version 6 release 2

# **TCP/IP LDAP Administration Guide**

version 6 release 2

#### Note:

Before using this information and the product it supports, read the information under "Notices" on page 375.

This edition applies to version 6, release 2, modification 0 of IBM z/VM (product number 5741-A07) and to all subsequent releases and modifications until otherwise indicated in new editions.

This edition replaces SC24-6236-00.

Ι

Considerations in the use of Modify DN operations	
Concurrency considerations between Modify DN operations and other LDAP	
operations.	. 47
Access control and ownership	
Relocating an entry	
Relocating an entry with DN realignment requested	
Access control changes	
Ownership changes	
Modify DN operations related to suffix DNs	
Scenario constraints	
Example scenarios	
Modify DN operations and replication.	
Initial validation of compatible server versions in consumer and replica servers	
Periodic validation of compatible server versions in basic replication replicas	
Loss of basic replication synchronization because of incompatible replica	
server versions	. 62
Loss of basic replication synchronization because of incompatible replica	
server versions - recovery	. 62
Chapter 5. Accessing RACF information	
SDBM authorization	
Binding using a RACF user ID and password or password phrase	
Binding with SDBM using password policy.	
SDBM group gathering	
Associating LDAP attributes to RACF fields	
Special usage of racfAttributes, racfConnectAttributes, racfResourceAttributes,	
and racfSetroptsAttributes	
RACF namespace entries	
SDBM schema information	
SDBM support for special characters.	
Control of access to RACF data	
SDBM operational behavior	
SDBM search capabilities	
Retrieving RACF user password and password phrase envelopes	
Using SDBM to change a user password or password phrase in RACF	
Using LDAP client utilities with SDBM	
Deleting attributes.	. 90
Chapter 6. Password policy	
Password policy entries.	
Activating password policy.	
Password policy attributes.	
Password policy evaluation	
Evaluation of a user's individual and composite group password policy	103
Effective password policy examples	
Password policy operational attributes	
PasswordPolicy control	
Replicating password policy operational attributes	
Password policy related extended operations	
Overriding password policy and unlocking accounts	
Unlocking or unexpiring the account of the LDAP administrator	
Password policy examples	
Global password policy example	
Group password policy example	114

I I L L Т I Τ Т 1 T I L I L L

   	Individual password policy example
1	<b>Chapter 7. CRAM-MD5 and DIGEST-MD5 authentication</b>
Ì	DIGEST-MD5 authentication.
	CRAM-MD5 and DIGEST-MD5 configuration option
	Example of setting up for CRAM-MD5 and DIGEST-MD5
	Chapter 8. Static, dynamic, and nested groups
	Static groups
	Dynamic groups
	Nested groups
	Determining group membership
	Displaying group membership
	ACL restrictions on displaying group membership
	ACL restrictions on group gathering
	Group examples
	Examples of adding, modifying, and deleting group entries
	Examples of querying group membership.
	Chapter 9. Using access control
	Access control attributes
	aclEntry attribute.
	aclPropagate attribute
	aclSource attribute
	entryOwner attribute
	ownerPropagate attribute.
	ownerSource attribute
1	ACL filters
	Initializing ACLs with LDBM.
	Default ACLs with LDBM.
	Initializing ACLs with GDBM
I	Initializing ACLs with CDBM.
	Initializing ACLs with schema entry
	Access determination
	Access determination examples
	Search
	Filter
	Compare
	Requested attributes
1	Querying effective permissions
	Propagating ACLs
	Example of propagation
	Examples of overrides
	Other examples
	Access control groups.
	Associating DNs, access groups, and additional bind and directory entry
I	access information with a bound user
	Deleting a user or a group
	Retrieving ACL information from the server
	Creating and managing access controls
	Creating an ACL

	Modifying an ACL
	Deleting an ACL
	Creating an owner for an entry
	Modifying an owner for an entry
	Deleting an owner for an entry
	Creating a group for use in ACLs and entry owner settings
I	Chapter 10. Basic replication
	ibm-entryuuid replication
	Complex modify DN replication
I	Password encryption and basic replication
	Replicating server
	Replica entries
	Adding replica entries in LDBM
	Searching a replica entry.
I	Displaying basic replication status
I	Basic replication maintenance mode
	Replica server
	Populating a replica.
	Configuring the replica
	LDAP update operations on read-only replicas.
	Changing a read-only replica to a master
I	Basic peer to peer replication
	Server configuration
I	Basic replication conflict resolution
	Adding a peer replica to an existing server
	Upgrading a read-only replica to be a peer replica of the master server 180
	Downgrading a peer server to read-only replica
I	SSL/TLS and basic replication
	Replica server with SSL/TLS enablement
	Replicating server with SSL/TLS enablement
I	Basic replication error log
	Troubleshooting basic replication
I	Recovering from basic replication out-of-sync conditions
I	Chapter 11. Advanced replication
I	Advanced replication terminology
I	Replication topology
I	Advanced replication overview
I	Master-replica replication.
I	Forwarding (cascading) replication
I	Peer-to-peer replication
I	Gateway replication.
I	Advanced replication features
I	Partial replication
I	Replication scheduling.
I	Replication conflict resolution
I	Enabling advanced replication
I	Supplier server entries
I	Replication contexts
1	Replica groups
1	Replica subentries
1	Replication agreements
1	Credentials entries
1	Schedule entries
1	Consumer server entries

Things to consider before configuring advanced replica								
Advanced replication configuration examples								
Suppliers and consumers								208
Server ID								209
Advanced replication related entries summary								209
Creating a master-replica topology								211
Creating a peer-to-peer replication topology								215
Creating a master-forwarder-replica (cascading) topo								
Creating a gateway topology								
Replication topology hints and tips								
Replication of schema and password policy updates .								
Protecting replication topology entries								
Unconfiguring advanced replication								
Advanced replication maintenance mode								
Partial replication								
Replication filter examples								
SSL/TLS and advanced replication								
Replica server with SSL/TLS enablement.								
Replicating server with SSL/TLS enablement								
Displaying advanced replication configuration								
Command line tasks for managing replication								
Advanced replication related extended operations .								
Viewing replication configuration information								
Monitoring and diagnosing advanced replication problem	ms							240
Recovering from advanced replication errors								243
Advanced replication error recovery example								246
Chapter 12. Alias	 	· ·	•	•		•	 	251 252
Alias entry rules								
Dereferencing an alias								
Dereferencing during search								
Alias examples			•	•		•		254
Chapter 13. Change logging								
Configuring the GDBM backend								
Configuring a file-based GDBM backend								260
Additional required configuration								260
When changes are logged								261
RACF changes								261
LDBM, CDBM, and schema changes								261
Change log schema								261
Change log entries								262
Searching the change log								
Passwords in change log entries								
Unloading and loading the change log.								
Trimming the change log.								
Change log information in the root DSE entry								
How to set up and use the LDAP server for logging cha								
The to set up and use the LDAF server for logging that	ange	з.	•	•	•	•	• •	205
Chapter 14. Referrals								260
Using the referral object class and the ref attribute								
Creating referral entries								
Associating servers with referrals.								
Pointing to other servers								
	• •	• •	•	•	•	•	• •	210

I I I I I I L I L L L ۱ I L T I I I T I I Ι

Processing referrals	
Using LDAP Version 2 refer	rrals
	rals
	rrals
Example: associating servers t	through referrals and basic replication 274
Chapter 15. Organizing the d	lirectory namespace.
	rise directory namespace
Priming the directory servers v	with information
	sent LDAP entries
Setting up for replication	
	ver
Preparing the replica	
Notifying users of the replication	a
	<b>tions</b>
	e scope
	ree scope (null-based subtree search) 296
	oport
	rsion 2 protocol
	rned in lowercase
Abandon benavior	
Chanter 17 CCL Cartificate/k	(a) Management and CCI Tracing Information 200
Koy Databasa Filos	Key Management and SSL Tracing Information 299
SSI Tracing Information	
SSL Tracing Information

## About this document

This document is about administering the Lightweight Directory Access Protocol (LDAP) server on z/VM, which includes tasks such as:

- · Setting up schemas
- Modifying DN operations
- · Accessing security information and authenticating
- · Using access control
- · Replication directories
- · Creating aliases
- · Configuring change logs
- · Setting up referrals
- Organizing the directory namespace.

#### Intended audience

This document is intended to assist Lightweight Directory Access Protocol (LDAP) administration. This document is also intended for anyone who implements the directory service.

To do LDAP administration, you should be experienced in and have previous knowledge of directory services. You should have a good understanding of the TCP/IP in general and how z/VM implements the TCP/IP protocol suite. Also, you should understand the Lightweight Directory Access Protocol (LDAP).

#### **Conventions and terminology**

This topic describes important terminology and style conventions used in this document.

#### How the term "internet" is used in this document

In this document, an internet is a logical collection of networks supported by routers, gateways, bridges, hosts, and various layers of protocols, which permit the network to function as a large, virtual network.

**Note:** The term "internet" is used as a generic term for a TCP/IP network, and should not be confused with the Internet, which consists of large national backbone networks (such as MILNET, NSFNet, and CREN) and a myriad of regional and local campus networks worldwide.

#### How to Read Syntax Diagrams

This section describes how to read the syntax diagrams in this document.

*Getting Started:* To read a syntax diagram, follow the path of the line. Read from left to right and top to bottom.

- The ►►— symbol indicates the beginning of a syntax diagram.
- The → symbol, at the end of a line, indicates that the syntax diagram continues on the next line.
- The ►— symbol, at the beginning of a line, indicates that a syntax diagram continues from the previous line.

Syntax items (for example, a keyword or variable) may be:

- Directly on the line (required)
- Above the line (default)
- Below the line (optional).

Syntax Diagram Description	Example							
Abbreviations:								
Uppercase letters denote the shortest acceptable abbreviation. If an item appears entirely in uppercase letters, it cannot be abbreviated.	►►KEYWOrd►◄							
You can type the item in uppercase letters, lowercase letters, or any combination.								
In this example, you can enter KEYWO, KEYWOR, or KEYWORD in any combination of uppercase and lowercase letters.								
Symbols:	* Asterisk							
You must code these symbols exactly as they appear in	: Colon							
the syntax diagram.	, Comma							
	= Equal Sign							
	- Hyphen							
	() Parentheses							
	. Period							
Variables:								
Highlighted lowercase items (like this) denote variables.	►►—KEYWOrd— <i>var_name</i>							
In this example, <i>var_name</i> represents a variable you must specify when you code the KEYWORD command.								
Repetition:								
An arrow returning to the left means that the item can be repeated.	►► repeat							
A character within the arrow means you must separate repeated items with that character.	▶ repeat							
A footnote (1) by the arrow references a limit that tells how many times the item can be repeated.	(1) repeat Notes:							
	1 Specify <i>repeat</i> up to 5 times.							

Syntax Diagram Description	Example
Required Choices:	
When two or more items are in a stack and one of them is on the line, you <i>must</i> specify one item.	►► A → ■ A → ► A → ■ A
In this example, you must choose A, B, or C.	
Optional Choice:	
When an item is below the line, the item is optional. In this example, you can choose A or nothing at all.	
When two or more items are in a stack below the line, all of them are optional. In this example, you can choose A, B, C, or nothing at all.	►AB C
Defaults:	
Defaults are above the line. The system uses the default unless you override it. You can override the default by coding an option from the stack below the line.	► B 
In this example, A is the default. You can override A by choosing B or C.	
Repeatable Choices:	
A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item.	► A
In this example, you can choose any combination of A, B, or C.	
Syntax Fragments:	
Some diagrams, because of their length, must fragment the syntax. The fragment name appears between vertical bars in the diagram. The expanded fragment appears in the diagram after a heading with the same fragment	► A Fragment A Fragment:
name. In this example, the fragment is named "A Fragment."	

### Where to Find More Information

Other z/VM manuals contain information about LDAP:

- For information about configuring the LDAP server, see *z/VM: TCP/IP Planning and Customization*.
- LDAP client utilities are documented in *z/VM: TCP/IP User's Guide*.
- Information about LDAP messages is in *z/VM: TCP/IP Messages and Codes*.

Appendix E, "Abbreviations and Acronyms," on page 371, lists the abbreviations and acronyms that are used throughout this document.

The "Glossary" on page 379, defines terms used throughout this document that are associated with TCP/IP communication in an internet environment.

For more information about related publications, see the documents listed in the "Bibliography" on page 381.

#### Links to Other Online Documents

The online version of this document contains links to other online documents. These links are to editions that were current when this document was published. However, due to the nature of some links, if a new edition of a linked document has been published since the publication of this document, the linked document might not be the latest edition. Also, a link from this document to another document works only when both documents are in the same directory.

## How to send your comments to IBM

We appreciate your input on this publication. Feel free to comment on the clarity, accuracy, and completeness of the information or give us any other feedback that you might have.

Use one of the following methods to send us your comments:

- 1. Send an email to mhvrcfs@us.ibm.com.
- Go to IBM z/VM Reader's Comments (www.ibm.com/systems/z/os/zvm/ zvmforms/webqs.html).
- Mail the comments to the following address: IBM Corporation Attention: MHVRCFS Reader Comments Department H6MA, Building 707 2455 South Road Poughkeepsie, NY 12601-5400 U.S.A.
- Fax the comments to us as follows: From the United States and Canada: 1+845+432-9405 From all other countries: Your international access code +1+845+432-9405

Include the following information:

- Your name and address
- Your email address
- Your telephone or fax number
- The publication title and order number:
  - z/VM V6R2 TCP/IP LDAP Administration Guide SC24-6236-01
- · The topic name or page number related to your comment
- The text of your comment

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

IBM or any other organizations will use the personal information that you supply only to contact you about the issues that you submit to IBM.

#### If you have a technical problem

Do not use the feedback methods listed above. Instead, do one of the following:

- Contact your IBM service representative.
- Contact IBM technical support.
- See IBM: z/VM Service Resources (www.ibm.com/vm/service/).
- Go to IBM Support Portal (www.ibm.com/support/entry/portal/Overview/).

## Summary of changes

This document contains terminology, maintenance, and editorial changes. Technical changes are indicated by a vertical line to the left of the change. Some product changes might be provided through service and might be available for some prior releases.

#### SC24-6236-01, z/VM Version 6 Release 2

This edition includes changes or additions to support the general availability of z/VM<sup>®</sup> V6.2. Changes have been made for information about new functions in LDAP that are equivalent to the IBM<sup>®</sup> Tivoli<sup>®</sup> Directory Server for z/OS<sup>®</sup> at the z/OS 1.12 level. Those new functions are:

- Enhanced replication
- CDBM backend
- Access to RACF<sup>®</sup> resource profiles
- Password policy
- Mapping of RACF responses to password policy responses for native and SDBM authentication
- Using access control
- · Schema updates
- Salted SHA
- Activity log enhancements
- LDAPEXOP utility.

Client reason codes and return codes have been moved from this manual to *z/VM: TCP/IP Messages and Codes.* 

#### SC24-6236-00, z/VM Version 6 Release 1

This edition includes changes or additions to support the general availability of z/VM V6.1. For this edition, the following changes have been made:

- A clarification was added to the LDAP Program Call support. See "Additional required configuration" on page 260.
- Reference information for the gskkyman and gsktrace utilities has been moved to *z/VM: TCP/IP User's Guide*.

# Chapter 1. Introducing the LDAP server

	The z/VM Lightweight Directory Access Protocol (LDAP) server is based on a client/server model that provides client access to an LDAP server. An LDAP directory provides an easy way to maintain directory information in a central location for storage, update, retrieval, and exchange.
	<ul> <li>The LDAP server provides the following functions:</li> <li>Interoperability with any Version 2 or Version 3 LDAP directory client</li> <li>Access controls on directory information, using static, dynamic, and nested groups</li> </ul>
	<ul> <li>Secure Sockets Layer (SSL) communication (SSL V3 and TLS V1)</li> <li>Start TLS (Transport Layer Security) activation of secure communication</li> <li>Client and server authentication using SSL/TLS</li> </ul>
	<ul><li>Password encryption or hashing</li><li>Password policy</li><li>Basic replication</li></ul>
I	<ul> <li>Advanced replication</li> <li>Referrals</li> <li>Aliases</li> <li>Change logging</li> </ul>
	<ul> <li>LDAP Version 2 and Version 3 protocol support</li> <li>Schema publication and update</li> <li>Native authentication</li> </ul>
	<ul> <li>CRAM-MD5 (Challenge-Response Authentication Method) and DIGEST-MD5 authentication</li> <li>Root DSE information</li> <li>LDAP access to information stored in RACF</li> <li>Plug-in support to extend the LDAP server.</li> </ul>

#### What is a directory service?

A directory is like a database, but tends to contain more descriptive, attribute-based information. The information in a directory is generally read much more often than it is written. As a consequence, directories do not usually implement the complicated transaction or rollback schemes that relational databases use for doing high-volume complex updates. Directory updates are typically simple all-or-nothing changes, if they are allowed at all. Directories are tuned to give quick-response to high-volume lookup or search operations. They may have the ability to replicate information widely in order to increase availability and reliability, while reducing response time. When directory information is replicated, temporary inconsistencies between the replicas are considered acceptable, as long as they get in sync eventually.

There are many different ways to provide a directory service. Different methods allow different kinds of information to be stored in the directory, place different requirements on how that information can be referenced, queried and updated, how it is protected from unauthorized access, and so on. Some directory services are local, providing service to a restricted context (for example, the finger service on a single machine). Other services are global, providing service to a much broader context (for example, the entire Internet). Global services are usually distributed, meaning that the data they contain is spread across many machines, all of which cooperate to provide the directory service. Typically a global service defines a uniform namespace which gives the same view of the data no matter where you are in relation to the data itself.

#### What is LDAP?

The LDAP server's model for the directory service is based on a global directory model called LDAP, which stands for the Lightweight Directory Access Protocol. LDAP Version 2 (V2) and LDAP Version 3 (V3), both supported in z/VM, are directory service protocols that run over TCP/IP. The details of LDAP V2 are defined in Internet Engineering Task Force (IETF) Request for Comments (RFC) 1777, *The Lightweight Directory Access Protocol*, and the details of LDAP V3 are defined in IETF RFCs 2251 through 2256. For a list of supported RFCs, see Appendix D, "Related Protocol Specifications," on page 365.

This section gives an overview of LDAP from a user's perspective.

#### How is information stored in the directory?

The LDAP directory service model is based on *entries*. An entry is a collection of attributes that has a name, called a *distinguished name* (DN). The DN is used to refer to the entry unambiguously. Each of the entry's attributes has a type and one or more values. The types are typically mnemonic strings, like **cn** for common name, or **mail** for e-mail address. The values depend on what type of attribute it is. For example, a **mail** attribute might contain an e-mail address with an attribute value of thj@vnet.ibm.com. A **jpegPhoto** attribute would contain a photograph in binary JPEG format.

#### How is the information arranged?

In LDAP, directory entries are arranged in a hierarchical tree-like structure that sometimes reflects political, geographic or organizational boundaries. Entries representing countries appear at the top of the tree. Below them are entries representing states or national organizations. Below them might be entries representing people, organizational units, printers, documents, or just about anything else you can think of. Figure 1 on page 3 shows an example LDAP directory tree.

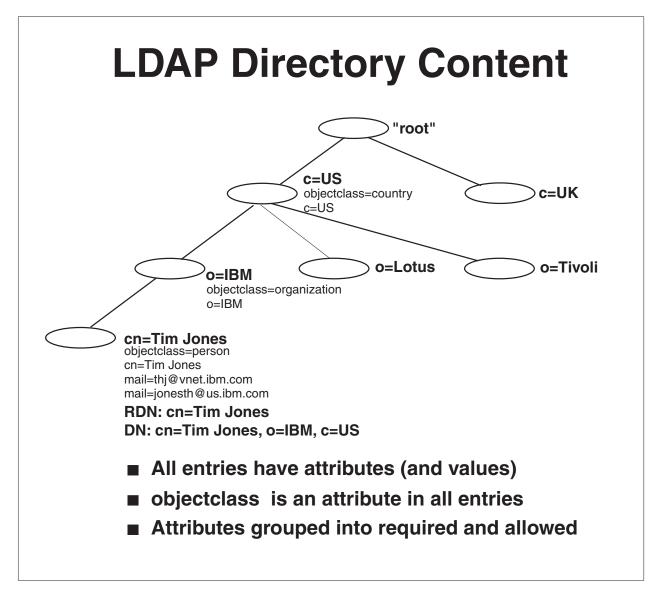

Figure 1. Directory hierarchy example

In addition, LDAP allows you to control which attributes are required and allowed in an entry through the use of a special attribute called *object class*. The values of the **objectClass** attribute determine the attributes that can be specified in the entry.

#### How is the information referenced?

An entry is referenced by its distinguished name, which is constructed by taking the name of the entry itself (called the *relative distinguished name*, or RDN) and concatenating the names of its ancestor entries. For example, the entry for Tim Jones in the example above has an RDN of cn=Tim Jones and a DN of cn=Tim Jones, o=IBM, c=US. The full DN format is described in IETF RFC 2253, *LDAP* (*V3*): *UTF-8 String Representation of Distinguished Names*.

The LDAP server supports different naming formats. While naming based on country, organization, and organizational unit is one method, another method is to name entries based on an organization's registered DNS domain name. Names of this form look like: cn=Tim Smith,dc=vnet,dc=ibm,dc=com. These naming formats can be mixed as well, for example: cn=Tim Brown,ou=Sales,dc=ibm,dc=com.

#### How is the information accessed?

LDAP defines operations for interrogating and updating the directory. Operations are provided for adding an entry to, and deleting an entry from, the directory, changing an existing entry, and changing the name of an entry. Most of the time, though, LDAP is used to search for information in the directory. The LDAP search operation allows some portion of the directory to be searched for entries that match some criteria specified by a search filter. Information can be requested from each entry that matches the criteria. The LDAP compare operation allows a value to be tested in an entry without returning that value to the client.

An example of search is, you might want to search the entire directory subtree below IBM for people with the name Tim Jones, retrieving the e-mail address of each entry found. LDAP lets you do this easily. Or you might want to search the entries directly below the c=US entry for organizations with the string Acme in their name, and that have a FAX number. LDAP lets you do this too. The section "How does LDAP work?" describes in more detail what you can do with LDAP and how it might be useful to you.

#### How is the information protected from unauthorized access?

LDAP client requests can be performed using an anonymous identity or the LDAP bind operation can be used to supply an authentication identity. The LDAP server can use the identity to perform authorization checking when accessing entries in the directory. An Access Control List (ACL) provides a means to protect information stored in an LDAP directory. An ACL is used to restrict access to different portions of the directory, to specific directory entries, or to information within an entry. Access control can be specified for individual users or for groups. This authentication process can be used by distributed applications which need to implement some form of authentication.

#### How does LDAP work?

LDAP directory service is based on a client/server model. One or more LDAP servers contain the data making up the LDAP directory tree. An LDAP client application connects to an LDAP server using LDAP APIs and asks it a question. The server responds with the answer, or with a pointer to where the application can get more information (typically, another LDAP server). With a properly-constructed namespace, no matter which LDAP server an application connects to, it sees the same view of the directory; a name presented to one LDAP server references the same entry it would at another LDAP server. This is an important feature of a global directory service, which LDAP servers can provide.

#### What about X.500?

LDAP was originally developed as a front end to X.500, the OSI directory service. X.500 defines the Directory Access Protocol (DAP) for clients to use when contacting directory servers. DAP has been characterized as a heavyweight protocol that runs over a full OSI stack and requires a significant amount of computing resources to run. LDAP runs directly over TCP and provides most of the functionality of DAP at a much lower cost.

An LDAP server is meant to remove much of the burden from the server side just as LDAP itself removed much of the burden from clients. If you are already running an X.500 service and you want to continue to do so, you can probably stop reading this guide, which is all about running LDAP through an LDAP server without running X.500. If you are not running X.500, want to stop running X.500, or have no immediate plans to run X.500, read on.

#### What are the capabilities of the z/VM LDAP server?

You can use the z/VM LDAP server to provide a directory service of your very own. Your directory can contain just about anything you want to put in it. Some of the z/VM LDAP server's more interesting features and capabilities include:

- Multiple concurrent database instances (referred to as backends). The LDAP server can be configured to serve multiple databases at the same time. This means that a single z/VM LDAP server can respond to requests for many logically different portions of the LDAP tree. A z/VM LDAP server can be configured to provide access to RACF, as well as store application-specific information.
- **Robust general-purpose databases**. The LDAP server comes with an LDBM backend. There are no restrictions on the types of information that this backend can contain. The LDBM backend keeps its entries in memory for quick access and requires a minimum amount of setup. When the LDAP server is not running, LDBM stores its directory information in Byte File System (BFS) files.
- Access to RACF data. The LDAP server can be configured to provide read/write access to RACF user, group, connection, and general resource profiles using the LDAP protocol. The LDAP server can also be used to manage RACF options that affect classes. The LDAP server's access to RACF is managed by an additional configurable backend called SDBM. For more information, see Chapter 5, "Accessing RACF information," on page 65.
  - **Note:** To use SDBM for ONLY authentication (LDAP bind processing), any security manager implementing the SAF service required by the \_\_\_**passwd()** function call can be used. To use SDBM for accessing and updating user, group, connection, and resource profile information, and to set class options, RACF is required.
- Configuration backend.

I

|

Т

L

Т

I

I

L

1

I

|

Т

The LDAP server can be configured with a CDBM backend. The CDBM backend is used to store configuration information. For more information, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*.

- Access control. The LDAP server provides a rich and powerful access control facility, allowing you to control access to the information in your database or databases. You can control access to entries based on LDAP authentication information, including users and groups. Group membership can be either static, dynamic, or nested. Access control is configurable down to individual attributes within entries. Also, access controls can be set up to explicitly deny access to information. For more information on access control, see Chapter 9, "Using access control," on page 135. For more information about groups, see Chapter 8, "Static, dynamic, and nested groups," on page 123.
- **Threads**. The LDAP server is threaded for optimal performance. A single multi-threaded z/VM LDAP server process handles all incoming requests, reducing the amount of system overhead required.
- **Basic replication**. The LDAP server can be configured to maintain replica copies of its database. Master/consumer replication scheme is vital in high-volume environments where a single LDAP server just does not provide the necessary availability or reliability. Peer-to-peer replication is also supported. For more information, see Chapter 10, "Basic replication," on page 169. This feature is contrasted with multiple concurrent servers.
- Advanced replication. The LDAP server can be configured to act as a supplier, consumer, cascading, or gateway server in an advanced replication environment. An advanced replication environment allows for only certain subtrees in an LDBM

or CDBM backend to be replicated to other servers. For more information, see Chapter 11, "Advanced replication," on page 185.

