel entities.

Servers use Automatic Server Initiation (ASI) to start automatically when they receive their first request.

Support for commands written in REXX

REXX/CICS supports the ability for users to write new REXX/CICS commands in REXX. These commands do not function as nested REXX execs, and unlike nested REXX execs have the ability to get and set the values of REXX variables in the user exec that issued the command. Therefore, commands written in REXX can have similar capabilities as commands written in Assembler or other languages. Also, commands can be quickly written in REXX to speed systems development (in a building block structure), and then can selectively be rewritten in Assembler (or any other CICS supported language) at a later date, if performance requirements dictate.

Command definition of REXX commands

REXX/CICS includes the ability for system administrators and users to dynamically define new REXX commands, on either a system-wide or user-by-user basis. REXX can interface cleanly with other products, applications, and system services. The goal for providing a command definition facility for new or existing commands is to facilitate the rapid and consistent high-level integration of various products and services together through the use of REXX. REXX command definition is accomplished with the REXX/CICS DEFCMD and DEFSCMD commands.

Support for system- and user-profile execs

To facilitate REXX/CICS system and user environment tailoring, REXX/CICS attempts to execute **CICSTART**, **CICSPROF**, and user PROFILE execs, if they exist. **CICSTART** is the system profile exec (STARTUP profile) and it is issued before the first user exec is run after CICS system restart. **CICSPROF** is the system user profile exec and it is issued when a user enters REXX/CICS for the first time since the CICS system restart. **CICSPROF** also invokes the user PROFILE.

Shared execs in virtual storage

REXX/CICS supports shared copies of REXX execs residing in virtual storage. Shared execs improve the interactive response time of REXX applications, and sharing reduces the total virtual storage requirement.

Execs can be preloaded by using the **EXECLOAD** command. Common system-wide execs are good candidates for preloading through the placement of **EXECLOAD** commands in the **CICSTART** exec.

Db2/SQL interface

REXX programs can contain SQL statements and Db2 commands. These statements are interpreted and executed dynamically. The results of the SQL statements and Db2 commands are placed into REXX variables for use within the REXX program.

Chapter 16. How to read the syntax diagrams

REXX command syntax is described using the following structure.

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line.

The >>- symbol indicates the beginning of a statement.

The --> symbol indicates that the statement syntax is continued on the next line.

The >-- symbol indicates that a statement is continued from the previous line.

The -->< symbol indicates the end of a statement.

Diagrams of syntactical units other than complete statements start with the >-- symbol and end with the --> symbol.

- Required items are on the horizontal line (the main path).

►► STATEMENT — *required_item* —><

- Optional items are below the main path.

►► STATEMENT — *optional_item* —><

- If you can choose from two or more items, they are shown as a vertical set of alternatives.

If you *must* choose one of the items, one item in the set is on the main path.

►► STATEMENT — *required_choice1* —><
 required_choice2

If choosing is optional, the entire set is below the main path.

►► STATEMENT — *optional_choice1* —><
 optional_choice2

- If one item in a set of alternatives is the default, it is shown above the main path with the remaining choices below.

►► STATEMENT — *default_choice* —><
 optional_choice
 optional_choice

- An arrow returning to the left above the main line indicates an item that can be repeated.

►► STATEMENT — *repeatable_item* —><

A repeat arrow above a stack indicates that you can repeat the items in the set.

- A set of vertical bars around an item indicates that the item is a *fragment*, a part of the syntax diagram that appears in greater detail following the main diagram.

►► STATEMENT — **fragment** —><

fragment

►► expansion_provides_greater_detail ◄◄

- Keywords appear in uppercase (for example, PARM1). They must be spelled exactly as shown but can be specified in any case. Variables appear in all lowercase letters (for example, *parm*). They represent user-supplied names or values.
- If punctuation marks, parentheses, arithmetic operators, or such symbols are shown, you must enter them as part of the syntax.

Chapter 17. REXX General Concepts

The REstructured eXtended eXecutor (REXX) language is particularly suitable for command procedures, application front ends, user-defined macros (such as editor subcommands), user-defined XEDIT subcommands, prototyping, and personal computing.

REXX is a general purpose programming language like PL/I. REXX has the usual structured-programming instructions such as IF, SELECT, DO WHILE, and LEAVE, and a number of useful built-in functions.

The language imposes no restrictions on program format. There can be more than one clause on a line, or a single clause can occupy more than one line. Indentation is allowed. You can, therefore, code programs in a format that emphasizes their structure, making them easier to read.

There is no limit to the length of the values of variables, as long as all variables fit into the storage available.

Implementation maximum: No single request for storage can exceed the fixed limit of 16MB. This limit applies to the size of a variable plus any control information. It also applies to buffers obtained to hold numeric results.

The limit on the length of symbols (variable names) is 250 characters.

You can use compound symbols to construct arrays and for other purposes, for example:

```
NAME.Y.Z
```

Y and Z can be the names of variables or can be constant symbols.

REXX programs can reside in REXX File System directories or in MVS partitioned data sets. REXX programs usually have a file type of EXEC.

A language processor (interpreter) runs REXX programs. That is, the program is processed line-by-line and word-by-word, without first being translated to another form (compiled). The advantage of this to the user is that if the program fails with a syntax error, the point of error is clearly indicated, which helps to understand the difficulty and correct it.

Structure and General Syntax

It is advisable to start REXX programs with a comment. A REXX program is built from a series of clauses.

REXX programs are recommended to start with a comment. REXX/CICS does not require that REXX programs start with a comment. However, for portability reasons, it is advisable to start each REXX program with a comment that begins on the first line and includes the word REXX, as shown in the following example.

```
/* REXX program */  
...  
...  
...  
EXIT
```

Figure 45. Example of using the REXX program identifier

A REXX program is built from a series of *clauses* that are composed of:

- Zero or more blanks (which are ignored)
- A sequence of tokens (see [“Tokens” on page 141](#))
- Zero or more blanks (which are ignored)
- A semicolon (;) delimiter that can be implied by line-end, certain keywords, or the colon (:).

Conceptually, each clause is scanned from left to right before processing, and the tokens that compose the clause are identified. At this stage, instruction keywords are recognized, comments are removed,

and multiple blanks (except in literal strings) are converted to single blanks. Blanks adjacent to operator characters and special characters are also removed (see [“Tokens” on page 141](#)).

Implementation maximum: The length of a clause cannot exceed 16K.

Characters

A character is a member of a defined set of elements that is used for the control or representation of data.

You can usually enter a character with a single keystroke. The coded representation of a character is its representation in digital form. A character, the letter A, for example, differs from its *coded representation* or encoding. Various coded character sets (such as ASCII and EBCDIC) use different encodings for the letter A (decimal values 65 and 193, respectively). This information uses characters to convey meanings and not to imply a specific character code, except where otherwise stated. The exceptions are certain built-in functions that convert between characters and their representations. The functions C2D, C2X, D2C, X2C, and XRANGE have a dependence on the character set in use.

A code page specifies the encodings for each character in a set. Be aware that:

- Some code pages do not contain all characters that REXX defines as valid (for example, ¬, the logical NOT character).
- Some characters that REXX defines as valid have different encodings in different code pages (for example, !, the exclamation point).

For information about Double-Byte Character Set characters, see [Chapter 33, “Double-Byte Character Set \(DBCS\) Support,” on page 457](#).

Comments

A comment is a sequence of characters (on one or more lines) delimited by /* and */. Any characters are allowed within these delimiters.

Comments can contain other comments, as long as each begins and ends with the necessary delimiters. They are called *nested comments*. Comments can be anywhere and can be of any length. They have no effect on the program, but they do act as separators. Two tokens with only a comment in between are not treated as a single token.

```
/* This is an example of a valid REXX comment */
```

Take special care when commenting out lines of code that contain /* or */ as part of a literal string. Consider the following program segment:

```
01  parse pull input
02  if substr(input,1,5) = '/*123'
03    then call process
04  dept = substr(input,32,5)
```

To comment out lines 2 and 3, the following change would be incorrect because the language processor would interpret the /* that is part of the literal string /*123 as the start of a nested comment. It would not process the rest of the program because it would be looking for a matching comment end (*/.):

```
01  parse pull input
02  /* if substr(input,1,5) = '/*123'
03    then call process
04  */ dept = substr(input,32,5)
```

You can avoid this type of problem by using concatenation for literal strings that contain /* or */; line 2 would be:

```
if substr(input,1,5) = '/' || '*123'
```

You could comment out lines 2 and 3 correctly as follows:

```
01  parse pull input
02  /* if substr(input,1,5) = '/' || '*123'
```

```
03      then call process
04 */ dept = substr(input,32,5)
```

For information about Double-Byte Character Set characters, see [Chapter 33, “Double-Byte Character Set \(DBCS\) Support,”](#) on page 457 and the [“OPTIONS”](#) on page 175 instruction.

Tokens

A token is the unit of low-level syntax from which clauses are built.

Programs written in REXX are composed of tokens. They are separated by blanks or comments or by the nature of the tokens themselves. The classes of tokens are:

Literal Strings:

A literal string is a sequence that includes any characters and that is delimited by the single quotation mark ' or the double quotation mark ". Use two consecutive double quotation marks "" to represent a " character in a string that is delimited by double quotation marks. Similarly, use two consecutive single quotation marks '' to represent a ' character in a string that is delimited by single quotation marks. A literal string is a constant and its contents are never modified when it is processed.

A literal string with no characters (that is, a string of length 0) is called a *null string*.

The following are examples of valid strings:

```
'Fred'
"Don't Panic!"
'You shouldn't't'      /* Same as "You shouldn't" */
''                     /* The null string      */
```

- A string that is followed immediately by a (is considered to be the name of a function.
- A string that is followed immediately by the symbol X or x is considered to be a hexadecimal string.
- A string that is followed immediately by the symbol B or b is considered to be a binary string.

Descriptions of these forms follow.

Implementation maximum: A literal string can contain up to 250 characters. The length of computed results is limited only by the amount of storage available. See the note in [Chapter 17, “REXX General Concepts,”](#) on page 139 for more information.

Hexadecimal Strings:

A hexadecimal string is a literal string, expressed using a hexadecimal notation of its encoding. It is any sequence of zero or more hexadecimal digits (0-9, a-f, A-F), grouped in pairs. A single leading 0 is assumed, if necessary, at the front of the string to make an even number of hexadecimal digits. The groups of digits are optionally separated by one or more blanks, and the whole sequence is delimited by single or double quotation marks, and immediately followed by the symbol X or x. (x or X cannot be part of a longer symbol.) The blanks, which can be present only at byte boundaries (and not at the beginning or end of the string), are to aid readability. The language processor ignores them. A hexadecimal string is a literal string formed by packing the hexadecimal digits given. Packing the hexadecimal digits removes blanks and converts each pair of hexadecimal digits into its equivalent character, for example: 'C1'X to A.

You can use hexadecimal strings to include characters in a program even if you cannot directly enter the characters themselves. The following are examples of valid hexadecimal strings:

```
'ABCD'x
"1d ec f8"X
"1 d8"x
```

Note: A hexadecimal string is not a representation of a number. Rather, it is an escape mechanism so that a user can describe a character in terms of its encoding (and, therefore, is machine-dependent). In EBCDIC, '40'X is the encoding for a blank. In every case, a string of the form '....'x is simply an alternative to a straightforward string. In EBCDIC 'C1'x and 'A' are identical, as are '40'x and a blank, and must be treated identically.

Also, be aware that in Assembler language, hexadecimal numbers are represented with the X in front of the number. REXX only accepts hexadecimal numbers in the format described previously. This information might show hexadecimal numbers represented in both ways, but when you code a hexadecimal string in REXX, place the X after the number.

Implementation maximum: The packed length of a hexadecimal string (the string with blanks removed) cannot exceed 250 bytes.

Binary Strings:

A binary string is a literal string, expressed using a binary representation of its encoding. It is any sequence of zero or more binary digits (0 or 1) in groups of 8 (bytes) or 4 (nibbles). The first group can have fewer than four digits; in this case, up to three 0 digits are assumed to the left of the first digit, making a total of four digits. The groups of digits are optionally separated by one or more blanks, and the whole sequence is delimited by matching single or double quotation marks and immediately followed by the symbol b or B. (b or B cannot be part of a longer symbol.) The blanks, which can be present only at byte or nibble boundaries (and not at the beginning or end of the string), are to aid readability. The language processor ignores them.

A binary string is a literal string formed by packing the binary digits given. If the number of binary digits is not a multiple of eight, leading zeros are added on the left to make a multiple of eight before packing. Binary strings allow you to specify characters explicitly, bit by bit.

The following are examples of valid binary strings:

```
'11110000'b      /* == 'f0'x      */
"101 1101"b      /* == '5d'x      */
'1'b             /* == '00000001'b and '01'x */
'10000 10101010'b /* == '0001 0000 1010 1010'b */
'b              /* == ''          */
```

Implementation maximum: The packed length of a hexadecimal string (the string with blanks removed) cannot exceed 250 bytes.

Symbols:

Symbols are groups of characters, selected from the following character sets:

- English alphabetic characters (A-Z and a-z)
Some code pages do not include lowercase English characters a-z
- Numeric characters (0-9)
- Characters . ! ? and _ (underscore).

The encoding of the exclamation point character ! depends on the code page in use.

- Double-Byte Character Set (DBCS) characters (X'41'-X'FE'). ETMODE must be in effect for these characters to be valid in symbols.

Any lowercase alphabetic character in a symbol is translated to uppercase (that is, lowercase a-z to uppercase A-Z) before use.

The following are examples of valid symbols:

```
Fred
Albert.Hall
WHERE?
<.H.E.L.L.O>          /* This is DBCS */
```

For information about Double-Byte Character Set (DBCS) characters, see [Chapter 33, “Double-Byte Character Set \(DBCS\) Support,”](#) on page 457.

If a symbol does not begin with a digit or a period, you can use it as a variable and can assign it a value. If you have not assigned it a value, its value is the characters of the symbol itself, translated to uppercase (that is, lowercase a-z to uppercase A-Z). Symbols that begin with a number or a period are constant symbols and cannot be assigned a value.

One other form of symbol is allowed to support the representation of numbers in exponential format. The symbol starts with a digit (0-9) or a period, and ends with the sequence E or e, followed immediately by an optional sign (- or +), followed immediately by one or more digits (which cannot be followed by any other symbol characters). The sign in this context is part of the symbol and is not an operator.

The following are examples of valid numbers in exponential notation:

```
17.3E-12
.03e+9
```

Implementation maximum: A symbol can consist of up to 250 characters. Its value, if it is a variable, is limited only by the amount of storage available. See the note in [Chapter 17, “REXX General Concepts,”](#) on page 139 for more information.

Numbers:

These are character strings that consist of one or more decimal digits, with an optional prefix of a plus or minus sign, and optionally including a single period (.) that represents a decimal point. A number can also have a power of 10 suffixed in conventional exponential notation: an E (uppercase or lowercase), followed optionally by a plus or minus sign, then followed by one or more decimal digits defining the power of 10. Whenever a character string is used as a number, rounding may occur to a precision specified by the NUMERIC DIGITS instruction (default nine digits). See [Chapter 21, “Numbers and arithmetic operations,”](#) on page 239 for a full definition of numbers.

Numbers can have leading blanks (before and after the sign, if any) and can have trailing blanks. Blanks may not be embedded among the digits of a number or in the exponential part. Note that a symbol or a literal string might be a number. A number cannot be the name of a variable.

The following are examples of valid numbers:

```
12
'-17.9'
127.0650
73e+128
' + 7.9E5 '
'0E000'
```

You can specify numbers with or without quotation marks around them. Note that the sequence -17.9 (without quotation marks) in an expression is not simply a number. It is a minus operator (which may be prefix minus if no term is to the left of it) followed by a positive number. The result of the operation is a number.

A *whole number* is a number that has a zero (or no) decimal part and that the language processor would not usually express in exponential notation. That is, it has no more digits before the decimal point than the current setting of NUMERIC DIGITS (the default is 9).

Implementation maximum: The exponent of a number expressed in exponential notation can have up to nine digits.

Operator Characters:

The characters: + - \ / % * | & = ~ > < and the sequences >= <= \> \< \= >< <> == \== // && || ** ~> ~< ~= ~== >> << >>= \<< ~<< \>> ~>> <<= /= /== indicate operations (see [“Operators”](#) on page 145). A few of these are also used in parsing templates, and the equal sign is also used to indicate assignment. Blanks adjacent to operator characters are removed. Therefore, the following are identical in meaning:

```
345>=123
345 >=123
345 >= 123
345 > = 123
```

Some of these characters might not be available in all character sets. In this situation, you can use appropriate translations. In particular, the vertical bar (|) or character is often shown as a split vertical bar.

Throughout the language, the *not* character, \neg , is synonymous with the backslash (\). You can use the two characters interchangeably according to availability and personal preference.

Special Characters

The following characters, together with the individual characters from the operators, have special significance when found outside of literal strings:

```
, ; : ) (
```

These characters constitute the set of special characters. They all act as token delimiters, and blanks adjacent to any of these are removed. The exception is a blank adjacent to the outside of a parenthesis, which is deleted only if it is also adjacent to another special character (unless the character is a parenthesis and the blank is outside it, too). For example, the language processor does not remove the blank in A (Z). This is a concatenation that is not equivalent to A(Z), a function call. The language processor does remove the blanks in (A) + (Z) because this is equivalent to (A)+(Z).

The following example shows how a clause is composed of tokens.

```
'REPEAT' A + 3;
```

This is composed of six tokens:

- a literal string ('REPEAT')
- a blank operator
- a symbol (A, which can have a value)
- an operator (+)
- a second symbol (3, which is a number and a symbol)
- the clause delimiter (;)

The blanks between the A and the + and between the + and the 3 are removed. However, one of the blanks between the 'REPEAT' and the A remains as an operator. Thus, this clause is treated as though written:

```
'REPEAT' A+3;
```

Implied Semicolons

The last element in a clause is the semicolon delimiter. The language processor implies the semicolon: at a line-end, after certain keywords, and after a colon if it follows a single symbol.

This means that you need to include semicolons only when there is more than one clause on a line, or to end an instruction whose last character is a comma.

A line-end usually marks the end of a clause and, thus, REXX implies a semicolon at most end of lines. However, there are the following exceptions:

- The line ends in the middle of a string.
- The line ends in the middle of a comment. The clause continues on to the next line.
- The last token was the continuation character (a comma) and the line does not end in the middle of a comment. (Note that a comment is not a token.)

REXX automatically implies semicolons after colons (when following a single symbol, a label) and after certain keywords when they are in the correct context. The keywords that have this effect are: ELSE, OTHERWISE, and THEN. These special cases reduce typographical errors significantly.

Note: The two characters forming the comment delimiters, /* and */ , must not be split by a line-end (that is, / and * should not appear on different lines) because they could not then be recognized correctly; an implied semicolon would be added. The two consecutive characters forming a literal quotation mark within a string are also subject to this line-end ruling.

Continuations

One way to continue a clause onto the next line is to use the comma, which is referred to as the *continuation character*.

The comma is functionally replaced by a blank, and, thus, no semicolon is implied. One or more comments can follow the continuation character before the end of the line. The continuation character cannot be used in the middle of a string or it will be processed as part of the string itself. The same situation holds true for comments. Note that the comma remains in execution traces.

The following example shows how to use the continuation character to continue a clause.

```
say 'You can use a comma',  
    'to continue this clause.'
```

This displays:

```
You can use a comma to continue this clause.
```

Expressions and Operators

Expressions in REXX are a general mechanism for combining one or more pieces of data in various ways to produce a result, usually different from the original data.

Expressions

Expressions consist of one or more *terms* (literal strings, symbols, function calls, or subexpressions) interspersed with zero or more operators that denote operations to be carried out on terms.

A *subexpression* is a term in an expression bracketed in a left and a right parenthesis.

Terms include:

- Literal Strings (delimited by quotation marks), which are constants.
- Symbols (no quotation marks), which are translated to uppercase. A symbol that does not begin with a digit or a period might be the name of a variable; in this case the value of that variable is used. Otherwise a symbol is treated as a constant string. A symbol can also be *compound*.
- Function calls (see [Chapter 19, “Functions,”](#) on page 191), which are of the form:

Evaluation of an expression is left to right, modified by parentheses and by operator precedence in the usual algebraic manner (see [“Parentheses and Operator Precedence”](#) on page 149). Expressions are wholly evaluated, unless an error occurs during evaluation.

All data is in the form of "typeless" character strings (because the data is not of a particular declared type, such as Binary, Hexadecimal, or Array). Therefore, when an expression is evaluated, the result is a character string. Terms and results (except arithmetic and logical expressions) can be the *null string* (a string of length 0). REXX imposes no restriction on the maximum length of results. However, there is a 16MB limitation on the amount of a single storage request available to the language processor. See the note in [Chapter 17, “REXX General Concepts,”](#) on page 139 for more information.

Operators

An *operator* is a representation of an operation, such as addition, to be carried out on one or two terms.

The following information describes how each operator (except for the prefix operators) acts on two terms, which can be symbols, strings, function calls, intermediate results, or subexpressions. Each prefix

operator acts on the term or subexpression that follows it. Blanks (and comments) adjacent to operator characters do not affect the operator; thus, operators constructed from more than one character can have embedded blanks and comments. In addition, one or more blanks, where they occur in expressions but are not adjacent to another operator, also act as an operator. There are four types of operators:

- Concatenation
- Arithmetic
- Comparison
- Logical

String concatenation operators

The concatenation operators combine two strings to form one string by appending the second string to the right-hand end of the first string.

The concatenation can occur with or without an intervening blank. The concatenation operators are:

(blank)

Concatenate terms with one blank in between

`||`

Concatenate without an intervening blank

(abuttal)

Concatenate without an intervening blank

You can force concatenation without a blank by using the `||` operator.

The abuttal operator is assumed between two terms that are not separated by another operator. This can occur when two terms are syntactically distinct, such as a literal string and a symbol, or when they are separated only by a comment.

Examples

An example of syntactically distinct terms is: if `Fred` has the value `37.4`, `Fred '%'` evaluates to `37.4%`.

If the variable `PETER` has the value `1`, `(Fred) (Peter)` evaluates to `37.41`.

In EBCDIC, the two adjoining strings, one hexadecimal and one literal,

```
'c1 c2'x'CDE'
```

evaluate to `ABCDE`.

:

In the following example, there is no abuttal operator implied, and the expression is not valid.:

```
Fred/* The NOT operator precedes Peter. */~Peter
```

However, the following example results in an abuttal, and evaluates to `37.40`:

```
(Fred)/* The NOT operator precedes Peter. *//(~Peter)
```

Arithmetic operators

You can combine character strings that are valid numbers (see [“Tokens” on page 141](#)) by using the following arithmetic operators:

`+`

Add

`-`

Subtract

Multiply

/
Divide

%
Integer divide (divide and return the integer part of the result)

//
Remainder (divide and return the remainder - not modulo, because the result may be negative)

Power (raise a number to a whole-number power)

Prefix -

Same as the subtraction: 0 - number

Prefix +

Same as the addition: 0 + number.

See [Chapter 21, “Numbers and arithmetic operations,” on page 239](#) for details about precision, the format of valid numbers, and the operation rules for arithmetic. If an arithmetic result is shown in exponential notation, it is likely that rounding has occurred.

Comparison operators

The comparison operators compare two terms and return the value 1 if the result of the comparison is true, or 0 otherwise.

The strict comparison operators all have one of the characters defining the operator doubled. The ==, \==, /=, and \/= operators test for an exact match between two strings. The two strings must be identical (character by character) and of the same length to be considered strictly equal. Similarly, the strict comparison operators such as >> or << carry out a simple character-by-character comparison, with no padding of either of the strings being compared. The comparison of the two strings is from left to right. If one string is shorter than and is a leading substring of another, then it is smaller than (less than) the other. The strict comparison operators also do not attempt to perform a numeric comparison on the two operands.

For all the other comparison operators, if both terms involved are numeric, a numeric comparison (in which leading zeros are ignored, see “Numeric Comparisons” on page 244) occurs. Otherwise, both terms are treated as character strings (leading and trailing blanks are ignored, and then the shorter string is padded with blanks on the right).

Character comparison and strict comparison operations are both case-sensitive, and for both the exact collating order depends on the character set used for the implementation. For example, in an EBCDIC environment, lowercase alphabetic characters precede uppercase, and the digits 0-9 are higher than all alphabetic characters.

The comparison operators and operations are:

=
True if the terms are equal (numerically or when padded, and so forth)

\=, \=, /=
True if the terms are not equal (inverse of =)

>
Greater than

<
Less than

><
Greater than or less than (same as not equal)

<>
Greater than or less than (same as not equal)

>=
Greater than or equal to

\<, ¬<
Not less than

<=
Less than or equal to

\>, ¬>
Not greater than

==
True if terms are strictly equal (identical)

\==, ¬==, /==
True if the terms are NOT strictly equal (inverse of ==)

>>
Strictly greater than

<<
Strictly less than

>>=
Strictly greater than or equal to

\<<, ¬<<
Strictly NOT less than

<<=
Strictly less than or equal to

\>>, ¬>>
Strictly NOT greater than

Note: Throughout the language, the *not* character, ¬, is synonymous with the backslash (\). You can use the two characters interchangeably, according to availability and personal preference. The backslash can appear in the following operators: \ (prefix not), \=, \==, \<, \>, \<<, and \>>.

Logical (Boolean) operators

A character string is taken to have the value false if it is 0, and true if it is 1. The logical operators take one or two such values (values other than 0 or 1 are not allowed) and return 0 or 1 as appropriate.

&
AND
Returns 1 if both terms are true.

|
Inclusive OR
Returns 1 if either term is true.

&&
Exclusive OR
Returns 1 if either (but not both) is true.

Prefix \, ¬
Logical NOT
Negates; 1 becomes 0, and 0 becomes 1.

Parentheses and Operator Precedence

Expression evaluation is from left to right; parentheses and operator precedence modify this.

When parentheses are encountered (other than those that identify function calls) the entire subexpression between the parentheses is evaluated immediately when the term is required.

When the following sequence is encountered, and `operator2` has a higher precedence than `operator1`, the subexpression (`term2 operator2 term3`) is evaluated first. The same rule is applied repeatedly as necessary.

```
term1 operator1 term2 operator2 term3
```

However, individual terms are evaluated from left to right in the expression (that is, as soon as they are encountered). The precedence rules affect only the order of *operations*.

For example, `*` (multiply) has a higher priority than `+` (add), so `3+2*5` evaluates to 13 (rather than the 25 that would result if strict left to right evaluation occurred). To force the addition to occur before the multiplication, you could rewrite the expression as `(3+2)*5`. Adding the parentheses makes the first three tokens a subexpression. Similarly, the expression `-3**2` evaluates to 9 (instead of -9) because the prefix minus operator has a higher priority than the power operator.

The order of precedence of the operators is as follows:

1. `+` `-` `~` `\` (prefix operators)
2. `**` (power)
3. `*` `/` `%` `//` (multiply and divide)
4. `+` `-` (add and subtract)
5. `(blank)` `||` `(abuttal)` (concatenation with or without blank)
6. Comparison operators:
 - `=` `>` `<`
 - `==` `>>` `<<`
 - `\=` `\=`
 - `><` `<>`
 - `\>` `\>`
 - `\<` `\<`
 - `\==` `\==`
 - `\>>` `\>>`
 - `\<<` `\<<`
 - `>=` `>=`
 - `<=` `<=`
 - `/=` `/=`
7. `&` (and)
8. `|` `&&` (or, exclusive or)

Examples

The symbol `A` is a variable with a value of 3, `DAY` is a variable with a value of Monday, and other variables are uninitialized. The example expressions have the following evaluations:

```
A+5          -> '8'
A-4*2        -> '-5'
A/2          -> '1.5'
0.5**2       -> '0.25'
(A+1)>7       -> '0'          /* that is, False */
' '= '       -> '1'          /* that is, True  */
```

```

' '=' -> '0' /* that is, False */
' != ' -> '1' /* that is, True */
(A+1)*3=12 -> '1' /* that is, True */
'077'>'11' -> '1' /* that is, True */
'077' >> '11' -> '0' /* that is, False */
'abc' >> 'ab' -> '1' /* that is, True */
'abc' << 'abd' -> '1' /* that is, True */
'ab' << 'abd' -> '1' /* that is, True */
Today is Day -> 'TODAY IS Monday'
'If it is' day -> 'If it is Monday'
Substr(Day,2,3) -> 'ond' /* Substr is a function */
'!'xxx!' -> '!XXX!'
'000000' >> '0E0000' -> '1' /* that is, True */

```

Note: In the last example, the answer is different if the operator is > rather than >>. Because '0E0000' is a valid number in exponential notation, a numeric comparison is done; thus '0E0000' and '000000' evaluate as equal. The REXX order of precedence usually causes no difficulty because it is the same as in conventional algebra and other computer languages. There are two differences from common notations:

- The prefix minus operator always has a higher priority than the power operator.
- Power operators (like other operators) are evaluated left-to-right.

For example:

```

-3**2 == 9 /* not -9 */
-(2+1)**2 == 9 /* not -9 */
2**2**3 == 64 /* not 256 */

```

Clauses and instructions

Clauses can be subdivided into null clauses, labels, instructions, assignments, keyword instructions, and commands.

Null clauses

A clause consisting only of blanks or comments or both is a *null clause*. It is completely ignored (except that if it includes a comment it is traced, if appropriate).

Note: A null clause is not an instruction; for example, putting an extra semicolon after the THEN or ELSE in an IF instruction is not equivalent to using a dummy instruction (as it would be in PL/I). The NOP instruction is provided for this purpose.

Labels

A clause that consists of a single symbol followed by a colon is a *label*. The colon in this context implies a semicolon (clause separator), so no semicolon is required. Labels identify the targets of CALL instructions, SIGNAL instructions, and internal function calls. More than one label may precede any instruction. Labels are treated as null clauses and can be traced selectively to aid debugging.

Any number of successive clauses can be labels. This permits multiple labels before other clauses. Duplicate labels are permitted, but control passes only to the first of any duplicates in a program. The duplicate labels occurring later can be traced but cannot be used as a target of a CALL, SIGNAL, or function invocation.

You can use DBCS characters. See [Chapter 33, “Double-Byte Character Set \(DBCS\) Support,”](#) on page 457.

Instructions

An *instruction* consists of one or more clauses describing some course of action for the language processor to take. Instructions can be: assignments, keyword instructions, or commands.

Assignments

A single clause of the form *symbol=expression* is an instruction known as an *assignment*. An assignment gives a variable a (new) value. See [“Assignments and Symbols” on page 151](#).

Keyword instructions

A *keyword instruction* is one or more clauses where the first clause starts with a keyword that identifies the instruction. Keyword instructions control the external interfaces and the flow of control. Some keyword instructions can include nested instructions. In the following example, the DO construct (DO, the group of instructions that follow it, and its associated END keyword) is considered to be a single keyword instruction.

```
DO
  instruction
  instruction
  instruction
END
```

A *subkeyword* is a keyword that is reserved within the context of some particular instruction, for example, the symbols TO and WHILE in the DO instruction.

Commands

A *command* is a clause that consists of only an expression. The expression is evaluated and the result is passed as a command string to some external environment.

Assignments and Symbols

A *variable* is an object whose value can change during the running of a REXX program. The process of changing the value of a variable is called *assigning* a new value to it.

The value of a variable is a single character string, of any length, that can contain any characters.

You can assign a new value to a variable with the ARG, PARSE, or PULL instructions, the VALUE built-in function, or the variable pool interface. The most common way of changing the value of a variable is the assignment instruction itself. Any clause of the following form is taken to be an assignment:

```
symbol=expression;
```

The result of *expression* becomes the new value of the variable named by the symbol to the left of the equal sign. Currently, on VM if you omit *expression*, the variable is set to the null string. However, it is advisable to set a variable explicitly to the null string: *symbol= ' '*. For example:

```
/* Next line gives FRED the value "Frederic" */
Fred='Frederic'
```

The symbol that names the variable cannot begin with a digit (0-9) or a period. (Without this restriction on the first character of a variable name, you could redefine a number; for example *3=4*; would give a variable called 3 the value 4.)

You can use a symbol in an expression even if you have not assigned it a value, because a symbol has a defined value at all times. A variable you have not assigned a value is *uninitialized*. Its value is the characters of the symbol itself, translated to uppercase (that is, lowercase a-z to uppercase A-Z). However, if it is a compound symbol, its value is the derived name of the symbol (see [“Compound symbols” on page 152](#)). For example:

```
/* If Freda has not yet been assigned a value, */
/* then next line gives FRED the value "FREDA" */
Fred=Freda
```

The meaning of a symbol in REXX varies according to its context. As a term in an expression (rather than a keyword), a symbol belongs to one of four groups: constant symbols, simple symbols, compound

symbols, and stems. Constant symbols cannot be assigned new values. You can use simple symbols for variables where the name corresponds to a single value. You can use compound symbols and stems for more complex collections of variables, such as arrays and lists.

Constant Symbols

A *constant symbol* starts with a digit (0-9) or a period.

You cannot change the value of a constant symbol. It is simply the string that consists of the characters of the symbol (that is, with any lowercase alphabetic characters translated to uppercase).

These are constant symbols:

```
77
827.53
.12345
12e5      /* Same as 12E5 */
3D
17E-3
```

Simple Symbols

A *simple symbol* does not contain any periods and does not start with a digit (0-9).

By default, its value is the characters of the symbol (that is, translated to uppercase). If the symbol has been assigned a value, it names a variable and its value is the value of that variable.

These are simple symbols:

```
FRED
Whatagoodidea? /* Same as WHATAGOODIDEA? */
?12
<.D.A.T.E>
```

Compound symbols

A *compound symbol* permits the substitution of variables within its name when you refer to it.

A compound symbol contains at least one period and at least two other characters. It cannot start with a digit or a period, and if there is only one period in the compound symbol, it cannot be the last character.

The name begins with a *stem* (that part of the symbol up to and including the first period). This is followed by a *tail*, parts of the name (delimited by periods) that are constant symbols, simple symbols, or null. The *derived name* of a compound symbol is the stem of the symbol, in uppercase, followed by the tail, in which all simple symbols have been replaced with their values. A tail itself can be comprised of the characters A-Z, a-z, 0-9, and @ # \$ % . ! ? and underscore. The value of a tail can be any character string, including the null string and strings containing blanks. For example:

```
taila='* ('
tailb=''
stem.taila=99
stem.tailb=stem.taila
say stem.tailb      /* Displays: 99 */
/* But the following instruction would cause an error */
/*          say stem.* ( */
```

You cannot use constant symbols with embedded signs (for example, 12.3E+5) after a stem; in this case, the whole symbol would not be a valid symbol.

These are compound symbols:

```
FRED.3
Array.I.J
AMESSY..One.2.
<.F.R.E.D>.<.A.B>
```

Before the symbol is used (that is, at the time of reference), the language processor substitutes the values of any simple symbols in the tail (I, J, and One in the examples), thus generating a new derived name. This derived name is then used just like a simple symbol. That is, its value is by default the derived name, or (if it was used as the target of an assignment) its value is the value of the variable named by the derived name.

The substitution into the symbol that takes place permits arbitrary indexing (subscripting) of collections of variables that have a common stem. The values substituted can contain any characters (including periods and blanks). Substitution is done only one time.

To summarize: the derived name of a compound variable that is referred to by the symbol

```
s0.s1.s2. --- .sn
```

is given by

```
d0.v1.v2. --- .vn
```

where d0 is the uppercase form of the symbol s0, and v1 to vn are the values of the constant or simple symbols s1 through sn. Any of the symbols s1-sn can be null. The values v1-vn can also be null and can contain any characters (in particular, lowercase characters are not translated to uppercase, blanks are not removed, and periods have no special significance).

Some examples follow in the form of a small extract from a REXX program:

```
a=3      /* assigns '3' to the variable A */
z=4      /* '4' to Z */
c='Fred' /* 'Fred' to C */
a.z='Fred' /* 'Fred' to A.4 */
a.fred=5 /* '5' to A.FRED */
a.c='Bill' /* 'Bill' to A.Fred */
c.c=a.fred /* '5' to C.Fred */
y.a.z='Annie' /* 'Annie' to Y.3.4 */

say a z c a.a a.z a.c c.a a.fred y.a.4
/* displays the string: */
/* "3 4 Fred A.3 Fred Bill C.3 5 Annie" */
```

You can use compound symbols to set up arrays and lists of variables in which the subscript is not necessarily numeric, thus offering great scope to a programmer. A useful application is to set up an array in which the subscripts are taken from the value of one or more variables, effecting a form of associative memory (content addressable).

Implementation maximum: The length of a variable name, before and after substitution, cannot exceed 250 characters.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ %. See also [Conventions and terminology used in the CICS documentation](#).

Stems

A *stem* is a symbol that contains just one period, which is the last character. It cannot start with a digit or a period.

These are stems:

```
FRED.
A.
<.A.B>.
```

By default, the value of a stem is the string that consists of the characters of its symbol (that is, translated to uppercase). If the symbol has been assigned a value, it names a variable and its value is the value of that variable.

When a stem is used as the target of an assignment, all possible compound variables whose names begin with that stem receive the new value, whether they previously had a value or not. Following the

assignment, a reference to any compound symbol with that stem returns the new value until another value is assigned to the stem, or to the individual variable.

For example:

```
hole. = "empty"
hole.9 = "full"

say hole.1 hole.mouse hole.9

/* says "empty empty full" */
```

Thus, you can give a whole collection of variables the same value. For example:

```
total. = 0
do forever
  say "Enter an amount and a name:"
  pull amount name
  if datatype(amount)='CHAR' then leave
  total.name = total.name + amount
end
```

Note: You can always obtain the value that has been assigned to the whole collection of variables by using the stem. However, this is not the same as using a compound variable whose derived name is the same as the stem. For example:

```
total. = 0
null = ""
total.null = total.null + 5
say total. total.null          /* says "0 5" */
```

You can manipulate collections of variables, referred to by their stem, with the DROP and PROCEDURE instructions. DROP FRED. drops all variables with that stem (see [“DROP” on page 170](#)), and PROCEDURE EXPOSE FRED. exposes all possible variables with that stem (see [“PROCEDURE” on page 178](#)).

Note:

1. When the ARG, PARSE, or PULL instruction, or the VALUE built-in function, or the variable pool interface changes a variable, the effect is identical with an assignment. Anywhere a value can be assigned, using a stem sets an entire collection of variables.
2. Because an expression can include the operator =, and an instruction can consist purely of an expression (see [“Commands to External Environments” on page 155](#)), a possible ambiguity is resolved by the following rule: any clause that starts with a symbol and whose second token is (or starts with) an equal sign (=) is an *assignment*, rather than an expression (or a keyword instruction). This is not a restriction, because you can ensure the clause is processed as a command in several ways, such as by putting a null string before the first name, or by enclosing the first part of the expression in parentheses.

Similarly, if you unintentionally use a REXX keyword as the variable name in an assignment, this should not cause confusion. For example, the following clause is an assignment, not an ADDRESS instruction:

```
Address='10 Downing Street';
```

3. You can use the SYMBOL function to test whether a symbol has been assigned a value (see [“SYMBOL” on page 215](#)). In addition, you can set SIGNAL ON NOVALUE to trap the use of any uninitialized variables (except when they are tails in compound variables; see [Chapter 22, “Conditions and condition traps,” on page 249](#)).

Commands to External Environments

Issuing commands to the surrounding environment is an integral part of REXX.

Environment

The system under which REXX programs run is assumed to include at least one environment for processing commands. An environment is selected by default on entry to a REXX program. You can change the environment by using the ADDRESS instruction. You can find out the name of the current environment by using the ADDRESS built-in function. The underlying operating system defines environments external to the REXX program. The default environment for a REXX/CICS program is REXXCICS.

Commands

To send a command to the currently addressed environment, use a clause of the form:

```
expression;
```

The expression is evaluated, resulting in a character string (which may be the null string), which is then prepared as appropriate and submitted to the underlying system. Any part of the expression not to be evaluated should be enclosed in quotation marks.

The environment then processes the command, which might have side-effects. It eventually returns control to the language processor, after setting a return code. A *return code* is a string, typically a number, that returns some information about the command that has been processed. A return code usually indicates if a command was successful or not, but can also represent other information. The language processor places this return code in the REXX special variable RC. See [“Special variables” on page 252](#).

In addition to setting a return code, the underlying system might also indicate to the language processor if an error or failure occurred.

- An error is a condition raised by a command for which a program that uses that command would usually be expected to be prepared. For example, a locate command to an editing system might report `requested string not found` as an error.
- A failure is a condition raised by a command for which a program that uses that command would not usually be expected to recover (for example, a command that is not executable or cannot be found).

Errors and failures in commands can affect REXX processing if a condition trap for ERROR or FAILURE is ON (see [Chapter 22, “Conditions and condition traps,” on page 249](#)). They might also cause the command to be traced if TRACE E or TRACE F is set. TRACE Normal is the same as TRACE F and is the default. See [“TRACE” on page 185](#).

Here is an example of submitting a command to the default REXX/CICS command environment. The following sequence results in the string EXECIO * READ TSQUEUE1 MYDATA. being submitted to REXX/CICS:

```
TSQ1 = 'TSQUEUE1'  
"EXECIO * READ" TSQ1 "MYDATA."
```

On return, the return code placed in RC has the value 0 if the CICS temporary storage queue TSQUEUE1 was successfully read into MYDATA array. If TSQUEUE1 is empty, the appropriate return code is placed in RC.

Note: Remember that the expression is evaluated before it is passed to the environment. Enclose any part of the expression that is not to be evaluated in quotation marks. For example:

```
"EXECIO * READ"          /* * does not mean "multiplied by" */
```

Basic structure of REXX running under CICS

REXX/CICS support provides a main interface program named CICREXD for the REXX/CICS Development System, and CICREXR for the REXX/CICS Runtime Facility, which is used to load and issue REXX execs within a CICS region.

Each REXX exec runs under a separate CICS task. Any nested REXX execs run under the CICS task of the parent exec.

Note: To determine whether the exec is running in the development system or the runtime facility, you can use the GETVERS command. See [“GETVERS” on page 393](#).

REXX exec invocation

- Execs started from a terminal

CICS uses transaction identifiers associated with programs to determine which programs to execute. REXX/CICS uses a table created by the REXX/CICS command, DEFTRNID, to associate CICS transaction identifiers with specific REXX execs. The CICS transaction identifier associated with the REXX/CICS supplied exec, CICRXTRY, is known as the default REXX/CICS transaction identifier. The supplied default is REXX.

If REXX alone is entered from a CICS screen, the CICRXTRY exec is started. If other operands are specified, for example: REXX MYEXEC ABC, the exec MYEXEC is started and ABC is passed to it as an argument. CICS transaction identifiers other than the REXX/CICS default transaction identifier cause the associated exec to be started and any other operands are passed as an argument to the exec. For example: EDIT TEST.EXEC causes the REXX/CICS editor exec, CICEDIT, to start and TEST.EXEC, the argument, names the file to edit or create. All REXX/CICS transaction identifiers must have CICS definitions which associate them with the REXX/CICS main module, CICREXD.

- Execs started using a CICS START command

REXX/CICS execs can be started by using the CICS START command. The START command names the CICS transaction identified to start and the table created by the REXX/CICS DEFTRNID command names the exec to start.

If the exec is CICRXTRY and CICS start data is present, the first operand names the exec to start and any other operands are passed to the exec as an argument. If no start data is present, CICRXTRY is started.

For execs other than CICRXTRY, start data is passed to the exec as an argument. Usually, REXX/CICS execs have a terminal associated with them. However, if a REXX/CICS exec does not have a terminal associated to the transaction, any terminal output is either discarded or directed to a CICS temporary storage queue as specified by the REXX/CICS SET TERMOUT command. An error is generated if terminal input is requested for a transaction for which no terminal is associated.

- Execs started using a CICS LINK or XCTL command

The REXX/CICS interface program, CICREXD or CICREXR, can be invoked by using the CICS LINK or XCTL command. A COMMAREA must be passed to the interface program when invoked in this way.

- If a CICS LINK is used to invoke REXX, the communications area must be at least 16 characters in length. The first four characters are used to return a completion code to the calling application. This completion code is a return code of REXX/CICS processing, as listed in [“Return codes not associated with a specific command” on page 438](#), not the return code of the called exec. The next 12 characters are reserved for future use. Data that follows the 16 character prefix can be used to pass a blank delimited REXX exec name, and arguments to be passed to the exec. An exec started with CICS LINK must run in conversational mode. This is necessary to protect the caller's storage for returning to the calling application.
- If CICS XCTL is used to invoke REXX, the communications area might contain an MVS SIB type 1 control block. If a SIB is not used, the area must be at least 16 characters long. The 16 character prefix is reserved for future use. Data that follows the 16 character prefix can be used to pass a blank delimited REXX exec name, and arguments to be passed to the exec.

- Execs issued from an MVS SIB type 1 control block

REXX execs can be invoked from OfficeVision or MVS by an Application Type Description (ATD). When creating an ATD, use XCTL or START for the invocation. If you use XCTL, use CICREXD or CICREXR as the application program. If you use START, place the default transaction ID for REXX/CICS (for example, REXX) in the application program field.

There are two ways to pass the exec name and any parameters:

- The MSG-TEXT field - (MSG-REDEF = '1')
- The Parameter Description Record (PDR) - 'REXXEXEC'

The MSG-TEXT field is filled in with the data keyed on the command line if the ATD name and at least one parameter is specified. If the PDR REXXEXEC is used, the exec name plus any parameters needed must be in the data area for the PDR. If both the MSG-TEXT and the PDR REXXEXEC are used, the data in the MSG-TEXT takes precedence. If neither of the two are used, the REXXTRY interactive utility (CICRTRY exec) is invoked.

Note: A utility called REXXTRY (CICRTRY exec) is provided with REXX/CICS that allows the interactive execution of REXX instructions and REXX/CICS commands. To invoke this utility, enter the REXX/CICS transaction identifier associated with CICRTRY without any operands.

Where execs execute

REXX/CICS execs are executed as part of the CICS task that issues them, within the CICS region. The REXX interpreter is fully reentrant and runs above the 16 megabyte line (AMODE=31, RMODE=ANY).

Locating and loading Execs

The following rules are used to locate and load an exec into storage so it can be started:

1. Execs loaded into storage using EXECLOAD are searched and if the exec is found, the copy that is loaded by EXECLOAD is used.
2. The user's current RFS directory, as defined by the REXX/CICS CD command, is searched. If found, the exec is loaded and started.
3. The user's path, as defined by the REXX/CICS PATH command, is searched. If found, the exec is loaded and started.
4. If the user is an authorized user, data sets specified with the ddname of CICAUTH in the CICS startup JCL are searched.. If the exec is found, it is loaded and started.
5. Data sets specified with the ddnames of CICEXEC and CICUSER, in that order, are searched. If the exec is not found, an error code is returned.

Editing execs

If the REXX/CICS Development System is installed, REXX execs can be edited using the supplied REXX/CICS editor. See [Chapter 23, “REXX/CICS text editor,”](#) on page 255. Also, if REXX/CICS execs reside in an MVS PDS, they can be edited using the ISPF/PDF editor under TSO (or other compatible editors).

The sequence numbers are not allowed in columns 73 through 80 of REXX/CICS execs.

REXX file system

Execs can be stored as members in the VSAM-based REXX File System (RFS), provided with REXX/CICS, or in MVS partitioned data sets. See [Chapter 24, “REXX/CICS File System,”](#) on page 285.

Note: If the file identifier you specified for invoking an exec does not include a file type extension, only RFS file identifiers with a file type of EXEC are searched when you attempt to locate and issue the REXX exec. If the file identifier includes a file type extension, only RFS files with a matching file type are searched (when you attempt to locate and run the exec). For MVS PDS searches, only the file name is compared to the PDS member name.

Control of exec execution search order

The CD and PATH commands define the search order of user REXX libraries when you attempt to load an exec. After the current directory (set by the CD command) is searched, all directories specified with the PATH command are searched, followed by system MVS PDS libraries specified in the startup JCL for the CICS region. For more detailed information on the search order, see [“Functions and subroutines” on page 191](#).

Adding user-written commands

An exec can be defined so that it can be invoked as a REXX/CICS command. The DEFCMD command is used to define REXX/CICS user commands. DEFCMD supports commands written in REXX as well as the standard CICS supported languages. See [“DEFCMD” on page 377](#).

Support of Standard REXX Features

Standard REXX features such as SAY and TRACE statements, PULL and PARSE EXTERNAL statements, REXX stacking, and REXX functions are supported.

SAY and TRACE statements

The REXX SAY and TRACE terminal I/O output statements use CICS Terminal Control support to provide simulated line-mode output. Also, the SET TERMOUT command can be used to route line-mode output into a temporary storage queue. See [“SET” on page 406](#).

PULL and PARSE EXTERNAL statements

The REXX PULL and PARSE EXTERNAL terminal I/O input statements use CICS Terminal Control support to provide simulated line-mode input.

1. PULL (or PARSE PULL) first attempts to pull a line from the program stack and, only if it is empty, issues a read to the terminal.
2. Attempting to perform terminal line-mode input from a REXX exec that is running as part of a non-terminal attached transaction, is an error, which causes the exec to terminate with an error message.

REXX stack support

Each user has a shared program stack between multiple generations of REXX execs. This single automatic program stack is not named. If named program stacks are required, use the RLS LPUSH, LQUEUE, and LPULL commands.

REXX function support

REXX/CICS supports the standard SAA Level 2 built-in function set, with the following exceptions:

- Stream I/O functions are not supported.
- The USERID function returns a 1 to 8 character CICS user ID if the user is signed on. If the CICS user has not signed on and a default user has been specified for the CICS region (by the CICS Systems Programmer specifying DFLTUSER in the CICS startup parameters) then that value is used.

Note: The default user shares REXX File System and REXX List System directories.

- The STORAGE function, which allows a REXX user to display or modify the virtual storage of the CICS region. This function can only be successfully invoked from an authorized exec or by an authorized user.

REXX command environment support

REXX command environments that are currently available (to use with the REXX ADDRESS command) are REXXCICS, CICS, EXEC SQL, EDITSVR, FLSTSVR, RFS and RLS.

Adding REXX host command environments

Support is provided for allowing new REXX/CICS commands and command environments to be dynamically defined. New commands may be written in REXX or in any REXX/CICS supported language (for example: Assembler, COBOL, C, PL/I). For more information on how commands and command environments are defined to REXX/CICS, see [Chapter 26, “REXX/CICS Command Definition,”](#) on page 309.

Support for standard CICS features

Support for standard CICS features or facilities is described. This includes CICS mapped I/O support, data set I/O services, interfaces to CICS facilities and services, issuing user applications from execs, REXX interfaces to CICS temporary and transient storage queues, pseudo-conversational transaction support, and DBCS support.

CICS mapped I/O support

Support for CICS basic mapping support (BMS) I/O is provided by the CICS SEND MAP, RECEIVE MAP, and CONVERSE MAP commands and the REXX/CICS CONVTPMAP and COPYS2R commands. See [Chapter 36, “Basic mapping support example,”](#) on page 477.

Note: BMS maps must be predefined by using normal CICS procedures.

Dataset I/O services

Standard CICS File I/O commands (such as EXEC CICS READ and WRITE) are supported. High-level I/O can be performed from an EXEC to the VSAM-based REXX File System (RFS) by using the provided RFS command. Also, dynamic allocation is used to allow standard MVS partitioned data sets to be used with the IMPORT and EXPORT commands and the REXX/CICS editor.

Interfaces to CICS facilities and services

From the ADDRESS CICS command environment, support is provided for most CICS commands (as defined in [Application development reference](#)). See [Chapter 30, “REXX/CICS commands,”](#) on page 351 for detailed information on the commands supported.

Issuing user applications from execs

REXX/CICS supports the EXEC CICS START, LINK, and XCTL commands to provide the ability to START CICS transactions or invoke CICS programs from within a REXX exec.

REXX interfaces to CICS storage queues

Command support exists for reading, writing, and deleting CICS temporary storage and transient data queues from REXX/CICS.

Pseudo-conversational transaction support

CICS pseudo-conversational support for REXX execs is supported through the use of the CICS RETURN TRANSID() command, by the REXX/CICS PSEUDO command (see [“PSEUDO”](#) on page 399), and the SETSYS PSEUDO command (see [“SETSYS”](#) on page 408).

Execution Diagnostic Facility (EDF)

Use of EDF for REXX execs is supported, but only in dual-screen mode.

Interfaces to other programming languages

REXX/CICS supports (by support for CICS LINK and CICS XCTL REXX/CICS commands) the ability to invoke CICS programs written in any REXX/CICS supported language. It provides the same support for the programs used to implement new REXX commands, which are defined by using the DEFCMD and DEFSCMD commands. Support is also provided to allow an EXEC CICS START to be issued from REXX execs.

DBCS support

The full range of DBCS functions and handling techniques that are included in SAA Level 2 REXX are available to the REXX/CICS user.

Other features

- A TERMID command has been provided to return the four character terminal identifier of a CICS user.
- A retrieve PF key can be specified to retrieve the last input line entered using line-mode I/O while in the REXXTRY interactive utility (CICRTRY exec). See the SET RETRIEVE command ([“SET” on page 406](#)).
- The SET TERMOUT command allows line-mode terminal output (from SAY or TRACE) to be directed to a CICS temporary storage queue instead of, or in addition to, the terminal.
- The PULL instruction sets the REXX variable PULLKEY, with the name of the AID key pressed if PULL read data from the terminal.
- Line-mode output to the terminal causes MORE to appear in the lower right hand corner of the screen, when the screen is full. Press `Clear` or `Enter` to proceed.
- Line-mode input from the terminal causes READ to appear in the lower right hand corner of the screen.

Chapter 18. Keyword instructions

A *keyword instruction* is one or more clauses, where the first clause starts with a keyword that identifies the instruction. Some keyword instructions affect the flow of control, while others provide services to the programmer. Some keyword instructions, like DO, can include nested instructions.

In the syntax diagrams, symbols (words) in capitals denote keywords or sub-keywords; other words (such as *expression*) denote a collection of tokens as defined previously. However, the keywords and subkeywords are not case dependent; the symbols if, If, and iF all have the same effect. You can usually omit most of the clause delimiters (;) shown because they are implied by the end of a line.

As explained in “Clauses and instructions” on page 150, a keyword instruction is recognized only if its keyword is the first token in a clause, and if the second token does not start with an = character (implying an assignment) or a colon (implying a label). The keywords ELSE, END, OTHERWISE, THEN, and WHEN are recognized in the same situation. Any clause that starts with a keyword defined by REXX cannot be a command. Therefore, the following is an ARG keyword instruction, not a command that starts with a call to the ARG built-in function.

```
arg(fred) rest
```

A syntax error results if the keywords are not in their correct positions in a DO, IF, or SELECT instruction. (The keyword THEN is also recognized in the body of an IF or WHEN clause.) In other contexts, keywords are not reserved and can be used as labels or as the names of variables (though this is generally not recommended).

Certain other keywords, known as subkeywords, are reserved within the clauses of individual instructions. For example, the symbols VALUE and WITH are subkeywords in the ADDRESS and PARSE instructions, respectively. For details, see the description of each instruction. For a general discussion on reserved keywords, see “Reserved keywords” on page 473.

Blanks adjacent to keywords have no effect other than to separate the keyword from the subsequent token. One or more blanks following VALUE are required to separate the *expression* from the subkeyword in the example following:

```
ADDRESS VALUE expression
```

However, no blank is required after the VALUE subkeyword in the following example, although it would add to the readability:

```
ADDRESS VALUE 'ENVIR' || number
```

ADDRESS

ADDRESS temporarily or permanently changes the destination of commands. Commands are strings sent to an external environment. You can send commands by specifying clauses consisting of only an expression or by using the ADDRESS instruction.

The concept of alternative subcommand environments is described in [Syntax of REXX instructions](#).

To send a single command to a specified environment, code an *environment*, a literal string or a single symbol, which is taken to be a constant, followed by an *expression*. (The environment name is the name

of an external procedure or process that can process commands.) The environment name is limited to eight characters. The *expression* is evaluated, and the resulting string is routed to the *environment* to be processed as a command. (Enclose in quotation marks any part of the expression you do not want to be evaluated.) After execution of the command, *environment* is set back to whatever it was before, thus temporarily changing the destination for a single command. The special variable RC is set, just as it would be for other commands. (See [“Commands to External Environments”](#) on page 155.) Errors and failures in commands processed in this way are trapped or traced as usual.

Examples

```
ADDRESS CICS "READQ TSQ QUEUE('QUEUE1') INTO(VAR1)" /* CICS */
```

If you specify only *environment*, a lasting change of destination occurs: all commands that follow (clauses that are neither REXX instructions nor assignment instructions) are routed to the specified command environment, until the next ADDRESS instruction is processed. The previously selected environment is saved.

```
address cics
"READQ TSQ QUEUE('QUEUE1') INTO(VAR1)"
ADDRESS RFS
'COPY PROFILE.EXEC TEMP.EXEC'
```

Similarly, you can use the VALUE form to make a lasting change to the environment. Here *expression1* (which may be simply a variable name) is evaluated, and the result forms the name of the environment. You can omit the subkeyword VALUE if *expression1* does not begin with a literal string or symbol (that is, if it starts with a special character, such as an operator character or parenthesis).

```
ADDRESS ('ENVIR'||number) /* Same as ADDRESS VALUE 'ENVIR'||number */
```

With no arguments, commands are routed back to the environment that was selected before the previous lasting change of environment was made, and the current environment name is saved. After changing the environment, repeated execution of ADDRESS alone, therefore, switches the command destination between two environments alternately.

The two environment names are automatically saved across internal and external subroutine and function calls. See [“CALL”](#) on page 163.

The address setting is the currently selected environment name. You can retrieve the current address setting by using the ADDRESS built-in function (see [“ADDRESS”](#) on page 195).

ARG

ARG retrieves the argument strings provided to a program or internal routine and assigns them to variables.

```
➤ ARG _____ ; ➤
      |_____|
      template_list
```

ARG is a short form of the instruction:

```
➤ PARSE UPPER ARG _____ ; ➤
      |_____|
      template_list
```

The *template_list* is often a single template but can be several templates separated by commas. If specified, each template is a list of symbols separated by blanks, patterns, or both.

Unless a subroutine or internal function is being processed, the strings passed as parameters to the program are parsed into variables according to the rules described in the section on parsing ([Chapter 20, “Parsing,”](#) on page 225).

If a subroutine or internal function is being processed, the data used will be the argument strings that the caller passes to the routine.

In either case, the language processor translates the passed strings to uppercase (that is, lowercase a-z to uppercase A - Z) before processing them. Use the PARSE ARG instruction if you do not want uppercase translation.

You can use the ARG and PARSE ARG instructions repeatedly on the same source string or strings (typically with different templates). The source string does not change. The only restrictions on the length or content of the data parsed are those the caller imposes.

Examples

```
/* String passed is "Easy Rider" */
Arg adjective noun .

/* Now: ADJECTIVE contains 'EASY' */
/*      NOUN       contains 'RIDER' */
```

If you expect more than one string to be available to the program or routine, you can use a comma in the parsing *template_list* so each template is selected in turn.

```
/* Function is called by FRED('data X',1,5) */
Fred: Arg string, num1, num2

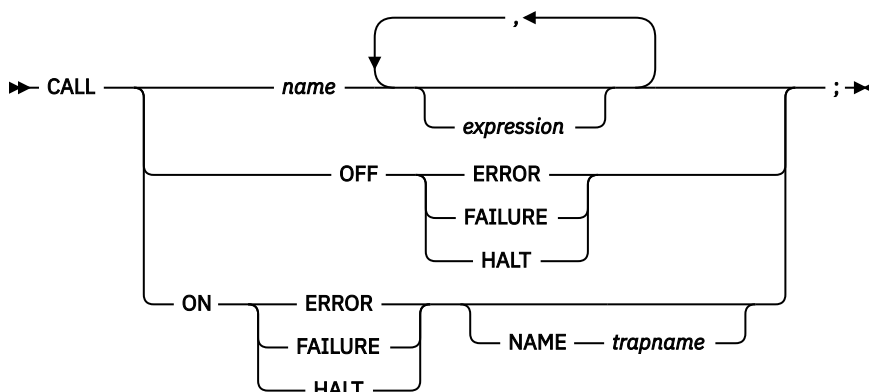

/* Now:  STRING contains 'DATA X' */
/*      NUM1   contains '1' */
/*      NUM2   contains '5' */
```

Note:

1. The ARG built-in function can also retrieve or check the argument strings to a REXX program or internal routine, see [“ARG \(Argument\)”](#) on page 195.
2. The source of the data being processed is also made available on entry to the program. See the PARSE instruction (SOURCE option) [“PARSE”](#) on page 176 for details.

CALL

CALL calls a routine (if you specify *name*) or controls the trapping of certain conditions (if you specify ON or OFF).

To control trapping, you specify OFF or ON and the condition you want to trap. OFF turns off the specified condition trap. ON turns on the specified condition trap. For information on condition traps, see [Chapter 22, “Conditions and condition traps,”](#) on page 249.

To call a routine, specify *name*, a literal string or symbol that is taken as a constant. The *name* must be a symbol, which is treated literally, or a literal string. The routine called can be:

An internal routine

A function or subroutine that is in the same program as the CALL instruction or function call that calls it.

A built-in routine

A function (which may be called as a subroutine) that is defined as part of the REXX language.

An external routine

A function or subroutine that is not built-in or is not in the same program as the CALL instruction or function call that calls it.

If *name* is a string (that is, you specify *name* in quotation marks), the search for internal routines is bypassed, and only a built-in function or an external routine is called. The names of built-in functions (and generally the names of external routines, too) are in uppercase; therefore the name in the literal string must also be in uppercase.

The called routine can optionally return a result, and when it does, the CALL instruction is functionally identical with the following clause:

If the called routine does not return a result, you get an error if you call it as a function (as previously shown).

REXX/CICS supports specifying up to 20 expressions, separated by commas. The expressions are evaluated in order from left to right and form the argument strings during execution of the routine. Any ARG or PARSE ARG instruction, or ARG built-in function, in the called routine accesses these strings rather than any previously active in the calling program, until control returns to the CALL instruction. You can omit expressions, if appropriate, by including extra commas.

The CALL then causes a branch to the routine called *name*, using exactly the same mechanism as function calls, see [Chapter 19, “Functions,” on page 191](#). The search order is in the section on functions but briefly is as follows:

Internal routines:

These are sequences of instructions inside the same program, starting at the label that matches *name* in the CALL instruction. If you specify the routine name in quotation marks, an internal routine is not considered for that search order. You can use SIGNAL and CALL together to call an internal routine whose name was determined at the time of execution; this is known as a multi-way call (see [“SIGNAL” on page 183](#)). The RETURN instruction completes the execution of an internal routine.

Built-in routines:

These are routines built into the language processor for providing various functions. They always return a string that is the result of the routine. (See [“Built-in Functions” on page 194](#).)

External routines:

Users can write or use routines that are external to the language processor and the calling program. External routines must be coded in REXX. If the CALL instruction calls an external routine written in REXX as a subroutine, you can retrieve any argument strings with the ARG or PARSE ARG instructions or the ARG built-in function.

During execution of an internal routine, all variables previously known are generally accessible. However, the PROCEDURE instruction can set up a local variables environment to protect the subroutine and caller from each other. The EXPOSE option on the PROCEDURE instruction can expose selected variables to a routine.

Calling an external program as a subroutine is similar to calling an internal routine. The external routine, however, is an implicit PROCEDURE in that all the caller's variables are always hidden. The status of internal values (NUMERIC settings, and so forth) start with their defaults (rather than inheriting those of the caller). In addition, you can use EXIT to return from the routine.

When control reaches an internal routine, the line number of the CALL instruction is available in the variable SIGL (in the caller's variable environment). This may be used as a debug aid, as it is, therefore, possible to find out how control reached a routine. If the internal routine uses the PROCEDURE instruction, it needs to EXPOSE SIGL to get access to the line number of the CALL.

Eventually the subroutine should process a RETURN instruction, and at that point control returns to the clause following the original CALL. If the RETURN instruction specified an expression, the variable RESULT is set to the value of that expression. Otherwise, the variable RESULT is dropped (becomes uninitialized).

An internal routine can include calls to other internal routines, as well as recursive calls to itself.

Implementation maximum: The total nesting of control structures, which includes internal routine calls, is dependent upon available storage.

Example

```
/* Recursive subroutine execution... */
arg z
call factorial z
say z'!' = ' result
exit

factorial: procedure      /* Calculate factorial by */
  arg n                  /* recursive invocation. */
  if n=0 then return 1
  call factorial n-1
  return result * n
```

During internal subroutine (and function) execution, all important pieces of information are automatically saved and then restored upon return from the routine. These are:

- The status of DO loops and other structures.

Executing a SIGNAL while within a subroutine is safe because DO loops, and so forth, that were active when the subroutine was called are not ended. (But those currently active within the subroutine are ended.)

- Trace action.

After a subroutine is debugged, you can insert a TRACE Off at the beginning of it, and this does not affect the tracing of the caller. Conversely, if you simply want to debug a subroutine, you can insert a TRACE Results at the start and tracing is automatically restored to the conditions at entry (for example, Off) upon return. Similarly, ? (interactive debug) and ! (command inhibition) are saved across routines.

- NUMERIC settings.

The DIGITS, FUZZ, and FORM of arithmetic operations (see [“NUMERIC” on page 174](#)) are saved and then restored on return. A subroutine can, therefore, set the precision, and so forth, that it needs to use without affecting the caller.

- ADDRESS settings.

The current and previous destinations for commands (see [“ADDRESS” on page 161](#)) are saved and then restored on return.

- Condition traps.

Condition traps (CALL ON and SIGNAL ON) are saved and then restored on return. This means that CALL ON, CALL OFF, SIGNAL ON, and SIGNAL OFF can be used in a subroutine without affecting the conditions the caller set up.

- Condition information.

This information describes the state and origin of the current trapped condition. The CONDITION built-in function returns this information. See [“CONDITION” on page 199](#).

- Elapsed-time clocks.

A subroutine inherits the elapsed-time clock from its caller (see [“TIME” on page 216](#)), but because the time clock is saved across routine calls, a subroutine or internal function can independently restart and

use the clock without affecting its caller. For the same reason, a clock started within an internal routine is not available to the caller.

- OPTIONS settings.

ETMODE and EXMODE are saved and then restored on return. For more information, see [“OPTIONS” on page 175](#).

DO

DO groups instructions together and optionally processes them repetitively. During repetitive execution, a control variable (*name*) can be stepped through some range of values.

repetitor

conditional

DO groups instructions together and optionally processes them repetitively. During repetitive execution, a control variable (*name*) can be stepped through some range of values.

Syntax Notes

- The *exprr*, *expri*, *exprb*, *exprt*, and *exprf* options (if present) are any expressions that evaluate to a number. The *exprr* and *exprf* options are further restricted to result in a positive whole number or zero. If necessary, the numbers are rounded according to the setting of NUMERIC DIGITS.
- The *exprw* or *expru* options (if present) can be any expression that evaluates to 1 or 0.
- The TO, BY, and FOR phrases can be in any order, if used, and are evaluated in the order in which they are written.
- The *instruction* can be any instruction, including assignments, commands, and keyword instructions (including any of the more complex constructs such as IF, SELECT, and the DO instruction itself).
- The subkeywords WHILE and UNTIL are reserved within a DO instruction, in that they cannot be used as symbols in any of the expressions. Similarly, TO, BY, and FOR cannot be used in *expri*, *exprt*, *exprb*, or *exprf*. FOREVER is also reserved, but only if it immediately follows the keyword DO and an equal sign does not follow it.
- The *exprb* option defaults to 1, if relevant.

Simple DO group

If you do not specify *repetitor* or *conditional*, the construct merely groups a number of instructions together. These are processed one time.

In the following example, the instructions are processed one time.

```

/* The two instructions between DO and END are both */
/* processed if A has the value "3".                  */
If a=3 then Do

```

```

a=a+2
Say 'Smile!'
End

```

Repetitive DO loops

If a DO instruction has a repetitor phrase, a conditional phrase, or both, the group of instructions forms a *repetitive DO loop*. The instructions are processed according to the repetitor phrase, optionally modified by the conditional phrase. See [“Conditional phrases \(WHILE and UNTIL\)” on page 168](#).

- Simple repetitive loops

A simple repetitive loop is a repetitive DO loop in which the repetitor phrase is an expression that evaluates to a count of the iterations.

If *repetitor* is omitted but there is a *conditional* or if the *repetitor* is FOREVER, the group of instructions is nominally processed "forever", that is, until the condition is satisfied or a REXX instruction is processed that ends the loop (for example, LEAVE).

Note: For a discussion on conditional phrases, see [“Conditional phrases \(WHILE and UNTIL\)” on page 168](#)

In the simple form of a repetitive loop, *expr* is evaluated immediately (and must result in a positive whole number or zero), and the loop is then processed that many times. For example:

```

/* This displays "Hello" five times */
Do 5
  say 'Hello'
end

```

Similar to the distinction between a command and an assignment, if the first token of *expr* is a symbol and the second token is (or starts with) =, the controlled form of *repetitor* is expected.

- Controlled Repetitive Loops

The controlled form specifies *name*, a *control variable* that is assigned an initial value (the result of *expri*, formatted as though 0 had been added) before the first execution of the instruction list. The variable is then stepped (by adding the result of *exprb*) before the second and subsequent times that the instruction list is processed.

The instruction list is processed repeatedly while the end condition (determined by the result of *expri*) is not met. If *exprb* is positive or 0, the loop is ended when *name* is greater than *expri*. If negative, the loop is ended when *name* is less than *expri*.

The *expri*, *expri*, and *exprb* options must result in numbers. They are evaluated only one time, before the loop begins and before the control variable is set to its initial value. The default value for *exprb* is 1. If *expri* is omitted, the loop runs indefinitely unless some other condition stops it. For example:

```

Do I=3 to -2 by -1      /* Displays: */
  say i                 /*      3      */
end                     /*      2      */
                        /*      1      */
                        /*      0      */
                        /*     -1      */
                        /*     -2      */

```

The numbers do not have to be whole numbers:

```

I=0.3
Do Y=I to I+4 by 0.7    /* Displays: */
  say Y                 /*      0.3    */
end                     /*      1.0    */
                        /*      1.7    */
                        /*      2.4    */
                        /*      3.1    */
                        /*      3.8    */

```

The control variable can be altered within the loop, and this may affect the iteration of the loop. Altering the value of the control variable is not usually considered good programming practice, though it may be appropriate in certain circumstances.

The end condition is tested at the start of each iteration (and after the control variable is stepped, on the second and subsequent iterations). Therefore, if the end condition is met immediately, the group of instructions can be skipped entirely. Note also that the control variable is referred to by name. If (for example) the compound name A.I is used for the control variable, altering I within the loop causes a change in the control variable.

The execution of a controlled loop can be bounded further by a FOR phrase. In this case, you must specify *exprf*, and it must evaluate to a positive whole number or zero. This acts just like the repetition count in a simple repetitive loop, and sets a limit to the number of iterations around the loop if no other condition stops it. Like the TO and BY expressions, it is evaluated only one time: when the DO instruction is first processed and before the control variable receives its initial value. Like the TO condition, the FOR condition is checked at the start of each iteration. For example:

```
Do Y=0.3 to 4.3 by 0.7 for 3 /* Displays: */
  say Y                    /*    0.3    */
end                        /*    1.0    */
                          /*    1.7    */
```

In a controlled loop, the *name* describing the control variable can be specified on the END clause. This *name* must match *name* in the DO clause in all respects except case (note that no substitution for compound variables is carried out); a syntax error results if it does not. This enables the nesting of loops to be checked automatically, with minimal overhead. For example:

```
Do K=1 to 10
  ...
  ...
End k /* Checks that this is the END for K loop */
```

Note: The NUMERIC settings can affect the successive values of the control variable, because REXX arithmetic rules apply to the computation of stepping the control variable.

Conditional phrases (WHILE and UNTIL)

A conditional phrase can modify the iteration of a repetitive DO loop. It may cause the termination of a loop. It can follow any of the forms of *repetitor* (none, FOREVER, simple, or controlled). If you specify WHILE or UNTIL, *exprw* or *expru*, respectively, is evaluated each time around the loop using the latest values of all variables (and must evaluate to either 0 or 1), and the loop is ended if *exprw* evaluates to 0 or *expru* evaluates to 1.

For a WHILE loop, the condition is evaluated at the top of the group of instructions. For an UNTIL loop, the condition is evaluated at the bottom; before the control variable has been stepped. For example:

```
Do I=1 to 10 by 2 until i>6
  say i
end
/* Displays: "1" "3" "5" "7" */
```

Note: Using the LEAVE or ITERATE instructions can also modify the execution of repetitive loops.

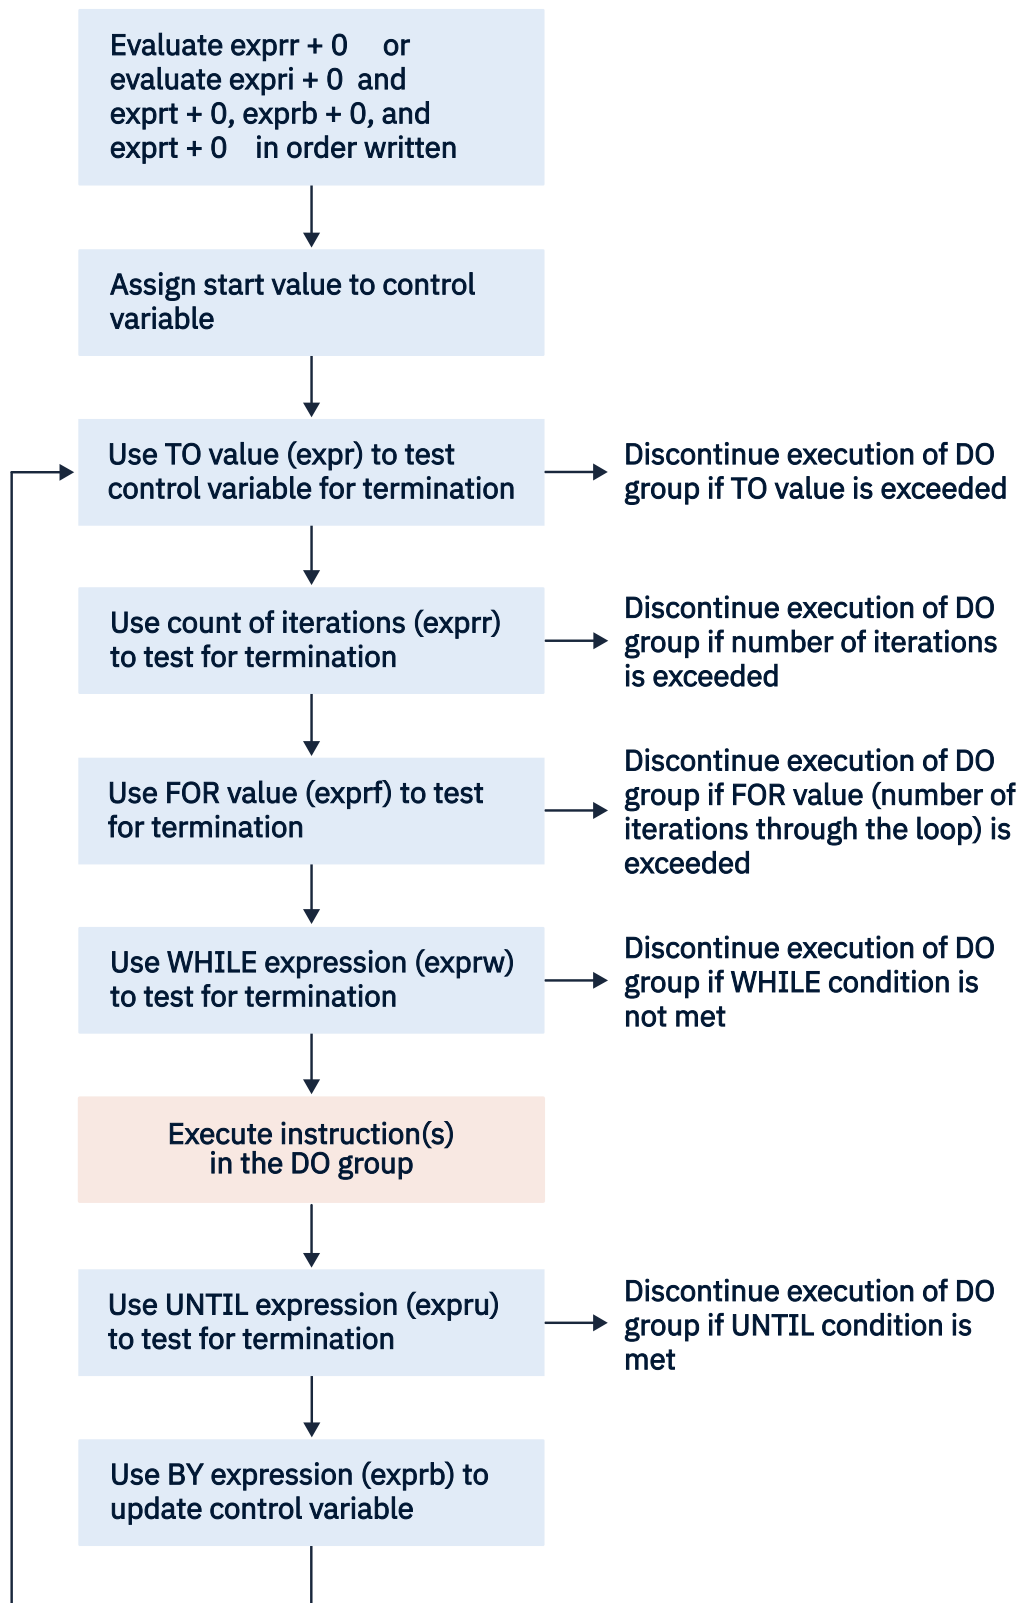

Figure 46. Concept of a DO Loop

DROP

DROP *unassigns* variables, that is, restores them to their original uninitialized state.

If *name* is not enclosed in parentheses, it identifies a variable you want to drop and must be a symbol that is a valid variable name, separated from any other *name* by one or more blanks or comments.

If parentheses enclose a single *name*, then its value is used as a subsidiary list of variables to drop. (Blanks are not necessary either inside or outside the parentheses, but you can add them.) This subsidiary list must follow the same rules as the original list (that is, be valid variable names, separated by blanks) except that no parentheses are allowed.

Variables are dropped in sequence from left to right. It is not an error to specify a name more than one time or to DROP a variable that is not known. If an exposed variable is named (see [“PROCEDURE”](#) on page 178), the variable in the older generation is dropped.

Examples

```
j=4
Drop a z.3 z.j
/* Drops the variables: A, Z.3, and Z.4      */
/* so that reference to them returns their names. */
```

Here, a variable name in parentheses is used as a subsidiary list.

```
mylist='c d e'
drop (mylist) f
/* Drops the variables C, D, E, and F      */
/* Does not drop MYLIST                    */
```

Specifying a stem (that is, a symbol that contains only one period, as the last character), drops all variables starting with that stem.

```
Drop z.
/* Drops all variables with names starting with Z. */
```

EXIT

EXIT leaves a program unconditionally.

Optionally, EXIT returns a character string to the caller. The program is stopped immediately, even if an internal routine is currently being run. If no internal routine is active, RETURN (see [“RETURN”](#) on page 182) and EXIT are identical in their effect on the program that is being run.

If you specify *expression*, it is evaluated and the string resulting from the evaluation is passed back to the caller when the program stops. For example:

```
j=3
Exit j*4
/* Would exit with the string '12' */
```

If you do not specify *expression*, no data is passed back to the caller. If the program was called as an external function, this is detected as an error; either immediately (if RETURN was used), or on return to the caller (if EXIT was used).

"Running off the end" of the program is always equivalent to the instruction EXIT, in that it stops the whole program and returns no result string.

Note: If the program was called through a command interface, an attempt is made to convert the returned value to a return code acceptable by the underlying operating system. If the conversion fails, it is deemed to be unsuccessful because of the underlying operating system and thus is not subject to trapping with SIGNAL ON SYNTAX. The returned string must be a whole number whose value fits in a general register (that is, must be in the range -2^{31} through $2^{31}-1$).

IF

IF conditionally processes an instruction or group of instructions depending on the evaluation of the *expression*. The *expression* is evaluated and must result in 0 or 1.

The instruction after the THEN is processed only if the result is 1 (true). If you specify an ELSE, the instruction after the ELSE is processed only if the result of the evaluation is 0 (false).

Examples

```
if answer='YES' then say 'OK!'
                    else say 'Why not?'
```

Remember that if the ELSE clause is on the same line as the last clause of the THEN part, you need a semicolon before the ELSE.

```
if answer='YES' then say 'OK!'; else say 'Why not?'
```

The ELSE binds to the nearest IF at the same level. You can use the NOP instruction to eliminate errors and possible confusion when IF constructs are nested, as in the following example.

```
If answer = 'YES' Then
  If name = 'FRED' Then
    say 'OK, Fred.'
  Else
    nop
Else
  say 'Why not?'
```

Note:

1. The *instruction* can be any assignment, command, or keyword instruction, including any of the more complex constructs such as DO, SELECT, or the IF instruction itself. A null clause is not an instruction, so putting an extra semicolon (or label) after the THEN or ELSE is not equivalent to putting a dummy instruction (as it would be in PL/I). The NOP instruction is provided for this purpose.
2. The symbol THEN cannot be used within *expression*, because the keyword THEN is treated differently, in that it need not start a clause. This allows the expression on the IF clause to be ended by the THEN, without a ; being required. If this were not so, people who are accustomed to other computer languages would experience considerable difficulties.

INTERPRET

INTERPRET processes instructions that have been built dynamically by evaluating *expression*.

➡ INTERPRET — *expression* — ; ➡

The *expression* is evaluated and is then processed (interpreted) just as though the resulting string were a line inserted into the program (and bracketed by a DO; and an END;).

Any instructions (including INTERPRET instructions) are allowed, but note that constructions such as DO...END and SELECT...END must be complete. For example, a string of instructions being interpreted cannot contain a LEAVE or ITERATE instruction (valid only within a repetitive DO loop) unless it also contains the whole repetitive DO...END construct.

A semicolon is implied at the end of the expression during execution, if one was not supplied.

Examples

1.

```
data='FRED'
interpret data '= 4'
/* Builds the string "FRED = 4" and          */
/* Processes: FRED = 4;                      */
/* Thus the variable FRED is set to "4"      */
```
2.

```
data='do 3; say "Hello there!"; end'
interpret data
/* Displays:                                */
/* Hello there!                             */
/* Hello there!                             */
/* Hello there!                             */
```

Note:

1. Label clauses are not permitted in an interpreted character string.
2. If you are new to the concept of the INTERPRET instruction and are getting results that you do not understand, you may find that executing it with TRACE R or TRACE I in effect is helpful. For example:

```
/* Here is a small REXX program. */
Trace Int
name='Kitty'
indirect='name'
interpret 'say "Hello" indirect'!"'
```

When this is run, it gives the following trace:

```
kitty
3 *-* name='Kitty'
>L> "Kitty"
4 *-* indirect='name'
>L> "name"
5 *-* interpret 'say "Hello" indirect'!"'
>L> "say "Hello"
>V> "name"
>O> "say "Hello" name"
>L> "!"
>O> "say "Hello" name"!"
*-* say "Hello" name"!
>L> "Hello"
>V> "Kitty"
>O> "Hello Kitty"
>L> "!"
>O> "Hello Kitty!"
Hello Kitty!
```

Here, lines 3 and 4 set the variables used in line 5. Execution of line 5 then proceeds in two stages. First the string to be interpreted is built up, using a literal string, a variable (INDIRECT), and another literal string. The resulting pure character string is then interpreted, just as though it were actually part of the original program. Because it is a new clause, it is traced as such (the second *-* trace flag

under line 5) and is then processed. Again a literal string is concatenated to the value of a variable (NAME) and another literal, and the final result (Hello Kitty!) is then displayed.

3. For many purposes, you can use the VALUE function (see “VALUE” on page 219) instead of the INTERPRET instruction. The following line could, therefore, replace line 5 in the last example:

```
say "Hello" value(indirect)"!"
```

INTERPRET is usually required only in special cases, such as when two or more statements are to be interpreted together, or when an expression is to be evaluated dynamically.

ITERATE

ITERATE alters the flow within a repetitive DO loop (that is, any DO construct other than that with a simple DO).

➡ ITERATE ———— ; ➡
 └── *name* ─┘

Execution of the group of instructions stops, and control is passed to the DO instruction just as though the END clause had been encountered. The control variable (if any) is incremented and tested, as usual, and the group of instructions is processed again, unless the DO instruction ends the loop.

The *name* is a symbol, taken as a constant. If *name* is not specified, ITERATE steps the innermost active repetitive loop. If *name* is specified, it must be the name of the control variable of a currently active loop (which may be the innermost), and this is the loop that is stepped. Any active loops inside the one selected for iteration are ended (as though by a LEAVE instruction).

Example

```
do i=1 to 4
  if i=2 then iterate
  say i
end
/* Displays the numbers:  "1" "3" "4" */
```

Note:

1. If specified, *name* must match the symbol naming the control variable in the DO clause in all respects except case. No substitution for compound variables is carried out when the comparison is made.
2. A loop is active if it is currently being processed. If a subroutine is called (or an INTERPRET instruction is processed) during execution of a loop, the loop becomes inactive until the subroutine has returned or the INTERPRET instruction has completed. ITERATE cannot be used to step an inactive loop.
3. If more than one active loop uses the same control variable, ITERATE selects the innermost loop.

LEAVE

LEAVE causes an immediate exit from one or more repetitive DO loops (that is, any DO construct other than a simple DO).

➡ LEAVE ———— ; ➡
 └── *name* ─┘

Processing of the group of instructions is ended, and control is passed to the instruction following the END clause, just as though the END clause had been encountered and the termination condition had been met. However, on exit, the control variable (if any) will contain the value it had when the LEAVE instruction was processed.

The *name* is a symbol, taken as a constant. If *name* is not specified, LEAVE ends the innermost active repetitive loop. If *name* is specified, it must be the name of the control variable of a currently active loop

(which may be the innermost), and that loop (and any active loops inside it) is then ended. Control then passes to the clause following the END that matches the DO clause of the selected loop.

Example

```
do i=1 to 5
  say i
  if i=3 then leave
end
/* Displays the numbers:  "1" "2" "3" */
```

Note:

1. If specified, *name* must match the symbol naming the control variable in the DO clause in all respects except case. No substitution for compound variables is carried out when the comparison is made.
2. A loop is active if it is currently being processed. If a subroutine is called (or an INTERPRET instruction is processed) during execution of a loop, the loop becomes inactive until the subroutine has returned or the INTERPRET instruction has completed. LEAVE cannot be used to end an inactive loop.
3. If more than one active loop uses the same control variable, LEAVE selects the innermost loop.

NOP

NOP is a dummy instruction that has no effect. It can be useful as the target of a THEN or ELSE clause:

➤ NOP — ; ➤

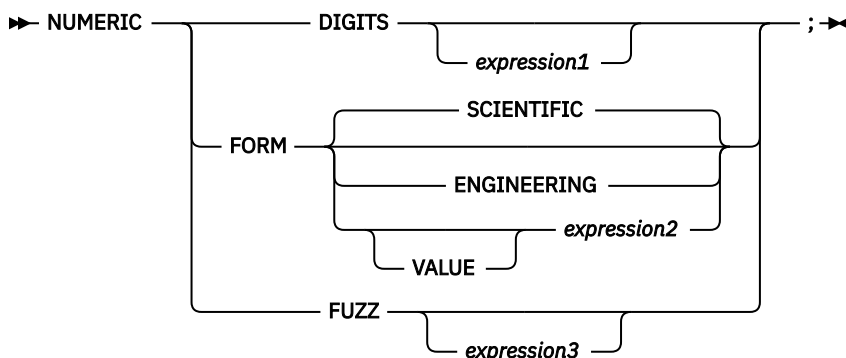

Example

```
Select
  when a=c then nop          /* Do nothing */
  when a>c then say 'A > C'
  otherwise      say 'A < C'
end
```

Note: Putting an extra semicolon instead of the NOP would merely insert a null clause, which would be ignored. The second WHEN clause would be seen as the first instruction expected after the THEN, and would, therefore, be treated as a syntax error. NOP is a true instruction, however, and is, therefore, a valid target for the THEN clause.

NUMERIC

NUMERIC changes the way in which a program carries out arithmetic operations.

The options of this instruction are described in detail in [Chapter 21, “Numbers and arithmetic operations,”](#) on page 239 and [“Errors”](#) on page 246, but in summary:

NUMERIC DIGITS

This option controls the precision to which arithmetic operations and arithmetic built-in functions are evaluated. If you omit *expression1*, the precision defaults to 9 digits. Otherwise, *expression1* must evaluate to a positive whole number and must be larger than the current NUMERIC FUZZ setting.

There is no limit to the value for DIGITS (except the amount of storage available; see the note in [Chapter 17, “REXX General Concepts,”](#) on page 139 for more information) but note that high precisions are likely to require a good deal of processing time. It is recommended that you use the default value wherever possible.

You can retrieve the current NUMERIC DIGITS setting with the DIGITS built-in function. See [“DIGITS”](#) on page 204.

NUMERIC FORM

This option controls which form of exponential notation REXX uses for the result of arithmetic operations and arithmetic built-in functions. This may be either SCIENTIFIC (in which case only one, nonzero digit appears before the decimal point) or ENGINEERING (in which case the power of 10 is always a multiple of 3). The default is SCIENTIFIC. The subkeywords SCIENTIFIC or ENGINEERING set the FORM directly, or it is taken from the result of evaluating the expression (*expression2*) that follows VALUE. The result in this case must be either SCIENTIFIC or ENGINEERING. You can omit the subkeyword VALUE if *expression2* does not begin with a symbol or a literal string (that is, if it starts with a special character, such as an operator character or parenthesis).

You can retrieve the current NUMERIC FORM setting with the FORM built-in function. See [“FORM”](#) on page 206.

NUMERIC FUZZ

This option controls how many digits, at full precision, are ignored during a numeric comparison operation. See [“Numeric Comparisons”](#) on page 244. If you omit *expression3*, the default is 0 digits. Otherwise, *expression3* must evaluate to 0 or a positive whole number, rounded if necessary according to the current NUMERIC DIGITS setting, and must be smaller than the current NUMERIC DIGITS setting.

NUMERIC FUZZ temporarily reduces the value of NUMERIC DIGITS by the NUMERIC FUZZ value during every numeric comparison. The numbers are subtracted under a precision of DIGITS minus FUZZ digits during the comparison and are then compared with 0.

You can retrieve the current NUMERIC FUZZ setting with the FUZZ built-in function. See [“FUZZ”](#) on page 207.

Note: The three numeric settings are automatically saved across internal and external subroutine and function calls. See the CALL instruction ([“CALL”](#) on page 163) for more details.

OPTIONS

OPTIONS passes special requests or parameters to the language processor. For example, these may be language processor options or perhaps define a special character set.

➡ OPTIONS — *expression* — ; ➡

The *expression* is evaluated, and the result is examined one word at a time. The language processor converts the words to uppercase. If the language processor recognizes the words, then they are obeyed. Words that are not recognized are ignored and assumed to be instructions to a different processor.

The language processor recognizes the following words:

ETMODE

specifies that literal strings and symbols and comments containing DBCS characters are checked for being valid DBCS strings. If you use this option, it must be the first instruction of the program.

If the *expression* is an external function call, for example OPTIONS 'GETETMOD' (), and the program contains DBCS literal strings, enclose the name of the function in quotation marks to ensure that the entire program is not scanned before the option takes effect. It is not recommended to use internal

function calls to set ETMODE because of the possibility of errors in interpreting DBCS literal strings in the program.

NOETMODE

specifies that literal strings and symbols and comments containing DBCS characters are not checked for being valid DBCS strings. NOETMODE is the default. The language processor ignores this option unless it is the first instruction in a program.

EXMODE

specifies that instructions, operators, and functions handle DBCS data in mixed strings on a logical character basis. DBCS data integrity is maintained.

NOEXMODE

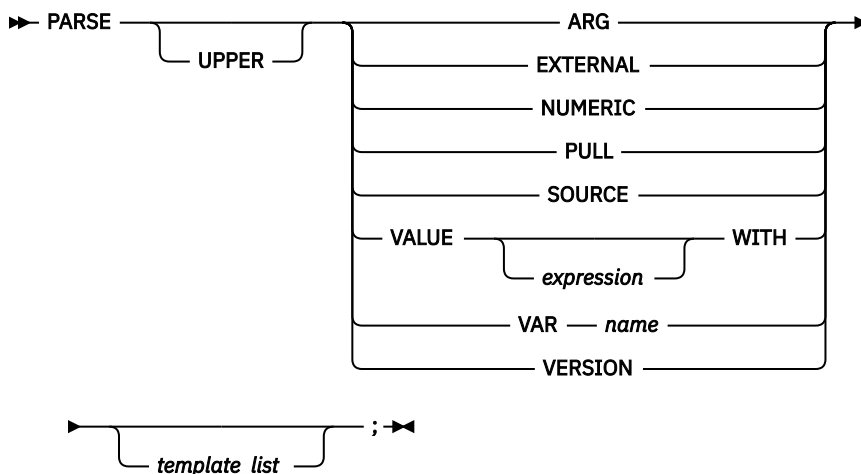

specifies that any data in strings is handled on a byte basis. The integrity of DBCS characters, if any, may be lost. NOEXMODE is the default.

Note:

1. Because of the language processor's scanning procedures, you must place an `OPTIONS 'ETMODE'` instruction as the first instruction in a program containing DBCS characters in literal strings, symbols, or comments. If you do not place `OPTIONS 'ETMODE'` as the first instruction and you use it later in the program, you receive error message CICREX488E. If you do place it as the first instruction of your program, all subsequent uses are ignored. If the expression contains anything that would start a label search, all clauses tokenized during the label search process are tokenized within the current setting of ETMODE. Therefore, if this is the first statement in the program, the default is NOETMODE.
2. To ensure proper scanning of a program containing DBCS literals and DBCS comments, enter the words ETMODE, NOETMODE, EXMODE, and NOEXMODE as literal strings (that is, enclosed in quotation marks) in the `OPTIONS` instruction.
3. The EXMODE setting is saved and restored across subroutine and function calls.
4. To distinguish DBCS characters from 1-byte EBCDIC characters, sequences of DBCS characters are enclosed with a shift-out (SO) character and a shift-in (SI) character. The hexadecimal values of the SO and SI characters are X'0E' and X'0F', respectively.
5. When you specify `OPTIONS 'ETMODE'`, DBCS characters within a literal string are excluded from the search for a closing quotation mark in literal strings.
6. The words ETMODE, NOETMODE, EXMODE, and NOEXMODE can appear several times in the result. The one that takes effect is determined by the last valid one specified between the pairs ETMODE-NOETMODE and EXMODE-NOEXMODE.

PARSE

PARSE assigns data (from various sources) to one or more variables according to the rules of parsing.

See [Chapter 20, "Parsing,"](#) on page 225.

The *template_list* is often a single template but may be several templates separated by commas. If specified, each template is a list of symbols separated by blanks or patterns or both.

Each template is applied to a single source string. Specifying multiple templates is never a syntax error, but only the PARSE ARG variant can supply more than one non-null source string. See [“Parsing multiple strings”](#) on page 234.

If you do not specify a template, no variables are set but action is taken to prepare the data for parsing, if necessary. Thus for PARSE EXTERNAL and PARSE PULL, a data string is removed from the queue, for PARSE LINEIN (and PARSE PULL if the queue is empty), a line is taken from the default input stream, and for PARSE VALUE, *expression* is evaluated. For PARSE VAR, the specified variable is accessed. If it does not have a value, the NOVALUE condition (if it is enabled) is raised.

If you specify the UPPER option, the data to be parsed is first translated to uppercase (that is, lowercase a-z to uppercase A-Z). Otherwise, no uppercase translation takes place during the parsing.

The following list describes the data for each variant of the PARSE instruction.

PARSE ARG

parses the string or strings passed to a program or internal routine as input arguments. (See [“ARG”](#) on page 162 for details and examples.)

Note: You can also retrieve or check the argument strings to a REXX program or internal routine with the ARG built-in function (see [“ARG \(Argument\)”](#) on page 195.)

PARSE EXTERNAL

This is a non-SAA subkeyword provided in REXX/CICS. The next string from the terminal input buffer is parsed. This queue may contain data that is the result of external asynchronous events such as user console input, or messages. If that queue is empty, a console read results. Note that this mechanism should not be used for typical console input, for which PULL is more general, but rather for special applications (such as debugging) where the program stack cannot be disturbed.

PARSE NUMERIC

This is a non-SAA subkeyword provided in REXX/CICS. The current numeric controls (as set by the NUMERIC instruction) are available. These controls are in the order DIGITS FUZZ FORM. For example:

```
Parse Numeric Var1
```

After this instruction, Var1 would be equal to: 9 0 SCIENTIFIC. See [“NUMERIC”](#) on page 174 and the built-in functions in [“DIGITS”](#) on page 204, [“FORM”](#) on page 206, and [“FUZZ”](#) on page 207.

PARSE PULL

parses the next string from the external data queue. If the external data queue is empty, PARSE PULL reads a line from the default input stream (the user's terminal), and the program pauses, if necessary, until a line is complete. You can add data to the head or tail of the queue by using the PUSH and QUEUE instructions. You can find the number of lines currently in the queue with the QUEUED built-in function; see [“QUEUED”](#) on page 211. Other programs in the system can alter the queue and use it as a means of communication with programs written in REXX. See also the PULL instruction ([“PULL”](#) on page 180).

Note: PULL and PARSE PULL read from the program stack. If that is empty, they read from the terminal input buffer; and if that too is empty, they read from the console.

PARSE SOURCE

parses data describing the source of the program running. The language processor returns a string that is fixed (does not change) while the program is running. The PARSE SOURCE instruction returns a source string containing the following tokens:

1. The characters CICS.
2. The string COMMAND, FUNCTION, or SUBROUTINE depending on whether the program was invoked as a host command, from a function call in an expression, by a CALL instruction, or as a server process.

3. The name of the exec in uppercase. The name of the file (RFS), or MVS partitioned dataset or DDNAME/member from which the exec was originally loaded. The three formats are:
 - DDNAME - member
 - RFS fully qualified file identifier
 - Dataset name (member)
4. Initial (default) host command environment that is always REXXCICS.
5. Identifier of the specific CICS environment, which in this case is CICS-TS.

PARSE VALUE

parses the data that is the result of evaluating *expression*. If you specify no *expression*, the null string is used. Note that WITH is a subkeyword in this context and cannot be used as a symbol within *expression*.

Thus, the following example gets the current time and splits it into its constituent parts:

```
PARSE VALUE time() WITH  hours ':' mins ':' secs
```

PARSE VAR *name*

parses the value of the variable *name*. The *name* must be a symbol that is valid as a variable name (that is, it cannot start with a period or a digit). The variable *name* is not changed unless it appears in the template. For example the following instruction removes the first word from *string*, puts it in the variable *word1*, and assigns the remainder back to *string*:

```
PARSE VAR string word1 string
```

Similarly, the following example in addition translates the data from *string* to uppercase before it is parsed.

```
PARSE UPPER VAR string word1 string
```

PARSE VERSION

parses information describing the language level and the date of the language processor. This information consists of five words delimited by blanks:

1. The string REXX370, signifying the 370 implementation.
2. The language level description (for example, 3.48).
3. The language processor release date (for example, 05 April 2000).

PROCEDURE

PROCEDURE, within an internal routine (subroutine or function), protects variables by making them unknown to the instructions that follow it.

After a RETURN instruction is processed, the original variables environment is restored and any variables used in the routine (that were not exposed) are dropped. (An exposed variable is one belonging to a caller of a routine that the PROCEDURE instruction has exposed. When the routine refers to, or alters, the variable, the original (caller's) copy of the variable is used.) An internal routine need not include a PROCEDURE instruction; in this case the variables it is manipulating are those the caller "owns". If used, the PROCEDURE instruction must be the first instruction processed after the CALL or function invocation; that is, it must be the first instruction following the label.

If you use the EXPOSE option, any variable specified by *name* is exposed. Any reference to it (including setting and dropping) refers to the variables environment the caller owns. Hence, the values of existing variables are accessible, and any changes are persistent even on RETURN from the routine. If *name* is not enclosed in parentheses, it identifies a variable you want to expose and must be a symbol that is a valid variable name, separated from any other *name* with one or more blanks.

If parentheses enclose a single *name*, then, after the variable *name* is exposed, the value of *name* is immediately used as a subsidiary list of variables. (Blanks are not necessary either inside or outside the parentheses, but you can add them.) This subsidiary list must follow the same rules as the original list (that is, valid variable names, separated by blanks) except that no parentheses are allowed.

Variables are exposed in sequence from left to right. It is not an error to specify a name more than one time, or to specify a name that the caller has not used as a variable.

Any variables in the main program that are not exposed are still protected. Therefore, some limited set of the caller's variables can be made accessible, and these variables can be changed (or new variables in this set can be created). All these changes are visible to the caller upon RETURN from the routine.

Examples

```
/* This is the main REXX program */
j=1; z.1='a'
call toft
say j k m          /* Displays "1 7 M"          */
exit

/* This is a subroutine */
toft: procedure expose j k z.j
      say j k z.j   /* Displays "1 K a"          */
      k=7; m=3      /* Note: M is not exposed */
      return
```

If Z.J in the EXPOSE list was placed before J, the caller's value of J would not be visible at that time, so Z.1 would not be exposed.

The variables in a subsidiary list are also exposed from left to right.

```
/* This is the main REXX program */
j=1;k=6;m=9
a='j k m'
call test
exit

/* This is a subroutine */
test: procedure expose (a) /* Exposes A, J, K, and M */
      say a j k m         /* Displays "j k m 1 6 9" */
      return
```

You can use subsidiary lists to more easily expose a number of variables at one time or, with the VALUE built-in function, to manipulate dynamically named variables.

```
/* This is the main REXX program */
c=11; d=12; e=13
Showlist='c d'    /* but not E          */
call Playvars
say c d e f       /* Displays "11 New 13 9" */
exit

/* This is a subroutine */
Playvars: procedure expose (showlist) f
      say word(showlist,2) /* Displays "d"          */
      say value(word(showlist,2),'New') /* Displays "12" and sets new value */
      say value(word(showlist,2))      /* Displays "New"        */
      e=8                             /* E is not exposed      */
      f=9                             /* F was explicitly exposed */
      return
```

Specifying a *stem* as *name* exposes this stem and all possible compound variables whose names begin with that stem. See “Stems” on page 153)

```
/* This is the main REXX program */
a.=11; i=13; j=15
i = i + 1
C.5 = 'FRED'
call lucky7
say a. a.1 i j c. c.5
say 'You should see 11 7 14 15 C. FRED'
exit
lucky7:Procedure Expose i j a. c.
/* This exposes I, J, and all variables whose      */
/* names start with A. or C.                      */
A.1='7' /* This sets A.1 in the caller's          */
/* environment, even if it did not                */
/* previously exist.                              */
return
```

Variables can be exposed through several generations of routines by ensuring that they are included on all intermediate PROCEDURE instructions.

For details and examples of how routines are called, see the CALL instruction “CALL” on page 163 and function descriptions Chapter 19, “Functions,” on page 191.

PULL

PULL reads a string from the program stack. If the program stack is empty, PULL then tries reading a line from the current terminal input device.

➡ PULL ————— ; ➡
 template_list

PULL is a short form of the following instruction:

➡ PARSE UPPER PULL ————— ; ➡
 template_list

The current head-of-queue is read as one string. Without a *template_list* specified, no further action is taken (and the string is thus effectively discarded). If specified, a *template_list* is usually a single template, which is a list of symbols separated by blanks or patterns or both. (The *template_list* can be several templates separated by commas, but PULL parses only one source string; if you specify several comma-separated templates, variables in templates other than the first one are assigned the null string.) The string is translated to uppercase (that is, lowercase a-z to uppercase A-Z) and then parsed into variables according to the rules described in the section on parsing (Chapter 20, “Parsing,” on page 225). Use the PARSE PULL instruction if you do not desire uppercase translation.

Note:

1. The REXX/CICS implementation of the external data queue is the program stack. The language processor reads a line from the program stack. If the program stack is empty, a terminal read occurs. The program stack for you is in an RLS queue named \SYSTEM\userid*PROGSTACK*.
2. If the PULL causes a read from the terminal, the variable PULLKEY is set upon completion of the PULL command. It will contain the name of the aid key pressed in response to the PULL command (for example: ENTER, PFKEY 1, PAKEY 1, MSR, PEN, or CLEAR).

For information on named queues, see the REXX List System LPULL command “LPULL” on page 303.

Example

```
Say 'Do you want to erase the file? Answer Yes or No:'
Pull answer .
if answer='NO' then say 'The file will not be erased.'
```

Here the dummy placeholder, a period (.), is used on the template to isolate the first word the user enters.

If the external data queue is empty, a console read is issued and the program pauses, if necessary, until a line is complete.

The QUEUED built-in function (see [“QUEUED” on page 211](#)) returns the number of lines currently in the program stack.

PUSH

PUSH stacks the string resulting from the evaluation of *expression* LIFO (Last In, First Out) onto the external data queue.

➤ PUSH ————— ; ➤
 └── *expression* ─┘

If you do not specify *expression*, a null string is stacked.

Note: The REXX/CICS implementation of the external data queue is the program stack. The language processor reads a line from the program stack. If the program stack is empty, a terminal read occurs. The program stack for you is in an RLS queue named `\SYSTEM\userid*PROGSTACK*`.

For information on named queues, see the REXX List System LPUSH command, [“LPUSH” on page 304](#).

Example

```
a='Fred'
push      /* Puts a null line onto the queue */
push a 2  /* Puts "Fred 2" onto the queue */
```

The QUEUED built-in function (described in [“QUEUED” on page 211](#)) returns the number of lines currently in the external data queue.

QUEUE

QUEUE appends the string resulting from *expression* to the tail of the external data queue. That is, it is added FIFO (First In, First Out).

➤ QUEUE ————— ; ➤
 └── *expression* ─┘

If you do not specify *expression*, a null string is queued.

Note: The REXX/CICS implementation of the external data queue is the program stack. The language processor reads a line from the program stack. If the program stack is empty, a terminal read occurs. The program stack for you is in an RLS queue named `\SYSTEM\userid*PROGSTACK*`.

Example

```
a='Toft'
queue a 2 /* Enqueues "Toft 2" */
queue    /* Enqueues a null line behind the last */
```

The QUEUED built-in function (described in [“QUEUED” on page 211](#)) returns the number of lines currently in the external data queue.

RETURN

RETURN returns control (and possibly a result) from a REXX program or internal routine to the point of its invocation.

➤ RETURN  ; ➤

If no internal routine (subroutine or function) is active, RETURN and EXIT are identical in their effect on the program that is being run. See [“EXIT” on page 170](#).

If a subroutine is being run (see the CALL instruction), *expression* (if any) is evaluated, control passes back to the caller, and the REXX special variable RESULT is set to the value of *expression*. If *expression* is omitted, the special variable RESULT is dropped (becomes uninitialized). The various settings saved at the time of the CALL (such as tracing and addresses) are also restored. See [“CALL” on page 163](#).

If a function is being processed, the action taken is identical, except that *expression* must be specified on the RETURN instruction. The result of *expression* is then used in the original expression at the point where the function was called. See the description of functions in [Chapter 19, “Functions,” on page 191](#) for more details.

If a PROCEDURE instruction was processed within the routine (subroutine or internal function), all variables of the current generation are dropped (and those of the previous generation are exposed) after *expression* is evaluated and before the result is used or assigned to RESULT.

SAY

SAY writes a line to the default output stream (the terminal) so the user sees it displayed.

➤ SAY  ; ➤

The result of *expression* can be of any length. If you omit *expression*, the null string is written.

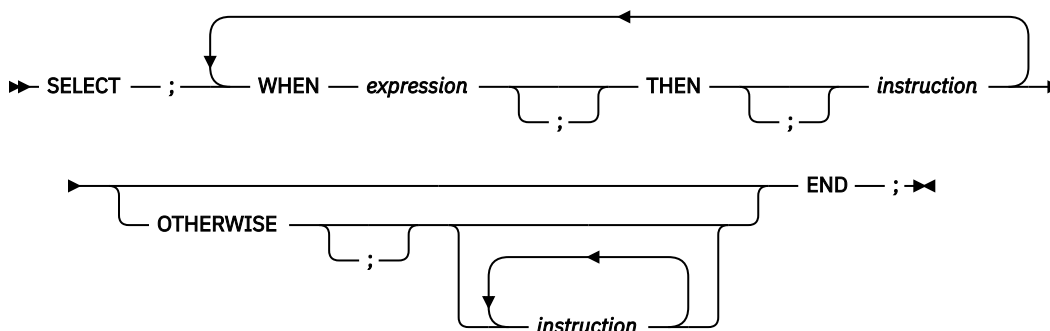

You can use the SET TERMOUT command to redirect SAY output.

Example

```
data=100
Say data 'divided by 4 =>' data/4
/* Displays: "100 divided by 4 => 25" */
```

SELECT

SELECT conditionally calls one of several alternative instructions.

To control trapping, you specify OFF or ON and the condition you want to trap. OFF turns off the specified condition trap. ON turns on the specified condition trap. See [Chapter 22, “Conditions and condition traps,”](#) on page 249.

To change the flow of control, a label name is derived from *labelname* or taken from the result of evaluating the *expression* after VALUE. The *labelname* you specify must be a literal string or symbol that is taken as a constant. If you use a symbol for *labelname*, the search is independent of alphabetic case. If you use a literal string, the characters should be in uppercase. This is because the language processor translates all labels to uppercase, regardless of how you enter them in the program. Similarly, for SIGNAL VALUE, the *expression* must evaluate to a string in uppercase or the language processor does not find the label. You can omit the subkeyword VALUE if *expression* does not begin with a symbol or literal string (that is, if it starts with a special character, such as an operator character or parenthesis). All active pending DO, IF, SELECT, and INTERPRET instructions in the current routine are then ended (that is, they cannot be resumed). Control then passes to the first label in the program that matches the given name, as though the search had started from the top of the program.

Example

```
Signal fred; /* Transfer control to label FRED below */
....
....
Fred: say 'Hi!'
```

Because the search effectively starts at the top of the program, control always passes to the first occurrence, if duplicates are present, of the label in the program.

When control reaches the specified label, the line number of the SIGNAL instruction is assigned to the special variable SIGL. This can aid debugging because you can use SIGL to determine the source of a transfer of control to a label.

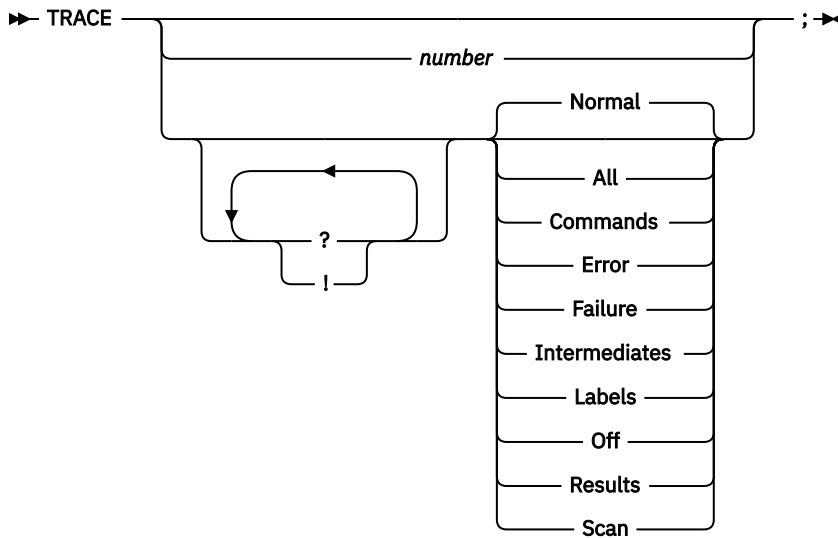

Using SIGNAL VALUE

The VALUE form of the SIGNAL instruction allows a branch to a label whose name is determined at the time of execution. This can safely effect a multi-way CALL (or function call) to internal routines because any DO loops, and so forth, in the calling routine are protected against termination by the call mechanism. For example:

```
fred='PETE'
call multiway fred, 7
....
....
exit
Multiway: procedure
  arg label .          /* One word, uppercase          */
                      /* Can add checks for valid labels here */
  signal value label   /* Transfer control to wherever      */
  ....
Pete: say arg(1) '!' arg(2) /* Displays: "PETE ! 7"          */
return
```

TRACE

TRACE controls the tracing action (that is, how much is displayed to the user) during processing of a REXX program.

Alternatively:

Tracing describes some or all of the clauses in a program, producing descriptions of clauses as they are processed. TRACE is mainly used for debugging. Its syntax is more concise than that of other REXX instructions because TRACE is usually entered manually during interactive debugging. (This is a form of tracing in which the user can interact with the language processor while the program is running.) For this use, economy of key strokes is especially convenient.

If specified, the *number* must be a whole number.

The *string* or *expression* evaluates to:

- A numeric option
- One of the valid prefix or alphabetic character (word) options described later
- Null.

The *symbol* is taken as a constant, and is, therefore:

- A numeric option
- One of the valid prefix or alphabetic character (word) options described later.

The option that follows TRACE or the result of evaluating *expression* determines the tracing action. You can omit the subkeyword VALUE if *expression* does not begin with a symbol or a literal string (that is, if it starts with a special character, such as an operator or parenthesis).

Alphabetic character (word) options

Although you can enter the word in full, only the capitalized and highlighted letter is needed; all characters following it are ignored. That is why these are referred to as alphabetic character options. See [“Commands to External Environments”](#) on page 155 for definitions of ERROR and FAILURE.

TRACE actions correspond to the alphabetic character options as follows:

All

Traces (that is, displays) all clauses before execution.

Commands

Traces all commands before execution. If the command results in an error or failure, tracing also displays the return code from the command.

Error

Traces any command resulting in an error or failure after execution, together with the return code from the command.

Failure

Traces any command resulting in a failure after execution, together with the return code from the command. This is the same as the `Normal` option.

Intermediates

Traces all clauses before execution. Also traces intermediate results during evaluation of expressions and substituted names.

Labels

Traces only labels passed during execution. This is especially useful with debug mode, when the language processor pauses after each label. It also helps the user to note all internal subroutine calls and transfers of control because of the `SIGNAL` instruction.

Normal

Traces any command resulting in a negative return code after execution, together with the return code from the command. **This is the default setting.**

Off

Traces nothing and resets the special prefix options (described later) to OFF.

Results

Traces all clauses before execution. Displays final results (contrast with `Intermediates`, preceding) of evaluating an expression. Also displays values assigned during `PULL`, `ARG`, and `PARSE` instructions. **This setting is recommended for general debugging.**

Scan

Traces all remaining clauses in the data without them being processed. Basic checking (for missing `ENDs` and so forth) is carried out, and the trace is formatted as usual. This is valid only if the `TRACE S` clause itself is not nested in any other instruction (including `INTERPRET` or interactive debug) or in an internal routine.

Prefix options

The prefixes `!` and `?` are valid either alone or with one of the alphabetic character options. You can specify both prefixes, in any order, on one `TRACE` instruction. You can specify a prefix more than one time. Each occurrence of a prefix on an instruction reverses the action of the previous prefix. The prefix(es) must immediately precede the option (no intervening blanks).

The prefixes `!` and `?` modify tracing and execution as follows:

?

Controls interactive debug. During usual execution, a `TRACE` option with a prefix of `?` causes interactive debug to be switched on. See [“Interactive debugging of programs”](#) on page 475. While interactive debug is on, interpretation pauses after most clauses that are traced. For example, the instruction `TRACE ?E` makes the language processor pause for input after executing any command that returns an error (that is, a nonzero return code).

Any TRACE instructions in the program being traced are ignored. (This is so that you do not exit from interactive debug unexpectedly.)

You can switch off interactive debug in several ways:

- Entering TRACE 0 turns off all tracing.
- Entering TRACE with no options restores the defaults. It turns off interactive debug but continues tracing with TRACE Normal (which traces any failing command after execution) in effect.
- Entering TRACE ? turns off interactive debug and continues tracing with the current option.
- Entering a TRACE instruction with a ? prefix before the option turns off interactive debug and continues tracing with the new option.

Using the ? prefix, therefore, switches you alternately in or out of interactive debug. (Because the language processor ignores any further TRACE statements in your program after you are in interactive debug, use CALL TRACE '?' to turn off interactive debug.)

!

Inhibits host command execution. During regular execution, a TRACE instruction with a prefix of ! suspends execution of all subsequent host commands. For example, TRACE !C causes commands to be traced but not processed. As each command is bypassed, the REXX special variable RC is set to 0. You can use this action for debugging potentially destructive programs. This does not inhibit any commands entered manually while in interactive debug. These are always processed.

You can switch off command inhibition, when it is in effect, by issuing a TRACE instruction with a prefix !. Repeated use of the ! prefix, therefore, switches you alternately in or out of command inhibition mode. Or, you can turn off command inhibition at any time by issuing TRACE 0 or TRACE with no options.

Numeric options

If interactive debug is active and if the option specified is a positive whole number (or an expression that evaluates to a positive whole number), that number indicates the number of debug pauses to be skipped over. (See [“Interactive debugging of programs”](#) on page 475.) However, if the option is a negative whole number (or an expression that evaluates to a negative whole number), all tracing, including debug pauses, is temporarily inhibited for the specified number of clauses. For example, TRACE -100 means that the next 100 clauses that would usually be traced are not, in fact, displayed. After that, tracing resumes as before.

Tracing tips

1. When a loop is being traced, the DO clause itself is traced on every iteration of the loop.
2. You can retrieve the trace actions currently in effect by using the TRACE built-in function (see [“TRACE”](#) on page 217).
3. If available at the time of execution, comments associated with a traced clause are included in the trace, as are comments in a null clause, if you specify TRACE A, R, I, or S.
4. Commands traced before execution always have the final value of the command (that is, the string passed to the environment), and the clause generating it produced in the traced output.
5. Trace actions are automatically saved across subroutine and function calls. See [“CALL”](#) on page 163.

Example

One of the most common traces to use is:

```
TRACE ?R
/* Interactive debug is switched on if it was off, */
/* and tracing Results of expressions begins.      */
```

Format of TRACE output

Every clause traced appears with automatic formatting (indentation) according to its logical depth of nesting and so forth. The language processor may replace any control codes in the encoding of data (for example, EBCDIC values less than '40'x) with a question mark (?) to avoid console interference. Results (if requested) are indented an extra two spaces and are enclosed in double quotation marks so that leading and trailing blanks are apparent.

A line number precedes the first clause traced on any line. If the line number is greater than 99999, the language processor truncates it on the left, and the ? prefix indicates the truncation. For example, the line number 100354 appears as ?00354. All lines displayed during tracing have a three-character prefix to identify the type of data being traced. These can be:

-

Identifies the source of a single clause, that is, the data actually in the program.

+++

Identifies a trace message. This may be the nonzero return code from a command, the prompt message when interactive debug is entered, an indication of a syntax error when in interactive debug, or the traceback clauses after a syntax error in the program.

>>>

Identifies the result of an expression (for TRACE R) or the value assigned to a variable during parsing, or the value returned from a subroutine call.

>.>

Identifies the value "assigned" to a placeholder during parsing (see [“The period as placeholder” on page 226](#)).

The following prefixes are used only if TRACE Intermediates is in effect:

>C>

The data traced is the name of a compound variable, traced after substitution and before use, provided that the name had the value of a variable substituted into it.

>F>

The data traced is the result of a function call.

>L>

The data traced is a literal (string, uninitialized variable, or constant symbol).

>O>

The data traced is the result of an operation on two terms.

>P>

The data traced is the result of a prefix operation.

>V>

The data traced is the contents of a variable.

If no option is specified on a TRACE instruction, or if the result of evaluating the expression is null, the default tracing actions are restored. The defaults are TRACE N, command inhibition (!) off, and interactive debug (?) off.

Following a syntax error that SIGNAL ON SYNTAX does not trap, the clause in error is always traced. Any CALL or INTERPRET or function invocations active at the time of the error are also traced. If an attempt to transfer control to a label that could not be found caused the error, that label is also traced. The special trace prefix +++ identifies these traceback lines.

UPPER

UPPER translates the contents of one or more variables to uppercase. The variables are translated in sequence from left to right.

This is a non-SAA instruction provided in REXX/CICS.

The *variable* is a symbol, separated from any other *variables* by one or more blanks or comments. Specify only simple symbols and compound symbols. See [“Simple Symbols” on page 152](#).

Using this instruction is more convenient than repeatedly invoking the `TRANSLATE` built-in function.

Example

```
a1='Hello';  b1='there'
Upper a1 b1
say a1 b1    /* Displays "HELLO THERE" */
```

An error is signaled if a constant symbol or a stem is encountered. Using an uninitialized variable is not an error, and has no effect, except that it is trapped if the `NOVALUE` condition (`SIGNAL ON NOVALUE`) is enabled.

Chapter 19. Functions

A *function* is an internal, built-in, or external routine that returns a single result string. (A *subroutine* is a function that is an internal, built-in, or external routine that may or may not return a result and that is called with the CALL instruction.)

Syntax

A *function call* is a term in an expression that calls a routine that carries out some procedures and returns a string. This string replaces the function call in the continuing evaluation of the expression.

You can include function calls to internal and external routines in an expression anywhere that a data term (such as a string) would be valid, using the notation:

The *function_name* is a literal string or a single symbol, which is taken to be a constant.

There can be up to an implementation-defined maximum number of expressions, separated by commas, between the parentheses. In REXX/CICS, the implementation maximum is up to 20 expressions. These expressions are called the *arguments* to the function. Each argument expression may include further function calls.

The left parenthesis must be adjacent to the name of the function, with no blank in between, or the construct is not recognized as a function call. (A blank operator would be assumed at this point instead.) Only a comment (which has no effect) can appear between the name and the left parenthesis.

The arguments are evaluated in turn from left to right and the resulting strings are all then passed to the function. This then runs some operation (usually dependent on the argument strings passed, though arguments are not mandatory) and eventually returns a single character string. This string is then included in the original expression just as though the entire function reference had been replaced by the name of a variable whose value is that returned data.

For example, the function SUBSTR is built-in to the language processor (see section [“SUBSTR \(Substring\)”](#) on page 214) and could be used as:

```
N1='abcdefghijk'  
Z1='Part of N1 is: 'substr(N1,2,7)  
/* Sets Z1 to 'Part of N1 is: bcdefgh' */
```

A function can have a variable number of arguments. You need to specify only those that are required. For example, SUBSTR('ABCDEF' , 4) would return DEF.

Functions and subroutines

The function calling mechanism is identical to that for subroutines. The only difference between functions and subroutines is that functions must return data, whereas subroutines do not need to.

The following types of routines can be called as functions:

Internal

If the routine name exists as a label in the program, the current processing status is saved, so that it is later possible to return to the point of invocation to resume execution. Control is then passed to the first label in the program that matches the name. As with a routine called by the CALL instruction, various other status information (such as TRACE and NUMERIC settings) is saved too. For details, see the CALL instruction ([“CALL” on page 163](#)). You can use SIGNAL and CALL together to call an internal

routine whose name is determined at the time of execution; this is known as a multi-way call (see [“SIGNAL” on page 183](#)).

If you are calling an internal routine as a function, you must specify an expression in any RETURN instruction to return from it. This is not necessary if it is called as a subroutine. For example:

```
/* Recursive internal function execution... */
arg x
say x'!' = factorial(x)
exit

factorial: procedure /* Calculate factorial by */
  arg n             /* recursive invocation. */
  if n=0 then return 1
  return factorial(n-1) * n
```

While searching for an internal label, syntax checking is performed and the exec is tokenized. See [Performance considerations](#) for more details. FACTORIAL is unusual in that it calls itself (this is recursive invocation). The PROCEDURE instruction ensures that a new variable n is created for each invocation.

Note: When there is a search for a routine, the language processor currently scans the statements in the REXX program to locate the internal label. During the search, the language processor might encounter a syntax error. As a result, a syntax error might be raised on a statement different from the original line being processed.

Built-in

These functions are always available and are defined in [“Built-in Functions” on page 194](#).

External

You can write or use functions that are external to your program and to the language processor. External routines must be written in REXX. You can call a REXX program as a function and, in this case, pass more than one argument string. The ARG or PARSE ARG instructions or the ARG built-in function can retrieve these argument strings. When called as a function, a program must return data to the caller.

Note:

1. External REXX functions can easily perform an EXEC CICS LINK to a program written in any CICS-supported language. Also, REXX/CICS command routines can be written in assembler.
2. Calling an external REXX program as a function is similar to calling an internal routine. The external routine is, however, an implicit PROCEDURE in that all the caller's variables are always hidden and the status of internal values (such as NUMERIC settings) start with their defaults (rather than inheriting those of the caller).
3. Other REXX programs can be called as functions. You can use either EXIT or RETURN to leave the called REXX program, and in either case you must specify an expression.
4. With care, you can use the INTERPRET instruction to process a function with a variable function name. However, avoid this if possible because it reduces the clarity of the program.

Search order

The search order for functions is: internal routines, built-in functions, external functions.

Internal routines are not used if the function name is given as a literal string (that is, specified in quotation marks); in this case, the function must be built-in or external. This lets you usurp the name of, say, a built-in function to extend its capabilities, yet still be able to call the built-in function when needed. For example:

```
/* This internal DATE function modifies the */
/* default for the DATE function to standard date. */
date: procedure
  arg in
  if in='' then in='Standard'
  return 'DATE'(in)
```

Built-in functions have uppercase names, and so the name in the literal string must be in uppercase for the search to succeed, as in the example. The same is usually true of external functions.

External functions and subroutines have a system-defined search order.

Whenever an exec, command, external function, or subroutine that is written in REXX is invoked by REXX/CICS (for example, from the CICS command line, CALL instruction, EXEC command, or a command in an exec), the search order for locating the target exec is as follows:

- Search order for a DEFCMD defined command exec or other called exec.

If this is an attempt to execute an authorized command, a check is made to see if this is an authorized user or the command is in an exec loaded from ddname CICEXEC or CICAUTH. If none of these are true, the command fails with a return code of -4.

1. In the current exec for an internal function or subroutine.

This search can be bypassed by explicitly identifying the function (or subroutine) as external by enclosing its name in quotes.

2. Execs in storage (from an earlier EXECLOAD).
3. The current RFS directory.
4. The current PATH. RFS directories and MVS partitioned data sets are searched in the order listed in the most recent PATH command, if it was executed. See [“PATH” on page 398](#).
5. PDS data sets allocated (or concatenated) to ddname CICAUTH.

If user is an authorized user or if the current exec was loaded from CICEXEC and the search is for an authorized command's program, then check CICAUTH ddname.

6. PDS data sets allocated (or concatenated) to ddname CICEXEC.
7. PDS data sets allocated (or concatenated) to ddname CICUSER.

For more information on the DEFCMD command, see [“DEFCMD” on page 377](#).