- **Referrals**. The LDAP server provides the ability to refer clients to additional directory servers. Using referrals you can distribute processing overhead, distribute administration of data along organizational boundaries, and provide potential for widespread interconnection beyond an organization's own boundaries. For more information, see Chapter 14, "Referrals," on page 269.
- Aliases. An alias entry can be created in the directory to point to another entry in the directory. During search operations, an alias entry can provide a convenient public name for an entry or subtree, hiding the more complex actual name of the entry or subtree. It can also avoid the need to duplicate an entry in multiple subtrees. For more information, see Chapter 12, "Alias," on page 251.
- **Change Logging**. The LDAP server can be configured to create change log entries in the GDBM backend. Each change log entry contains information about a change to an entry in an LDBM or CDBM backend, to the LDAP server schema, or to a RACF user, group, connection, or resource profile. For more information, see Chapter 13, "Change logging," on page 259.
- **Configuration**. The LDAP server is highly configurable through a single configuration file which allows you to change just about everything you would ever want to change. Configuration options have reasonable defaults, making your job much easier. For more information, see "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.
- Secure communications. The LDAP server can be configured to encrypt data to and from LDAP clients using SSL. The LDAP server supports the Start TLS extended operation to switch a non-secure connection to a secure connection. It has a variety of ciphers for encryption to choose from, all of which provide server and optionally client authentication through the use of X.509 certificates. For more information, see "Setting up for SSL/TLS" in *z/VM: TCP/IP Planning and Customization*.
- Native authentication. The z/VM LDAP server allows clients to bind to entries in an LDBM or CDBM backend by using the system for verifying the authentication attempt. The client can perform a simple bind supplying an LDAP DN of an entry in an LDBM or CDBM backend along with a security manager-maintained password. Password authentication is then performed by the security manager. For more information, see "Native authentication" in z/VM: TCP/IP Planning and Customization.
  - **Note:** To use native authentication, any security manager implementing the SAF service required by the \_\_passwd() function call can be used.
- LDAP Version 3 protocol support. The LDAP server provides support for Version 3 of the LDAP protocol in addition to the LDAP Version 2 protocol. Version 3 includes:
  - All protocol operations
  - Implicit bind
  - Certificate (or Simple Authentication and Security Layer) bind
  - Version 3 referrals
  - Aliases
  - Controls
  - Root DSE support
  - Internationalization (UTF-8) support
  - Modify name supported for all entries including subtree move
  - Schema publication
  - Additional syntax support
  - Online schema update capability.

|

T

I

L

L

T

T

- **Dynamic schema**. The LDAP server allows the schema to be changed dynamically through the LDAP protocol. For more information, see Chapter 3, "LDAP directory schema," on page 15.
- Internationalization (UTF-8) support. The LDAP server allows storage, update and retrieval, through LDAP operations, of national language data using LDAP Version 3 protocol. For more information, see "Internationalization Support" in *z/VM: TCP/IP Planning and Customization*.
- SASL external bind and client and server authentication. The LDAP server allows client applications to use a certificate when communicating with the server using SSL/TLS communications. In order to use a certificate on bind, the server must be configured to perform both client and server authentication. This configuration ensures both entities are who they claim to be. For more information, see "Setting up for SSL/TLS" in *z/VM: TCP/IP Planning and Customization*.
- SASL CRAM-MD5 and DIGEST-MD5 authentication. The LDAP server allows clients to bind to the server using DIGEST-MD5 (RFC 2831) and CRAM-MD5 (Challenge-Response Authentication Method RFC 2195) authentication bind methods. For more information, see Chapter 7, "CRAM-MD5 and DIGEST-MD5 authentication," on page 119.
- Support for root DSE. The LDAP server supports search operations, including subtree search, against the root of the directory tree as described in IETF RFC 2251, *The Lightweight Directory Access Protocol (V3)*. The so-called Root DSE can be accessed using LDAP V3 search operations. For more information, see "Root DSE" on page 291.
- Extended group membership searching. The LDAP server supports extended group membership searching which allows the LDAP server to find a DN that may be a member of static and nested groups in a backend (LDBM or CDBM) where the DN does not reside. The LDAP server can find the group memberships for the DNs in the other backends that are configured. For more information about the **extendedGroupSearching** configuration file option, see "extendedGroupSearching" in *z/VM: TCP/IP Planning and Customization*.
- Supported server controls. The LDAP server supports the following: authenticateOnly Do Not Replicate IBMModifyDNRealignDNAttributesControl IBMModifyDNTimelimitControl IBMSchemaReplaceByValueControl manageDsalT No Replication Conflict Resolution PasswordPolicy PersistentSearch Refresh Entry replicateOperationalAttributes Replication Supplier ID Bind Server Administration

For more information, see Appendix B, "Supported server controls," on page 337.

For more information about extended operations, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

 Attribute encryption. The LDAP server supports encryption of the values of several critical attributes to prevent unauthorized access to these attribute values in LDBM and CDBM backends. The attributes that can be encrypted are as follows:

ibm-replicaKeyPwd ibm-slapdMasterPw replicaCredentials secretKey userPassword

For more information, see "Configuring for Encryption or Hashing" in *z/VM: TCP/IP Planning and Customization*.

- **Multiple socket ports**. The LDAP server can be configured to listen for secure and nonsecure connections from clients on one or more IPv4 or IPv6 interfaces on a system. With the **listen** configuration option on the LDAP server, the hostname or the IPv4 or IPv6 address, along with the port number, can target one or multiple IPv4 or IPv6 interfaces on a system. For more information, see "listen" in *z/VM: TCP/IP Planning and Customization*.
- **Persistent search**. The LDAP server provides an event notification mechanism for applications, directories, and meta directories that need to maintain a cache of directory information or to synchronize directories when changes are made to an LDAP directory. Persistent search will allow these applications to be notified when a change has occurred. For more information, see Appendix B, "Supported server controls," on page 337.
- **ibm-entryuuid** attribute. The LDAP server now generates a unique identifier for any entry that is created or modified and does not already have a unique identifier assigned. The unique identifier is stored in the **ibm-entryuuid** attribute. The **ibm-entryuuid** attribute is replicated to servers that support the **ibm-entryuuid** attribute. To configure the **serverEtherAddr** option in the LDAP server configuration file, see "serverEtherAddr" in *z/VM: TCP/IP Planning and Customization*.
- ibm-entryCheckSum and ibm-entryCheckSumOp attributes. The LDAP server supports the querying of a checksum of all non-operational attributes with the ibm-entryCheckSum operational attribute. The LDAP server also supports the ibm-entryCheckSumOp operational attribute, which is a checksum of the following operational attributes: aclEntry, aclPropagate, entryOwner, ownerPropagate, creatorsName, modifiersName, createTimestamp, modifyTimestamp, and ibm-entryuuid.
- **ibm-allMembers** and **ibm-allGroups**. The LDAP server now supports the querying of the members of static, dynamic, and nested groups in an LDBM or CDBM backend by using the **ibm-allMembers** operational attribute. The LDAP server also supports the querying of the static, dynamic, and nested groups that a user belongs to with the **ibm-allGroups** operational attributes.
- **Plug-in support**: The LDAP server can be configured with extensions called plug-ins. The plug-ins are supplied by other products or created by you. Plug-ins are invoked before, during, or after the LDAP server processes a client request. For more information on configuring a plug-in, see "Configuring the LDAP Server"

in *z/VM: TCP/IP Planning and Customization*. For information about creating a plug-in, see *z/VM: TCP/IP Programmer's Reference*.

• Extended operations utility.

I

I

L

L

I

L

I

The LDAPEXOP utility provides a command line interface for the following extended operations: **Cascading control replication**, **Control replication error log**, **Control replication queue**, **Quiesce or unquiesce context**, and **Replication topology**. For more information, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

• **Password policy**. The LDAP server supports password policy, which is a set of rules that control how passwords are defined, used, and administered. For more information, see Chapter 6, "Password policy."

## Chapter 2. Data model

The LDAP data model is closely aligned with the X.500 data model. In this model, a directory service provides a hierarchically organized set of *entries*. Each of these entries is represented by an *object class*. The object class of the entry determines the set of *attributes* which are required to be present in the entry as well as the set of attributes that can optionally appear in the entry. An attribute is represented by an *attribute type* and one or more *attribute values*. In addition to the attribute type and values, each attribute has an associated *syntax* which describes the format of the attribute values. Examples of attribute syntaxes for LDAP directory include directory string and binary.

To summarize, the directory is made up of entries. Each entry contains a set of attributes. These attributes can be single or multi-valued (have one or more values associated with them). The object class of an entry determines the set of attributes that must exist and the set of attributes that may exist in the entry.

Every entry in the directory has a *distinguished name (DN)*. The DN is the name that uniquely identifies an entry in the directory. A DN is made up of attribute=value pairs, separated by commas. For example:

cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US

The order of the component attribute=value pairs is important. The DN contains one component for each level of the directory hierarchy. LDAP directory DNs begin with the most specific attribute (typically some sort of name), and continue with progressively broader attributes, often ending with a country attribute.

#### **Relative distinguished names**

I

I

1

I

L

L

|

Each component of a DN is referred to as a *relative distinguished name (RDN)*. It identifies an entry distinctly from any other entries which have the same parent. In the examples above, the RDN cn=Ben Gray separates the first entry from the second entry, (with RDN cn=Lucille White). The attribute=value pair or pairs making up the RDN for an entry must also be present as an attribute=value pair or pairs in the entry. This is not true of the other components of the DN. The LDBM and CDBM backends add the attribute=value pairs in the RDN to the entry if they are not already present.

RDNs can contain multiple attribute=value pairs. So-called multivalued RDNs use two or more attribute=value pairs from the directory entry to define the name of the entry relative to its parent. An example where this would be useful would be where a directory hierarchy of users was being defined for a large university. This hierarchy would be segmented by campus. A problem is encountered, however, when it is discovered that there is more than one John Smith at the downtown campus. The RDN cannot simply be the name of the user. What can be done, however, is to add a unique value to the RDN, therefore, ensuring its uniqueness across the campus. Typically universities hand out serial numbers to their students. Coupling the student number with the person's name is one method of solving the problem of having a unique RDN under a parent in the directory hierarchy. The entry's RDN might look something like:

cn=John Smith+studentNumber=123456.

The plus sign (+) is used to delimit separate attribute=value pairs within an RDN. The entry's DN might look like:

cn=John Smith+studentNumber=123456, ou=downtown, o=Big University, c=US

Any attribute can be used to make up an RDN except:

- attributes with binary syntax, UTC time syntax, or generalized time syntax.
  - **Note:** The **userPassword** attribute is binary, therefore, it cannot appear in an RDN. Time stamp attributes use one of the time syntaxes, therefore, they cannot appear in an RDN.
- attributes that are marked NO-USER-MODIFICATION in the schema, because these attributes cannot be added to an entry by a user.
- the aclEntry, aclPropagate, entryOwner, and ownerPropagate attributes.

#### Distinguished name syntax

The Distinguished Name (DN) syntax supported by this server is based on IETF RFC 2253 *LDAP (v3): UTF-8 String Representation of Distinguished Names.* A semicolon (;) character may be used to separate RDNs in a distinguished name, although the comma (,) character is the typical notation. A plus sign (+) is used to separate attribute=value pairs in an RDN.

White space (blank) characters may be present on either side of the comma or semicolon. The white space characters are ignored, and the semicolon replaced with a comma.

In addition, space characters may be present between an attribute=value pair and a plus sign (+), between an attribute type and an equal sign (=), and between an equal sign (=) and an attribute value. These space characters are ignored when parsing.

A value may be surrounded by quotation marks, which are not part of the value. Inside the quoted value, the following characters can occur without any escaping:

- A space or pound sign (#) character occurring at the beginning of the string
- A space character occurring at the end of the string
- One of the characters
  - apostrophe (')
  - equal sign (=)
  - plus sign (+)
  - backslash (\)
  - less than sign (<)</li>
  - greater than sign (>)
  - semicolon (;)

Alternatively, a single character to be escaped may be prefixed by a backslash (\). This method may be used to escape any of the characters listed above, plus the quotation mark. Pound signs (#) and space characters that do not occur at the beginning of a string can also be escaped, but this is not required.

This notation is designed to be convenient for common forms of name. This section gives a few examples of distinguished names written using this notation. First is a name containing three components:

OU=Sales+CN=J. Smith,O=Widget Inc.,C=US

This example shows a method of escaping a comma in an organization name:

CN=R. Smith,O=Big Company\, Inc.,C=US

# Domain component naming

Domain component naming as specified by RFC 2247 is also supported in the LDAP server. For example, the domain name ibm.com could be specified as an entry in the LDAP server with the following distinguished name: dc=ibm,dc=com

# **RACF-style distinguished names**

If you are using SDBM (the RACF database backend of the LDAP server), the format of the DNs is restricted in order to match the schema of the underlying RACF data.

A RACF-style DN for a user or group contains two required attributes plus a suffix:

racfid Specifies the user ID or group ID.

#### profiletype

Specifies user or group.

suffix Specifies the SDBM suffix.

A RACF-style DN for a user's connection to a group contains three required attributes plus a suffix:

#### racfuserid+racfgroupid

Specifies the user and the group.

#### profiletype

Specifies connect.

*suffix* Specifies the SDBM suffix.

A RACF-style DN for a general resource profile contains two required attributes plus a suffix:

#### profilename

I

1

L

|

1

I

Specifies the name of the resource profile. The case of the name is important if the class containing the resource profile supports mixed case names.

#### profiletype

The name of the class containing the resource profile.

suffix Specifies the SDBM suffix.

The suffix for SDBM may contain additional attributes. For example, if the suffix has been specified as:

suffix cn=myRACF,c=US

in the LDAP configuration file, any RACF-style DN would end with: cn=myRACF,c=US

Following is DN format and a sample DN for a user:

racfid=userid,profiletype=user,suffix
racfid=ID1,profiletype=user,cn=myRACF,c=US

Following is the DN format and a sample DN for a connection: racfuserid=userid+racfgroupid=groupid,profiletype=connect,suffix racfuserid=ID1+racfgroupid=GRP1,profiletype=connect,cn=myRACF,c=US

1	Following is the DN format and a sample DN for a resource profile:
	profilename= <i>resourcename</i> ,profiletype= <i>classname</i> , <i>suffix</i>
	profilename=ABC.KEN,profiletype=FACILITY,cn=myRACF,c=US

# Chapter 3. LDAP directory schema

The LDAP Version 3 (V3) protocol, as defined in IETF RFC 2252 *Lightweight Directory Access Protocol (v3): Attribute Syntax Definitions* and IETF RFC 2256 *A Summary of the X.500(96) User Schema for use with LDAPv3*, describes schema publication and update. Schema publication provides the ability to query the active directory schema through the use of the LDAP search function. Schema update is the ability to change the schema while the directory server is running.

#### Note:

I

I

L

L

I

I

I

• The z/VM LDAP server implements both schema publication and update. The schema is stored as an entry in the database and search (publication) and modify (update) operations may be performed on this entry. The distinguished name of the schema entry is cn=schema.

The **schemaPath** option in the LDAP server configuration file defines the location where the LDAP server will save the schema entry. The default is **/var/ldap/schema**. This directory should be backed up as part of the normal system backup procedure since the loss of the schema directory will invalidate all existing directory entries.

- When the z/VM LDAP server is first started, the server supplies an initial schema. This initial schema is sufficient for usage of the SDBM, CDBM (with configuration related entries), and GDBM backends, but needs to be updated for usage of LDBM and CDBM with user defined entries. The initial schema elements cannot be deleted and can be modified only in limited ways. For the contents of the initial schema, see Appendix A, "Initial LDAP server schema," on page 317.
- Access to the schema entry is controlled by an access control list (ACL), even if the LDAP server is in maintenance mode. All requests to access the schema entry except those from the LDAP administrator are subject to ACL checking. In particular for a basic replica server, requests from the masterServerDN or peerServerDN are subject to access control. The default ACL allows all users to display the schema but only the LDAP administrator can update the schema. This ACL can be modified. See Chapter 9, "Using access control" for more information.

# Setting up the schema for LDBM and CDBM

The LDAP server is shipped with two predefined schema files representing schema definitions that the user might want to load into the LDAP server schema when using LDBM or CDBM. These files are USRSCHEM LDIF and IBMSCHEM LDIF and are located on the TCPMAINT 591 disk.

Determine which of these schema files, if any, could be used to represent the data to be stored in the LDBM or CDBM database, or locate or create other schema files to use. Note that the IBMSCHEM LDIF schema definitions require that the definitions contained in USRSCHEM LDIF are loaded prior to loading IBMSCHEM LDIF.

Use the LDAPMDFY command to load the schema. For example, the commands to load the USRSCHEM LDIF and IBMSCHEM LDIF schema files would be similar to:

ldapmdfy -h *ldaphost* -p *ldapport* -D *adminDN* -w *passwd* -f //usrschem.ldif ldapmdfy -h *ldaphost* -p *ldapport* -D *adminDN* -w *passwd* -f //ibmschem.ldif

For more information about LDAPMDFY, see z/VM: TCP/IP User's Guide.

I	Notes:
	<ol> <li>Check that schemaReplaceByValue off is not specified in the global section of the LDAP server configuration file, or send the IBMSchemaReplaceByValueControl control with a value of TRUE on the modify request. This control can be sent by specifying the -u option on the LDAPMDFY utility. For more information about the schemaReplaceByValue configuration option, see "Configuring the LDAP Server" in <i>z/VM: TCP/IP</i> <i>Planning and Customization.</i> For more information about the IBMSchemaReplaceByValueControl control, see "IBMSchemaReplaceByValueControl" on page 339.</li> </ol>
       	2. When the LDAP schema is modified using the USRSCHEM LDIF and IBMSCHEM LDIF files, each attribute and object class definition in the file replaces the existing definition in the schema. Any changes previously made in the schema to these attributes and object classes needs to be made again. This includes any changes that are allowed to attributes and object classes in the initial LDAP schema.

# Schema introduction

Entries in the directory are made up of attributes which consist of an attribute type and one or more attribute values. These are referred to as *attribute=value* pairs. Every entry contains one or more objectclass=*value* pairs that identify what type of information the entry contains. The object classes associated with the entry determine the set of attributes which must or may be present in the entry.

The z/VM LDAP server has a single schema for the entire server. This schema is stored as an entry whose distinguished name is cn=schema. Following is a portion of the schema entry.

```
cn=SCHEMA
subtreespecification=NULL
objectclass=TOP
objectclass=SUBSCHEMA
objectclass=SUBENTRY
objectclass=IBMSUBSCHEMA
...
attributetypes= ( 2.5.4.3 NAME ( 'cn' 'commonName' ) SUP name )
...
ibmattributetypes = ( 2.5.4.3 ACCESS-CLASS normal )
...
objectclasses = ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectclass )
...
ldapsyntaxes = ( 1.3.6.1.4.1.1466.115.121.1.15 DESC 'directory string' )
...
matchingrules = ( 2.5.13.5 NAME 'caseExactMatch' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
...
```

#### Figure 2. Sample Schema Entry

The objectClass values specified for the schema entry are top, subEntry, subSchema, and ibmSubschema. This set of object classes result in the objectClass, cn, and subtreeSpecification attributes being required for a schema entry and the attributeTypes, objectClasses, IdapSyntaxes, matchingRules, and IBMAttributeTypes attributes being allowed in a schema entry.

#### Note: The ditContentRules, ditStructureRules, nameforms, and matchingRuleUse attributes are allowed in a schema entry, but usage of these directives is not implemented by the z/VM LDAP server.

Every entry in the directory including the schema entry contains the **subschemaSubentry** attribute. The value shown for this attribute is the DN of the schema entry, cn=schema. Therefore, a search operation requesting the **subschemasubentry** for an entry always returns:

subschemasubentry=cn=schema

Attribute types, object classes, LDAP syntaxes, and matching rules have assigned unique numeric object identifiers. These numeric object identifiers are in dotted decimal format, for example, 2.5.6.6. Attribute types, object classes, and matching rules are also identified by a textual name, for example, person or names. The numeric object identifier and the textual names may be used interchangeably when an attribute type or object class definition specifies an object identifier. Most schema definitions use the textual name as the object identifier for these definitions.

**Note:** Non-numeric object identifiers, for example myattr-oid, can be used instead of numeric object identifiers.

The attributes that comprise a directory schema include attribute types, IBM attribute types, object classes, LDAP syntaxes, and matching rules. There is a fixed set of LDAP syntaxes and matching rules supported by the z/VM LDAP server. These are listed in Table 4, Table 5, and Table 6. Each of the schema attributes are described below:

Attribute types

Attribute types define the characteristics of the data values stored in the directory. Each attribute type defined in a schema must contain a unique numeric object identifier and optionally contain a textual name, zero or more alias names, and a description of the attribute type. The characteristics defined for each attribute type include the syntax, number of values, and matching rules.

The **SYNTAX** defines the format of the data stored for the attribute type. The server checks the attribute values that are to be added to the directory by comparing the values against the set of allowed characters based on the syntax. For example, if the syntax of an attribute type is Boolean (where the acceptable values are **TRUE** or **FALSE**) and the attribute value specified is **yes**, the update will fail. The syntaxes supported by the z/VM LDAP server are shown in Table 4 and Table 5.

Matching rules may be specified for **EQUALITY**, **ORDERING**, and **SUBSTR** (substring matching). The matching rule determines how comparisons between values are done. The **EQUALITY** matching rule determines if two values are equal. Examples of **EQUALITY** matching rules are **caseIgnoreMatch**, **caseExactMatch**, and **telephoneNumberMatch**. The **ORDERING** matching rule determines how two values are ordered (**greaterThanOrEqual**, **lessThanOrEqual**). Examples of **ORDERING** matching rules are

caselgnoreOrderingMatch and generalizedTimeOrderingMatch. The SUBSTR matching rule determines if the presented value is a substring of an attribute value from the directory. Examples of SUBSTR matching rules are caselgnoreSubstringsMatch and telephoneNumberSubstringsMatch.

If **EQUALITY**, **ORDERING**, or **SUBSTR** matching rules are not specified in the definition of an attribute type or through the inheritance hierarchy, the z/VM LDAP server will perform evaluations to the best of its ability, but the results may not be as expected. The z/VM LDAP server uses the matching rules shown in the

# following table based on attribute type syntax to evaluate **EQUALITY**, **ORDERING**, and **SUBSTR** if those matching rules are not specified.

Table 2. Syntax and acceptable matching rules (EQUALITY, ORDERING, and SUBSTR) (continued)

L

The syntax or matching rule values may be inherited by specifying a superior attribute type. This is done by specifying the keyword **SUP**, followed by the object identifier of the superior attribute type. This is known as an attribute type hierarchy and referred to as inheritance. A superior hierarchy may be created with multiple levels of inheritance. In the following partial example, ePersonName and personName would inherit their SYNTAX from name.

ePersonName SUP personName personName SUP name name SYNTAX 1.3.6.1.4.1.1466.115.121.1.15

When the SYNTAX, EQUALITY, ORDERING, or SUBSTR values are not specified for an attribute type, the attribute type hierarchy are used to determine these values. The SYNTAX must be specified on the attribute type or through inheritance.

The number of values that may be stored in each entry for an attribute type is limited to one value if the keyword **SINGLE-VALUE** is specified. Otherwise, any number of attribute values may exist in the entry.

The **OBSOLETE** keyword indicates that the attribute type cannot be used to add data to existing entries or to store data in new entries. Modifications to entries which contain data values of an attribute type which has been made obsolete will fail unless all data values for all obsolete attribute types are removed during the modification. Searches specifying the obsolete attribute type will return the entries containing the attribute type. If an obsolete attribute type is referred to in a superior hierarchy, the inherited values will continue to be resolved.