Note:

1. The only MVS dataset type that REXX/CICS execs invoke from is the MVS Partitioned Organization (DSORG=PO). MVS sequential data sets (DSORG=PS) are not supported.
2. REXX execs residing in MVS partitioned data sets may not have sequence numbers in columns 73 through 80.
3. An attempt is made to dynamically allocate (by SVC 99) any MVS partitioned data sets specified on the last PATH statement, if the target exec has not been located before the dataset name is reached (when processing the PATH list from left to right).
4. The DEFSCMD AUTH parameter is used to specify that a REXX/CICS command is an authorized command.
5. EXECLOAD and EXECDROP commands are authorized commands and will allow only REXX/CICS authorized users or execs loaded from CICEXEC to execute them.

Errors during execution

If an external or built-in function detects any error, the language processor is informed and a syntax error results. Execution of the clause that included the function call is, therefore, ended. Similarly, if an external function fails to return data correctly, the language processor detects this and reports it as an error.

If a syntax error occurs during the execution of an internal function, it can be trapped (using SIGNAL ON SYNTAX) and recovery may then be possible. If the error is not trapped, the program is ended.

Built-in Functions

REXX provides a rich set of built-in functions, including character manipulation, conversion, and information functions.

Other built-in and external functions are generally available; see [“External Functions Provided in REXX/CICS”](#) on page 223.

General notes on the built-in functions are as follows:

- The parentheses in a function are always needed, even if no arguments are required. The first parenthesis must follow the name of the function with no space in between.
- The built-in functions work internally with NUMERIC DIGITS 9 and NUMERIC FUZZ 0 and are unaffected by changes to the NUMERIC settings, except where stated. Any argument named as a *number* is rounded, if necessary, according to the current setting of NUMERIC DIGITS (just as though the number had been added to 0) and checked for validity before use. This occurs in the following functions: ABS, FORMAT, MAX, MIN, SIGN, and TRUNC, and for certain options of DATATYPE. This is not true for RANDOM.
- Any argument named as a *string* can be a null string.
- If an argument specifies a *length*, it must be a positive whole number or zero. If it specifies a start character or word in a string, it must be a positive whole number, unless otherwise stated.
- Where the last argument is optional, you can always include a comma to indicate that you omitted it; for example, DATATYPE (1,), like DATATYPE(1), would return NUM. You can include any number of trailing commas; they are ignored. (Where there are actual parameters, the default values apply.)
- If you specify a *pad* character, it must be exactly one character long. (A pad character extends a string, usually on the right. For an example, see the LEFT built-in function [“LEFT” on page 209.](#))
- If a function has an *option* you can select by specifying the first character of a string, that character can be in upper- or lowercase.
- Some built-in functions support DBCS. For a complete list and descriptions of these functions, see Chapter 33, “Double-Byte Character Set (DBCS) Support,” on page 457.

ABBREV (Abbreviation)

The ABBREV function returns 1 if *info* is equal to the leading characters of *information* **and** the length of *info* is not less than *length*. ABBREV returns 0 if either of these conditions is not met.

► ABBREV(— information — , — info —) ◀

If you specify *length*, it must be a positive whole number or zero. The default for *length* is the number of characters in *info*.

Examples

```

ABBREV('Print','Pri')      -> 1
ABBREV('PRINT','Pri')      -> 0
ABBREV('PRINT','PRI',4)    -> 0
ABBREV('PRINT','PRY')      -> 0
ABBREV('PRINT','')         -> 1
ABBREV('PRINT','',1)       -> 0

```

Note: A null string always matches if a length of 0 (or the default) is used. This allows a default keyword to be selected automatically; for example:

```
say 'Enter option:'; pull option .
select /* keyword1 is to be the default */
  when abbrev('keyword1',option) then ...
  when abbrev('keyword2',option) then ...
```

```
...
otherwise nop;
end;
```

ABS (Absolute Value)

The ABS function returns the absolute value of *number*. The result has no sign and is formatted according to the current NUMERIC settings.

➡ ABS(— *number* —) ➡

Examples

```
ABS('12.3')      ->    12.3
ABS('-0.307')     ->    0.307
```

ADDRESS

The ADDRESS function returns the name of the environment to which commands are currently being submitted. The environment may be a name of a subcommand environment.

➡ ADDRESS(—) ➡

See the ADDRESS instruction ([“ADDRESS” on page 161](#)) for more information. Trailing blanks are removed from the result.

Examples

```
ADDRESS()      ->    'CICS'      /* default under CICS */
ADDRESS()      ->    'EDITSVR'   /* default under CICS editor */
```

ARG (Argument)

The ARG function returns an argument string or information about the argument strings to a program or internal routine.

➡ ARG(—————) ➡

└─ *n* ─┘

└─ , — *option* ─┘

If you do not specify *n*, the number of arguments passed to the program or internal routine is returned.

If you specify only *n*, the *n*th argument string is returned. If the argument string does not exist, the null string is returned. The *n* must be a positive whole number.

If you specify *option*, ARG tests for the existence of the *n*th argument string. The following are valid options. (Only the capitalized and highlighted letter is needed; all characters following it are ignored.)

Exists

returns 1 if the *n*th argument exists; that is, if it was explicitly specified when the routine was called.
Returns 0 otherwise.

Omitted

returns 1 if the *n*th argument was omitted; that is, if it was not explicitly specified when the routine was called. Returns 0 otherwise.

Examples

```

/* following "Call name;" (no arguments) */
ARG()      -> 0
ARG(1)     -> ''
ARG(2)     -> ''
ARG(1,'e') -> 0
ARG(1,'0') -> 1

/* following "Call name 'a',,'b';" */
ARG()      -> 3
ARG(1)     -> 'a'
ARG(2)     -> ''
ARG(3)     -> 'b'
ARG(n)     -> '' /* for n>=4 */
ARG(1,'e') -> 1
ARG(2,'E') -> 0
ARG(2,'0') -> 1
ARG(3,'o') -> 0
ARG(4,'o') -> 1

```

Note:

1. The number of argument strings is the largest number *n* for which ARG(*n*, 'e') would return 1 or 0 if there are no explicit argument strings. That is, it is the position of the last explicitly specified argument string.
2. Programs called as commands can have only 0 or 1 argument strings. The program has 0 argument strings if it is called with the name only and has 1 argument string if anything else (including blanks) is included with the command.
3. You can retrieve and directly parse the argument strings to a program or internal routine with the ARG or PARSE ARG instructions. (See [“ARG”](#) on page 162, [“PARSE”](#) on page 176, and [Chapter 20](#), [“Parsing,”](#) on page 225.)

BITAND (Bit by Bit AND)

The BITAND function returns a string composed of the two input strings logically ANDed together, bit by bit.

The encodings of the strings are used in the logical operation. The length of the result is the length of the longer of the two strings. If no *pad* character is provided, the AND operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If *pad* is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for *string2* is the zero length (null) string.

Examples

```

BITAND('12'x)      -> '12'x
BITAND('73'x,'27'x) -> '23'x
BITAND('13'x,'5555'x) -> '1155'x
BITAND('13'x,'5555'x,'74'x) -> '1154'x
BITAND('pQrS',,'BF'x) -> 'pqrs' /* EBCDIC */

```

BITOR (Bit by Bit OR)

The BITOR function returns a string composed of the two input strings logically inclusive-ORed together, bit by bit.

The encodings of the strings are used in the logical operation. The length of the result is the length of the longer of the two strings. If no *pad* character is provided, the OR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If *pad* is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for *string2* is the zero length (null) string.

Examples

```
BITOR('12'x)          -> '12'x
BITOR('15'x, '24'x)    -> '35'x
BITOR('15'x, '2456'x)  -> '3556'x
BITOR('15'x, '2456'x, 'F0'x) -> '35F6'x
BITOR('1111'x, '4D'x)  -> '5D5D'x
BITOR('pQrS', '40'x)   -> 'PQRS' /* EBCDIC */
```

BITXOR (Bit by Bit Exclusive OR)

The BITXOR function returns a string composed of the two input strings logically eXclusive-ORed together, bit by bit.

The encodings of the strings are used in the logical operation. The length of the result is the length of the longer of the two strings. If no *pad* character is provided, the XOR operation stops when the shorter of the two strings is exhausted, and the unprocessed portion of the longer string is appended to the partial result. If *pad* is provided, it extends the shorter of the two strings on the right before carrying out the logical operation. The default for *string2* is the zero length (null) string.

Examples

```
BITXOR('12'x)          -> '12'x
BITXOR('12'x, '22'x)    -> '30'x
BITXOR('1211'x, '22'x)  -> '3011'x
BITXOR('1111'x, '444444'x) -> '555544'x
BITXOR('1111'x, '444444'x, '40'x) -> '555504'x
BITXOR('1111'x, '4D'x)  -> '5C5C'x
BITXOR('C711'x, '222222'x, ' ') -> 'E53362'x /* EBCDIC */
```

B2X (Binary to Hexadecimal)

The B2X function returns a string, in character format, that represents *binary_string* converted to hexadecimal.

The *binary_string* is a string of binary (0 or 1) digits. It can be of any length. You can optionally include blanks in *binary_string* (at four-digit boundaries only, not leading or trailing) to aid readability; they are ignored.

If *binary_string* is the null string, B2X returns a null string. If the number of binary digits in *binary_string* is not a multiple of four, then up to three 0 digits are added on the left before the conversion to make a total that is a multiple of four.

```
B2X('11000011')    -> 'C3'
B2X('10111')        -> '17'
B2X('101')           -> '5'
B2X('1 1111 0000')  -> '1F0'
```

```
X2D(B2X('10111'))  ->  '23'    /* decimal 23 */
```

The `CENTER` or `CENTRE` function returns a string of length *length* with *string* centered in it, with *pad* characters added as necessary to make up length.

The *length* must be a positive whole number or zero. The default *pad* character is blank. If the string is longer than *length*, it is truncated at both ends to fit. If an odd number of characters are truncated or added, the right-hand end loses or gains one more character than the left-hand end.

```
CENTER(abc,7)          -> '  ABC  '
CENTER(abc,8,'-')      -> '--ABC--'
CENTRE('The blue sky',8) -> 'e blue s'
CENTRE('The blue sky',7) -> 'e blue '
```

The COMPARE function returns 0 if the strings, *string1* and *string2*, are identical. Otherwise, returns the position of the first character that does not match.

```
COMPARE('abc','abc')      -> 0
COMPARE('abc','ak')        -> 2
COMPARE('ab','ab')         -> 0
COMPARE('ab','ab','')      -> 0
COMPARE('ab','ab','x')     -> 3
COMPARE('ab--','ab','-')   -> 5
```

CONDITION

The `CONDITION` function returns the condition information associated with the current trapped condition.

➡ `CONDITION(— option —)` ➡

See [Chapter 22, “Conditions and condition traps,”](#) on page 249 for a description of condition traps. You can request the following information:

- The name of the current trapped condition
- Any descriptive string associated with that condition
- The instruction processed as a result of the condition trap (`CALL` or `SIGNAL`)
- The status of the trapped condition.

To select the information to return, use the following options. (Only the capitalized and highlighted letter is needed; all characters following it are ignored.)

Condition name

returns the name of the current trapped condition.

Description

returns any descriptive string associated with the current trapped condition. If no description is available, returns a null string.

Instruction

returns either `CALL` or `SIGNAL`, the keyword for the instruction processed when the current condition was trapped. This is the default if you omit *option*.

Status

returns the status of the current trapped condition. This can change during processing, and can be:

- ON - the condition is enabled
- OFF - the condition is disabled
- DELAY - any new occurrence of the condition is delayed or ignored.

If no condition has been trapped, the `CONDITION` function returns a null string in all four cases.

Examples

```
CONDITION()      -> 'CALL'      /* perhaps */
CONDITION('C')   -> 'FAILURE'
CONDITION('I')    -> 'CALL'
CONDITION('D')    -> 'FailureTest'
CONDITION('S')    -> 'OFF'       /* perhaps */
```

Note: The `CONDITION` function returns condition information that is saved and restored across subroutine calls (including those a `CALL ON` condition trap causes). Therefore, after a subroutine called with `CALL ON trapname` has returned, the current trapped condition reverts to the condition that was current before the `CALL` took place (which might be none). `CONDITION` returns the values it returned before the condition was trapped.

COPIES

The `COPIES` function returns *n* concatenated copies of *string*. The *n* must be a positive whole number or zero.

➡ `COPIES(— string — , — n —)` ➡

Examples

```
COPIES('abc',3)    -> 'abcbcabcb'
COPIES('abc',0)    -> ''
```

C2D (Character to Decimal)

The C2D function returns the decimal value of the binary representation of *string*.

➡ C2D(— *string* — , — *n* —) ➡

If the result cannot be expressed as a whole number, an error results. That is, the result must not have more digits than the current setting of NUMERIC DIGITS. If you specify *n*, it is the length of the returned result. If you do not specify *n*, *string* is processed as an unsigned binary number.

If *string* is null, returns 0.

Implementation maximum: The input string cannot have more than 250 characters that are significant in forming the final result. Leading sign characters ('00'x and 'FF'x) do not count toward this total.

Examples

```
C2D('09'X)    ->      9
C2D('81'X)    ->     129
C2D('FF81'X)  ->    65409
C2D('')       ->      0
C2D('a')      ->     129    /* EBCDIC */
```

If you specify *n*, the string is taken as a signed number expressed in *n* characters. The number is positive if the leftmost bit is off, and negative, in two's complement notation, if the leftmost bit is on. In both cases, it is converted to a whole number, which may, therefore, be negative. The *string* is padded on the left with '00'x characters (note, not “sign-extended”), or truncated on the left to *n* characters. This padding or truncation is as though RIGHT(*string*,*n*, '00'x) had been processed. If *n* is 0, C2D always returns 0.

```
C2D('81'X,1)   ->    -127
C2D('81'X,2)   ->     129
C2D('FF81'X,2) ->    -127
C2D('FF81'X,1) ->    -127
C2D('FF7F'X,1) ->     127
C2D('F081'X,2) ->   -3967
C2D('F081'X,1) ->    -127
C2D('0031'X,0) ->      0
```

C2X (Character to Hexadecimal)

The C2X function returns a string, in character format, that represents *string* converted to hexadecimal.

➡ C2X(— *string* —) ➡

The returned string contains twice as many bytes as the input string. For example, on an EBCDIC system, C2X(1) returns F1 because the EBCDIC representation of the character 1 is 'F1'X.

The string returned uses uppercase alphabetic for the values A-F and does not include blanks. The *string* can be of any length. If *string* is null, returns a null string.

Examples

```
C2X('72s')    -> 'F7F2A2' /* 'C6F7C6F2C1F2'X in EBCDIC */
C2X('0123'X)  -> '0123'  /* 'F0F1F2F3'X   in EBCDIC */
```

DATATYPE

The DATATYPE function returns NUM if you specify only *string* and if *string* is a valid REXX number that can be added to 0 without error. DATATYPE returns CHAR if *string* is not a valid number.

➤ DATATYPE(— *string* — , — *type* —) ➤

If you specify *type*, returns 1 if *string* matches the type; otherwise returns 0. If *string* is null, the function returns 0 (except when *type* is X, which returns 1 for a null string). The following are valid *types*. Only the capitalized letter is needed; all characters following it are ignored. For the hexadecimal option, you must start your string specifying the name of the option with x rather than h.)

Alphanumeric

returns 1 if *string* contains only characters from the ranges a-z, A-Z, and 0-9.

Binary

returns 1 if *string* contains only the characters 0 or 1 or both.

C

returns 1 if *string* is a mixed SBCS/DBCS string.

Dbcs

returns 1 if *string* is a DBCS-only string enclosed by SO and SI bytes.

Lowercase

returns 1 if *string* contains only characters from the range a-z.

Mixed case

returns 1 if *string* contains only characters from the ranges a-z and A-Z.

Number

returns 1 if *string* is a valid REXX number.

Symbol

returns 1 if *string* contains only characters that are valid in REXX symbols. (See [“Tokens” on page 141.](#)) Note that both uppercase and lowercase alphabetics are permitted.

Uppercase

returns 1 if *string* contains only characters from the range A-Z.

Whole number

returns 1 if *string* is a REXX whole number under the current setting of NUMERIC DIGITS.

heXadecimal

returns 1 if *string* contains only characters from the ranges a-f, A-F, 0-9, and blank (as long as blanks appear only between pairs of hexadecimal characters). Also returns 1 if *string* is a null string, which is a valid hexadecimal string.

Note: The DATATYPE function tests the meaning or type of characters in a string, independent of the encoding of those characters (for example, ASCII or EBCDIC).

Examples

```
DATATYPE(' 12 ') -> 'NUM'
DATATYPE('') -> 'CHAR'
DATATYPE('123*') -> 'CHAR'
DATATYPE('12.3', 'N') -> 1
DATATYPE('12.3', 'W') -> 0
DATATYPE('Fred', 'M') -> 1
DATATYPE('', 'M') -> 0
DATATYPE('Fred', 'L') -> 0
DATATYPE('?20K', 's') -> 1
DATATYPE('BCd3', 'X') -> 1
DATATYPE('BC d3', 'X') -> 1
```

DATE

The DATE function returns, by default, the local date in the format: *dd mon yyyy* (day month year, for example, 13 Mar 1992), with no leading zero or blank on the day.

►► DATE(—————) ◄◄
 option

If the active language has an abbreviated form of the month name, then it is used (for example, Jan or Feb).

You can use the following options to obtain specific formats. Only the capitalized letter is needed; all characters following it are ignored.

Base

returns the number of complete days (that is, not including the current day) since and including the base date, 1 January 0001, in the format: *dddddd* (no leading zeros or blanks). The expression `DATE('B')//7` returns a number in the range 0-6 that corresponds to the current day of the week, where 0 is Monday and 6 is Sunday.

Thus, this function can be used to determine the day of the week independent of the national language in which you are working.

Note: The base date of 1 January 0001 is determined by extending the current Gregorian calendar backward (365 days each year, with an extra day every year that is divisible by 4 except century years that are not divisible by 400). It does not take into account any errors in the calendar system that created the Gregorian calendar originally.

Century

returns the number of days, including the current day, since and including January 1 of the last year that is a multiple of 100 in the format: *dddddd* (no leading zeros). Example: A call to `DATE(C)` on 13 March 1992 returns 33675, the number of days from 1 January 1900 to 13 March 1992. Similarly, a call to `DATE(C)` on 2 January 2000 returns 2, the number of days from 1 January 2000 to 2 January 2000.

Days

returns the number of days, including the current day, so far in this year in the format: *ddd* (no leading zeros or blanks).

European

returns date in the format: *dd/mm/yy*.

Julian

returns date in the format: *yyddd*.

Month

returns full English name of the current month, for example, August.

Normal

returns date in the format: *dd mon yyyy*. **This is the default.**

Ordered

returns date in the format: *yy/mm/dd* (suitable for sorting, and so forth).

Standard

returns date in the format: *yyyymmdd* (suitable for sorting, and so forth).

Usa

returns date in the format: *mm/dd/yy*.

Weekday

returns the English name for the day of the week, in mixed case, for example, Tuesday.

Note: The first call to DATE or TIME in one clause causes a time stamp to be made that is then used for all calls to these functions in that clause. Therefore, multiple calls to any of the DATE or TIME functions or both in a single expression or clause are guaranteed to be consistent with each other.

Examples

The examples assume that today is 13 March 1992:

```
DATE()      -> '13 Mar 1992'
DATE('B')   -> 727269
DATE('C')   -> 33675
DATE('D')   -> 73
DATE('E')   -> '13/03/92'
DATE('J')   -> 92073
DATE('M')   -> 'March'
DATE('N')   -> '13 Mar 1992'
DATE('O')   -> '92/03/13'
DATE('S')   -> '19920313'
DATE('U')   -> '03/13/92'
DATE('W')   -> 'Friday'
```

DBCS (Double-Byte Character Set Functions)

The functions that are part of DBCS processing functions are listed.

- DBADJUST
- DBBRACKET
- DBCENTER
- DBCJUSTIFY
- DBLEFT
- DBRIGHT
- DBRLEFT
- DBRRIGHT
- DBTODBCS
- DBTOSBCS
- DBUNBRACKET
- DBVALIDATE
- DBWIDTH

See [Chapter 33, “Double-Byte Character Set \(DBCS\) Support,”](#) on page 457.

DELSTR (Delete String)

The DELSTR function returns *string* after deleting the substring that begins at the *n*th character and is of *length* characters.

➡ DELSTR(— *string* — , — *n* — ) ➡

If you omit *length*, or if *length* is greater than the number of characters from *n* to the end of *string*, the function deletes the rest of *string* (including the *n*th character). The *length* must be a positive whole number or zero. The *n* must be a positive whole number. If *n* is greater than the length of *string*, the function returns *string* unchanged.

Examples

```
DELSTR('abcd',3)      -> 'ab'
DELSTR('abcde',3,2)    -> 'abe'
DELSTR('abcde',6)      -> 'abcde'
```

DELWORD (Delete Word)

The DELWORD function returns *string* after deleting the substring that starts at the *n*th word and is of *length* blank-delimited words.

➤ DELWORD(— *string* — , — *n* — , — *length* —) ➤

If you omit *length*, or if *length* is greater than the number of words from *n* to the end of *string*, the function deletes the remaining words in *string* (including the *n*th word). The *length* must be a positive whole number or zero. The *n* must be a positive whole number. If *n* is greater than the number of words in *string*, the function returns *string* unchanged. The string deleted includes any blanks following the final word involved but none of the blanks preceding the first word involved.

Examples

```
DELWORD('Now is the time',2,2) -> 'Now time'
DELWORD('Now is the time',3)   -> 'Now is '
DELWORD('Now is the time',5)   -> 'Now is the time'
DELWORD('Now is the time',3,1) -> 'Now is time'
```

DIGITS

The DIGITS function returns the current setting of NUMERIC DIGITS.

➤ DIGITS(—) ➤

See the NUMERIC instruction [“NUMERIC” on page 174](#) for more information.

Example

```
DIGITS() -> 9 /* by default */
```

D2C (Decimal to Character)

The D2C function returns a string, in character format, that represents *wholenumber*, a decimal number, converted to binary.

➤ D2C(— *wholenumber* — , — *n* —) ➤

If you specify *n*, it is the length of the final result in characters; after conversion, the input string is sign-extended to the required length. If the number is too big to fit into *n* characters, then the result is truncated on the left. The *n* must be a positive whole number or zero.

If you omit *n*, *wholenumber* must be a positive whole number or zero, and the result length is as needed. Therefore, the returned result has no leading '00'x characters.

Implementation maximum: The output string may not have more than 250 significant characters, though a longer result is possible if it has additional leading sign characters ('00'x and 'FF'x).

Examples

```
D2C(9)          -> ' ' /* '09'x is unprintable in EBCDIC */
D2C(129)        -> 'a' /* '81'x is an EBCDIC 'a' */
D2C(129,1)      -> 'a' /* '81'x is an EBCDIC 'a' */
D2C(129,2)      -> ' a' /* '0081'x is EBCDIC ' a' */
D2C(257,1)      -> ' ' /* '01'x is unprintable in EBCDIC */
D2C(-127,1)     -> 'a' /* '81'x is EBCDIC 'a' */
D2C(-127,2)     -> ' a' /* 'FF'x is unprintable EBCDIC; */
```

```

D2C(-1,4)    -> ' ' /* '81'x is EBCDIC 'a' */
D2C(12,0)    -> '' /* 'FFFFFFF'x is unprintable in EBCDIC */
               /* '' is a null string */

```

D2X (Decimal to Hexadecimal)

The D2X function returns a string, in character format, that represents *wholenumber*, a decimal number, converted to hexadecimal.

►► D2X(— *wholenumber* — , — *n* —) ►►

The returned string uses uppercase alphabets for the values A-F and does not include blanks.

If you specify *n*, it is the length of the final result in characters; after conversion the input string is sign-extended to the required length. If the number is too big to fit into *n* characters, it is truncated on the left. The *n* must be a positive whole number or zero.

If you omit *n*, *wholenumber* must be a positive whole number or zero, and the returned result has no leading zeros.

Implementation maximum: The output string may not have more than 500 significant hexadecimal characters, though a longer result is possible if it has additional leading sign characters (0 and F).

Examples

```

D2X(9)        -> '9'
D2X(129)       -> '81'
D2X(129,1)     -> '1'
D2X(129,2)     -> '81'
D2X(129,4)     -> '0081'
D2X(257,2)     -> '01'
D2X(-127,2)    -> '81'
D2X(-127,4)    -> 'FF81'
D2X(12,0)      -> ''

```

ERRORTXT

The ERRORTXT function returns the REXX error message associated with error number *n*.

►► ERRORTXT(— *n* —) ►►

The *n* must be in the range 0-99, and any other value is an error. Returns the null string if *n* is in the allowed range but is not a defined REXX error number. See [Chapter 31, “Error numbers and messages,”](#) on page 413 for a complete description of error numbers and messages.

Examples

```

ERRORTXT(16)   -> 'Label not found'
ERRORTXT(60)   -> ''

```

EXTERNALS

The EXTERNALS function returns the number of elements in the terminal input buffer (system external event queue).

►► EXTERNALS(—) ►►

In CICS, there is no equivalent buffer. Therefore, in the CICS implementation of REXX, the EXTERNALS function always returns a 0. For example:

```
EXTERNALS()    ->    0    /* Always */
```

FIND

The FIND function returns the word number of the first word of *phrase* found in *string*, or returns 0 if *phrase* is not found or if there are no words in *phrase*.

WORDPOS is the preferred built-in function for this type of word search. See [“WORDPOS \(Word Position\)”](#) on page 221.

➤ FIND(— *string* — , — *phrase* —) ➤

The *phrase* is a sequence of blank-delimited words. Multiple blanks between words in *phrase* or *string* are treated as a single blank for the comparison.

Examples

```
FIND('now is the time','is the time')    ->    2
FIND('now is the time','is the')         ->    2
FIND('now is the time','is time ')       ->    0
```

FORM

The FORM function returns the current setting of NUMERIC FORM.

➤ FORM(—) ➤

See the NUMERIC instruction [“NUMERIC”](#) on page 174

Example

```
FORM()    ->    'SCIENTIFIC' /* by default */
```

FORMAT

The FORMAT function returns *number*, rounded and formatted.

The *number* is first rounded according to standard REXX rules, just as though the operation *number*+0 had been carried out. The result is precisely that of this operation if you specify only *number*. If you specify any other options, the *number* is formatted as follows.

The *before* and *after* options describe how many characters are used for the integer and decimal parts of the result, respectively. If you omit either or both of these, the number of characters used for that part is as needed.

If *before* is not large enough to contain the integer part of the number (plus the sign for a negative number), an error results. If *before* is larger than needed for that part, the number is padded on the left with blanks. If *after* is not the same size as the decimal part of the number, the number is rounded (or extended with zeros) to fit. Specifying 0 causes the number to be rounded to an integer.

Examples

```
FORMAT('3',4)      -> ' 3'
FORMAT('1.73',4,0) -> ' 2'
FORMAT('1.73',4,3) -> ' 1.730'
FORMAT('- .76',4,1) -> ' -0.8'
FORMAT('3.03',4)   -> ' 3.03'
FORMAT(' -12.73',,4) -> '-12.7300'
FORMAT(' -12.73')  -> '-12.73'
FORMAT('0.000')    -> '0'
```

The first three arguments are as described previously. In addition, *expp* and *expt* control the exponent part of the result, which, by default, is formatted according to the current NUMERIC settings of DIGITS and FORM. The *expp* sets the number of places for the exponent part; the default is to use as many as needed (which may be zero). The *expt* sets the trigger point for use of exponential notation. The default is the current setting of NUMERIC DIGITS.

If *expp* is 0, no exponent is supplied, and the number is expressed in *simple* form with added zeros as necessary. If *expp* is not large enough to contain the exponent, an error results.

If the number of places needed for the integer or decimal part exceeds *expt* or twice *expt*, respectively, exponential notation is used. If *expt* is 0, exponential notation is always used unless the exponent would be 0. (If *expp* is 0, this overrides a 0 value of *expt*.) If the exponent would be 0 when a nonzero *expp* is specified, then *expp*+2 blanks are supplied for the exponent part of the result. If the exponent would be 0 and *expp* is not specified, simple form is used. The *expp* must be less than 10, but there is no limit on the other arguments.

Examples:

```
FORMAT('12345.73',,,2,2) -> '1.234573E+04'
FORMAT('12345.73',,3,,0) -> '1.235E+4'
FORMAT('1.234573',,3,,0) -> '1.235'
FORMAT('12345.73',,,3,6) -> '12345.73'
FORMAT('1234567e5',,3,0) -> '123456700000.000'
```

FUZZ

The FUZZ function returns the current setting of NUMERIC FUZZ.

➡ FUZZ(—) ➡

See the NUMERIC instruction [“NUMERIC” on page 174](#).

Example

```
FUZZ() -> 0 /* by default */
```

INDEX

The INDEX function returns the character position of one string, *needle*, in another, *haystack*, or returns 0 if the string *needle* is not found or is a null string.

POS is the preferred built-in function for obtaining the position of one string in another. See [“POS \(Position\)” on page 211](#).

➡ INDEX(— *haystack* — , — *needle* — , — *start* —) ➡

By default the search starts at the first character of *haystack* (*start* has the value 1). You can override this by specifying a different *start* point, which must be a positive whole number.

Examples

```
INDEX('abcdef','cd')      -> 3
INDEX('abcdef','xd')      -> 0
INDEX('abcdef','bc',3)    -> 0
INDEX('abcabc','bc',3)    -> 5
INDEX('abcabc','bc',6)    -> 0
```

INSERT

The INSERT function inserts the string *new*, padded or truncated to length *length*, into the string *target* after the *n*th character.

➔ INSERT(— *new* — , — *target* —) ➔

The default value for *n* is 0, which means insert before the beginning of the string. If specified, *n* and *length* must be positive whole numbers or zero. If *n* is greater than the length of the target string, padding is added before the string *new* also. The default value for *length* is the length of *new*. If *length* is less than the length of the string *new*, then INSERT truncates *new* to length *length*. The default *pad* character is a blank.

Examples

```
INSERT(' ','abcdef',3)      -> 'abc def'
INSERT('123','abc',5,6)     -> 'abc 123 '
INSERT('123','abc',5,6,'+') -> 'abc++123+++'
INSERT('123','abc')         -> '123abc'
INSERT('123','abc',5,'-')   -> '123--abc'
```

JUSTIFY

The JUSTIFY function returns *string* formatted by adding *pad* characters between blank-delimited words to justify to both margins.

➔ JUSTIFY(— *string* — , — *length* —) ➔

This is done to width *length* (*length* must be a positive whole number or zero). The default *pad* character is a blank.

The first step is to remove extra blanks as though SPACE(*string*) had been run (that is, multiple blanks are converted to single blanks, and leading and trailing blanks are removed). If *length* is less than the width of the changed string, the string is then truncated on the right and any trailing blank is removed. Extra *pad* characters are then added evenly from left to right to provide the required length, and the *pad* character replaces the blanks between words.

Examples

```
JUSTIFY('The blue sky',14) -> 'The blue sky'
JUSTIFY('The blue sky',8)  -> 'The blue'
```

```
JUSTIFY('The blue sky',9)    -> 'The  blue'
JUSTIFY('The blue sky',9,'+') -> 'The++blue'
```

LASTPOS (Last Position)

The LASTPOS function returns the position of the last occurrence of one string, *needle*, in another, *haystack*.

➤ LASTPOS(— *needle* — , — *haystack* — , — *start* —) ➤

LASTPOS returns 0 if *needle* is the null string or is not found. By default the search starts at the last character of *haystack* and scans backward. You can override this by specifying *start*, the point at which the backward scan starts. *start* must be a positive whole number and defaults to LENGTH(*haystack*) if larger than that value or omitted. See also the POS function, “POS (Position)” on page 211.

Examples

```
LASTPOS(' ', 'abc def ghi')    -> 8
LASTPOS(' ', 'abcdefghi')      -> 0
LASTPOS('xy', 'efgxyz')        -> 4
LASTPOS(' ', 'abc def ghi', 7) -> 4
```

LEFT

The LEFT function returns a string of length *length*, containing the leftmost *length* characters of *string*.

➤ LEFT(— *string* — , — *length* — , — *pad* —) ➤

The string returned is padded with *pad* characters (or truncated) on the right as needed. The default *pad* character is a blank. *length* must be a positive whole number or zero. The LEFT function is exactly equivalent to:

➤ SUBSTR — (— *string* — , — 1 — , — *length* — , — *pad* —) ➤

Examples

```
LEFT('abc d', 8)    -> 'abc d   '
LEFT('abc d', 8, '.') -> 'abc d...'
LEFT('abc def', 7)  -> 'abc de'
```

LENGTH

The LENGTH function returns the length of *string*.

➤ LENGTH(— *string* —) ➤

Examples

```
LENGTH('abcdefgh') -> 8
LENGTH('abc defg')  -> 8
LENGTH('')           -> 0
```

LINESIZE

The LINESIZE function returns the current terminal line width (the point at which the language processor breaks lines displayed using the SAY instruction).

➤ LINESIZE(—) ➤

LINESIZE returns a default value of 80 if:

- No terminal is attached. Output is being redirected.

Note: To determine whether a terminal is attached, specify the REXX/CICS command `SCRNINFO`, “`SCRNINFO`” on [page 405](#). The values for screen height and screen width are 0 if there is no terminal attached.

MAX (Maximum)

The MAX function returns the largest number from the list specified, formatted according to the current NUMERIC settings.

➤ MAX(— *number* —) ➤

Implementation maximum: You can specify up to 20 numbers, and can nest calls to MAX if more arguments are needed.

Examples

MAX(12,6,7,9)	->	12
MAX(17.3,19,17.03)	->	19
MAX(-7,-3,-4.3)	->	-3
MAX(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,MAX(20,21))	->	21

MIN (Minimum)

The MIN function returns the smallest number from the list specified, formatted according to the current NUMERIC settings.

➤ MIN(— *number* —) ➤

Implementation maximum: You can specify up to 20 numbers, and can nest calls to MIN if more arguments are needed.

Examples

MIN(12,6,7,9)	->	6
MIN(17.3,19,17.03)	->	17.03
MIN(-7,-3,-4.3)	->	-7
MIN(21,20,19,18,17,16,15,14,13,12,11,10,9,8,7,6,5,4,3,MIN(2,1))	->	1

OVERLAY

The OVERLAY function returns the string *target*, which, starting at the *n*th character, is overlaid with the string *new*, padded or truncated to length *length*.

➤ OVERLAY(— *new* — , — *target* →

The overlay might extend beyond the end of the original *target* string. If you specify *length*, it must be a positive whole number or zero. The default value for *length* is the length of *new*. If *n* is greater than the length of the target string, padding is added before the *new* string. The default *pad* character is a blank, and the default value for *n* is 1. If you specify *n*, it must be a positive whole number.

Examples

```
OVERLAY(' ', 'abcdef', 3)      -> 'ab def'
OVERLAY(' ', 'abcdef', 3, 2)   -> 'ab. ef'
OVERLAY('qq', 'abcd')          -> 'qqcd'
OVERLAY('qq', 'abcd', 4)       -> 'abcqq'
OVERLAY('123', 'abc', 5, 6, '+') -> 'abc+123+++'
```

POS (Position)

The POS function returns the position of one string, *needle*, in another, *haystack*.

➤ POS(— *needle* — , — *haystack* —) ➤

POS returns 0 if *needle* is the null string or is not found or if *start* is greater than the length of *haystack*. By default the search starts at the first character of *haystack* (that is, the value of *start* is 1). You can override this by specifying *start* (which must be a positive whole number), the point at which the search starts. See also the INDEX and LASTPOS functions, [“INDEX” on page 207](#) and [“LASTPOS \(Last Position\)” on page 209](#).

Examples

```
POS('day', 'Saturday')      -> 6
POS('x', 'abc def ghi')     -> 0
POS(' ', 'abc def ghi')     -> 4
POS(' ', 'abc def ghi', 5)  -> 8
```

QUEUED

The QUEUED function returns the number of lines remaining in the external data queue when the function is called. If no lines are remaining, a PULL or PARSE PULL reads from the terminal input buffer. If no terminal input is waiting, this causes a console read.

➤ QUEUED(—) ➤

Example

```
QUEUED() -> 5 /* Perhaps */
```

RANDOM

The RANDOM function returns a quasi-random nonnegative whole number in the range *min* to *max* inclusive.

If you specify *max* or *min* or both, *max* minus *min* cannot exceed 100000. The *min* and *max* default to 0 and 999, respectively. To start a repeatable sequence of results, use a specific *seed* as the third argument, as described in Note “1” on page 212. This *seed* must be a positive whole number ranging from 0 to 999999999.

Examples

```
RANDOM()      -> 305
RANDOM(5,8)    -> 7
RANDOM(2)      -> 0 /* 0 to 2 */
RANDOM(,1983)  -> 123 /* reproducible */
```

Note:

1. To obtain a predictable sequence of quasi-random numbers, use RANDOM a number of times, but specify a *seed* only the first time. For example, to simulate 40 throws of a 6-sided, unbiased die:

```
sequence = RANDOM(1,6,12345) /* any number would */
                                /* do for a seed */
do 39
  sequence = sequence RANDOM(1,6)
end
say sequence
```

The numbers are generated mathematically, using the initial *seed*, so that as far as possible they appear to be random. Running the program again produces the same sequence; using a different initial *seed* almost certainly produces a different sequence. If you do not supply a *seed*, the first time RANDOM is called, the microsecond field of the time-of-day clock is used as the *seed*; and hence your program almost always gives different results each time it is run.

2. The random number generator is global for an entire program; the current seed is not saved across internal routine calls.

REVERSE

The REVERSE function returns *string*, swapped end for end.

```
➡ REVERSE( — string — ) ➡
```

Examples

```
REVERSE('ABc.') -> '.cBA'
REVERSE('XYZ ') -> ' ZYX'
```

RIGHT

The RIGHT function returns a string of length *length* containing the rightmost *length* characters of *string*.

►► RIGHT(— *string* — , — *length* —) ►◄

The string returned is padded with *pad* characters (or truncated) on the left as needed. The default *pad* character is a blank. The *length* must be a positive whole number or zero.

Examples

```
RIGHT('abc d',8)    -> '  abc d'
RIGHT('abc def',5)  -> 'c def'
RIGHT('12',5,'0')   -> '00012'
```

SIGN

The SIGN function returns a number that indicates the sign of *number*. The *number* is first rounded according to standard REXX rules, just as though the operation *number*+0 had been carried out.

►► SIGN(— *number* —) ►◄

SIGN returns -1 if *number* is less than 0, returns 0 if it is 0, and returns 1 if it is greater than 0.

Examples

```
SIGN('12.3')        -> 1
SIGN('-0.307')       -> -1
SIGN(0.0)            -> 0
```

SOURCELINE

The SOURCELINE function returns the line number of the final line in the program if you omit *n*, or returns the *n*th line in the program if you specify *n*.

►► SOURCELINE(—  —) ►◄

If specified, *n* must be a positive whole number and must not exceed the number of the final line in the program.

Examples

```
SOURCELINE()        -> 10
SOURCELINE(1)        -> '/* This is a 10-line REXX program */'
```

SPACE

The SPACE function returns the blank-delimited words in *string* with *n pad* characters between each word.

►► SPACE(— *string* — ) ►◄

If you specify *n*, it must be a positive whole number or zero. If it is 0, all blanks are removed. Leading and trailing blanks are always removed. The default for *n* is 1, and the default *pad* character is a blank.

Examples

```
SPACE('abc def ') -> 'abc def'
SPACE(' abc def',3) -> 'abc def'
SPACE('abc def ',1) -> 'abc def'
SPACE('abc def ',0) -> 'abcdef'
SPACE('abc def ',2,'+') -> 'abc++def'
```

STORAGE

See [“External Functions Provided in REXX/CICS”](#) on page 223.

STRIP

The STRIP function returns *string* with leading or trailing characters or both removed, based on the *option* you specify.

➔ STRIP(— *string* — , — *option* — , — *char* —) ➔

The following are valid options. Only the capitalized letter is needed; all characters following it are ignored.

Both

removes both leading and trailing characters from *string*. This is the default.

Leading

removes leading characters from *string*.

Trailing

removes trailing characters from *string*.

The third argument, *char*, specifies the character to be removed, and the default is a blank. If you specify *char*, it must be exactly one character long.

Examples

```
STRIP(' ab c ') -> 'ab c'
STRIP(' ab c ', 'L') -> 'ab c'
STRIP(' ab c ', 'T') -> ' ab c'
STRIP('12.7000',0) -> '12.7'
STRIP('0012.700',0) -> '12.7'
```

SUBSTR (Substring)

The SUBSTR function returns the substring of *string* that begins at the *n*th character and is of length *length*, padded with *pad* if necessary.

➔ SUBSTR(— *string* — , — *n* — , — *length* — , — *pad* —) ➔

The *n* must be a positive whole number. If *n* is greater than LENGTH(*string*), then only pad characters are returned.

If you omit *length*, the rest of the string is returned. The default *pad* character is a blank.

Examples

```
SUBSTR('abc',2)      -> 'bc'
SUBSTR('abc',2,4)     -> 'bc '
SUBSTR('abc',2,6,'.') -> 'bc...'
```

Note: In some situations the positional (numeric) patterns of parsing templates are more convenient for selecting substrings, especially if more than one substring is to be extracted from a string. See also the LEFT and RIGHT functions.

SUBWORD

The SUBWORD function returns the substring of *string* that starts at the *n*th word, and is up to *length* blank-delimited words.

►► SUBWORD(— *string* — , — *n* — , — *length* —) ►►

The *n* must be a positive whole number. If you omit *length*, it defaults to the number of remaining words in *string*. The returned string never has leading or trailing blanks, but includes all blanks between the selected words.

Examples

```
SUBWORD('Now is the time',2,2) -> 'is the'
SUBWORD('Now is the time',3)  -> 'the time'
SUBWORD('Now is the time',5)  -> ''
```

SYMBOL

The SYMBOL function returns the state of the symbol named by *name*.

►► SYMBOL(— *name* —) ►►

SYMBOL returns BAD if *name* is not a valid REXX symbol. SYMBOL returns VAR if it is the name of a variable (that is, a symbol that has been assigned a value). Otherwise, returns LIT, indicating that it is either a constant symbol or a symbol that has not yet been assigned a value (that is, a literal).

As with symbols in REXX expressions, lowercase characters in *name* are translated to uppercase and substitution in a compound name occurs if possible.

Note: Specify *name* as a literal string (or it should be derived from an expression) to prevent substitution before it is passed to the function.

Examples

```
/* following: Drop A.3; J=3 */
SYMBOL('J')      -> 'VAR'
SYMBOL(J)         -> 'LIT' /* has tested "3" */
SYMBOL('a.j')     -> 'LIT' /* has tested A.3 */
SYMBOL(2)         -> 'LIT' /* a constant symbol */
SYMBOL('*')       -> 'BAD' /* not a valid symbol */
```

TIME

The TIME function returns the local time in the 24-hour clock format: hh:mm:ss (hours, minutes, and seconds) by default, for example, 04:41:37.

►► TIME() ►►

You can use the following options to obtain alternative formats, or to gain access to the elapsed-time clock. Only the capitalized letter is needed; all characters following it are ignored.

Civil

returns the time in Civil format: hh:mmxx. The hours may take the values 1 through 12, and the minutes the values 00 through 59. The minutes are followed immediately by the letters am or pm. This distinguishes times in the morning (12 midnight through 11:59 a.m. - appearing as 12:00am through 11:59am) from noon and afternoon (12 noon through 11:59 p.m. - appearing as 12:00pm through 11:59pm). The hour has no leading zero. The minute field shows the current minute (rather than the nearest minute) for consistency with other TIME results.

Elapsed

returns ssssssss.uuuuuu, the number of seconds.microseconds since the elapsed-time clock (described later) was started or reset. The number has no leading zeros or blanks, and the setting of NUMERIC DIGITS does not affect the number. The fractional part always has six digits.

Hours

returns up to two characters giving the number of hours since midnight in the format: hh (no leading zeros or blanks, except for a result of 0).

Long

returns time in the format: hh:mm:ss.uuuuuu (uuuuuu is the fraction of seconds, in microseconds). The first eight characters of the result follow the same rules as for the Normal form, and the fractional part is always six digits.

Minutes

returns up to four characters giving the number of minutes since midnight in the format: mmmm (no leading zeros or blanks, except for a result of 0).

Normal

returns the time in the default format hh:mm:ss, as described previously. The hours can have the values 00 through 23, and minutes and seconds, 00 through 59. All these are always two digits. Any fractions of seconds are ignored (times are never rounded up). **This is the default.**

Reset

returns ssssssss.uuuuuu, the number of seconds.microseconds since the elapsed-time clock (described later) was started or reset and also resets the elapsed-time clock to zero. The number has no leading zeros or blanks, and the setting of NUMERIC DIGITS does not affect the number. The fractional part always has six digits.

Seconds

returns up to five characters giving the number of seconds since midnight in the format: sssss (no leading zeros or blanks, except for a result of 0).

Note: The first call to DATE or TIME in one clause causes a time stamp to be made that is then used for all calls to these functions in that clause. Therefore, multiple calls to any of the DATE or TIME functions or both in a single expression or clause are guaranteed to be consistent with each other.

Implementation maximum: If the number of seconds in the elapsed time exceeds nine digits (equivalent to over 31.6 years), an error results.

Examples

The following examples, assume that the time is 4:54 p.m.:

```

TIME()      -> '16:54:22'
TIME('C')   -> '4:54pm'
TIME('H')   -> '16'
TIME('L')   -> '16:54:22.123456' /* Perhaps */
TIME('M')   -> '1014' /* 54 + 60*16 */
TIME('N')   -> '16:54:22'
TIME('S')   -> '60862' /* 22 + 60*(54+60*16) */

```

The elapsed-time clock

You can use the TIME function to measure real (elapsed) time intervals. On the first call in a program to TIME('E') or TIME('R'), the elapsed-time clock is started, and either call returns 0. From then on, calls to TIME('E') and to TIME('R') return the elapsed time since that first call or since the last call to TIME('R').

The clock is saved across internal routine calls, which is to say that an internal routine inherits the time clock its caller started. Any timing the caller is doing is not affected, even if an internal routine resets the clock. An example of the elapsed-time clock:

```

time('E')   -> 0 /* The first call */
/* pause of one second here */
time('E')   -> 1.002345 /* or thereabouts */
/* pause of one second here */
time('R')   -> 2.004690 /* or thereabouts */
/* pause of one second here */
time('R')   -> 1.002345 /* or thereabouts */

```

Note: See the previous note about consistency of times in a single clause. The elapsed-time clock is synchronized to the other calls to TIME and DATE, so multiple calls to the elapsed-time clock in a single clause always return the same result. For the same reason, the interval between two usual TIME/DATE results can be calculated exactly using the elapsed-time clock.

TRACE

The TRACE function returns trace actions currently in effect and, optionally, alters the setting.

➡ TRACE() ➡
└─ option ─┘

If you specify *option*, it selects the trace setting. It must be one of the valid prefixes ? or ! or one of the alphabetic character options associated with the TRACE instruction (that is, starting with A, C, E, F, I, L, N, O, R, or S) or both.

Unlike the TRACE instruction, the TRACE function alters the trace action even if interactive debug is active. Also unlike the TRACE instruction, *option* cannot be a number.

Examples

```

TRACE()      -> '?R' /* maybe */
TRACE('O')   -> '?R' /* also sets tracing off */
TRACE('?I')   -> 'O' /* now in interactive debug */

```

TRANSLATE

The TRANSLATE function returns *string* with each character translated to another character or unchanged. You can also use this function to reorder the characters in *string*.

➤ TRANSLATE(— *string* ➤

The output table is *tableo* and the input translation table is *tablei*. TRANSLATE searches *tablei* for each character in *string*. If the character is found, the corresponding character in *tableo* is used in the result string; if there are duplicates in *tablei*, the first (leftmost) occurrence is used. If the character is not found, the original character in *string* is used. The result string is always the same length as *string*.

The tables can be of any length. If you specify neither translation table and omit *pad*, *string* is simply translated to uppercase (that is, lowercase a-z to uppercase A-Z), but, if you include *pad*, the language processor translates the entire string to *pad* characters. *tablei* defaults to X RANGE ('00' x , 'FF' x), and *tableo* defaults to the null string and is padded with *pad* or truncated as necessary. The default *pad* is a blank.

Examples

```
TRANSLATE('abcdef')      -> 'ABCDEF'
TRANSLATE('abbc', '&', 'b') -> 'a&&c'
TRANSLATE('abcdef', '12', 'ec') -> 'ab2d1f'
TRANSLATE('abcdef', '12', 'abcd', '. ') -> '12..ef'
TRANSLATE('APQRV', 'PR') -> 'A Q V'
TRANSLATE('APQRV', X RANGE('00' x, 'Q')) -> 'APQ '
TRANSLATE('4123', 'abcd', '1234') -> 'dabc'
```

Note: The last example shows how to use the TRANSLATE function to reorder the characters in a string. In the example, the last character of any four-character string specified as the second argument would be moved to the beginning of the string.

TRUNC (Truncate)

The TRUNC function returns the integer part of *number* and *n* decimal places.

➤ TRUNC(— *number* — *n*) ➤

The default *n* is 0 and returns an integer with no decimal point. If you specify *n*, it must be a positive whole number or zero. The *number* is first rounded according to standard REXX rules, just as though the operation *number*+0 had been carried out. The number is then truncated to *n* decimal places (or trailing zeros are added if needed to make up the specified length). The result is never in exponential form.

Note: The *number* is rounded according to the current setting of NUMERIC DIGITS if necessary before the function processes it.

Examples

```
TRUNC(12.3)      -> 12
TRUNC(127.09782, 3) -> 127.097
TRUNC(127.1, 3)   -> 127.100
TRUNC(127, 2)     -> 127.00
```

USERID

The USERID function returns the CICS signon user ID if the user is signed on to CICS, or the CICS region default user ID (if one was specified by the CICS systems programmer).

➤ USERID(—) ➤

User IDs are padded on the right with blanks so that the returned value is always eight bytes long.

Example

```
USERID() -> 'ARTHUR' /* Maybe */
```

VALUE

The VALUE function returns the value of the symbol that *name* (often constructed dynamically) represents and optionally assigns it a new value.

➤ VALUE(— *name* — , — *newvalue* — , — *selector* —) ➤

By default, VALUE refers to the current REXX variables environment, however, if you want to specify *selector* the value must be RLS. If the selector of RLS is specified, the variable operated on is a REXX List System (RLS) variable, rather than a REXX variable. If you use the function to refer to REXX variables, *name* must be a valid REXX symbol. (You can confirm this by using the SYMBOL function.) Lowercase characters in *name* are translated to uppercase. Substitution in a compound name (see “Compound symbols” on page 152) occurs if possible.

If you specify *newvalue*, the named variable is assigned this new value. This does not affect the result returned; that is, the function returns the value of *name* as it was before the new assignment.

Examples

```
/* After: Drop A3; A33=7; K=3; fred='K'; list.5='Hi' */
VALUE('a'k) -> 'A3' /* looks up A3 */
VALUE('a'k|k) -> '7' /* looks up A33 */
VALUE('fred') -> 'K' /* looks up FRED */
VALUE(fred) -> '3' /* looks up K */
VALUE(fred,5) -> '3' /* looks up K and */
/* then sets K=5 */
VALUE(fred) -> '5' /* looks up K */
VALUE('LIST.'k) -> 'Hi' /* looks up LIST.5 */
```

The following example returns the VALUE of the REXX variable FRED that has been stored in an RLS variable.

```
/* REXX EXEC - ASSIGN FIND VALUE OF FRED */
FRED = 7
'RLS VARPUT FRED \USERS\userid\'
X = VALUE(FRED,,RLS)
SAY X
/* X now = 7 */
```

Note:

1. If the VALUE function refers to an uninitialized REXX variable, the default value of the variable is always returned; the NOVALUE condition is not raised. A reference to RLS variables never raises NOVALUE.
2. If you specify the *name* as a single literal string and omit *newvalue* and *selector*, the symbol is a constant and so the string between the quotation marks can usually replace the whole function call. For example, `fred=VALUE('k')`; is identical with the assignment `fred=k`;, unless the NOVALUE condition is being trapped. See [Chapter 22, “Conditions and condition traps,”](#) on page 249.

VERIFY

The VERIFY function returns a number that, by default, indicates whether *string* is composed only of characters from *reference*.

➤ VERIFY(— *string* — , — *reference* — , — *option* — , — *start* —) ➤

VERIFY returns 0 if all characters in *string* are in *reference*, or returns the position of the first character in *string* that is not in *reference*.

The *option* can be either Nomatch (the default) or Match. (Only the capitalized letter is needed. All characters following it are ignored, and it can be in upper- or lowercase, as usual.) If you specify Match, the function returns the position of the first character in *string* that is in *reference*, or returns 0 if none of the characters are found.

The default for *start* is 1; thus, the search starts at the first character of *string*. You can override this by specifying a different *start* point, which must be a positive whole number.

If *string* is null, the function returns 0, regardless of the value of the third argument. Similarly, if *start* is greater than LENGTH(*string*), the function returns 0. If *reference* is null, the function returns 0 if you specify Match; otherwise the function returns the *start* value.

Examples

```
VERIFY('123','1234567890')      -> 0
VERIFY('123','1234567890')      -> 2
VERIFY('AB4T','1234567890')     -> 1
VERIFY('AB4T','1234567890','M') -> 3
VERIFY('AB4T','1234567890','N') -> 1
VERIFY('1P3Q4','1234567890',3)  -> 4
VERIFY('123','',N,2)             -> 2
VERIFY('ABCDE','',3)            -> 3
VERIFY('AB3CD5','1234567890','M',4) -> 6
```

WORD

The WORD function returns the *n*th blank-delimited word in *string* or returns the null string if fewer than *n* words are in *string*.

➤ WORD(— *string* — , — *n* —) ➤

The *n* must be a positive whole number. This function is exactly equivalent to SUBWORD(*string*,*n*,1).

Examples

```
WORD('Now is the time',3)      -> 'the'
WORD('Now is the time',5)      -> ''
```

WORDINDEX

The WORDINDEX function returns the position of the first character in the *n*th blank-delimited word in *string* or returns 0 if fewer than *n* words are in *string*.

➤ WORDINDEX(— *string* — , — *n* —) ➤

The *n* must be a positive whole number.

Examples

```
WORDINDEX('Now is the time',3)    -> 8
WORDINDEX('Now is the time',6)    -> 0
```

WORDLENGTH

The WORDLENGTH function returns the length of the *n*th blank-delimited word in *string* or returns 0 if fewer than *n* words are in *string*.

►► WORDLENGTH(— *string* — , — *n* —) ►◄

The *n* must be a positive whole number.

Examples

```
WORDLENGTH('Now is the time',2)    -> 2
WORDLENGTH('Now comes the time',2) -> 5
WORDLENGTH('Now is the time',6)    -> 0
```

WORDPOS (Word Position)

The WORDPOS function returns the word number of the first word of *phrase* found in *string* or returns 0 if *phrase* contains no words or if *phrase* is not found.

►► WORDPOS(— *phrase* — , — *string* — , — *start* —) ►◄

Multiple blanks between words in either *phrase* or *string* are treated as a single blank for the comparison, but otherwise the words must match exactly.

By default the search starts at the first word in *string*. You can override this by specifying *start* (which must be positive), the word at which to start the search.

Examples

```
WORDPOS('the','now is the time')    -> 3
WORDPOS('The','now is the time')    -> 0
WORDPOS('is the','now is the time') -> 2
WORDPOS('is the','now is the time') -> 2
WORDPOS('is time ','now is the time') -> 0
WORDPOS('be','To be or not to be')  -> 2
WORDPOS('be','To be or not to be',3) -> 6
```

WORDS

The WORDS function returns the number of blank-delimited words in *string*.

►► WORDS(— *string* —) ►◄

Examples

```
WORDS('Now is the time')    -> 4
WORDS(' ')                   -> 0
```

XRANGE (Hexadecimal Range)

The XRANGE function returns a string of all valid 1-byte encodings (in ascending order) between and including the values *start* and *end*.

➡ XRANGE(— *start* — , — *end* —) ➡

The default value for *start* is '00'x, and the default value for *end* is 'FF'x. If *start* is greater than *end*, the values wrap from 'FF'x to '00'x. If specified, *start* and *end* must be single characters.

Examples

```
XRANGE('a','f')      -> 'abcdef'
XRANGE('03'x,'07'x)  -> '0304050607'x
XRANGE(, '04'x)      -> '0001020304'x
XRANGE('i','j')      -> '898A8B8C8D8E8F9091'x /* EBCDIC */
XRANGE('FE'x,'02'x)  -> 'FEFF000102'x
```

X2B (Hexadecimal to Binary)

The function returns a string, in character format, that represents *hexstring* converted to binary.

➡ X2B(— *hexstring* —) ➡

The *hexstring* is a string of hexadecimal characters. It can be of any length. Each hexadecimal character is converted to a string of four binary digits. You can optionally include blanks in *hexstring* (at byte boundaries only, not leading or trailing) to aid readability; they are ignored.

The returned string has a length that is a multiple of four, and does not include any blanks.

If *hexstring* is null, the function returns a null string.

Examples

```
X2B('C3')      -> '11000011'
X2B('7')        -> '0111'
X2B('1 C1')     -> '000111000001'
```

You can combine X2B with the functions D2X and C2X to convert numbers or character strings into binary form. For example:

```
X2B(C2X('C3'x)) -> '11000011'
X2B(D2X('129')) -> '10000001'
X2B(D2X('12'))  -> '1100'
```

X2C (Hexadecimal to Character)

The X2C function returns a string, in character format, that represents *hexstring* converted to character.

➡ X2C(— *hexstring* —) ➡

The returned string is half as many bytes as the original *hexstring*. *hexstring* can be of any length. If necessary, it is padded with a leading 0 to make an even number of hexadecimal digits.

You can optionally include blanks in *hexstring* (at byte boundaries only, not leading or trailing) to aid readability; they are ignored.

If *hexstring* is null, the function returns a null string.

Examples

```
X2C('F7F2 A2') -> '72s' /* EBCDIC */
X2C('F7f2a2') -> '72s' /* EBCDIC */
X2C('F') -> ' ' /* '0F' is unprintable EBCDIC */
```

X2D (Hexadecimal to Decimal)

The X2D function returns the decimal representation of *hexstring*.

➔ X2D(— *hexstring* — , — *n*) ➔

The *hexstring* is a string of hexadecimal characters. If the result cannot be expressed as a whole number, an error results. That is, the result must not have more digits than the current setting of NUMERIC DIGITS.

You can optionally include blanks in *hexstring* (at byte boundaries only, not leading or trailing) to aid readability; they are ignored.

If *hexstring* is null, the function returns 0.

If you do not specify *n*, *hexstring* is processed as an unsigned binary number.

Implementation maximum: The input string may not have more than 500 hexadecimal characters that will be significant in forming the final result. Leading sign characters (0 and F) do not count towards this total.

Examples

```
X2D('0E') -> 14
X2D('81') -> 129
X2D('F81') -> 3969
X2D('FF81') -> 65409
X2D('c6 f0'X) -> 240 /* EBCDIC */
```

If you specify *n*, the string is taken as a signed number expressed in *n* hexadecimal digits. If the leftmost bit is off, then the number is positive; otherwise, it is a negative number in two's complement notation. In both cases it is converted to a whole number, which may, therefore, be negative. If *n* is 0, the function returns 0.

If necessary, *hexstring* is padded on the left with 0 characters (note, not “sign-extended”), or truncated on the left to *n* characters. For example:

```
X2D('81',2) -> -127
X2D('81',4) -> 129
X2D('F081',4) -> -3967
X2D('F081',3) -> 129
X2D('F081',2) -> -127
X2D('F081',1) -> 1
X2D('0031',0) -> 0
```

External Functions Provided in REXX/CICS

Additional external functions are provided in the REXX/CICS environment.

STORAGE

The STORAGE function returns *length* bytes from the user's memory starting at *address*.

Important: This is an authorized function. The STORAGE function, which allows a REXX user to display and/or modify the 31-bit virtual storage of the CICS region, can be successfully invoked only from an authorized exec or by an authorized user.

➤ STORAGE(— *address* — , — *length* — , — *data* —) ➤

The *length* is in decimal; the default is 1 byte. The *address* is a hexadecimal number. The high-order bit of *address* is ignored. Ensure that you specify a 31-bit address, otherwise results might be unpredictable. You cannot specify a 64-bit address.

If you specify *data*, after the old value has been retrieved, storage starting at *address* is overwritten with *data* (the *length* argument has no effect on this).

Note: The STORAGE function can operate on a 31-bit address. The STORAGE function cannot operate on a 64-bit address.

Example

```
/* The following results vary from system to system. */
STORAGE(200000,32)
/* This returns 32 bytes of storage at hex address 200000 as a result. */
```

SYSSBA

The function

➤ SYSSBA(— *row* — , — *col* —) ➤

SYSSBA converts screen *row,col* to a set buffer address (SBA).

row

specifies the row number counting from the top of the screen.

col

specifies the column number (counting from the left of the screen).

Note: The SYSSBA function queries the terminal model on each invocation and uses this to adjust the SBA calculation to terminal type.

Example

```
x = SYSSBA(10,20)
```

This example returns a three byte set buffer address for screen row 10, column 20 into REXX variable x.

Chapter 20. Parsing

Parsing splits up the data in a source string and assigns pieces of it into the variables named in a template.

The parsing instructions are ARG, PARSE, and PULL. See [“ARG” on page 162](#), [“PARSE” on page 176](#), and [“PULL” on page 180](#).

The data to parse is a *source string*. A *template* is a model specifying how to split the source string. The simplest kind of template consists of only a list of variable names. For example:

```
variable1 variable2 variable3
```

This kind of template parses the source string into blank-delimited words. More complicated templates contain patterns in addition to variable names.

String patterns

Match characters in the source string to specify where to split it. See [“Templates that contain string patterns” on page 227](#).

Positional patterns

Indicate the character positions at which to split the source string. See [“Templates that contain positional \(numeric\) patterns” on page 227](#).

Parsing is essentially a two-step process.

1. Parse the source string into appropriate substrings by using patterns.
2. Parse each substring into words.

Simple templates for parsing into words

Here is a parsing instruction:

```
parse value 'time and tide' with var1 var2 var3
```

The template in this instruction is: `var1 var2 var3`. The data to parse is between the keywords `PARSE VALUE` and the keyword `WITH`, the source string `time and tide`. Parsing divides the source string into blank-delimited words and assigns them to the variables named in the template as follows:

```
var1='time'  
var2='and'  
var3='tide'
```

In this example, the source string to parse is a literal string, `time and tide`. In the next example, the source string is a variable.

```
/* PARSE VALUE using a variable as the source string to parse */  
string='time and tide'  
parse value string with var1 var2 var3          /* same results */
```

`PARSE VALUE` does not convert lowercase `a–z` in the source string to uppercase `A–Z`. If you want to convert characters to uppercase, use `PARSE UPPER VALUE`. See [“Using UPPER” on page 231](#) for a summary of the effect of parsing instructions on case.

All of the parsing instructions assign the parts of a source string into the variables named in a template. There are various parsing instructions because of differences in the nature or origin of source strings. See [“Parsing instructions summary” on page 232](#).

The `PARSE VAR` instruction is similar to `PARSE VALUE` except that the source string to parse is always a variable. In `PARSE VAR`, the name of the variable containing the source string follows the keywords `PARSE`

VAR. In the next example, the variable stars contains the source string. The template is star1 star2 star3.

```
/* PARSE VAR example */
stars='Sirius Polaris Rigil'
parse var stars star1 star2 star3          /* star1='Sirius' */
                                           /* star2='Polaris' */
                                           /* star3='Rigil' */
```

All variables in a template receive new values. If there are more variables in the template than words in the source string, the leftover variables receive null (empty) values. This is true for all parsing: for parsing into words with simple templates and for parsing with templates containing patterns. Here is an example using parsing into words.

```
/* More variables in template than (words in) the source string */
satellite='moon'
parse var satellite Earth Mercury          /* Earth='moon' */
                                           /* Mercury='' */
```

If there are more words in the source string than variables in the template, the last variable in the template receives all leftover data. Here is an example:

```
/* More (words in the) source string than variables in template */
satellites='moon Io Europa Callisto...'
parse var satellites Earth Jupiter          /* Earth='moon' */
                                           /* Jupiter='Io Europa Callisto...'*/
```

Parsing into words removes leading and trailing blanks from each word before it is assigned to a variable. The exception to this is the word or group of words assigned to the last variable. The last variable in a template receives leftover data, preserving extra leading and trailing blanks. Here is an example:

```
/* Preserving extra blanks */
solar5='Mercury Venus Earth Mars Jupiter '
parse var solar5 var1 var2 var3 var4
/* var1 ='Mercury' */
/* var2 ='Venus' */
/* var3 ='Earth' */
/* var4 =' Mars Jupiter ' */
```

In the source string, Earth has two leading blanks. Parsing removes both of them (the word-separator blank and the extra blank) before assigning var3= 'Earth'. Mars has three leading blanks. Parsing removes one word-separator blank and keeps the other two leading blanks. It also keeps all five blanks between Mars and Jupiter and both trailing blanks after Jupiter.

Parsing removes no blanks if the template contains only one variable. For example:

```
parse value ' Pluto ' with var1          /* var1=' Pluto '*/
```

The period as placeholder

A period in a template is a placeholder. It is used instead of a variable name, but it receives no data. A placeholder saves the overhead of unneeded variables. It is useful:

- As a "dummy variable" in a list of variables
- To collect unwanted information at the end of a string.

The period in the first example is a placeholder. Be sure to separate adjacent periods with spaces; otherwise, an error results.

```
/* Period as a placeholder */
stars='Arcturus Betelgeuse Sirius Rigil'
parse var stars . . brightest .          /* brightest='Sirius' */

/* Alternative to period as placeholder */
stars='Arcturus Betelgeuse Sirius Rigil'
parse var stars drop junk brightest rest /* brightest='Sirius' */
```

Templates that contain string patterns

A *string pattern* matches characters in the source string to indicate where to split it.

A string pattern can be literal or variable:

Literal string pattern

One or more characters within quotation marks.

Variable string pattern

A variable within parentheses with no plus (+) or minus (-) or equal sign (=) before the left parenthesis. See [“Parsing with variable patterns” on page 231](#) for details.

Here are two templates: a simple template and a template containing a literal string pattern:

```
var1 var2      /* simple template          */
var1 ', ' var2 /* template with literal string pattern */
```

The literal string pattern is: ' , '. This template:

- Puts characters from the start of the source string up to (but not including) the first character of the match (the comma) into `var1`
- Puts characters starting with the character after the last character of the match (the character after the blank that follows the comma) and ending with the end of the string into `var2`.

A template with a string pattern can omit some of the data in a source string when assigning data into variables. The next two examples contrast simple templates with templates containing literal string patterns.

```
/* Simple template          */
name='Smith, John'
parse var name ln fn      /* Assigns: ln='Smith, ' */
                          /*          fn='John' */
```

Notice that the comma remains (the variable `ln` contains 'Smith, '). In the next example, the template is `ln ' , ' fn`. This removes the comma.

```
/* Template with literal string pattern */
name='Smith, John'
parse var name ln ' , ' fn      /* Assigns: ln='Smith' */
                          /*          fn='John' */
```

First, the language processor scans the source string for ' , '. It splits the source string at that point. The variable `ln` receives data, starting with the first character of the source string and ending with the last character before the match. The variable `fn` receives data, starting with the first character after the match and ending with the end of string.

A template with a string pattern omits data in the source string that matches the pattern. There is a special case in which a template with a string pattern does *not* omit matching data in the source string; see [“Combining string and positional patterns: a special case” on page 234](#). We used the pattern ' , ' (with a blank) instead of ' , ' (no blank) because, without the blank in the pattern, the variable `fn` receives ' John' (including a blank).

If the source string does not contain a match for a string pattern, any variables preceding the unmatched string pattern get all the data in question. Any variables after that pattern receive the null string.

A null string is never found. It always matches the end of the source string.

Templates that contain positional (numeric) patterns

A *positional pattern* is a number that identifies the character position at which to split data in the source string. The number must be a whole number.

An *absolute positional pattern* is:

- A number with no plus (+) or minus (-) sign preceding it, or with an equal sign (=) preceding it.

- A variable in parentheses with an equal sign before the left parenthesis. See [“Parsing with variable patterns”](#) on page 231 for details on variable positional patterns.

The number specifies the absolute character position at which to split the source string.

Here is a template with absolute positional patterns:

```
variable1 11 variable2 21 variable3
```

The numbers 11 and 21 are absolute positional patterns. The number 11 refers to the 11th position in the input string, 21 to the 21st position. This template:

- Puts characters 1 through 10 of the source string into `variable1`
- Puts characters 11 through 20 into `variable2`
- Puts characters 21 to the end into `variable3`.

Positional patterns are probably most useful for working with a file of records, such as:

```

character positions:
  1      11      21      40
+-----+-----+-----+end of
FIELDS: |LASTNAME |FIRST  |PSEUDONYM |record
+-----+-----+-----+

```

The following example uses this record structure.

```

/* Parsing with absolute positional patterns in template */
record.1='Clemens Samuel Mark Twain '
record.2='Evans Mary Ann George Eliot '
record.3='Munro H.H. Saki '
do n=1 to 3
  parse var record.n lastname 11 firstname 21 pseudonym
  If lastname='Evans' & firstname='Mary Ann' then say 'By George!'
end
/* Says 'By George!' after record 2 */

```

The source string is first split at character position 11 and at position 21. The language processor assigns characters 1 to 10 into `lastname`, characters 11 to 20 into `firstname`, and characters 21 to 40 into `pseudonym`.

The template could have been:

```
1 lastname 11 firstname 21 pseudonym
```

instead of

```
lastname 11 firstname 21 pseudonym
```

Specifying the 1 is optional.

Optionally, you can put an equal sign before a number in a template. An equal sign is the same as no sign before a number in a template. The number refers to a particular character position in the source string. These two templates work the same:

```
lastname 11 first 21 pseudonym
lastname =11 first =21 pseudonym
```

A *relative positional pattern* is a number with a plus (+) or minus (-) sign preceding it. (It can also be a variable within parentheses, with a plus (+) or minus (-) sign preceding the left parenthesis; for details see [“Parsing with variable patterns”](#) on page 231.)

The number specifies the relative character position at which to split the source string. The plus or minus indicates movement right or left, respectively, from the start of the string (for the first pattern) or from the position of the last match. The position of the last match is the first character of the last match. Here is the same example as for absolute positional patterns done with relative positional patterns:

```

/* Parsing with relative positional patterns in template */
record.1='Clemens Samuel Mark Twain '

```

```

record.2='Evans      Mary Ann  George Eliot      '
record.3='Munro      H.H.      Saki                '
do n=1 to 3
  parse var record.n lastname +10 firstname + 10 pseudonym
  If lastname='Evans' & firstname='Mary Ann' then say 'By George!'
end
/* same results */

```

Blanks between the sign and the number are insignificant. Therefore, +10 and + 10 have the same meaning. Note that +0 is a valid relative positional pattern.

Absolute and relative positional patterns are interchangeable (except in the special case when a string pattern precedes a variable name and a positional pattern follows the variable name; see “Combining string and positional patterns: a special case” on page 234). The templates from the examples of absolute and relative positional patterns give the same results.

	lastname 11	firstname 21	pseudonym
	lastname +10	firstname + 10	pseudonym
+-----+	+-----+	+-----+	+-----+
(Implied starting point is position 1.)	Put characters 1 through 10 in lastname. (Non-inclusive stopping point is 11 (1+10).)	Put characters 11 through 20 in firstname. (Non-inclusive stopping point is 21 (11+10).)	Put characters 21 through end of string in pseudonym.

Only with positional patterns can a matching operation *back up* to an earlier position in the source string. Here is an example using absolute positional patterns:

```

/* Backing up to an earlier position (with absolute positional) */
string='astronomers'
parse var string 2 var1 4 1 var2 2 4 var3 5 11 var4
say string 'study' var1||var2||var3||var4
/* Displays: "astronomers study stars" */

```

The absolute positional pattern 1 backs up to the first character in the source string.

With relative positional patterns, a number preceded by a minus sign backs up to an earlier position. Here is the same example using relative positional patterns:

```

/* Backing up to an earlier position (with relative positional) */
string='astronomers'
parse var string 2 var1 +2 -3 var2 +1 +2 var3 +1 +6 var4
say string 'study' var1||var2||var3||var4 /* same results */

```

In the previous example, the relative positional pattern -3 backs up to the first character in the source string.

The templates in the last two examples are equivalent.

	var1 4	1	var2 2	4 var3 5	11 var4
	var1 +2	-3	var2 +1	+2 var3 +1	+6 var4
+-----+	+-----+	+-----+	+-----+	+-----+	+-----+
Start at 2.	Non- inclusive stopping point is 4 (2+2=4).	Go to 1. (4-3=1)	Non- inclusive stopping point is 2 (1+1=2).	Go to 4 (2+2=4). Non-inclusive stopping point is 5 (4+1=5).	Go to 11 (5+6=11).

You can use templates with positional patterns to make multiple assignments:

```

/* Making multiple assignments */
books='Silas Marner, Felix Holt, Daniel Deronda, Middlemarch'
parse var books 1 Eliot 1 Evans
/* Assigns the (entire) value of books to Eliot and to Evans. */

```

Combining patterns and parsing into words

What happens when a template contains patterns that divide the source string into sections containing multiple words? String and positional patterns divide the source string into substrings. The language processor then applies a section of the template to each substring, following the rules for parsing into words.

```
/* Combining string pattern and parsing into words          */
name='      John      Q.      Public'
parse var name fn init '.' ln      /* Assigns: fn='John' */
/*                               /* init='      Q' */
/*                               /* ln='      Public' */
```

The pattern divides the template into two sections:

- fn init
- ln

The matching pattern splits the source string into two substrings:

- ' John Q'
- ' Public'

The language processor parses these substrings into words based on the appropriate template section.

John had three leading blanks. All are removed because parsing into words removes leading and trailing blanks except from the last variable.

Q has six leading blanks. Parsing removes one word-separator blank and keeps the rest because init is the last variable in that section of the template.

For the substring ' Public ', parsing assigns the entire string into ln without removing any blanks. This is because ln is the only variable in this section of the template. (For details about treatment of blanks, see [“Simple templates for parsing into words”](#) on page 225.)

```
/* Combining positional patterns with parsing into words    */
string='R E X X'
parse var string var1 var2 4 var3 6 var4      /* Assigns: var1='R' */
/*                               /* var2='E' */
/*                               /* var3=' X' */
/*                               /* var4=' X' */
```

The pattern divides the template into three sections:

- var1 var2
- var3
- var4

The matching patterns split the source string into three substrings that are individually parsed into words:

- 'R E'
- ' X'
- ' X'

The variable var1 receives 'R'; var2 receives 'E'. Both var3 and var4 receive ' X' (with a blank before the X) because each is the only variable in its section of the template. (For details on treatment of blanks, see [“Simple templates for parsing into words”](#) on page 225.)

Parsing with variable patterns

You might want to specify a pattern by using the value of a variable instead of a fixed string or number. You do this by placing the name of the variable in parentheses. This is a *variable reference*.

About this task

Blanks are not necessary inside or outside the parentheses, but you can add them if you want.

The template in the next parsing instruction contains the following literal string pattern ' . ' .

```
parse var name fn init ' . ' ln
```

Here is how to specify that pattern as a variable string pattern:

```
stringptrn=' . '
parse var name fn init (stringptrn) ln
```

If no equal, plus, or minus sign precedes the parenthesis that is before the variable name, the value of the variable is then treated as a string pattern. The variable can be one that has been set earlier in the same template. For example:

```
/* Using a variable as a string pattern */
/* The variable (delim) is set in the same template */
SAY "Enter a date (mm/dd/yy format). =====> " /* assume 11/15/90 */
pull date
parse var date month 3 delim +1 day +2 (delim) year
/* Sets: month='11'; delim='/'; day='15'; year='90' */
```

If an equal, a plus, or a minus sign precedes the left parenthesis, the value of the variable is treated as an absolute or relative positional pattern. The value of the variable must be a positive whole number or zero.

The variable can be one that has been set earlier in the same template. In the following example, the first two fields specify the starting character positions of the last two fields.

```
/* Using a variable as a positional pattern */
dataline = '12 26 .....Samuel ClemensMark Twain'
parse var dataline pos1 pos2 6 =(pos1) realname =(pos2) pseudonym
/* Assigns: realname='Samuel Clemens'; pseudonym='Mark Twain' */
```

Why is the positional pattern 6 needed in the template? Remember that word parsing occurs after the language processor divides the source string into substrings by using patterns. Therefore, the positional pattern =(pos1) cannot be correctly interpreted as =12 until after the language processor has split the string at column 6 and assigned the blank-delimited words 12 and 26 to pos1 and pos2, respectively.

Using UPPER

Specifying UPPER on any of the PARSE instructions converts characters to uppercase (lowercase a-z to uppercase A-Z) before parsing.

About this task

The following table summarizes the effect of the parsing instructions on case.

Converts alphabetic characters to uppercase before parsing	Maintains alphabetic characters in case entered
ARG PARSE UPPER ARG	PARSE ARG
PARSE UPPER EXTERNAL	PARSE EXTERNAL
PARSE UPPER NUMERIC	PARSE NUMERIC

Converts alphabetic characters to uppercase before parsing	Maintains alphabetic characters in case entered
PULL PARSE UPPER PULL	PARSE PULL
PARSE UPPER SOURCE	PARSE SOURCE
PARSE UPPER VALUE	PARSE VALUE
PARSE UPPER VAR	PARSE VAR
PARSE UPPER VERSION	PARSE VERSION

The ARG instruction is simply a short form of PARSE UPPER ARG. The PULL instruction is simply a short form of PARSE UPPER PULL. If you do not desire uppercase translation, use PARSE ARG (instead of ARG or PARSE UPPER ARG) and use PARSE PULL (instead of PULL or PARSE UPPER PULL).

Parsing instructions summary

All parsing instructions assign parts of the source string into the variables named in the template.

About this task

The following table summarizes where the source string comes from.

Instruction	Where the source string comes from
ARG PARSE ARG	Arguments you list when you call the program or arguments in the call to a subroutine or function.
PARSE EXTERNAL	Next line from terminal input buffer
PARSE NUMERIC	Numeric control information (from NUMERIC instruction).
PULL PARSE PULL	The string at the head of the external data queue. (If queue empty, uses default input, typically the terminal.)
PARSE SOURCE	System-supplied string giving information about the executing program.
PARSE VALUE	Expression between the keyword VALUE and the keyword WITH in the instruction.
PARSE VAR <i>name</i>	Parses the value of <i>name</i> .
PARSE VERSION	System-supplied string specifying the language, language level, and (three-word) date.

Parsing instructions examples

Examples that parse source strings into words are shown.

About this task

ARG

```
/* ARG with source string named in REXX program invocation      */
/* Program name is PALETTE. Specify 2 primary colors (yellow,  */
/* red, blue) on call. Assume call is: palette red blue        */
arg var1 var2 /* Assigns: var1='RED'; var2='BLUE' */
If var1<>'RED' & var1<>'YELLOW' & var1<>'BLUE' then signal err
If var2<>'RED' & var2<>'YELLOW' & var2<>'BLUE' then signal err
```

```

total=length(var1)+length(var2)
SELECT;
  When total=7 then new='purple'
  When total=9 then new='orange'
  When total=10 then new='green'
  Otherwise new=var1                                /* entered duplicates */
END
Say new; exit                                       /* Displays: "purple" */

Err:
say 'Input error--color is not "red" or "blue" or "yellow"'; exit

```

ARG converts alphabetic characters to uppercase before parsing. An example of ARG with the arguments in the CALL to a subroutine is in [“Parsing multiple strings” on page 234](#).

PARSE ARG

Works the same as ARG except that PARSE ARG does not convert alphabetic characters to uppercase before parsing.

PARSE EXTERNAL

```

Say "Enter Yes or No =====> "
parse upper external answer 2 .
If answer='Y'
  then say "You said 'Yes'!"
  else say "You said 'No'!"

```

PARSE NUMERIC

```

parse numeric digits fuzz form
say digits fuzz form                                /* Displays: '9 0 SCIENTIFIC' */
                                                    /* (if defaults are in effect) */

```

PARSE PULL

```

PUSH '80 7'                                         /* Puts data on queue */
parse pull fourscore seven /* Assigns: fourscore='80'; seven='7' */
SAY fourscore+seven                                /* Displays: "87" */

```

PARSE SOURCE

```

parse source sysname .
Say sysname                                         /* Displays: "CICS" */

```

PARSE VALUE

See the example in [“Simple templates for parsing into words” on page 225](#).

PARSE VAR

See the examples throughout the parsing information, starting in [“Simple templates for parsing into words” on page 225](#).

PARSE VERSION

```

parse version . level .
say level                                           /* Displays: "3.48" */

```

PULL

Works the same as PARSE PULL except that PULL converts alphabetic characters to uppercase before parsing.

Advanced parsing information

Advanced parsing includes parsing multiple strings, parsing with DBCS characters, and special cases.

Flow charts that depict a conceptual view of parsing are provided.

Parsing multiple strings

Only ARG and PARSE ARG can have more than one source string. To parse multiple strings, you can specify multiple comma-separated templates.

About this task

Here is an example:

```
parse arg template1, template2, template3
```

This instruction consists of the keywords PARSE ARG and three comma-separated templates. (For an ARG instruction, the source strings to parse come from arguments you specify when you call a program or CALL a subroutine or function.) Each comma is an instruction to the parser to move on to the next string.

Example:

```
/* Parsing multiple strings in a subroutine          */
num='3'
musketeers="Porthos Athos Aramis D'Artagnon"
CALL Sub num,musketeers /* Passes num and musketeers to sub */
SAY total; say fourth /* Displays: "4" and " D'Artagnon"    */
EXIT

Sub:
parse arg subtotal, . . . fourth
total=subtotal+1
RETURN
```

When a REXX program is started as a command, only one argument string is recognized. You can pass multiple argument strings for parsing:

- When one REXX program calls another REXX program with the CALL instruction or a function call.
- When programs written in other languages start a REXX program.

If there are more templates than source strings, each variable in a leftover template receives a null string. If there are more source strings than templates, the language processor ignores leftover source strings. If a template is empty (two commas in a row) or contains no variable names, parsing proceeds to the next template and source string.

Combining string and positional patterns: a special case

There is a special case in which absolute and relative positional patterns do not work identically.

About this task

We have shown how parsing with a template that contains a string pattern skips over the data in the source string that matches the pattern (see [“Templates that contain string patterns” on page 227](#)). But a template that contains the following sequence does *not* skip over the matching data.:

- string pattern
- variable name
- relative positional pattern

A relative positional pattern moves relative to the first character matching a string pattern. As a result, assignment includes the data in the source string that matches the string pattern.

```
/* Template containing string pattern, then variable name, then */
/* relative positional pattern does not skip over any data.      */
string='REstructured eXtended eXecutor'
parse var string var1 3 junk 'X' var2 +1 junk 'X' var3 +1 junk
say var1||var2||var3 /* Concatenates variables; displays: "REXX" */
```

Here is how this template works:

var1 3	junk 'X'	var2 +1	junk 'X'	var3 +1	junk
+-----+	+-----+	+-----+	+-----+	+-----+	+-----+
Put	Starting	Starting	Starting	Starting	Starting
characters	at 3, put	with first	with char-	with	with char-
1 through	characters	'X' put 1	acter after	second 'X'	acter

Parsing with DBCS characters

Parsing with DBCS characters generally follows the same rules as parsing with SBCS characters.

About this task

Literal strings and symbols can contain DBCS characters, but numbers must be in SBCS characters. See [“PARSE” on page 460](#) for examples of DBCS parsing.

Details of steps in parsing

Figures that give a conceptual view of parsing are provided.

The three figures that follow are to help you understand the concept of parsing. Please note that the figures do not include error cases.

The figures include terms whose definitions are as follows:

string start

is the beginning of the source string (or substring).

string end

is the end of the source string (or substring).

length

is the length of the source string.

match start

is in the source string and is the first character of the match.

match end

is in the source string. For a string pattern, it is the first character after the end of the match. For a positional pattern, it is the same as match start.

match position

is in the source string. For a string pattern, it is the first matching character. For a positional pattern, it is the position of the matching character.

token

is a distinct syntactic element in a template, such as a variable, a period, a pattern, or a comma.

value

is the numeric value of a positional pattern. This can be either a constant or the resolved value of a variable.

Chapter 21. Numbers and arithmetic operations

REXX defines the usual arithmetic operations (addition, subtraction, multiplication, and division) in as natural a way as possible. What this really means is that the rules followed are those that are conventionally taught in schools and colleges.

During the design of these facilities, however, it was found that unfortunately the rules vary considerably (indeed much more than generally appreciated) from person to person and from application to application and in ways that are not always predictable. The arithmetic described here is, therefore, a compromise that (although not the simplest) should provide acceptable results in most applications.

Introduction: numbers

Numbers (that is, character strings used as input to REXX arithmetic operations and built-in functions) can be expressed very flexibly. Leading and trailing blanks are permitted, and exponential notation can be used.

Some valid numbers are:

```
12          /* a whole number          */
'-76'       /* a signed whole number       */
12.76       /* decimal places             */
' + 0.003 '  /* blanks around the sign and so forth */
17.         /* same as "17"               */
.5          /* same as "0.5"              */
4E9         /* exponential notation        */
0.73e-7     /* exponential notation        */
```

In exponential notation, a number includes an exponent, a power of ten by which the number is multiplied before use. The exponent indicates how the decimal point is shifted. Thus, in the preceding examples, 4E9 is simply a short way of writing 4000000000, and 0.73e-7 is short for 0.000000073.

The *arithmetic operators* include addition (+), subtraction (-), multiplication (*), power (**), division (/), prefix plus (+), and prefix minus (-). In addition, there are two further division operators: integer divide (%) divides and returns the integer part; remainder (/ /) divides and returns the remainder.

The result of an arithmetic operation is formatted as a character string according to definite rules. The most important of these rules are as follows (for full details, see [“Definition of arithmetic facilities” on page 240](#)):

- Results are calculated up to some maximum number of significant digits (the default is 9, but you can alter this with the NUMERIC DIGITS instruction to give whatever accuracy you need). Thus, if a result requires more than 9 digits, it would usually be rounded to 9 digits. For example, the division of 2 by 3 would result in 0.66666667 (it would require an infinite number of digits for perfect accuracy).
- Except for division and power, trailing zeros are preserved (this is in contrast to most popular calculators, which remove all trailing zeros in the decimal part of results). So, for example:

```
2.40 + 2    ->    4.40
2.40 - 2    ->    0.40
2.40 * 2    ->    4.80
2.40 / 2    ->    1.2
```

This behavior is desirable for most calculations (especially financial calculations).

If necessary, you can remove trailing zeros with the STRIP function (see [“STRIP” on page 214](#)), or by division by 1.

- A zero result is always expressed as the single digit 0.
- Exponential form is used for a result depending on its value and the setting of NUMERIC DIGITS (the default is 9). If the number of places needed before the decimal point exceeds the NUMERIC DIGITS

setting, or the number of places after the point exceeds twice the NUMERIC DIGITS setting, the number is expressed in exponential notation:

```
1e6 * 1e6    ->    1E+12          /* not 1000000000000 */
1 / 3E10     ->    3.3333333E-11 /* not 0.000000000033333333 */
```

Definition of arithmetic facilities

A precise definition of the arithmetic facilities of the REXX language is given here.

Numbers

A *number* in REXX is a character string that includes one or more decimal digits, with an optional decimal point.

See “Exponential notation” on page 244 for an extension of this definition. The decimal point can be embedded in the number, or can be a prefix or suffix. The group of digits (and optional decimal point) constructed this way can have leading or trailing blanks and an optional sign (+ or -) that must come before any digits or decimal point. The sign can also have leading or trailing blanks.

Therefore, number is defined as follows:

blanks

are one or more spaces

sign

is either + or -

digits

are one or more of the decimal digits 0-9.

Note that a single period alone is not a valid number.

Precision

Precision is the maximum number of significant digits that can result from an operation.

Precision is controlled by the following instruction:

```
➡ NUMERIC DIGITS expression ; ➡
```

The *expression* is evaluated and must result in a positive whole number. This defines the precision (number of significant digits) to which calculations are carried out. Results are rounded to that precision, if necessary.

If you do not specify *expression* in this instruction, or if no NUMERIC DIGITS instruction has been processed since the start of a program, the default precision is used. The REXX standard for the default precision is 9.

Note that NUMERIC DIGITS can set values below the default of nine. However, use small values with care; the loss of precision and rounding thus requested affects all REXX computations, including, for example, the computation of new values for the control variable in DO loops.

Arithmetic Operators

REXX arithmetic is performed by the operators +, -, *, /, %, //, and ** (add, subtract, multiply, divide, integer divide, remainder, and power), which all act on two terms, and the prefix plus and minus operators, which both act on a single term.

Before every arithmetic operation, the term or terms being operated upon have leading zeros removed (noting the position of any decimal point, and leaving only one zero if all the digits in the number are zeros). They are then truncated (if necessary) to DIGITS + 1 significant digits before being used in the computation. (The extra digit is a “guard” digit. It improves accuracy because it is inspected at the end of an operation, when a number is rounded to the required precision.) The operation is then carried out under up to double that precision, as described under the individual operations that follow. When the operation is completed, the result is rounded if necessary to the precision specified by the NUMERIC DIGITS instruction.

Rounding is done in the traditional manner. The digit to the right of the least significant digit in the result (the “guard digit”) is inspected and values of 5 through 9 are rounded up, and values of 0 through 4 are rounded down. Even/odd rounding would require the ability to calculate to arbitrary precision at all times and is, therefore, not the mechanism defined for REXX.

A conventional zero is supplied in front of the decimal point if otherwise there would be no digit before it. Significant trailing zeros are retained for addition, subtraction, and multiplication, according to the rules that follow, except that a result of zero is always expressed as the single digit 0. For division, insignificant trailing zeros are removed after rounding.

The FORMAT built-in function (see [“FORMAT” on page 206](#)) allows a number to be represented in a particular format if the standard result provided does not meet your requirements.

Arithmetic operation rules: basic operators

The basic operators (addition, subtraction, multiplication, and division) operate on numbers as follows.

Addition and subtraction

If either number is 0, the other number, rounded to NUMERIC DIGITS digits, if necessary, is used as the result (with sign adjustment as appropriate). Otherwise, the two numbers are extended on the right and left as necessary, up to a total maximum of DIGITS + 1 digits (the number with the smaller absolute value may, therefore, lose some or all of its digits on the right) and are then added or subtracted as appropriate.

Example:

```
xxx.xxx + yy.yyyyy
```

becomes:

```
  xxx.xxx00
+ 0yy.yyyyy
-----
  zzz.zzzzz
```

The result is then rounded to the current setting of NUMERIC DIGITS if necessary (taking into account any extra “carry digit” on the left after addition, but otherwise counting from the position corresponding to the most significant digit of the terms being added or subtracted). Finally, any insignificant leading zeros are removed.

The prefix operators are evaluated using the same rules; the operations +number and -number are calculated as 0+number and 0-number, respectively.

Multiplication

The numbers are multiplied together (“long multiplication”) resulting in a number that can be as long as the sum of the lengths of the two operands.

Example:

```
xxx.xxx * yy.yyyyy
```

becomes:

```
zzzzz.zzzzzzzz
```

The result is then rounded, counting from the first significant digit of the result, to the current setting of NUMERIC DIGITS.

Division

For the following division, the following steps are taken:

```
yyy / xxxxx
```

First the number yyy is extended with zeros on the right until it is larger than the number xxxxx (with note being taken of the change in the power of ten that this implies). Thus, in this example, yyy might become yyy00. Traditional long division then takes place. This might be written:

```
      zzzz
      +-----
xxxxx | yyy00
```

The length of the result (zzzz) is such that the rightmost z is at least as far right as the rightmost digit of the (extended) y number in the example. During the division, the y number is extended further as necessary. The z number may increase up to NUMERIC DIGITS+1 digits, at which point the division stops and the result is rounded. Following completion of the division (and rounding if necessary), insignificant trailing zeros are removed.

Examples of basic operators

The following examples illustrate the main implications of the rules just described.

```
/* With: Numeric digits 5 */
12+7.00    -> 19.00
1.3-1.07   -> 0.23
1.3-2.07   -> -0.77
1.20*3     -> 3.60
7*3        -> 21
0.9*0.8    -> 0.72
1/3        -> 0.33333
2/3        -> 0.66667
5/2        -> 2.5
1/10       -> 0.1
12/12      -> 1
8.0/2      -> 4
```

Note: With all the basic operators, the position of the decimal point in the terms being operated upon is arbitrary. The operations may be carried out as integer operations with the exponent being calculated and applied afterward. Therefore, the significant digits of a result are not in any way dependent on the position of the decimal point in either of the terms involved in the operation.

Arithmetic operation rules: additional operators

The operation rules for the power (**), integer divide (%), and remainder (/ /) operators are described.

Power

The **** (power) operator** raises a number to a power, which can be positive, negative, or 0. The power must be a whole number. (The second term in the operation must be a whole number and is rounded to DIGITS digits, if necessary, as described in “Numbers used directly by REXX” on page 246.) If negative, the absolute value of the power is used, and then the result is inverted (divided into 1). For calculating the

power, the number is effectively multiplied by itself for the number of times expressed by the power, and finally trailing zeros are removed (as though the result were divided by 1).

In practice, the power is calculated by the process of left-to-right binary reduction (see “1” on page 243 for the reason). For $a**n$: n is converted to binary, and a temporary accumulator is set to 1. If $n = 0$ the initial calculation is complete. (Thus, $a**0 = 1$ for all a , including $0**0$.) Otherwise each bit (starting at the first nonzero bit) is inspected from left to right. If the current bit is 1, the accumulator is multiplied by a . If all bits have now been inspected, the initial calculation is complete; otherwise the accumulator is squared and the next bit is inspected for multiplication. When the initial calculation is complete, the temporary result is divided into 1 if the power was negative.

The multiplications and division are done under the arithmetic operation rules, using a precision of $\text{DIGITS} + L + 1$ digits. L is the length in digits of the integer part of the whole number n (that is, excluding any decimal part, as though the built-in function $\text{TRUNC}(n)$ had been used). Finally, the result is rounded to NUMERIC DIGITS digits, if necessary, and insignificant trailing zeros are removed.

Integer division

The *% (integer divide) operator* divides two numbers and returns the integer part of the result. The result returned is defined to be that which would result from repeatedly subtracting the divisor from the dividend while the dividend is larger than the divisor. During this subtraction, the absolute values of both the dividend and the divisor are used: the sign of the final result is the same as that which would result from regular division.

The result returned has no fractional part (that is, no decimal point or zeros following it). If the result cannot be expressed as a whole number, the operation is in error and will fail; that is, the result must not have more digits than the current setting of NUMERIC DIGITS . For example, $10000000000\%3$ requires 10 digits for the result (3333333333) and would, therefore, fail if $\text{NUMERIC DIGITS} = 9$ were in effect. Note that this operator may not give the same result as truncating regular division (which could be affected by rounding).

Reminder

The *// (remainder) operator* returns the remainder from integer division and is defined as being the residue of the dividend after the operation of calculating integer division as previously described. The sign of the remainder, if nonzero, is the same as that of the original dividend.

This operation fails under the same conditions as integer division (that is, if integer division on the same two terms would fail, the remainder cannot be calculated).

Examples of additional operators

The following examples use the power, integer divide, and remainder operators:

```
/* Again with: Numeric digits 5 */
2**3      ->      8
2**-3     ->     0.125
1.7**8    ->    69.758
2%3       ->      0
2.1//3    ->     2.1
10%3      ->      3
10//3     ->      1
-10//3    ->     -1
10.2//1   ->     0.2
10//0.3   ->     0.1
3.6//1.3  ->     1.0
```

Note:

1. A particular algorithm for calculating powers is used, because it is efficient (though not optimal) and considerably reduces the number of actual multiplications performed. It, therefore, gives better performance than the simpler definition of repeated multiplication. Because results may differ from those of repeated multiplication, the algorithm is defined here.

2. The integer divide and remainder operators are defined so that they can be calculated as a by-product of the standard division operation. The division process is ended as soon as the integer result is available; the residue of the dividend is the remainder.

Numeric Comparisons

You can use any of the comparison operators for comparing numeric strings.

The comparison operators are listed in section [“Comparison operators” on page 147](#). However, you should not use `==`, `\==`, `!=`, `>>`, `\>>`, `!>>`, `<<`, `\<<`, and `!<<` for comparing numbers because leading and trailing blanks and leading zeros are significant with these operators.

A comparison of numeric values is effected by subtracting the two numbers (calculating the difference) and then comparing the result with 0. That is, the operation:

```
A ? Z
```

where `?` is any numeric comparison operator, is identical with:

```
(A - Z) ? '0'
```

It is, therefore, the difference between two numbers, when subtracted under REXX subtraction rules, that determines their equality.

A quantity called *fuzz* affects the comparison of two numbers. This controls the amount by which two numbers can differ before being considered equal for the purpose of comparison. The FUZZ value is set by the following instruction:

```
➔ NUMERIC FUZZ expression ; ➔
```

Here *expression* must result in a positive whole number or zero. The default is 0.

The effect of FUZZ is to temporarily reduce the value of DIGITS by the FUZZ value for each numeric comparison. That is, the numbers are subtracted under a precision of DIGITS minus FUZZ digits during the comparison. Clearly the FUZZ setting must be less than DIGITS.

Thus if DIGITS = 9 and FUZZ = 1, the comparison is carried out to 8 significant digits, just as though NUMERIC DIGITS 8 had been put in effect for the duration of the operation.

Example

```
Numeric digits 5
Numeric fuzz 0
say 4.9999 = 5      /* Displays "0" */
say 4.9999 < 5      /* Displays "1" */
Numeric fuzz 1
say 4.9999 = 5      /* Displays "1" */
say 4.9999 < 5      /* Displays "0" */
```

Exponential notation

Exponential notation is useful for both large and small numbers.

The preceding description of numbers describes "pure" numbers, in the sense that the character strings that describe numbers can be very long. For example:

```
10000000000 * 10000000000
```

would give

```
100000000000000000000
```

and

```
.000000000001 * .000000000001
```

would give

```
0.000000000000000000000000000001
```

For both large and small numbers some form of exponential notation is useful, both to make long numbers more readable, and to make execution possible in extreme cases. In addition, exponential notation is used whenever the "simple" form would give misleading information.

For example:

```
numeric digits 5  
say 54321*54321
```

would display 2950800000 in long form. This is clearly misleading, and so the result is expressed as 2.9508E+9 instead.

The definition of numbers is, therefore, extended as:

The integer following the E represents a power of ten that is to be applied to the number. The E can be in uppercase or lowercase.

Certain character strings are numbers even though they do not appear to be numeric to the user. Specifically, because of the format of numbers in exponential notation, strings, such as 0E123 (0 raised to the 123 power) and 1E342 (1 raised to the 342 power), are numeric. In addition, a comparison such as 0E123=0E567 gives a true result of 1 (0 is equal to 0). To prevent problems when comparing nonnumeric strings, use the strict comparison operators.

Here are some examples:

```
12E7   =   120000000      /* Displays "1" */  
12E-5  =   0.00012        /* Displays "1" */  
-12e4  =  -120000         /* Displays "1" */  
0e123  =   0e456         /* Displays "1" */  
0e123  ==  0e456         /* Displays "0" */
```

The preceding numbers are valid for input data at all times. The results of calculations are returned in either conventional or exponential form, depending on the setting of NUMERIC DIGITS. If the number of places needed before the decimal point exceeds DIGITS, or the number of places after the point exceeds twice DIGITS, exponential form is used. The exponential form REXX generates always has a sign following the E to improve readability. If the exponent is 0, then the exponential part is omitted; that is, an exponential part of E+0 is never generated.

You can explicitly convert numbers to exponential form, or force them to be displayed in long form, by using the FORMAT built-in function (see "FORMAT" on page 206).

Scientific notation is a form of exponential notation that adjusts the power of ten so a single nonzero digit appears to the left of the decimal point. *Engineering notation* is a form of exponential notation in which from one to three digits (but not simply 0) appear before the decimal point, and the power of ten is always expressed as a multiple of three. The integer part may, therefore, range from 1 through 999. You can control whether Scientific or Engineering notation is used with the following instruction:

Scientific notation is the default.

```
/* after the instruction */
Numeric form scientific

123.45 * 1e11    ->    1.2345E+13

/* after the instruction */
Numeric form engineering

123.45 * 1e11    ->    12.345E+12
```

Numeric information

To determine the current settings of the NUMERIC options, use the built-in functions DIGITS, FORM, and FUZZ.

These functions return the current settings of NUMERIC DIGITS, NUMERIC FORM, and NUMERIC FUZZ, respectively.

Whole numbers

Within the set of numbers REXX understands, it is useful to distinguish the subset defined as whole numbers.

A *whole number* in REXX is a number that has a decimal part that is all zeros (or that has no decimal part). In addition, it must be possible to express its integer part simply as digits within the precision set by the NUMERIC DIGITS instruction. REXX would express larger numbers in exponential notation, after rounding, and, therefore, these could no longer be safely described or used as whole numbers.

Numbers used directly by REXX

As discussed, the result of any arithmetic operation is rounded (if necessary) according to the setting of NUMERIC DIGITS.

Similarly, when REXX directly uses a number (which has not necessarily been involved in an arithmetic operation), the same rounding is also applied. It is just as though the number had been added to 0.

In the following cases, the number used must be a whole number, and the largest number you can use is 999999999.

- The positional patterns in parsing templates (including variable positional patterns)
- The power value (right hand operand) of the power operator
- The values of *expr* and *exprf* in the DO instruction
- The values given for DIGITS or FUZZ in the NUMERIC instruction
- Any number used in the numeric option in the TRACE instruction.

Errors

Two types of errors can occur during arithmetic operations.

- Overflow or Underflow

This error occurs if the exponential part of a result would exceed the range that the language processor can handle, when the result is formatted according to the current settings of NUMERIC DIGITS and NUMERIC FORM. The language defines a minimum capability for the exponential part, namely the

largest number that can be expressed as an exact integer in default precision. Because the default precision is 9, REXX/CICS supports exponents in the range -999999999 through 999999999.

Because this allows for (very) large exponents, overflow or underflow is treated as a syntax error.

- **Insufficient storage**

Storage is needed for calculations and intermediate results, and on occasion an arithmetic operation may fail because of lack of storage. This is considered a terminating error as usual, rather than an arithmetic error.

Chapter 22. Conditions and condition traps

A *condition* is a specified event or state that CALL ON or SIGNAL ON can trap. A condition trap can modify the flow of execution in a REXX program.

Condition traps are turned on or off using the ON or OFF subkeywords of the SIGNAL and CALL instructions (see “CALL” on page 163 and “SIGNAL” on page 183).

condition and *trapname* are single symbols that are taken as constants. Following one of these instructions, a condition trap is set to either ON (enabled) or OFF (disabled). The initial setting for all condition traps is OFF.

If a condition trap is enabled and the specified *condition* occurs, control passes to the routine or label *trapname* if you have specified *trapname*. Otherwise, control passes to the routine or label *condition*. CALL or SIGNAL is used, depending on whether the most recent trap for the condition was set using CALL ON or SIGNAL ON, respectively.

Note: If you use CALL, the *trapname* can be an internal label, a built-in function, or an external routine. If you use SIGNAL, the *trapname* can be only an internal label.

The conditions and their corresponding events that can be trapped are:

ERROR

raised if a command indicates an error condition upon return. It is also raised if any command indicates failure and neither CALL ON FAILURE nor SIGNAL ON FAILURE is active. The condition is raised at the end of the clause that called the command but is ignored if the ERROR condition trap is already in the delayed state. The delayed state is the state of a condition trap when the condition has been raised but the trap has not yet been reset to the enabled (ON) or disabled (OFF) state. See [Note](#).

CALL ON ERROR and SIGNAL ON ERROR trap all positive return codes, and negative return codes only if CALL ON FAILURE and SIGNAL ON FAILURE are not set.

FAILURE

raised if a command indicates a failure condition upon return. The condition is raised at the end of the clause that called the command but is ignored if the FAILURE condition trap is already in the delayed state.

CALL ON FAILURE and SIGNAL ON FAILURE trap all negative return codes from commands.

HALT

raised if an external attempt is made to interrupt and end execution of the program. The condition is usually raised at the end of the clause that was being processed when the external interruption occurred.

NOVALUE

raised if an uninitialized variable is used:

- As a term in an expression
- As the *name* following the VAR subkeyword of a PARSE instruction
- As a variable reference in a parsing template, a PROCEDURE instruction, or a DROP instruction.

Note: SIGNAL ON NOVALUE can trap any uninitialized variables except tails in compound variables.

```
/* The following does not raise NOVALUE. */
signal on novalue
a.=0
say a.z
say 'NOVALUE is not raised.'
```

```
exit  
  
novalue:  
say 'NOVALUE is raised.'
```

You can specify this condition only for SIGNAL ON.

SYNTAX

raised if any language processing error is detected while the program is running. This includes all kinds of processing errors, including true syntax errors and "run-time" errors, such as attempting an arithmetic operation on nonnumeric terms. You can specify this condition only for SIGNAL ON.

Any ON or OFF reference to a condition trap replaces the previous state (ON, OFF, or DELAY, and any *trapname*) of that condition trap. Thus, a CALL ON HALT replaces any current SIGNAL ON HALT (and a SIGNAL ON HALT replaces any current CALL ON HALT), a CALL ON or SIGNAL ON with a new trap name replaces any previous trap name, any OFF reference disables the trap for CALL or SIGNAL, and so on.

Note: The state (ON, OFF, or DELAY, and any *trapname*) of each condition trap is saved on entry to a subroutine and is then restored on RETURN. This means that CALL ON, CALL OFF, SIGNAL ON, and SIGNAL OFF can be used in a subroutine without affecting the conditions set up by the caller. See the CALL instruction ([CALL](#)) for details of other information that is saved during a subroutine call.

Related reference

[“Action when a condition is trapped” on page 250](#)

When a condition trap is currently enabled (ON) and the specified condition occurs, instead of the usual flow of control, a CALL *trapname* or SIGNAL *trapname* instruction is processed automatically.

Action when a condition is not trapped

When a condition trap is currently disabled (OFF) and the specified condition occurs, the default action depends on the condition.

- For HALT and SYNTAX, the processing of the program ends, and a message (see Chapter 31, “Error numbers and messages,” on page 413) describing the nature of the event that occurred usually indicates the condition.
- For all other conditions, the condition is ignored and its state remains OFF.

Action when a condition is trapped

When a condition trap is currently enabled (ON) and the specified condition occurs, instead of the usual flow of control, a CALL *trapname* or SIGNAL *trapname* instruction is processed automatically.

You can specify the *trapname* after the NAME subkeyword of the CALL ON or SIGNAL ON instruction. If you do not specify *trapname*, the name of the condition itself (ERROR, FAILURE, HALT, NOTREADY, NOVALUE, or SYNTAX) is used.

For example, the instruction `call on error` enables the condition trap for the ERROR condition. If the condition occurred, then a call to the routine identified by the name ERROR is made. The instruction `call on error name commanderror` would enable the trap and call the routine COMMANDERROR if the condition occurred.

The sequence of events, after a condition has been trapped, varies depending on whether a SIGNAL or CALL is processed:

- If the action taken is a SIGNAL, execution of the current instruction ceases immediately, the condition is disabled (set to OFF), and the SIGNAL takes place in exactly the same way as usual (see [SIGNAL](#)).

If any new occurrence of the condition is to be trapped, a new CALL ON or SIGNAL ON instruction for the condition is required to re-enable it when the label is reached. For example, if SIGNAL ON SYNTAX is enabled when a SYNTAX condition occurs, then, if the SIGNAL ON SYNTAX label name is not found, a usual syntax error termination occurs.

- If the action taken is a CALL (which can occur only at a clause boundary), the CALL is made in the usual way (see [CALL](#)) except that the call does not affect the special variable RESULT. If the routine should RETURN any data, then the returned character string is ignored.

Because these conditions (ERROR, FAILURE, and HALT) can arise during execution of an INTERPRET instruction, execution of the INTERPRET may be interrupted and later resumed if CALL ON was used.

As the condition is raised, and before the CALL is made, the condition trap is put into a delayed state. This state persists until the RETURN from the CALL, or until an explicit CALL (or SIGNAL) ON (or OFF) is made for the condition. This delayed state prevents a premature condition trap at the start of the routine called to process a condition trap. When a condition trap is in the delayed state it remains enabled, but if the condition is raised again, it is either ignored (for ERROR, FAILURE, or NOTREADY) or (for the other conditions) any action (including the updating of the condition information) is delayed until one of the following events occurs:

1. A CALL ON or SIGNAL ON, for the delayed condition, is processed. In this case a CALL or SIGNAL takes place immediately after the new CALL ON or SIGNAL ON instruction has been processed.
2. A CALL OFF or SIGNAL OFF, for the delayed condition, is processed. In this case the condition trap is disabled and the default action for the condition occurs at the end of the CALL OFF or SIGNAL OFF instruction.
3. A RETURN is made from the subroutine. In this case the condition trap is no longer delayed and the subroutine is called again immediately.

On RETURN from the CALL, the original flow of execution is resumed (that is, the flow is not affected by the CALL).

Note:

1. You must be extra careful when you write a syntax trap routine. Where possible, put the routine near the beginning of the program. This is necessary because the trap routine label might not be found if there are certain scanning errors, such as a missing ending comment. Also, the trap routine should not contain any statements that might cause more of the program in error to be scanned. Examples of this are calls to built-in functions with no quotation marks around the name. If the built-in function name is in uppercase and is enclosed in quotation marks, REXX goes directly to the function, rather than searching for an internal label.
2. In all cases, the condition is raised immediately upon detection. If SIGNAL ON traps the condition, the current instruction is ended, if necessary. Therefore, the instruction during which an event occurs may be only partly processed. For example, if SYNTAX is raised during the evaluation of the expression in an assignment, the assignment does not take place. Note that the CALL for ERROR, FAILURE, HALT, and NOTREADY traps can occur only at clause boundaries. If these conditions arise in the middle of an INTERPRET instruction, execution of INTERPRET may be interrupted and later resumed. Similarly, other instructions, for example, DO or SELECT, may be temporarily interrupted by a CALL at a clause boundary.
3. The state (ON, OFF, or DELAY, and any *trapname*) of each condition trap is saved on entry to a subroutine and is then restored on RETURN. This means that CALL ON, CALL OFF, SIGNAL ON, and SIGNAL OFF can be used in a subroutine without affecting the conditions set up by the caller. See the CALL instruction ([CALL](#)) for details of other information that is saved during a subroutine call.
4. The state of condition traps is not affected when an external routine is called by a CALL, even if the external routine is a REXX program. On entry to any REXX program, all condition traps have an initial setting of OFF.
5. While user input is processed during interactive tracing, all condition traps are temporarily set OFF. This prevents any unexpected transfer of control; for example, should the user accidentally use an uninitialized variable while SIGNAL ON NOVALUE is active. For the same reason, a syntax error during interactive tracing does not cause exit from the program but is trapped specially and then ignored after a message is given.
6. The system interface detects certain execution errors either before execution of the program starts or after the program has ended. SIGNAL ON SYNTAX cannot trap these errors.

Note that a *label* is a clause consisting of a single symbol followed by a colon. Any number of successive clauses can be labels; therefore, multiple labels are allowed before another type of clause.

Related information

[Conditions and condition traps](#)

Condition information

When any condition is trapped and causes a SIGNAL or CALL, this becomes the current trapped condition, and certain condition information associated with it is recorded.

You can inspect this information by using the CONDITION built-in function (see [“CONDITION” on page 199](#)).

The condition information includes:

- The name of the current trapped condition
- The name of the instruction processed as a result of the condition trap (CALL or SIGNAL)
- The status of the trapped condition
- Any descriptive string associated with that condition.

The current condition information is replaced when control is passed to a label as the result of a condition trap (CALL ON or SIGNAL ON). Condition information is saved and restored across subroutine or function calls, including one because of a CALL ON trap. Therefore, a routine called by a CALL ON can access the appropriate condition information. Any previous condition information is still available after the routine returns.

Descriptive strings

The descriptive string varies, depending on the condition trapped.

ERROR

The string that was processed and resulted in the error condition.

FAILURE

The string that was processed and resulted in the failure condition.

HALT

Any string associated with the halt request. This can be the null string if no string was provided.

NOVALUE

The derived name of the variable whose attempted reference caused the NOVALUE condition. The NOVALUE condition trap can be enabled only using SIGNAL ON.

SYNTAX

Any string the language processor associated with the error. This can be the null string if you did not provide a specific string. Note that the special variables RC and SIGL provide information on the nature and position of the processing error. You can enable the SYNTAX condition trap only by using SIGNAL ON.

Special variables

A special variable is one that can be set automatically during processing of a REXX program.

There are three special variables: RC, RESULT, and SIGL. None of these has an initial value, but the program can alter them. (For information about RESULT, see [“RETURN” on page 182](#).)

RC

For ERROR and FAILURE, the REXX special variable RC is set to the command return code, as usual, before control is transferred to the condition label.

For SIGNAL ON SYNTAX, RC is set to the syntax error number.

SIGL

Following any transfer of control because of a CALL or SIGNAL, the program line number of the clause causing the transfer of control is stored in the special variable SIGL. Where the transfer of control is because of a condition trap, the line number assigned to SIGL is that of the last clause processed (at the current subroutine level) before the CALL or SIGNAL took place. This is especially useful for SIGNAL ON SYNTAX when the number of the line in error can be used, for example, to control a text editor. Typically, code following the SYNTAX label may PARSE SOURCE to find the source of the data, then call an editor to edit the source file positioned at the line in error. Note that in this case you may have to run the program again before any changes made in the editor can take effect.

Alternatively, SIGL can be used to help determine the cause of an error (such as the occasional failure of a function call) as in the following example:

```
signal on syntax
a = a + 1      /* This is to create a syntax error */
say 'SYNTAX error not raised'
exit

/* Standard handler for SIGNAL ON SYNTAX */
syntax:
  say 'REXX error' rc 'in line' sigl ':' "ERRORTEXT"(rc)
  say "SOURCELINE"(sigl)
  trace ?r; nop
```

This code first displays the error code, line number, and error message. It then displays the line in error, and finally drops into debug mode to let you inspect the values of the variables used at the line in error.

Chapter 23. REXX/CICS text editor

REXX/CICS provides a general purpose CICS-based text editor.

The editor is provided so that execs and data can be created, updated, and viewed from within the CICS environment.

The REXX/CICS editor includes several prefix commands (for example: C, CC, M, MM, B, A, F, P). To use the editor, enter EDIT.

While in an editor session, commands entered on the command line can be chained by placing a ";" between each command. Support is also provided for macros written in REXX. This lets you customize editor settings with a profile exec, add new commands to the editor, or use the editor facilities as part of an application.

Note: The REXX/CICS text editor does not support binary files.

Invoking the REXX/CICS text editor

You can start a REXX/CICS edit session from a CICS terminal (clear screen), a REXX/CICS session, another edit session, or a REXX exec. You can enter the editor by executing the CICS EDIT transaction identifier (or your site-defined transaction identifier for the REXX/CICS editor). From a clear REXX/CICS screen, enter EDIT followed by a REXX File System (RFS) file identifier and an edit session is issued for this file.

Note: If you specify REXX as a CICS transaction identifier with no exec name, the IBM-supplied REXXTRY interactive utility (CICRXTY exec) is issued. REXXTRY provides an interactive shell for performing REXX statements and commands.

While you are in the editor, you can start another edit session by entering `EDIT fileid`. The syntax for this method of invocation is defined in the EDIT command, [“EDIT” on page 264](#). When you write an exec, you can start the REXX/CICS editor session by issuing the CICS EDIT transaction identifier as a command. If a file ID is not specified when you invoke the editor, the file ID defaults to file NONAME in your current RFS directory. A fully qualified file ID is: `poolid:\dir1\dir2\fn.ft`

However, you can specify a partial file ID if the target file is in (or is going to be created in) your current directory (as specified by the CD command).

The following examples show four different ways to start an edit session:

```
EDIT TEST.EXEC (From terminal using CICS transaction ID EDIT)
EDIT TEST.EXEC (From within an edit session using the EDIT editor command)
'EDIT TEST.EXEC' (From within an exec using the EDIT command)
'EDIT TEST.EXEC' (From terminal using the REXX/CICS REXXTRY utility)
```

The first example starts a session from REXX/CICS. The second starts a new session from an existing session. The third starts a session from a REXX exec. The fourth starts a session from the REXX/CICS REXXTRY utility.

Screen format

When you call the editor without a profile, the default screen definition is displayed as shown in the following figure.

```

EDIT ---- POOL1:\USERS\USER1\TEST ----- COLUMN 1 73
COMMAND ==>
00000 ***** TOP OF DATA *****
00001
00002
00003
00004
00005
00006
00007
00008
00009
00010
00011
00012
00013 ***** BOTTOM OF DATA *****

```

F1=HELP F2=LADD F3=FIL F4=SPLT F5=F F6=JN F7=BA F8=FWD F10=LFT F11=RGF F12=QUI

The first line is reserved for the title line that contains the following:

- Fully qualified file ID
- Column numbers
- Displayed messages.

The informational lines that let you know where the top and bottom of the file is are the only lines that are displayed when you start a new edit session. These lines consist of a *prefix area* and a *data area*. The line where *** TOP OF DATA *** is displayed, in this example, is the current line. This is distinguished, from the rest, by being highlighted and it is the line most of the command line commands affect. The *command line* lets you interact with the editor on a high level basis. All of the screen lines, except for the title line, may be moved for convenience.

Prefix commands

The editor provides several prefix commands. These commands are entered in the prefix area and give you the ability to copy, move, insert, delete, and replicate lines on either an individual or a consecutive block basis.

- Individual line commands.

The following commands work with individual lines and consist of one character:

/	Specify current line in file
I	Insert a line
D	Delete a line
C	Copy a line
M	Move a line
R	Replicate a line
"	Synonym for replicate

When you enter one of the previous commands in the prefix area of a line, the command performs its respective function on that line. If you enter an "I" in the prefix area of line 00000, the editor opens a new line just below it for input. You can also append a number to the end of the prefix command. This acts as a replication factor. If the number "5" is appended to the "I", five lines are opened for input instead of one.

- Consecutive block commands.

The following commands work with consecutive blocks of lines and consist of two characters:

DD

Delete a block of lines

CC

Copy a block of lines

MM

Move a block of lines

RR

Replicate a block of lines

'''

Synonym for replicate

Block commands are processed in pairs. You place one command in the prefix area of the first line of the block and place the same command in the prefix area of the last line of the block. For example, to delete a block of lines, you place a "DD" in the prefix area of line 00001 and another "DD" in the prefix area of line 00005. This deletes all lines between line 00001 and line 00005, inclusive. The only block prefix command that allows a replication factor is the replicate command. So, when you specify a number with the replicate block command you need to know how many times you want the block (not individual lines) replicated. The replication factor must be specified with the first RR replication command.

- Destination commands.

The following commands are called destination prefix commands:

A

After

B

Before

F

Following

P

Preceding

These commands give the move and copy prefix commands a destination for a block of text. When you enter these in the prefix area, the text from a copy or a move is placed either before or after that line according to what destination command is specified. The replicate prefix command does not use a destination prefix command. Instead, it places its output immediately after the block that is to be replicated.

Macros under the REXX/CICS editor

The editor supports REXX macros, giving the macros the ability to alter the editor settings and display the editor screens. Macros can process all of the editor command line commands.

The following example addresses the editor command environment and alters the editor settings.

```
/* Macro to alter the setting of the REXX/CICS editor */
ADDRESS EDITSVR
'SET NUMBERS OFF'
'SET CURLINE 10'
'SET MSGLINE 2'
```

```
'SET CMDLINE TOP'  
'SET CASE MIXED IGNORE'
```

The following example enters the text Some, More, and DATA on three separate lines and then displays the current edit screen.

```
/* Macro to use the REXX/CICS editor as an I/O interface */  
ADDRESS EDITSVR  
'INPUT Some'  
'INPUT More'  
'INPUT DATA'  
'DISPLAY'
```

Command Line Commands

The syntax and description for each of the command line commands is described.

ARBCHAR

ARBCHAR sets the arbitrary characters.

➤ ARBCHAR — *arbchar* ➤

Operands

arbchar

specifies a printable (typeable) character.

Return codes

0

Normal return

202

Invalid operand

Example

```
'ARBCHAR . '
```

This example defines the character "." as being the arbitrary character.

Note: The arbitrary character takes the place of text in a string. The default value for the arbitrary character is a ".". For more information on how you can do searches with the arbitrary character, see the FIND command, [“FIND” on page 267](#).

ARGS

ARGS stores the default parameters to be passed to the program being edited when invoked with the text editor EXEC command.

➤ ARGS —  ➤

Notes:

¹ If *arguments* is not specified, any previously defined arguments are deleted.

Operands

arguments

specifies the parameter string to be passed. If you do not specify *arguments*, any previously defined arguments are deleted.

Return codes

0

Normal return

Example

```
'ARGS A B C'  
'EXEC '  
'ARGS '
```

The first line of this example defines the arguments to be passed as A, B, and C. The second line executes the last saved copy of the file that is currently being edited, passing it the arguments defined in line one. The last line deletes the arguments.

BACKWARD

BACKWARD scrolls backward toward the beginning of a file for a specified number of screen displays.

Operands

n

specifies the number of screen displays you want to scroll backward. If you specify an asterisk (*), the screen scrolls to the top of the file and the current line is set to the top of the file. If *n* is not specified, the screen scrolls back one display.

Return codes

0

Normal return

202

Invalid operand

Example

```
'BACKWARD'
```

This example scrolls one screen toward the top of the file.

Note: The editor, by default, sets PF7 to BACKWARD and PF8 to FORWARD.

BOTTOM

BOTTOM scrolls to the bottom of the file.

➡ BOTTOM ➡

Return codes

0

Normal return

Example

```
'BOTTOM'
```

This example scrolls to the bottom of the file.

CANCEL

CANCEL ends the current edit session without saving the changes.

➤ CANCEL ➤

Return codes

0

Normal return

210

Request failed

Example

```
'CANCEL'
```

This example quits the current editor session unconditionally, without saving any file changes.

Note:

1. CANCEL lets you exit the editor without saving changes, and without any warning messages that changes have been made.
2. CANCEL is a synonym for QQUIT.

CASE

CASE sets the case translation and interpretation preferences.

Notes:

- ¹ The default is set in the user profile.

Operands

UPPER

translates lowercase characters to uppercase when entered.

MIXED

works with each character in its original form.

RESPECT

respects the case of each character while doing a search.

IGNORE

ignores the case of each character while doing a search.

Return codes**0**

Normal request

202

Invalid operand

Example

```
'CASE MIXED RESPECT'
```

This example sets the case to MIXED and the sensitivity to RESPECT. For more information on sensitivity, see the FIND command, [“FIND” on page 267](#).

CHANGE

CHANGE changes a string in the file.

```
➔ CHANGE — /string1/string2/ ———— ➔
                        |
                        | ALL
                        |
```

Operands***string1***

specifies the string being replaced.

string2

specifies the string that replaces *string1*.

ALL

is a keyword indicating that all occurrences on all lines, from the current line, to the end of the file, are changing.

/

is the delimiting character.

Return codes**0**

Normal return

202

Invalid operand

210

Request failed

223

Search argument not found

Example

```
'CHANGE /noeditor/editor/'
```

This example replaces the first occurrence of `noeditor` with `editor`.

Note: The `CHANGE` command respects the sensitivity settings of the editor when locating *string1* and when changing *string2* as defined by the `CASE` command or the system default.

CMDLINE

`CMDLINE` sets the command line display preferences.

Operands

TOP

displays the command line on the second line of the screen.

BOTTOM

displays the command line on the bottom line of the screen.

Return codes

0

Normal return

202

Invalid operand

Example

```
'CMDLINE TOP'
```

This example places the command line on the second line of the screen.

CTLCHAR

`CTLCHAR` sets a control character's function.

Operands

character

specifies a control character to use.

OFF

drops all definitions of control characters if `OFF` is used without specifying a character or drops the specific character if one is specified.

ESCAPE

specifies that the following character in the string, passed to the `RESERVED` command, is a control character.

PROTECT

specifies that the string passed to the `RESERVED` command is protected from user input.

NOPROTECT

specifies that user input, passed to the RESERVED command, is allowed on this string.

Return codes

0

Normal return

202

Invalid operand

Example

```
'CTLCHAR ! ESCAPE'  
'CTLCHAR % PROTECT'  
'RESERVED 20 HIGH !% Important Info'
```

This example defines ! as the escape character and % as the field protection character. After you enter these commands, the screen line 20 will be protected and contain the text that follows the control characters, !%.

CURLINE

CURLINE sets the current line display preferences.

➤ CURLINE — *number* ➤

Operands

number

specifies the screen line number.

Return codes

0

Normal return

202

Invalid operand

Example

```
'CURLINE 3'
```

This example sets the current display line to screen line 3.

Note: The current line is displayed at the screen line number specified in this command. However, the current line cannot be displayed on line 1 because line 1 is reserved for the title line.

DISPLAY

DISPLAY shows the current edit screen.

➤ DISPLAY ➤

Return codes

0

Normal return

210

Request failed

Example

```
'DISPLAY'
```

This example displays the current edit screen.

Note: The DISPLAY command is only useful when it runs from a macro. It displays the current edit session's screen. When it runs from a normal terminal edit session there is no noticeable effect.

DOWN

DOWN scrolls forward in the file.

Operands

number

specifies the number of lines to scroll. If you do not specify *number*, the screen moves down only one line.

Return codes

0

Normal return

202

Invalid operand

Example

```
'DOWN 5'
```

This example scrolls forward through the file five lines.

EDIT

EDIT opens a new edit session.

Operands

fileid

specifies the file ID of the file to be created or edited.

PDS_name(mem)

specifies a fully qualified MVS PDS name and member name to be edited.

PDS

is a keyword that follows a the PDS member name when a PDS is being edited.

MACRO

is a keyword specifying a group of instructions applied to the file being edited.

macroname

specifies the file name portion of the profile macro file ID (REXX exec name).

Return codes**0**

Normal return

203

File not found

204

Not authorized

211

Invalid file ID

226

File is currently being edited

299

Internal error

1748

No entry for ddname in Task Input/Output Table (TIOT)

1749

Cannot export to multi unit dataset

1750

ddname has more than one dataset in concatenation

Example

```
'EDIT TEST.EXEC'
```

This example opens an edit session for the file TEST.EXEC.

Note:

1. The directory used when editing a file, is determined as follows:
 - If a fully qualified directory ID is explicitly given, it is always used.
 - If a partially qualified file ID is specified, the current directory and path are searched in an attempt to find an existing file that would match the file ID (if it were fully resolved using that directory name).
 - If such a match is successful, the edit session is for an existing file and the file ID is fully resolved using the directory the file was found in.
 - If the file is not located in the search order, an edit session for a new file is created, with the fully resolved file ID specifying the current working directory (as specified by the CD command).
2. An MVS PDS member is distinguished by using the keyword PDS after the member name. Members must be enclosed in parentheses, quotes are not allowed.
3. The default user profile macro that the editor tries to call is CICEPROF. The CICEPROF macro creates an ISPF/PDF like environment. A second profile macro, named CICXPROF, is provided. CICXPROF creates a VM/CMS XEDIT like environment.
4. If a file ID or PDS name is not specified, an RFS file with the special name, NONAME, is created.