#### Example 1:

attributeTypes: ( 1.2.3.4 NAME 'obsattr1' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 OBSOLETE ) attributeTypes: ( 5.6.7.8 NAME 'validattr1' SUP obsattr1 )

would be the same as

attributeTypes: ( 5.6.7.8 NAME 'validattr' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )

#### Example 2:

1

attributeTypes: ( 50.60.70.80 NAME 'obsattr3'
    EQUALITY caseIgnoreMatch SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )
attributeTypes: ( 90.100.110.120 NAME 'validattr2' SUP obsattr2 )
```

would be the same as

attributeTypes: ( 90.100.110.120 NAME 'validattr2' EQUALITY caseIgnoreMatch SYNTAX 1.3.6.1.4.1.1466.115.121.1.26 )

The USAGE keyword's valid values are userApplications or one of three operational values (directoryOperation, distributedOperation, or dSAOperation). An attribute type which has an operational USAGE value is called an operational attribute. Operational attributes are treated differently than non-operational attributes. In particular, the value of an operational attribute type in an entry is only returned by a search operation if the attribute type is specified in the list of attributes to be returned. If a plus sign, '+', is specified in the list of attributes to be returned, then all operational attributes other than **ibm-allMembers, ibm-allGroups, ibm-entryCheckSum, ibm-entryCheckSumOp**, and hasSubordinates are returned on the search response, if the user is authorized to read those operational attributes. Also, operational attribute types do not have to belong to an object class. The default for USAGE is userApplications.

The z/VM LDAP server restricts users from modifying data values specified for an attribute type when **NO-USER-MODIFICATION** is specified on the definition of the attribute type. In general, **NO-USER-MODIFICATION** should only be specified for attribute types that are set by the server because they cannot be assigned a value by the user. Attribute types which are **NO-USER-MODIFICATION** can be modified during replication processing and when the LDAP server is in maintenance mode. See Chapter 10, "Basic replication" for more information.

- **Note:** The LDAP V3 protocol also defines a **COLLECTIVE** key word for attribute types. The LDAP server does not support this key word. All attribute types are assumed to be not **COLLECTIVE**.
- IBM attribute types

Additional information required by IBM LDAP servers for each attribute type defined in the schema is specified using the **IBMAttributeTypes** schema attribute. The **IBMAttributeTypes** schema attribute is an extension of the **attributeTypes** schema attribute. If the **attributeTypes** value is not defined, then the corresponding **IBMAttributeTypes** value cannot be defined. For the z/VM LDAP server, the additional information defined using this attribute is the **ACCESS-CLASS** of the associated attribute type.

**ACCESS-CLASS** specifies the level of access users have to data values of this attribute type. The levels that may be specified for user-defined attribute types are **normal**, **sensitive**, and **critical**. The **system** and **restricted** keywords are for LDAP server use and are specified for some of the attribute types controlled by the server. See "Attribute access classes" on page 138 for the definition of access classes.

# Note: Other LDAP servers from IBM use the **DBNAME** and **LENGTH** characteristics to specify additional information for their implementations. These may be specified in the schema but are not used by the z/VM LDAP server.

Object classes

Object classes define the characteristics of individual directory entries. The object classes listed in a directory entry determine the set of required and optional attributes for the entry. Each object class defined in a schema must contain a unique numeric object identifier and optionally contain a textual name, zero or more alias names, a description of the object class, and lists of required (**MUST**) or optional (**MAY**) attribute types.

Required and optional attribute types for an object class may be inherited by specifying one or more superior object classes in an object class definition. This is done by specifying the keyword **SUP** followed by the object identifiers of the superior object classes. This is known as an object class hierarchy and referred to as multiple inheritance. A superior hierarchy may be created with multiple levels of inheritance.

Each object class is defined as one of three types: **STRUCTURAL**, **ABSTRACT**, or **AUXILIARY**. The type can be specified when the object class is defined. If the type is not specified, it defaults to **STRUCTURAL**.

The structural object class defines the characteristics of a directory entry. Each entry must specify exactly one base structural object class. A base structural object class is defined as the most subordinate object class in an object class hierarchy. **The structural object class of an entry can not be changed.** Once an entry is defined in the directory, it must be deleted and recreated to change the structural object class.

Abstract and auxiliary object classes are used to provide common characteristics to entries with different structural object classes. Abstract object classes are used to derive additional object classes. Abstract object classes must be referred to in a structural or auxiliary superior hierarchy. Auxiliary object classes are used to extend the set of required or optional attribute types of an entry.

When using the keyword **SUP** to create an object class hierarchy, an auxiliary class should only specify superior object classes that are either auxiliary or abstract object classes. Similarly, a structural object class should only specify superior object classes that are either structural or abstract object classes. If these rules are not followed, the z/VM LDAP server might not be able to determine the base structural object class of the entry, resulting in the rejection of the entry.

An example of the relationship between structural, abstract, and auxiliary object classes is the schema entry shown in Figure 2. The schema entry specifies **top**, **subEntry**, **subSchema**, and **ibmSubschema** as object classes. The object classes form the following hierarchy:

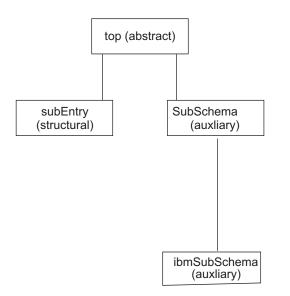

Figure 3. Object class hierarchy example

In this example, the **subEntry** object class is the base structural object class. The **OBSOLETE** keyword indicates that the object class cannot be used to define entries in the directory. When an object class is made obsolete, new entries specifying the obsoleted object class cannot be added to the directory and existing entries cannot be modified unless the obsolete object class is removed from the entries' object class list. When the obsolete object class is removed from the entry, any attributes in the entry that are associated only with that object class must also be removed. These changes must be made through the same modify operation. If an obsolete object class is specified in a superior hierarchy for a new entry, then attempts to add the entry to the LDAP directory will fail.

#### LDAP syntaxes

Each attribute type definition includes the LDAP syntax which applies to the values for the attribute. The LDAP syntax defines the set of characters which are allowed when entering data into the directory.

The z/VM LDAP server is shipped with predefined supported syntaxes. See Table 4 and Table 5 for the list of syntaxes supported by the z/VM LDAP server. The set of syntaxes cannot be changed, added to, or deleted by users.

#### Matching rules

Matching rules allow entries to be selected from the database based on the evaluation of the matching rule assertion. Matching rule assertions are propositions which may evaluate to true, false, or undefined concerning the presence of the attribute value or values in an entry.

The z/VM LDAP server is shipped with predefined supported matching rules. See Table 6 for the list of matching rules supported by the z/VM LDAP server. The set of matching rules cannot be changed, added to, obsoleted, or deleted by users.

# Schema attribute syntax

The attributes which are used in the schema entry use specific character representations in their values. These character representations are described in Table 3. The terms shown in this table are used in the schema attribute definitions in the next section.

Table 3. Character representations

Term	Definition			
noidlen	Represented as:			
	numericoid{length}			
	where <i>length</i> is a numeric string representing the maximum length of values of this attribute type.			
	Example:			
	1.3.6.1.4.1.1466.115.121.1.7{5}			
	Implementation note: The z/VM LDAP server allows values to be any length, regardless of the specification of a length in the attribute type definition. User installations that want to limit the length of values need to handle this during data input.			
numericoid	A dotted decimal string.			
	Example:			
	2.5.13.72 <b>Note:</b> A non-numeric object identifier, for example myattr-oid, can be used instead of a numeric object identifier.			
oid	A single object identifier. This may be specified either as a name or as a numeric object identifier.			
	Examples:			
	name 2.5.4.41			
oidlist	A list of object identifiers specified as names or numeric object identifiers separated by dollar signs (\$) within parentheses.			
	Example:			
	( cn \$ sn \$ postaladdress \$ 2.5.4.6 )			
oids	Either an <i>oid</i> or <i>oidlist</i> .			
qdescrs	A quoted description shown as ' <i>descr</i> ' for one and as (' <i>descr</i> ' ' <i>descr</i> ') for more than one. The description ( <i>descr</i> ) must have an alphabetic character as the first character, followed by any combination of alphabetic or numeric characters, the dash character (-), or the semicolon character (;). Each value must be in single quotation marks (').			
	If there is more than one value, they must be enclosed in parentheses.			
	Examples:			
	'x121address' ('cn' 'commonName') 'userCertificate;binary'			
	<b>Note:</b> Although the LDAP V3 protocol does not support an underscore character (_) as a valid character in a <i>descr</i> , the z/VM LDAP server allows the use of an underscore character to facilitate data migration. This use should be minimized whenever possible and may not be supported by other servers.			

Table 3. Character representations (continued)

Term	Definition
qdstring	A quoted descriptive string shown as ' <i>dstring</i> '. The descriptive string ( <i>dstring</i> ) is composed of one or more UTF-8 characters.
	Example: 'This is an example of a quoted descriptive string.'

# LDAP schema attributes

The five attributes used to define an LDAP schema are discussed below. For these schema attributes, the *numericoid* must be the first item in the definition. All other keywords and values may be in any order.

#### LDAP syntaxes

The set of syntaxes which are supported by the z/VM LDAP server cannot be modified, added to, or deleted by users. The descriptive material included here is for information aboutly.

The format of the LDAP syntaxes attribute in a dynamic schema is:

ldapSyntaxes: ( numericoid [DESC qdstring] )

#### numericoid

The unique, assigned numeric object identifier.

**DESC** *qdstring* 

Text description of the LDAP syntax

**Note:** LDAP syntaxes do not have a textual name. They are identified only by the numeric object identifier.

Following is an example of the definition of an LDAP syntax: ldapSyntaxes: (1.3.6.1.4.1.1466.115.121.1.7 DESC 'Boolean')

The LDAP syntaxes supported by the z/VM LDAP server fall into two categories. The first set, as shown in Table 4, would be used when defining attribute types that are used for directory data.

Table 4. Supported LDAP syntaxes - general use

Ι	Numeric object identifier	Description	Valid values
Ι	1.3.6.1.4.1.1466.115.121.1.5	Binary	Binary data
Τ	1.3.6.1.4.1.1466.115.121.1.6	Bit String	Bit data format (for example '0110'B)
Ι	1.3.6.1.4.1.1466.115.121.1.7	Boolean	TRUE, FALSE
Т	1.3.6.1.4.1.1466.115.121.1.8	Certificate	Binary data (no format checking)

Ι	1.3.6.1.4.1.1466.115.121.1.21	Enhanced Guide	UTF-8 characters (no format checking)

	Table 4.	Supported	LDAP	syntaxes	- general	use	(continued)
--	----------	-----------	------	----------	-----------	-----	-------------

Num	neric object identifier	Description	Valid values
1.3.6	6.1.4.1.1466.115.121.1.22	Facsimile Telephone Number	Printable string (alphabetic, digits, ', (, ), +, ,, -, ., /, :, ?, space) and \$ (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.23	Fax	Binary data (no format checking)
Note the I	6.1.4.1.1466.115.121.1.24 e: The effective time zone for LDAP server is assumed when ulating GMT from local time.	Generalized Time	yyyymmddhhmmss.ffffff (local time) yyyymmddhhmmss.ffffffZ (GMT) yyyymmddhhmmss.ffffff-hhmm (Time zone west) yyyymmddhhmmss.ffffff+hhmm (Time zone east) The seconds ( <i>ss</i> ) and microseconds ( <i>fffff</i> ) can
			be omitted and defaults to 0.
	6.1.4.1.1466.115.121.1.25	Guide	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.26	IA5 String	IA5 characters (commonly known as 7-bit ASCII)
1.3.6	6.1.4.1.1466.115.121.1.27	Integer	+/- 62 digit integer
1.3.6	6.1.4.1.1466.115.121.1.28	JPEG	Binary data (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.33	MHS OR Address	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.34	Name And Optional UID	Sequence of attribute type and value pairs
1.3.6	6.1.4.1.1466.115.121.1.36	Numeric String	List of space-separated numbers
1.3.6	6.1.4.1.1466.115.121.1.38	Object Identifier	Name or numeric object identifier
1.3.6	6.1.4.1.1466.115.121.1.39	Other Mailbox	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.40	Octet String	Octet data
1.3.6	6.1.4.1.1466.115.121.1.41	Postal Address	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.42	Protocol Information	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.43	Presentation Address	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.44	Printable String	Printable string (alphabetic, digits, ', (, ), +, ,, - ., /, :, ?, space)
1.3.6	6.1.4.1.1466.115.121.1.49	Supported Algorithm	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.50	Telephone Number	Printable string (alphabetic, digits, ', (, ), +, ,, - ., /, :, ?, and space) and "
1.3.6	6.1.4.1.1466.115.121.1.51	Teletex Terminal Identifier	UTF-8 characters (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.52	Telex Number	Printable string (alphabetic, digits, ', (, ), +, ,, - ., /, :, ?, space) and \$ (no format checking)
1.3.6	6.1.4.1.1466.115.121.1.53	UTC Time	Like Generalized Time above, but with a two-digit year specification (yy)

Values defined using the binary and octet string syntaxes are transferred in binary and do not consist of UTF-8 characters.

The second set of syntaxes defined by the z/VM LDAP server are used in the definition of the LDAP schema. These would not typically be used in user schema attribute type definitions. They are listed here for reference.

Table 5. Supported LDAP syntaxes - server use

Numeric object identifier	Description
1.3.6.1.4.1.1466.115.121.1.3	Attribute Type Description

1.3.6.1.4.1.1466.115.121.1.54	LDAP Syntax Description
1.3.6.1.4.1.1466.115.121.1.30	Matching Rule Description
1.3.6.1.4.1.1466.115.121.1.31	Matching Rule Use Description
1.3.6.1.4.1.1466.115.121.1.35	Name Form Description
1.3.6.1.4.1.1466.115.121.1.37	Object Class Description
1.3.6.1.4.1.1466.115.121.1.58	Substring Assertion

#### Matching rules

The set of matching rules which are supported by the z/VM LDAP server cannot be modified, added to, obsoleted, or deleted by users. The descriptive material included here is for information aboutly.

The format of the matching rules attribute in a dynamic schema is:

matchingRules: ( numericoid [NAME qdescrs] [DESC qdstring] [OBSOLETE] SYNTAX numericoid )

#### numericoid

The unique, assigned numeric object identifier.

#### NAME qdescrs

The name by which this matching rule is known.

#### **DESC** qdstring

Text description of the matching rule.

#### OBSOLETE

Indicates that the matching rule is obsolete.

#### SYNTAX numericoid

Specifies the numeric object identifier of the syntax for this matching rule.

Following is an example of the definition of a matching rule:

matchingRules: ( 2.5.13.5 NAME 'caseExactMatch' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )

The matching rules supported by the z/VM LDAP server is a fixed set as listed in the following table.

Ι	Name	Numeric object identifier	Assertion syntax
Ι	bitStringMatch	2.5.13.16	Bit String. Must have same length and bits set.
 	booleanMatch	2.5.13.13	Boolean. Both values are either TRUE or FALSE. Case is ignored.
   	caseExactIA5Match	1.3.6.1.4.1.1466.109.114.1	IA5 String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case must be the same.

#### Table 6. Supported matching rules (continued)

Name	Numeric object identifier	Assertion syntax
caseExactMatch	2.5.13.5	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case must be the same.
caseExactOrderingMatch	2.5.13.6	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case must be the same. Collating sequence is based on the UTF-8 representation.
caseExactSubstringsMatch	2.5.13.7	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case must be the same.
caseIgnoreIA5Match	1.3.6.1.4.1.1466.109.114.2	IA5 String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
caseIgnoreIA5SubstringsMatch	1.3.6.1.4.1.1466.109.114.3	IA5 String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
caseIgnoreListMatch	2.5.13.11	Postal Address. Leading and trailing whitespace ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
caseIgnoreListSubstringsMatch	2.5.13.12	Postal Address. Leading and trailing whitespace ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
caselgnoreMatch	2.5.13.2	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
caseIgnoreOrderingMatch	2.5.13.3	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored. Collating sequence is based on the UTF-8 representation.
caseIgnoreSubstringsMatch	2.5.13.4	Directory String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
certificateExactMatch	2.5.13.34	Certificate. Exact match of entire value.
certificateMatch	2.5.13.35	Certificate. Exact match of entire value.
distinguishedNameMatch	2.5.13.1	Distinguished Name. Each name must have the same number of RDN components and each attribute within each RDN must match using the EQUALITY rule for that attribute type.
distinguishedNameOrderingMatch	1.3.18.0.2.4.405	Distinguished Name. The normalized string representation of each name is compared. The collating sequence is based on the UTF-8 representation.
generalizedTimeMatch	2.5.13.27	Generalized Time. The value is normalized as yyyymmddhhmmss.fffffZ.
generalizedTimeOrderingMatch	2.5.13.28	Generalized Time. The value is normalized as yyyymmddhhmmss.ffffffZ.
IBM-EntryUUIDMatch	1.3.18.0.2.22.2	IBM Entry UUID. Hyphens are removed and a case-insensitive string comparison is performed.
integerFirstComponentMatch	2.5.13.29	Integer.

#### Table 6. Supported matching rules (continued)

Name	Numeric object identifier	Assertion syntax
integerMatch	2.5.13.14	Integer.
integerOrderingMatch	2.5.13.15	Integer.
numericStringMatch	2.5.13.8	Numeric String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank.
numericStringOrderingMatch	2.5.13.9	Numeric String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Perform string order processing. Collating sequence is based on the UTF-8 representation.
numericStringSubstringsMatch	2.5.13.10	Numeric String. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank.
objectIdentifierMatch	2.5.13.0	Object Identifier. The value is normalized as an attribute descriptor.
objectIdentifierFirstComponentMatch	2.5.13.30	Object Identifier. The value is normalized as an attribute descriptor.
octetStringMatch	2.5.13.17	Octet String. Both values must contain the same number of octets and each octet must have the same value.
octetStringOrderingMatch	2.5.13.18	Octet String. Perform string order processing. Collating sequence is based on the UTF-8 representation.
presentationAddressMatch	2.5.13.22	Presentation Address. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
protocolInformationMatch	2.5.13.24	Protocol Information. Leading and trailing whitespace is ignored. Embedded whitespace is replaced by a single blank. Case is ignored.
telephoneNumberMatch	2.5.13.20	Telephone Number
telephoneNumberSubstringsMatch	2.5.13.21	Telephone Number. The value is normalized using the telephoneNumberMatch rule.
uniqueMemberMatch	2.5.13.23	Name And Optional UID. Each name must have the same number of RDN components and each attribute within each RDN must match using the EQUALITY rule for that attribute type. The optional UID is considered part of the rightmost RDN.
utcTimeMatch	2.5.13.25	UTC Time. The value is normalized as yyyymmddhhmmss.fffffZ.

Notes<sup>®</sup> on matching rules:

- 1. An undefined attribute type within a distinguished name uses the directory string matching rules.
- 2. The **aclEntry** and **entryOwner** attribute types use the distinguished name matching rules for **access-id**, **group**, and **role** scopes of protection. The assertion value is just the DN portion of the attribute value. The matching rules used by **aclEntry** and **entryOwner** attribute types for the **aclFilter** and

I

1

L

**ownerFilter** scopes of protection are dependent on the filter attributes specified within the corresponding access control filter.

- 3. Attribute types with a binary transfer syntax cannot be used in a search filter but can be used in a compare operation.
- 4. The **ibm-allGroups** and **ibm-allMembers** attribute types cannot be used in a search filter. These are read-only operational attributes and will result in a FALSE match status when used in a search filter.
- The LDBM and CDBM backends ignore the ORDERING and SUBSTR matching rules and always use the EQUALITY matching rule when processing a search filter.

#### Attribute types

The format of the attribute types attribute in a dynamic schema is:

```
attributeTypes: ( numericoid [NAME qdescrs] [DESC qdstring] [OBSOLETE] [SUP oid]
[EQUALITY oid] [ORDERING oid] [SUBSTR oid] [SYNTAX noidlen] [SINGLE-VALUE]
[NO-USER-MODIFICATION] [USAGE attributeUsage] )
```

#### numericoid

|

L

The unique, assigned numeric object identifier.

#### NAME qdescrs

The name and alias names by which this attribute type is known. This is also known as the object identifier. The first name in the list is used as the base name and the other names are referred to as alias names. It is suggested the shortest name be listed first. If a name is not specified, the numeric object identifier is used to refer to the attribute type.

#### **DESC** qdstring

Text description of the attribute type.

#### OBSOLETE

Indicates that the attribute type is obsolete.

#### SUP oid

Specifies the superior attribute type. When a superior attribute type is defined, the **EQUALITY**, **ORDERING**, **SUBSTR**, and **SYNTAX** values may be inherited from the superior attribute type. The referenced superior attribute type must also be defined in the schema. When the **SYNTAX**, **EQUALITY**, **ORDERING**, or **SUBSTR** values are not specified for an attribute type, the attribute type hierarchy is used to determine these values. The **SYNTAX** must be specified on the attribute type or through inheritance.

#### EQUALITY oid

Specifies the object identifier of the matching rule which is used to determine the equality of values.

#### **ORDERING** oid

Specifies the object identifier of the matching rule which is used to determine the order of values.

#### SUBSTR oid

Specifies the object identifier of the matching rule which is used to determine substring matches of values.

#### SYNTAX noidlen

The syntax defines the format of the data stored for this attribute type. It is specified using the numeric object identifier of the LDAP syntax and, optionally, the maximum length of data stored for this attribute type.

Implementation note: The z/VM LDAP server allows values to be any length, regardless of the specification of a length in the attribute type definition. User installations that want to manage the lengths of values need to handle this when values are put into the directory.

#### SINGLE-VALUE

T

T

Т

Т

T

Т

1

T

Limits entries to only one value for this attribute type.

#### **NO-USER-MODIFICATION**

When specified, users may not modify values of this attribute type.

#### **USAGE** *attributeUsage*

Specify **userApplications** for *attributeUsage*. If **USAGE** is not specified, the default is **userApplications**.

The directoryOperation, distributedOperation, and DSAOperation keywords are used to create operational attributes. Operational attributes are treated differently than non-operational attributes. In particular, the value of an operational attribute type in an entry is only returned by a search operation if the attribute type is specified in the list of attributes to be returned. If a plus sign ('+') is specified in the list of attributes to be returned, then all operational attributes other than **ibm-allMembers**, **ibm-allGroups, ibm-entryCheckSum, ibm-entryCheckSumOp**, and **hasSubordinates** are returned on the search response, if the user is authorized to read those operational attributes. Also, operational attribute types do not have to belong to an object class.

Following are examples of the definition of attribute types:

#### **IBM** attribute types

The format of the IBM attribute types attribute in a dynamic schema is: **IBMAttributeTypes:** ( *numericoid* [ACCESS-CLASS *IBMAccessClass*] )

#### numericoid

The unique, assigned numeric object identifier of the associated attribute type.

#### ACCESS-CLASS ibmAccessClass

The level of sensitivity of the data values for this attribute type. The acceptable values are **normal**, **sensitive**, and **critical**. See "Attribute access classes" on page 138 for the definition of these values. The default attribute access class for an attribute is **normal**.

The **IBMAttributeTypes** schema element is an extension of the **attributeTypes** schema element. If the **attributeTypes** value is not defined, then the corresponding **IBMAttributeTypes** value cannot be defined.

Some schema elements are shipped with **ACCESS-CLASS** set to **restricted** or **system**. These values are used by the LDAP server. Other IBM LDAP servers may also specify **DBNAME**, **LENGTH**, and other keywords and values. These keywords are not used by the z/VM LDAP server and do not need to be specified when creating schemas. If they are specified in a schema used by the z/VM LDAP server, they are ignored.

Following is an example of the definition of an IBM attribute type: IBMAttributeTypes: (2.5.4.6 ACCESS-CLASS normal)

#### **Object classes**

The format of the object classes attribute in a dynamic schema is:

objectClasses: ( numericoid [NAME qdescrs] [DESC qdstring]

[OBSOLETE] [SUP oids] [ABSTRACT|STRUCTURAL|AUXILIARY] [MUST oids] [MAY oids] )

#### numericoid

The unique, assigned numeric object identifier.

#### **NAME** *qdescrs*

The name and alias names by which this object class is known. This is also known as the object identifier. The first name in the list is used as the base name. If name is not specified, the numeric object identifier is used to refer to the object class.

#### **DESC** qdstring

Text description of the object class.

#### OBSOLETE

Indicates that the object class is obsolete.

#### SUP oids

List of one or more superior object classes. When a superior object class is defined, entries specifying the object class must adhere to the superset of **MUST** and **MAY** values. The supersets of **MUST** and **MAY** values include all **MUST** and **MAY** values specified in the object class definition and all **MUST** and **MAY** values specified in the object class's superior hierarchy. When an attribute type is specified as a **MUST** in an object class in the hierarchy and a **MAY** in another object class in the hierarchy, the attribute type is treated as a **MUST**. Referenced superior object classes must be defined in the schema.

#### ABSTRACT | STRUCTURAL | AUXILIARY

Indicates the type of object class. **STRUCTURAL** is the default.

#### **MUST** oids

List of one or more mandatory attribute types. Attribute types which are mandatory must be specified when adding or modifying a directory entry.

#### MAY oids

List of one or more optional attribute types. Attribute types which are optional may be specified when adding or modifying a directory entry.

The **extensibleObject** object class is an **AUXILIARY** object class which allows an entry to optionally hold any attribute type. The **extensibleObject** object class is supported by the z/VM LDAP server. This allows any attribute type that is known by the schema to be specified in an entry which includes **extensibleObject** in its list of object classes.

The **top** object class is an abstract object class used as a superclass of all structural object classes. For each structural object class, **top** must appear in the **SUP** list of this object class or of an object class in the superior hierarchy of this object class.

Following is an example of the definition of an object class:

objectClasses: ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectclass ) objectClasses: ( 2.5.6.6 NAME 'person' SUP top STRUCTURAL MUST ( cn \$ sn ) MAY ( userpassword \$ telephonenumber \$ seealso \$ description ) objectClasses: ( 5.6.7.8 NAME 'company'SUP top MUST ( department \$ telephoneNumber ) MAY ( postalAddress \$ street ) ) objectClasses: ( 1.2.3.4 NAME 'companyPerson' SUP ( company \$ person ) )

## Defining new schema elements

You can define new schema elements for use by applications that you develop to use the directory. You can add new object classes and attribute types to the schema. To define a new object class or attribute type, create an LDIF file containing the new schema information, and perform an LDAP modify operation on the schema entry. Object classes and attribute types must be defined using the formats described in the previous section, and must include unique numeric object identifiers and names. Ensuring that the numeric object identifier and names are unique is essential to the correct operation of the directory when using your newly defined schema elements.

Numeric object identifiers (OIDs) are strings of numbers, separated by periods. OID "ranges" or "arcs" are allocated by naming authorities. If you are going to define new schema elements, you should obtain an "OID arc" from a naming authority. One such location to get an "OID arc" assigned is managed by Internet Assigned Numbers Authority (IANA) and, can be found at:

```
http://www.iana.org
```

Search the site for the "Private Enterprise Number" to apply for a Private Enterprise number.

Once you have obtained an "OID arc" you can begin assigning OIDs to object classes and attribute types that you define.

For the example below, assume that we have been assigned OID arc 1.3.18.0.2.1000.100. (**Note**: Do not use this OID arc for defining your own schema elements. This arc is assigned to IBM for its use.) The following example adds a new object class that refers to two new attribute types. As you can see, the object class and attribute types can be added to the schema using a single LDAP modify operation. The changes to the schema are represented in LDIF mode input below:

```
dn: cn=schema
changetype: modify
add: attributetypes
attributetypes: ( 1.3.18.0.2.1000.100.4.1 NAME 'YourCompanyDeptNo'
   DESC 'A users department number.'
   SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 EQUALITY caseIgnoreMatch
  USAGE userApplications
 )
ibmattributetypes: ( 1.3.18.0.2.1000.100.4.1 ACCESS-CLASS normal )
attributetypes: ( 1.3.18.0.2.1000.100.4.2 NAME 'YourCompanyEmployeeID'
   DESC 'A user employee ID.'
   SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 EQUALITY caseIgnoreMatch
  USAGE userApplications
 )
ibmattributetypes: ( 1.3.18.0.2.1000.100.4.2 ACCESS-CLASS sensitive )
add: objectclasses
objectclasses: ( 1.3.18.0.2.1000.100.6.1 NAME 'YourCompanyPerson'
  DESC 'Attached to inetOrgPerson to add more attributes.'
  SUP top
  AUXILIARY
  MAY ( YourCompanyDeptNo $ YourCompanyEmployeeID )
 )
```

This short description has described how to update the schema with new schema elements. Defining new schema elements is a complex undertaking and requires a thorough understanding of schema.

# Updating the schema

|

Τ

L

#### Attention

Updating the schema, if not done properly, can result in being unable to access data. Read this section thoroughly to avoid this situation.

When the z/VM LDAP server is first started, the server supplies an initial schema. This initial schema is sufficient for usage of the SDBM, CDBM (with configuration related entries) and GDBM backends, but will need to be updated for usage of LDBM and CDBM with user defined entries. The schema files shipped with the LDAP server, USRSCHEM LDIF and IBMSCHEM LDIF, might be sufficient for your usage of LDBM or CDBM. (For more information about adding these files to the schema, see "Setting up the schema for LDBM and CDBM" on page 15.) If they are not sufficient, you can change the schema as needed. The schema entry is required and cannot be deleted. When deleting an attribute type or object class definition, you need to provide just the object identifier enclosed in parentheses. Any additional fields that are specified are checked for proper syntax but are not used.

The operations supported include adding, modifying, or deleting any object class, attribute type, or IBM attribute type that is not part of the initial schema definition required by the LDAP server. Changes to the initial schema are very restricted. See Changing the initial schema for more information. The modifications (additions, changes, and deletions) specified by the LDAP modify function are applied to the schema entry. The resulting schema entry becomes the active schema and is used by all backends to verify that directory changes adhere to it.

Updates to the schema must be performed such that the schema fully resolves. This includes:

- All attribute types referred to in object classes must exist in the schema.
- All superior attribute types or object classes must exist.
- Only the syntaxes and matching rules supported by the schema may be specified in attribute type definitions.
- All attribute types referred to in IBM attribute type definitions must also be defined as attribute types.
- All structural object classes must include the **top** object class in their object class hierarchy.

Modifications to the schema are rejected if they would possibly make existing entries no longer valid. If there is an entry in an LDBM or CDBM backend that is using an attribute or object class:

- The attribute or object class cannot be deleted. Instead, "delete" the schema element by modifying it to mark it as **OBSOLETE** rather than deleting its definition from the schema entry. Therefore, no new entries can be created using the schema element and the existing entries which do use the schema element are still accessible. An existing entry that uses the **OBSOLETE** schema element must be modified to use only non-**OBSOLETE** schema elements during the next modification of the entry in order for the modification to succeed.
- The attribute or object class cannot be modified in a way that could affect the data in the entry. For example, the syntax of an attribute cannot be changed when that attribute is in use. You must modify the entries first so they do not use the object class or attribute, then change the schema.

The following fields in an attribute type definition are the only fields that can be modified if the attribute type is in use by an entry:

DESC OBSOLETE SINGLE-VALUE (can be removed but not added) NO-USER-MODIFICATION USAGE

The following fields in an IBM attribute type definition can be modified:

#### ACCESS-CLASS RACFFIELD

The following fields in an object class definition can be modified when the object class is in use by an entry:

DESC

OBSOLETE MUST (can only move an attribute to MAY) MAY (can only add an attribute)

## Changing the initial schema

I

The initial schema contains the **IdapSyntaxes**, **matchingRules**, **attributeTypes**, **IBMAttributeTypes**, and **objectClasses** needed by the LDAP server. See Appendix A, "Initial LDAP server schema" for the contents of the initial schema.

The syntaxes, matching rules, attribute types, and IBM attribute types in the initial schema cannot be deleted or modified. The object classes in the initial schema cannot be deleted or modified, with the following exceptions:

- 1. groupOfNames
- 2. groupOfUniqueNames

These object classes allow the following fields to be modified: DESC MUST MAY

The **MUST** and **MAY** lists can be modified in any way if no directory entries are using this object class. If there is a directory entry using this object class, the only **MUST** and **MAY** changes allowed are to move an attribute from the **MUST** list to the **MAY** list and to add an attribute to the **MAY** list.

Any part of a schema modification that attempts to add LDAP syntaxes or matching rules to the schema or to modify the initial schema except as described above is ignored, with no message issued to indicate this. The rest of the schema modification is performed and the result of those changes is returned to the client.

# Replacing individual schema values

It is often necessary to apply an updated schema file to an existing schema. Optimally, this would replace changed values in the existing schema with their updated values from the file and add new values from the file to the existing schema, leaving all other values in the existing schema unchanged. However, this is not the way the RFC 2251 definition for such a modify with replace operation works: the RFC requires that ALL the existing values in the schema be replaced by the values specified in the schema file. Therefore, the schema file would have to contain all the unchanged values from the schema in addition to the updated and new values so that no unchanged existing values are lost.

To address this problem, the LDAP server supports two different behaviors when using a modify with replace operation on the schema entry:

- Standard RFC behavior, in which all the existing values for an attribute are replaced by the ones specified in the modify operation. In order for the modification to succeed, the replacement values must include definitions for all schema definitions that are in use by existing directory entries and the replacement values must conform to the rules described above about what fields can be modified in an active schema entry.
- 2. Schema-replace-by-value behavior, in which each replace value in the modify operation either replaces the existing value (if one exists) in the schema or is added to the schema (if an existing value does not exist). All other values in the schema remain as they are. A replace value replaces a schema value if the schema value and replace value have the same numeric object identifier (NOID). Otherwise, the replace value is considered a new value and is added to the schema.

In all cases, the values of the attribute that are in the initial LDAP server schema cannot be deleted and can only be modified in limited ways as described in Changing the initial schema.

The behavior used by the LDAP server is selected in one of two ways:

- Specify the schemaReplaceByValue option in the global section of the LDAP server configuration file to set the behavior for all modify with replace operations of the schema. Specifying on activates the schema-replace-by-value behavior; off activates the standard RFC behavior. For more information, refer to "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.
- Specify the IBMschemaReplaceByValueControl control on the modify with replace operation to set the behavior for just that specific modify operation, overriding the schemaReplaceByValue configuration option. Specifying TRUE in the control activates the schema-replace-by-value behavior; FALSE activates the standard RFC behavior. Refer to Appendix B, "Supported server controls" for more information.

If neither the **schemaReplaceByValue** configuration option nor the **IBMschemaReplaceByValueControl** control is specified, the default behavior is schema-replace-by-value.

Example: assume that the objectclasses attribute for cn=schema contains the following values:

objectclasses: ( 1.130.255 NAME 'oldObjectclass1' DESC 'old description 1' ... ) objectclasses: ( 1.130.256 NAME 'oldObjectclass2' DESC 'old description 2' ... ) objectclasses: ( 1.130.257 NAME 'oldObjectclass3' DESC 'old description 3' ... )

We would like to replace 'oldObjectclass1' and add a value for 'newObjectclass4'.

This is the update file for the modify operation:

```
dn: cn=schema
changetype: modify
replace: objectclasses
objectclasses: ( 1.130.255 NAME 'newObjectClass1' DESC 'new description 1' ... )
objectclasses: ( 1.3.5.9 NAME 'newObjectClass4' DESC 'description 4' ... )
```

After the modify operation with schema-replace-by-value behavior, the objectclasses attribute in the schema would have the following values:

objectclasses: ( 1.130.255 NAME 'newObjectClass1' DESC 'new description 1' ... ) objectclasses: ( 1.130.256 NAME 'oldObjectclass2' DESC 'old description 2' ... ) objectclasses: ( 1.130.257 NAME 'oldObjectclass3' DESC 'old description 3' ... ) objectclasses: ( 1.3.5.9 NAME 'newObjectClass4' DESC 'description 4' ... )

If the modify operation with traditional RFC behavior is performed instead, the object classes attribute in the schema would end up with the following values:

objectclasses: ( 1.130.255 NAME 'newObjectClass1' DESC 'new description 1' ... )
objectclasses: ( 1.3.5.9 NAME 'newObjectClass4' DESC 'description 4' ... )

IBM attribute types are extensions to the attribute type definition. The IBM attribute type is deleted when the corresponding attribute type is deleted. IBM attribute types are always replaced by value even when **schemaReplaceByValue off** is specified in the LDAP server configuration file. This ensures that access class protection isn't inadvertently removed from an existing attribute type.

# Updating a numeric object identifier (NOID)

It may become necessary to update the numeric object identifier (NOID) of an attribute type or object class in the schema. This NOID change can be accomplished by a special modify operation. The modify operation must consist only of a value to delete followed by a value to add. The value to delete must specify the current NOID of the attribute type or object class whose NOID is to be changed; the value to add must specify the new NOID for the attribute type or object class, along with all the other parts of the attribute type or object class definition. For an attribute type, the NAME, SUP, EQUALITY, ORDERING, SUBSTR, and SYNTAX must be identical in the existing definition and the value to add. SINGLE-VALUE can be removed but not added. For an object class, NAME, SUP, MUST, MAY, and type (ABSTRACT, STRUCTURAL, or AUXILIARY) must be identical in the existing definition and the value to add. The entire attribute type or object class definition is replaced by the contents of the add. Note that the object identifier assigned to an attribute type or object class cannot be changed if there are any directory entries using the attribute type or object class. Also, the object identifier of an attribute type or object class in the initial LDAP schema cannot be changed.

Example: suppose we want to change the NOID of the xyz attribute type from 1.3.5.7 to 2.4.6.8. The update file for the modify operation to accomplish this would look like:

cn=schema

-attributetypes=( 1.3.5.7 NAME 'xyz' DESC 'xyz attribute added for application abc' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.5 USAGE userApplications )
+attributetypes=( 2.4.6.8 NAME 'xyz' DESC 'xyz attribute added for application abc' \
SYNTAX 1.3.6.1.4.1.1466.115.121.1.5 USAGE userApplications )

Changing a NOID should not need to be done as part of normal LDAP server operations. It is intended to be used as an error recovery device for when an incorrect NOID has been added to the schema.

# Analyzing schema errors

Following is some information about the possible cause of some schema errors that may be encountered when updating schema:

- For enhanced readability, *type:value* pairs in LDIF files may be split across multiple lines. The indicator to LDIF that the subsequent lines are continuations is that the first character on the subsequent line is a space. This character is ignored by parsers and it is assumed that the next character immediately follows the previous line. Therefore, if a space is needed between the last value on one line and the first value on the subsequent line, a second space needs to exist on the subsequent LDIF line. Various reason codes related to unrecognized values may be issued.
- Only limited changes are allowed to the initial schema, as described in Changing the initial schema. All other changes to the initial schema are ignored by the LDAP server with no error returned.
- The IBM attribute type schema attribute is an extension to the associated attribute type in the schema. If the schema update contains an IBM attribute type value for which an attribute type value is not defined, the schema update will fail. For example,

```
IBMAttributeTypes: ( 1.2.3.4 ACCESS-CLASS normal )
```

```
cannot be specified unless
```

```
attributeTypes: ( 1.2.3.4 NAME 'sample' ... ) is also defined.
```

- While the UTC Time syntax is supported, usage of the Generalized Time syntax is recommended. For UTC Time syntax, year values between 70 and 99 assume 1970 to 1999 and values between 00 and 69 assume 2000 to 2069.
- When searching attribute type values of GMT or UTC Time syntax, use GMT syntax in the search filter rather than local time. All time values are stored in the data store as GMT times.

# **Retrieving the schema**

The following sections describe how you can display the schema entry and also find the **subschemaSubentry** DN.

# Displaying the schema entry

The following command shows how to search for the schema entry. Note that the scope must be **base** in the search request to display the schema.

```
ldapsrch -h ldaphost -p ldapport -s base -b "cn=schema" "objectclass=subschema"
```

Immediately after the server is started for the first time, this command produces the results shown in Appendix A, "Initial LDAP server schema." After the schema has been updated by the administrator, the search results will show the full schema as the union of the initial schema and the added schema elements.

The search results will contain these attributes:

```
cn=SCHEMA
cn=schema
subtreespecification=NULL
objectclass=TOP
objectclass=SUBSCHEMA
objectclass=SUBENTRY
objectclass=IBMSUBSCHEMA
...
attributetypes = ( 2.5.4.3 NAME ( 'cn' 'commonName' ) SUP name )
...
```

```
ibmattributetypes = ( 2.5.4.3 ACCESS-CLASS normal )
...
objectclasses = ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectclass )
...
ldapsyntaxes = ( 1.3.6.1.4.1.1466.115.121.1.15 DESC 'directory string' )
...
matchingrules = ( 2.5.13.5 NAME 'caseExactMatch' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
...
```

# Finding the subschemaSubentry DN

The **subschemaSubentry** attribute in each directory entry contains the DN of the LDAP server schema entry. To find the value of the **subschemaSubentry** attribute, specify **subschemaSubentry** as an attribute to be returned on an LDAP search of the entry.

ldapsrch -h ldaphost -p ldapport -s base -b "o=Acme Company, c=UK" "objectclass=\*"
subschemasubentry

o=Acme Company, c=UK subschemasubentry=cn=schema

# **Chapter 4. Modify DN operations**

The Modify DN Operation allows a client to change the leftmost (least significant) component of the name of an entry in the directory, or to move a subtree of entries to a new location in the directory. This topic explains the function of the Modify DN operation and the options supported to influence the scope and duration of the operation. In addition, it instructs on the techniques necessary to achieve certain forms of directory renames and movement, and it advises on issues which may result in unintentional or unwanted results.

In LDAP, modify DN operations are supported only in the LDBM (file-based) and CDBM (file-based) backends.

# Modify DN operation syntax

The z/VM implementation of the Modify DN operation supports all required and optional parameters described for the operation in RFC 2251. Specifically, these parameters are required:

- **entryDN:** This is the Distinguished Name (DN) of the entry whose name will be changed. This entry may or may not have subordinate entries. This parameter may not be a zero-length string.
- **newRdn:** The Relative Distinguished Name (RDN) that will form the leftmost component of the new name of the entry. This parameter may not be a zero-length string. If the intent of the Modify DN operation is to move the target entry to a new superior without changing its RDN, the old RDN value must be supplied in the **newRdn** parameter. The attributes and values in the **newRdn** parameter are added to the entry if they are not already present in the entry.
- **deleteoldrdn:** A boolean parameter that controls whether the old RDN attribute values are to be retained attributes of the entry or whether they will be deleted from the entry.

The following parameter to the Modify DN operation is optional:

• **newSuperior:** The Distinguished Name (DN) of the entry which will become the immediate superior of the renamed entry (identified by the **entryDN** parameter). If this parameter is present, it may consist of a zero-length string or a non-zero-length string. See "Modify DN operations related to suffix DNs" on page 53 for more information on the use of a zero-length string for this parameter. A zero-length string value for this parameter ("") will signify that the new superior entry is the root DN.

This operation also supports optional values, or controls, to influence the behavior of the operation. Two controls are supported (see Appendix B, "Supported server controls," on page 337):

- **IBMModifyDNTimelimitControl:** This control causes the Modify DN operation to be abandoned if its duration exceeds the time limit represented by the control value expressed in seconds. No changes are made if the operation is abandoned. This control is honored even if it is set by the admin DN for the server. When this control is present, it will **not** be propagated to the replica servers. (See Modify DN operations and replication for more information about replication of Modify DN operations.)
- **IBMModifyDNRealignDNAttributesControl:** This control causes the server to search for all attributes whose attribute type is based on a DN syntax (designated by OID 1.3.6.1.4.1.1466.115.121.1.12) and whose values match any

of the old DN values being renamed as part of the Modify DN operation, and to modify the old DN values to reflect the corresponding renamed DN attribute values. This includes modifications to two other attribute types which have constructed DN-type attribute values (those whose attribute syntax is not distinguished name but which may be used to store DN values). They are **aclEntry** and ownership **entryOwner** attributes. Updates to constructed DN types will be limited to these two attributes defined by the LDAP Server. No changes will be made to any user constructed types.

This control is an all-or-none operation in which the server attempts to realign all appropriately-matched DN attribute values in the LDBM or CDBM backend. Users cannot limit the scope of values which should be realigned. If a failure arises during the realignment operation, it realigns none of the values, and the Modify DN operation fails. No changes are made if the operation is abandoned. It should be noted that even if the control is designated as non-critical, the server will still try to honor the intent of the control and if this attempt fails, the entire Modify DN operation will fail.

When **IBMModifyDNRealignDNAttributesControl** is present on a request to a master server on which replication of Modify DN operations is enabled, it will be propagated to the replica servers. (See Modify DN operations and replication for more information about replication of Modify DN operations.)

A few simple examples of the use of the Modify DN operation follow. Each request will be expressed in the format of the ModifyDNRequest defined in RFC 2251, as well as in the corresponding invocation command for the z/VM client utility program LDAPMRDN (**Idapmodrdn**). For more information on LDAPMRDN, see z/VM: TCP/IP User's Guide.

#### Example 1: Simple Modify DN of leaf node

ModifyDNRequest ::= { entry cn=Kevin Heard, o=Athletics, o=Human Resources, o=Deltawing, c=AU newrdn cn=Kevin T. Heard deleteoldrdn TRUE }

ldapmrdn -h ldaphost -p ldapport -D binddn -w passwd -r "cn=Kevin Heard, o=Athletics, o=Human Resources, o=Deltawing, c=AU" "cn=Kevin T. Heard"

T

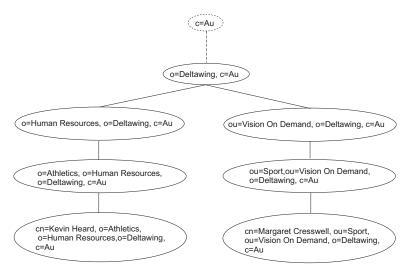

Figure 4. Before Modify DN operation

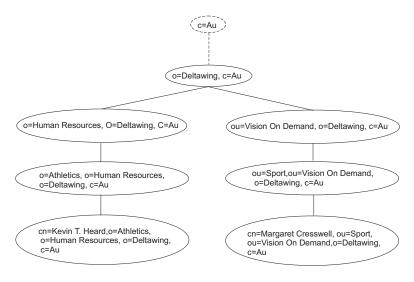

Figure 5. After Modify DN operation

**Note:** The **-r** parameter specifies that the old RDN attribute value (cn=Kevin Heard) will be deleted from the target entry after this operation.

Example 2: Simple Modify DN of non-leaf node

```
ldapmrdn -h ldaphost -p ldapport -D binddn -w passwd "o=Athletics,
o=Human Resources, o=Deltawing, c=AU" "ou=College Athletics Dept."
```

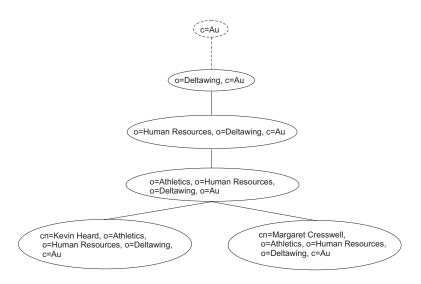

Figure 6. Before Modify DN operation

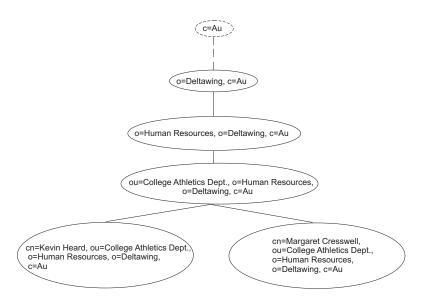

Figure 7. After Modify DN operation

**Note:** The absence of the **-r** parameter specifies that the old RDN attribute value (o=Athletics) will be preserved in the target entry after this operation.

Example 3: Modify DN of non-leaf node with relocation (newSuperior)