EXEC

EXEC executes a REXX program within an editor session.

Notes:

¹ If *REXX_program* is not specified, the last saved copy of the file that is currently being edited is executed.

Operands

REXX_program

specifies the REXX program name to execute. If you do not specify a name, the last saved copy of the file that is currently being edited will be executed. If any arguments have been defined using the ARG\$ command, these will be passed.

arguments

specifies the arguments to be passed to the program specified in the *REXX_program* operand.

Return codes

n

The return code set by the exit of the called exec. See [“EXIT” on page 170](#).

0

Normal return

-3

Exec not found

-10

Exec name not specified

-11

Invalid exec name

-12

GETMAIN error

-99

Internal error

Example

```
'EXEC TEST1.EXEC X Y Z'
```

This example executes program TEST1.EXEC and passes X, Y, and Z as arguments.

FILE

FILE saves the current file being edited.

Notes:

¹ If *fileid* is not specified, the file is saved as the default file ID.

Operands

fileid

specifies the file ID of the file. If you do not specify *fileid*, the file is saved as the default file ID.

Return codes

0

Normal return

202

Invalid operand

204

Not authorized

207

Insufficient space in file pool

210

Request failed

Example

```
'FILE '
```

This example saves the current file being edited, using the current file ID specification for the edit session. The current file ID is initially taken from the file ID specified on the edit command, when an edit session is created.

FIND

FIND locates a string of text in the file.

Operands

searcharg

specifies the text string to be searched on. If you do not specify *searcharg*, a search is performed on the previous search string (*previous_searcharg*).

Return codes

0

Normal return

202

Invalid operand

223

Search argument not found

Example

```
'FIND REDT '
```

This example finds the first occurrence of REDT.

```
'FIND Redt'
```

If CASE is set to RESPECT then this example will not find the first occurrence of REDT. It will find the first occurrence of Redt. For more information, see the CASE command, “CASE” on page 260.

The *searcharg* can contain the arbitrary character, in which case the arbitrary character represents any text string which might be imbedded at the arbitrary character's location.

```
'FIND ONE.THREE'
```

This example finds the first occurrence of any string with ONE and THREE joined by another string.

Note:

1. When the RESPECT flag is set with the CASE command, the case of the *searcharg* is respected.
2. The search begins at the current line and continues downward until BOTTOM OF DATA is reached, or a match is made. If BOTTOM OF DATA is reached without a match, then the current line remains where it was before the FIND was processed, rather than making BOTTOM OF DATA the current line.

FORWARD

FORWARD scrolls forward toward the end of the file for a specified number of screen displays.

Operands

n

specifies the number of screen displays you want to scroll forward. If you specify an asterisk (*), the screen scrolls to the bottom of the file and the current line is set to the last line of data. If *n* is not specified, the screen scrolls forward one display.

Return codes

0

Normal return

202

Invalid operand

Example

```
'FORWARD'
```

This example scrolls one screen toward the end of the file.

Note: The editor, by default, sets PF7 to BACKWARD and PF8 to FORWARD.

GET

GET imports an RFS file into the current edit session.

Operands

fileid

specifies the file ID of the file.

Return codes

0

Normal return

203

File not found

204

Not authorized

210

Request failed

Example

```
'GET P00L1:\USERS\USER1\TEST.EXEC'
```

This example pulls the REXX File System file TEST.EXEC in after the current line.

GETPDS

GETPDS imports a member from an MVS PDS into the current edit session. The file is inserted after the current line.

➡ GETPDS — *PDS_name(mem)* →

Operands

PDS_name(mem)

specifies a fully qualified MVS PDS and member name.

Return codes

0

Normal return

203

File not found

204

Not authorized

210

Request failed

Example

```
'GETLIB MYFILE.PROJ1(MEM1)'
```

This example gets PDS member MEM1 and puts it after the current line in an edit session.

Note: You cannot use GETPDS to get the member of a dataset unless the CICS region has RACF access to the dataset and your CICS sign on matches the high level dataset prefix.

INPUT

INPUT inserts a new line after the current line.

Notes:

¹ If *text* is not specified, the new line is blank.

Operands

text

specifies the text being inserted on the new line. If you do not specify *text*, the new line is blank.

Return codes

0

Normal return

Example

```
'INPUT Test Input Data'
```

This example places the text `Test Input Data` on a newly inserted line after the current line.

JOIN

JOIN joins two lines into one.

➡ JOIN ⬅

Return codes

0

Normal return

210

Request failed

Example

```
'JOIN'
```

This example joins the line that the cursor is on with the line immediately following it.

LEFT

LEFT scrolls left in the file.

Operands

number

specifies the number of characters to scroll. If you do not specify *number*, the screen scrolls left one character in the file. If you specify 0 for *number*, the file scrolls to the far left side.

Return codes

0

Normal return

202

Invalid operand

210

Request failed

Example

```
' LEFT 20 '
```

This example scrolls 20 characters to the left.

LINEADD

LINEADD adds a blank line after the cursor line.

➤ LINEADD ➤

Return codes

0

Normal return

230

Cursor is not in file area

Example

```
' PFKEY 2 LINEADD '
```

This example causes the addition of a blank line after the line where the cursor resides (if it is a file line) whenever PF2 is pressed.

Note: LINEADD is mainly useful when assigned to a program function (PF) key. It is by default assigned to PF2.

LPREFIX

LPREFIX enters a prefix command into the current line prefix area.

➤ LPREFIX — *prefix* ➤

Operands

prefix

specifies any standard prefix (such as C, CC, M, MM, B, A) that is entered during an edit session.

Return codes

0

Normal return

202

Invalid operand

Example

```
'LPREFIX D'
```

This example causes the deletion of the current file line.

Note: LPREFIX is provided to let you use the prefix commands from within edit macros.

MACRO

MACRO calls a macro.

➤ MACRO — *fileid* ➤

Operands

fileid

specifies the file ID of the macro you want to run. If this file ID includes a file type suffix, then an attempt is made to call an exec with that suffix. Otherwise, an attempt is made to call an exec whose suffix is EXEC.

Return codes

n

The return code that is set by the exit of the called exec. See [“EXIT” on page 170](#).

0

Normal return

-3

Exec not found

-10

Exec name not specified

-11

Invalid exec name

-12

GETMAIN error

-99

Internal error

Example

```
'MACRO P00L1:\USERS\USER1\TEST'
```

This example calls the macro, P00L1:\USERS\USER1\TEST.EXEC.

Note: Macros can make calls to the REXX/CICS editor server. Any command that you can enter from the command line of the editor can be run from a macro.

MSGLINE

MSGLINE sets the message line display preferences.

Operands

number

displays the message line on the corresponding screen line.

OFF

does not display the message line.

INFO

displays messages in the header line.

Return codes

0

Normal return

202

Invalid operand

Example

```
'MSGLINE 2'
```

This example places the message line on screen line 2.

NULLS

NULLS controls whether the fields on the screen will be written with trailing blanks or trailing nulls.

Operands

ON

specifies that fields on the screen are written with trailing nulls.

OFF

specifies that fields on the screen are written with trailing blanks.

Return codes

0

Normal return

202

Invalid operand

Example

```
'NULLS ON'
```

This example causes trailing nulls on the fields of the screen.

NUMBERS

NUMBERS sets the prefix area display preferences.

Operands

ON

displays sequential numbers in the prefix area.

OFF

displays equal signs in the prefix area.

Return codes

0

Normal return

202

Invalid operand

Example

```
'NUMBERS ON'
```

This example displays sequential numbers in the prefix area.

Note: Line number sequencing is not done on the data within the edit session, but are pseudo line numbers associated with the file lines during the edit session only.

PFKEY

PFKEY sets or processes a program function (PF) key.

Notes:

¹ If *text* is not specified, the PF key is processed.

Operands

number

specifies the PF key that is set or processed.

text

specifies the text that the PF key is set to. If you do not specify *text*, the PF key is processed.

Return codes

0

Normal return

202

Invalid Operand

229

Number out of range

Example

```
'PFKEY 3,quit'  
'PFKEY 3'
```

This example first sets PFKEY 3 to quit and then processes the PF key.

PFKLINE

PFKLINE sets the program function (PF) key line display preferences.

Operands

TOP

displays the PF key line on the second line of the screen.

BOTTOM

displays the PF key line on the bottom line of the screen.

number

specifies the screen line number.

OFF

removes the PF key from the display screen.

Return codes

0

Normal return

202

Invalid operand

Example

```
'PFKLINE BOTTOM'
```

This example places the PF key line on the bottom line of the screen.

QQUIT

QQUIT ends the current edit session without saving changes.

➤ QQuit ➤

Return codes

0

Normal return

Example

```
'QQUIT'
```

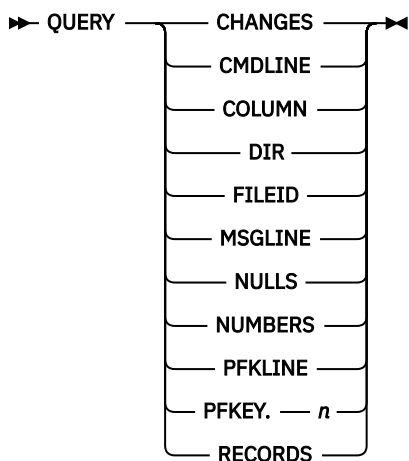

This example quits the current editor session unconditionally, without saving any file changes.

Note:

1. QQUIT lets you exit the editor without saving changes, and without any warning messages that changes have been made.
2. A synonym for QQUIT is CANCEL.

QUERY

QUERY displays the current settings of the editor.

Operands

CHANGES

displays the number of modifications to the file since it was last saved.

CMDLINE

displays the current setting of the command line. For more information see the Text Editor command [“CMDLINE”](#) on page 262.

COLUMN

displays the starting column in the file that is displayed on the screen.

DIR

displays the directory that is associated with the file.

FILEID

displays the name of the file being edited.

MSGLINE

displays the current setting of the message line. For more information see the Text Editor command [“MSGLINE”](#) on page 273.

NULLS

displays the current setting of NULLS. For more information see the Text Editor command [“NULLS”](#) on page 273.

NUMBERS

displays the current setting of NUMBERS. For more information see the Text Editor command [“NUMBERS” on page 274](#).

PFKLINE

displays the current setting of the PFKLINE. For more information see the Text Editor command [“PFKLINE” on page 275](#).

PFKEY.*n*

displays the command that is processed if PFKEY *n* is pressed. The *n* is any number from 1 to 24.

RECORDS

displays the number of lines in the file.

Return codes

0

Normal return

202

Invalid operand

236

Not defined

Example

```
'QUERY PFKEY.1'
```

This example displays the command that is processed when PFKEY 1 is pressed.

QUIT

QUIT ends the current edit session.

➡ QUIT →

Return codes

0

Normal return

210

Request failed

Example

```
'QUIT'
```

This example exits the editor.

Note: When the current file has been changed, the editor does not let you exit until either a save is done or you enter the QQUIT command.

RESERVED

RESERVED reserves a line on the screen for your output.

Operands

line

specifies the line that is reserved and the text is displayed.

HIGH

is a keyword specifying that the text is highlighted.

NOHIGH

is a keyword specifying that the text is the usual intensity.

OFF

is a keyword specifying that the line is freed from its reserved state.

text

specifies a string of text, with optional control characters, that is displayed on the reserved line.

Return codes

0

Normal return

202

Invalid operand

210

Request failed

229

Number out of range

Example

```
'CTLCHAR ! ESCAPE'  
'CTLCHAR % PROTECT'  
'RESERVED 20 HIGH !% Important Info'
```

This example displays Important Info in a high intensity, protected field on screen line 20.

RESET

RESET terminates any pending prefix commands.

➡ RESET ➡

Return codes

0

Normal return

Example

```
'RESET'
```

This example cancels all pending prefix commands.

RIGHT

RIGHT scrolls right in the file.

Operands

number

specifies the number of characters to scroll. If you do not specify *number*, the screen scrolls to the right one character in the file. If you specify 0 for *number*, the file scrolls to the far right.

Return codes

0

Normal return

202

Invalid operand

Example

```
'RIGHT 20'
```

This example scrolls 20 characters to the right in the file.

Note: If the value you specified causes a target outside of the record, scrolling stops at the right side of the record.

SAVE

SAVE saves a file to an RFS file or PDS member.

Notes:

¹ If *fileid* is not specified, the file is saved as the default file ID.

Operands

fileid

specifies the file ID of the file. If you do not specify *fileid*, the file is saved as the default file ID.

Return codes

0

Normal return

202

Invalid operand

207

Insufficient space in file pool

210

Request failed

Example

```
'SAVE SYSTEM:\USERS\USER1\TEST.EXEC'
```

This example saves the current file to the RFS and names it as SYSTEM:\USERS\USER1\TEST.EXEC.

SORT

SORT sorts the lines from the current line on down.

Operands

specifies that all the lines from the current line to the end of the file are sorted.

num

specifies that the lines from the current line for the value of *num* are sorted.

A

specifies that the lines are sorted in ascending order. (This is the default.)

D

specifies that the lines are sorted in descending order.

fromcol

specifies that the lines are sorted on data beginning in this column. If you do not specify *fromcol tocol*, sorting begins at the first column.

tocol

specifies that the lines are sorted on data ending in this column.

Return codes

0

Normal return

202

Invalid operand

229

Number out of range

Example

```
'SORT * A 5 10'
```

This example sorts all lines in the file from the current line down and is sorted on columns 5 to 10.

Note: If you sort a large number of lines, the sort will work very slowly.

SPLIT

SPLIT splits a line into two lines.

➡ SPLIT ➡

Return codes

0

Normal return

210

Request failed

Example

```
'SPLIT'
```

This example splits the line, that the cursor is on, into two lines. One line contains all the text on that line to the left of the cursor and the line following contains the remaining text (under and to the right of the cursor).

STRIP

STRIP strips the trailing blanks off all file lines.

➤ STRIP ➤

Return codes

0

Normal return

Example

```
'STRIP'
```

This example strips all trailing blanks of each file line.

Note: This command is especially useful when you import data sets from partitioned data sets, then save them into an RFS, because partitioned data sets pad with blanks.

SYNONYM

SYNONYM assigns a command action to any other valid command.

➤ SYNONYM — *syn* — *command* ➤

Operands

syn

specifies any valid command that executes the command action for which it is a synonym.

command

specifies any valid command.

Return codes

0

Normal return

Example

```
'SYNONYM GL GETLIB'
```

This example makes GL equivalent to the command GETLIB.

TOP

TOP scrolls to the top of the file.

➤ TOP ➤

Return codes

0

Normal return

Example

```
'TOP'
```

This example scrolls to the top of the file.

TRUNC

TRUNC truncates each line in the file to the given length.

➤ TRUNC — *column* ➤

Operands

column

specifies the last column you want to keep.

Return codes

0

Normal return

202

Invalid operand

Example

```
'TRUNC 72'
```

This example truncates all lines in the file to a length of 72 characters.

Note: This command is useful when you are working with data sets that have sequence numbers that require removing. The editor does not currently have support for placing or maintaining sequence numbers in a file.

UP

UP scrolls backward in the file (towards the top of the file).

➤ UP — { 1
 number } ➤

Operands

number

specifies the number of lines to scroll. If you do not specify *number*, the default scroll amount is set to 1.

Return codes

0

Normal return

202

Invalid operand

Example

```
'UP 20'
```

This example scrolls 20 lines backward in the file.

Chapter 24. REXX/CICS File System

The REXX File System (RFS) is provided for the storage of text files and execs created with the REXX/CICS editor, and by execs using RFS commands and data imported from outside of the REXX File System.

RFS was modeled after the Advanced Interactive Executive (AIX) and OS/2 file systems. The concept of directories is the main idea taken from these environments. Partitioning each directory into several subdirectories will give a hierarchical organization.

You can access RFS functions by using the RFS command. In addition to providing the ability to perform file I/O, the RFS command provides you the ability to do essential file system maintenance.

A file list utility (FLST) is provided as a full screen interface to the REXX File System. This utility can also be used as a platform where other CICS work can be performed.

File pools, directories, and files

File pools are sets of VSAM files. In each file pool, there is a root directory. Files are either data files or REXX execs.

The first VSAM file in the pool contains information about the pool and must be formatted before data can be written to the pool. All other VSAM files in the pool are extensions of the first file and only need to be defined in the pool's list of VSAM files after they have been allocated and defined to Access Method Services and CICS. VSAM files can be added to a file pool, at will, to provide additional storage space in that pool. However, defining and adding space to file pools is a task for REXX/CICS administrators or CICS Systems Programmers. File pools are given a unique one to eight character name.

The root directory for a file pool is named `file_pool_name:\`. This directory can contain files as well as subdirectories. A subdirectory is a directory within another directory. Subdirectories can be created within any other directory. A new directory can be created with the RFS MKDIR command. All directories, except the root, are distinguished by a one to eight character directory file name joined, by a period, with an optional one to eight character directory file type. This is called the directory ID.

A file pool can be defined to be a user or non-user file pool. One directory that should exist in all user file pools is the USERS directory. This directory contains several subdirectories that correspond to the users on the system. When you save a file into the RFS for the first time, a new subdirectory is created in the USERS directory. This new directory is named with your user ID if you are signed onto CICS. Otherwise, the directory name will default to the CICS DFLTUSER value. After this directory is created, you can create any number of subdirectories within that personal directory. You can place files in any of the directories that you create.

Files are either data files or REXX execs. They use the same naming conventions as directories (a file name and an optional file type joined with a period). The default file type for REXX execs is EXEC. Files are created with the REXX/CICS editor or with the RFS DISKW command.

A fully qualified file ID consists of a file pool name followed by a `:`, each directory's ID in the path followed by a `\`, and the file ID, which is comprised of a file name and an optional file type.

Examples

The following example shows a fully qualified file ID. POOL1 is the file pool name, USERS and USER1 are directory ID's, and TEST.EXEC is the file ID.

```
POOL1:\USERS\USER1\TEST.EXEC
```

The following example shows file pools, directories, and files.

POOL1:	File Pool
\	Root Directory
TEST1.EXEC	File
USERS\	Subdirectory

USER1\	Subdirectory
TEST2.EXEC	File
DOCS\	Subdirectory
TEST3.DOCUMENT	File
USER2\	Subdirectory
LETTER.DOCUMENT	File
PROJECT1\	Subdirectory
PROD1.EXEC	File
DATA\	Subdirectory
PROD1.DATA	File
WORK:\	File Pool and Root Directory
TEST1.DATA	File
CHARTS\	Subdirectory
CHART1.DATA	File
CHART2.DATA	File

This example shows two file pools (POOL1 and WORK). File pool POOL1 contains a file (TEST1.EXEC) and two subdirectories (USERS and PROJECT1). Inside the USERS subdirectory are two subdirectories (USER1 and USER2) that correspond to user IDs (USER1 and USER2). User USER1 has a file (TEST2.EXEC) and a subdirectory (DOCS) inside its directory. Inside the DOCS subdirectory there is another file (TEST3.DOCUMENT). User USER2 has a file (LETTER.DOCUMENT) inside its directory. File pool WORK contains a file (TEST1.DATA) and a subdirectory (CHARTS). Inside subdirectory CHARTS are two files (CHART1.DATA and CHART2.DATA).

Current directory and path

The current directory is the current working directory, and is first in the search order when working with REXX File System (RFS).

The current directory can be set using the CD command, [“CD” on page 353](#). The CD command has a similar format to the cd command in operating systems such as DOS. The syntax is CD followed by the partially or fully qualified directory name. To change from a subdirectory back to the parent directory, type CD .. To change to another subdirectory, CD can be followed by the subdirectory name.

Examples

In the following example, the first command sets the current directory to POOL1:\USERS\USER1 and the second command sets the current directory to POOL1:\USERS\USER1\DOCS. The third command changes the current directory back to POOL1:\USERS\USER1.

```
'CD POOL1:\USERS\USER1'
'CD DOCS'
'CD ..'
```

The PATH command is used to define the search order for REXX execs, after the current directory is searched. See [“PATH” on page 398](#) for more information. The syntax is PATH, followed by a list, separated by spaces, of fully qualified directory names.

The following example first sets a current directory, then defines the search order.

```
'CD POOL1:\USERS\USER1\EXECS'
'PATH POOL1:\ POOL1:\USERS\USER1'
'EXEC TEST2.EXEC'
```

The exec name is fully qualified, using the directory ID of each directory in the search before the search of each respective directory is performed. The fully qualified names are as follows:

```
'POOL1:\USERS\USER1\EXECS\TEST2.EXEC'
'POOL1:\TEST2.EXEC'
'POOL1:\USERS\USER1\TEST2.EXEC'
```

When the REXX/CICS command EXEC is invoked, all three directories above are searched resulting in REXX/CICS finding the exec in the POOL1:\USERS\USER1 directory. If TEST2.EXEC existed in the POOL1:\ directory, RFS would have stopped searching when it was found. The first copy found in the search order is accessed.

Note: Whenever a file name is not fully qualified, RFS follows the search order looking for the exec, beginning with the current directory. The first copy found is executed. If none are found, an error is returned indicating the target file or exec was not found.

Security

There are two general types of REXX/CICS File System security: file access security and command execution security.

- *File access security* controls access to execs and data. RFS file security can be controlled at two levels; the CICS level, and at the RFS directory level.
 1. At the CICS level, authorization to access file pool VSAM files can be given to specific users. This gives a high level of security.
 2. At the RFS directory level, user directories are private directories and can be accessed only by the owning user (by default).

However, the owner of a directory can use the RFS AUTH command to define a directory as being publicr, publicw, or secured. publicr means any other REXX/CICS user has read/only access to this directory. publicw means any other REXX/CICS user has read/write access to this directory. secured means that the RFS security exit will be invoked to determine whether access should be allowed. For more information, see the RFS AUTH command, “AUTH” on page 287. Non-user directories can be created and their access levels defined by an authorized user.

- *Command execution security* controls the use of certain REXX/CICS commands, or command keywords. For more information, see [Security](#).

RFS commands

Under the RFS command environment, you issue commands to interface with RFS. If you set the command environment to RFS, you should not specify RFS in front of RFS commands.

Example

```
'RFS DISKR POOL1:\USERS\USER1\TEST.EXEC DATA.'
```

This example reads the contents of the RFS file TEST.EXEC into the REXX compound variable DATA. TEST.EXEC is in the fully qualified directory: POOL1:\USERS\USER1\.

The syntax for the RFS commands follow.

AUTH

AUTH authorizes access to RFS directories.

Operands

dirid

specifies a REXX File System directory identifier. This is partially or fully qualified. See the CD command, “CD” on page 353, for more information.

PRIVATE

specifies that only the owner of the directory has read/write access to the files. This is the default.

PUBLICR

specifies that any user has read-only access to the files in the directory.

PUBLICW

specifies that any user has read/write access to the files in the directory.

SECURED

specifies that RACF grants access to the files in the directory.

Return codes

See the RFS command [“RFS” on page 400](#).

Example

```
'RFS AUTH POOL1:\USERS\USER1\DOCS PUBLICR'
```

This example makes directory DOCS a public directory. All users have read/only access to the files in directory DOCS.

CKDIR

CKDIR checks for an existing RFS directory level.

➤ RFS — CKDIR — *dirid* ➤

Operands***dirid***

specifies a REXX File System directory identifier. This is partially or fully qualified. See the CD command, [“CD” on page 353](#), for more information.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS CKDIR POOL1:\USERS\USER1\DOCS'
```

This example checks for a directory called DOCS in the existing directory POOL1:\USERS\USER1.

CKFILE

CKFILE checks to see if the specified, partially or fully qualified, file ID exists.

➤ RFS — CKFILE — *fileid* ➤

Operands***fileid***

specifies the file identifier.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'CKFILE POOL1:\USERS\USER1\TEST.EXEC'
```

This example checks for a file called TEST.EXEC in the existing directory POOL1:\USERS\USER1.

COPY

COPY copies a file.

➤ RFS — COPY — *fileid1* — *fileid2* ➤

Operands

fileid1

specifies the source file identifier, it may be a fully or partially qualified directory and file identifier.

fileid2

specifies the target file identifier, it may be a fully or partially qualified directory and file identifier.

Note: If the target file (*fileid2*) already exists, the contents of *fileid1* replaces it.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS COPY POOL1:\USERS\USER1\TEST1.EXEC POOL1:\USERS\USER1\TEST2.EXEC'
```

This example copies TEST1.EXEC to TEST2.EXEC within the directory POOL1:\USERS\USER1.

DELETE

DELETE deletes an RFS file.

➤ RFS — DELETE — *fileid* ➤

Operands

fileid

specifies the name of the file to be deleted. This can be partially or fully qualified. See the CD command, [“CD” on page 353](#), for more information.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS DELETE POOL1:\USERS\USER1\TEST1.EXEC'
```

This example deletes file TEST1.EXEC within directory POOL1:\USERS\USER1.

DISKR

DISKR reads records from an RFS file.

Operands

fileid

specifies the file identifier.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS DISKR POOL1:\USERS\USER1\TEST.DATA DATA.'
```

This example stores the entire contents of the RFS file POOL1:\USERS\USER1\TEST.DATA in the DATA. REXX compound variable.

Note: DATA.0 is set to the number of records read from the file. DATA.*n* contains the *n*th record read from the file.

DISKW

DISKW writes records to an RFS file from a stem. The file is overlaid with the data in the stem.

Operands

fileid

specifies the file identifier.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

Return codes

See [“RFS” on page 400](#).

Example

```
'RFS DISKW POOL1:\USERS\USER1\TEST.EXEC DATA.'
```

This example stores the contents of the DATA. REXX compound variable into the RFS file POOL1:\USERS\USER1\TEST.EXEC.

Note: Set DATA.0 to the number of records to be written to the file.

GETDIR

GETDIR returns a list of the contents of the current or specified directory into the specified REXX array.

➤ RFS — GETDIR — *stem.* — *dirid* ➤

Operands

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#).

dirid

specifies a REXX File System directory level identifier. This is partially or fully qualified. See the CD command [“CD” on page 353](#) for more information.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS GETDIR DIRDOC. POOL1:\USERS\USER1\DOCS'
```

This example places the contents of directory DOCS in the DIRDOC. REXX compound variable.

MKDIR

MKDIR creates a new RFS directory level.

➤ RFS — MKDIR — *dirid* ➤

Operands

dirid

specifies a REXX File System directory identifier. This is partially or fully qualified. See the CD command, [“CD” on page 353](#), for more information.

Return codes

See the RFS command, [“RFS” on page 400](#).

Example

```
'RFS MKDIR POOL1:\USERS\USER1\DOCS'
```

This example creates a new directory called DOCS in the existing directory POOL1:\USERS\USER1.

Note: Only authorized users can create directories outside of their \USERS*userid* directory structure.

RDIR

RDIR removes the specified RFS directory.

➤ RFS — RDIR — *dirid* ➤

Operands

dirid

specifies a REXX File System directory identifier. This is partially or fully qualified. Refer to the CD command, “CD” on [page 353](#), for more information.

Return codes

Refer to the RFS command, “RFS” on [page 400](#).

Example

```
'RFS RDIR POOL1:\USERS\USER1\DOCS'
```

This example deletes a directory called DOCS in the existing directory POOL1:\USERS\USER1.

RENAME

RENAME renames an RFS file to a new name.

➡ RFS — RENAME — *fileid1* — *fileid2* ➡

Operands

fileid1

specifies the source file identifier, it may be a fully or partially qualified directory and file identifier.

fileid2

specifies the source target file identifier, it may be a fully or partially qualified directory and file identifier.

Note: If the target file (*fileid2*) already exists, the contents of *fileid1* replaces it.

Return codes

See the RFS command, “RFS” on [page 400](#).

Example

```
'RFS RENAME POOL1:\USERS\USER1\TEST1.EXEC POOL1:\USERS\USER1\TEST2.EXEC'
```

This example renames the file POOL1:\USERS\USER1\TEST1.EXEC to POOL1:\USERS\USER1\TEST2.EXEC.

REXX/CICS File List Utility

The File List Utility (FLST) provides a full screen interface to the REXX File System.

When running, FLST manages RFS, calls an exec, or starts a transaction. It is meant to be a high level interface to REXX, RFS, and CICS.

Invocation

When you want to run FLST, go to a cleared CICS screen or a cleared REXX/CICS screen, enter FLST and FLST starts running.

The FLST screen format follows.

```

USER=USER1 - DIRECTORY=\USERS\USER1
CMD  FILENAME FILETYPE ATTRIBUTES RECORDS SIZE  DATE    TIME
      TEST1    EXEC    FILE        11      1    1994/03/27 10:30:29
      TEST2    EXEC    FILE         5      1    1994/03/27 10:31:04

```

```

COMMAND ===>
F1=HELP F2=REFRESH F3=END F7=UP 18 F8=DOWN 18 F11=EDIT F12=CANCEL

```

Your user ID is displayed in the upper left hand corner. The current directory is displayed beside your user ID. The rest of the screen looks very similar to a REXX/CICS editor session. FLST uses the editor for all I/O except for the first two lines that are displayed using the RESERVED command in the editor. The advantages of using the REXX/CICS editor for the I/O shell are seen in the ability to search for a file name or file type in a large directory and your ability to save the directory to a file on disk.

Macros under the REXX/CICS File List Utility

The REXX File List Utility supports REXX macros, giving the macros the ability to alter the FLST settings and display the FLST screens. Macros can process all of the FLST commands.

Example

The following example addresses the FLST environment and alters the FLST settings.

```

/* Macro to set some FLST settings */
ADDRESS FLSTSVR
'SET PFKEY 11 EDIT'
'SET PFKEY 12 CANCEL'
'SYNONYM DISCARD RFS DELETE'

```

FLST Commands

This section describes the FLST commands. You can type these commands anywhere on the source FLST command column or from the command line.

Note: If data is entered in multiple places, program function keys take precedence, followed by data entered on the command line, and finally data entered on the command column.

CANCEL

CANCEL terminates without executing any commands in the command column.

When you type CANCEL from the command line, use the following syntax:

```
➡ CANCEL ➡
```

COPY

COPY copies a file.

When you type COPY on the FLST command column, use the following syntax:

➤➤ COPY — / — *fileid* ➤➤

1 Operands

fileid

specifies the file ID of the file where the results are placed.

Note: If *fileid* already exists, it is replaced.

1 Example

```
'COPY / TEST3.EXEC'
```

This example, executed from the command column next to TEST1.EXEC, creates a new file, TEST3.EXEC, that is identical to TEST1.EXEC.

When you type COPY from the command line, use the following syntax:

➤➤ COPY — *fileid1* — *fileid2* ➤➤

2 Operands

fileid1

specifies the file ID of the file the command acts on.

fileid2

specifies the file ID of the file where the results are placed.

Note: If *fileid2* already exists, the contents of *fileid1* replaces it.

2 Example

```
'COPY TEST1.EXEC TEST3.EXEC'
```

This example, executed from the command line, creates a new file (TEST3.EXEC) that is identical to TEST1.EXEC.

DELETE

DELETE deletes a file.

When you type DELETE on the FLST command column, use the following syntax:

➤➤ DELETE ➤➤

When you type DELETE from the command line, use the following syntax:

➤➤ DELETE — *fileid* ➤➤

Operands

fileid

specifies the file ID of the file the command acts on.

Example

```
'DELETE TEST1.EXEC'
```

This example, executed from the command line, deletes file TEST1.EXEC.

DOWN

DOWN scrolls down one or more lines.

When you type DOWN from the command line, use the following syntax:

➤ DOWN —  ➤

Operands

n
specifies the number of lines to be scrolled down.

Example

```
'DOWN 5'
```

This example scrolls forward through the list five lines.

END

END executes all commands you typed, then terminates when END is typed on the command line or used as a PF key.

When you type END from the command line, use the following syntax:

➤ END ➤

EXEC

EXEC executes the exec, then terminates.

When you type EXEC on the FLST command column, use the following syntax:

➤ EXEC —  ➤

1 Operands

parameter
specifies the parameters passed to the exec as arguments.

1 Example

```
'EXEC / PARMS'
```

This example, executed on the command column next to TEST3.EXEC, executes exec TEST3.EXEC and passes PARMS as the argument.

When you type EXEC from the command line, use the following syntax:

➤ EXEC — *fileid1* —  ➤

2 Operands

fileid
specifies the file ID of the file the command acts on.

Operands

fileid

specifies the file ID of the macro you want to run. If this file ID includes a file type suffix, then an attempt is made to call an exec with that suffix. Otherwise, an attempt is made to call an exec whose suffix is EXEC.

Return codes

n

The return code that is set by the exit of the called exec. See [“EXIT” on page 170](#).

0

Normal return

-3

Exec not found

-10

Exec name not specified

-11

Invalid exec name

-12

GETMAIN error

-99

Internal error

Example

```
'MACRO POOL1:\USERS\USER1\TEST'
```

This example calls the macro, POOL1:\USERS\USER1\TEST.EXEC.

Note: Macros can make calls to the REXX/CICS FLST server. Any command that can be entered from the command line of the FLST can be run from a macro.

PFKEY

PFKEY sets or processes a program function (PF) key.

When you type PFKEY from the command line, use the following syntax:

➤ PFkey — *number*  ➤

The diagram shows a horizontal line with a right-pointing arrowhead. Below the line, a bracket spans a portion of the line, with the word "text" centered underneath the bracket.

Operands

number

specifies the PF key that is set or processed.

text

specifies the text that the PF key is set to.

Example

```
'PFKEY 3 quit'  
'PFKEY 3'
```

This example first sets PFKEY 3 to quit and then processes the PF key.

Note: If you specify *text*, the PF key is set with the text. If you do not specify *text*, the PF key is processed.

REFRESH

REFRESH refreshes the file list.

When you type REFRESH on the FLST command column, use the following syntax:

➤ REFRESH —  dirid ➤

Operands

dirid

specifies a REXX File System directory identifier. This is partially or fully qualified. See the CD command, “CD” on [page 353](#), for more information.

Example

```
'REFRESH'
```

This example refreshes the file list for the member of the current working directory.

RENAME

RENAME renames a file

When you type RENAME on the FLST command column, use the following syntax:

➤ RENAME — / — *fileid* ➤

1 Operands

fileid

specifies the new file ID.

Note: If *fileid* already exists, it is replaced.

1 Example

```
'RENAME / TEST4.EXEC'
```

This example, executed from the command column next to TEST3.EXEC, renames TEST3.EXEC to TEST4.EXEC.

When you type RENAME from the command line, use the following syntax:

➤ RENAME — *fileid1* — *fileid2* ➤

2 Operands

fileid1

specifies the file ID of the file the command acts on.

fileid2

specifies the new file ID.

Note: If *fileid2* already exists, the contents of *fileid1* replaces it.

2 Example

```
'RENAME TEST3.EXEC TEST4.EXEC'
```

This example, executed from the command line, renames file TEST3.EXEC to TEST4.EXEC.

SORT

SORT sorts the file list.

When you type SORT from the command line, use the following syntax:

Operands

DT

specifies sorting the files by date/time. (This is the default.)

FN

specifies sorting the files by file name.

FT

specifies sorting the files by file type.

AT

specifies sorting the files by attribute.

RC

specifies sorting the file by number of records.

SZ

specifies sorting the files by size.

Example

```
'SORT FN'
```

This example sorts the file list by file name.

SYNONYM

SYNONYM assigns a command action to any other valid command.

When you type SYNONYM from the command line, use the following syntax:

Operands

syn

specifies any valid command that executes the command action for which it is a synonym.

command

specifies any valid command.

Example

```
'SYNONYM DISCARD RFS DELETE'
```

This example makes DISCARD equivalent to the RFS command DELETE.

UP

UP scrolls up one or more lines.

When you type UP from the command line, use the following syntax:

➡ UP 

Operands

n

specifies the number of lines to be scrolled up.

Example

```
'UP 5'
```

This example scrolls backward through the list five lines.

FLST return codes

FLST uses the standard return codes for the REXX/CICS File System, except for when it is specified differently.

See the RFS command [“RFS” on page 400](#) for more information.

Running execs and transactions from FLST

Most REXX/CICS execs can be run from FLST by simply entering the exec name. The exec name with its arguments is entered on the command line, or the exec name is typed on a FLST command column. The latter case uses the file ID as the argument for the transaction. REXX execs are run by issuing an EXECUTE command either on the command line, in which case a file ID is needed, or on a FLST command column.

Chapter 25. REXX/CICS List System

REXX/CICS provides a facility for maintaining tables or lists of data in virtual storage. This facility is called the REXX List System (RLS).

This system provides management of lists of temporary system and user information. The externals for accessing the RLS are the RLS and CLD commands, instead of RFS and CD commands used with the REXX File System. Also, the RLS is only for data, not for execs.

Directories and lists

RLS has one root directory. You access the RLS system by reading its anchor address from a CICS temporary storage queue named *CICREX*.

This *CICREX* queue contains one item after the first access of RLS. This item contains the address of an area of 6 fullwords. It contains RLS control information and a pointer to the root directory. The root directory RLS is named \. This directory can contain lists, saved variables, or special lists called queues as well as subdirectories. A subdirectory is a directory within another directory. Subdirectories can be created within any other directory. A new directory can be created with the RLS MKDIR command. All directories, except the root, are distinguished by a one to 250 character directory file name. This is called the directory ID.

One RLS directory that always exists is the USERS directory. This directory contains several subdirectories which correspond to the users on the system. When you save a list into the RLS for the first time, a new subdirectory may be created in the USERS directory. This new directory is named with your user ID if you are signed onto CICS. Otherwise, the directory name defaults to the value in CICS DFLTUSER. After this directory is created, you can create any number of subdirectories within that personal directory. You can place lists in any of the directories that you create.

Lists are always data files. They use the same naming conventions as directories.

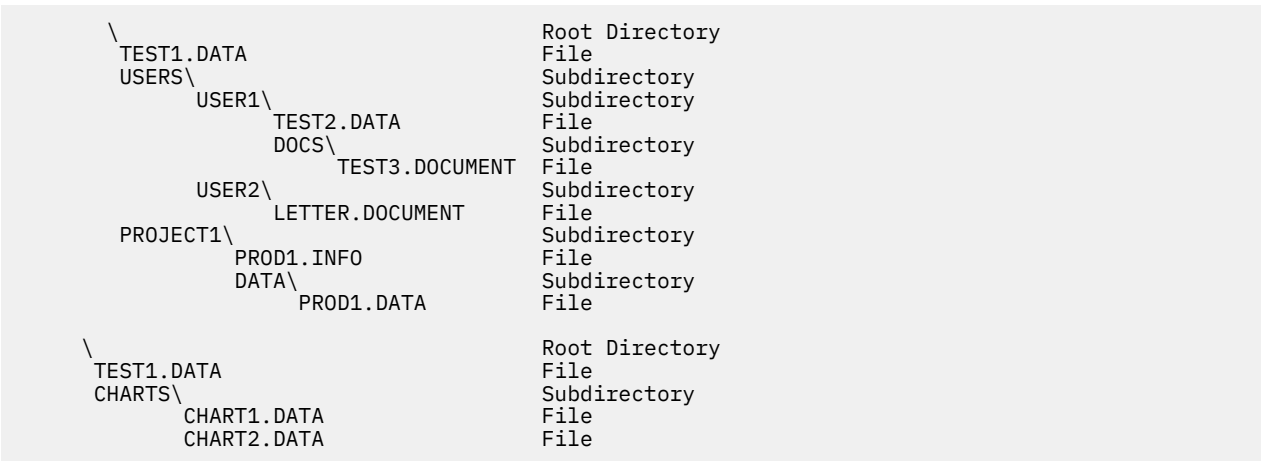

A fully qualified list ID consists of a \, each directory's ID in the path followed by a \, and the list ID.

Examples

The following example shows a fully qualified list ID. USERS and USER1 are directory ID's, and TEST.DATA is the list ID.

```
\USERS\USER1\TEST.DATA
```

The following example shows RLS directories and lists.

This example shows a list directory structure. The root directory contains a file (TEST1.DATA) and two subdirectories (USERS and PROJECT1). Inside the USERS subdirectory are two subdirectories (USER1

and USER2) that correspond to user IDs (USER1 and USER2). User USER1 has a list (TEST2.DATA) and a subdirectory (DOCS) inside its directory. Inside the DOCS subdirectory there is another list (TEST3.DOCUMENT). User USER2 has a file (LETTER.DOCUMENT) inside its directory. The root directory contains a file (TEST1.DATA) and a subdirectory (CHARTS). Inside subdirectory CHARTS are two files (CHART1.DATA and CHART2.DATA).

Current directory and path

The current list directory is the current working directory, and is first in the search order when working with REXX List System (RLS).

The current list directory can be set using the CLD command “CLD” on page 370. The syntax is CLD followed by the fully or partially qualified directory name. To change from a subdirectory back to the parent directory, type CLD .. To change to another subdirectory, CLD can be followed by the subdirectory name.

Example

In the following example, the first command sets the current directory to \USERS\USER1 and the second command sets the current directory to \USERS\USER1\DOCS. The third command changes the current directory back to \USERS\USER1.

```
CLD \USERS\USER1
CLD DOCS
CLD ..
```

Note: If CLD is never specified, the default directory is \USERS\userid\.

Security

The RLS commands are authorized REXX/CICS commands.

This means that they can be executed only by an authorized user, or from within an exec that is loaded from CICAUTH or CICEXEC ddnames in the region startup JCL.

RLS commands

Under the RLS command environment, you issue commands to interface with RLS.

If you set the command environment to RLS, you should not specify RLS in front of RLS commands.

Example

```
'RLS READ \USERS\USER1\TEST.DATA DATA.'
```

This example reads the contents of the RLS list \USERS\USER1\TEST.DATA into the DATA. REXX compound variable.

The syntax for the RLS commands follow.

CKDIR

CKDIR checks for an existing RLS directory level.

➡ RLS — CKDIR — *dirid* ➡

Operands

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. See the CLD command “CLD” on page 370 for more information.

Return codes

See the RLS command “RLS” on page 403.

Example

```
'RLS CKDIR \USERS\USER1\DOCS'
```

This example checks for a directory called DOCS in the existing directory \USERS\USER1.

DELETE

DELETE deletes an RLS list.

➡ RLS — DELETE — *listname* ➡

Operands

listname

specifies a REXX List System list identifier. This is partially or fully qualified. See the CLD command “CLD” on page 370 for more information.

Return codes

See the RLS command “RLS” on page 403.

Example

```
'RLS DELETE \USERS\USER1\TEST.DATA'
```

This example deletes RLS list TEST.DATA.

LPULL

LPULL pulls a record from the top of the RLS queue.

➡ RLS — LPULL — *varname* — { **QUEUE** / *queid* } ➡

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

QUEUE

is a keyword specifying the special default name.

queid

specifies the identifier for a special type of RLS list accessed by LPULL, LPUSH, or LQUEUE.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS LPULL VARA QUEUE1'
```

This example pulls a record from the top of the RLS queue QUEUE1.

LPUSH

LPUSH pushes a record onto the top of the RLS queue (LIFO).

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

QUEUE

is a keyword specifying the special default name.

queid

specifies the identifier for a special type of RLS list accessed by LPULL, LPUSH, or LQUEUE.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS LPUSH VARA QUEUE1'
```

This example pushes a record (the contents of VARA) onto the top of the RLS queue QUEUE1.

LQUEUE

LQUEUE adds a record to the end of the RLS queue (FIFO).

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

QUEUE

is a keyword specifying the special default name.

queid

specifies the identifier for a special type of RLS list accessed by LPULL, LPUSH, or LQUEUE.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS LQUEUE VARA QUEUE1'
```

This example adds a record (the contents of VARA) to the end of the RLS queue QUEUE1.

MKDIR

MKDIR creates a new RLS directory level.

➡ RLS — MKDIR — *dirid* →

Operands

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. See the CLD command [“CLD” on page 370](#) for more information.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS MKDIR \USERS\USER1\DOCS'
```

This example creates a new directory called DOCS in the existing directory \USERS\USER1.

READ

READ reads records from an RLS list.

➡ RLS — READ — *listname* —  (— UPD — →

Operands

listname

specifies the list identifier.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

UPD

is a keyword that enqueues on a file for update.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS READ \USERS\USER1\TEST.DATA DATA.'
```

This example stores the entire contents of the RLS list \USERS\USER1\TEST.DATA in the DATA. REXX compound variable.

Note: DATA.0 is set to the number of records read from the list. DATA.*n* contains the *n*th record read from the list.

VARDROP

VARDROP deletes an RLS saved variable.

➤ RLS — VARDROP — *varname* — *dirid* ➤

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. See the CLD command [“CLD” on page 370](#) for more information.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS VARDROP VAR1'
```

This example deletes variable VAR1 from the current directory.

VARGET

VARGET takes an RLS saved variable and copies it into a REXX variable of the same name.

➤ RLS — VARGET — *varname* — *dirid* ➤

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. See the CLD command [“CLD” on page 370](#).

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS VARGET VAR1'
```

This example copies the value of variable VAR1 from the current directory into a REXX variable named VAR1.

VARPUT

VARPUT takes a REXX variable and copies it into an RLS saved variable of the same name.

➤ RLS — VARPUT — *varname* — *dirid* ➤

Operands

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. See the CLD command [“CLD” on page 370](#) for more information.

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS VARPUT VAR1'
```

This example takes the value of REXX variable VAR1 and copies it into variable VAR1 in the current directory.

WRITE

WRITE writes records to an RLS list.

➤ RLS — WRITE — *listname* —  ➤

Operands

listname

specifies the list identifier.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

Return codes

See the RLS command [“RLS” on page 403](#).

Example

```
'RLS WRITE \USERS\USER1\TEST.DATA DATA.'
```

This example stores the entire contents of the REXX compound variable DATA. into the RLS list \USERS\USER1\TEST.DATA.

Note: Set DATA.0 to the number of records to be written to the list.

Chapter 26. REXX/CICS Command Definition

The REXX/CICS Command Definition Facility provides a way to define or redefine REXX commands and environments.

The Command Definition Facility provides the capability to:

- Define new commands and environments from a REXX exec.
- Share a common command environment with multiple independent developers.
- Write new REXX commands in the REXX language.
- Change command's implementation language transparently.
- Define authorized commands selectively.
- Redefine existing command names (without a code change).

Background

A strength of REXX is its extendibility. You can write your own external functions, subroutines, or commands to extend the capabilities of the REXX language. Because of this, one use for REXX is as an application integration platform.

REXX/CICS provides you the ability to seamlessly integrate your Line Of Business (LOB) application facilities, REXX language facilities, CICS system facilities, and various software products into an integrated software platform.

The main methods used to extend the REXX language to add function, or to provide an interface to an external facility or product, are:

- REXX External Functions (or subroutines)
- REXX Commands (sometimes called subcommands).

As an example to distinguish between the two, let's say we want to add the capability to REXX to sort a REXX array. You can do this by adding a sort function called ARRYSORT:

```
x = ARRYSORT(STEM1.)
```

You can also do this by adding a REXX command called ARRYSORT:

```
'ARRYSORT STEM1.'
```

Note: In the command example, it is not necessary to place quotes around the command. However, it is good coding practice to place single or double quotes around portions of command strings that do not involve REXX variable substitution.

REXX external functions are traditionally used to extend the capabilities of the REXX language, whereas REXX commands are traditionally used to interface to outside applications, products or system facilities. However, both methods can be used in either way.

Some major differences between REXX commands and external functions are:

- Functions always return a result; commands do not.
- Functions raise an error condition; commands always set a return code.

Defining commands

Use the DEFCMD command to perform basic command definitions that affect only your user ID. If you are a systems administrator or system programmer, use the DEFSCMD command to perform system-wide REXX/CICS command definitions.

The DEFCMD and DEFSCMD commands are used from within a REXX exec to define or change REXX command definitions. You can add or change your own command definitions, using the DEFCMD command, without any special authorization. You must be a REXX/CICS authorized user to use DEFSCMD to change command definitions that affect other REXX/CICS users. See [“DEFCMD” on page 377](#) and [“DEFSCMD” on page 379](#) for details.

Command arguments passed to REXX programs

When a REXX/CICS command is written in REXX and that command is used, the REXX program (defined by DEFCMD or DEFSCMD) is either invoked or awakened (from a WAITREQ induced "sleep").

If the program is invoked, the command string is passed as an argument to the exec. Also, if it is invoked, the very first WAITREQ command issued (if any) falls through immediately, with the command string being placed in the REXX variable REQUEST. If the REXX exec was already started earlier and waiting for a request (because of an earlier WAITREQ command), the command string is only placed in the REXX variable REQUEST.

Note: Command programs written in REXX can get and set the contents of REXX variables in the REXX exec that caused them to be invoked, by using the C2S and S2C commands. See [“C2S” on page 376](#) and [“S2C” on page 410](#) for more information.

Command arguments passed to assembler programs

REXX/CICS command programs can be written in assembler language.

Assembler language routines must exist in a CICS program properly defined (for example, by using the CEDA DEFINE PROGRAM command). These programs are invoked by an EXEC CICS LINK if the CICSLINK option was specified on the DEFCMD or DEFSCMD commands.

Alternatively, if the DEFCMD or DEFSCMD command specifies the CICSLOAD option, the program is EXEC CICS LOAded by the first command that causes it to be invoked for the current CICS task, and its load address is remembered. Any subsequent commands in the same CICS task that use this program perform a direct branch entry (by an assembler BASSM instruction) into the program. It is recommended that these assembler programs return control by using an assembler BSM instruction so that the correct mode switching (if any) occurs.

The following information describes the contents of the registers when an assembler language command program gets control, and the parameters upon entry to these programs.

Entry Specifications when DEFCMD CICSLOAD is specified:

When the code for the command program gets control by a direct branch, the contents of the registers are:

Register 0

Unpredictable

Register 1

Address of the CICPARMS control block

Registers 2-12

Unpredictable

Register 13

Address of 18 fullword register save area

Register 14

Return address

Register 15

Entry point address

Before the program returns to the caller, it should place the return code it wants reflected into the CICPARMS RETCODE field.

Entry Specifications when DEFCMD CICS LINK is specified:

When the code for the command program gets control by an EXEC CICS LINK, the CICS commarea contains the CICPARMS control block.

Before the program returns to the caller, it should place the return code it wants reflected into the CICPARMS RETCODE field.

CICPARMS control block

This topic contains Product-sensitive Programming Interface information.

The following table shows the CICPARMS control block for mapping passed parameters to assembler routines.

Table 4. CICPARMS control block			
Offset (decimal)	Number of bytes	Field name	Description
0	12		Reserved for IBM use.
12	4	RXWBADDR	REXX work block address which is required to be placed into register 10 before calls to the CICGETV stub routine (for REXX variable access)
16	8	ENVNAME	Internal environment name taken from the DEFCMD or DEFSCMD command definition
24	16	CICCMD	Internal command name taken from the command definition, or in the case where an asterisk was specified, the actual command name from the command string
40	4	ARGSTR	Address of the command argument string beginning with the first non-blank character after the command name in the command string
44	4	ARGLEN	Length of above argument string, in characters
48	4	PLIST	Address of a standard parsed parameter list of the command line parsed into 8 character tokens, followed by a end of list fence of hex high values (X'FFFFFFFFFFFFFFFF')
52	4	EPLIST	Address of an extended parameter list that matches up with the standard PLIST listed earlier, but is in a different format. The extended PLIST has an 8 byte entry for each token. The first 4 bytes is a fullword address of the start of the string that comprises a token. The second word contains the length of a token, in bytes.
56	4	RETCODE	Return code to be reflected in the exec immediately after the execution of the command. This return code is automatically placed into the special REXX variable RC.
60	4		Reserved for IBM use

Table 4. CICPARMS control block (continued)			
Offset (decimal)	Number of bytes	Field name	Description
64	4	USERWORD	For user use so information can be passed across multiple command routine calls
68	4		Reserved for IBM use
72	4		Reserved for IBM use
76	1	TYPEFLAG	One character code that identifies the call type of the DEFCMD or DEFSCMD definition. The code for REXX is R, for CICSLINK is C, and for CICSLOAD is L
77	1	ITRACE	Internal trace flag. This is a one character code, which has a value of 0 through 9 to indicate if internal tracing is active and what level of tracing is active. The value of zero indicates the normal situation of no tracing. Values from 1 to 9 indicate that increasingly progressively detailed tracing has been requested.

Non-REXX language interfaces

REXX/CICS makes it possible to convert a REXX process to a non-REXX process.

To do this requires that non-REXX command routines can access REXX variables in the REXX exec that issued the command to be processed. The routine used to accomplish this is called CICGETV and must be linkedited with your command routine, and called as is described in the following information.

CICGETV: call to get, set, or drop a REXX variable

CICGETV calls this linkedit stub subroutine from an assembler REXX/CICS command routine, to retrieve from, set ,or drop REXX variables in the REXX program that issued the command.

This topic contains Product-sensitive Programming Interface information.

►► CALL — CICGETV — , — (— operands —) ►►

operands

►► *varname_addr* — , *varname_len* — , *data_addr* — , *data_len* — , *function_name* ►►

Operands

varname_addr

specifies the address of a character string containing the name of the REXX variable. The variable name (that this address points to) must be in uppercase.

varname_len

specifies the length of the variable name.

data_addr

specifies the fullword address where the address of variable contents are.

data_len

specifies the length of area pointed to by *data_addr* (fullword).

function_name

specifies the particular CICGETV function to be performed. There are three choices:

GET

retrieves the address and length of a REXX variable.

PUT

creates or replaces a REXX variable.

DEL

deletes a REXX variable.

Note:

1. Immediately before any call to the CICGETV linkedited routine stub, register 10 must be loaded with the value of the RXWBADDR field in the passed parms (CICPARMS).
2. If a get request is issued for a variable that does not exist, the value returned is the same as the variable name.
3. CICGETV uses a standard save area convention with R13 pointing to an 18 fullword length area. R1 points to a standard parameter list. R14 contains the return address. R15, upon entry to CICGETV, returns CICGETV's entry point. Upon return, R15 contains the return code.
4. The CICGETV module is located in the REXX/CICS distribution library.
5. A return code of zero is reflected to indicate the success of the operation, or a decimal 99 indicating an internal error (such as a storage limit exceeded situation).

Chapter 27. REXX/CICS Db2 interface

The REXX/CICS Db2 interface provides a means of executing SQL statements and Db2 commands from a REXX exec.

The SQL are prepared and executed dynamically. You issue the Db2 commands by using the Db2 instrumentation facility interface (IFI). The REXX/CICS Db2 interface provides the results of the SQL in REXX predefined variables. The REXX/CICS Db2 interface supports DB2® Version 2.3 and later. This information explains how to use the interface to Db2 from REXX/CICS.

For more information about SQL statements or Db2 commands, see [SQL: The language of Db2 in Db2 for z/OS product documentation](#) and [Db2 commands](#). For more information about IFI, see [Programming for the instrumentation facility interface \(IFI\) in Db2 for z/OS product documentation](#).

Note: REXX/CICS transaction identifiers must be entered in the Db2 Resource Control Table (RCT). Refer to sample JCL CICRCT.

Programming considerations

To embed SQL within a REXX exec, the host command environment must be changed. The ADDRESS instruction, followed by the name of the environment, is used to change the host command environment.

The ADDRESS instruction has two forms; one affects all commands issued after the instruction, and one affects only a single command. For more information about host command environments, see [Changing the host command environment](#) and for more information about the ADDRESS instruction, see “ADDRESS” on page 161.

The REXX/CICS command environments that support the REXX/CICS Db2 interface are:

EXECDB2

the command environment that supports Db2 commands.

EXECSQL

the command environment that supports SQL statements.

Note: EXECSQL and EXECDB2 are authorized commands. You must be a REXX/CICS authorized user to use the EXECSQL and EXECDB2 command environments.

REXX/CICS provides an exec called CICRXTRY that can be used to process REXX statements and commands interactively. CICRXTRY can be pseudo-conversational. The PSEUDO and SETSYS PSEUDO commands are used to turn pseudo-conversational mode on or off. If the environment is set to pseudo-conversational, SQL statements issued from CICRXTRY will be committed. If the environment is set to conversational, any SQL statements issued from the CICRXTRY exec will not be committed and any resources that are locked will remain locked until you exit the CICRXTRY exec or issue a CICS SYNCPOINT command. Similar considerations should be made if embedding SQL statements in lengthy REXX execs.

Embedding SQL statements

You can use the EXECSQL command environment to process the SQL. Each SQL statement is prepared and executed dynamically by using the CICS Db2 attachment facility.

You can make each request by writing a valid SQL statement as a REXX command directed to the EXECSQL environment. The SQL statement is made up of the following elements:

- SQL keywords
- Pre-declared identifiers
- Literal values.

Use the following syntax:

```
"EXECSQL statement"
```

or

```
ADDRESS EXECSQL  
"statement"  
"statement"  
.  
.  
.
```

SQL can exist on more than one line. Each part of the statement is enclosed in quotes and a comma delimits additional statement text as follows:

```
ADDRESS EXECSQL  
"SQL text",  
"additional text",  
.  
.  
.  
"final text"
```

The following rules apply to embedded SQL:

- You can pass the following SQL directly to the EXECSQL command environment:

```
ALTER  
CREATE  
COMMENT ON  
DELETE  
DROP  
EXPLAIN  
GRANT  
INSERT  
LABEL ON  
LOCK  
REVOKE  
SELECT  
SET CURRENT SQLID  
UPDATE.
```

- You cannot use the following SQL statements:

```
BEGIN DECLARE SECTION  
CLOSE  
COMMIT  
CONNECT  
DECLARE CURSOR  
DECLARE STATEMENT  
DECLARE TABLE  
DESCRIBE  
END DECLARE SECTION  
EXECUTE  
EXECUTE IMMEDIATE  
FETCH  
INCLUDE  
OPEN  
PREPARE  
ROLLBACK  
SET CURRENT PACKAGESET
```

SET HOST VARIABLE
WHenever

- Host variables are not allowed in the SQL. Instead, you can use REXX variables to pass input data to the EXEC SQL environment. The REXX variables are not embedded in quotes. The output from the EXEC SQL environment is provided in REXX predefined variables (see [“Receiving the results”](#) on page 317).
- When you code a SQL SELECT statement, you cannot use the INTO clause. Instead, the REXX/CICS Db2 interface returns the requested items in compound variables with stem names equal to the Db2 column names.
- The default number of rows returned for a SELECT statement is 250. If you need more or less rows, you can set the REXX variable SQL_SELECT_MAX before issuing the SELECT statement.

Receiving the results

The EXEC SQL command environment returns results in predefined REXX variables.

These variables are:

RC

Each operation sets this return code. Possible values are:

n

The SQLCODE if the SQL statement resulted in an error or warning.

0

The SQL statement was processed by the EXEC SQL environment. The REXX variables for the SQLCA contain the completion status of the SQL statement.

30

There was not enough memory to build the SQLDSECT variable.

31

There was not enough memory to build the SQL statement area.

32

There was not enough memory to build the SQLDA variable.

33

There was not enough memory to build the results area for the SELECT statement.

SQLCA

A set of SQLCA variables are updated after SQL statements are processed. The entries of the SQLCA are described in [“Using the SQL communications area”](#) on page 318.

SQL_COLNAME.n

Contains the name of each Db2 column whose data was returned by a SELECT statement. SQL_COLUMNS should be used as the maximum value for *n*.

SQL_COLTYPE.n

Contains the type of each Db2 column whose data was returned by a SELECT statement. SQL_COLUMNS should be used as the maximum value for *n*.

Note: Although all data types are supported, not all are displayable. REXX functions can be used to convert the data into the format that you want.

For information about the meaning of specific SQLTYPE codes found in SQL_COLTYPE, see [SQL: The language of Db2 in Db2 for z/OS product documentation](#).

SQL_COLLEN.n

Contains the length of each Db2 column whose data was returned by a SELECT statement. If the data type is DECIMAL, the scale is placed after the length of the column (after one blank space). SQL_COLUMNS should be used as the maximum value for *n*.

SQL_COLUMNS

Contains the count of the number of columns returned.

column.n

The results of a SQL SELECT statement are stored in these REXX compound variables. The *column* is the name of the Db2 column. Each item contains data for one row from Db2. The count of the number of SQL rows returned is contained in *column.0*. The count should be used as the maximum value for *n*.

SQLCOLn.1

Some SELECT functions, such as CURRENT SQLID, MAX, and AVG, are not associated with a particular Db2 column. To view the results, you must reference column name SQLCOLn.1.

The *n* begins with, and is incremented by one, for each function included in the SELECT statement. All columns represented by SQLCOLn appear in the SQL_COLNAME compound variable.

Using the SQL communications area

The fields that make up the SQL Communications Area (SQLCA) are automatically included by the REXX/CICS Db2 interface when you issue SQL statements.

The SQLCODE and SQLSTATE fields of the SQLCA contain SQL return codes. These values are set by the REXX/CICS Db2 interface after each SQL statement is executed.

The SQLCA fields are maintained in separate variables rather than in a contiguous data area. The variables that are maintained are defined as follows:

SQLCODE

The primary SQL return code.

SQLERRM

Error and warning message tokens. Adjacent tokens are separated by a byte containing X'FF'.

SQLERRP

Product code and, if there is an error, the name of the module that returned the error.

SQLERRD.n

Six variables containing diagnostic information. (The variable *n* is a number between 1 and 6.)

Note: The count of the number of SQL rows affected by the DELETE, INSERT, and UPDATE command is contained in SQLERRD.3.

SQLWARN.n

Eleven variables containing warning flags. (The variable *n* is a number between 0 and 10.)

SQLSTATE

The alternate SQL return code.

Example using SQL statements

In the example, the program prompts for the name of a department, obtains the names and phone numbers of all members of that department from the EMPLOYEE table, and presents that information on the screen.

```

/*****
/* Exec to list names and phone numbers by department */
*****/

/*-----*/
/* Get the department number to be used in the select statement */
/*-----*/
  Say 'Enter a department number'
  Pull dept

/*-----*/
/* Retrieve all rows from the EMPLOYEE table for the department */
/*-----*/
  "EXECSQL SELECT LASTNAME, PHONENO FROM EMPLOYEE ",
    "WHERE WORKDEPT = '"dept'"
  If rc <> 0 then
    do
      Say ' '
      Say 'Error accessing EMPLOYEE table'
      Say 'RC      =' rc
```

```

        Say 'SQLCODE =' SQLCODE
        Exit rc
    end

/*-----*/
/* Display the members of the department */
/*-----*/
    Say 'Here are the members of Department' dept
    Do n = 1 to lastname.0
        Say lastname.n phoneno.n
    End

Exit

```

Embedding Db2 commands

You can use the EXECDB2 command environment to process the Db2 commands. Each Db2 command is passed to the Db2 instrumentation facility interface (IFI).

Most Db2 commands that are issued using DSN under TSO can be issued from CICS using the REXX/CICS Db2 Interface. The Db2 messages are returned in the predefined REXX compound variable DB2_OUTPUT.n.

You can make each request by writing a valid Db2 command as a REXX command directed to the EXECDB2 environment. Use the following syntax:

```
ADDRESS EXECDB2 "DB2 command"
```

or

```

ADDRESS EXECDB2
"DB2 command"
"DB2 command"
.
.
.