```
ModifyDNRequest ::= {
entry o=Athletics, o=Human Resources, o=Deltawing, c=AU
newrdn o=Adult Athletics
deleteoldrdn FALSE,
newSuperior ou=Sport, ou=Vision On Demand, o=Deltawing, o=AU
}
```

ldapmrdn -h ldaphost -p ldapport -D binddn -w passwd -s "ou=Sport, ou=Vision On Demand, o=Deltawing, c=AU" "o=Athletics,o=Human Resources, o=Deltawing, c=AU" "o=Adult Athletics"

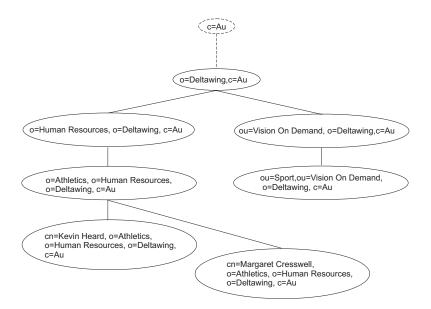

Figure 8. Before Modify DN operation

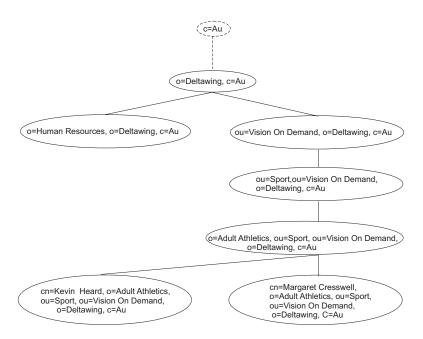

Figure 9. After Modify DN operation

**Note:** The absence of the **-r** parameter specifies that the old RDN attribute value (o=Athletics) will be preserved in the target entry after this operation. The target entry and descendants in its subtree will be relocated in the directory hierarchy.

# Considerations in the use of Modify DN operations

As this operation has the potential to significantly change directory data and how it can be accessed, it is important that the user fully understand the data before using the Modify DN operation. Specifically, the user needs to know that:

- The ability of this operation to move directory subtrees has the potential for affecting many entries in the directory in a single operation.
- Certain options may result in modification of additional directory entries which are outside the scope of the directory subtrees being moved. This topic will explain and give examples of how that can occur.
- Because the changes performed to the directory as a result of the operation are committed as a single transaction (or reversed if an error occurs), it may result in a long-running transaction, which may reduce concurrency of other LDAP operations targeted for the same directory entries. See Concurrency considerations between Modify DN operations and other LDAP operations for more information.
- The scope of the changes may result in unanticipated effects in the directory and may affect user access to these entries. See Access control changes for more information.
- There are limitations to which directory entries are eligible for the Modify DN operation. See Eligibility of entries for rename for more information.
- In case the directory needs to be returned to a state before a Modify DN operation, the directory should be backed up by using DS2LDIF (the **ds2ldif** utility program). For more information about DS2LDIF, see *z/VM: TCP/IP Planning and Customization*. In addition to backing up the directory contents, activity logging should be enabled before nontrivial changes are made to the directory.
- There are considerations if the data to be modified by this operation is being replicated. See Modify DN operations and replication for more information.

# Eligibility of entries for rename

T

T

Entries in the directory which are targeted to be renamed in a single Modify DN operation are subject to these constraints:

- 1. All entries to be renamed must be located in the same LDBM or CDBM backend targeted by the Modify DN operation. The Modify DN operation with *newSuperior* option will move subtree entries within the same LDBM or CDBM backend and will not permit movement of subtree entries from one backend to another. The entry to be renamed must exist in the backend, and the new DN for the entry must not already exist in the backend.
- 2. Referral entries may be renamed as part of a Modify DN operation. If a referral entry is renamed as part of a Modify DN operation, its corresponding entry in the referral server must be manually updated to reflect the name changes; no automatic updates are propagated to those backends from the target backend. Referrals which exist in other directory servers which refer to any of the entries whose DNs were modified in the local directory by a Modify DN operation will need to be manually updated to reflect the changes; no automatic updates are propagated to reflect the changes; no automatic updates are propagated to those servers from the local one.
- 3. The LDAP server schema entry can not be renamed.
- 4. Entries renamed by a Modify DN operation must conform to the LDAP server schema. As such, the RDN attribute type must be consistent with the schema rules for the object classes of the entry: a Modify DN operation fails if the attribute type of *newRdn* is not in the **MUST** or **MAY** list for the entry's object classes.
- 5. If a new superior entry is specified, it must be in the same backend as the entry to be renamed but may be under a different suffix managed by that backend. If the IBMModifyDNRealignDNAttributesControl is specified, only entries within the same backend as the renamed entry will be processed.

- 6. When IBMModifyDNRealignDNAttributesControl is present on a Modify DN request, the operation looks for occurrences of each renamed DN (this can be multiple DNs if renaming a subtree) in certain attributes within all the entries in the backend and replaces each renamed DN with its new DN. The affected attributes are:
  - a. Any attribute whose syntax is DN syntax (OID 1.3.6.1.4.1.1466.115.121.1.12).
  - b. The **aclEntry** and **entryOwner** attributes (these contain DNs in a structured format).
- 7. If newRdn is specified on a Modify DN operation, each attribute in the newRdn value is added to the entry when it is moved. If a newRdn attribute already has a different value in the entry and the attribute is defined as SINGLE-VALUE in the schema, the Modify DN operation fails. For example, suppose an entry with DN of dept=AAA,ou=mydivision,o=MyCompany,c=us is to be renamed with the newRdn sector=northeast and that the entry already contains the SINGLE-VALUE attribute sector with a value of northwest. This rename fails because it attempts to add a second value (northeast) to the sector attribute.

If the *newRdn* attribute is contained in the current RDN, then the *deleteoldrdn* parameter can be added to the Modify DN operation to allow it to succeed. In this case, the current attribute value is removed so that the attribute only contains the one value from *newRdn* in the renamed entry. For example, suppose an entry with DN of

sector=northwest,ou=mydivision,o=MyCompany,c=us is to be renamed with the *newRdn* sector=northeast and *deleteoldrdn* is specified on the Modify DN operation. This rename succeeds because northwest is replaced by northeast as the single value of the **sector** attribute in the renamed entry.

- 8. Entries may be renamed only if all access control requirements are satisfied for the bound user, as determined by the effective ACL and ownership permissions for those entries and attributes. See Access control and ownership for detailed explanation and examples of this effect.
- 9. Alias entries (entries containing the aliasedObjectName attribute and either the alias or aliasObject object class) can be renamed as part of a modify DN operation as long as this does not result in an aliasedObjectName value that is a DN equal to the DN of the renamed alias entry.
- 10. When advanced replication is configured, a Modify DN operation from one replication context to a different replication context is not supported. The Modify DN operation must occur within the same replication context.
- 11. The global password policy entry, **cn=pwdpolicy,cn=ibmpolicies**, cannot be renamed. If a user or group entry has a reference to a password policy entry in an **ibm-pwdIndividualPolicyDN** or **ibm-pwdGroupPolicyDN** attribute value, the individual or group password policy entry cannot be renamed or deleted until the association is removed from all user or group entries.

# Concurrency considerations between Modify DN operations and other LDAP operations

|

I

I

I

I

I

The ability of the Modify DN operation to rename non-leaf nodes in the directory (which causes all entries which are hierarchical subordinates of the target entry to be renamed) and the ability to move directory subtrees have the potential for affecting many entries in the directory in a single operation. Use of **IBMModifyDNRealignDNAttributesControl** with this operation may further result in modification of additional directory entries which are outside the scope of the directory subtrees being renamed or moved.

Changes to all entries affected by the operation are committed at the same time. While modified entries are awaiting the transaction commit point, database locks are held which prevent other concurrent operations from sharing and modifying the data. If many entries undergo modification with this operation, it may result in a long-running transaction which has potential for reducing concurrency of other operations targeted for the same directory entries.

Although the LDAP server is capable of processing concurrent LDAP operations targeted at a given LDBM or CDBM backend while the Modify DN operation is in progress, the extent to which such concurrency is possible will depend on what data in the directory may be needed and locked by the competing operations.

## Access control and ownership

T

For all entries being renamed, the caller must have **w**(rite) permissions for the attribute values that will have to change in all affected entries. In addition, if the *newSuperior* parameter is present on the Modify DN request, the caller must have permissions of **object:a** on the *newSuperior* entry and **object:d** on the target entry at the top of the subtree of entries being moved. If the caller lacks one or more of these permissions, the operation is denied. No access control checking is done against any of the target entry's subordinates even though their DN is changed. It should be noted that if the caller is an effective owner of any of the entries being renamed, the permissions are automatically satisfied for those entries.

In addition, if the **IBMModifyDNRealignDNAttributesControl** accompanies a Modify DN request, then the bound DN must have w(rite) permission to all of the attributes that are changed as a result of realignment of the DN values.

#### **Example:**

Assume our sample directory contains the following entry which will be the target of a Modify DN operation, and which contains explicit ACL information:

dn: o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU aclEntry: access-id: cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU:normal:rswc:sensitive:rsc:object:d

(other attributes not shown)

The directory also contains an entry with DN ou=Production, ou=Vision On Demand,o=Deltawing, c=AU which will be the new Superior of the Modify DN operation. This entry inherits the following ACL information (propagated from a superior entry):

aclEntry: access-id: dn: cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU:normal:rwsc:sensitive:rsc:object:a

In addition, there are several entries containing attributes of DN syntax. For this example, assume that these attribute types and their respective attribute access classes are as follows:

attribute: reportingOrganization	access-class: sensitive
attribute: workingOrganization	access-class: normal

The LDIF format representation of the entries containing **reportingOrganization** or **workingOrganization** attributes are:

dn: cn=Lisa Fare, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU cn: Lisa Fare objectclass: organizationalPerson objectclass: person objectclass: TOP aclEntry: access-id: cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU:normal:rsc:sensitive:rs sn: Fare title: Occupational Health and Safety Administrator telephonenumber: (07) 635 1432 manager: cn=John Gardner, ou=Human Resources Group, ou=Deltawing InfoSystems, o=Deltawing, c=AU secretary: cn=Ian Campbell, o=Deltawing, c=AU reportingOrganization: o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU dn: cn=Laurie Wood, ou=Human Resources Group, ou=Deltawing Automotive Ltd., o=Deltawing, c=AU cn: Laurie Wood objectclass: organizationalPerson objectclass: person objectclass: TOP aclEntry: access-id: cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU:normal:rswc:sensitive:rsw sn: Wood telephonenumber: (03) 9335 2114 title: Pav Officer workingOrganization: o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU

#### **Relocating an entry**

User "cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU" submits the following Modify DN operation request to the server to relocate the target entry:

ldapmrdn -h ldaphost -p ldapport -D "cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU" -w passwd -s "ou=Production, ou=Vision On Demand, o=Deltawing, c=AU" "o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU" "o=Athletics Division"

The **-s** parameter specifying *newSuperior* is present on this operation request, so in addition to the access permissions needed for all Modify DN operations (**w** on affected attributes), the user also needs **object:d** on the target entry and **object:a** on the newSuperior entry. The bound user is in the **aclEntry** for the target entry as well as in the **aclEntry** for the newSuperior entry, and has all required access permissions (can write attributes and delete the target entry, and can add objects under the newSuperior entry), so the operation is permitted.

#### Relocating an entry with DN realignment requested

If the same user submits a Modify DN operation request to the server to relocate the same target entry under the same newSuperior entry, but with the addition of the control requesting realignment of DN attribute values (**-a** parameter):

ldapmrdn -h ldaphost -p ldappart -D "cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU" -w passwd -a -s "ou=Production, ou=Vision On Demand, o=Deltawing, c=AU" "o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU" "o=Athletics Division"

In addition to the permissions required on the previous example, this operation requires additional permissions to be checked on entries containing values which qualify for realignment. The DN being modified ("o=Athletics, o=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU") is found in DN-syntax attributes of two entries: The entry with DN "cn=Laurie Wood, ou=Human Resources Group, ou=Deltawing Automotive Ltd., o=Deltawing, c=AU" contains this value in the

workingOrganization attribute, and the entry with DN "cn=Lisa Fare, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU" contains this value in the **reportingOrganization** attribute.

The bound user is in the aclEntry for "cn=Laurie Wood, ou=Human Resources Group, ou=Deltawing Automotive Ltd., o=Deltawing, c=AU". The **workingOrganization** attribute is in the access-class of normal, and the bound user is granted **w** access to this class of attributes, so the realignment of the DN value would be permitted in this entry.

The bound user is also in the **aclEntry** for "cn=Lisa Fare, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing, c=AU". The **reportingOrganization** attribute is in the access-class of sensitive, and the bound user is granted only **rs** permissions on **sensitive** attributes in the entry, so the realignment of this value would be denied. Even though the bound user had adequate permissions to perform the relocation of the target entry and had adequate permissions to perform realignment of the DN value in one of the two entries containing a matching DN, the operation would fail because the bound user does not have the necessary permissions on everything needed to complete the operation.

#### Access control changes

If a Modify DN operation is accompanied by the *newSuperior* parameter, changes in effective ACLs and in effective ownership of the relocated entries may result. Regardless of the effective ACLs which applied to the moved subtree in its old location, the moved subtree inherits any propagating ACLs applying to the *newSuperior* entry. As a consequence, entries to which a user had access before the request may no longer be accessible by that user, and entries to which access was denied for a given user before the request is accessible by that user.

Explicit ACLs in the entry or subtree override propagating ACLs. All explicit ACLs which were in the moved subtree at its original location move along with the entries.

When renaming a DN, it is possible that ACLs and entryOwners containing the renamed DN will be modified. Therefore, before such a move or rename users should carefully consider how ownership and accessibility to entries protected by these attributes may change after the move, and what ACL and ownership changes may be desired, if any.

The following is an example of how a Modify DN operation might affect access controls:

ldapmrdn -h ldaphost -p ldapport -D binddn -w passwd -s "ou=Sport, ou=Vision On Demand, o=Deltawing, c=AU" "o=Athletics,o=Human Resources, o=Deltawing, c=AU" "o=Adult Athletics"

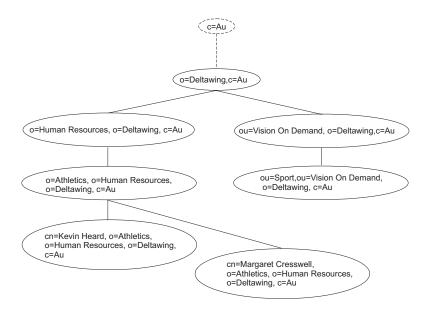

Figure 10. Before Modify Dn operation

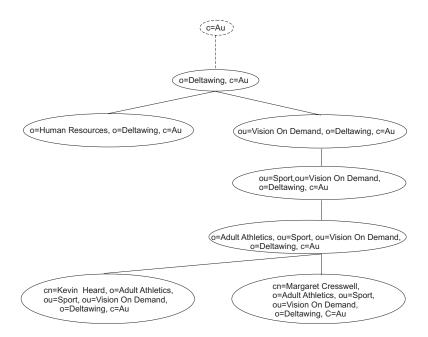

Figure 11. After Modify DN operation

Assume that the entry with DN o=Human Resources, o=Deltawing, c=AU has an explicit propagating ACL containing the following **aclEntry**:

aclEntry: access-id: cn=Mark Edmondson, ou=Vision On Demand, ou=Delta Home Media Ltd., o=Deltawing,c=au:normal:rwcs:sensitive:rwcs:critical:rws:object:d

Also, assume that the entry with DN ou=Sport, ou=Vision On Demand, o=Deltawing, c=AU has an explicit propagating ACL containing the following **aclEntry**:

aclEntry: access-id: cn=Mark Edmondson, ou=Vision On Demand, ou=Delta Home Media Ltd., o=Deltawing,c=au:normal:rws:sensitive:r:critical:r:object:a

If the user bound as DN cn=Mark Edmondson, ou=Vision On Demand, ou=Delta Home Media Ltd., o=Deltawing,c=AU performs the example Modify DN operation, there are at least two consequences which should be noted:

- While this DN previously had **rwcs** permissions on sensitive attributes in the entry o=Athletics, o=Human Resources, o=Deltawing, c=AU and **rws** permissions on critical attributes in the same entry, this DN has only **r** access on both sensitive and critical attributes in the entry after the relocation. It might be expected that a given DN will have the same accessibility to specific entries and data in the directory after a Modify DN operation as it had to those entries and data before the operation, but this example demonstrates that such an expectation is not valid.
- If, after completion of the Modify DN operation, the bound user decides that they want to return the moved entry (and its subordinates) back to their original location in the directory hierarchy, this will not be possible with the access controls currently in place. The bound DN has only **object:d** permission on the old superior node ("o=Human Resources, o=Deltawing, c=AU") where **object:a** is needed to effect the move of an entry or subtree under the superior node, and the bound DN has only **object:a** permission on the moved entry ("o=Adult Athletics, ou=Sport, ou=Vision On Demand, O=Deltawing, c=AU") where **object:d** is needed to move the entry. Therefore, while it may be expected that a given DN can reverse a Modify DN operation under all circumstances, this example demonstrates that such an expectation is not valid.

#### **Ownership changes**

When the *newSuperior* parameter accompanies the Modify DN request, any entries in a relocated subtree which had explicit owners before the relocation will preserve that explicit ownership after the relocation has been performed. Any entries in the relocated subtree which inherited ownership before relocation will continue to inherit ownership following relocation. If the owning entry before relocation was a node superior to the relocated entry, the owning entry will be the new superior entry. If the owning entry was an entry within the relocated subtree, the owning entry is preserved following the relocation.

Any entries in the relocated subtree which propagated ownership to subordinates before relocation continue to propagate ownership to subordinates after the relocation.

Refer to the example in Access control changes.

Assume that the entry with DN o=Human Resources, o=Deltawing, c=AU has an explicit propagating owner of cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd.,o=Deltawing,c=AU.

Also, assume that the entry with DN ou=Sport, ou=Vision On Demand, o=Deltawing, c=AU has an explicit propagating owner of cn=Neville McAuliffe, ou=Human Resources Group, ou=Deltawing Infosystems, o=Deltawing, c=AU.

Before the Modify DN operation, the effective owner of the renamed entry is cn=Mark Crawford, ou=Human Resources, ou=Delta Home Media Ltd., o=Deltawing,c=AU; after completion of the operation, the effective owner of the renamed entry is now cn=Neville McAuliffe, ou=Human Resources Group, ou=Deltawing Infosystems, o=Deltawing,c=AU. Therefore, the act of relocating an entry may change the effective owner of that entry and of its subordinates.

#### Modify DN operations related to suffix DNs

The Modify DN operation can be used to modify the DNs of any and all entries in an LDBM backend. In addition to renaming leaf entries (directory entries with no subordinate entries) and mid-hierarchy entries (directory entries which have both superior entries and subordinate entries), suffix entries may also be renamed. Suffix entries may be renamed to become non-suffix entries and suffix entries may be renamed such that they continue to be suffix entries. In addition, non-suffix entries may be renamed to become suffix entries. This section provides example scenarios for rename operations which involve suffix entries. It summarizes constraints which have been adopted for the LDAP directory implementation which are not defined in the protocol behavior prescribed by RFC 2251 for the Modify DN operation. Examples are provided on how various renaming scenarios may be accomplished, and factors to be considered when performing these operations are discussed.

Note: Do not rename the cn=ibmpolicies and cn=configuration CDBM suffix entries. Renaming these suffixes can cause configuration related problems. The global password policy entry, cn=pwdpolicy,cn=ibmpolicies, cannot be renamed. If a user or group entry has a reference to a password policy entry in an ibm-pwdIndividualPolicyDN or ibm-pwdGroupPolicyDN attribute value, the individual or group password policy entry cannot be renamed or deleted until the association is removed from all user or group entries.

### Scenario constraints

|

L

L

I

I

Several constraints will apply which are not defined by RFC 2251 in the description of the protocol behavior:

- 1. If an entry being renamed will become (or remain) a suffix, the new DN must be designated in the server's configuration file as a suffix for the backend, otherwise the operation will not be permitted.
- 2. The *newRdn* parameter of the Modify DN request must contain a non-null value, otherwise the operation request will be treated as an error.
- 3. If the *newSuperior* parameter is present, it may contain a zero-length string signifying that the new entry does not have a superior entry, therefore is a suffix entry.

In the directory hierarchy diagrams which follow, a circle outlined with a dashed line represents a component of a suffix DN. Circles containing gray fill represent DNs for which an entry exists in the directory.

#### **Example scenarios**

The following are example scenarios:

1. Rename a suffix RDN with no accompanying *newSuperior*, and the new DN remains a suffix after the rename is completed.

For example:

Suffixes defined in the server configuration file:

suffix: ou=End\_GPL, o=MyCompany, c=US
suffix: ou=Endicott, o=MyCompany, c=US

Rename operation is to rename suffix entry ou=End\_GPL, o=MyCompany, c=US to suffix entry ou=Endicott, o=MyCompany, c=US The following figure shows an example of this operation:

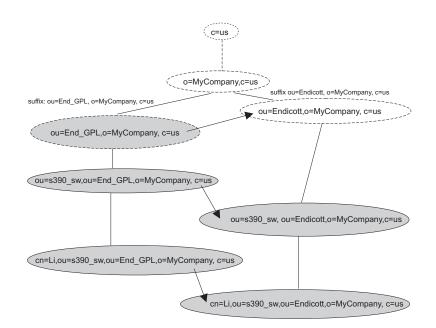

Figure 12. Suffix rename with no new superior

The new DN must be already designated as a suffix for this backend, otherwise this operation will fail.

The operation is performed the same as a rename of any other  $\ensuremath{\mathsf{RDN}}^{\ensuremath{\mathbb{S}}}$  in the directory

 a. Send Modify DN operation request with target=ou=End\_GPL, o=MyCompany, c=US newRdn=ou=Endicott

This results in renaming ou=End\_GPL, o=MyCompany, c=US to ou=Endicott, o=MyCompany, c=US and in renaming subordinate entries accordingly.

2. Rename of suffix DN with an accompanying *newSuperior*, and the new DN remains a suffix after the rename is completed. For example:

Suffix defined in the server configuration file: suffix: ou=Endicott, o=MyCompany, c=us

Rename operation is to rename suffix entry ou=Endicott, o=MyCompany, c=us to suffix entry o=MyCompany, c=us

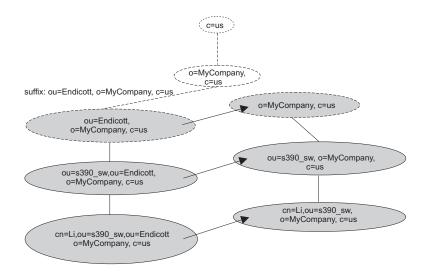

Figure 13. Suffix rename with new superior

This scenario, which involves renaming an existing suffix to an overlapping new suffix, must be performed in several steps, since the product does not permit designation in the server configuration file of overlapping suffixes. The definition of overlapping suffixes is when two suffixes with differing numbers of naming components are equal to the extent of the shorter of the two suffixes. For example, ou=Endicott, o=MyCompany, c=US and o=MyCompany,c=US are considered to be overlapping suffixes, while ou=Endicott, o=MyCompany, c=US and ou=Raleigh, o=MyCompany, c=US are not considered to be overlapping suffixes.

This rename can be accomplished by having a temporary suffix pre-defined for the backend (for example, o=OurTemporarySuffix), renaming the target entry to become the temporary suffix, stopping the server and deleting the suffix ou=Endicott, o=MyCompany, c=us and adding the suffix o=MyCompany, c=us, and restarting the server. The temporary suffix would later be deleted from the list of suffixes for the backend.

 a. Send a Modify DN operation request with target= ou=Endicott, o=MyCompany, c=us newRdn= o=OurTemporarySuffix newSuperior= "" (present in request with zero-length string) This results in renaming ou=Endicott, o=MyCompany, c=us to o=OurTemporarySuffix Note that the server treats newRdn as an error

o=OurTemporarySuffix. Note that the server treats *newRdn* as an error if it contains a zero-length string, but zero-length strings are permitted in the *newSuperior* argument to signify that the superior entry is the root DN.

- b. Stop server, remove suffix ou=Endicott, o=MyCompany, c=us from the server configuration file, add suffix o=MyCompany, c=us, and restart server.
   This results in adding the desired target suffix without a resulting conflict from overlapping suffixes.
- c. Send a Modify DN operation request with:

target= o=OurTemporarySuffix
newRdn= o=MyCompany
newSuperior= c=us

This step results in renaming the temporary suffix o=OurTemporarySuffix to the desired suffix o=MyCompany, c=us, thereby accomplishing the rename

from ou=Endicott, o=MyCompany, c=us to o=MyCompany, c=us. In the process, subordinate entries would be renamed accordingly.

3. This example shows the renaming of a suffix to another overlapping suffix higher in the directory hierarchy. A similar scenario could also be performed involving the rename of a suffix to another overlapping suffix, where the new name is a suffix lower in the directory hierarchy. For example:

Suffix defined in the server configuration file suffix:

ou=Endicott, o=MyCompany, c=us

Rename operation is to rename suffix entry:

ou=Endicott, o=MyCompany, c=us

to suffix entry:

div=S390, ou=Endicott, o=MyCompany, c=us

The following figure shows an example of this operation:

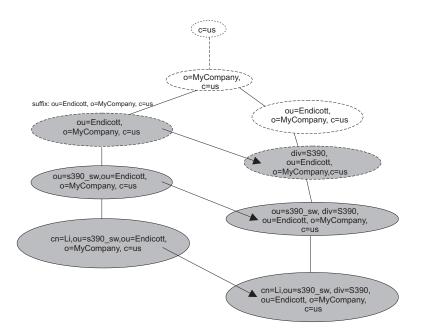

Figure 14. Overlapping suffix rename A

This rename can be accomplished by having a temporary suffix pre-defined for this backend in the server configuration file (for example, o=0urTemporarySuffix), renaming the target entry to become the temporary

suffix, stopping the server and deleting the suffix ou=Endicott, o=MyCompany, c=us and adding the suffix div=S390, ou=Endicott, o=MyCompany, c=us, and restarting the server. The temporary suffix would later be deleted from the list of suffixes for the backend. This scenario would be done as follows:

a. Send a Modify DN operation request with:

target= ou=Endicott, o=MyCompany, c=us newRdn= o=OurTemporarySuffix newSuperior= "" (present in request with zero-length string)

- b. Stop server, remove suffix ou=Endicott, o=MyCompany, c=us, add suffix div=S390, ou=Endicott, o=MyCompany, c=us, and restart server.
- c. Send a Modify DN operation request with