```

Db2 commands can exist on more than one line. Each part of the command is enclosed in single quotes and a comma delimits additional command text as follows:

```

ADDRESS EXECDB2
"DB2 command",
"additional text",
.
.
.
"final text"

```

The following rules apply to embedded Db2 commands:

- The REXX exec can issue many Db2 commands, but be careful which commands you use. For example, do not use "-STOP DB2".
- The following Db2 commands are passed directly to the EXECDB2 command environment:
 - ALTER BUFFERPOOL
 - ARCHIVE LOG
 - CANCEL DDF THREAD
 - DISPLAY ARCHIVE
 - DISPLAY BUFFERPOOL
 - DISPLAY DATABASE
 - DISPLAY LOCATION
 - DISPLAY RLIMIT
 - DISPLAY THREAD
 - DISPLAY TRACE
 - DISPLAY UTILITY
 - MODIFY TRACE

- RECOVER BSDS
 - RECOVER INDOUBT
 - RESET INDOUBT
 - SET ARCHIVE
 - START DATABASE
 - START DDF
 - START RLIMIT
 - START TRACE
 - STOP DATABASE
 - STOP DB2
 - STOP DDF
 - STOP RLIMIT
 - STOP TRACE
 - TERM UTILITY
- You cannot use the following Db2 command:
 - START DB2. You can issue this command only from an MVS console.
 - You can use REXX variables when passing input data to the EXECDB2 environment. The REXX variables are not embedded in quotes. The output from the EXECDB2 environment is provided in REXX predefined variables (see [“Receiving the results” on page 320](#)).
 - The Db2 command string must be between six and 4092 characters long.
 - The total length of all messages returned from the Db2 IFI is limited to 24K. If there are more messages than will fit in 24K bytes of memory, you can issue the Db2 command again, but with more specific parameter values, thus reducing the number of output messages.

Receiving the results

The EXECDB2 command environment returns results in predefined REXX variables.

These variables are:

RC

Each operation sets this return code. Possible values are:

n

A positive value that indicates the results of the call to the Db2 instrumentation facility interface (IFI). If the RC from the Db2 IFI is not zero, the REXX variable DB2_RC2 contains the Db2 IFI reason code. The DB2_RC2 value is used in conjunction with the RC by using Db2 codes for error determination. See [Db2 codes in Db2 for z/OS product documentation](#).

0

The Db2 command was processed by the Db2 IFI.

50

The specified Db2 command is either too short or too long to be accepted for processing by the Db2 IFI. The Db2 command cannot be less than 6 or greater than 4092 characters long.

51

There was not enough memory to build the output area for the Db2 IFI.

52

There was not enough memory to build the communications area for the Db2 IFI.

53

There was not enough memory to build the return area for the Db2 IFI.

54

The DB2_RC2 REXX variable could not be built.

55

The DB2_BNM REXX variable could not be built.

56

The DB2_OUTPUT.*n* REXX variable could not be built.

57

The DB2_OUTPUT.0 REXX variable could not be built.

DB2_OUTPUT.*n*

The Db2 messages returned from the Db2 IFI are stored in this REXX compound variable. Each DB2_OUTPUT.*n* item contains one Db2 message. DB2_OUTPUT.0 contains the count of the number of Db2 messages returned. The count is used as the maximum value for *n*.

DB2_RC2

If the return code from the Db2 IFI is not zero, this variable contains the reason code associated with the return code. The DB2_RC2 variable contains a hexadecimal value. To convert it to a printable value, use the C2X built-in REXX function. See “C2X (Character to Hexadecimal)” on page 200. The DB2_RC2 value is used in conjunction with the RC by using Db2 codes for error determination. See [Db2 codes in Db2 for z/OS product documentation](#).

DB2_BNM

If the Db2 IFI cannot return all Db2 messages, DB2_BNM contains the number of bytes not moved. This situation might occur if the length of all messages returned exceeds 24K. You can issue the Db2 command again, specifying more parameter values to reduce the output.

Example using Db2 commands

The example of REXX code checks to see whether all tablespaces in a database are in RW status.

```
/******  
/* Exec to verify that tablespaces are in RW status */  
/******  
  
db_name = 'DSN8D23A'  
cmd = "-DISPLAY DATABASE("db_name") LIMIT(500)"  
"EXECDB2" cmd  
If rc <> 0 then  
do  
  Say ' '  
  Say 'Error in DB2 -DISPLAY DATABASE command'  
  Say 'RC      =' rc  
  Say 'DB2_RC2 =' C2X(DB2_RC2)  
  Exit rc  
end  
  
/*-----*/  
/* Scan the DB2 messages, skipping over the "header" */  
/* and "trailer" messages.                               */  
/*-----*/  
first = 10  
last = DB2_OUTPUT.0 - 2  
Do n = first to last  
  If substr(DB2_OUTPUT.n, 20, 2) <> "RW" then  
    Say "Tablespace" substr(DB2_OUTPUT.n, 1, 8) "is not in RW status"  
End  
  
Exit
```

Chapter 28. REXX/CICS high-level client/server support

REXX/CICS introduces REXX language Client/Server support. REXX/CICS provides a high-level client/server capability.

This capability includes:

- High-level, natural, transparent REXX client interface
- Support for REXX-based application clients and servers.

Some advantages of client/server computing are:

- The ability to effectively integrate the strengths of z/OS systems, mini-computers, and workstations in a transparent fashion.
- The ability to incrementally scale the size of computers' systems up or down (right-sizing).
- The simplification of complex application systems by breaking them down into manageable sets of clients and servers.
- Applications and data can be distributed throughout a network for better performance, integrity, or security.
- The ability for enterprise-wide access to data and applications, wherever they reside in the network, from a variety of unlike computer systems or workstations.

High-level, natural, transparent REXX client interface

REXX/CICS supports a high-level, easy to use interface from client REXX execs to application servers through the ADDRESS keyword instruction in REXX.

The ADDRESS instruction includes an external environment name that is used to determine the name of the external procedure that is called to process subsequent REXX command strings.

REXX/CICS provides the optional ability for the environment name (specified in the ADDRESS instruction) to be the name of an application server. This capability is provided by the REXX/CICS DEFCMD and DEFSCMD commands.

The DEFCMD command provides the ability to define (or redefine) REXX commands and environments, and it provides the ability to specify whether an environment-command combination is to be handled by a traditional CALLED routine or by an REXX application server.

Support for REXX-based application clients and servers

In addition to the REXX client interface, several facilities provide support for the use of application servers written in REXX.

One facility is the WAITREQ command, which is used by servers to wait for requests from clients. Another facility, the C2S and S2C commands, provide the ability for servers to fetch or set the contents of client variables. Another capability, Automatic Server Initiation (ASI) provides for servers to be started automatically when a request arrives from a client.

Value of REXX in client/server computing

Some advantages of using REXX for implementing client/server solutions are listed.

- The availability of REXX interpreter support under REXX/CICS with its quick development cycle and source-based interactive debugging allows the rapid prototyping and development of complex systems.

- The high-level client/server interfaces in REXX/CICS can improve development productivity and lower maintenance costs.
- Because REXX/CICS allows REXX clients and servers to be recoded in non-REXX languages, performance intensive parts of an application system can be selectively rewritten, if needed.

The FLST and EDIT commands that REXX/CICS provides are examples of client/server environments.

REXX/CICS client exec example

```
/* EXAMPLE REXX/CICS EXEC */

TRACE '0' /* turn off source tracing */

ARG parm1 parm2 parm3

"CICS READQ TS QUEUE(MYQ) INTO(DATA) ITEM(5) NUMITEMS(1)"
if rc ~= 0 then EXIT 100

SAY 'TSQ Data=' data
"CICS SEND TEXT FROM(DATA) ERASE"

/* Define the SERVER EXEC as a REXX/CICS command */
'DEFCMD REXXCICS SERVER = SERVER1 (REXX)'

/* example of directing a subcommand to a server */
/* named SERVER1, which is written in REXX also */
DATA = 1
'SERVER COMMAND1 DATA'
say data /* ==> 2 */
if rc ~= 0 then SAY 'Request to SERVER1 failed, RC=' rc
EXIT
```

REXX/CICS server exec example

```
/* EXAMPLE REXX/CICS SERVER1 EXEC */

TRACE '0' /* turn off source tracing */

/*-----*/
/* Loop waiting on requests from clients */
/*-----*/
Do Forever
  'WAITREQ'
  parse var request cmd varname
  Select
    When request = 'COMMAND1' then CALL command1
    When request = 'COMMAND2' then CALL command2
    When request = 'STOP'      then CALL stop_server
    Otherwise
  End /* Select */
End /* Do Forever */
exit

/* subroutine to process command1 */
Command1:
'C2S' varname 'WORK'
WORK = WORK + 1
'S2C WORK' varname
return

/* subroutine to process command2 */
Command2:
return

/* routine to shut down this server */
stop_server:
say 'The Server is stopping'
exit
```

Chapter 29. REXX/CICS Panel Facility

The REXX panel facility provides the REXX programmer with simple tools and commands for panel definition and for panel input/output to 3270 type terminals.

The panel facility allows easy definition of panels using any editor. The requirement is that the panel source definition file should be in the REXX File System (RFS) before it is further processed. The panel input/output command provides the ability within a REXX program to change dynamically many of the field attributes statically defined by the panel definition facility. The following example demonstrates the capability and function of the panel facility and also helps you understand and visualize the general concepts described in this information. An overview of the example is as follows:

- It defines field control characters that set the characteristics of panel fields.
- It uses the field control characters to define a panel layout. The control character definition and the panel definition (the two parts together are called *panel source*) is saved in the REXX File System.
- It uses the panel source to generate a *panel object* that is used to send or receive panels in a REXX program.

Example of panel definition

```

** SAMPLE PANEL DEFINITION.

    define the field control characters to be used in the panel layout.
.DEFINE < blue protect
.DEFINE @ blue skip
.DEFINE ! red protect
.DEFINE > green unprotect underline
.DEFINE # green unprotect numeric right underline

define a panel named applican, which
queries an applicant's name and address.
(this line and the above lines are treated as comments).

.PANEL applican

< Please type the requested information below @

                                !Applicant's name
@Last name ...:>&lname                @
@First name ..:>&fname                @
@MI.....:>&mi

                                !Applicant's mailing address

@Street.....:>&mail_street                @
@City.....:>&mail_city                    @
@State.....:>&2mail_state
@Zip...:#5&mail_zip

.PANEL

**  END OF SAMPLE PANEL DEFINITION.

** START OF REXX PROGRAM USING THE PREVIOUS PANEL.

/* program to query applicant's name and address */
lname = ''; /* null out all name parts */
fname = '';
mi = '';
mail_street = '';
mail_city = 'DALLAS'; /* prefill the most likely response for city/state */
mail_state = 'TX';
mail_zip = '';
do forever;
    'panel send applican cursor(lname)';
    if rc > 0 then
        call error_routine;
end
```

```

'panel receive applican'; /* pseudo-conversational this would be separate */
if pan.aid = 'PF3' | pan.aid = 'PF12' then
  leave;
if pan.aid = 'ENTER' & pan.rea = 124 then
  iterate;
if pan.aid = 'CLEAR' | substr(pan.aid,1,2) = 'PA' then
  iterate; /* go to beginning of loop */
if rc > 0 then
  call error_routine;

/* process the name and address */

end;
'panel end';
exit

error_routine:
  Say 'An error has occurred'
  return;

** END OF REXX PROGRAM and end of sample.

```

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Defining panels

Defining a panel requires two steps.

1. Use an editor to create the panel source file in the REXX File System. The panel source should contain field control characters and the panel layout. The panel layout can contain field control characters, regular displayable text characters, and possibly, imbedded variable names.
2. Convert the panel source into an intermediate form (panel object) that can be used by the panel input/output commands. The panel facility automatically generates the intermediate file when the input/output command that is referencing that panel is first invoked or an explicit command in the REXX environment (or a REXX exec containing the command) can be invoked to generate the intermediate file.

Note: This automatic generation is executed whenever the panel object cannot be found, or when the panel source has a date or time change that is later than the panel object. Any change to the panel source causes a new panel object to be created. Therefore, be cautious when you change a panel source after a program that uses that panel is out of the testing phase. It is to your advantage to move the panel source out of the RFS, or into an RFS directory that the program cannot access, after the project goes into production.

Defining the field control characters with the .DEFINE verb

The field control characters define the attributes of fields on the panel.

These control characters are definable by using the .DEFINE verb and must precede the panel layout. The .DEFINE verb is terminated at 'End of line', unless the continuation character (a comma) is the last character on the line. The continuation character cannot follow the .DEFINE verb immediately because it would be ambiguous whether the comma is the control character being defined or a continuation character.

Spaces delimit each keyword and order is unimportant except that the control character that is defined must immediately follow the verb.

If any text does not start with .DEFINE in column one, it is ignored and treated as a comment unless the line is a continuation.

A total of 32 control characters (including default control characters) can be actively defined at one time.

If all characters are deleted by using the DROP keyword, the five default control characters are re-activated.

Certain keyword combinations are incompatible and are not allowed. Others that might appear to be meaningless are allowed, for example, INVISIBLE and color. This combination might be useful if the field attribute is changed dynamically in a REXX program (the invisible field can be made visible, which makes color meaningful).

The .DEFINE verb has the following characteristics:

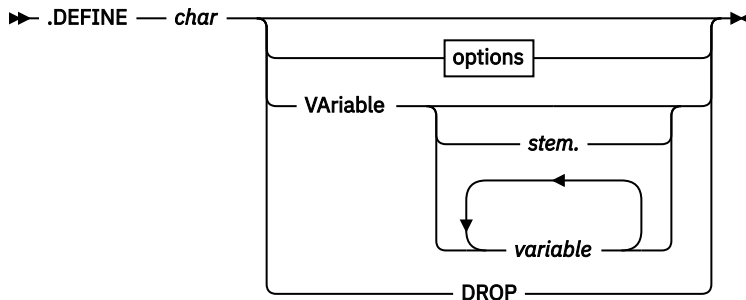

- It must start on the first column, followed by a space, and capitalized.
- It terminates at 'End of line' unless a continuation character (a comma) is used.
- All keywords have a minimum of a two-character abbreviation.
- The maximum number of control characters that you can define at one time is 32. (The default control characters are included in this count.)
- It must be placed before the .PANEL verb.

You can also define variable identifier control characters that let you associate REXX variables with Panel Facility variables. Then you can imbed the variable identifier control character in your panel definition, instead of the REXX variable name. The same REXX variable can be assigned to different variable identifier control characters.

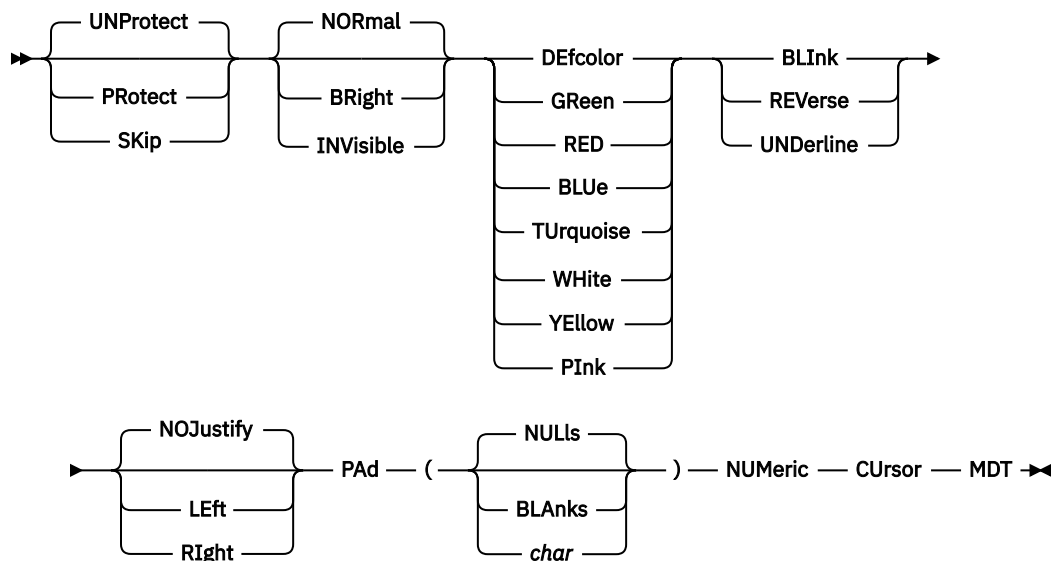

- A stem name must end in a period.
- A variable list can have more variables listed than are used.
- A variable list cannot have less listed than are used; this causes an error.
- Multiple variable identifier control characters can be defined and each one is independent of any other.

.DEFINE

The format of the .DEFINE verb is shown, with the default control characters that are specified if you do not want to define your own.

options

Default field control characters

- # Defcolor skip normal
- + Defcolor protect bright
- % Defcolor unprotect normal
- ! Defcolor unprotect bright
- & Variable identifier

Operands

char

specifies the control character being defined.

Variable

defines a REXX variable identifier control character. Variable identifier control characters are used to associate Panel Facility control characters with REXX variable names. More than one variable control character can be defined at one time. Following the VARIABLE keyword may be a list of variable names (*variable*) or a single stem name (*stem.*). The variable list can contain one to 32,767 variable names. Only one stem name can be specified and the stem name must end in a period. This period identifies the variable as a stem and leaving off the period causes the name to be interpreted as a simple variable.

Using a variable list and a stem name cannot be mixed. When the panel generator encounters a variable control character, a substitution is done. Simple variable lists are substituted in the same order as listed. For example, the third variable control character is replaced with the third variable listed for that control character. The stem variable is replaced by appending a three-character number (tail) to the stem name. The number starts at 1 and is incremented as that stem control character is encountered. Therefore, the tenth stem control character for a particular stem would have a 10 as the tail (STEM.10). Because these variables are REXX variables, they must follow the REXX variable naming rules.

DROP

drops *char* as a field control character.

Options

UNProtect

specifies that the field is not protected from operator input. (This is the default.)

PRotect

specifies that the field is protected from operator input.

SKip

specifies a protected field with the auto-skip feature. Operator entering a character in the last position of the previous unprotected field causes the cursor to skip over this field.

NORmal

specifies that the field is not highlighted. (This is the default.)

BRight

specifies that the field is highlighted.

INVisible

specifies that the field is invisible.

GReen

RED

BLUe

TURquoise

WHite

YELlow

PInk

DEfcolor

are the choices for the color.

Note:

1. When you do not specify a default color, the color is based on the field type and intensity values: protect/normal displays blue, protect/bright displays white, unprotect/normal displays green, and unprotect/bright displays red.
2. If any field on a panel has explicitly specified a color (including DEFCOLOR), all bright fields with DEFCOLOR or no color specified are displayed white and all normal fields with DEFCOLOR or no color specified are displayed green. This is a 3270 hardware limitation and not the panel facility.

BLInk

specifies that the field blinks.

REVerse

specifies that the field is in reverse video.

UNDerline

specifies that the field is underlined.

NOJustify

specifies that justification is not done (left justified but blanks are not stripped).

LEft

specifies that the field is left justified (leading blanks are stripped).

RIght

specifies that the field is right justified (trailing blanks are stripped).

PAd()

specified only in the context of fields having variables. In an unprotected field the pad character fills the character positions that are not occupied by a variable value. In a protected field, the pad character is similar but the scope of the fill area is not the whole field as in the unprotected field. It is bound by where the variable starts, within the protected field to either the end of the field or the start of the next variable or text.

NULls

specifies that a field will be padded with the null character.

BLAnks

specifies that a field will be padded with blanks.

char

specifies a single character to be used to pad a field.

NUMeric

specifies a field is numeric (unprotected field only).

CURsor

specifies that the cursor is positioned at the beginning of this field. If multiple cursor fields are defined, then the last one defined contains the cursor. The cursor is placed in the top left corner if a cursor field is not defined.

MDT

sets the modify bit tag on for the field. Always return this field on a read, even if the field was not modified by the operator.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ ¢. See also [Conventions and terminology used in the CICS documentation](#).

Defining the actual PANEL layout with the .PANEL verb

A .PANEL verb that signals the start of the panel layout follows the .DEFINE verbs.

This verb must also start at column one and be capitalized. Specify the lines in the panel definition in the same positions that you want them displayed. All text entered after the panel verb is significant to the panel generator, including blank lines, and therefore comment lines are not allowed. The first character must be a protect, skip, or unprotect control character. The panel definition ends at the end of file or the next .PANEL verb starting in column one. Only one panel definition per file is supported.

The panel layout is close to what you see, with the exception of the control characters and the imbedded variables that are not shown when the panel is displayed. A field typed on the third line after the .PANEL starting at column ten is positioned on the terminal screen third line, column ten.

The .PANEL verb has the following characteristics:

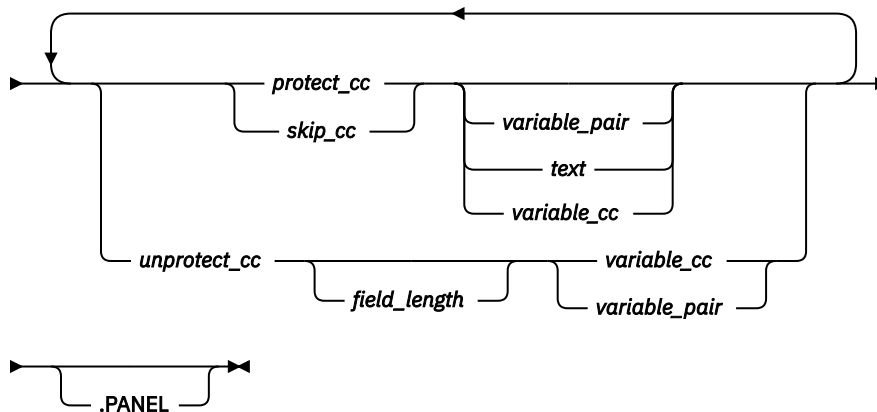

- It must start in the first column, followed by a space, and capitalized.
- It must have a panel name on the same line as .PANEL, unless it is an end of panel indicator.
- It must have at least one field and the first character following the .PANEL line must be a protect, skip, or unprotect control character.
- The field ends at the start of the next field unless an explicit input field length is being used. An empty field can be used to terminate a field.
- To use a control character as a regular displayable character, type two consecutive control characters. To display two consecutive control characters, type four consecutive control characters. For each pair of control characters that get displayed as one character, the subsequent text in the field will be displayed one position to the left, except if there are 7 or more consecutive spaces following the pair of control characters.
- The protect or skip field can have any number of variables or text that will fit in that field. A variable in a protected field has area available for substitution, starts at the variable identifier control character, and ends just before the next control character or text.
- Space is not allowed between a variable identifier control character and the variable name. A space causes the variable name to be interpreted as plain text.
- The unprotect field can have only one associated variable.
- The unprotected field can have a number explicitly stating the field length. The number must be between the unprotect and variable control characters. When the explicit field length is used, a field does not need termination. If an explicit length field is the last field of a line then a terminating field is created with a skip attribute to force a field end.

- When an explicit input field length is used, all of the following field's column positions are adjusted left or right to force proper alignment, so the explicit length field and the field immediately after abut each other. Other fields on that line keep their spacing intact. This alignment only affects that one line; the fields on the next line are unaffected. For example, a line has 5 fields with the 1st and 4th fields having explicit length and spacing. Between fields 1 and 2 is 4, between 2 and 3 is 5, between 3 and 4 is 6, and between 4 and 5 is 7. When this line is displayed, field 2 starts immediately after field 1 (no space), separation between fields 2 and 3 is still 5, separation between fields 3 and 4 is still 6, and field 5 follows immediately after field 4 (no space). If the explicit length causes the current field or subsequent fields to overflow into the next field, an error is returned when the panel is displayed.
- When a field does not terminate on the same line (for example, field spans lines), the field length varies with the width of the screen on which the panel is displayed. Also, if the last field has no terminator, that field wraps the screen until the first field start is encountered.
- Only the fields containing a variable can have its attributes dynamically changed during panel output.
- If a protect or skip field is changed dynamically to an unprotected field, only the first variable in the field has the operator input assigned to it. All of the contents of the input field are assigned.
- The panel source file must reside in the REXX File System before it can be processed into the intermediate file (panel object) used by the runtime panel facility.

.PANEL

The format of the .PANEL verb is shown.

➔ .PANEL — *panel_name* ➔

Operands

panel_name

specifies the panel being defined. It must be one to eight characters in length and follow the rules for REXX File System file names. See [Chapter 24, “REXX/CICS File System,”](#) on page 285.

Note: The *panel_name* must be the same as the RFS file name. The complete RFS file name should be *panel_name.PANSRC*.

protect_cc

specifies the protect field control character.

skip_cc

specifies the skip field control character.

variable_pair

specifies the variable control character followed by the variable name. (There cannot be a space between them.)

text

displayable characters.

variable_cc

specifies the variable identifier control character.

unprotect_cc

specifies the unprotect control character.

field_length

specifies the explicit input field length value.

Panel generation and panel input/output

Panel definition can be done outside the REXX environment; however, panel generation and input/output is performed in a REXX exec or in the REXX interactive environment.

The REXX interactive environment is an ideal place to test the initial panel development. To test display the panel, use the TEST panel command. This displays the panel with no panel object file created. Also, there is no substitution for the variables on the panel. To create the panel object, use either the GENERATE, SEND, or the CONVERSE panel commands. Use the FILE keyword to explicitly state what directory in RFS to find the panel source, or let it default to the current directory.

The panel source name must have the panel name as the file name and PANSRC as the file type. The panel object is created and filed in the same directory as the panel source with the file name equal to the source file name and with a file type of PANOBJ. GENERATE creates the panel object and does not display the panel. SEND creates the panel object, displays the panel, and attempts variable substitution. CONVERSE is similar to SEND with an implied wait and receive.

Note: There are side effects of being in a REXX interactive environment. Several panel keywords act differently: the cursor position on the SEND is ignored and keyboard lock is also ignored for SEND and CONVERSE.

The characteristics of the PANEL command are as follows:

- All the arguments or keywords are not meaningful or valid for all commands.
- The last panel command in a REXX exec is the END command. This releases any storage held by previous panel commands. This command needs no other operands.
- Only the fields with associated variables can have their attributes changed dynamically.
- A panel object file is created for the panel that is being displayed if one does not exist. The file name is the same as the panel source file name and the file type will be 'PANOBJ'.
- Only the first variable in a protect/skip field is assigned the input entered by the terminal operator when the field is changed to an input field.
- The dynamic attribute changes effect the present panel execution and do not last. Subsequent panel displays revert to what was defined statically by the panel definition step unless the attributes are again dynamically changed.
- A SEND must be performed before a RECEIVE and the panel names must match.
- Only the attributes indicate change, the others stay as defined statically.
- A panel sent with a position argument needs to be received with the same position values so the operator input is assigned correctly to the REXX variables.
- Enclose the field ID list within parenthesis, when multiple fields are listed.
- There must be one ATTRIBUTE argument for each different attribute change.

Note:

- To change the number of ATTRIBUTE arguments dynamically, you must use a REXX variable (put the literal attribute string in REXX variable and use the variable). For example, a program needs to change one field to blue, or change one field to blue and another field to blinking, depending on operator input. One solution is as follows:

```
field_id = 'xxxx'; /* name of field needing attribute changed*/
attr_string = 'attr(' field_id 'blue )';
```

```

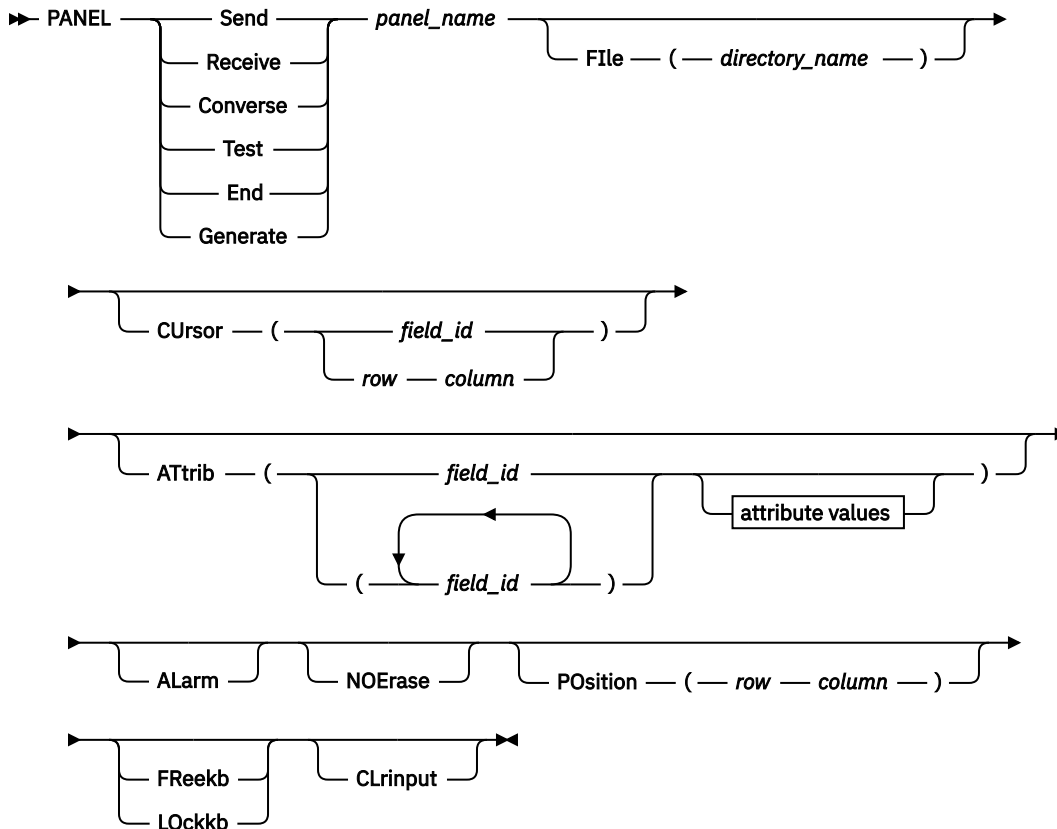

if operator_input = y then
  attr_string = attr_string 'attr(' field_id2 'blink )'
  'panel send panel_name' attr_string;

```

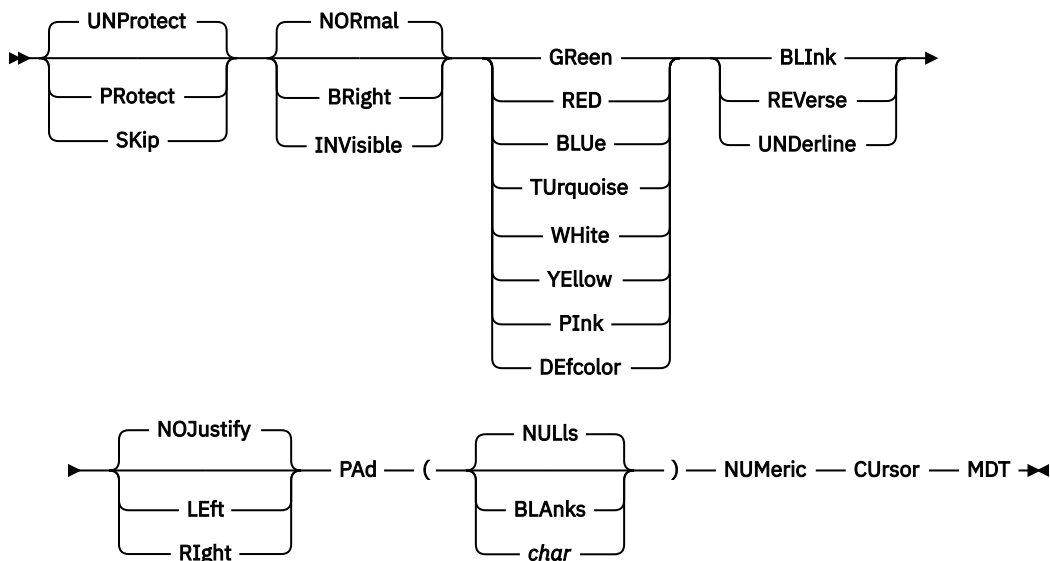

- The REXX panel facility generates the panel object if the object is not found or if the object is older than the source.

PANEL RUNTIME

The format of the PANEL RUNTIME commands is shown.

attribute values

Operands

Send

is the panel command that sends a panel.

Receive

is the panel command that receives a panel.

Converse

is the panel command that sends a panel and waits for operator input.

Test

is the panel command that displays a panel. An intermediate file (panel object) is not created and variable substitutions are not attempted.

End

is a command that terminates the panel session. Command releases all storage held by the panel facility. This command does not have arguments and any arguments supplied are ignored.

Generate

is an explicit command that creates a panel object. The panel is not displayed.

panel_name

specifies the name of the panel to input/output or generate.

FILE()

specifies the name of the RFS directory (*directory_name*) containing this panel. (Specified for all panel commands except END.)

CURSOR()

(specified for SEND and CONVERSE only) positions the cursor on the panel.

field_id

specifies the REXX variable name where the cursor should be positioned on the panel.

row

specifies the row within the panel where the cursor should be positioned. The row value is relative to the starting row of the panel. The default starting row of the panel is 1, but may be changed using the POSITION() keyword.

column

specifies the column within the panel where the cursor should be positioned. The column value is relative to the starting column of the panel. The default starting column of the panel is 1, but may be changed using the POSITION() keyword.

ATTRIB(*field_id attribute_values*)[(*field_ids*) *attribute_values*]

(specified for SEND and CONVERSE only) dynamically sets attributes to override those specified in the panel definition.

field_id

specifies the field whose attributes are dynamically set. It must be a variable name associated with the field. If you specify a list of fields, they must be enclosed with parentheses.

attribute_values

specifies the attributes to set. Only the stated attributes are changed; other attributes default to what was statically defined. For example, if BLUE is specified for a field that was originally defined as RED and UNDERLINE, that field becomes BLUE and UNDERLINE.

For the list of attributes, see [“Attributes” on page 335](#).

ALARM

(specified for SEND and CONVERSE only) sounds the bell when displaying panel. (The default is no alarm).

NOERASE

(specified for SEND and CONVERSE only) do not erase the screen before displaying this one. (The default is erase before a panel write).

To avoid unexpected results, such as changing attributes in the underlying panel while displaying this second panel, or the display of characters from the underlying panel in the second panel, use the following guidelines:

- If you use variables in the second panel, position the panel in a blank area of the underlying panel.
- Position the second panel so that it ends at the right boundary of the screen, or it is followed by only blank columns of the underlying panel.

POsition()

(specified for SEND, CONVERSE, and RECEIVE only) positions the panel on the output screen. Row (*row*) and column (*column*) specifies where the top left corner of the panel should begin. (The default is row 1 col 1). For example, POS(5 10) means to have the panel start in row 5 and column 10, the actual movement is 4 rows down and 9 columns to the right.

FReekb

(specified for SEND and CONVERSE only) frees the keyboard, allowing operator input. (This is the default.)

LOckkb

(specified for SEND and CONVERSE only) locks the keyboard.

CLrinput

(specified for SEND and CONVERSE only) clears all input fields before displaying the panel. Variable substitution is not attempted and pad characters fill the input area.

Attributes**UNProtect**

specifies that the field is not protected from operator input.

PRotect

specifies that the field is protected from operator input.

SKip

specifies a protected field with the auto-skip feature. An operator entering a character in the last position of the previous unprotected field causes the cursor to skip over this field.

NORmal

specifies that the field is not highlighted.

BRight

specifies that the field is highlighted.

INVisible

specifies that the field is invisible.

GRreen**RED****BLUe****TURquoise****WHite****YELLow****PInk****DEfcolor**

are the choices for the color.

Note:

1. When you do not specify a default color, the color is based on the field type and intensity values: protect/normal displays blue, protect/bright displays white, unprotect/normal displays green, and unprotect/bright displays red.
2. If any field on a panel has explicitly specified a color (including DEFCOLOR), all bright fields with DEFCOLOR or no color specified are displayed white and all normal fields with DEFCOLOR or no color specified are displayed green. This is a 3270 hardware limitation and not the panel facility.

BLInk

specifies that the field blinks.

REVerse

specifies that the field is in reverse video.

UNDerline

specifies that the field is underlined.

NOJustify

specifies that no justification is done.

For input, leading and trailing blanks and leading and trailing pad characters are not stripped.

For output, leading and trailing blanks and leading and trailing pad characters are not stripped. Data is truncated on the right, if necessary. Truncation does not cause a break in execution, but results in a Return Code of 4 and Reason Code of 117. Pad characters replace null positions to the right of the variable data.

LEft

specifies that the field is left justified.

For input, leading and trailing blanks and leading and trailing pad characters are stripped.

For output, leading blanks are stripped, and nulls to the right of the variable data are replaced by pad characters. After leading blanks are stripped, data is truncated on the right, if necessary. Truncation does not cause a break in execution, but results in a Return Code of 4 and Reason Code of 117.

RIght

specifies that the field is right justified.

For input, leading and trailing blanks and leading and trailing pad characters are stripped.

For output, trailing blanks are stripped, and nulls to the left of the variable data are replaced by pad characters. After trailing blanks are stripped, data is truncated on the left, if necessary. Truncation does not cause a break in execution, but results in a Return Code of 4 and Reason Code of 117. For output, pad characters replace null and blank positions to the left of the variable data.

PAd()

specified only in context of fields having variables. In an unprotected field the pad character fills the character positions that are not occupied by a variable value. In a protected field, the pad character is similar but the scope of the fill area is not the whole field as in the unprotected field. It is bound by where the variable starts, within the protected field to either the end of the field or the start of the next variable or text.

NULLs

specifies that a field will be padded with the null character.

BLanks

specifies that a field will be padded with blanks.

char

specifies a single character to be used to pad a field.

NUMeric

specifies a field is numeric (unprotected field only).

Cursor

specifies that the cursor is positioned at the beginning of this field. If multiple cursor fields are defined, then the last one defined contains the cursor. The cursor is placed in the top left corner if a cursor field is not defined.

MDT

(specified for SEND and CONVERSE only) sets the modify bit tag for all input fields on the panel.

PANEL Variables

The implicitly defined PANEL variables that can be used by the REXX program and the PANEL error related variables are listed.

PAN.AID

Attention identifier that last caused panel input.

```
ENTER    ENTER
CLEAR    CLEAR
CLRP     CLEAR PARTITION
PEN      SELECTOR PEN
OPID     OPERATOR ID
MSRE     MAGNETIC READER
STRF     STRUCTURE FIELD
TRIG     TRIGGER
PA1
PA2
PA3
PF1
PF2
PF3
PF4
PF5
PF6
PF7
PF8
PF9
PF10
PF11
PF12
PF13
PF14
PF15
PF16
PF17
PF18
PF19
PF20
PF21
PF22
PF23
PF24
```

PAN.CURS

Position of cursor in last panel input. This is in the form of row column, separated by a blank. For example, '10 5' would be row 10 and column 5. The row and column values are absolute to the start of the screen and are unaffected by the POSITION() keyword.

PAN.CNAM

REXX variable name (field ID) associated with the cursor position. If the field has no associated variable then PAN_CNAM is not updated.

The PANEL error related variables are as follows.

PAN.REA

Reason code if warning or error occurs. REXX return code, RC, should be examined first. If the RC is 10, PAN.REA contains state codes and input codes to help in error determination. See [“State codes and input codes”](#) on page 340 for more information.

PAN.LOC

Internal location code. Three- to four-digit number used by IBM support. If the REXX variable RC contains the value 10, use PAN.LOC in conjunction with PAN.REA for error determination.

PAN.LINE

Line number in the source panel definition where an error that occurred during panel object generation was detected.

Panel facility return code information

The main return code for the panel command is set in the REXX variable, RC. Each level of return code is accompanied by additional information in the form of a reason code and a line number (if applicable).

When an error is detected while processing panel source code (location code of 11xx or 12xx) and RC is not 12 or 16, the REXX variable *PAN.LINE* contains the number of the line in error.

Return codes

4

Warning. Panel facility continues processing. Processing stops for other return code values.

8

Programmer error

10

Programmer error; PAN.REA contains more information to help determine the cause of the error. See [“State codes and input codes” on page 340](#) for more information.

12

CICS command error; the CICS EIBRESP is returned in the panel reason code. If the error is not programmer resolvable, save and collect as much information as needed to recreate the error and contact IBM support.

14

RFS errors; reason code contains the RFS return code.

16

Internal system error; save and collect as much information as needed to recreate the error and contact IBM support.

System error reason codes

401

Panel facility ran out of storage space while processing the command.

402

Internal control character identifier table and control character informational table are out of synchronization.

403

Panel object data has been corrupted. First check that the file is correct and that it is a panel object.

404

CICS receive buffer corrupted.

405

Bad validation request.

406

Storage free request failed.

407

Storage get request failed

408

Attempt to get or put REXX variable failed.

409

Aid is unknown

410

Dynamic match error.

Programmer-introduced warning and error reason codes

101

Keyword repeated or keyword within a like category was repeated. For example, RED and BLUE; UNDERLINE and REVERSE.

102

Keywords are incompatible. For example, PROTECT and NUMERIC.

103

Missing keyword or panel name.

104

The control character being defined is invalid or missing.

105

Panel is too large for the screen.

108

Parenthesis missing.

109

Pad character invalid.

110

Task has no associated terminal.

111

Panel has no input fields defined during a receive.

112

Panel name is invalid.

115

REXX variable name (or field ID) is invalid.

116

Number is specified incorrectly. Explicit length value in panel source or row col value.

117

Variable value was too long and was truncated to fit output field.

118

Text field was truncated. Check to see if explicit length did not force a subsequent field to overlay another field.

119

Bad or missing panel command. It should be SEND, RECEIVE, CONVERSE, TEST, or END.

122

A modified field was received but it had no corresponding input field definition.

124

Empty received buffer. Clear, ENTER, and the PA keys will cause this.

125

File name is invalid.

126

Field identifier for the ATTRIBUTE keyword was not found in the panel.

129

Too many arguments supplied with the command.

130

SEND must be performed before a RECEIVE.

131

Panel source has no panel definition. .PANEL was probably not in column 1 or did not have a space after.

132

Keyword encountered is unknown.

133

DROP asked for a control character not presently active.

136

Continuation is in effect but end of source was encountered.

137

Row or column specified is too large for the current display CURSOR() or POSITION() the likely source of error.

138

Variable identifier control character was being defined and more than one stem name was listed.

139

More variable fields defined than listed in the control character definition.

140

Explicit input field value caused field to go past screen end.

143

Panel name in file does not match the panel name in the panel runtime command.

144

Panel has more rows than the present screen allows.

145

Panel has more columns than the present screen allows.

State codes and input codes

For return code 10, the reason code (in PAN.REA) has a special meaning.

The reason code consists of two 2-digit numeric codes, the first number stating what keyword is being processed (*state code*) and the second number stating the input that caused the error condition (*input code*). Use the location code in PAN.LOC to determine which state code list and input code list to use.

For example:

```
RC = 10  
PAN.REA = 0199  
PAN.LOC = 1177
```

When you use the state code and input code lists for the 11xx location codes, the keyword being processed was .DEFINE for state code 01 and the input code contained an unknown symbol for input code 99.

Chapter 30. REXX/CICS commands

Detailed reference information for all REXX/CICS commands is provided. Return code information for all commands is returned after command execution in the special REXX variable RC.

You can use all the commands in this section with the command environment name REXXCICS. This is also the default. However, depending on how you define the command, you can use a more specific environment name (such as CICS) instead. If you need to reset the command environment because another command environment is in use, enter the following command before you issue the REXX/CICS command:

```
ADDRESS REXXCICS
```

REXX/CICS supports all EXEC CICS commands, except for the following:

- System Programming (SPI) commands
- Handle Condition
- Handle Aid
- Handle Abend
- Ignore Condition
- Push
- Pop

The syntax for CICS commands under REXX/CICS is documented in [Application development reference](#). Mapping between the existing EXEC CICS command definitions with the REXX commands is as follows:

- Use CICS as the prefix for CICS commands, rather than EXEC CICS.
- All data value fields can be specified as a literal character string or as a REXX variable name.
- All data area fields can be specified as a REXX variable name, which is either the source or the target for the intended data.
- Do not use the same REXX variable as both the source and target fields on a CICS command. If you do this, the result of the command execution will be unpredictable.
- Whenever you do not specify a LENGTH option, the length is automatically determined from the length of the related REXX variable or character string.
- When using the CICS ENQ command from REXX/CICS, use the LENGTH parameter, or unpredictable results might occur.
- NOHANDLE is automatically specified for all CICS commands. The EIBRESP value from the execution of each command is returned in the REXX special variable RC. Also, EIB fields are placed in REXX variables DFHEIBLK, EIBRESP, EIBRESP2, and EIBRCODE.
- For an explanation of the return code values, see [Application development reference](#). For information on return codes with negative values, see [Chapter 32, “Return Codes,” on page 425](#).

Example of EXEC CICS to REXX/CICS command mapping

- Non-REXX:

```
EXEC CICS XCTL PROGRAM('PGMA') COMMAREA(COMA) LENGTH(COMAL)
```

- REXX/CICS:

```
"CICS XCTL PROGRAM('PGMA') COMMAREA(COMA)"
```

Note: The **EXEC CICS READ, WRITE, and DELETE** commands are implemented by default as REXX/CICS authorized commands, to control their use. Refer to [Authorized REXX/CICS commands and authorized command options](#) and to [Security](#).

ALLOC

ALLOC associates a dataset with a data definition name.

This is an authorized command.

➤ ALLOC — *ddname* — *dsname* — (— *member* —) — 

Operands

ddname

specifies the data definition name.

dsname

specifies the fully qualified dataset name.

member

specifies the member name in the dataset.

SHR

dataset exists but exclusive control is not required.

OLD

dataset exists and exclusive control is required.

Return codes

The return code given by SVC 99

For more information, see [z/OS MVS Programming: Authorized Assembler Services Guide](#).

1702

Invalid operand

Note:

- The *dsname* contains your user ID as the high level prefix for security reasons. Also, a user exit is provided for additional security handling of data definition names and dataset names. When you leave the member name off of the ALLOC command, a sequential dataset is allocated. For performance reasons, if the dataset has been migrated, the allocation request is refused.
- An allocation sample exit, CICSECX1, is provided with this command, to let installations perform security checking.

AUTHUSER

AUTHUSER authorizes a list of user IDs.

This is an authorized command.

➤ AUTHUSER —  *userid* —

Operands

userid

is a CICS signon user ID that becomes REXX/CICS authorized.

Return codes

0

Normal return

2602

Invalid operand or operand missing

2621

Specified user ID invalid length

2642

Error storing user ID

Example

```
'AUTHUSER USER2 SYSPGMR'
```

This example makes USER2 and SYSPGMR REXX/CICS authorized users.

Note:

1. If you are an authorized user you can use REXX/CICS authorized commands, regardless of whether you are running in an exec that was loaded from an authorized REXX/CICS library.
2. If an error is detected in the list of user IDs, the user ID with the error is placed in the REXX special variable RESULT and processing of the list stops.
3. AUTHUSER commands are cumulative; previous AUTHUSER command definitions remain in effect until the CICS region is recycled.

CD

CD changes the RFS file system directory.

Operands

dirid

specifies a partial or full REXX File System directory that becomes the new current working directory for you.

If *dirid* is not specified, the current working directory is retrieved and placed in the REXX special variable RESULT, instead of changing the current working directory.

A full directory ID is in the form: *poolid*:*dirid1*\...\i>diridn

When a full directory ID is specified, it completely replaces the previous directory setting.

A partial directory ID does not begin with a *poolid*. In this case, the partial directory ID is appended to the end of the existing directory ID. If the partial directory ID begins with two periods, this indicates that one directory level is removed (from the right), before the new partial directory ID is appended to the end. In this case, a backslash is required before the directory ID.

For example: If the current directory is `P00L1:\USERS\USER1\ABC` and you enter `CD ..\XYZ`, the new current directory will be `P00L1:\USERS\USER1\XYZ`.

The default directory ID for you is *poolid*:*USERS\userid*\, where *poolid*: is the file pool identifier of the first RFS file pool defined and *userid* is your CICS signon user ID. If you are not signed onto CICS, *userid* defaults to the value in CICS DFLTUSER.

Return codes

0

Normal return

521

Error in retrieving file pool definition

522

Error in creating default RFS directory

523

Error in storing current RFS directory information

524

RFS directory does not exist or access not authorized

525

Error in retrieving directory information

526

Invalid file pool/directory

527

Cannot go back past root directory

528

Error setting result value

Example

```
'CD \USERS\USER2\XYZ'
```

This example changes your current working directory to \USERS\USER2\XYZ in the file pool you are currently using, regardless of the previous directory setting.

If your current directory is \USERS\USER2 and you enter:

```
'CD XYZ'
```

your current directory is changed to \USERS\USER2\XYZ.

Note: The CD command works in conjunction with the PATH command identifying the search order for the execution of REXX execs. The current directory (specified by the CD command) is always searched first for execs. Then, the directories and MVS partitioned data sets listed in the PATH command are searched. Finally, any MVS partitioned data sets allocated in the CICS region startup JCL are searched.

CEDA

Executes a CEDA command for resource definition online (RDO).

➤ CEDA — *RDO_Command* ➤

Operands

RDO_Command

specifies a command string passed as input to the CEDA transaction program.

Return codes

n

The return code that is passed back by CICS if an error is detected

0

Normal return

-101

Invalid command

Any warning or error messages are placed in the variable CEDATOUT. The results of the execution, if any, are placed in the variable CEDAEOUT. The maximum length returned in CEDAEOUT is approximately 28K bytes. Each variable has the following format:

- Binary halfword containing inclusive length of field.
- Binary halfword containing the number of messages produced.
- Binary halfword containing the highest message-severity: 0 and 4 continue to execution; 8 and 12 do not continue to execution.
- Variable-length data containing:
 - For CEDATOUT: any diagnostic messages
 - For CEDAEOUT: data that would normally appear on CEDA screen, including messages. Each line begins with a new line (NL) character and otherwise, consists of blanks and uppercase alphanumeric characters.

The format of this data is not guaranteed from release to release, but it is the same as that displayed by CEDA.

Example

```
'CEDA INSTALL PROGRAM(XYZ) GROUP(ABC) '
```

This example shows a CICS command that is passed to the CEDA transaction program for execution.

CEMT

CEMT executes a CICS main terminal command from REXX.

➡ CEMT — *main_term_cmd* ➡

Operands

main_term_cmd

specifies a command string passed as input to the CEMT transaction program.

Return codes

n

The return code that is passed back by CICS if an error is detected. Calling CEMT from REXX uses the DFHEMTA (CEMT programmable interface), so the codes returned will be those for the CEMT command. Possible return codes are:

- 1** NOT FOUND
- 2** CLASS NOT FOUND
- 3** ERROR

Note: Not all return codes are possible in all CICS releases.

0
Normal return

-102
Invalid command

Any warning or error messages are placed in the variable CEMTTOUT. The results of the execution, if any, are placed in the variable CEDAEOUT. The maximum length returned in CEMTEOUT is approximately 28K bytes. Each variable has the following format:

- Binary halfword containing inclusive length of field.

- Binary halfword containing the number of messages produced.
- Binary halfword containing the highest message-severity: 0 and 4 continue to execution; 8 and 12 do not continue to execution.
- Variable-length data containing:
 - For CEMTTOUT: any diagnostic messages
 - For CEMTEOUT: data that would normally appear on CEMT screen, including messages. Each line begins with a new line (NL) character and otherwise, consists of blanks and uppercase alphanumeric characters.

The format of this data is not guaranteed from release to release, but it is the same as that displayed by CEMT.

To parse the contents of CEMTEOUT, you can use the following example:

```
PARSE VAR CEMTEOUT BUFFLEN 3 MSGCOUNT 5 MAXRC REST
```

This example places:

- the first halfword (containing the inclusive length of CEMTEOUT) into the REXX variable BUFFLEN
- the second halfword (containing the number of messages produced) into the REXX variable MSGCOUNT
- the third halfword (containing the highest message-severity) into the REXX variable MAXRC
- the remainder of CEMTEOUT into the REXX variable REST

The values contained in the first 3 halfwords usually display as periods because they are unprintable binary fields. To display their values, they must first be converted. For example, to display the value of BUFFLEN, you could use one of the following:

- ```
SAY C2X(BUFFLEN)
```
- ```
VAR1 = C2X(BUFFLEN)
SAY VAR1
```

Example

```
'CEMT SET PROGRAM(XYZ) NEWCOPY'
```

This example shows a CICS command passed to the CEMT transaction program for execution.

CLD

CLD changes your current RLS list directory.

Operands

dirid

specifies a partial or full REXX List System directory that becomes the new current working directory for you.

If *dirid* is not specified, the current working directory is retrieved and placed into the REXX variable RESULT, instead of changing the current working directory.

A full directory ID starts with a slash and is in the form: `\dirid1\...\diridn`

When you specify a full directory ID, it completely replaces the previous directory setting.

A partial directory ID does not begin with a slash. In this case, the partial directory ID is appended to the end of the existing directory ID. If the partial directory ID begins with two periods, this indicates that one directory level is removed (from the right), before the new partial directory ID is appended to the end. In this case, a backslash is required before the directory ID.

For example: If the current directory is \USERS\USER1\ABC and you enter CLD . . \XYZ, the new current directory will be \USERS\USER1\XYZ.

The default directory ID for you is \USERS\genid\, where *genid* is your CICS signon user ID. If you are not signed onto CICS, *genid* defaults to the value in DFLTUSER.

Return codes

0

Normal return

923

Error in storing current RLS directory information

924

RLS directory does not exist or access not authorized

925

Error in retrieving directory information

926

Invalid directory

927

Cannot go back past root directory

928

Error setting result value

Example

```
'CLD \USERS\USER2\XYZ'
```

This example changes your current working list directory to \USERS\USER2\XYZ, regardless of the previous directory setting.

If your current directory is \USERS\USER2 and you enter:

```
'CLD XYZ'
```

your current directory is changed to \USERS\USER2\XYZ.

Note:

1. The current directory (specified by the CLD command) is always searched first, attempting to locate an RLS list with the appropriate list name.
2. A fully qualified RLS file name bypasses the search of your directories.

CONVTMAP

CONVTMAP reads an MVS sequential file or member of a PDS and converts a DSECT (created by a previously assembled BMS map) into a structure, and stores the result in a REXX File System file.

➤ CONVTMAP — *mvs_dataset_name* — *rfs_fileid* ➤

The BMS map used as input to CONVTMAP must be in assembler language format. The resulting output file is formatted as a REXX file structure. See [Chapter 36, “Basic mapping support example,”](#) on page 477.

Operands

mvs_dataset_name

specifies a fully qualified MVS dataset name. The dataset must be a physical sequential dataset, or, if its a PDS, the PDS member must be specified in parenthesis.

rfs_fileid

specifies a fully qualified REXX File system file, or only the REXX file name. If a fully qualified name is not supplied, the current REXX directory is used to store the file.

Return codes

n

The return code from the attempt to process the MVS data set.

0

Normal return

-302

Invalid operand

-321

Invalid input record

-322

RFS error writing output file

Example

```
'CONVTMAP USER1.TEST.DATA(MAP1) POOL1:\USERS\USER1\MAP1.DATA'
```

This example shows the input BMS map DSECT, MAP1, a member of the MVS PDS dataset USER1.TEST.DATA, being formatted and written out to the RFS file POOL1:\USERS\USER1\MAP1.DATA.

COPYR2S

COPYR2S copies REXX variable contents to 31-bit storage that was obtained earlier by a GETMAIN request.

This is an authorized command.

If the intended storage area addressed by *stor_anchor* exceeds 32767 bytes, ensure that the GETMAIN request specified the FLENGTH option.

Note: COPYR2S can operate on a 31-bit address. COPYR2S cannot operate on a 64-bit address.

Operands

source_vname

specifies the REXX variable containing the value copied to the storage area that was obtained earlier by a GETMAIN request.

Note: This value should be in quotes so that substitution does not occur.

specifies that all the REXX variables are copied. If you specify an asterisk (*), you cannot specify *fieldname*.

stor_anchor

specifies the REXX variable containing the anchor for the target storage area that was obtained earlier by a GETMAIN request. This anchor consists of four bytes, containing the 31-bit address of the storage that was obtained by a GETMAIN request. Ensure that the anchor specifies a 31-bit address, otherwise results might be unpredictable.

offset

specifies the displacement into the storage area (obtained by a GETMAIN request) that the contents of the REXX variable is copied to. The first byte of the area is indicated by a displacement of zero.

length

specifies the length in decimal bytes of the copy performed. If this length is specified, the contents of the source REXX variable is truncated, or padded with blanks to match this length, and then copied. However, the source REXX variable is not altered in this process. If this length is omitted, the current length of the source REXX variable is used.

struct_vname

specifies a REXX variable containing a structure definition (or mapping) of the fields in the storage area that was obtained by a GETMAIN request. The format of the data in this variable is: *field1_name length ... fieldn_name length*. This capability is provided so that field displacements are easily calculated and changed, from a central location.

struct_name

specifies the structure file ID containing a structure definition (or mapping) of the fields in the storage area that was obtained by a GETMAIN request.

Structures are made up of records in the following format: *fieldname location length type*, where:

fieldname

specifies a 1 to 12 character symbolic name of the field.

location

specifies the position in structure that this field starts (the first position is 1).

length

specifies decimal length of this field in bytes.

type

specifies the field data type: C (character), F (fullword), or H (halfword).

fieldname

is a 1 to 12 character symbolic name associated with the destination field for this copy. This name must exist in the above specified REXX variable or structure definition file. The *fieldname* must be specified when *struct_vname* or *struct_name* is specified.

Return codes**0**

Normal return

2002

Invalid operand

2021

Invalid structure definition

2022

Invalid variable structure definition

2023

Field name not found

2025

Failure processing GETVAR request

2026

Invalid numeric input

2027

RFS read error

2028

Invalid offset

2029

Invalid length value

Examples

The following example requests 200 bytes of virtual storage and copies the hex value of '00000000'x into bytes 4 through 7 of that area.

```
/* Needed if entering example from the REXXTRY utility */
'PSEUDO OFF'
'CICS GETMAIN SET(WORKANC) LENGTH(200)' /* get 200 bytes of working storage */
VAR1 = '00000000'x /* set a REXX variable with 4 bytes of hex */
'COPYR2S VAR1 WORKANC 4'
```

The following example requests 200 bytes of virtual storage and copies the character string ABC to position 7 of the area that was obtained by a GETMAIN request that is referenced by anchor WORKANC.

```
'CICS GETMAIN SET(WORKANC) LENGTH(200)' /* get 200 bytes of working storage */
VAR1 = 'ABC' /* set a REXX variable with 3 characters */
struct1 = 'flda 4 fldb 2 fldc 3 fldd 8 flde 5'
'COPYR2S VAR1 WORKANC STRUCT1 FLDC'
```

COPYS2R

COPYS2R copies data from 31-bit storage that was obtained earlier by a GETMAIN request to a REXX variable.

This is an authorized command.

If the intended storage area addressed by *stor_anchor* exceeds 32767 bytes, ensure that the GETMAIN request specified the FLENGTH option.

Note: COPYS2R can operate on a 31-bit address. COPYS2R cannot operate on a 64-bit address.

Operands

stor_anchor

specifies the REXX variable containing the anchor for the target storage area that was obtained earlier by a GETMAIN request. This anchor consists of four bytes, containing the address of the 31-bit storage that was obtained earlier by a GETMAIN request. Ensure that the anchor specifies a 31-bit address, otherwise results might be unpredictable.

vname

specifies the REXX variable containing the value to be copied from the storage area that was obtained earlier by a GETMAIN request..

Note: This value should be in quotes so that substitution does not occur.

*

specifies that all the REXX variables are copied. If you specify an asterisk (*) you cannot specify *fieldname*.

offset

specifies the displacement into the storage area (obtained by a GETMAIN request), that the contents of the REXX variable is copied from. The first byte of the area is indicated by a displacement of zero.

length

specifies the length in decimal bytes of the copy performed. If this length is specified, the contents of the source REXX variable is truncated, or padded with blanks to match this length, and then copied. However, the source REXX variable is not altered in this process. If this length is omitted, the current length of the source REXX variable is used.

struct_vname

specifies a REXX variable containing a structure definition (or mapping) of the fields in the storage area that was obtained by a GETMAIN request. The format of the data in this variable is: *field1_name length ... fieldn_name length*. This capability is provided so that field displacements are easily calculated and changed, from a central location.

struct_name

specifies the structure file ID containing a structure definition (or mapping) of the fields in the storage area that was obtained by a GETMAIN request.

Structures are made up of records in the following format: *fieldname location length type*, where:

fieldname

specifies a 1 to 12 character symbolic name of the field.

location

specifies the position in structure that this field starts (the first position is 1).

length

specifies decimal length of this field in bytes.

type

specifies the field data type: C (character), F (fullword), or H (halfword).

fieldname

is a 1 to 12 character symbolic name associated with the destination field for this copy. This name must exist in the above specified REXX variable or structure definition file. The *fieldname* must be specified when *struct_vname* or *struct_name* is specified.

Return codes

0

Normal return

2102

Invalid operand

2121

Invalid structure definition

2122

Invalid variable structure definition

2123

Field name not found

2125

Failure processing GETVAR request

2126

Invalid numeric input

2127

RFS read error

2128

Invalid offset

2129

Invalid length value

Example

```
var1 = '' /* set REXX variable VAR1 to null */
struct1 = 'flda 4 fldb 2 fldc 3 fldd 8 flde 5'
'COPYS2R WORKANC VAR1 STRUCT1 FLDC'
```

This example copies three bytes of data from positions 7 through 9 of the earlier GETMAINED storage area anchored by the fullword address in REXX variable WORKANC, and copies it to REXX variable VAR1.

Note:

1. Anchor addresses are not limited to being set by the GETMAIN command. For example, a COPYS2R can be used to copy a fullword address of an area obtained by a GETMAIN request to a REXX variable that is used as the anchor for a subsequent COPYS2R or COPYR2S.
2. There can be multiple structure (field) definitions for an area obtained by a GETMAIN request; they can overlap, be nested, and used to redefine fields.
3. Anchor addresses do not need to point to the beginning of an area obtained by a GETMAIN request. However, it is important that anchor addresses are within an area obtained by a GETMAIN request that you own, and that any operation on them does not exceed their boundaries.

C2S

C2S copies a client REXX variable to a server REXX variable.

Operands

client_rexx_varname

specifies the client REXX variable to copy from.

server_rexx_varname

is an optional name that specifies the server REXX variable to copy into. If it is not specified, it defaults to the same as the *client_rexx_varname*.

Return codes

0

Normal return

2440

No variable name specified

2441

Error retrieving variable

2442

Error storing variable

2448

No client available

Example

```
'C2S VARA VARB'
```

This example shows that the contents of the client REXX variable VARA are copied into the server REXX variable VARB. The length of VARB is the same as the length of VARA.

Note:

1. The maximum variable name length supported for this command is 250 characters.
2. This command is intended for use only by REXX/CICS server execs (for example, exec defined by DEFCMD or DEFSCMD).

DEFCMD

DEFCMD defines (or redefines) REXX user commands.

Operands

etarget

is the 1 to 8 character name of the external target environment you used in a REXX exec issuing this command. This is the external environment name that you directed the command string to. This environment name is looked up in a table and together with the command name determines which REXX program the command string is directed to for processing.

Note: The external target can match the environment name on the ADDRESS keyword instruction or, if REXXCICS is the current environment (the default condition), can be specified as the first token of the command string.

ecmdnm

is the first command name token that you used issuing this command. This is the first word of the command name as it is known to you. If a special value of asterisk (*) is specified (as part of this definition), then all commands that you issued with an environment name of *etarget* and that are not more explicitly defined elsewhere, are covered by this command definition. Command names may be up to 16 characters long.

itarget

specifies an internal environment name that this command definition passes to the agent that processes the command string. This is needed so that the external environment names known to you can be redefined without breakage of the agents that process these commands. If the internal and external names are identical, then there is no need for you to specify the internal name. A special value of "=" indicates that *itarget* is the same as *etarget*.

icmdnm

is the first word of the internal command name. This is the first part of the command name that is passed to the REXX command agent to specify what command is processed. This is specified only if it is different from *ecmdnm*. A special value of "=" indicates that *icmdnm* is the same as *ecmdnm*.

pgmname

specifies the CICS program that is called by an EXEC CICS LINK to process the command.

CICS_loadmod

specifies the name of the CICS program called because the CICSLOAD option was specified.

Note: The program is loaded only on the first instance of a command and its address is remembered for subsequent commands.

execname

specifies the exec called as a REXX command server processing this command (or commands). If this server exec is already running, this command is routed to the executing server. If a REXX server by this name is not running, Automatic Server Initiation (ASI) is used to start the server automatically. The *execname* can be either a file name (where the file type defaults to EXEC) or it can be in the form *filename.filetype*.

CICSLINK

is a keyword indicating that the processing agent for the defined REXX command is a standard CICS program that is called by an EXEC CICS LINK.

CICSLOAD

is a keyword indicating that the processing agent is a CICS program that is loaded by an EXEC CICSLOAD.

REXX

is a keyword indicating that the processing agent for this REXX command is a REXX exec that operates as a command server.

AUTH

This is an authorized option.

This is a keyword indicating that this is an authorized REXX/CICS command. It is a command that can be executed only by an authorized REXX/CICS user (specified on AUTHUSER command) or from within an exec loaded from an authorized library.

CLEAR

is a keyword indicating that the purpose of this DEFCMD is to clear any previous definitions for the specified external target environment and command names.

Return codes

0

Normal return

1001

Invalid command

1021

Cannot load program

1023

Entry not found

1048

No client available

1099

Internal error

Example

```
'DEFCMD CICS SEND = = SENDPGM (CICSLINK'
```

This example defines a command called SEND for this user only. The user can issue this command, under the default command environment of REXXCICS, by entering:

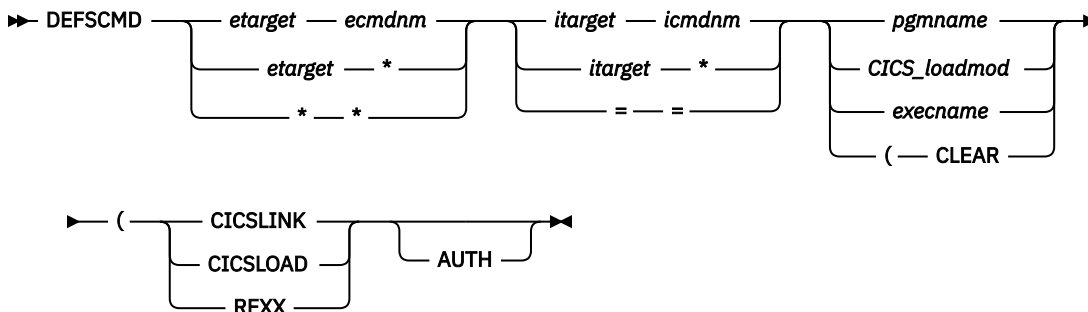

```
'CICS SEND arg1 arg2 ... argn'
```

This example shows program SENDPGM being called by an EXEC CICS LINK command to process this command.

Note:

1. When the REXX/CICS environment name is REXXCICS (which is the default when all execs or macros are called), the first token of the command string is the environment name that could have been used with an ADDRESS environment REXX instruction. This provides a more integrated command environment and removes the need for constant environment switching by ADDRESS instructions.
2. The calling and parameter passing sequences for command programs receiving control by an EXEC CICS LINK and an Assembler BASSM instruction (the CICSLOAD option) are similar. Refer to [Chapter 26, "REXX/CICS Command Definition,"](#) on page 309 for more information on writing command programs.
3. You can use DEFCMD to tailor a user's command set dynamically on a user by user, or application by application basis. DEFCMD commands can be placed in the user's PROFILE EXEC or in application execs. DEFCMD can also be used to override system command definitions.
4. DEFCMD REXXCICS * is not allowed.
5. User command definitions are searched before system command definitions (except for DEFCMD, which cannot be overridden).
6. REXX commands can be written in REXX. These REXX commands in turn call other REXX commands which are written in REXX, in a building block fashion. Since DEFCMD hides the implementation detail from the REXX user (programmer), a command can be quickly written in REXX and later transparently rewritten in another language, if it becomes performance critical.

DEFSCMD defines (or redefines) REXX system commands.

etarget

Note: The external target can match the environment name on the ADDRESS keyword instruction or can be specified as the first token of the command string, if REXXCICS is the current environment (which is the default).

is the first command name token that you used issuing this command. This is the first word of the command name as it is known to you. If a special value of asterisk (*) is specified (as part of this definition), then all commands that you issued with an environment name of *etarget* and that are not more explicitly defined elsewhere, are covered by this command definition.

specifies an internal environment name that this command definition passes to the agent that processes the command string. This is needed so that the external environment names known to you can be redefined without breakage of the agents that process these commands. If the internal

and external names are identical, then there is no need for you to specify the internal name. A special value of "=" indicates that *itarget* is the same as *etarget*.

icmdnm

is the first word of the internal command name. This is the first part of the command name that is passed to the REXX command agent to specify what command is processed. This is specified only if it is different from *ecmdnm*. A special value of "=" indicates that *icmdnm* is the same as *ecmdnm*.

pgmname

specifies the CICS program that is called by an EXEC CICS LINK to process the command.

CICS_loadmod

specifies the name of the CICS program called because the CICSLOAD option was specified.

Note: The program is only loaded on the first instance of a command and its address is remembered for subsequent commands.

execname

specifies the exec called as a REXX command server processing this command (or commands). If this server exec is already running then this command is routed to the executing server. If a REXX server by this name is not running, then Automatic Server Initiation (ASI) is used to start the server automatically. The *execname* can be either a file name (where the file type defaults to EXEC) or in the form *filename.filetype*.

CICSLINK

is a keyword indicating that the processing agent for the defined REXX command is a standard CICS program that is called by an EXEC CICS LINK.

CICSLOAD

is a keyword indicating that the processing agent is a CICS program that is loaded by an EXEC CICSLOAD.

REXX

is a keyword indicating that the processing agent for this REXX command is a REXX exec that operates as a command server.

AUTH

is a keyword indicating that this is an authorized REXX/CICS command. It is a command that can be executed only by an authorized REXX/CICS user (specified on AUTHUSER command) or from within an exec loaded from an authorized library.

CLEAR

is a keyword indicating that the purpose of this DEFSCMD is to clear any previous definitions for the specified external target environment and command names.

Return codes

0

Normal return

1101

Invalid command

1121

Cannot load program

1123

Entry not found

1148

No client available

1199

Internal error

Example

```
'DEFSCMD CICS SEND = = SENDPGM (CICSLINK'
```

This example defines a command called SEND for this user only. The user can issue this command, under the default command environment of REXXCICS, by entering:

```
'CICS SEND arg1 arg2 ... argn'
```

This example shows program SENDPGM being called by an EXEC CICS LINK command to process this command.

Note:

1. When the REXX/CICS environment name is REXXCICS (which is the default when all execs or macros are called), then the first token of the command string is the environment name that could have been used with an ADDRESS environment REXX instruction. This provides a more integrated command environment and removes the need for constant environment switching by ADDRESS instructions.
2. The calling and parameter passing sequences for command programs receiving control by an EXEC CICS LINK and an Assembler BASSM instruction (the CICSLOAD option) are similar. Refer to [Chapter 26, “REXX/CICS Command Definition,” on page 309](#) for more information on writing command programs.
3. If the first two operands of DEFSCMD are all asterisks (* *), this is a catch-all definition that specifies a command processing agent issued for REXX commands that are not under the scope (do not match) of any more specific command definitions.
4. User command definitions are searched before system command definitions (except for DEFSCMD, which cannot be overridden).
5. REXX commands can be written in REXX. These REXX commands in turn call other REXX commands which are written in REXX, in a building block fashion. Since DEFSCMD hides the implementation detail from the REXX user (programmer), a command can be quickly written in REXX and later transparently rewritten in another language, if it becomes performance critical.

DEFTRNID

DEFTRNID is a region-wide authorized command that can be used to define the name of an exec to be invoked for a particular CICS transaction identifier.

This is an authorized command.

➔ DEFTRNID — *trnid* — *execname* — CLEAR ➔

Operands

trnid

Specifies a one to four character CICS transaction ID.

execname

Specifies a 1 to 17 character REXX/CICS exec name, in the form: *filename.filetype* if it is in the REXX File System. If the exec exists in an MVS partitioned data set, it is a one to eight character name.

CLEAR

Is a keyword indicating that the definition be removed for this transaction ID.

Return codes

0

Normal return

1202

Invalid operand

1222

Invalid option

1223

Error storing trantable information

1225

Error retrieving trantable information

1226

Exec name length error

1228

Error setting trantable value

1233

Transaction not found in table

Example

Define a new CICS transaction ID named XYZ, make it call exec TESTEXEC when it is started, and then complete the following steps:

1. Create TESTEXEC in the dataset allocated or concatenated to ddname CICUSER.
2. Under the REXX/CICS REXXTRY utility, enter the command DEFTRNID XYZ TESTEXEC and exit the REXXTRY utility.
3. Under RDO, for the REXX Development System for CICS, enter:

```
CEDA DEFINE TRAN(XYZ) PROGRAM(CICREXD) GROUP(CICREXX)
```

For the REXX Runtime Facility for CICS, enter:

```
CEDA DEFINE TRAN(XYZ) PROGRAM(CICREXR) GROUP(CICREXX)
```

Then enter:

```
CEDA INSTALL TRAN(XYZ) GROUP(CICREXX)
```

4. Clear the screen, type CICS transaction identifier XYZ, and press Enter. The TESTEXEC exec should now run.

Note:

1. DEFTRNID definitions should usually be placed in the **CICSTART** exec that executes at REXX/CICS startup.
2. The transaction ID must be defined to invoke the supplied CICREXD or CICREXR program. See step “3” on page 382 in the example.

DIR

DIR displays the current directory contents or optionally returns the directory contents in a REXX compound variable.

Operands

dirid

specifies the partial or full REXX File System directory that is displayed. If you omit this, then the current directory is displayed.

stem.

specifies the name of a stem. A stem must end in a period; see “Stems” on page 153. Stem.0 contains the number of elements in the entry. If you omit this, the contents are displayed on the screen.

Return codes

0

Normal return

321

Cannot access current RFS directory information

322

Invalid stem name

325

Error retrieving RFS directory

Example

```
'DIR \USERS\USER2 (X.'
```

This example places the directory contents of \USERS\USER2 into the REXX compound variable X.1 through X.n. X.0 contains the number of elements returned.

Note: The current directory is specified by the CD command.

EDIT

EDIT opens a new edit session.

Operands

NONAME

a file ID is not specified. This is the default.

fileid

is the file ID of the file you are editing.

PDS_name(mem)

specifies a fully qualified MVS PDS name and member name.

PDS

is a keyword that follows the PDS member name when a PDS is being edited.

MACRO

is a keyword specifying a group of instructions applied to the file being edited.

macroname

is the file name portion of the profile macro file ID (REXX exec name).

Return codes

0

Normal return

201

Invalid command

211

Invalid file ID

226

File is currently being edited

299

Internal error

Example

```
'CD \USERS\USER2\' /* specify current working directory */  
'EDIT TEST.EXEC' /* edit an existing file in the PATH */  
/* or create new file in current dir */
```

This example edits member TEST.EXEC in directory \USERS\USER2.

Refer to [Chapter 23, “REXX/CICS text editor,” on page 255](#) for more information about the REXX/CICS editor.

EXEC

EXEC calls a REXX exec at a lower level (as a nested exec). All variables for this new exec are kept separate from the higher level exec, which is suspended until the nested exec ends.

➤ EXEC — *execid* — *args* ➤

Operands

execid

is the 1 to 17 character identifier of the exec in the format *name.modifier*, where *name* and *modifier* are each up to 8 characters. If you do not specify *modifier*, EXEC is assumed.

args

is the argument string for the called exec.

Return codes

n

A return code that is set by the exit of the called exec. See [“EXIT” on page 170](#).

0

Normal return

-3

Exec not found

-10

Exec name not specified

-11

Invalid exec name

-12

GETMAIN error

-99

Internal error

Example

```
'EXEC ABC'
```

This example executes exec ABC.EXEC.

EXECDROP

EXECDROP removes an exec from virtual storage that was previously loaded by using the EXECLOAD command.

This is an authorized command.

Operands

ddn

specifies the ddname that is read.

member

specifies the member of the partitioned dataset that is used.

name

specifies a fully qualified RFS file name or the fully qualified PDS name and member.

MEM

indicates that a ddname and member name has been specified.

RFS

indicates that an RFS file has been specified.

PDS

indicates that a partitioned dataset name and member has been specified.

Return codes

0

Normal return

1401

Invalid command

1402

Invalid operand

1423

Error storing EXECLOAD information

1425

Error retrieving EXECLOAD information

1448

No client available

Example

```
'EXECDROP P00L1:\USERS\USER2\TEST.EXEC (RFS'
```

This example removes RFS file from virtual storage.

Note: If a partial directory ID is given, it is temporarily appended to the end of the current working directory value to get a fully qualified directory ID.

EXECIO

EXECIO performs file input or output to a CICS temporary storage queue.

Operands

lines

specifies the number of lines to read or write. An asterisk (*) is a special case that is specified for READ operations only, and indicates that the file is read from the target line (or line 1 if no target line is specified) to the end of the file.

READ

reads one or more records from a CICS temporary storage queue (TSQ).

WRITE

writes (or re-writes) one or more records to a CICS temporary storage queue.

tsqname

specifies a 1 to 8 character temporary storage queue name.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#).

varname

specifies a REXX variable name that is the source or target for this EXECIO operation.

recno

specifies a record number in the temporary storage queue that READ or WRITE begins with.

reclen

specifies the length of the record written to CICS temporary storage. If *reclen* is omitted, the length defaults to 80 bytes.

Return codes

n

The return code that is passed back by CICS if an error is detected

0

Normal return

-202

Invalid operand

-221

Too many operands specified

-222

Recno operand out of range

-224

Lines operand invalid

Example

```
x.1 = 'line 1'  
x.2 = 'Line Two'  
'EXECIO 2 WRITE QUEUE1 X.'
```

This example writes data to a CICS temporary storage queue.

```
'EXECIO 2 READ QUEUE1 Y.'  
say y.0 /* ==> 2 */  
say y.1 /* ==> 'line 1' */  
say y.2 /* ==> 'Line Two' */
```

This example reads data from a temporary storage queue.

Note:

1. The maximum record length allowed is 256 bytes.
2. If a *stem* is specified for a READ operation (and a *stem* should be specified if more than one record is read), the actual number of records read is placed into stem.0.
3. Use the CICS-supplied CEBR transaction to browse temporary storage queues. For example, enter: CEBR QUEUE1 to look at the queue created in the example.
4. CEBR provides PUT and GET functions that you can use to copy between CICS transient data queues and CICS temporary storage queues.

EXECLOAD

EXECLOAD loads an exec into virtual storage.

This is an authorized command.

Operands

ddn

specifies the ddname that is read.

member

specifies the member of the partitioned dataset that is used.

name

specifies a fully qualified RFS file name or the fully qualified PDS name and member.

MEM

indicates that a ddname and member name has been specified.

RFS

indicates that an RFS file has been specified.

PDS

indicates that a partitioned dataset name and member has been specified.

Return codes

0

Normal return

1501

Invalid command

1502

Invalid operand

1523

Error storing EXECLOAD information

1525

Error retrieving EXECLOAD information

1530

Unable to link to CICPDS routine

1531

Error returned from CICPDS routine

1532

Error returned from RFS READ

1532

Error returned from PDS build

1547

GETMAIN error

1548

No client available

1599

Internal error

Example

```
'EXECLOAD POOL1:\USERS\USER2\TEST.EXEC (RFS'
```

This example loads the exec TEST.EXEC from RFS into virtual storage. Subsequent calls of TEXT.EXEC will use the loaded copy.

Note:

1. If an exec is loaded into virtual storage, it is automatically shared by all users.
2. If an EXECLOAD is performed to replace an in-storage exec with a newer copy, a shadow of previous copies is kept in virtual storage until all active execs based on these copies end. This is accomplished by a use count.
3. Execs that are loaded into virtual storage are always used before other execs. Name your programs carefully because, if two execs have the same name and one resides in your RFS current directory and one is loaded into virtual storage, you cannot run your RFS copy.
4. When an exec is loaded into virtual storage, the copy of the exec inherits security characteristics from where it was loaded. For example, any user can run an exec from a CICEXEC data set and any exec loaded from CICEXEC can use REXX/CICS authorized commands. See [Modify the CICS initialization JCL](#).

EXECMAP

EXECMAP returns the ddnames and members, the number of users, the descriptor table start (in hex), and the amount of storage required of the execs that were loaded by using EXECLOAD.

➤ EXECMAP ➤

Return codes**0**

Normal return

1623

EXECLOAD directory not found

Example

```
'EXECMAP'
```

If the exec POOL1:\USERS\USER1\TEST.EXEC was previously loaded by using EXECLOAD, the resulting display is as follows.

EXEC name	Use	Location	Size	Fully Qualified Name
TEST.EXEC	0	09369083	287	POOL1:\USERS\USER1\TEST.EXEC

EXPORT

EXPORT exports an RFS file to an MVS dataset.

➤ EXPORT — *rfs_fileid* — *dsn* ➤

Operands

dsn

specifies a fully qualified (without quotes) MVS physical sequential or partitioned organization dataset name. If the dataset is partitioned (DSORG=PO), the member name must be provided in parenthesis.

rfs_fileid

specifies a fully qualified REXX File System file ID.

Return codes

0

Normal return

1701

Invalid command

1702

Invalid operand

1723

RFS write error

1724

RFS read error

1725

Dynamic allocation failed

1726

Dynamic free failed

1727

Transient data queue open failed

1728

Member not enqueued

1729

Member in use

1730

Records truncated

1733

Input for export not found

- 1735**
Transient data error
- 1736**
Unexpected CICS error.
- 1737**
Invalid request
- 1738**
Invalid dataset name
- 1739**
Invalid disposition
- 1741**
Unsupported DSORG
- 1742**
Error building transient data pool
- 1743**
REXX transient data queue not available/found
- 1744**
User not signed on/authorized for dataset access
- 1745**
Empty dataset
- 1746**
REXX queue not found
- 1748**
No entry for ddname in Task Input/Output Table (TIOT)
- 1749**
Cannot export to multi unit dataset
- 1750**
ddname has more than one dataset in concatenation
- 1799**
Internal error

Example

```
'EXPORT POOL1:\USERS\USER1\TEST.DATA USER1.TEST.DATA'
```

This example copies POOL1:\USERS\USER1\TEST.DATA from an RFS file to an MVS sequential dataset.

Note:

1. This command performs an SVC 99 and therefore is not recommended for frequent use because performance concerns.
2. The REXX/CICS-supplied CICSECX1 security exit is invoked to verify that your CICS sign-on user ID is authorized to access the specified MVS dataset. By default, the high level prefix of the dataset name must match your CICS sign on user ID. The CICS region must also have authorization to access the specified MVS dataset (for example, by RACF if external security is enabled).
3. The MVS dataset is allocated DISP=OLD.
4. The MVS data specified in dsn must already be allocated. If the dataset is sequential, it is replaced by the contents of the RFS file specified in rfs_fileid. If the dataset is partitioned and the member name specified already exists, it is replaced by the contents of the RFS file.
5. If you export to an MVS dataset that is defined to the CICS region, the disposition of the dataset will be changed to OLD until the CICS region is recycled.

FILEPOOL

FILEPOOL performs RFS file pool administration activities.

This is an authorized command.

Operands

DEFINE

defines a new RFS file pool.

poolid

specifies the name of the target file pool.

dirid

specifies the CICS file identifier of the file pool directory.

fileid

specifies the CICS file identifier of the VSAM file for the file pool.

USER

is an optional keyword indicating that this is a user file pool, and you automatically have a \USERS directory created, so that multiple users share this file pool, using RFS security (as compared to CICS security) to control access to directories.

FORMAT

formats the first file in a new RFS file pool.

ADD

adds an additional VSAM file to an existing file pool.

Return codes

0

Normal return

1802

Invalid operand

1821

Invalid file pool subcommand

1822

File pool subcommand not specified

1823

Error storing file pool information

1824

File pool ID not specified

1825

Error retrieving file pool information

1826

Invalid file pool ID

1827

Invalid file pool data retrieved

1828

File pool not defined

1829

RFS could not add library to file pool

1830

RFS could not create users directory

1831

DDNAME for file pool must be specified

1832

Invalid DDNAME

1833

File pool variable corrupted

1834

Pool ID already exists

1835

DDNAME already used

1836

Could not format file pool

1837

File pool needs to be formatted first

1838

File pool ADD record is full

1839

File ID is not found

Example

```
'FILEPOOL DEFINE POOL1 REXXDIR1 REXXLIB1 (USER'
```

This example defines file pool POOL1 and tells RFS the CICS file definition to use is REXXLIB1. It also indicates to the FILEPOOL FORMAT command to issue an RFS MKDIR to build the \USERS directory.

Note: This is an authorized command, performed by a REXX/CICS administrator or systems programmer.

FLST

FLST calls the file list utility to work with the files.

**Operands*****dirid***

specifies an optional full or partial directory ID that a file list is displayed. If you do not specify *dirid*, it defaults to the current working directory.

Return codes

FLST returns the return code given by RFS.

Example

```
'FLST'
```

This example displays the file list for the member of the current working directory.

Note:

1. The default user profile macro that the FLST tries to call is EXEC ID FLSTPROF. The FLSTPROF macro provides the capability for you (or a group of users) to specify your own unique defaults.
2. Refer to [Chapter 24, “REXX/CICS File System,” on page 285](#) for more information about the REXX File System.

FREE

FREE unallocates a data definition name.

►► FREE — DDNAME — *ddname* ►◄

Operands

DDNAME

is a keyword indicating free is by *ddname*.

ddname

specifies the data definition name.

Return codes

The return code given by SVC 99

For more information, see [z/OS MVS Programming: Authorized Assembler Services Guide](#).

1702

Invalid operand

Example

```
'ALLOC USER1A USER1.REXX(TEST)'  
'FREE DDNAME USER1A'
```

This example allocates the member TEST of dataset USER1.REXX into the *ddname* USER1A and then frees the *ddname* USER1A for use with another dataset.

GETVERS

GETVERS retrieves the current REXX/CICS, program name, version, and compile time information, and places it into the REXX variable VERSION.

►► GETVERS ►◄

The returned information is in the form: *pgmname* VxRyMmmmm dd/mm/yyyy hh:mm, where:

pgmname

Specifies CICREXD for the REXX/CICS Development System or CICREXR for the REXX/CICS Runtime Facility.

x

Specifies the REXX/CICS Version number.

y

Specifies the REXX/CICS Release number.

dd/mm/yyyy

Specifies the compilation date for the REXX/CICS base program.

hh.mm

Specifies the compilation time for the REXX/CICS base program.

Return codes

0

Normal return

1910

Request failed

Example

```
'GETVERS'
```

This example retrieves the current REXX/CICS version and compile time information and places it into the REXX variable VERSION. Its format could look like: CICREXR V1R1M0000 14/12/2018 12:00.

HELP

HELP browses or searches this product information online.

➤ HELP ————— ➤
 └─ *search_term* ─┘

Operands

search_term

specifies the string you want located.

Return codes

n

The return code that is passed by from internal RFS or PANEL commands

0

Normal return

IMPORT

IMPORT imports an MVS sequential dataset or partitioned dataset member into an RFS file.

➤ IMPORT — *dsn* — *rfs_fileid* ➤

Operands

dsn

specifies a fully qualified (without quotes) MVS physical sequential or partitioned organization dataset name. If the dataset is partitioned (DSORG=PO), the member name must be provided in parentheses.

rfs_fileid

specifies a fully qualified REXX File System file ID.

Return codes

0

Normal return

1701

Invalid command

1702

Invalid operand

1723

RFS write error

1724

RFS read error

1725

Dynamic allocation failed

1726

Dynamic free failed

1727

Transient data queue open failed

1728

Member not enqueued

1729

Member in use

1730

Records truncated

1733

Input for export not found

1735

Transient data error

1736

Unexpected CICS error.

1737

Invalid request

1738

Invalid dataset name

1739

Invalid disposition

1741

Unsupported DSORG

1742

Error building transient data pool

1743

REXX transient data queue not available/found

1744

User not signed on/authorized for dataset access

1745

Empty dataset

1746

REXX queue not found

1799

Internal error

Example

```
'IMPORT USER1.TEST.DATA POOL1:\USERS\USER1\TEST.DATA'
```

This example copies USER1.TEST.DATA from an MVS sequential dataset to an RFS file POOL1:\USERS\USER1\TEST.DATA.

Note:

1. This command performs an SVC 99 and therefore is not recommended for frequent use because of performance concerns.
2. The REXX/CICS-supplied CICSECX1 security exit is invoked to verify that your CICS sign-on user ID is authorized to access the specified MVS dataset. By default, the high level prefix of the dataset name must match your CICS sign on user ID. The CICS region must also have authorization to access the specified MVS dataset (for example, by RACF if external security is enabled).
3. The MVS dataset is allocated with DISP=SHR.
4. If the RFS file specified in *rfs_fileid* already exists, it is replaced by the contents of the MVS dataset.

LISTCMD

LISTCMD lists REXX command definition information (previously specified by DEFCMD).

➤ LISTCMD 

Operands

envname

specifies the name of the command environment defined using DEFCMD or DEFSCMD.

cmdname

specifies the name of a command specified in DEFCMD or DEFSCMD.

Return codes

0

Normal return

821

Invalid environment name

822

Invalid command name

Example

```
'LISTCMD EDITSVR MYCMD'
```

This example returns the information defined in DEFCMD for the subcommand MYCMD.

LISTPOOL

LISTPOOL displays RFS file pool information to the terminal or to a specified stem array, if a stem has been specified.

➤ LISTPOOL 

Operands

stem.

specifies the name of a stem. A stem must end in a period; see “Stems” on page 153. Three columns of information are returned:

- the pool ID
- the ddname of the first file in the file pool
- whether or not it contains a user's directory.

Return codes

0

Normal return

2225

Error retrieving file pool information

2226

Invalid stem variable name

Example

```
'LISTPOOL LST.'
```

This example places information about the RFS file pools into REXX compound variable LST.1 through LST.n. LST.0 contains the number of elements returned.

Note: This is a general user command that displays all defined RFS file pools.

LISTTRNID

LISTTRNID lists the current transaction ID definitions created by the **DEFTRNID** command.

This is an authorized command.

➤ LISTTRNID ➤

Return codes

0

Normal return

2325

Error retrieving trantable information

Example

```
'LISTTRNID'
```

The **CICSTART** exec defines the default transactions and their EXEC names. The resulting display is:

TRNID	EXEC name
REXX	CICRXTRY
EDIT	CICEDIT
FLST	CICFLST
*SIB	CICOVSIB
End of Transaction table list.	

PATH

PATH defines the search path for REXX execs.

Note: The SET command (without parameters) is used to retrieve the current path setting.

Operands

dirid

specifies one or more fully qualified REXX File System directories that are searched when you are attempting to locate an exec to be executed.

A full RFS directory ID starts with a pool ID and is in the form: P00L1:*dirid1*\...\i>diridn

When more than one directory ID is specified, a blank is used to separate them.

pdsid

specifies one or more MVS partitioned dataset names.

Return codes

0

Normal return

625

Error retrieving path information

626

Invalid RFS directory name

627

Invalid PDS name

628

Error setting RESULT value

629

Invalid dataset name

630

Error storing path information

631

No path currently defined

632

Resulting PATH contains no RFS directories or PDS names

Examples

```
'PATH P00L1:\USERS\USER2 P00L2:\USERS\USER2\PROJECT1'
```

This example shows that the directories in this list are searched in the order specified (from left to right).

```
'PATH MYUSERID.REXX1.EXECS MYUSERID.REXX2.EXECS'
```

This example shows you that the search is started with the first partitioned dataset.

Note:

1. The *dirids* and *pdsids* can be mixed in a single PATH statement.
2. You can create a very long PATH directory list by concatenating strings together into a variable, and then specifying this variable on the PATH command.
3. PATH command definitions are not carried across CICS restarts. To change a PATH definition permanently, insert a PATH command into your PROFILE exec in the base directory for your user ID.
4. The PATH command is not cumulative, that is, the last PATH command replaces the previous PATH definition.
5. If *dirid* or *pdsid* is not specified, the users current working path is retrieved and placed in the REXX special variable RESULT.
6. If you receive a non-zero return code, the contents of the RESULT special variable are unpredictable.

PSEUDO

PSEUDO turns the pseudo-conversational mode on or off.

Operands

ON

enables automatic pseudo-conversational support so that when one the following conditions is encountered in the current exec, instead of a conversational terminal read occurring immediately, an EXEC CICS RETURN TRANSID is used to suspend the exec until terminal input occurs, and then the terminal read occurs:

- REXX PULL instruction
- REXX/CICS WAITREAD command
- PANEL RECEIVE command
- screen is full and MORE appears in the lower right corner of the screen (implicit READ, waiting for screen to be cleared)

OFF

disables (turns off) automatic pseudo-conversational support.

Return codes

0

Normal return

2502

Invalid operand

2521

Operand not specified

Example

```
'PSEUDO ON'
```

This example turns the pseudo-conversational mode on.

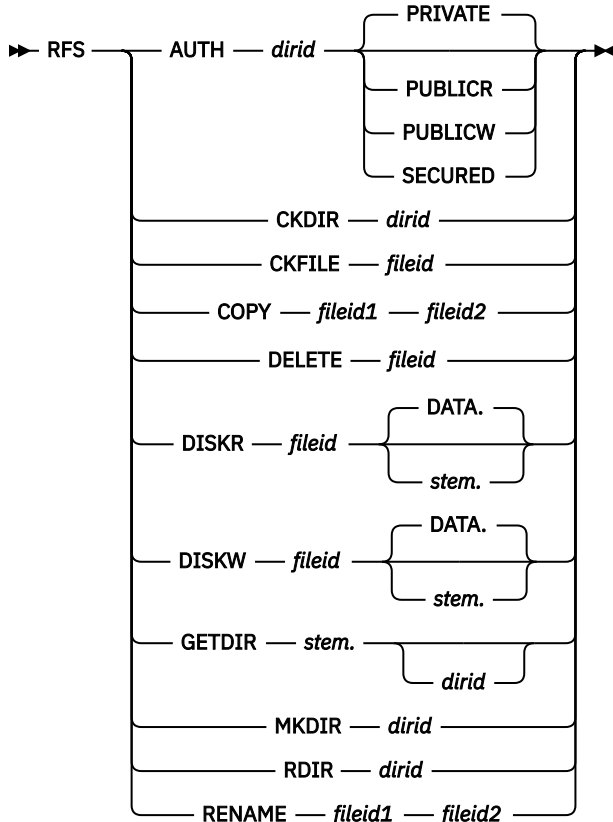

Note: The PSEUDO ON/OFF setting is temporary. The pseudo setting exists while the current exec is executing. Any nested execs inherit the current setting of PSEUDO. When the current exec ends, the value of pseudo upon entry to the exec will be restored. The SETSYS PSEUDO command defines the systems default setting of PSEUDO.

CAUTION: PSEUDO ON causes your REXX exec to immediately become pseudo-conversational, which will cause CICS to commit any file changes, and free any non-shared GETMAINed areas, at the next pseudo-conversational terminal read.

RFS

RFS performs file input/output to the REXX File System.

Operands

AUTH

is a command that authorizes access to RFS directories. The specified access applies to all files in this directory.

dirid

specifies a REXX File System directory identifier. This is partially or fully qualified. Refer to the CD command [“CD”](#) on page 353 for more information.

PRIVATE

specifies that only the owner of the directory has read/write access to the files. This is the default.

PUBLICR

specifies that any user has read-only access to the files in the directory.

PUBLICW

specifies that any user has read/write access to the files in the directory.

SECURED

specifies that RACF grants access to the files in the directory.

CKDIR

is a command that checks for an existing RFS directory level.

CKFILE

is a command that checks to see if the specified, partially or fully qualified, file ID exists.

fileid

specifies the file identifier.

COPY

is a command that copies a file, replacing any existing file.

fileid1

specifies the source file identifier. It can be a fully or partially qualified directory and file identifier.

fileid2

specifies the target file identifier. It can be a fully or partially qualified directory and file identifier.

DELETE

is a command that deletes an RFS directory level or RFS file.

fileid

specifies the source file identifier. It can be fully or partially qualified.

DISKR

is a command that reads records from an RFS file.

stem

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

DISKW

is a command that writes records to an RFS file.

GETDIR

is a command that returns a list of the contents of the current or specified directory into the specified REXX array.

MKDIR

is a command that creates a new RFS directory level.

RDIR

is a command that removes the specified RFS directory.

RENAME

is a command that renames an RFS file to a new name.

fileid1

specifies the source file identifier. It can be a fully or partially qualified directory and file identifier.

fileid2

specifies the source target file identifier. It can be a fully or partially qualified directory and file identifier.

Return codes**0**

Normal return

101

Invalid command

102

Invalid operand

103

File not found

104

Not authorized

105

File already exists

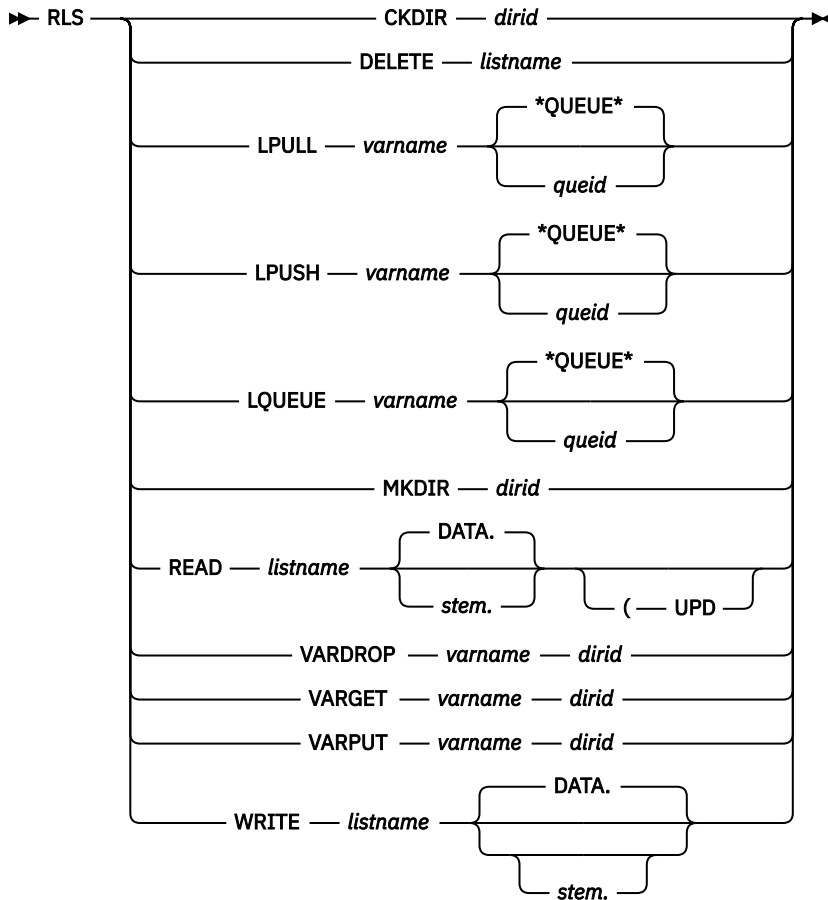

107

Insufficient space in file pool

- 110**
Request failed
- 111**
Invalid file ID
- 113**
Directory not found
- 115**
Directory already exists
- 116**
Directory not specified
- 121**
File corrupted
- 122**
Invalid or out of range stem.0
- 126**
Path error
- 127**
CICS I/O error
- 128**
Command not valid from this location
- 130**
Directory not empty
- 131**
Missing operand
- 132**
Missing file pool data record. File pool is probably not formatted.
- 199**
Internal error

Note: File access security checking is performed at the directory level, rather than the file level. If a specified file ID is not a fully qualified ID, the current directory or PATH directories are used in an attempt to resolve the partial name into a fully qualified name; in this case no further checking is necessary. If a fully qualified file ID is used, the directory it resides in is checked for proper access authorization, at file open time.

RLS performs list input/output to the REXX List System.

Operands

CKDIR

is a command that checks for an existing RLS directory level.

dirid

specifies a REXX List System directory level identifier. This is partially or fully qualified. Refer to the CLD command “CLD” on page 370 for more information.

DELETE

is a command that deletes an RLS directory level or RLS list.

listname

specifies a REXX List System list identifier. This is partially or fully qualified.

LPULL

is a command that pulls a record from the top of the queue.

varname

specifies a simple REXX variable name. It does not end in a period, distinguishing a variable name from a stem name.

QUEUE

specifies the special default name.

queid

is the identifier for a special type of RLS list accessed by LPULL, LPUSH, or LQUEUE.

LPUSH

is a command that pushes a record onto the top of the queue (LIFO).

LQUEUE

is a command that adds a record to the end of the queue (FIFO).

MKDIR

is a command that creates a new RLS directory level.

READ

is a command that reads records from an RLS list into a stem.

listname

specifies the list identifier.

stem.

specifies the name of a stem. A stem must end in a period; see [“Stems” on page 153](#). The default stem is DATA..

UPD

enqueues on a list for update.

VARDROP

is a keyword indicating that an RLS variable is deleted.

VARGET

is a command that takes an RLS variable and copies it into a REXX variable of the same name.

VARPUT

is a command that takes a REXX variable and copies it into an RLS variable of the same name.

WRITE

is a command that writes records to an RLS list from a stem.

Return codes**0**

Normal return

701

Invalid command

702

Invalid operand

713

Directory not found

715

Directory already exists

716

Directory not specified

723

List not found

726

SCRNINFO

SCRNINFO returns a two-digit decimal screen height (in lines) in the variable SCRNH_T, and returns a three-digit decimal screen width (in columns) in the variable SCRNW_D.

➡ SCRNINFO ➡

Return codes

- n***
The return code that is passed back by CICS if an error is detected
- 0**
Normal return
- 499**
Internal error

Example

```
'SCRNINFO'
```

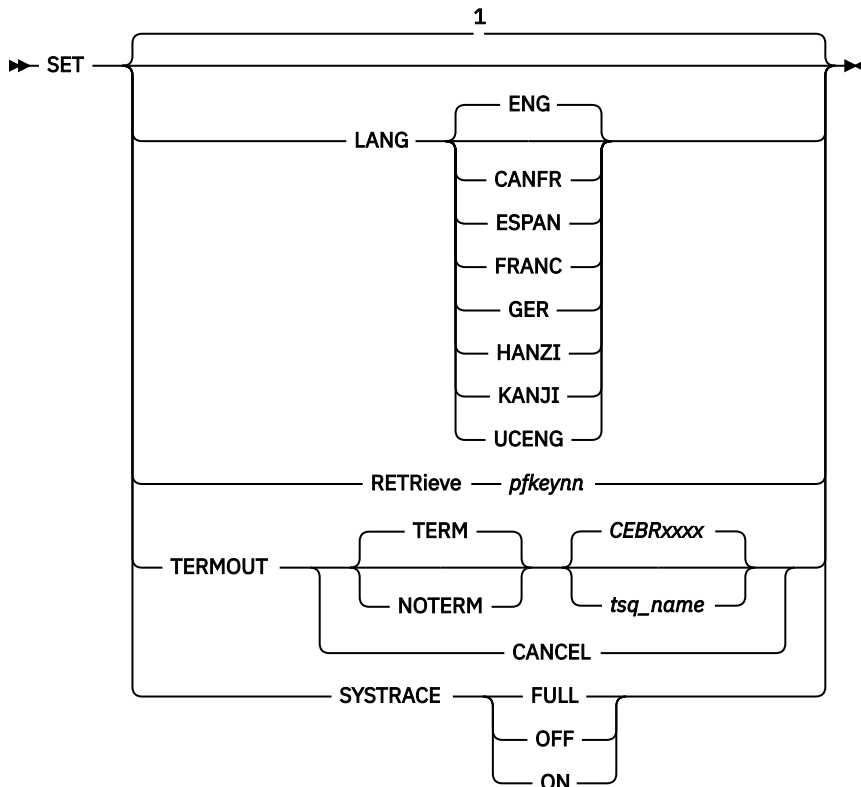

Note:

1. The screen information that is returned is obtained by doing an EXEC CICS ASSIGN SCRNH_T(*scrnht*) SCRNW_D(*scrnwd*).

2. The values for screen height and screen width is 0 if there is no terminal attached.

SET

SET sets the REXX/CICS processing options for the current user. It is advisable to place any SET commands that you require in your user profile exec.

Notes:

¹ If no parameters are passed to the SET command, SET creates a stem variable (SET.) that contains all of the processing options for the user that was created by the SET, SETSYS, or PATH commands.

Operands

LANG

specifies the language that the REXX runtime environment uses for messages and dates.
Multiple REXX/CICS users can use different languages at the same time in the same region.

ENG

English. This is the default.

CANFR

Canadian French

ESPAÑ

Spanish

FRANC

French

GER

German

HANZI

Traditional Chinese

KANJi

Kanji

UCENG

Uppercase English

RETRieve

specifies a PF key to retrieve the last line entered.

pfkeynn

specifies the PF key number.

TERMOUT

sends terminal line-mode output to a CICS temporary storage queue (for example, SAY and TRACE output) even when a terminal is attached.

CANCEL

specifies that line-mode output is not sent to a CICS temporary storage queue.

NOTERM

specifies that terminal line-mode output is not displayed on the terminal.

TERM

specifies that line-mode output is sent to the terminal.

tsq_name

specifies the CICS temporary storage queue name. The default *tsq_name* is CEBRxxxx where xxxx is your terminal ID. (If you enter the CEBR transaction without specifying a TSQ name, this is the default name that is used.)

SYSTRACE

specifies whether REXX/CICS system trace is on. Use this option only under the guidance of IBM service.

REXX/CICS system trace is emitted only if CICS user trace is also active.

FULL

specifies that basic REXX/CICS system trace (entry and return) and supplementary trace is on, in addition to exception trace.

OFF

specifies that REXX/CICS system trace is off. Only exception trace is on.

ON

specifies that basic REXX/CICS system trace is on, in addition to exception trace.

Return codes**0**

Normal return

421

Invalid SET subcommand

422

Error storing variable

423

Invalid language

426

Invalid or missing RETRIEVE PFkey operand

427

Invalid TERMOUT operand

428

Invalid or missing SYSTRACE operand

Example

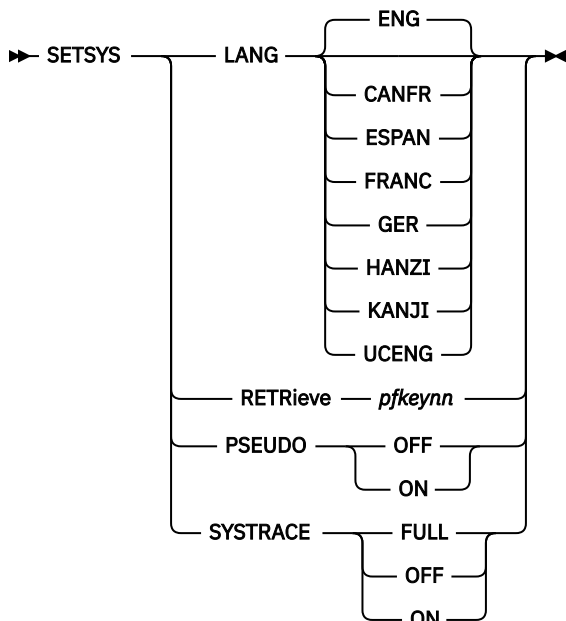

```
'SET TERMOUT TERM TSQ1'
```

This example sets the processing option to send terminal line-mode output to temporary storage queue TSQ1.

SETSYS

SETSYS sets the REXX/CICS processing options for the system. It is advisable to place system-wide **SETSYS** commands in the **CICSTART** exec.

This is an authorized command.

Operands

LANG

Specifies the language that the REXX runtime environment uses for messages and dates.

ENG

English. This is the default.

CANFR

Canadian French

ESPAÑ

Spanish

FRANC

French

GER

German

HANZI

Traditional Chinese

KANJI

Kanji

UCENG

Uppercase English

RETRieve

Specifies a PF key to retrieve the last line entered.

pfkeynn

Specifies the PF key number.

PSEUDO

Specifies the default region-wide REXX/CICS automatic pseudo-conversational setting. See [“PSEUDO” on page 399](#).

If this option has not been set before, the automatic pseudo-conversational setting is on.

OFF

Specifies that the automatic pseudo-conversational setting is off.

ON

Specifies that the automatic pseudo-conversational setting is on.

SYSTRACE

Specifies whether REXX/CICS system trace is on. Use this option only under the guidance of IBM service.

REXX/CICS system trace is emitted only if CICS user trace is also active. If this option has not been set before, REXX/CICS system trace is off.

FULL

Specifies that basic REXX/CICS system trace (entry and return) and supplementary trace is on, in addition to exception trace.

OFF

Specifies that REXX/CICS system trace is off. Only exception trace is on.

ON

Specifies that basic REXX/CICS system trace is on, in addition to exception trace.

Return codes

0

Normal return

2721

Invalid SETSYS subcommand

2722

Error storing variable

2723

Invalid language

2726

Invalid or missing RETRIEVE PFkey operand

2728

Invalid or missing SYSTRACE operand

2732

Invalid or missing PSEUDO operand

Example

```
'SETSYS RETRIEVE 12'
```

This example sets PF key 12 as the retrieve key.

```
SETSYS SYSTRACE ON
```

This example sets basic REXX/CICS system trace on for all users.

S2C

S2C copies a server REXX variable to a client REXX variable.

Operands

server_rexx_varname

is the name of the server REXX variable copying from.

client_rexx_varname

is the optional name of the client REXX variable copying into. If you do not specify, it defaults to the same as the *server_rexx_varname*.

Return codes

0

Normal return

2840

No variable name specified

2841

Error retrieving variable

2842

Error storing variable

2848

No client available

Example

```
'S2C VARA VARB'
```

This example shows the contents of the server REXX variable VARA copying into the client REXX variable VARB. The length of VARB is the same as the length of VARA.

Note:

1. The maximum allowed length for a *varname* for this command is 250 characters. If a longer name is specified, only the first 250 characters are used.
2. The maximum length of a variable copied by S2C is 6000 bytes.
3. You can use the S2C command from only a server exec.

TERMID

TERMID returns the four-character CICS terminal ID from the CICS field EIBTRMID in the variable TERMID.

```
➡ TERMID ➡
```

Return codes

0

Normal return

2921

Error in obtaining terminal ID

2928

Error setting TERMID value

Example

```
'TERMID'
```

This example places the CICS terminal ID from the CICS field EIBTRMID in the variable TERMID.

WAITREAD

WAITREAD performs full screen terminal input and places the results into the compound variable.

➤ WAITREAD ➤

The results in the compound variable are as follows:P

WAITREAD.0

contains the number of elements returned.

WAITREAD.1

contains the AID description.

WAITREAD.2

contains the cursor position.

WAITREAD.3 through WAITREAD.n

contains the remaining 3270 fields that have been modified.

Return codes

0

Normal return

3021

No terminal is attached

3099

Internal error

Example

```
'WAITREAD'
```

This example reads input from the terminal screen and places the results in the REXX compound variable WAITREAD.1 through WAITREAD.n.

Note: A read modified is performed to the terminal and an array is returned with information from this read. The format of these elements is: *field_row field_column data*

WAITREQ

WAITREQ is used only in REXX servers, causing the server to wait for a request. After a request is received, it is placed into REXX variable REQUEST.

➤ WAITREQ ➤

Return codes

0

Normal return

3121

WAITREQ not enabled

3122

Exec not a server

3123

Error saving request variable

3199

Internal error

The return code reflected to the client program is the value of the REXX server variable at entry to the WAITREQ command, or at exit of the server exec.

Example

```
'WAITREQ'
```

This example causes the server exec to be suspended until another request for the server is encountered. When the request is encountered, the server exec is restored to its presuspended status with a new request value.

Chapter 31. Error numbers and messages

Error codes and their associated CICS messages are listed.

External interfaces to the language processor can generate three error messages either before the language processor gains control, or after control has left the language processor. Therefore, SIGNAL ON SYNTAX cannot trap the following errors:

- 3 and 5 (if the initial requirements for storage could not be met)
- 26 (if on exit the returned string could not be converted to form a valid return code)

Error 4 can be trapped only by SIGNAL ON HALT or CALL ON HALT.

The following five errors that the language processor detects cannot be trapped by SIGNAL ON SYNTAX unless the label SYNTAX appears earlier in the program than the clause with the error:

- 6
- 12
- 13
- 22
- 30

Table 5. Error Codes and CICS Messages

Error code	CICS message	Error code	CICS message
No number	CICREX255T	Error 26	CICREX466E
Error 3	CICREX451E	Error 27	CICREX467E
Error 4	CICREX452E	Error 28	CICREX486E
Error 5	CICREX450E	Error 29	CICREX487E
Error 6	CICREX453E	Error 30	CICREX468E
Error 7	CICREX454E	Error 31	CICREX469E
Error 8	CICREX455E	Error 32	CICREX492E
Error 9	CICREX456E	Error 33	CICREX488E
Error 10	CICREX457E	Error 34	CICREX470E
Error 11	CICREX458E	Error 35	CICREX471E
Error 12	CICREX459E	Error 36	CICREX472E
Error 13	CICREX460E	Error 37	CICREX473E
Error 14	CICREX461E	Error 38	CICREX489E
Error 15	CICREX462E	Error 39	CICREX474E
Error 16	CICREX463E	Error 40	CICREX475E
Error 17	CICREX465E	Error 41	CICREX476E
Error 18	CICREX491E	Error 42	CICREX477E
Error 19	CICREX482E	Error 43	CICREX478E
Error 20	CICREX483E	Error 44	CICREX479E
Error 21	CICREX464E	Error 45	CICREX480E

Table 5. Error Codes and CICS Messages (continued)

Error code	CICS message	Error code	CICS message
Error 22	CICREX449E	Error 46	CICREX218E
Error 23	CICREX1106E	Error 47	CICREX219E
Error 24	CICREX484E	Error 48	CICREX490E
Error 25	CICREX485E	Error 49	CICREX481E

In these messages, the term *language processor* refers to the REXX/CICS interpreter.

In addition to the error messages in the following section, the language processor issues the following terminal (unrecoverable) message “CICREX255T” on page 414.

CICREXnnn error messages

CICREX218E Error 46 Invalid variable reference

Explanation

Within an ARG, DROP, PARSE, PULL, or PROCEDURE instruction, the syntax of a variable reference (a variable whose value is to be used, indicated by its name being enclosed in parentheses) is incorrect. The right parenthesis that should immediately follow the variable name might be missing.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX219E Error 47 Unexpected label

Explanation

A label, being used incorrectly, was encountered in the expression being evaluated for an INTERPRET instruction or in an expression entered during interactive debug.

System action

Execution stops.

User response

Do not use a label in these expressions.

CICREX255T Insufficient storage for Exec interpreter

Explanation

There is insufficient storage for the language processor to initialize itself.

System action

Execution is terminated at the point of the error.

User response

Redefine storage and reissue the command.

CICREX449E Error 22 running *fn ft*, line *nn*: Invalid character string

Explanation

A character string scanned with OPTIONS ETMODE in effect contains one of the following:

- Unmatched shift-out (SO) and shift-in (SI) control characters
- An odd number of bytes between the shift-out (SO) and shift-in (SI) characters.

System action

Execution stops.

User response

Correct the incorrect character string in the EXEC file.

CICREX450E Error 5 running *fn ft*, line *nn*: User storage exhausted or request exceeds limit

Explanation

While trying to process a program, the language processor could not get the resources it needed to

continue. (For example, it could not get the space needed for its work areas or variables.) The program that called the language processor might have used up most of the available storage, or a request for storage might have been for more than the implementation maximum.

System action

Execution stops.

User response

Run the exec or macro on its own, or check a program issuing NUCXLOAD for a possible loop that has not terminated properly. See your system administrator for additional storage requirements.

CICREX451E Error 3 running *fn ft*: Program is unreadable

Explanation

The REXX program could not be read. This is probably due to bad data in the exec file or an I/O error.

System action

Execution stops.

User response

Examine and correct the exec file.

Note: Sequence numbers are not allowed in columns 73 through 80 in a REXX exec.

CICREX452E Error 4 running *fn ft*, line *nn*: Program interrupted

Explanation

The system interrupted execution of your REXX program. Certain utility modules might force this condition if they detect a disastrous error condition.

System action

Execution stops.

User response

Look for a problem with a utility module called in your exec or macro.

CICREX453E Error 6 running *fn ft*, line *nn*: Unmatched */ or quote**

Explanation

A comment or literal string was started but never finished. This could be because the language processor detected:

- The end of the file (or the end of data in an INTERPRET statement) without finding the ending **/* for a comment or the ending quote for a literal string
- The end of the line for a literal string.

System action

Execution stops.

User response

Edit the exec and add the closing **/* or quote. You can also insert a TRACE SCAN statement at the top of your program and rerun it. The resulting output should show where the error exists.

CICREX454E Error 7 running *fn ft*, line *nn*: WHEN or OTHERWISE expected

Explanation

The language processor expects a series of WHENs and an OTHERWISE in a SELECT statement. This message is issued when any other instruction is found, or if all WHEN expressions are found to be false and an OTHERWISE is not present. The error is often caused by forgetting the DO and END instructions around the list of instructions following a WHEN. For example:

WRONG	RIGHT
Select When a1=b1 then Say 'A1 equals B1' B1' exit Otherwise nop end	Select When a1=b1 then DO Say 'A1 equals exit end Otherwise nop end

System action

Execution stops.

User response

Make the necessary corrections.

CICREX455E Error 8 running *fn ft*, line *nn*: Unexpected THEN or ELSE

Explanation

The language processor has found a THEN or an ELSE that does not match a corresponding IF clause. This

situation is often caused by using an incorrect DO-END in the THEN part of a complex IF-THEN-ELSE construction. For example,

WRONG	RIGHT
If a1=b1 then do; Say EQUALS exit else Say NOT EQUALS	If a1=b1 then do; Say EQUALS exit end else Say NOT EQUALS

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX456E Error 9 running *fn ft*, line *nn*:
Unexpected WHEN or OTHERWISE**

Explanation

The language processor has found a WHEN or OTHERWISE instruction outside of a SELECT construction. You might have accidentally enclosed the instruction in a DO-END construction by leaving off an END instruction, or you might have tried to branch to it with a SIGNAL statement (which cannot work because the SELECT is then terminated).

System action

Execution stops.

User response

Make the necessary correction.

**CICREX457E Error 10 running *fn ft*, line *nn*:
Unexpected or unmatched END**

Explanation

The language processor has found more ENDS in your program than DOs or SELECTs, or the ENDS were placed so that they did not match the DOs or SELECTs. Putting the name of the control variable on ENDS that close repetitive loops can help locate this kind of error.

This message can be caused if you try to signal into the middle of a loop. In this case, the END will be unexpected because the previous DO will not have been executed. Remember, also, that SIGNAL terminates any current loops, so it cannot be used to transfer control from one place inside a loop to another.

This message can also be caused if you place an END immediately after a THEN or ELSE construction or if you specified a *name* on the END keyword that does not match the *name* following DO.

System action

Execution stops.

User response

Make the necessary corrections. It can be helpful to use TRACE Scan to show the structure of the program, making it easier to find your error. Putting the name of the control variable on ENDS that close repetitive loops can also help locate this kind of error.

**CICREX458E Error 11 running *fn ft*, line *nn*:
Control stack full**

Explanation

This message is issued if you exceed the limit of 250 levels of nesting of control structures (DO-END, IF-THEN-ELSE, and so forth) or when user storage limit is reached, whichever is less.

This message could be caused by a looping INTERPRET instruction, such as:

```
line='INTERPRET line'  
INTERPRET line
```

These lines would loop until they exceeded the nesting level limit and this message would be issued. Similarly, a recursive subroutine that does not terminate correctly could loop until it causes this message.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX459E Error 12 running *fn ft*, line *nn*:
Clause too long**

Explanation

You have exceeded the limit for the length of the internal representation of a clause. The actual limit is the amount of storage that can be obtained on a single request.

If the cause of this message is not obvious, it might be because of a missing quote that has caused a number of lines to be included in one long string. In this case, the error probably occurred at the start of the data

included in the clause traceback (flagged by +++ on the console).

The internal representation of a clause does not include comments or multiple blanks that are outside of strings. Note also that any symbol (name) or string gains two characters in length in the internal representation.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX460E Error 13 running *fn ft*, line *nn*:
Invalid character in program**

Explanation

The language processor found an incorrect character outside of a literal (quoted) string. Valid characters are:

- A-Z a-z 0-9 (alphanumeric characters)
- @ # \$ % . ? ! _ (name characters)
- & * () - + = \ ~ ' " ; : < , > / | (special characters)

If surrounded by X'0E' (shift-out) and X'0F' (shift-in), and if ETMODE is on, the following are also valid characters:

- X'41' - X'FE' (DBCS Characters)

Some causes of this error are:

1. Using accented and other language-specific characters in symbols.
2. Using DBCS characters without ETMODE in effect.

Note: The following characters might display differently in the REXX online help depending on the code page used in your emulator configuration: @ # \$ %. See also [Conventions and terminology used in the CICS documentation](#).

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX461E Error 14 running *fn ft*, line *nn*:
Incomplete DO/SELECT/IF**

Explanation

The language processor has reached the end of the file (or end of data for an INTERPRET instruction) and has found that there is a DO or SELECT without a matching END, or an IF that is not followed by a THEN clause.

System action

Execution stops.

User response

Make the necessary corrections. You can use TRACE Scan to show the structure of the program, making it easier to find where the missing END or THEN should be. Putting the name of the control variable on ENDS that close repetitive loops can also help locate this kind of error.

**CICREX462E Error 15 running *fn ft*, line *nn*:
Invalid hexadecimal or binary string**

Explanation

Binary strings are new in REXX and the language processor might now be considering the string in your statement to be binary when that was not your intention.

For the language processor, hexadecimal strings cannot have leading or trailing blanks and can have imbedded blanks only at byte boundaries. Only the digits 0-9 and the letters a-f and A-F are allowed. Similarly, binary strings can have blanks only at the boundaries of groups of four binary digits, and only the digits 0 and 1 are allowed.

The following are all valid hexadecimal or binary constants:

'13'x	'0101 1100'b
'A3C2 1c34'x	'001100'B
'1de8'x	"0 11110000"b

You might have mistyped one of the digits, for example, typing a letter o instead of 0. Or you might have put the 1-character symbol X, x, B, or b (the name of the variable X or B, respectively) after a literal string, when the string is not intended as a hexadecimal or binary specification. In this case, use the explicit concatenation operator (| |) to concatenate the string to the value of the symbol.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX463E Error 16 running *fn ft*, line *nn*:
Label not found**

Explanation

The language processor could not find the label specified by a SIGNAL instruction or a label matching an enabled condition when the corresponding (trapped) event occurred. You might have mistyped the label or forgotten to include it, or you might have typed it in mixed case when it needs to be in uppercase.

System action

Execution stops. The name of the missing label is included in the error traceback.

User response

Make the necessary corrections.

**CICREX464E Error 21 running *fn ft*, line *nn*:
Invalid data on end of clause**

Explanation

You have followed a clause, such as SELECT or NOP, by some data other than a comment.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX465E Error 17 running *fn ft*, line *nn*:
Unexpected PROCEDURE**

Explanation

The language processor encountered a PROCEDURE instruction in an incorrect position. This could occur because no internal routines are active, because a PROCEDURE instruction has already been encountered in the internal routine, or because the PROCEDURE instruction was not the first instruction executed after the CALL or function invocation. This error can be caused by "dropping through" to an internal routine, rather than invoking it with a CALL or a function call.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX466E Error 26 running *fn ft*, line *nn*:
Invalid whole number**

Explanation

The language processor found an expression in the NUMERIC instruction, a parsing positional pattern, or the right-hand term of the exponentiation (**) operator that did not evaluate to a whole number, or was greater than the limit, for these uses, of 999999999.

This message can also be issued if the return code passed back from an EXIT or RETURN instruction (when a REXX program is called as a command) is not a whole number or will not fit in a general register. This error might be caused by mistyping the name of a symbol so that it is not the name of a variable in the expression on any of these statements. This might be true, for example, if you entered "EXIT CR" instead of "EXIT RC".

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX467E Error 27 running *fn ft*, line *nn*:
Invalid DO syntax**

Explanation

The language processor found a syntax error in the DO instruction. You might have used BY, TO, FOR, WHILE, OR UNTIL twice, or used a WHILE and an UNTIL.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX468E Error 30 running *fn ft*, line *nn*:
Name or string > 250 characters**

Explanation

The language processor found a variable or a literal (quoted) string that is longer than the limit.

The limit for names is 250 characters, following any substitutions. A possible cause of this error is the use of a period (.) in a name, causing an unexpected substitution.

The limit for a literal string is 250 characters. This error can be caused by leaving off an ending quote (or putting a single quote in a string) because several clauses can be included in the string. For example, the string 'don't' should be written as 'don't' or "don't".

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX469E Error 31 running *fn ft*, line *nn*:
Name starts with number or .**

Explanation

The language processor found a symbol whose name begins with a numeric digit or a period (.). The REXX language rules do not allow you to assign a value to a symbol whose name begins with a number or a period because you could then redefine numeric constants, and that would be catastrophic.

System action

Execution stops.

User response

Rename the variable correctly. It is best to start a variable name with an alphabetic character, but some other characters are allowed.

**CICREX470E Error 34 running *fn ft*, line *nn*:
Logical value not 0 or 1**

Explanation

The language processor found an expression in an IF, WHEN, DO WHILE, or DO UNTIL phrase that did not result in a 0 or 1. Any value operated on by a logical operator (¬, \, |, &, or &&) must result in a 0 or 1. For example, the phrase "If result then exit rc" will fail if result has a value other than 0 or 1. Thus, the phrase would be better written as `If result¬=0 then exit rc`.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX471E Error 35 running *fn ft*, line *nn*:
Invalid expression**

Explanation

The language processor found a grammatical error in an expression. This could be because:

- You ended an expression with an operator.
- You specified, in an expression, two operators next to one another with nothing in between them.
- You did not specify an expression when one was required.
- You did not specify a right parenthesis when one was required.
- You used special characters (such as operators) in an intended character expression without enclosing them in quotation marks.

An example of the last case is that `LISTFILE ***` should be written as `LISTFILE '* * *'` (if `LISTFILE` is not a variable) or even as `'LISTFILE * * *'`.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX472E Error 36 running *fn ft*, line *nn*:
Unmatched (in expression**

Explanation

The language processor found an unmatched parenthesis in an expression. This message occurs if you include a single parenthesis in a command without enclosing it in quotation marks. For example, write `COPY A B C A B D (REP as COPY A B C A B D '(' REP`.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX473E Error 37 running *fn ft*, line *nn*:
Unexpected , or)**

Explanation

The language processor found a comma (,) outside a routine invocation or too many right parentheses in an expression. This message occurs if you include a comma in a character expression without enclosing it in quotation marks. For example, the following instruction:

```
Say Enter A, B, or C
```

should be written as:

```
Say 'Enter A, B, or C'
```

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX474E Error 39 running *fn ft*, line *nn*:
Evaluation stack overflow**

Explanation

The language processor was not able to evaluate the expression because it is too complex (such as many nested parentheses and functions).

System action

Execution stops.

User response

Break up the expressions by assigning subexpressions to temporary variables.

**CICREX475E Error 40 running *fn ft*, line *nn*:
Invalid call to routine**

Explanation

The language processor encountered an incorrectly used call to a routine. Some possible causes are:

- You passed incorrect data (arguments) to the built-in or external routine (this depends on the actual routine).
- You passed too many arguments to the built-in, external, or internal routine.
- The module invoked was not compatible with the language processor.

If you were not trying to invoke a routine, you might have a symbol or a string adjacent to a parenthesis (when you meant it to be separated by a space or an operator. This causes it to be seen as a function call. For example, TIME(4+5) should probably be written as TIME*(4+5).