```
target= o=OurTemporarySuffix
newRdn= div=S390
newSuperior= ou=Endicott, o=MyCompany, c=us
```

L

L

L

|

If basic replication is configured, it should be noted that if these operational scenarios are to be replicated from a master server to one or more replica servers, there is a procedure that must be followed to permit this. Advanced replication does not support a Modify DN operation from one replication context to another replication context. Therefore, the following procedure only works with basic replication.

- a. Stop the replica server(s), add the temporary suffix (o=OurTemporarySuffix in our examples), restart the replica server(s).
- b. On the master server, perform the previous Steps 3a and 3b from the examples above. This will result in the intermediate rename to be performed on the master server and the results to be propagated to the replica server(s).
- c. Stop the replica server(s), delete the original suffix (ou=Endicott, o=MyCompany, c=us in both examples above), add the new suffix (o=MyCompany, c=us in the first example above, div=S390, ou=Endicott, o=MyCompany, c=us in the second example above), and restart the replica server(s).
- d. On the master server, perform the previous Step 3c from the examples above. This will result in the rename of entries to the final destination on the master server and in the results being propagated to the replica server(s).
- 4. Rename of suffix DN (some component other than RDN), and the new DN remains a suffix after the rename is completed. For example:

Suffixes defined in the server configuration file: suffix: ou=Endicott, o=MyCompany, c=us suffix: ou=Endicott, o=MyCompany\_ny, c=us

Rename operation is to rename suffix entry: ou=Endicott, o=MyCompany, c=us to suffix entry ou=Endicott, o=MyCompany\_ny, c=us

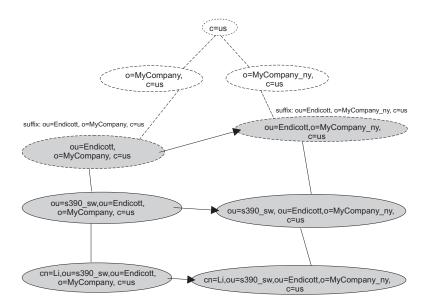

Figure 15. Overlapping suffix rename B

The new DN must be already designated as a suffix for this backend, otherwise this operation will fail. The operation is performed the same as a rename of any other DN in the directory. The product will permit the rename to occur in one step, even if an entry for *newSuperior* does not already exist, since the newly-named entry will become a suffix entry.

 a. Send a Modify DN operation request with target= ou=Endicott, o=MyCompany, c=us newRdn= ou=Endicott newSuperior= o=MyCompany ny, c=us

This results in renaming the DN from ou=Endicott, o=MyCompany, c=us to u=Endicott,  $o=MyCompany_ny$ , c=us and in renaming subordinate entries accordingly.

5. Rename of suffix DN (including some component other than RDN), with an accompanying *newSuperior*, but the new DN is no longer a suffix. For example:

Suffixes defined in the server configuration file:

suffix: ou=End, o=MyCompany, c=us
suffix: ou=End, ou=MyCompany na, o=MyCompany, c=us

Rename operation is to rename suffix entry ou=End, o=MyCompany, c=us to non-suffix entry ou=GPL, ou=End, ou=MyCompany na, o=MyCompany, c=us

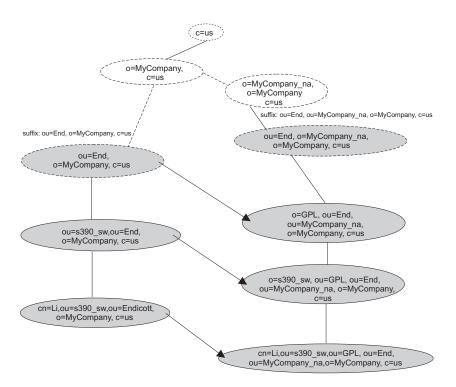

Figure 16. Suffix rename to non-suffix entry

The *newSuperior* entry must already exist before this operation will be permitted.

 a. Send a Modify DN operation request with target= ou=End, o=MyCompany, c=us newRdn= ou=GPL newSuperior= ou=End, ou=MyCompany\_na, o=MyCompany,c=us

This results in renaming ou=End, o=MyCompany, c=us to ou=GPL, ou=End, ou=MyCompany\_na, o=MyCompany, c=us and in renaming subordinate entries accordingly.

6. Rename of a non-suffix DN (including some component other than RDN), with an accompanying *newSuperior*, and the new DN is now a suffix. For example:

Suffixes defined in the server configuration file: suffix: ou=End, o=MyCompany, c=us suffix: o=Lotus, c=us

Rename operation is to rename non-suffix div=Lotus, ou=End, o=MyCompany, c=us to suffix o=Lotus, c=us

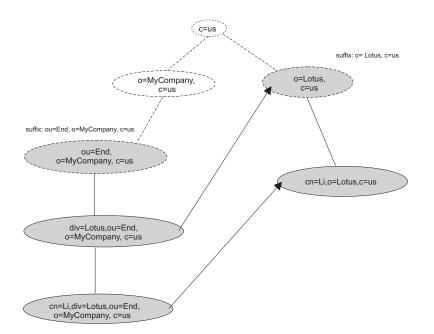

Figure 17. Rename non-suffix entry to suffix entry

The new DN must be already designated as a suffix for this backend, otherwise this operation will fail.

 a. Send a Modify DN operation request with target= div=Lotus, ou=Endicott, o=MyCompany, c=us newRdn= o=Lotus newSuperior= c=us

This step results in renaming div=Lotus, ou=Endicott, o=MyCompany, c=us to o=Lotus, c=us and in renaming subordinate entries accordingly.

#### Modify DN operations and replication

Modify DN operations may be classified into two categories:

1. Simple Modify DN operations are those that rename a leaf node, and that are not accompanied by the newSuperior parameter or the IBMModifyDNRealignDNAttributesControl control or the IBMModifyDNTimelimitControl control. 2. Complex Modify DN operations are those that either rename a mid-tree (non-leaf) node, or that are accompanied by the *newSuperior* parameter, or that are accompanied by either the IBMModifyDNRealignDNAttributesControl control or the IBMModifyDNTimelimitControl control. If basic replication is configured, simple Modify DN operations are always accepted by the master server, and are replicated if replica entries are present in the LDBM or CDBM backend where a Modify DN operation is applied. If advanced replication is configured, simple Modify DN operations are accepted only by the supplier server when the operation occurs within the same replication context. A compatible server version is one known to support for Modify DN operations all features and controls implemented by the LDAP server including: the IBMModifyDNRealignDNAttributesControl control

1

 the IBMModifyDNTimelimitControl control Т L • the *newSuperior* parameter · rename of non-leaf entries (complex Modify DN operations). L If one or more of these features or controls is not supported by a replica or L consumer server, all complex Modify DN operations are refused at the master L server. If advanced replication is configured, complex Modify DN operations are Т I only allowed within the same replication context. Initial validation of compatible server versions in consumer and replica L servers L Checks are made of consumer or replica servers by the supplier or master server I which are intended to increase the likelihood that complex Modify DN operations I will be successfully replicated. I The LDAP server must be able to establish a connection to each of the consumer or replica servers represented by replication agreement entries or replica entries in a LDBM backend. When the connection is established to a given consumer or I replica server, the supplier or master server determines if the consumer or replica server is at a compatible server version based on a query of the root DSE on that server. If a connection cannot be established to a consumer or replica server, it is assumed that the server does not provide the requisite support for replication of Modify DN operations, and complex Modify DN operations are refused on the consumer or master server. If a connection is established to a consumer or replica server and it is determined that the consumer or replica is not at a compatible server version, complex Modify DN operations are refused at the consumer or Т master server. In a basic replication environment, the replication of simple Modify I DN operations is always permitted, and such operations are always performed at T the master server. In an advanced replication environment, simple and complex I Modify DN operations must occur within the same replication context, otherwise I I they are not allowed.

# Periodic validation of compatible server versions in basic replication replicas

L

I

The following periodic replica checks are performed only in a basic replication environment and not in an advanced replication environment.

The master server might enable or disable processing of complex Modify DN operations, depending on dynamically changing states of replica servers and of replica entries within the master server's LDBM backend. It is possible for the server to refuse complex Modify DN operations after having accepted them for some period of time, and it is possible for the server to accept complex Modify DN operations after having refused them for some period of time. Such a change can be triggered by several events. Each replication cycle tests connections to all replica servers defined by replica entries in the LDBM backend, and if a connection can no longer be established to any of the replica servers (even if it had been established to the same replica on the previous replication cycle), the master server begins refusing complex Modify DN operations. If all connections succeed but it is determined that one or more of the replica servers is not at a compatible server version (such as might happen, for example, when the replica server has been stopped when running one version of the LDAP server code and subsequently restarted using a different version of the LDAP server code), the master server begins refusing complex Modify DN operations. Only if connections can be

established successfully to all replica servers and if they are determined to be running a compatible server version will the master server resume accepting complex Modify DN operations.

Other possible events which may influence whether the master server accepts or refuses complex Modify DN operations involve:

- The addition of new replica entries
- · The deletion of existing replica entries
- The modification of existing replica entries in the LDBM backend.

Each of these causes the master server to temporarily suspend processing of complex Modify DN operations, until the check of replica servers at the start of the next replication cycle, at which point the replica server version levels will be used to determine whether the master server resumes accepting complex Modify DN operations.

To determine whether a replica server is at a compatible version level, submit a root DSE search to that server, similar to the following. The **-D** and **-w** options need only to be specified if the replica server does not support anonymous binds.

ldapsrch -h ldaphost -p ldapport -D binddn -w passwd -s base -b "" objectclass=\* ibm-enabledCapabilities

where *ldaphost* represents the hostname on which the replica server runs, *ldapport* is the port number on which the replica server is listening, and *binddn* and *passwd* are the distinguished name and password of a user on the replica server.

If the **ibm-enabledCapabilities** attribute is returned on the root DSE search and its values contain 1.3.18.0.2.32.33 (subtree move) or 1.3.18.0.2.32.34 (subtree rename), then the replica server is capable of supporting those operations.

# Loss of basic replication synchronization because of incompatible replica server versions

The LDAP server basic replication model runs periodically, rather than continuously, and the state of the replica is not checked until the start of each replication cycle. A complex Modify DN operation could be accepted or rejected based on inaccurate information about the state of a replica server between the start of two replication cycles. As a consequence, the basic replication process could stall and the synchronization between the master server and its replicas could be lost.

#### Attention

It is highly recommended that the LDAP server administrator ensure that each replica server is at a compatible server version level before starting a master server which may be the recipient of complex Modify DN operations.

# Loss of basic replication synchronization because of incompatible replica server versions - recovery

If at some point a master server accepts a complex Modify DN operation which can not be replicated, there are several means of recovering from this situation. The best method of recovering from this situation is to ensure that all replica servers are reachable from the master server, and that all replica servers are running at a compatible version level (this may entail stopping some replica servers and restarting them at a compatible version level). Once this state has been reached, queued changes awaiting propagation to replica servers will drain from the queue at the master server and the replication process will resume normal operation.

An alternative is to delete the replica entry from the master server corresponding to the replica server which is currently unreachable or which is running at an incompatible server level. Note that this will result in loss of synchronization with that replica server, and if you want to later restart the offending replica (such as, after it has been brought up to a compatible server version) it will be necessary to take a backup of the master server contents and restore those contents to the replica server before restarting it, to ensure the two directories are synchronized.

## **Chapter 5. Accessing RACF information**

	RACF provides definitions of users, groups, classes, and general resources, and access control for resources. The LDAP server can provide LDAP access to this information stored in RACF.
	<ul> <li>Using SDBM, the RACF database backend of the LDAP server, you can:</li> <li>Add, modify, and delete RACF users, groups, and general resources. Note that dataset resources are not supported.</li> <li>Add, modify, and delete user connections to groups</li> <li>Add and remove users and groups in general resource access lists</li> <li>Modify SETROPTS options that affect classes (for example, RACLIST)</li> <li>Retrieve RACF information for users, groups, connections, general resources, and class options</li> <li>Retrieve RACF user password and password phrase envelopes</li> </ul>
	The SDBM backend of the LDAP server implements portions of the <b>adduser</b> , <b>addgroup</b> , <b>rdefine</b> , <b>altuser</b> , <b>altgroup</b> , <b>ralter</b> , <b>permit</b> , <b>setropts</b> , <b>deluser</b> , <b>delgroup</b> , <b>rdelete</b> , <b>connect</b> , <b>remove</b> , and <b>search</b> RACF commands.
   	<b>Note:</b> While it is possible for the SDBM backend to issue a SETROPTS RACLIST(FACILITY) REFRESH command to refresh SETROPTS options, it is currently not possible for the backend to issue a SETEVENT REFRESH command to activate VMXEVENT profile changes.
	For more information about the supported RACF commands, see <i>z/VM: RACF</i> Security Server Command Language Reference.

For information about getting your LDAP server configured with SDBM, see "Setting up for SDBM" in *z/VM: TCP/IP Planning and Customization*.

#### **SDBM** authorization

SDBM operations can be performed after several different types of binds to the LDAP server. In each of these binds, the LDAP server associates a RACF user ID with the bound user. SDBM invokes RACF commands under the context of this RACF user ID, and RACF uses its normal authorization processing to determine what this RACF user ID can do.

The supported bind mechanisms are:

- Simple bind to SDBM: The RACF user ID is specified in the bind DN. See "Binding using a RACF user ID and password or password phrase" on page 66 for more information.
- LDBM or CDBM native authentication bind: The RACF user ID specified in the native authentication entry is used. For more information, see "Native Authentication" in *z/VM: TCP/IP Planning and Customization*.
- Certificate bind: The RACF user ID associated with the certificate is used.

L

#### Binding using a RACF user ID and password or password phrase

The SDBM backend allows for directory authentication (or bind) using the RACF user ID and password or password phrase. The RACF user and group information that make up an identity can be used to establish access control on other LDAP directory entities. This expands use of the RACF identity to the rest of the LDAP-managed namespace. Note the following when using RACF access:

- An LDAP simple bind to a z/VM LDAP server using RACF access support but having a non-RACF security manager succeeds if the \_\_passwd() call made by the LDAP server is successful. However, no group membership information will be available for the bound distinguished name if the security manager is not RACF.
- An LDAP simple bind made to a z/VM LDAP server using RACF access support provides a successful or unsuccessful LDAP return code. In addition, if the LDAP return code is LDAP\_INVALID\_CREDENTIALS, additional information is provided in the "message" portion of the LDAP result. The additional information is an LDAP-unique reason code and reason code text in the following format:

Rnnnnn text

The following *errno* values returned by **\_\_\_passwd()** has an LDAP reason code defined for them:

errno value	Reason	Text
EACCES	R000104	The password is not correct
EINVAL	R000105	A bind argument is not valid
EMVSERR	R004107	Thepasswd function failed; not loaded from a program controlled library
EMVSEXPIRE	R000100	The password has expired
EMVSPASSWORD	R000101	The new password is not valid
EMVSSAFEXTRERR	R000102	The user id has been revoked
EMVSSAF2ERR	R000104	The password is not correct
EMVSSAF2ERR (system problem)	R004176	Thepasswd() function failed with error <i>error_code</i>
EMVSSAF2ERR (userid problem)	R000104	The password is not correct
ESRCH	R000104	The password is not correct or the user id is not completely defined (missing password or uid)

Table 7. The errno values returned by \_passwd()

**Note:** The same reason codes are issued when binding using a password or a password phrase.

The return code returned by LDAP is **LDAP\_OPERATIONS\_ERROR** when the errno value is EMVSERR or EMVSSAF2ERR (system problem). For the other errno values, the return code is **LDAP\_INVALID\_CREDENTIALS**.

#### Binding with SDBM using password policy

When authenticating with a user in the SDBM backend, the password policy applied is determined by RACF. Therefore, any configured LDAP password policy does not apply in these scenarios.

1

T

1	When the <b>PasswordPolicy</b> server control is sent on a bind request, the
I	PasswordPolicy response control is returned on the bind response and has
1	additional warning and error information about the authenticating user's password.
1	Based on information returned from RACF, the SDBM backend supports only the
1	following <b>PasswordPolicy</b> response control error codes during bind:
I	accountLocked, insufficientPasswordQuality, mustSupplyOldPassword, and
I	passwordExpired. See PasswordPolicy for more information.

#### SDBM group gathering

I

I

|

I

After successfully authenticating to the LDAP server, a list is created of the groups to which the authenticated RACF user ID belongs. Only groups in which the user ID's membership is active (has not been revoked) are included in the list. This group membership list is used in authorization checking when trying to access entries in directories on the LDAP server.

If the SDBM backend is to be used for authentication purposes only and group membership is not needed, consider having your clients use the **authenticateOnly** server control, to streamline bind processing. This control overrides any extended group membership searching and default group membership gathering and is supported for Version 3 clients. See Appendix B, "Supported server controls" for more information.

Note the **authenticateOnly** control is not necessary if there is no LDBM, GDBM, or CDBM backend configured. In this case, SDBM does not do any group gathering.

#### Associating LDAP attributes to RACF fields

Each RACF field in a user, group, connection, and resource profile and in the RACF class options must be associated with an LDAP attribute. The LDAP attribute is used to set the RACF field value in LDAP add and modify operations and to represent the RACF field in LDAP search output.

The user, group, and connection profile fields defined by RACF are mapped to predefined attributes in the LDAP schema. These LDAP attributes cannot be deleted or modified and the attribute names cannot be changed. The following tables show the RACF fixed field names and the associated LDAP attribute names for user (Table 8), group (Table 9), and connection (Table 10) profiles. The RACF names in the table are the keywords used to set the field in RACF commands or used by RACF in display output (for display-only fields). Not all names apply to all versions of LDAP and RACF.

RACF segment name	RACF keyword in altuser/adduser/listuser	LDAP attribute name
User base	ADDCATEGORY	racfSecurityCategoryList
User base	Multi-value: ADSP, SPECIAL, OPERATIONS, GRPACC, AUDITOR, UAUDIT, or any other one-word values, such as NOEXPIRED and NOOVM	racfAttributes
User base	AUTH not displayed by LDAP	racfConnectGroupAuthority
User base	CLAUTH	racfClassName
User base	DFLTGRP	racfDefaultGroup

Table 8. Mapping of LDAP attribute names to RACF fields (user)

RACF segment name	RACF keyword in altuser/adduser/listuser	LDAP attribute name
User base	GROUP	racfConnectGroupName
User base	Not modifiable - displayed as LAST-ACCESS	racfLastAccess
User base	NAME	racfProgrammerName

Setropts base	STATISTICS	racfStatistics

#### Special usage of racfAttributes, racfConnectAttributes, racfResourceAttributes, and racfSetroptsAttributes L

The **racfAttributes** attribute is a multi-valued attribute that can be used to specify any single-word keywords that can be specified on a RACF adduser or altuser command. For example, racfAttributes can be used to add a RACF user entry with 'ADSP GRPACC NOPASSWORD' or modify a RACF user entry with 'NOGRPACC SPECIAL NOEXPIRED RESUME NOOVM'. Additional values, such as PASSWORD, can be returned in **racfAttributes** that are not returned by the listuser command.

Similarly, racfConnectAttributes can be used to specify any single-word keywords that are valid on a RACF connect command, as can racfResourceAttributes for the RACF rdefine and ralter commands. racfSetroptsAttributes can be used for the RACF setropts command, but only those values listed in Table 11 can be specified.

#### **RACF** namespace entries

L L

L L

	When the SDBM backend is used to make RACF information accessible over the
I	LDAP protocol, SDBM creates a set of top entries to set up a hierarchical
I	representation of RACF users, groups, connections, classes, resources, and class
I	options. These top entries consist of the suffix, top user entry, top group entry, top
I	connection entry, a top entry for each RACF class (except DATASET, which is not
I	supported), and a setropts entry. For example, the top entries in Figure 18 and
I	Figure 19 are:
I	<ul> <li>cn=RACFA,o=IBM,c=US (suffix entry)</li> </ul>
I	<ul> <li>profileType=User, cn=RACFA, o=IBM, c=US (top user entry)</li> </ul>
I	<ul> <li>profileType=Group,cn=RACFA,o=IBM,c=US (top group entry)</li> </ul>
I	<ul> <li>profileType=Connect,cn=RACFA,o=IBM,c=US (top connect entry)</li> </ul>
I	<ul> <li>profileType=Facility,cn=RACFA,o=IBM,c=US (top facility class entry)</li> </ul>
I	<ul> <li>cn=Setropts,cn=RACFA,o=IBM,c=US (setropts entry)</li> </ul>

The top entries cannot be added or deleted. With the exception for the setropts entry, the top entries can only be compared and searched.

The setropts entry can be modified, compared, and searched.

The value used for the suffix entry DN is the value specified for the **suffix** option in the SDBM section of the LDAP server configuration file (see "Setting up for SDBM" in *z/VM: TCP/IP Planning and Customization*).

Following is a high-level diagram of the RACF backend.

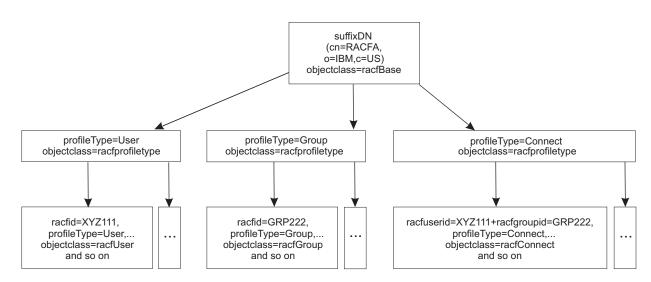

Figure 18. RACF namespace hierarchy (Part 1 of 2)

1

Т

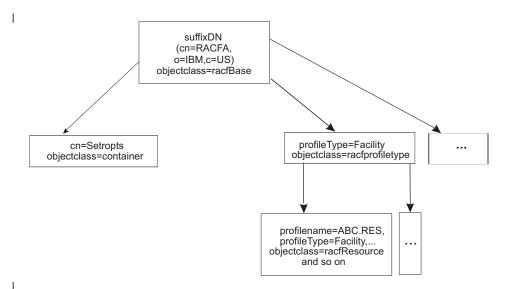

Figure 19. RACF namespace hierarchy (Part 2 of 2)

#### **SDBM schema information**

The attributes and object classes used by SDBM to represent RACF values are always in the LDAP server schema.

### SDBM support for special characters

1	An SDBM DN, including the SDBM suffix, can contain the following special characters:
1	<ul> <li>A plus sign (+), double quote ("), or backslash (\) anywhere in a DN.</li> <li>A pound sign (#) at the beginning of a value in a DN.</li> </ul>
   	When present in a DN, a special character must be escaped by preceding it with a single backslash (\). Note that the suffix in the LDAP server configuration file must use two back slashes (\\) to escape a special character, but only a single backslash is used in a DN.
l I	For example, if the SDBM suffix in the configuration file is suffix cn=\\#sys#1
	then the DN for the RACF resource profile a+b in class #x#y would be profilename=a\+b,profiletype=\#x#y,cn=\#sys#1
   	Special characters in a DN returned by SDBM are always escaped by a single backslash. Pound signs that are not at the beginning of a value and equal signs (=) might be escaped, depending on the usage of the DN.
     	When specifying a value containing a special character for an attribute within an add or modify request, escape the special character with a back slash if the attribute is part of a DN, otherwise, do not escape the special character. For instance, to add a user with the default group #d1grp, specify either: racfdefaultgroup: racfid=\#d1grp,profiletype=group,cn=\#sys#1
	<b>Or</b> racfdefaultgroup: #dlgrp
Ι	within the entry.
   	When specifying a value containing a special character for an attribute within a search filter, the special character can be escaped or not. For instance, to search for all RACF users starting with #user, use the search filter racfid=#user* or racfid=\#user*.

#### Control of access to RACF data

As explained above, SDBM operations result in issuing RACF commands. Table 12 and Table 13 indicate which commands are issued for various SDBM operations. The RACF commands are issued under the context of the RACF user ID that has bound to SDBM. RACF determines the results of the RACF commands based on the RACF authority of that user ID. If the RACF command fails, the SDBM operation fails and returns any error information issued by RACF.

In particular, the RACF **search** command can fail because of lack of authority, even if the bound user is able to extract RACF data from user IDs that match the RACF **search**. In this case, SDBM searches that result in issuing a RACF **search** command fail and return:

ldap\_search: Unknown error
ldap\_search: additional info: ICH31005I NO ENTRIES MEET SEARCH CRITERIA

## SDBM operational behavior

Table 12 shows how SDBM behaves during different LDAP operations.

Table 12. RACF backend behavior

Target DN	LDAP o	operation behavior		
suffixDN	Add	Error: Unwilling to perform		
	Modify	Error: Unwilling to perform		
	Delete	Error: Unwilling to perform		
	Modify DN Error: Unwilling to perform

Target DN	peration behavior	
profilename=ABC.RES,profiletype=Facility, <i>suffixDN</i>	Add	Perform an <b>rdefine</b> and, possibly, <b>permit</b> RACF commands for PROFILE=ABC.RES in CLASS=FACILITY. A separate <b>permit</b> command is performed for each <b>racfAccessControl</b> attribute value that is specified.
	Modify	Perform an <b>ralter</b> or <b>permit</b> , or both RACF commands for PROFILE=ABC.RES in CLASS=FACILITY. A separate <b>permit</b> command is performed for each <b>racfAccessControl</b> attribute value that is specified. An <b>ralter</b> command is performed if an attribute other than <b>racfAccessControl</b> is specified.
	Delete	Perform an <b>rdelete</b> RACF command for PROFILE=ABC.RES in CLASS=FACILITY
	Modify	DN Error: Unwilling to perform
	Compa	re Compare requested attribute with data returned from a profile extract RACF command using PROFILE=ABC.RES in CLASS=FACILITY
	Search	<b>base</b> Perform a profile extract RACF command using PROFILE=ABC.RES in CLASS=FACILITY
	Search	one level Empty search results (this is a leaf node in the hierarchy)
	Search	subtree Perform a profile extract RACF command using PROFILE=ABC.RES in CLASS=FACILITY
	Bind	Error: No credentials

If LDAP is running with an SDBM backend, the **Idap\_modify** and **Idap\_add** APIs can return **LDAP\_OTHER** or **LDAP\_SUCCESS** and have completed a partial update to an entry in RACF. The results will match what occurs if the update were done using the RACF **altuser, altgroup, connect, ralter**, and **permit** commands. If several RACF attributes are being updated and one of them is in error, RACF might still update the other attributes, without, in some cases, returning an error message. If there is a RACF message, LDAP always returns it in the result.

This is further complicated when adding or modifying a general resource profile because this can involve multiple RACF commands: a **rdefine** or **ralter** command followed by one or more **permit** commands. If one of the commands fails, processing ends but the resource profile is still updated with the results of the prior successful commands.

The RACF **connect** command is used to both add a user connection to a group and to modify a user's connection to a group. As a result, the SDBM add and modify support for connection entries is different than normal LDAP support:

• When adding a connection entry that already exists, the entry is modified using the specified attributes. There is no indication returned that the entry already existed.

Τ

Т

T

Т

Т

Т

Т

L

Т

T

• When modifying a connection entry that does not exist, the entry is added using the specified attributes. There is no indication returned that the entry did not exist.

#### Notes about specifying attribute values:

 There are several SDBM attributes whose value is a RACF user, group name, or class name. For convenience, this value can be specified either as just the RACF name or as the complete LDAP DN. For example, when adding a user with a default group of grp222, the **racfDefaultGroup** attribute can be specified as

racfDefaultGroup: grp222

or

I

L

I

I

L

T

Т

I

1

I

I

T

T

1

1

1

I

I

I

I

L

Т

racfDefaultGroup: racfid=grp222,profiletype=group,cn=racfu01,o=ibm,c=us

where cn=racfu01,o=ibm,c=us is the SDBM suffix.

The value returned by SDBM from a search is always the complete LDAP DN.

- 2. For multi-value attributes, the RACF **altuser** and **ralter** commands do not always support the ability to both add a value and replace the existing value. As a result, SDBM does not always respect the type of modification (add versus replace) that is specified in a modify command.
  - Values for the following multi-value attributes are always added to the existing value (even if replace is specified): racfAttributes, racfAudit, racfClassAct, racfClassName, racfConnectAttributes, racfGenCmd, racfGeneric, racfGenList, racfGlobal, racfLevelKeyword, racfLogonDays, racfLogOptionsAlways, racfLogOptionsDefault, racfLogOptionsFailures, racfMonitorKeyword, racfRacList, racfResourceAttributes, racfSecurityCategoryList, racfSetroptsAttributes, racfStatistics, racfVolumeList.
  - Values for the following multi-value attributes always replace the existing value (even if add is specified): racfCdtinfoFirst, racfCdtinfoOther, racfDlfdataJobNames, racfDomains, racflcsfSymExportCerts, racflcsfSymExportKeys, racfMscopeSystems, racfNetviewOperatorClass, racfOperatorClass, racfResourceAudit, racfResourceGlobalAudit, racfRoutcodeKeyword, racfRsIKey, racfTsIKey.
  - Values for the following multi-value attributes either are added to the existing values or replace the existing values, depending on the new and existing values: racfAuthKeyword, racfAccessControl, and racflcsfAsymUsage.

For single-value attributes, there is no difference between using an add modification or a replace modification to set the value. For either type of modification, the value is added if the attribute value does not exist and the value replaces the existing attribute value, if there is one.

3. For modify, if a request is made to delete a specific attribute value for an attribute where specific values cannot be selectively deleted, an LDAP\_UNWILLING\_TO\_PERFORM error code is returned. Similarly, if a request is made to delete the entire attribute for an attribute where specific values to delete must be specified, an LDAP\_UNWILLING\_TO\_PERFORM error code is returned.

The following attributes require that specific values to delete be specified: racfAudit, racfClassAct, racfClassName, racfGenCmd, racfGeneric, racfGenList, racfGlobal, racfMemberList, racfRacList, racfStatistics, racfVolumeList. The following attributes allow specifying specific values to delete but also support deleting the entire attribute: racfAccessControl, racfAttributes, racfConnectAttributes, racfResourceAttributes, racfSecurityCategoryList, racfSetroptsAttributes.

All other attributes that have a delete command in RACF only allow deleting the entire attribute. If an attempt is made to delete any attribute that has no corresponding delete command in RACF, an

LDAP\_UNWILLING\_TO\_PERFORM error code is returned.

4. The **racfCopyProfileFrom** attribute is used to specify any combination of the RACF **rdefine** FCLASS, FGENERIC, FROM, and FVOLUME keywords and values to indicate a resource profile to use as a model when creating a new resource profile. The value specified for this attribute must be syntactically correct for an **rdefine** command and is inserted as is in the command. For example, the following uses the RES.MODEL resource profile in the FACILITY class as a model:

racfcopyprofilefrom: FROM(RES.MODEL) FCLASS(FACILITY)

- 5. The racfAccessControl attribute is used to manage the access control lists for a general resource profile. Each attribute value is used to create a separate RACF permit command. Each value must be a syntactically-correct RACF permit command, without the class and profile names. SDBM adds the class and profile names before issuing the RACF permit command. It also adds the DELETE keyword for a modify request to delete the value.
  - Note: When issuing multiple RACF permit commands for the same resource, the order of the permit commands can be critical. SDBM issues a permit command for each racfAccessControl value in the order that SDBM receives the values. Be aware that if you specify multiple add, replace, and delete changes to an attribute in a single modify operation, many LDAPMDFY utilities (including the client z/VM LDAPMDFY) may reorder the changes to put all the changes of the same type together. Therefore, the values as presented to SDBM might not be in the original order and the results of the permit commands might not be as desired. To avoid this, separate different racfAccessControl attribute changes into separate modify operations.

When LDAP returns the **racfAccessControl** value during a search operation, the value might contain the COUNT field if this is part of the RACF output, for example:

racfaccesscontrol: ID(X) ACCESS(READ) COUNT(5)

If SDBM finds the COUNT field in a **racfAccessControl** value during an add or modify operation, the field is removed from the value before the value is used to generate a RACF **permit** command. This allows LDAP search output to be used as add or modify input.

When using the **racfAccessControl** attribute in a compare operation, the comparison is done only on the value specified for the ID keyword within the attribute value. The rest of the attribute value is not used. If the ID value is contained in any access control list within the resource profile, the compare returns **LDAP\_COMPARE\_TRUE**. If the attribute value does not have the ID keyword, has more than one ID value, or the value is not contained in any access list within the resource profile, compare returns

**LDAP\_COMPARE\_FALSE**. Basically, a **racfAccessControl** compare operation can be used to determine if a specific RACF user or group appears in the access control lists within a resource profile.

### **SDBM** search capabilities

I

L

|
|

| | |

|

 SDBM supports a limited set of search filters. The following table describes each supported filter and indicates from what bases it is valid, what sort of entries it returns (a complete entry or entries that just contain the DN of the entry), and what RACF commands are issued to perform the search. Most searches can only be performed from one of these top entries: the *suffix* entry, the profiletype=user, *suffix* entry, the profiletype=group, *suffix* entry, the profiletype=connect, *suffix* entry, and the profiletype=*class*, *suffix* entries.

Table 13. SDBM search filters

Filter	Search behavior				
objectclass=*	Description: match any user, group, connection, resource profile, and setropts				
	Allowed base: any SDBM entry				
	Returns:				
	<ul> <li>DN-only entries if scope includes all users, groups, connections, resource profiles, or setropts</li> </ul>				
	Complete entry if scope includes a single entry				
	Commands:				
	<ul> <li>if scope includes all users: search class(user) filter(*)</li> </ul>				
	<ul> <li>if scope includes all groups: search class(group) filter(*)</li> </ul>				
	<ul> <li>if scope includes all connections:</li> </ul>				
	<ul> <li>search class(group) filter(*)</li> </ul>				
	<ul> <li>followed by group profile extract for each group</li> </ul>				
	<ul> <li>if scope includes all classes:</li> </ul>				
	<ul> <li>RACROUTE STAT to retrieve all class names</li> </ul>				
	<ul> <li>followed by search class(className)</li> <li>filter(**) for each class</li> </ul>				
	<ul> <li>if scope includes a specific class:</li> </ul>				
	<ul> <li>RACROUTE STAT to determine if the class exists</li> </ul>				
	<ul> <li>followed by search class(className)</li> <li>filter(**) for the class</li> </ul>				
	<ul> <li>if scope includes a single user: user profile extract</li> </ul>				
	<ul> <li>if scope includes a single group: group profile extract</li> </ul>				
	<ul> <li>if scope includes a single connection: connect profile extract</li> </ul>				
	<ul> <li>if scope includes a single resource: resource profile extract</li> </ul>				
	<ul> <li>if scope includes just the cn=setropts entry: setropts extract</li> </ul>				

Table 13. SDBM search filters	(continued)
-------------------------------	-------------

Filter	Search behavior				
profilename= <i>any_value</i>	Description: find the RACF general resource profiles whose names match <i>any_value</i> (can contain wildcards) Note: RACF profile names might be case-sensitive, depending on the class.				
	Allowed base: <pre>suffix profiletype=className,suffix</pre>				
	Returns: DN-only entries				
	Commands:				
	if scope includes all classes:				
	<ul> <li>RACROUTE STAT to retrieve all class names</li> </ul>				
	<ul> <li>followed by search class(className) filter(any_value) for each class</li> </ul>				
	<ul> <li>if scope includes a single class:</li> </ul>				
	<ul> <li>RACROUTE STAT to determine if the class exists</li> </ul>				
	<ul> <li>followed by search class(className) filter(any_value) for the class</li> </ul>				
racfgroupid=any_value	Description:				
	find connection profiles for members of the RAC groups whose names match <i>any_value</i> (can contain wildcards)				
	Allowed base: suffix profiletype=connect,suffix				
	Returns: DN-only entries				
	Commands:				
	<ul> <li>if no wildcard in <i>any_value</i>:</li> <li>group profile extract</li> </ul>				
	<ul> <li>if wildcard in <i>any_value</i>:</li> </ul>				
	– search class(group) filter(any_value)				
	<ul> <li>followed by group profile extract for each group</li> </ul>				

Table 13.	SDBM	search	filters	(continued)
-----------	------	--------	---------	-------------

Filter	Search behavior				
racfid= <i>any_value</i>	<b>Description:</b> find user and group profiles for the RACF users and groups whose names match <i>any_value</i> (can contain wildcards)				
	Allowed base: suffix profiletype=user,suffix profiletype=group,suffix				
	Returns: DN-only entries				
	Commands:				
	<ul> <li>if scope includes all users: search class(user) filter(any_value)</li> </ul>				
	<ul> <li>if scope includes all groups: search class(group) filter(any_value)</li> </ul>				
racfuserid= <i>any_value</i>	Description: find connection profiles for RACF users whose names match any_value (can contain wildcards)				
	Allowed base: suffix profiletype=connect,suffix				
	Returns: DN-only entries				
	Commands:				
	<ul> <li>if no wildcard in any_value: user profile extract</li> </ul>				
	<ul> <li>if wildcard in any_value</li> </ul>				
	<ul> <li>search class(user) filter(any_value)</li> </ul>				

Table 13.	SDBM	search	filters	(continued)
-----------	------	--------	---------	-------------

Filter	Search behavior
(&(racfuserid= <i>any_value1</i> ) (racfgroupid= <i>any_value2</i> ))	Description: find connection profiles for RACF users whose names match <i>any_value</i> 1 and who belong to RACF groups whose names match <i>any_value2</i> (both can contain wildcards)
	Allowed base: suffix
	profiletype=connect, <i>suffix</i>
	Returns:
	DN-only entries
	Commands:
	<ul> <li>if no wildcard in any_value1:</li> </ul>
	user profile extract
	<ul> <li>if no wildcard in any_value2</li> </ul>
	group profile extract
	<ul> <li>if wildcard in both any_value1 and any_value2</li> </ul>
	<ul> <li>search class(group) filter(any_value2)</li> </ul>
	<ul> <li>followed by group profile extract for each group</li> </ul>

Except for the AND filter for connections, complex search filters that include NOT, AND, OR, LE, or GE constructs are not supported.

The values for the **profilename**, **racfgroupid**, **racfid**, and **racfuserid** filters can include the wildcards supported by RACF. These wildcards are '\*' which represents any number of characters, and '%' which represents one character. For example: (&(racfuserid=usr\*)(racfgroupid=\*grp))

searches for all the connections between users whose names begin with usr and groups whose names end with grp.

To include multiple levels of qualifiers in a resource profile name search, include either \\*\* or \*\\* in the **profilename** filter. For example, profilename=XYZ.\\*\* searches for all resource profiles that have XYZ as the first qualifier. Do not use \*\* in the filter because this is not a valid LDAP filter. The result of a search with the filter profilename=\*\* is:

ldap\_search: Protocol error ldap\_search: additional info: R010043 Substring filter for attribute 'profilename' has no value

Although an <sup>1\*1</sup> or <sup>1\*\*1</sup> can be part of a resource profile name, there is no way to indicate in the **profilename** filter that an asterisk or double asterisk is part of the name rather than a wildcard. For example, a search using a filter such as profilename=ABC\* returns all profile names beginning with ABC, including the ABC\* profile (if it exists).

**Note about searching universal groups:** Most of the members of a RACF universal group are not actually contained in the group's list of members. As a result, a search of the entry for a universal group does not return most of the

Т

Т

Т

Т

Т

Т

T

group's members. In addition, a search for the connection entry corresponding to a member of a universal group can return different results depending on the connection search filter that is used:

- If the **racfuserid** part of the connection search filter does not contain a wild card, then the connection entry is returned for the specified **racfuserid**.
- If the **racfuserid** part of the connection search filter contains a wild card, then the connection entry for a user is returned only if the user is explicitly contained in the universal group's list of members.

#### Searching the entire RACF database

L

L

Т

Т

L

|

Т

L

L

Searches that query the entire RACF database, for example, a subtree search from any of the top directory entries except the setopts entry, return only the DN (distinguished name) attribute. You may then obtain more specific data about a particular user, group, connection, or resource on a follow-up search using a specific DN as the search base.

**RACF restriction on amount of input:** RACF limits the number of operands that are specified in RACF commands. If the number of operands surpasses this limit, RACF ignores some of the operands and processes the command. Therefore, an SDBM add or modify operation containing many attributes appears to run successfully but some of the attributes might not be set. For more information, see *z/VM: RACF Security Server Command Language Reference*.

**LDAP restriction on RACF data:** If a RACF field contains unprintable characters, the value returned in the LDAP output will probably not match the RACF value and will probably not be printable. If a RACF field contains binary zeros, the LDAP output might be truncated. In particular, make sure that the installation DATA field in RACF user and resource profiles does not contain binary zeros or other unprintable characters.

# **Retrieving RACF user password and password phrase envelopes**

SDBM returns the RACF user password envelope when the **racfPasswordEnvelope** attribute is specified in the attributes to be returned from a search of a RACF user. Similarly, the RACF user password phrase envelope is returned when the **racfPassPhraseEnvelope** attribute is specified on the search. Each envelope is returned by the LDAP server as a binary data berval (binary data and length). If the **racfPasswordEnvelope** and **racfPassPhraseEnvelope** attributes are not specified on the search request, the RACF envelopes are not returned.

**Note:** When using a utility such as LDAPSRCH (**Idapsearch**) to retrieve the password or password phrase envelopes, the returned value is base-64 encoded.

# Using SDBM to change a user password or password phrase in RACF

There are two ways to use SDBM to change a user password or password phrase in RACF.

 The user password or password phrase of the bind user can be changed during an LDAP simple bind to SDBM. The simple bind occurs as part of an LDAP function such as search, add, modify, compare, or delete. The password or password phrase change is provided in the password portion of the LDAP simple bind. The change must be in the following format:

currentvalue/newvalue

The current and new value must both be passwords or password phrases. An error is returned if one of the values is a password and the other is a password phrase.

The forward slash (/) is used as the indication of a password or password phrase change during the LDAP simple bind. Password or password phrase changes made using the LDAP simple bind to the SDBM backend of the z/VM LDAP server are subject to the system password rules. A password or password phrase change fails with LDAP return code LDAP\_INVALID\_CREDENTIALS and LDAP reason code of:

R000101 The new password is not valid

if the new password or password phrase does not pass the rules established on the system.

**Note:** A forward slash (/) is a legal character in a password phrase (but not in a password). During SDBM bind, a backward slash (\) is an escape character to indicate the next character is part of the password or password phrase and has no special meaning. The backward slash is removed during bind processing. Therefore, during bind, a forward slash in a password phrase must be preceded by a backward slash to indicate the forward slash is part of the password phrase and is not the password phrase change indicator. For example, the password phrase thislslash/ispartofthevalue2use during bind. A backward slash is also a legal character in a password phrase (but not in a password). Therefore, a backward slash in a password phrase must be preceded by another backward slash is also to indicate that it is not an escape character.

Once the bind succeeds, the password or password phrase is changed even if the LDAP function eventually fails.

For example, the following command changes the password for RACF user U1 from abc to xyz, assuming the SDBM suffix is cn=racfu01,o=ibm,c=us:

ldapsrch -h ldaphost -p ldapport -D racfid=u1,profiletype=user, cn=racfu01,o=ibm,c=us -w abc/xyz -s base -b "" objectclass=\*

 To change any RACF user's password, create an LDIF file that modifies the racfPassword attribute for that user and then invoke LDAPMDFY to change the password. If the syntax of the new password is not valid, the command fails, returning "Idap\_modify: Unknown error". (Note that this response can also be returned under other circumstances.)

For example, the following LDIF file, pw.mod, resets the password for RACF user U1 to xyz, assuming the SDBM suffix is cn=racfu01,o=ibm,c=us. The racfAttributes: noexpired record is added to result in a new password that is not expired. If noexpired is not specified, then the password is reset but is expired, requiring U1 to change the password at next logon.

dn: racfid=u1,profiletype=USER,cn=racfu01,o=ibm,c=us
changetype: modify
add: x
racfpassword: xyz
racfattributes: noexpired

Then, assuming that the RACF user admin1 has the necessary RACF authorization to update RACF, the command:

ldapmdfy -h ldaphost -p ldapport -D racfid=admin1,profiletype=user, cn=racfu01,o=ibm,c=us -w passwd -f pw.mod

modifies the password or password phrase for U1.

A RACF user's password phrase is changed the same way as described above, using the **racfPassPhrase** attribute.

#### Using LDAP client utilities with SDBM

The LDAP client utilities described in *z/VM: TCP/IP User's Guide* can be used to update data in RACF. Following are some examples. These examples assume that the RACF user admin1 has the necessary RACF authorization to make these RACF updates and that cn=racfu01,o=ibm,c=us is the SDBM suffix.

#### Example: adding a user to RACF

If the LDIF file user.add contains:

```
dn: racfid=newuser,profiletype=user,cn=racfu01,o=ibm,c=us
objectclass: racfUser
racfid: newuser
```

The following command adds user ID newuser to RACF:

ldapadd -h *ldaphost* -p *ldapport* -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w *passwd* -f user.add

Note that the only required attribute to add a user is the user ID specified as **racfid**. This mimics the RACF **adduser** command.

#### Example: modifying a user in RACF

To add an OVM segment for newuser, the LDIF file user.mods could contain:

dn: racfid=newuser,profiletype=user,cn=racfu01,o=ibm,C=us

changetype: modify
objectclass: racfUserOvmSegment
racfOvmHome: /home/newuser
racfOvmInitialProgram: /home/newuser/bin/startup
racfOvmUid : 500

#### The command:

ldapmdfy -h ldaphost -p ldapport -D racfid=admin1,profiletype=user, cn=racfu01,o=ibm,c=us -w passwd -f user.mods

modifies the RACF user profile for user ID newuser, adding an OVM segment with the specified values.

#### Example: searching for user information in RACF

To see the information in RACF for newuser, the following search command can be performed:

```
ldapsrch -h ldaphost -p ldapport -D racfid=admin1,profiletype=user,
  cn=racfu01,o=ibm,c=us -w passwd -b "racfid=newuser,profiletype=user,cn=racfu01,o=ibm,c=us"
  "objectclass=*"
```

The results that are returned are most of the non-default data that RACF displays on a **listuser** command, but using LDAP attribute names. Following is an example for newuser:

```
racfid=NEWUSER,profiletype=USER,cn=RACFU01,o=IBM,c=US
racfid=NEWUSER
racfauthorizationdate=10/23/06
racfowner=RACFID=OPERATOR,PROFILETYPE=USER,CN=RACFU01,O=IBM,C=US
racfpasswordinterval=30
racfdefaultgroup=RACFID=SYS1,PROFILETYPE=GROUP,CN=RACFU01,O=IBM,C=US
racflogondays=SUNDAY
racflogondays=MONDAY
racflogondays=TUESDAY
racflogondays=WEDNESDAY
racflogondays=THURSDAY
```

```
racflogondays=FRIDAY
racflogondays=SATURDAY
racflogontime=ANYTIME
racfconnectgroupname=RACFID=SYS1,PROFILETYPE=GROUP,CN=RACFU01,0=IBM,C=US
racfhavepasswordenvelope=N0
racfattributes=PASSWORD
racfovmuid=500
racfovmhome=/home/newuser
racfovminitialprogram=/home/newuser/bin/startup
objectclass=RACFBASECOMMON
objectclass=RACFUSER
objectclass=RACFUSEROVMSEGMENT
```

# Example: searching for a user's password and password phrase envelopes in RACF

The following search returns the **racfPasswordEnvelope** and **racfPassPhraseEnvelope** attributes:

ldapsrch -h ldaphost -p ldapport -D racfid=admin1,profiletype=user,cn=racfu01, o=ibm,c=us -w passwd -L -b racfid=newuser,profiletype=user,cn=racfu01,o=ibm,c=us "objectclass=\*" racfpasswordenvelope racfpassphraseenvelope

The result returned is:

dn: racfid=newuser,profiletype=user,cn=racfu01,o=ibm,c=us
racfpasswordenvelope:: base-64\_encoded\_password\_envelope
racfpassphraseenvelope:: base-64\_encoded\_passphrase\_envelope

#### Example: adding a group to RACF

If the LDIF file group.add contains:

```
dn: racfid=grp222,profiletype=group,cn=racfu01,o=ibm,c=us
objectclass: racfGroup
racfid: grp222
```

The following command adds group ID grp222 to RACF:

```
ldapadd -h ldaphost -p ldapport -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us
-w passwd -f group.add
```

Note that the only required attribute to add a group is the group ID specified as racfid. This mimics the RACF **addgroup** command.

The LDAP commands for modifying, searching, and removing a RACF group using SDBM are very similar to the corresponding commands for a RACF user. See the examples in this section for a RACF user for more information.

#### Example: connecting a user to a group in RACF

To connect newuser to group grp222, the LDIF file connect.add could contain:

```
dn: racfuserid=newuser+racfgroupid=grp222,profiletype=connect,cn=racfu01,o=ibm,c=us
objectclass: racfconnect
racfuserid: newuser
```

racfgroupid: grp222

The command:

ldapadd -h *ldaphost* -p *ldapport* -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w *passwd* -f connect.add

makes newuser a member of the grp222 group. Note that grp222 must be an existing RACF group ID, newuser must be an existing RACF user ID, and the only required attributes to add a connection are **racfuserid** (the user ID) and **racfgroupid** (the group ID).

# Example: searching for information about a user's connection to a group in RACF

To see information about newuser's connection to the grp222 group, the following search can be performed:

The result returned is the non-default information from the GROUP section that RACF displays on a **listuser** command, but using LDAP attribute names. Following is an example for newuser's connection to grp222:

racfuserid=NEWUSER+racfgroupid=GRP222,profiletype=CONNECT,cn=racfu01,o=ibm,c=us
racfuserid=NEWUSER
racfgroupid=GRP222
racfconnectauthdate=07/18/05
racfconnectowner=RACFID=ADMIN1,PROFILETYPE=USER,cn=racfu01,o=ibm,c=us
racfconnectgroupauthority=USE
racfconnectgroupaucc=NONE
racfconnectcount=0
objectclass=RACFBASECOMMON
objectclass=RACFCONNECT

# To see all the groups that newuser is connected to, either of the following searches can be performed:

ldapsrch -h ldaphost -p ldapport -D racfid=admin1,profiletype=user, cn=racfu01,o=ibm,c=us
-w passwd -b "profiletype=connect,cn=racfu01,o=ibm,c=us" "racfuserid=newuser"

#### or

I

L

|

```
ldapsrch -h ldaphost -p ldapport -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us
-w passwd -b "profiletype=connect,cn=racfu01,o=ibm,c=us"
"(&(racfuserid=newuser)(racfgroupid=*))"
```

For both commands, the results are:

racfuserid=NEWUSER+racfgroupid=G1,profiletype=CONNECT,cn=racfu01,o=ibm,c=us

racfuserid=NEWUSER+racfgroupid=GRP222,profiletype=CONNECT,cn=racfu01,o=ibm,c=us

Note that G1 was the default group to which newuser was connected when newuser was created.

#### Example: removing a user from a group in RACF

The following command removes newuser from the grp222 group (the equivalent of the RACF **remove** command):