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX476E Error 41 running *fn ft*, line *nn*: Bad
arithmetic conversion**

Explanation

The language processor found a term in an arithmetic expression that was not a valid number or that had an exponent outside the allowed range of -999999999 to +999999999.

You might have mistyped a variable name, or included an arithmetic operator in a character expression without putting it in quotation marks. For example, the command MSG * Hi! should be written as 'MSG * Hi! ', otherwise the language processor will try to multiply "MSG" by "Hi!".

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX477E Error 42 running *fn ft*, line *nn*:
Arithmetic overflow/underflow**

Explanation

The language processor encountered a result of an arithmetic operation that required an exponent greater than the limit of 9 digits (more than 999999999 or less than -999999999).

This error can occur during evaluation of an expression (often as a result of trying to divide a number by 0), or during the stepping of a DO loop control variable.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX478E Error 43 running *fn ft*, line *nn*:
Routine not found**

Explanation

The language processor was unable to find a routine called in your program. You invoked a function within an expression, or in a subroutine invoked by CALL, but the specified label is not in the program, or is not the name of a built-in function, and REXX/CICS cannot locate it externally.

The simplest, and probably most common, cause of this error is mistyping the name. Another possibility might be that one of the standard function packages is not available.

If you were not trying to invoke a routine, you might have put a symbol or string adjacent to a "(" when you meant it to be separated by a space or operator. The language processor would see that as a function invocation. For example, the string 3(4+5) should be written as 3*(4+5).

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX479E Error 44 running *fn ft*, line *nn*:
Function did not return data**

Explanation

The language processor invoked an external routine within an expression. The routine seemed to end without error, but it did not return data for use in the expression.

This might be caused by specifying the name of a module that is not intended for use as a REXX function. It should be called as a command or subroutine.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX480E Error 45 running *fn ft*, line *nn*: No
data specified on function RETURN**

Explanation

A REXX program has been called as a function, but an attempt is being made to return (by a RETURN; instruction) without passing back any data. Similarly, an internal routine, called as a function, must end with a RETURN statement specifying an expression.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX481E Error 49 running *fn ft*, line *nn*:
Language processor failure**

Explanation

The language processor carries out numerous internal self-consistency checks. It issues this message if it encounters a severe error.

System action

Execution stops.

User response

Report any occurrence of this message to your IBM representative.

**CICREX482E Error 19 running *fn ft*, line *nn*:
String or symbol expected**

Explanation

The language processor expected a symbol following the CALL or SIGNAL instructions, but none was found. You might have omitted the string or symbol, or you might have inserted a special character (such as a parenthesis) in it.

System action

Execution stops.

User response

Make the necessary corrections.

**CICREX483E Error 20 running *fn ft*, line *nn*:
Symbol expected**

Explanation

The language processor either expected a symbol following the CALL ON, CALL OFF, END, ITERATE,

LEAVE, NUMERIC, PARSE, PROCEDURE, SIGNAL ON, or SIGNAL OFF keywords or expected a list of symbols or variable references following the DROP, UPPER, or PROCEDURE (with EXPOSE option) keywords. Either there was no symbol when one was required or some other characters were found.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX484E **Error 24 running *fn ft*, line *nn*:
Invalid TRACE request**

Explanation

The language processor issues this message when:

- The action specified on a TRACE instruction, or the argument to the TRACE built-in function, starts with a letter that does not match one of the valid alphabetic character options. The valid options are A, C, E, F, I, L, N, O, R, or S.
- An attempt is made to request TRACE Scan when inside any control construction or while in interactive debug
- In interactive trace, you enter a number that is not a whole number.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX485E **Error 25 running *fn ft*, line *nn*:
Invalid sub-keyword found**

Explanation

The language processor expected a specific sub-keyword at this position in an instruction and something else was found. For example, the NUMERIC instruction must be followed by the sub-keyword DIGITS, FUZZ, or FORM. If NUMERIC is followed by anything else, this message is issued.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX486E **Error 28 running *fn ft*, line *nn*:
Invalid LEAVE or ITERATE**

Explanation

The language processor encountered an incorrect LEAVE or ITERATE instruction. The instruction was incorrect because of one of the following:

- No loop is active.
- The name specified on the instruction does not match the control variable of any active loop.

Note that internal routine calls and the INTERPRET instruction protect DO loops by making them inactive. Therefore, for example, a LEAVE instruction in a subroutine cannot affect a DO loop in the calling routine.

You can cause this message to be issued if you use the SIGNAL instruction to transfer control within or into a loop. A SIGNAL instruction terminates all active loops, and any ITERATE or LEAVE instruction issued then would cause this message to be issued.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX487E **Error 29 running *fn ft*, line *nn*:
Environment name too long**

Explanation

The language processor encountered an environment name specified on an ADDRESS instruction that is longer than the limit of 8 characters.

System action

Execution stops.

User response

Specify the environment name correctly.

CICREX488E **Error 33 running *fn ft*, line *nn*:
Invalid expression result**

Explanation

The language processor encountered an expression result that is incorrect in its specific context. The result might be incorrect in one of the following:

- ADDRESS VALUE expression
- NUMERIC DIGITS expression
- NUMERIC FORM VALUE expression
- NUMERIC FUZZ expression
- OPTIONS expression
- SIGNAL VALUE expression
- TRACE VALUE expression.

(FUZZ must be smaller than DIGITS.)

System action

Execution stops.

User response

Make the necessary corrections.

CICREX489E	Error 38 running <i>fn ft</i>, line <i>nn</i>: Invalid template or pattern
-------------------	---

Explanation

The language processor found an incorrect special character, for example %, within a parsing template, or the syntax of a variable trigger was incorrect (no symbol was found after a left parenthesis). This message is also issued if the WITH sub-keyword is omitted in a PARSE VALUE instruction.

System action

Execution stops.

User response

Make the necessary corrections.

CICREX490E	Error 48 running <i>fn ft</i>, line <i>nn</i>: Failure in system service
-------------------	---

Explanation

The language processor halts execution of the program because some system service, such as user input or output or manipulation of the console stack, has failed to work correctly.

System action

Execution stops.

User response

Ensure that your input is correct and that your program is working correctly. If the problem persists, notify your system support personnel.

CICREX491E	Error 18 running <i>fn ft</i>, line <i>nn</i>: THEN expected
-------------------	---

Explanation

All REXX IF and WHEN clauses must be followed by a THEN clause. Another clause was found before a THEN statement was found.

System action

Execution stops.

User response

Insert a THEN clause between the IF or WHEN clause and the following clause.

CICREX492E	Error 32 running <i>fn ft</i>, line <i>nn</i>: Invalid use of stem
-------------------	---

Explanation

The REXX program attempted to change the value of a symbol that is a stem. (A stem is that part of a symbol up to the first period. You use a stem when you want to affect all variables beginning with that stem.) This might be in the UPPER instruction where the action in this case is unknown, and therefore in error.

System action

Execution stops.

User response

Change the program so that it does not attempt to change the value of a stem.

CICREX1106E	Error 23 running <i>fn ft</i>, line <i>nn</i>: Invalid SBCS/DBCS mixed string.
--------------------	---

Explanation

A character string that has unmatched SO-SI pairs (that is, an SO without an SI) or an odd number of bytes between the SO-SI characters was processed with OPTIONS EXMODE in effect.

System action

Execution stops.

User response

Correct the incorrect character string.

Chapter 32. Return Codes

The REXX/CICS return codes are listed.

A command might also return a return code that is listed in [“Return codes not associated with a specific command”](#) on page 438.

Panel facility return codes

- 4** Warning. Panel facility continues processing
- 8** Programmer error
- 10** Programmer error with state information
- 12** CICS command error
- 14** RFS errors; reason code contains the RFS return code
- 16** Internal system error

See [Chapter 29, “REXX/CICS Panel Facility,”](#) on page 325, for additional codes (for example: state and reason codes).

SQL return codes

- n** An SQLCODE if the SQL statement resulted in an error or warning
- 0** The SQL statement was processed by the EXEC SQL environment
- 30** There was not enough memory to build the SQLDSECT variable
- 31** There was not enough memory to build the SQL statement area
- 32** There was not enough memory to build the SQLDA variable
- 33** There was not enough memory to build the results area for the SELECT statement

Db2 return codes

- n** A positive value that indicates the results of the call to the Db2 instrumentation facility interface (IFI). If the RC from the Db2 IFI is not zero, the REXX variable DB2_RC2 contains the Db2 IFI reason code. The DB2_RC2 value is used in conjunction with the RC by using [Db2 codes in Db2 for z/OS product documentation](#) for error determination.
- 0** The Db2 command was processed by the Db2 IFI.

50

The specified Db2 command is either too short or too long to be accepted for processing by the Db2 IFI. The Db2 command cannot be less than 6 or greater than 4092 characters long.

51

There was not enough memory to build the output area for the Db2 IFI.

52

There was not enough memory to build the communications area for the Db2 IFI.

53

There was not enough memory to build the return area for the Db2 IFI.

54

The DB2_RC2 REXX variable could not be built.

55

The DB2_BNM REXX variable could not be built.

56

The DB2_OUTPUT.*n* REXX variable could not be built.

57

The DB2_OUTPUT.0 REXX variable could not be built.

Return codes not associated with a specific command

- 3**
Exec not found or unrecognized command.
- 4**
User not an authorized user, or EXEC not allowed to use authorized commands.
- 5**
TWA size was not specified, or TWA size specified was less than 4 characters in length for this CICS transaction definition.
- 6**
REXX/CICS started with a CICS LINK and less than 16 characters provided in the communications area. Or REXX/CICS started with a CICS XCTL and either the communications area does not contain an MVS SIB type 1 control block, or the communications area length is less than 16 characters.
- 99**
Internal error

EXEC

- n***
The return code that is set by the exit of the called exec. See [“EXIT” on page 170](#).
- 0**
Normal return
- 3**
Exec not found
- 10**
Exec name not specified
- 11**
Invalid exec name
- 12**
GETMAIN error

CEDA and CEMT

n

The return code that is passed back by CICS if an error is detected. Calling CEMT from REXX uses the DFHEMTA (CEMT programmable interface), so the codes returned will be those for the CEMT command. Possible return codes for CEMT are:

- 1** NOT FOUND
- 2** CLASS NOT FOUND
- 3** ERROR
- 4** BEGINS WITH DFH
- 5** CHANGE INVALID
- 6** CANNOT NEWCOPY
- 7** NOT AUTHORIZED
- 8** OPTION CONFLICT
- 9** PRIORITY > 255
- 10** NOT FOR CONSOLE
- 11** PROGRAM NOT FOUND

Chapter 33. Double-Byte Character Set (DBCS) Support

A Double-Byte Character Set supports languages that have more characters than can be represented by 8 bits (such as Korean Hangeul and Japanese kanji). REXX has a full range of DBCS functions and handling techniques.

These DBCS functions and handling techniques include:

- Symbol and string handling capabilities with DBCS characters
- An option that allows DBCS characters in symbols, comments, and literal strings.
- An option that allows data strings to contain DBCS characters.
- A number of functions that specifically support the processing of DBCS character strings
- Defined DBCS enhancements to current instructions and functions.

Note: The use of DBCS does not affect the meaning of the built-in functions as described in [Chapter 19, “Functions,”](#) on page 191. This explains how the characters in a result are obtained from the characters of the arguments by such actions as selecting, concatenating, and padding. This information describes how the resulting characters are represented as bytes. This internal representation is not usually seen if the results are printed. It might be seen if the results are displayed on certain terminals.

DBCS: general description

Characteristics that help to define the rules that DBCS uses to represent extended characters are listed.

- Each DBCS character consists of 2 bytes.
- There are no DBCS control characters.
- The codes are in the ranges defined in the following table, which shows the valid DBCS code for the DBCS blank. You cannot have a DBCS blank in a simple symbol, in the stem of a compound variable, or in a label.

Table 6. DBCS Ranges	
Byte	EBCDIC
1st	X'41' to X'FE'
2nd	X'41' to X'FE'
DBCS blank	X'4040'

- DBCS alphanumeric and special symbols:

A DBCS contains double-byte representation of alphanumeric and special symbols corresponding to those of the Single-Byte Character Set (SBCS). In EBCDIC, the first byte of a double-byte alphanumeric or special symbol is X'42' and the second is the same hex code as the corresponding EBCDIC code.

Here are some examples:

X'42C1' is an EBCDIC double-byte A

X'4281' is an EBCDIC double-byte a

X'427D' is an EBCDIC double-byte quote

- No case translation:

In general, there is no concept of lowercase and uppercase in DBCS.

- The following notation conventions are used in this information:

– DBCS character: .A .B .C .D

- SBCS character: a b c d e
- DBCS blank: ' . '
- EBCDIC shift-out (X'0E'): <
- EBCDIC shift-in (X'0F'): >

Note: In EBCDIC, the shift-out (SO) and shift-in (SI) characters distinguish DBCS characters from SBCS characters.

Enabling DBCS data operations and symbol use

The OPTIONS instruction controls how REXX regards DBCS data.

- To enable DBCS operations, use the EXMODE option.
- To enable DBCS symbols, use the ETMODE option on the OPTIONS instruction; this must be the first instruction in the program. See [“OPTIONS” on page 175](#).

If OPTIONS ETMODE is in effect, the language processor does validation to ensure that SO and SI are paired in comments. Otherwise, the contents of the comment are not checked. The comment delimiters (/* and */) must be SBCS characters.

Symbols and strings

In DBCS, there are DBCS-only symbols and strings, and mixed symbols and strings.

DBCS-only symbols and mixed SBCS/DBCS symbols

A DBCS-only symbol consists of only non-blank DBCS codes as indicated in the following table:

Table 7. DBCS Ranges	
Byte	EBCDIC
1st	X'41' to X'FE'
2nd	X'41' to X'FE'
DBCS blank	X'4040'

A mixed DBCS symbol is formed by a concatenation of SBCS symbols, DBCS-only symbols, and other mixed DBCS symbols. In EBCDIC, the SO and SI bracket the DBCS symbols and distinguish them from the SBCS symbols.

The default value of a DBCS symbol is the symbol itself, with SBCS characters translated to uppercase.

A *constant symbol* must begin with an SBCS digit (0-9) or an SBCS period. The delimiter (period) in a compound symbol must be an SBCS character.

DBCS-only strings and mixed SBCS/DBCS strings

A DBCS-only string consists of only DBCS characters.

A mixed SBCS/DBCS string is formed by a combination of SBCS and DBCS characters. In EBCDIC, the SO and SI bracket the DBCS data and distinguish it from the SBCS data. Because the SO and SI are needed only in the mixed strings, they are not associated with the DBCS-only strings.

In EBCDIC:

- DBCS-only string: . A . B . C
- Mixed string: ab< . A . B>
- Mixed string: < . A . B>
- Mixed string: ab< . C . D>e f

DBCS symbol validation

The rules and conditions that apply to use DBCS symbols are listed.

- The DBCS portion of the symbol must be an even number of bytes in length
- DBCS alphanumeric and special symbols are regarded as different to their corresponding SBCS characters. Only the SBCS characters are recognized by REXX in numbers, instruction keywords, or operators
- DBCS characters cannot be used as special characters in REXX
- SO and SI cannot be contiguous
- Nesting of SO or SI is not permitted
- SO and SI must be paired
- No part of a symbol consisting of DBCS characters can contain a DBCS blank.
- Each part of a symbol consisting of DBCS characters must be bracketed with SO and SI.

These examples show some possible misuses:

- `<.A.BC>` Incorrect because of odd byte length.
- `<.A.B><.C>` Incorrect contiguous SO/SI.
- `<>` Incorrect contiguous SO/SI (null DBCS symbol).
- `<.A<.B>.C>` Incorrectly nested SO/SI
- `<.A.B.C` Incorrect because SO/SI not paired
- `<.A. .B>` Incorrect because contains blank
- `' . A<.B><.C>` Incorrect symbol

Mixed string validation

The validation of mixed strings depends on the instruction, operator, or function.

If you use a mixed string with an instruction, operator, or function that does not allow mixed strings, this causes a syntax error.

The following rules apply for mixed string validation:

- DBCS strings must be an even number of bytes in length, unless you have SO and SI.

EBCDIC only:

- SO and SI must be paired in a string.
- Nesting of SO or SI is not permitted.

These examples show some possible misuses:

- `'ab<cd'` Incorrect - not paired.
- `'<.A<.B>.C>` Incorrect - nested.
- `'<.A.BC>'` Incorrect - odd byte length.

The end of a comment delimiter is not found within DBCS character sequences. For example, when the program contains `/* < */`, the `*/` is not recognized as ending the comment because the scanning is looking for the `>` (SI) to go with the `<` (SO) and not looking for `*/`.

When a variable is created, modified, or referred to in a REXX program under `OPTIONS EXMODE`, it is validated whether it contains a correct mixed string or not. When a referred variable contains a mixed string that is not valid, it depends on the instruction, function, or operator whether it causes a syntax error.

The `ARG`, `PARSE`, `PULL`, `PUSH`, `QUEUE`, `SAY`, `TRACE`, and `UPPER` instructions all require valid mixed strings with `OPTIONS EXMODE` in effect.

Instructions and DBCS

Descriptions and examples of how instructions work with DBCS are provided.

PARSE

Example of the PARSE instruction with DBCS.

In EBCDIC:

```
x1 = '<><.A.B><. . ><.E><.F><>'

PARSE VAR x1 w1
        w1 -> '<><.A.B><. . ><.E><.F><>'

PARSE VAR x1 1 w1
        w1 -> '<><.A.B><. . ><.E><.F><>'

PARSE VAR x1 w1 .
        w1 -> '<.A.B>'
```

The leading and trailing SO and SI are unnecessary for word parsing and, thus, they are stripped off. However, one pair is still needed for a valid mixed DBCS string to be returned.

```
PARSE VAR x1 . w2
        w2 -> '<. ><.E><.F><>'
```

Here the first blank delimited the word and the SO is added to the string to ensure the DBCS blank and the valid mixed string.

```
PARSE VAR x1 w1 w2
        w1 -> '<.A.B>'
        w2 -> '<. ><.E><.F><>'

PARSE VAR x1 w1 w2 .
        w1 -> '<.A.B>'
        w2 -> '<.E><.F>'
```

The word delimiting allows for unnecessary SO and SI to be dropped.

```
x2 = 'abc<>def <.A.B><><.C.D>'

PARSE VAR x2 w1 ' ' w2
        w1 -> 'abc<>def <.A.B><><.C.D>'
        w2 -> ' '

PARSE VAR x2 w1 '<>' w2
        w1 -> 'abc<>def <.A.B><><.C.D>'
        w2 -> ' '

PARSE VAR x2 w1 '<><>' w2
        w1 -> 'abc<>def <.A.B><><.C.D>'
        w2 -> ' '
```

Notice that for the last three examples " ", "<>", and "<><>" are each a null string (a string of length 0). When parsing, the null string matches the end of string. For this reason, w1 is assigned the value of the entire string and w2 is assigned the null string.

PUSH and QUEUE

PUSH and QUEUE instructions with DBCS.

The PUSH and QUEUE instructions add entries to the program stack. Because a stack entry is limited to 255 bytes, the *expression* must be truncated less than 256 bytes. If the truncation splits a DBCS string, REXX ensures that the integrity of the SO-SI pairing will be kept under OPTIONS EXMODE.

SAY and TRACE

SAY and TRACE instructions with DBCS.

The SAY and TRACE instructions write data to the output stream. In the same way as for the PUSH and QUEUE instructions, REXX guarantees that the SO-SI pairs are kept for any data that is separated to meet the requirements of the output stream. The SAY and TRACE instructions display data on the user's terminal. In the same way as for the PUSH and QUEUE instructions, REXX guarantees that the SO-SI pairs are kept for any data that is separated to meet the requirements of the terminal line size. This is generally 130 bytes or fewer if the DIAG-24 value returns a smaller value.

When the data is split up in shorter lengths, the DBCS data integrity is kept under OPTIONS EXMODE. In EBCDIC, if the terminal line size is less than 4, the string is treated as SBCS data, because 4 is the minimum for mixed string data.

UPPER

UPPER instruction with DBCS.

Under OPTIONS EXMODE, the UPPER instruction translates only SBCS characters in contents of one or more variables to uppercase; it never translates DBCS characters. If the content of a variable is not valid mixed string data, no uppercase translation occurs.

DBCS function handling

Some built-in functions can handle DBCS.

The functions that deal with word delimiting and length determining conform with the following rules under OPTIONS EXMODE:

- Counting characters.

Logical character lengths are used when counting the length of a string (that is, 1 byte for one SBCS logical character, 2 bytes for one DBCS logical character). In EBCDIC, SO and SI are considered to be transparent, and are not counted, for every string operation.

- Character extraction from a string.

Characters are extracted from a string on a logical character basis. In EBCDIC, leading SO and trailing SI are not considered as part of one DBCS character. For instance, .A and .B are extracted from <.A.B>, and SO and SI are added to each DBCS character when they are finally preserved as completed DBCS characters. When multiple characters are consecutively extracted from a string, SO and SI that are between characters are also extracted. For example, .A><.B is extracted from <.A><.B>, and when the string is finally used as a completed string, the SO prefixes it and the SI suffixes it to give <.A><.B>.

Here are some EBCDIC examples:

```
S1 = 'abc<>def'

SUBSTR(S1,3,1)    ->  'c'
SUBSTR(S1,4,1)    ->  'd'
SUBSTR(S1,3,2)    ->  'c<>d'

S2 = '<><.A.B>< >'

SUBSTR(S2,1,1)    ->  '<.A>'
SUBSTR(S2,2,1)    ->  '<.B>'
SUBSTR(S2,1,2)    ->  '<.A.B>'
SUBSTR(S2,1,3,'x') ->  '<.A.B><>x'

S3 = 'abc<><.A.B>'

SUBSTR(S3,3,1)    ->  'c'
SUBSTR(S3,4,1)    ->  '<.A>'
SUBSTR(S3,3,2)    ->  'c<><.A>'
DELSTR(S3,3,1)    ->  'ab<><.A.B>'
DELSTR(S3,4,1)    ->  'abc<><.B>'
DELSTR(S3,3,2)    ->  'ab<.B>'
```

- Character concatenation.

String concatenation can only be done with valid mixed strings. In EBCDIC, adjacent SI and SO (or SO and SI) that are a result of string concatenation are removed. Even during implicit concatenation as in the DELSTR function, unnecessary SO and SI are removed.

- Character comparison.

Valid mixed strings are used when comparing strings on a character basis. A DBCS character is always considered greater than an SBCS one if they are compared. In all but the strict comparisons, SBCS blanks, DBCS blanks, and leading and trailing contiguous SO and SI (or SI and SO) in EBCDIC are removed. SBCS blanks may be added if the lengths are not identical.

In EBCDIC, contiguous SO and SI (or SI and SO) between nonblank characters are also removed for comparison.

Note: The strict comparison operators do not cause syntax errors even if you specify mixed strings that are not valid.

In EBCDIC:

```
'<.A>' = '<.A. >'      -> 1      /* true */
'<><><.A>' = '<.A><><>' -> 1      /* true */
'<> <.A>' = '<.A>'      -> 1      /* true */
'<.A><><.B>' = '<.A.B>'  -> 1      /* true */
'abc' < 'ab<. >'      -> 0      /* false */
```

- Word extraction from a string

Word means that characters in a string are delimited by an SBCS or a DBCS blank.

In EBCDIC, leading and trailing contiguous SO and SI (or SI and SO) are also removed when words are separated in a string, but contiguous SO and SI (or SI and SO) in a word are not removed or separated for word operations. Leading and trailing contiguous SO and SI (or SI and SO) of a word are not removed if they are among words that are extracted at the same time.

In EBCDIC:

```
W1 = '<><. .A. . .B><.C. .D><>'
SUBWORD(W1,1,1)      -> '<.A>'
SUBWORD(W1,1,2)      -> '<.A. . .B><.C>'
SUBWORD(W1,3,1)      -> '<.D>'
SUBWORD(W1,3)        -> '<.D>'

W2 = '<.A. .B><.C><> <.D>'
SUBWORD(W2,2,1)      -> '<.B><.C>'
SUBWORD(W2,2,2)      -> '<.B><.C><> <.D>'
```

Built-in Function Examples

Examples for built-in functions, those that support DBCS and follow the rules defined, are provided.

For full function descriptions and the syntax diagrams, refer to [Chapter 19, “Functions,” on page 191](#).

ABBREV

Applying the character comparison and character extraction from a string rules.

In EBCDIC:

```
ABBREV('<.A.B.C>', '<.A.B>')      -> 1
ABBREV('<.A.B.C>', '<.A.C>')      -> 0
ABBREV('<.A><.B.C>', '<.A.B>')      -> 1
ABBREV('aa<>bbccdd', 'aabbcc')    -> 1
```

COMPARE

Applying the character concatenation for padding, character extraction from a string, and character comparison rules.

In EBCDIC:

```
COMPARE('<.A.B.C>', '<.A.B><.C>') -> 0
COMPARE('<.A.B.C>', '<.A.B.D>') -> 3
COMPARE('ab<>cde', 'abcdx') -> 5
COMPARE('<.A><>', '<.A>', '<. >') -> 0
```

COPIES

Applying the character concatenation rule.

In EBCDIC:

```
COPIES('<.A.B>', 2) -> '<.A.B.A.B>'
COPIES('<.A><.B>', 2) -> '<.A><.B.A><.B>'
COPIES('<.A.B><>', 2) -> '<.A.B><.A.B><>'
```

DATATYPE

Example of DATATYPE function.

```
DATATYPE('<.A.B>') -> 'CHAR'
DATATYPE('<.A.B>', 'D') -> 1
DATATYPE('<.A.B>', 'C') -> 1
DATATYPE('a<.A.B>b', 'D') -> 0
DATATYPE('a<.A.B>b', 'C') -> 1
DATATYPE('abcde', 'C') -> 0
DATATYPE('<.A.B>', 'C') -> 0
DATATYPE('<.A.B>', 'S') -> 1 /* if ETMODE is on */
```

If *string* is not a valid mixed string and C or D is specified as *type*, 0 is returned.

FIND

Applying the word extraction from a string and character comparison rules.

```
FIND('<.A. .B.C> abc', '<.B.C> abc') -> 2
FIND('<.A. .B><.C> abc', '<.B.C> abc') -> 2
FIND('<.A. .B> abc', '<.A> <.B>') -> 1
```

INDEX, POS, and LASTPOS

Applying the character extraction from a string and character comparison rules.

```
INDEX('<.A><.B><><.C.D.E>', '<.D.E>') -> 4
POS('<.A>', '<.A><.B><><.A.D.E>') -> 1
LASTPOS('<.A>', '<.A><.B><><.A.D.E>') -> 3
```

INSERT and OVERLAY

Applying the character extraction from a string and character comparison rules.

In EBCDIC:

```
INSERT('a', 'b<><.A.B>', 1) -> 'ba<><.A.B>'
INSERT('<.A.B>', '<.C.D><>', 2) -> '<.C.D.A.B><>'
INSERT('<.A.B>', '<.C.D><><.E>', 2) -> '<.C.D.A.B><><.E>'
INSERT('<.A.B>', '<.C.D><>', 3, '<.E>') -> '<.C.D><.E.A.B>'

OVERLAY('<.A.B>', '<.C.D><>', 2) -> '<.C.A.B>'
OVERLAY('<.A.B>', '<.C.D><><.E>', 2) -> '<.C.A.B>'
OVERLAY('<.A.B>', '<.C.D><><.E>', 3) -> '<.C.D><><.A.B>'
```

```
OVERLAY(' <.A.B>', '<.C.D><>', 4, '<.E>') -> '<.C.D><.E.A.B>'
OVERLAY(' <.A>', '<.C.D><.E>', 2) -> '<.C.A><.E>'
```

JUSTIFY

Applying the character concatenation for padding and character extraction from a string rules.

```
JUSTIFY(' <><. .A. . .B><.C. .D>', 10, 'p')
-> '<.A>ppp<.B><.C>ppp<.D>'
JUSTIFY(' <><. .A. . .B><.C. .D>', 11, 'p')
-> '<.A>pppp<.B><.C>ppp<.D>'
JUSTIFY(' <><. .A. . .B><.C. .D>', 10, '<.P>')
-> '<.A.P.P.P.B><.C.P.P.P.D>'
JUSTIFY(' <><.X. .A. . .B><.C. .D>', 11, '<.P>')
-> '<.X.P.P.A.P.P.B><.C.P.P.D>'
```

LEFT, RIGHT, and CENTER

Applying the character concatenation for padding and character extraction from a string rules.

In EBCDIC:

```
LEFT(' <.A.B.C.D.E>', 4) -> '<.A.B.C.D>'
LEFT('a<>', 2) -> 'a<>'
LEFT(' <.A>', 2, '*') -> '<.A>*'
RIGHT(' <.A.B.C.D.E>', 4) -> '<.B.C.D.E>'
RIGHT('a<>', 2) -> 'a'
CENTER(' <.A.B>', 10, '<.E>') -> '<.E.E.E.E.A.B.E.E.E.E>'
CENTER(' <.A.B>', 11, '<.E>') -> '<.E.E.E.E.A.B.E.E.E.E.E>'
CENTER(' <.A.B>', 10, 'e') -> 'eeee<.A.B>eeee'
```

LENGTH

Applying the counting characters rule.

In EBCDIC:

```
LENGTH(' <.A.B><.C.D><>') -> 4
```

REVERSE

Applying the character extraction from a string and character concatenation rules.

In EBCDIC:

```
REVERSE(' <.A.B><.C.D><>') -> '<><.D.C><.B.A>'
```

SPACE

Applying the word extraction from a string and character concatenation rules.

In EBCDIC:

```
SPACE('a<.A.B. .C.D>', 1) -> 'a<.A.B> <.C.D>'
SPACE('a<.A><><. .C.D>', 1, 'x') -> 'a<.A>x<.C.D>'
SPACE('a<.A><. .C.D>', 1, '<.E>') -> 'a<.A.E.C.D>'
```

STRIP

Applying the character extraction from a string and character concatenation rules.

In EBCDIC:

```
STRIP(' <><.A><.B><.A><>', '<.A>') -> '<.B>'
```

SUBSTR and DELSTR

Applying the character extraction from a string and character concatenation rules.

In EBCDIC:

```
SUBSTR('<><.A><><.B><.C.D>',1,2) -> '<.A><><.B>'
DELSTR('<><.A><><.B><.C.D>',1,2) -> '<><.C.D>'
SUBSTR('<.A><><.B><.C.D>',2,2) -> '<.B><.C>'
DELSTR('<.A><><.B><.C.D>',2,2) -> '<.A><><.D>'
SUBSTR('<.A.B><>',1,2) -> '<.A.B>'
SUBSTR('<.A.B><>',1) -> '<.A.B><>'
```

SUBWORD and DELWORD

Applying the word extraction from a string and character concatenation rules.

In EBCDIC:

```
SUBWORD('<><.A. .B><.C. .D>',1,2) -> '<.A. .B><.C>'
DELWORD('<><.A. .B><.C. .D>',1,2) -> '<><.D>'
SUBWORD('<><.A. .B><.C. .D>',1,2) -> '<.A. .B><.C>'
DELWORD('<><.A. .B><.C. .D>',1,2) -> '<><.D>'
SUBWORD('<.A. .B><.C><> <.D>',1,2) -> '<.A. .B><.C>'
DELWORD('<.A. .B><.C><> <.D>',1,2) -> '<.D>'
```

SYMBOL

Example of SYMBOL function.

In EBCDIC:

```
Drop A.3 ; <.A.B>=3 /* if ETMODE is on */
SYMBOL('<.A.B>') -> 'VAR'
SYMBOL('<.A.B>') -> 'LIT' /* has tested "3" */
SYMBOL('a.<.A.B>') -> 'LIT' /* has tested A.3 */
```

TRANSLATE

Applying the character extraction from a string, character comparison, and character concatenation rules.

In EBCDIC:

```
TRANSLATE('abcd','<.A.B.C>','abc') -> '<.A.B.C>d'
TRANSLATE('abcd','<><.A.B.C>','abc') -> '<.A.B.C>d'
TRANSLATE('abcd','<><.A.B.C>','ab<>c') -> '<.A.B.C>d'
TRANSLATE('a>bcd','<><.A.B.C>','ab<>c') -> '<.A.B.C>d'
TRANSLATE('a<>xcd','<><.A.B.C>','ab<>c') -> '<.A>x<.C>d'
```

VALUE

Example of VALUE function.

In EBCDIC:

```
Drop A3 ; <.A.B>=3 ; fred='<.A.B>'
VALUE('fred') -> '<.A.B>' /* looks up FRED */
VALUE(fred) -> '3' /* looks up <.A.B> */
VALUE('a'<.A.B>) -> 'A3' /* if ETMODE is on */
```

VERIFY

Applying the character extraction from a string and character comparison rules.

In EBCDIC:

```
VERIFY(' <>< .A.B><> .X>' , '< .B.A.C.D.E>') -> 3
```

WORD, WORDINDEX, and WORDLENGTH

Applying the word extraction from a string and, for WORDINDEX and WORDLENGTH, applying the counting characters rules.

In EBCDIC:

```
W = '<>< .A. . .B>< .C. .D>'
WORD(W,1)          -> '< .A>'
WORDINDEX(W,1)     -> 2
WORDLENGTH(W,1)    -> 1

Y = '<>< .A. . .B>< .C. .D>'
WORD(Y,1)          -> '< .A>'
WORDINDEX(Y,1)     -> 1
WORDLENGTH(Y,1)    -> 1

Z = '< .A .B>< .C> < .D>'
WORD(Z,2)          -> '< .B>< .C>'
WORDINDEX(Z,2)     -> 3
WORDLENGTH(Z,2)    -> 2
```

WORDS

Applying the word extraction from a string rule.

In EBCDIC:

```
W = '<>< .A. . .B>< .C. .D>'
WORDS(W)          -> 3
```

WORDPOS

Applying the word extraction from a string and character comparison rules.

In EBCDIC:

```
WORDPOS('< .B.C> abc' , '< .A. .B.C> abc') -> 2
WORDPOS('< .A.B>' , '< .A.B. .A.B>< .B.C. .A.B>' , 3) -> 4
```

DBCS Processing Functions

The functions that support DBCS mixed strings are described. These functions handle mixed strings, regardless of the OPTIONS mode.

Note: When used with DBCS functions, *length* is always measured in bytes (as opposed to LENGTH(*string*), which is measured in characters).

Counting option

In EBCDIC, when specified in the functions, the counting option can control whether the SO and SI are considered present when determining the length. Y specifies count SO and SI in mixed strings. N, the default, specifies do not count the SO and SI.

DBADJUST

In EBCDIC, DBADJUST adjusts all contiguous SI and SO (or SO and SI) characters in *string* based on the *operation* specified.

➤ DBADJUST — (— *string* — , — *operation* —) ➤

The following are valid operations. Only the capitalized and highlighted letter is needed; all characters following it are ignored.

Blank

changes contiguous characters to blanks (X'4040').

Remove

removes contiguous characters, and is the default.

EBCDIC examples

```
DBADJUST(' < .A>< .B>a<>b' , 'B') -> ' < .A. .B>a b'
DBADJUST(' < .A>< .B>a<>b' , 'R') -> ' < .A.B>ab'
DBADJUST(' <>< .A.B>' , 'B') -> ' < .A.B>'
```

DBBRACKET

In EBCDIC, DBBRACKET adds SO and SI brackets to a DBCS-only string.

➤ DBBRACKET — (— *string* —) ➤

If *string* is not a DBCS-only string, a SYNTAX error results. That is, the input string must be an even number of bytes in length and each byte must be a valid DBCS value.

EBCDIC examples

```
DBBRACKET(' .A.B') -> ' < .A.B>'
DBBRACKET('abc') -> SYNTAX error
DBBRACKET(' < .A.B>') -> SYNTAX error
```

DBCENTER

DBCENTER returns a string of length *length* with *string* centered in it, with *pad* characters added as necessary to make up length.

➤ DBCENTER — (— *string* — , — *length* — , — *pad* — , — *option* —) ➤

The default *pad* character is a blank. If *string* is longer than *length*, it is truncated at both ends to fit. If an odd number of characters are truncated or added, the right-hand end loses or gains one more character than the left-hand end.

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```
DBCENTER(' < .A.B.C>' , 4) -> ' < .B>'
DBCENTER(' < .A.B.C>' , 3) -> ' < .B>'
DBCENTER(' < .A.B.C>' , 10, 'x') -> 'xx < .A.B.C> xx'
DBCENTER(' < .A.B.C>' , 10, 'x', 'Y') -> 'x < .A.B.C> x'
```

```

DBCENTER(' <.A.B.C>',4,'x','Y')    -> ' <.B>'
DBCENTER(' <.A.B.C>',5,'x','Y')    -> 'x<.B>'
DBCENTER(' <.A.B.C>',8,'<.P>')      -> ' <.A.B.C> '
DBCENTER(' <.A.B.C>',9,'<.P>')      -> ' <.A.B.C.P>'
DBCENTER(' <.A.B.C>',10,'<.P>')     -> ' <.P.A.B.C.P>'
DBCENTER(' <.A.B.C>',12,'<.P>','Y') -> ' <.P.A.B.C.P>'

```

DBCJUSTIFY

DBCJUSTIFY formats *string* by adding *pad* characters between nonblank characters to justify to both margins and length of bytes *length* (*length* must be nonnegative).

➤ DBCJUSTIFY — (— *string* — , — *length* —) ➤

, — *pad* — , — *option* —

formats *string* by adding *pad* characters between nonblank characters to justify to both margins and length of bytes *length* (*length* must be nonnegative). Rules for adjustments are the same as for the JUSTIFY function. The default *pad* character is a blank.

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

Examples

```

DBCJUSTIFY(' <><AA  BB><CC>',20,, 'Y')
-> ' <AA>    <BB>    <CC>'

DBCJUSTIFY(' <>< AA  BB>< CC>',20,'<XX>', 'Y')
-> ' <AAXXXXXXBBXXXXXXCC>'

DBCJUSTIFY(' <>< AA  BB>< CC>',21,'<XX>', 'Y')
-> ' <AAXXXXXXBBXXXXXXCC> '

DBCJUSTIFY(' <>< AA  BB>< CC>',11,'<XX>', 'Y')
-> ' <AAXXXXBB> '

DBCJUSTIFY(' <>< AA  BB>< CC>',11,'<XX>', 'N')
-> ' <AAXXBBXXCC> '

```

DBLEFT

DBLEFT returns a string of length *length* containing the leftmost *length* characters of *string*.

➤ DBLEFT — (— *string* — , — *length* —) ➤

, — *pad* — , — *option* —

The string returned is padded with *pad* characters (or truncated) on the right as needed. The default *pad* character is a blank.

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```

DBLEFT(' ab<.A.B>',4)      -> ' ab<.A>'
DBLEFT(' ab<.A.B>',3)      -> ' ab '
DBLEFT(' ab<.A.B>',4,'x','Y') -> ' abxx'
DBLEFT(' ab<.A.B>',3,'x','Y') -> ' abx'
DBLEFT(' ab<.A.B>',8,'<.P>') -> ' ab<.A.B.P>'
DBLEFT(' ab<.A.B>',9,'<.P>') -> ' ab<.A.B.P> '
DBLEFT(' ab<.A.B>',8,'<.P>','Y') -> ' ab<.A.B>'
DBLEFT(' ab<.A.B>',9,'<.P>','Y') -> ' ab<.A.B> '

```

DBRIGHT

DBRIGHT returns a string of length *length* containing the rightmost *length* characters of *string*.

► DBRIGHT — (— string — , — length —) ►

,

pad

, — option —

The string returned is padded with *pad* characters (or truncated) on the left as needed. The default *pad* character is a blank.

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```

DBRIGHT('ab<.A.B>',4)      -> '<.A.B>'
DBRIGHT('ab<.A.B>',3)      -> '<.B>'
DBRIGHT('ab<.A.B>',5,'x','Y') -> 'x<.B>'
DBRIGHT('ab<.A.B>',10,'x','Y') -> 'xxab<.A.B>'
DBRIGHT('ab<.A.B>',8,'<.P>') -> '<.P>ab<.A.B>'
DBRIGHT('ab<.A.B>',9,'<.P>') -> '<.P>ab<.A.B>'
DBRIGHT('ab<.A.B>',8,'<.P>', 'Y') -> 'ab<.A.B>'
DBRIGHT('ab<.A.B>',11,'<.P>', 'Y') -> 'ab<.A.B>'
DBRIGHT('ab<.A.B>',12,'<.P>', 'Y') -> '<.P>ab<.A.B>'

```

DBRLEFT

DBRLEFT returns the remainder from the DBLEFT function of *string*. If *length* is greater than the length of *string*, returns a null string.

➡ DBRLEFT — (— *string* — , — *length* — , — *option* —) ➡

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```
DBRLEFT('ab<.A.B>',4)      -> '<.B>'
```

```
DBRLEFT('ab<.A.B>',3)      -> '<.A.B>'
```

```
DBRLEFT('ab<.A.B>',4,'Y')  -> '<.A.B>'
```

```
DBRLEFT('ab<.A.B>',3,'Y')  -> '<.A.B>'
```

```
DBRLEFT('ab<.A.B>',8)      -> ''
```

```
DBRLEFT('ab<.A.B>',9,'Y')  -> ''
```

DBRRIGHT

DBRRIGHT returns the remainder from the DBRIGHT function of *string*. If *length* is greater than the length of *string*, returns a null string.

DBRRIGHT — (— *string* — , — *length* —) — *. — option*

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```
DBRRIGHT('ab<.A.B>',4)      -> 'ab'  
DBRRIGHT('ab<.A.B>',3)      -> 'ab<.A>'  
DBRRIGHT('ab<.A.B>',5)      -> 'a'  
DBRRIGHT('ab<.A.B>',4,'Y')  -> 'ab<.A>'  
DBRRIGHT('ab<.A.B>',5,'Y')  -> 'ab<.A>'  
DBRRIGHT('ab<.A.B>',8)      -> ''  
DBRRIGHT('ab<.A.B>',8,'Y')  -> ''
```

DBTODBCS

DBTODBCS converts all passed, valid, SBCS characters (including the SBCS blank) within *string* to the corresponding DBCS equivalents.

➤ DBTODBCS — (— *string* —) ➤

Other single-byte codes and all DBCS characters are not changed. In EBCDIC, SO and SI brackets are added and removed where appropriate.

EBCDIC examples

```
DBTODBCS('Rexx 1988')      -> '<.R.e.x.x. .1.9.8.8>'  
DBTODBCS('<.A> <.B>')      -> '<.A. .B>'
```

Note: In these examples, the .x is the DBCS character corresponding to an SBCS x.

DBTOSBCS

DBTOSBCS converts all passed, valid DBCS characters (including the DBCS blank) within *string* to the corresponding SBCS equivalents.

➤ DBTOSBCS — (— *string* —) ➤

Other DBCS characters and all SBCS characters are not changed. In EBCDIC, SO and SI brackets are removed where appropriate.

EBCDIC examples

```
DBTOSBCS('<.S.d>/<.2.-.1>') -> 'Sd/2-1'  
DBTOSBCS('<.X. .Y>')        -> '<.X> <.Y>'
```

Note: In these examples, the .d is the DBCS character corresponding to an SBCS d. However, the .X and .Y do not have corresponding SBCS characters and are not converted.

DBUNBRACKET

In EBCDIC, DBUNBRACKET removes the SO and SI brackets from a DBCS-only *string* enclosed by SO and SI brackets. If the *string* is not bracketed, a SYNTAX error results.

➤ DBUNBRACKET — (— *string* —) ➤

EBCDIC examples

```
DBUNBRACKET('<.A.B>')      -> '.A.B'  
DBUNBRACKET('ab<.A>')     -> SYNTAX error
```

DBVALIDATE

DBVALIDATE returns 1 if the *string* is a valid mixed string or SBCS string. Otherwise, returns 0.

►► DBVALIDATE — (— *string* —) ◄◄

Mixed string validation rules are:

- Only valid DBCS character codes
- DBCS string is an even number of bytes in length
- EBCDIC only: Proper SO and SI pairing.

In EBCDIC, if C is omitted, only the leftmost byte of each DBCS character is checked to see that it falls in the valid range for the implementation it is being run on (that is, in EBCDIC, the leftmost byte range is from X'41' to X'FE').

EBCDIC examples

z= 'abc<de'

```
DBVALIDATE('ab<.A.B>')      -> 1
DBVALIDATE(z)                 -> 0
```

y='C1C20E111213140F'X

```
DBVALIDATE(y)          -> 1
DBVALIDATE(y, 'C')     -> 0
```

DBWIDTH

DBWIDTH returns the length of *string* in bytes.

➤ DBWIDTH — (— *string* — , — *option* —) ➤

The *option* controls the counting rule. Y counts SO and SI within mixed strings as one each. N does not count the SO and SI and is the default.

EBCDIC examples

```
DBWIDTH('ab<.A.B>', 'Y')    ->    8
DBWIDTH('ab<.A.B>', 'N')    ->    6
```

Chapter 34. Reserved keywords and special variables

You can use keywords as ordinary symbols in many situations where there is no ambiguity.

The precise rules are given here.

There are three special variables: RC, RESULT, and SIGL.

Reserved keywords

The free syntax of REXX implies that some symbols are reserved for the language processor's use in certain contexts. In specific instructions, some symbols might be reserved to separate the parts of the instruction. These symbols are referred to as keywords.

Examples of REXX keywords are the WHILE in a DO instruction and the THEN (which acts as a clause terminator in this case) following an IF or WHEN clause.

Apart from these cases, only simple symbols that are the first token in a clause and that are not followed by an = or : are checked to see if they are instruction keywords. You can use the symbols freely elsewhere in clauses without their being taken as keywords.

It is not, however, recommended for users to run host commands or commands with the same name as REXX keywords (QUEUE, for example). This can create problems for programmers whose REXX programs might be used for some time and in circumstances outside their control, and who want to make the program absolutely *watertight*.

In this case, a REXX program can be written with (at least) the first words in command lines enclosed in quotation marks, for example:

```
'SCRNINFO'
```

This also has the advantage of being more efficient, and, with this style, you can use the SIGNAL ON NOVALUE condition to check the integrity of an exec.

An alternative strategy is to precede such command strings with two adjacent quotation marks, which concatenates the null string on to the front, for example:

```
''SCRNINFO
```

A third option is to enclose the entire expression (or the first symbol) in parentheses, for example:

```
(SCRNINFO)
```

The choice of any strategy is a personal one by the programmer. The REXX language does not impose it.

Special variables

RC, RESULT, and SIGL are special variables.

There are three special variables that the language processor can set automatically:

RC

is set to the return code from any run host command (or subcommand). Following the SIGNAL events, SYNTAX, ERROR, and FAILURE, RC is set to the code appropriate to the event: the syntax error number (see [Chapter 31, "Error numbers and messages,"](#) on page 413 or the command return code. RC is unchanged following a NOVALUE or HALT event.

Note: Host commands run manually from debug mode do not change the value of RC.

RESULT

is set by a RETURN instruction in a subroutine that has been called if the RETURN instruction specifies an expression. If the RETURN instruction has no expression on it, RESULT is dropped (becomes uninitialized.)

SIGL

contains the line number of the clause currently executing when the last transfer of control to a label took place. (A SIGNAL, a CALL, an internal function invocation, or a trapped error condition could cause this.)

None of these variables has an initial value. You can alter them, just as with any other variable, and the PROCEDURE and DROP instructions affect these variables in the usual way.

Certain other information is always available to a REXX program. This includes the name that the program was called and the source of the program (which is available using the PARSE SOURCE instruction; see [“PARSE” on page 176](#)). PARSE SOURCE output consists of the string CICS followed by the call type, the name of the exec in uppercase, the name of the file, and the PDS or DDNAME/member being run. These are followed by the name by which the program was called and the initial (default) command environment.

In addition, PARSE VERSION (see [“PARSE” on page 176](#)) makes available the version and date of the language processor code that is running. The built-in functions TRACE and ADDRESS return the current trace setting and environment name, respectively.

You can obtain the current settings of the NUMERIC function by using the DIGITS, FORM, and FUZZ built-in functions.

Chapter 35. Debug aids

This section describes the interactive debugging of problems, interrupting execution, and controlling tracing.

Interactive debugging of programs

The debug facility permits interactively controlled execution of a program.

Changing the TRACE action to one with a prefix ? (for example, TRACE ?A or the TRACE built-in function) turns on interactive debug and indicates to the user that interactive debug is active. Further TRACE instructions in the program are ignored, and the language processor pauses after nearly all instructions that are traced at the console (see the following for the exceptions). When the language processor pauses, indicated by a READ in the lower corner of the screen, three debug actions are available:

1. Entering a null line (with no characters, even blanks) makes the language processor continue execution until the next pause for debug input. Repeatedly entering a null line, therefore, steps from pause point to pause point. For TRACE ?A, for example, this is equivalent to single-stepping through the program.
2. Entering an equal sign (=) with no blanks makes the language processor rerun the clause last traced. For example: if an IF clause is about to take the wrong branch, you can change the value of the variable(s) on which it depends, and then rerun it.

Once the clause has been rerun, the language processor pauses again.

3. Anything else entered is treated as a line of one or more clauses, and processed immediately (that is, as though DO; line; END; had been inserted in the program). The same rules apply as in the INTERPRET instruction (for example, DO-END constructs must be complete). If an instruction has a syntax error in it, a standard message is displayed and you are prompted for input again. Similarly all the other SIGNAL conditions are disabled while the string is processed to prevent unintentional transfer of control.

During execution of the string, no tracing takes place, except that nonzero return codes from host commands are displayed. Host commands are always run (that is, are not affected by the prefix ! on TRACE instructions), but the variable RC is not set.

Once the string has been processed, the language processor pauses again for further debug input unless a TRACE instruction was entered. In this latter case, the language processor immediately alters the tracing action (if necessary) and then continues executing until the next pause point (if any). To alter the tracing action (from All to Results, for example) and then rerun the instruction, you must use the built-in function TRACE (see "TRACE" on page 217). For example, CALL TRACE I changes the trace action to I and allows re-execution of the statement after which the pause was made. Interactive debug is turned off, when it is in effect, if a TRACE instruction uses a prefix, or at any time when a TRACE 0 or TRACE with no options is entered.

You can use the numeric form of the TRACE instruction to allow sections of the program to be run without pause for debug input. TRACE n (that is, positive result) allows execution to continue, skipping the next n pauses (when interactive debug is or becomes active). TRACE -n (that is, negative result) allows execution to continue without pause and with tracing inhibited for n clauses that would otherwise be traced.

The trace action selected by a TRACE instruction is saved and restored across subroutine calls. This means that if you are stepping through a program (say after using TRACE ?R to trace Results) and then enter a subroutine in which you have no interest, you can enter TRACE 0 to turn tracing off. No further instructions in the subroutine are traced, but on return to the caller, tracing is restored.

Similarly, if you are interested only in a subroutine, you can put a TRACE ?R instruction at its start. Having traced the routine, the original status of tracing is restored and (if tracing was off on entry to the subroutine) tracing (and interactive debug) is turned off until the next entry to the subroutine.

Because any instructions can be run in interactive debug, you have considerable control over execution.

Note: While in interactive debug, pauses might occur because of PULL statements as well as because of interactive debug. For programs containing PULL statements, it is important to be aware of the reason for each pause. In programs, PULL statements are often paired with SAY statements. The user should enter the data for the PULL at the pause after the trace line for the PULL (the pause specifically for entering data for the PULL). The user should not enter the data at the pause after the corresponding SAY statement (this is an interactive debug pause).

Note: Some clauses cannot safely be re-run, and, therefore, the language processor does not pause after them, even if they are traced. These are:

- Any repetitive DO clause, on the second or subsequent time around the loop.
- All END clauses (not a useful place to pause in any case).
- All THEN, ELSE, OTHERWISE, or null clauses.
- All RETURN and EXIT clauses.
- All SIGNAL and CALL clauses (the language processor pauses after the target label has been traced).
- Any clause that raises a condition that CALL ON or SIGNAL ON traps (the pause takes place after the target label for the CALL or SIGNAL has been traced).
- Any clause that causes a syntax error. (These may be trapped by SIGNAL ON SYNTAX, but cannot be re-run.)

Examples

```
Say expr      /* displays the result of evaluating the      */
              /* expression.                               */

name=expr     /* alters the value of a variable.                */

Trace 0       /* (or Trace with no options) turns off                */
              /* interactive debug and all tracing.                  */

Trace ?A      /* turns off interactive debug but continues            */
              /* tracing all clauses.                                  */

Trace L       /* makes the language processor pause at labels         */
              /* only. This is similar to the traditional            */
              /* "breakpoint" function, except that you              */
              /* do not have to know the exact name and              */
              /* spelling of the labels in the program.            */

exit          /* stops execution of the program.                      */

Do i=1 to 10; say stem.i; end
              /* displays ten elements of the array stem.          */
```

Interrupting execution and controlling tracing

You can use standard CICS facilities to interrupt a REXX exec (the REXX transaction).

If properly authorized, you can issue the CEMT SET TASK PURGE command to halt an exec. For more information, see [CEMT SET TASK](#).

Chapter 36. Basic mapping support example

This example shows the procedure to use the CICS basic mapping support (BMS) in the REXX/CICS environment.

1. BMS maps must be assembled and linked into a CICS library. This library must be in the LIBDEF in the CICS region startup JCL.
2. If you are going to use the REXX/CICS CONVTMAP command to generate a file structure, the BMS map must be assembled to produce the map DSECT.
3. BMS maps must be defined to CICS using Resource Definition Online (RDO).
4. If you want to read from or send data to the screen, you need to GETMAIN CICS storage for the length of the map input/output areas. The storage must be initialized to nulls.
5. If a field within a file structure is represented by more than one label, then the last label to reference that field in the structure must be used when referencing the field.

This example uses BMS map PANELG. The map definition is as follows.

```
TITLE 'PANEL GROUP FOR REXX/CICS' 00000010
PRINT ON,NOGEN 00000020
PANELG DFHMSD TYPE=MAP,LANG=ASM,MODE=INOUT,STORAGE=AUTO,SUFFIX= 00000030
        TITLE 'TEST PANEL FOR REXX/CICS' 00000040
DPANEL1 DFHMDI SIZE=(24,80),CTRL=(FREEKB),MAPATTS=(COLOR,HILIGHT), *00000050
        DSATTS=(COLOR,HILIGHT),COLUMN=1,LINE=1,DATA=FIELD, *00000060
        TIOAPFX=YES,OBFT=NO 00000070
        DFHMDI POS=(1,1),LENGTH=1,ATTRB=(PROT,BRT) 00000080
        DFHMDI POS=(5,27),LENGTH=22,INITIAL='REXXCICS HEADER PANEL1', *00000090
        ATTRB=(PROT,NORM) 00000100
        DFHMDI POS=(5,73),LENGTH=6,INITIAL='PANEL1',ATTRB=(PROT,NORM) 00000110
        DFHMDI POS=(9,6),LENGTH=25, *00000120
        INITIAL='PLEASE ENTER YOUR USERID:',ATTRB=(PROT,NORM) 00000130
* DUSERID 00000140
DUSERID DFHMDI POS=(9,32),LENGTH=8,ATTRB=(UNPROT,BRT,IC,FSET) 00000150
        DFHMDI POS=(9,41),LENGTH=1,ATTRB=(PROT,NORM) 00000160
        DFHMDI POS=(14,6),LENGTH=4,INITIAL='MSG:',ATTRB=(PROT,NORM) 00000170
* DMSG 00000180
DMSG DFHMDI POS=(14,11),LENGTH=29,ATTRB=(UNPROT,NORM,FSET) 00000190
        DFHMDI POS=(14,41),LENGTH=1,ATTRB=(PROT,NORM) 00000200
        DFHMSD TYPE=FINAL 00000210
END 00000220
```

The map DSECT is as follows. The DSECT is in an MVS PDS named USER.REXXCICS.MAPS(PANELG).

```
DS      0H      ENSURE ALIGNMENT
DPANEL1S EQU *      START OF MAP DEFINITION

00015 ***** BOTTOM OF DATA*****

```

The following example is exec BMSMAP1. It creates a simple panel that asks for a user ID.

```

/* This EXEC uses CICS SEND and RECEIVE commands */
/* The panel has two fields USERID and a message */
/* field. The panel is initially displayed with */
/* a message - "USERID must be 8 characters" */

/* GETMAIN storage to be used for data mapping */
/* and initialize */
'PSEUDO OFF'
ZEROES = '00'x
'CICS GETMAIN SET(WORKPTR) LENGTH(90) INITIMG(ZEROES)'

VAR1 = 'USERID must be 8 characters'

/* Copy the REXX variable VAR1 to the GETMAINED storage */
'COPYR2S VAR1 WORKPTR 30'

/* Copy the storage area to REXX variable */
'COPYS2R WORKPTR X 0 90'

'CICS SEND MAP(PANELG) FREEKB ERASE FROM(X)'
'CICS RECEIVE MAP(PANELG) INTO(Y)'

/* Copy Y into the GETMAINED storage area and then copy the data */
/* to REXX variables using the file structure generated */
/* previously by the CONVTPMAP command */
'COPYR2S Y WORKPTR 0 90'
'COPYS2R WORKPTR * POOL1:\USERS\USER1\PANELG.DATA'

/* loop until the user enters a USERID exactly 8 characters in */
/* length */
do forever
MUSERID = STRIP(DUSERIDO)
if LENGTH(MUSERID) < 8 then
do
DMSGO = 'Please enter 8 char USERID'
'COPYR2S * WORKPTR POOL1:\USERS\USER1\PANELG.DATA'
'COPYS2R WORKPTR X 0 90'
'CICS SEND MAP(PANELG) FREEKB ERASE FROM(X)'
'CICS RECEIVE MAP(PANELG) INTO(Z)'
'COPYR2S Z WORKPTR 0 90'
'COPYS2R WORKPTR * POOL1:\USERS\USER1\PANELG.DATA'
END
ELSE LEAVE
END
'SENDE'
say ' '

```

```
say 'Hello' DUSERID0', Welcome to REXX/CICS !!'  
exit
```

The BMSMAP1 exec created the following panels.

```
                REXX/CICS HEADER PANEL1                PANEL1  
PLEASE ENTER YOUR USERID:  
MSG: USERID must be 8 characters
```

```
                REXX/CICS HEADER PANEL1                PANEL1  
PLEASE ENTER YOUR USERID: TEST  
MSG: Please enter 8 character USERID
```

Chapter 37. Bibliography

Where to find more information

You can find more information about CICS TS and REXX in the following information:

- [Application development reference](#) contains information about the application programming commands.
- [Reference: system programming](#) contains information about the system programming commands.
- *The REXX Language, A Practical Approach to Programming*, by M. F. Cowlshaw offers general information about the REXX language.
- [CICS supplied transactions descriptions](#) contains information about CEMT and CEDA.
- [z/OS MVS Programming: Assembler Services Guide](#).
- [z/OS MVS Programming: Assembler Services Reference ABE-HSP](#).
- [z/OS MVS Programming: Assembler Services Reference IAR-XCT](#).

These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Programming interface information

This book is intended to help you write programs for the REXX/CICS interpreter. This book primarily documents General-use Programming Interface and Associated Guidance Information provided by REXX for Customer Information Control System (REXX for CICS). General-use programming interfaces allow the customer to write programs that obtain the services of REXX for CICS. However, this book also documents Product-sensitive Programming Interface and Associated Guidance Information provided by REXX for CICS. Product-sensitive programming interfaces allow the customer installation to perform tasks such as diagnosing, modifying, monitoring, repairing, tailoring, or tuning of REXX for CICS. Use of such interfaces creates dependencies on the detailed design or implementation of the IBM software product.

Product-sensitive programming interfaces should be used only for these specialized purposes. Because of their dependencies on detailed design and implementation, it is to be expected that programs written to such interfaces might need to be changed in order to run with new product releases or versions, or as a result of service.

Product-sensitive Programming Interface and Associated Guidance Information is identified where it occurs by an introductory statement to a chapter or section.

A

abuttal [29](#), [146](#)
action taken when a condition is not trapped [250](#)
action taken when a condition is trapped [250](#)
active loops [173](#)
ADDRESS instruction
 example [8](#)
address setting [161](#), [163](#)
advanced topics in parsing [233](#)
algebraic precedence [149](#)
ALLOC command [352](#)
alphanumeric checking with DATATYPE [201](#)
AND, logical operator [148](#)
ANDing character strings together [196](#)
ARBCHAR command [258](#)
ARG instruction [15](#), [75](#)
ARG option of PARSE instruction [176](#)
ARGS command [258](#)
arithmetic [239](#)
arithmetic operator
 type of [21](#)
assembler program
 command arguments passed [310](#)
associative storage [152](#)
assumption, XEDIT [11](#)
AUTH command [287](#)
AUTHUSER command [121](#), [122](#), [127](#), [352](#)
automatic server initiation (ASI) [323](#)

B

backslash, use of [141](#), [147](#)
BACKWARD command [259](#)
Base option of DATE function [202](#)
basic mapping support (BMS) [159](#), [371](#)
BASSM assembler instruction [310](#)
bits checked using DATATYPE [201](#)
blank line [10](#)
blanks, treatment of [85](#)
BMS example [477](#)
BMSMAP1 exec [477](#)
BOTTOM command [259](#)
bottom of program reached during execution [170](#)
BSM assembler instruction [310](#)
BY phrase of DO instruction [166](#)

C

C2S command [310](#), [323](#), [376](#)
CALL instruction [51](#), [68](#)
CANCEL command [260](#), [276](#)
CASE command [260](#)
CATMOUSE EXEC [104](#)
CD command [156](#), [255](#), [286](#), [353](#), [382](#)
CEDA command [354](#)
CEMT command [355](#)

Format the RFS Filepools [118](#)

FORWARD command [268](#)

FREE command [393](#)

free format

- REXX instruction [6](#)

fully qualified file ID [255](#)

function

- comparison to a subroutine [63](#)

- protecting a variable [73](#)

functions [191](#)

FUZZ function [207](#)

G

general concepts [139](#)

GET command [268](#)

GETDIR command [291](#)

GETPDS command [269](#)

GETVERS command [393](#)

greater than operator [147](#)

greater than or equal operator (\geq) [147](#)

greater than or less than operator ($><$) [147](#)

grouping instructions to run repetitively [166](#)

guard digit [241](#)

H

HALT condition of SIGNAL and CALL instructions [249](#), [252](#)

Halt Interpretation (HI) immediate command [475](#)

halt, trapping [249](#)

HELLO EXEC [11](#)

HELP command [394](#)

host command environment [92](#)

hours calculated from midnight [216](#)

I

identifying users [219](#)

implied semicolons [144](#)

IMPORT command [394](#)

imprecise numeric comparison [244](#)

inclusive OR operator [27](#), [148](#)

indefinite loops [166](#)

indentation during tracing [185](#)

INDEX [207](#)

indirect evaluation of data [172](#)

inequality, testing of [147](#)

infinite loops [166](#)

input

- preventing translation to uppercase [16](#)

INPUT command [270](#)

inserting a string into another [208](#)

Install resource definitions [115](#)

instruction

- PROCEDURE [73](#)

- SAY [5](#)

instrumentation facility interface (IFI) [315](#)

interactive debug [185](#), [475](#)

interpretive execution of data [172](#)

interrupt instructions [50](#)

J

JOIN command [270](#)

Julian option of DATE function [202](#)

justification, text right, RIGHT function [213](#)

justifying text with JUSTIFY function [208](#)

L

LEAVE instruction [49](#)

leaving your program [170](#)

LEFT command [270](#)

less than operator ($<$) [147](#)

less than or equal operator (\leq) [147](#)

less than or greater than operator ($<>$) [147](#)

LIFO (last-in/first-out) stacking [181](#)

line length and width of terminal [210](#)

LINEADD command [271](#)

LINEIN option of PARSE instruction [176](#)

LISTCMD command [396](#)

LISTPOOL command [396](#)

LISTTRNID command [397](#)

literal string [6](#), [141](#)