```
ldapdlet -h ldaphost -p ldapport
    -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w passwd
    "racfuserid=newuser+racfgroupid=grp222,profiletype=connect,cn=racfu01,o=ibm,c=us"
```

#### Example: removing a user from RACF

The following command removes the newuser user profile from RACF, also removing all of newuser's connections to groups (the equivalent of a RACF **deluser** command):

ldapdlet -h ldaphost -p ldapport

-D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w passwd

"racfid=newuser,profiletype=user,cn=racfu01,o=ibm,c=us"

# Example: adding a resource profile in the facility class and giving a user and a group access to the profile

If the LDIF file resource.add contains:

dn: profilename=NEW.RESOURCE,profiletype=facility,cn=racfu01,o=ibm,c=us
objectclass: racfResource
objectclass: extensibleObject

profilename: NEW.RESOURCE racfuacc: read racfnotify: admin1 racfaccesscontrol: ID(u1) ACCESS(UPDATE) racfaccesscontrol: ID(g1) ACCESS(CONTROL) WHEN(TERMINAL(T2))
The following command adds the NEW.RESOURCE resource profile to the facility class in RACF and gives the requested access:
ldapadd -h <i>ldaphost</i> -p <i>ldapport</i> -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w <i>passwd</i> -f resource.add
Note: A RACF rdefine command followed by two RACF permit commands are issued.
Example: refreshing the raclist for the facility class If the LDIF file setropts.mod contains:
<pre>dn: cn=setropts,cn=racfu01,o=ibm,c=us changetype: modify racfraclist: facility racfsetroptsattributes: refresh</pre>
The command:
ldapmdfy -h <i>ldaphost</i> -p <i>ldapport</i> -D racfid=admin1,profiletype=user,cn=racfu01,o=ibm,c=us -w <i>passwd</i> -f setropts.mod
issues a RACF <b>setropts</b> command to refresh the raclisted profiles in the facility class.

# **Deleting attributes**

Т

1

1

|

	If a request is made to delete the <b>racfAccessControl</b> , <b>racfAttributes</b> , <b>racfConnectAttributes</b> , <b>racfResourceAttributes</b> , or <b>racfSetroptsAttributes</b> attribute and no values are provided, SDBM adds the following to the appropriate RACF command (even if the profile does not currently have that value): • <b>racfAccessControl</b> - RESET(ALL) • <b>racfAttributes</b> - NOAUDITOR NOOPERATIONS NOSPECIAL NOUAUDIT • <b>racfConnectAttributes</b> - NOAUDITOR NOOPERATIONS NOSPECIAL • <b>racfResourceAttributes</b> - NOWARNING
	Deleting a specific value for these attributes requires that the value itself be specified on the delete operation. For example, to remove the OPERATIONS and AUDITOR values from the <b>racfAttributes</b> values of user ID user1 (leaving any other <b>racfAttributes</b> values the user has), issue an LDAPMDFY command with the following file: dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us changetype: modify
	<pre>delete: racfAttributes racfAttributes: OPERATIONS racfAttributes: AUDITOR To remove all the racfAttributes values listed above of user ID user1, issue an LDAPMDFY command with the following file: dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us changetype: modify delete: racfAttributes</pre>

In addition, you can use the **racfAttributes** attribute to remove an entire segment from a user. For example, to remove the OVM segment from user ID user1, issue an LDAPMDFY command with one of the following files:

dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us
changetype: modify
delete: racfAttributes
racfAttributes: 0VM

#### or

dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us
changetype: modify
add: racfAttributes
racfAttributes: NOOVM

Following are some additional examples of deleting attributes:

 dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us changetype: modify delete: racfProgrammerName

#### Returns: LDAP\_UNWILLING\_TO\_PERFORM

The racfProgrammerName attribute is one that cannot be deleted.

 dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us changetype: modify delete: racfBuilding racfBuilding: 001

#### Returns: LDAP\_UNWILLING\_TO\_PERFORM

You cannot specify a value to be removed for racfBuilding.

- dn: racfid=user1,profiletype=user,cn=racfu01,o=ibm,c=us changetype: modify delete: racfBuilding
  - Expected result: successful removal of the attribute **racfBuilding** and **LDAP\_SUCCESS** returned.

# Chapter 6. Password policy

Password policy is a set of rules that controls how passwords are used and administered in the LDAP server. These password policy rules are enforced to ensure that password values are changed periodically and meet the syntactic password requirements of your organization. These rules also restrict the reuse of old passwords, ensure that users are locked out after a defined number of failed bind attempts, and automatically expire passwords after a period of time.

The LDAP password policy rules apply only to entries that have a **userPassword** value stored in a LDBM or CDBM backend. Entries that are outside of a configured backend suffix and have their password values stored in the LDAP server configuration file rather than in a LDBM or CDBM are not subject to LDAP password policy. These users include the LDAP administrator when the password value is specified in the **adminPW** option, the master server DN when the password is specified in the **masterServerPW** configuration option, and the peer server DN when the password value is specified in the password value is

LDAP password policy is checked during authentication and compare operations involving the **userPassword** attribute value to ensure that the password has not expired or the user's account has not been locked from authenticating to the directory. The only supported bind mechanisms for password policy checking are simple, CRAM-MD5, and DIGEST-MD5 when the authenticating user's entry and password resides in a LDBM or CDBM backend. Because LDAP password policy is checked during simple, CRAM-MD5, and DIGEST-MD5 and DIGEST-MD5 authentications and compare operations involving the **userPassword** attribute value, when the term, authentication, is referenced in this section, it indicates each of these scenarios. LDAP password policy is not checked during anonymous or EXTERNAL binds as these authentication mechanisms do not access a password value. LDAP password policy also does not apply to LDBM or CDBM entries participating in native authentication or entries in the SDBM backend. RACF handles the password policy for these users. For more information, see "Binding with SDBM using password policy" on page 66.

During add and modify requests of password values in the LDBM and CDBM backends, the LDAP password policy is checked to verify that the password syntax is correct, the password is allowed to be changed at this time, and if the password must be changed at this time for the user.

# **Password policy entries**

The **cn=pwdpolicy,cn=ibmpolicies** entry is also known as the global password policy entry, and it controls if password policy is active in the LDAP server. By default, the global password policy is not active (set to false), but is activated by setting the **ibm-pwdPolicy** attribute value to true. When activated, the global password policy entry is the default password policy and applies to all LDBM and CDBM entries that have a **userPassword** attribute value. The default values specified in Table 14 on page 95 are the default values of the global password policy entry.

If an individual or group needs to use a special password policy that is different from the global password policy, additional password policy entries are added under the **cn=ibmpolicies** suffix in the CDBM backend. In these additional password policy entries, it is only necessary to specify a password policy attribute value if it is different from the value specified in the global password policy or the default for the attribute value. Depending on the password policy attributes used in these additional password policy entries, an objectclass attribute value of **pwdPolicy** or **ibm-pwdPolicyExt** is required. Because these objectclasses are auxiliary, it is necessary to include a structural objectclass value, such as **container**, to these password policy entries. See Table 14 on page 95 for information about the password policy attribute types.

These additional password policy entries are allowed to be referenced by individual or group entries in the directory. The distinguished name of a password policy entry is referenced by a static, dynamic, or nested group by adding or modifying the single-valued **ibm-pwdGroupPolicyDN** operational attribute value in a group entry. See Chapter 8, "Static, dynamic, and nested groups," on page 123 for more information about group entries. When referenced by a group entry, these password policy entries are referred to as group password policy entries. The distinguished name of a password policy entry is also referenced by an individual user by adding or modifying the single-valued **ibm-pwdIndividualPolicyDN** operational attribute value in a user entry. These password policy entries are referred to as individual password policy entries. Multiple users and groups can point to the same password policy entries. See "Password policy examples" on page 113 for examples on modifying user and group entries to reference password policies.

Individual and group password policy entries are only activated when the **ibm-pwdPolicy** attribute is set to true in their own entries and the **ibm-pwdGroupAndIndividualEnabled** attribute in the global password policy entry is set to true.

#### Notes:

Т

Т

- If the ibm-pwdIndividualPolicyDN attribute value is cn=noPwdPolicy in a user entry, that user is exempt from any password policy controls. A user can also be exempted from password policy controls if the ibm-pwdGroupPolicyDN attribute value is cn=noPwdPolicy in the user's groups.
- 2. The password policy entry must be created before it can be referenced by a user or group entry as an individual or group password policy. When a password policy entry is referenced by any user or group entry in an **ibm-pwdIndividualPolicyDN** and **ibm-pwdGroupPolicyDN** attribute value, the password policy entry cannot be renamed or deleted until all references to the password policy distinguished name (DN) are removed from all individual and group entries.
- 3. Password policy entries must be under the **cn=ibmpolicies** suffix in the CDBM backend. Entries located elsewhere in the directory are ignored.

See "Password policy evaluation" on page 102 for information about determining the effective password policy if a user belongs to individual and multiple password policy groups.

# Activating password policy

When the global password policy entry, **cn=pwdpolicy,cn=ibmpolicies**, is initially created, each attribute value is assigned the default value specified in Table 14 on page 95. If the global password policy is activated and these defaults are not updated, existing users are required to change their passwords on their next successful authentication to the LDAP server. The reason is because the default value for the **pwdMustChange** attribute in the global password policy entry is true that indicates users must change their password values. Before activating the global

1

password policy entry, carefully consider changing the **pwdMustChange** attribute value to false in the global password policy if it is not necessary to force all existing users to change their password values.

When the global password policy is activated, user entries are allowed to have only one **userPassword** attribute value. If there are existing users that have multiple passwords before the global password policy is activated, password policy checking is completed based on the global password policy configuration. When changing password values for users that have multiple **userPassword** values, all existing password values must be replaced with just one **userPassword** value.

# **Password policy attributes**

The password policy attributes in Table 14 are specified in individual and group password policy entries. When the global password policy entry is automatically created by the server, it uses the default values specified in this table. If a password policy attribute is not specified in an entry, it defaults to the value determined by the password policy evaluation rules. Table 14 describes the most restrictive value for each attribute for password policy evaluation. See "Password policy evaluation" on page 102 for more information.

1 Table 14. Password policy attributes and default values

Attribute description and example

#### ibm-pwdGroupAndIndividualEnabled

A boolean (true or false) indicating if group and individual password policy entries are to be considered when
 evaluating password policy. When the global password policy entry is initially created by the server, this attribute is
 set to false indicating that only the global policy is used when evaluating password policy. If set to true, the global,
 group, and individual password policies are to be considered when evaluating password policy.

This is a required attribute of the **ibm-pwdGroupAndIndividualPolicies** objectclass and is only evaluated in the global password policy entry.

Default: false

| Example:

Т

L

L

I

T

|

L

I

I

ibm-pwdGroupAndIndividualEnabled: false

ibm-pwdPolicy

A boolean (true or false) indicating if this password policy entry is active. If set to true, the password policy rules in this entry are enforced. If set to false, the password policy rules in this entry are not enforced. If this is an individual or group password policy entry, the **ibm-pwdPolicy** and the **ibm-pwdGroupAndIndividualEnabled** attributes in the global password policy, **cn=pwdpolicy,cn=ibmpolicies**, must be set to true to allow activation or evaluation of this password policy entry.

- This is an optional attribute of the **ibm-pwdPolicyExt** objectclass.
- Default: false
- Most restrictive value for composite group evaluation: true
- | Example:
- l ibm-pwdPolicy: true

1	Tabla 11	Paceword poli	w attributos a	nd dofault valu	ac (continued)
1	1able 14.	rassworu polic	y allindules a	inu uerault valu	es (continued)

	Attribute description and example
Ι	ibm-pwdPolicyStartTime
   	Specifies the time in Zulu format when the LDAP administrator activated this password policy entry. When the <b>ibm-pwdPolicy</b> attribute is set to true, this attribute automatically resets to the current time. This value is used during password expiration checking.
Ι	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
I	Most restrictive value for composite group evaluation: The oldest defined time is used.
 	Example: ibm-pwdPolicyStartTime: 20091001170933.867354Z
I	passwordMinAlphaChars
	Specifies the minimum number of alphabetic characters (A-Z and a-z) that a password value must have. It must be set to less than or equal to the value in the <b>pwdMinLength</b> attribute minus the value in the <b>passwordMinOtherChars</b> attribute. If set to 0, there is no minimum number of alphabetic characters that a password value must have. If the number of alphabetic characters cannot be checked (because of a one-way hashed password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, the password is accepted without checking it ('0' or '1') or is refused ('2').
I	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
I	Default: 0
 	<b>Most restrictive value for composite group evaluation:</b> See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
I	Example:
I	passwordMinAlphaChars: 3
I	passwordMinOtherChars
	Specifies the minimum number of numeric and special characters (other than A-Z and a-z) that a password value must have. It must be set to less than or equal to the value in <b>pwdMinLength</b> attribute minus the value in <b>passwordMinAlphaChars</b> attribute. If set to 0, there is no minimum number of other characters that a password value must have. If the number of numeric and special characters cannot be checked (because of a one-way hashed encrypted password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, either the password is accepted without checking it ('0' or '1') or is refused ('2').
I	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
Ι	Default: 0
 	<b>Most restrictive value for composite group evaluation:</b> See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
I	Example:
I	passwordMinOtherChars: 2

Ι	Attribute description and example
Ι	passwordMaxRepeatedChars
     	Specifies the maximum number of times a given character is used in a password value. If set to 0, there is no limit on the number of repeated characters that a password value must have. If the maximum number of repeated characters cannot be checked (because of a one-way hashed encrypted password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, either the password is accepted without checking it ('0' or '1') or is refused ('2').
Ι	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
I	Default: 0
 	Most restrictive value for composite group evaluation: See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
Ι	Example:
I	passwordMaxRepeatedChars: 2
Ι	passwordMaxConsecutiveRepeatedChars
   	Specifies the maximum number of successive repetitions of a given character in a password value. If set to 0, the number of consecutive repeated characters is not checked in the password value. If the maximum number of consecutive repeated characters cannot be checked (because of a one-way hashed encrypted password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, either the password is accepted without checking it ('0' or '1') or is refused ('2').
   	For example, if set to 1, a given character cannot be followed by another character of the same type. Therefore, 'aba' is valid and 'aab' is not valid. For example, if set to 2, the maximum number of times a given character can occur consecutively is 2. Therefore, 'aaba' is valid and 'aaab' is not valid.
I	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
Ι	Default: 0
 	<b>Most restrictive value for composite group evaluation:</b> See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
Ι	Example:
Ι	passwordMaxConsecutiveRepeatedChars: 2
I	passwordMinDiffChars
   	Specifies the minimum number of characters in the new password that must be different from the characters in the old password value. If set to 0, the number of different characters are not checked in the new password value. If the password characters cannot be checked (because of a one-way hashed encrypted password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, either the password is accepted without checking it ('0' or '1') or is refused ('2').
Ι	This is an optional attribute of the <b>ibm-pwdPolicyExt</b> objectclass.
I	Default: 0
 	Most restrictive value for composite group evaluation: See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
 	Example: passwordMinDiffChars: 0

I	Attribute description and example
I	pwdAllowUserChange
   	A boolean (true or false) indicating if users are allowed to change their own passwords. If set to false, users are not allowed to change their own password. If set to true, users are allowed to change their own password if they have the authority. If the <b>pwdMustChange</b> attribute is set to true, this attribute must also be set to true to allow users to change their passwords.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: true
I	Most restrictive value for composite group evaluation: false
	Example: pwdAllowUserChange: false
I	pwdAttribute
   	Specifies the name of the attribute this password policy applies to. This attribute is only allowed to be set to <b>userPassword</b> . If this attribute is attempted to be set to another value, an error is returned on the add or modify request of the password policy entry.
I	This is a required attribute of the <b>pwdPolicy</b> objectclass.
I	Default: userPassword
I	Example:
I	pwdAttribute: userPassword
I	pwdCheckSyntax
   	Specifies if the user's password value is checked for password policy syntax when adding or modifying a <b>userPassword</b> attribute value. The password policy attributes that affect password policy syntax are <b>passwordMinAlphaChars</b> , <b>passwordMinOtherChars</b> , <b>passwordMaxRepeatedChars</b> , <b>passwordMaxConsecutiveRepeatedChars</b> , <b>passwordMinDiffChars</b> , and <b>pwdMinLength</b> .
   	If set to 0, syntax checking of the password value is not enforced. If set to 1, the password syntax is checked and if it cannot be checked (because of a one-way hashed encrypted password or other reasons) it is accepted. If set to 2, the password syntax is checked and if it cannot be checked (because of a one-way hashed password or other reasons), an error is returned on the add or modify request of the user's password value.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
   	<b>Note:</b> Password policy syntax checking is not enforced when the LDAP administrator is adding or modifying another user's <b>userPassword</b> attribute value. However, when updating the LDAP administrator's own <b>userPassword</b> attribute value, password policy syntax checking is enforced.
I	Default: 0
I	Most restrictive value for composite group evaluation: The largest value is used.
	Example: pwdCheckSyntax: 2

Table 14. Password policy attributes and default values (continued) L L Attribute description and example L pwdExpireWarning Specifies the number of seconds before a password is due to expire that expiration warning messages are returned L during authentication in the **PasswordPolicy** response control. If set to 0, password policy expiration warnings are Т not returned during authentication in the **PasswordPolicy** response control. L L This is an optional attribute of the **pwdPolicy** objectclass. L Default: 0 Most restrictive value for composite group evaluation: The largest value is used. L L Example: L pwdExpireWarning: 600 L pwdFailureCountInterval L Specifies the number of seconds when password failures are removed from the failure counter although no L successful authentication has occurred. If set to 0, the failure counter is only reset by a successful authentication. This is an optional attribute of the **pwdPolicy** objectclass. L Default: 0 L L Most restrictive value for composite group evaluation: The largest value is used. Example: L pwdFailureCountInterval: 600 L pwdGraceLoginLimit L Specifies the number of times an expired password is used for authentication. If set to 0 and the password has expired, authentication fails. When the number of grace logins or authentications is exceeded by the user, the password is automatically expired and authentication fails. There is no time limit applied to this attribute. L This is an optional attribute of the **pwdPolicy** objectclass. L Default: 0 Most restrictive value for composite group evaluation: The smallest value is used. L L Example: pwdGraceLoginLimit: 3 L pwdInHistory L Specifies the maximum number of used password values stored in the **pwdHistory** operational attribute of user entries. If set to 0, used password values are not stored in the pwdHistory attribute of user entries, therefore, they L might be reused. The maximum value for this attribute is 30. The passwords stored in the pwdHistory operational L L attribute values are used to check new password values modified by the user. L This is an optional attribute of the **pwdPolicy** objectclass. L Default: 0 L Most restrictive value for composite group evaluation: The largest value is used. L Example: pwdInHistory: 15

I	Attribute description and example
	pwdLockout
   	A boolean (true or false) used to indicate if a password might be used for authentication when the maximum number of consecutive failed authentication attempts specified in the <b>pwdMaxFailure</b> attribute is exceeded. If set to true, the user's account is eligible to be locked for the number of seconds specified in the <b>pwdLockoutDuration</b> attribute value. If set to false, the user's account is not eligible to be locked.
	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: false
	Most restrictive value for composite group evaluation: true
	Example:
I	pwdLockout: true
	pwdLockoutDuration
   	Specifies the number of seconds a password cannot be used for authentication when the maximum number of consecutive failed authentication attempts in the <b>pwdMaxFailure</b> attribute is exceeded and the <b>pwdLockout</b> attribute is set to true. If set to 0 and the maximum number of consecutive failed authentication attempts is exceeded, the password cannot be used for authentication until it is reset by the LDAP administrator.
	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: 0
I	Most restrictive value for composite group evaluation: The largest value is used.
I	Example:
I	pwdLockoutDuration: 600
I	pwdMaxAge
	Specifies the maximum age, in seconds, when a modified password expires. If set to 0, the password value does not expire for the user. This value must be greater than or equal to the <b>pwdMinAge</b> attribute value.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: 0
I	Most restrictive value for composite group evaluation: The smallest value is used.
I	Example:
I	pwdMaxAge: 6000
I	pwdMaxFailure
   	Specifies the maximum number of consecutive failed authentication attempts allowed. If set to 0, there is no maximum number of consecutive failed authentication attempts and the <b>pwdLockout</b> attribute value is ignored. If greater than 0, the <b>pwdLockout</b> attribute is set to true, and the maximum number of failed authentication attempts is reached, authentication is not allowed until the lockout time specified in the <b>pwdLockoutDuration</b> attribute value is exceeded.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: 0
I	Most restrictive value for composite group evaluation: The smallest value is used.
	Example:
I	pwdMaxFailure: 5

I	Attribute description and example
Ι	pwdMinAge
 	Specifies the number of seconds that must elapse between modifications to the password. If set to 0, the password value is modified without waiting for time to elapse. This value must be less than or equal to the <b>pwdMaxAge</b> value.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: 0
I	Most restrictive value for composite group evaluation: The largest value is used.
 	Example: pwdMinAge: 600
Ι	pwdMinLength
   	Specifies the minimum length of the password value for the user. If set to 0, there is no minimum password value length checking enforced. If the password length cannot be checked (because of a one-way hashed password or other reasons), based on the value of the <b>pwdCheckSyntax</b> attribute, either the password is accepted without checking it ('0' or '1') or is refused ('2').
Ι	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: 0
 	Most restrictive value for composite group evaluation: See "Evaluation of a user's individual and composite group password policy" on page 103 for more information.
I	Example:
Ι	pwdMinLength: 8
Ι	pwdMustChange
     	A boolean (true or false) indicating users must change their passwords after their first successful authentication to the server after a password is set or reset by the LDAP administrator. If set to true, users are required to change their password after their first successful authentication. If set to false, users are not required to change their password upon successful authentication when the password is set or reset by the LDAP administrator. If this attribute is set to true, the <b>pwdAllowUserChange</b> attribute must also be set to true to allow users to change their password values.
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: true
I	Most restrictive value for composite group evaluation: true
	Most restrictive value for composite group evaluation: true Example:

I	Attribute description and example
I	pwdSafeModify
   	A boolean (true or false) indicating the existing or current password value must be sent when changing a password value. If set to true, the existing password value must be sent on the modify request. If set to false, the existing password value does not need to be sent on the modify request. The LDAPCHPW utility is used to change a user's password value. For more information about the LDAPCHPW utility, see <i>z/VM: TCP/IP User's Guide</i> .
I	This is an optional attribute of the <b>pwdPolicy</b> objectclass.
I	Default: false
I	Most restrictive value for composite group evaluation: true
I	Example:
	pwdSafeModify: true
I	
l	<b>Note:</b> When the <b>ibm-pwdPolicy</b> attribute is changed from false to true in the

**Iote:** When the **ibm-pwdPolicy** attribute is changed from false to true in the password policy entry, the **ibm-pwdPolicyStartTime** attribute is automatically set by the server to the current time. This password policy start time is used for performing password expiration and age checking of a user's password value if either of these password policy features are enabled for the user. When a password value is modified, the **pwdChangedTime** attribute value in the user's entry is updated with the time of the password modification. The password policy start time and the last password modification time are used to determine if the user's password has expired. However, if the **ibm-pwdPolicy** is changed from false to true later, user passwords that are scheduled to expire might no longer expire at the original time because the password policy start time is set to a more recent time.

## **Password policy evaluation**

T

|

1

T

T

Because users can belong to an individual password policy, belong to multiple groups that have varying password policies, and the global password policy, there are a set of rules that are followed for determining the user's effective password policy when conflicting password policies are in effect. Individual and group password policies are not evaluated when determining a user's effective password policy until the **ibm-pwdPolicy** and the **ibm-**

**pwdGroupAndIndividualEnabled** attribute values are set to true in the global password policy. In addition, each individual or group password policy is not activated or evaluated for determining a user's effective password policy until the **ibm-pwdPolicy** attribute value is set to true in those entries.

When the password policies are activated, the different levels of password policies (individual, group, and global) are accessed when evaluating a user's effective password policy. The password policies are evaluated in this order, if they exist:

- individual policy entry
- composite group policy entry
- global password policy entry
- · default password policy attribute value

Typically, when a password policy attribute is found in any of the password policy entries, the evaluation of that attribute stops and that attribute value is used as part of the user's effective password policy. See Table 14 on page 95 for the default password policy attribute values.

A user entry may belong to an individual password policy entry. Because the user also might belong to more than one group, multiple group password policy entries may be evaluated to determine a user's composite group policy. These are the rules for determining a user's effective password policy:

- 1. If the **ibm-pwdPolicy** attribute value is false or is not specified in the individual or group password policy entry, no attributes defined in the entry are used to determine the effective password policy.
- 2. If the ibm-pwdIndividualPolicyDN attribute value is cn=noPwdPolicy in a user entry, that user is exempt from any password policy controls. A user can also be exempted from any password policy controls if all the user's groups that have the ibm-pwdGroupPolicyDN attribute have a value of cn=noPwdPolicy and the user entry does not have an ibm-pwdIndividualPolicyDN. If any of the user's groups has the ibm-pwdGroupPolicyDN attribute referring to an active policy, then references to cn=noPwdPolicy in the user's other groups are ignored in the composite group policy evaluation.
- The ibm-pwdPolicyStartTime attribute is set to the current system time when ibm-pwdPolicy is set to true in the password policy entry. It is set to a new time whenever its value is changed from false to true. In determining the ibm-pwdPolicyStartTime value for a composite group, the oldest defined value is used.
- 4. The password policy attributes passwordMinAlphaChars, pwdMinLength, and passwordMinOtherChars are interdependent. For example, the value of passwordMinAlphaChars must be less than or equal to the value in pwdMinLength and pwdMinDiffChars minus the value in passwordMinOtherChars. Because of this interdependency among attribute values, if one attribute is selected from a policy, then the other two attributes are also selected from the same policy.

If an individual password policy is not enabled and there are multiple group password policies enabled, the order of selection is **pwdMinLength**, **passwordMinOtherChars**, **passwordMinAlphaChars**, and **pwdMinDiffChars**. This means that the selection is based on picking the most restrictive (the largest value) for **pwdMinLength**. If multiple group policies have the same largest value for the **pwdMinLength** attribute, then the one with the most restrictive (the largest value) for **passwordMinOtherChars** is selected. If multiple group policies also have the same largest **passwordMinOtherChars** value, then the group policy with the most restrictive (the largest value) **pwdMinDiffChars** is used. After an attribute is selected, the other three attributes are selected automatically from that same policy.

5. The password policy attributes pwdMinAge, pwdMaxAge, and pwdExpirationWarning are interdependent. For example, the value of pwdMinAge must be less than or equal to the value in pwdMaxAge and the value of pwdExpireWarning must be less than or equal to the value in pwdMaxAge. Because of this interdependency among attribute values, if one attribute is selected from a policy, then the other two attributes are also selected from the same policy.

If an individual password policy is not enabled and there are multiple group policies enabled, the order of selection is **pwdMaxAge**, **pwdMinAge**, and **pwdExpireWarning**. This means that the selection is based on picking the most restrictive value (the smallest value) for **pwdMaxAge**. In a situation where multiple group policies have the same value for the **pwdMaxAge** attribute, then the one with the most restrictive value (the largest value) for **pwdMinAge** is selected. In a situation where multiple group policies have the same value for the **pwdMaxAge** and **pwdMinAge** attributes, then the one with the most restrictive value (the largest value) for **pwdExpireWarning** is selected. After an attribute is selected, the other two attributes are selected automatically from that same policy.

 The passwordMaxConsecutiveRepeatedChars attribute is used to restrict the maximum successive repetitions of a given character in the password. passwordMaxRepeatedChars and

**passwordMaxConsecutiveRepeatedChars** attributes are allowed to be enabled or disabled, independent of each other. However, if both of these attributes are enabled, these rules are applicable:

- The value of the passwordMaxRepeatedChars attribute must be greater than or equal to the value of the passwordMaxConsecutiveRepeatedChars attribute.
- When multiple group password policies are enabled, the passwordMaxConsecutiveRepeatedChars value is obtained from the same policy where the passwordMaxRepeatedChars attribute value is obtained from. If passwordMaxRepeatedChars is disabled in all policies, then the most restrictive value of passwordMaxConsecutiveRepeatedChars is used.
- 7. The password policy attributes **pwdMustChange** and **pwdAllowUserChange** are interdependent. For example, setting the value of **pwdMustChange** to true and **pwdAllowUserChange** to false is not allowed, as this says that a user must change their password after it has been reset by an administrator, but does not give the user the ability to change their password. Because of this, when adding or modifying a policy, this combination is checked for and is not allowed. Therefore, considering this interdependency between the attributes, if one attribute is selected from a policy, then the other attribute is also selected from the same policy.

The default for the **pwdMustChange** and **pwdAllowUserChange** attributes is true. The most restrictive value for the **pwdMustChange** attribute is true. The most restrictive value for the **pwdAllowUserChange** attribute is false. When choosing which group policy supplies these two attributes, the one with the most restrictive value for **pwdAllowUserChange** is chosen. If all the values for **pwdAllowUserChange** are true, then the group with the most restrictive value for **pwdMustChange** is chosen.

8. Attributes in all active group password policy entries are combined to form a union of attributes with the most restrictive attribute values taking precedence. See "Password policy attributes" on page 95 and Table 15 on page 105 for information about how the most restrictive attribute values are determined.

To better understand how a composite group policy is determined, consider some examples given in Table 15 on page 105. The examples in Table 15 on page 105 only display values for the attributes specified in the various groups, not all the default values for the attributes that are not specified.

# Effective password policy examples

The **Effective password policy** extended operation is useful for the LDAP administrator to query a user's effective password policy when there are multiple password policies active. This extended operation is supported in the LDAPEXOP utility. For more information, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

Table 16 displays examples of how a user's effective password policy is determined when individual, group, and global password policies are active.

Table 16. Effective password policy examples

I

Individual password policy	Composite group password policy	Global password policy	Effective password policy
ibm-pwdpolicy=true ibm-pwdpolicy=true 20091102173246.353496Z pwdminlength=8 pwdgraceloginlimit=3 pwdinhistory=4 pwdattribute=userpassword	ibm-pwdpolicy=true ibm-pwdpolicystarttime= 20091102173256.250491Z pwdexpirewarning=2592000 pwdminlength=10 pwdchecksyntax=2 passwordminalphachars=5 passwordminalphachars=5 passwordmintherchars=2 pwdattribute=userpassword pwdmaxage=5184000	ibm-pwdpolicy=true ibm-pwdpolicystartime= 20091102163354.065965Z pwdgraceloginlimit=0 pwdsafemodify=FALSE pwdlockoutduration=0 pwdmaxlailure=5 pwdfailurecountinterval=0 pwdmaxage=7776000 pwdmaxage=776000 pwdexpirewarning=5184000 pwdminegth=5 pwdlockout=true pwdallowuserchange=TRUE pwdlockout=true pwdgroupandindividualenabled=true passwordmaxrepeatedchars=0 passwordmaxrepeatedchars=0 passwordminalphachars=0 passwordminalphachars=0 passwordmindiffchars=0 pwdminage=0 pwdinistory=3 pwdchecksyntax=0	ibm-pwdpolicy=TRUE ibm-pwdpolicy=TRUE ibm-pwdpolicystartime= 20091102173246.353496Z passwordMaxConsecutiveRepeatedChars=0 passwordminalphachars=0 passwordmindiffchars=0 passwordmindiffchars=0 pwdallowuserchange=TRUE pwdatribute=userpassword pwdatribute=userpassword pwdatribute=userpassword pwdatribute=userpassword pwdatailurecountinerval=0 pwdexpirewarning=2592000 pwdfailurecountinerval=0 pwdgraceloginlimit=3 pwdlockout=TRUE pwdlockoutduration=0 pwdmaxage=5184000 pwdminlength=8 pwdmustchange=TRUE pwdsafemodify=FALSE
ibm-pwdpolicy=true ibm-pwdpolicystarttime= 20091103132230.734257Z pwdgraceloginlimit=8 pwdmaxage=2592000 pwdminage=86400	ibm-pwdpolicy=true ibm-pwdpolicystarttime= 20091103131723.827250Z pwdminlength=10 pwdgraceloginlimit=10 pwdmaxage=5184000 pwdminage=86400 pwdexpirewarning=2592000 passwordmindifchars=2 passwordminotherchars=0 pwdinhistory=5	ibm-pwdpolicy=true ibm-pwdpolicystarttime= 20091102163354.065965Z pwdgraceloginlimit=10 pwdsafemodify=FALSE pwdlockoutduration=0 pwdmaxfailure=5 pwdfailurecountinterval=0 pwdmaxage=7776000 pwdexpirewarning=5184000 pwdminlength=5 pwdlockout=true pwdallowuserchange=TRUE pwdmustchange=TRUE ibm-pwdgroupandindividualenabled=true passwordmaxrepeatedchars=0 passwordminalphachars=0 passwordminotherchars=1 passwordminotherchars=1 passwordminotiffchars=3 pwdininge=2592000 pwdinhistory=0 pwdchecksyntax=0	ibm-pwdpolicy=TRUE ibm-pwdpolicystarttime= 20091103132230.734257Z ibm-pwdgroupandindividualenabled=TRUE passwordMaxConsecutiveRepeatedChars=0 passwordminalphachars=0 passwordmindiffchars=2 passwordmindiffchars=2 passwordmindiffchars=0 pwdallowuserchange=TRUE pwdattribute=userpassword pwdchecksyntax=0 pwdchecksyntax=0 pwdcpirewarning=0 pwdfailurecountintervaI=0 pwdgraceloginlimit=8 pwdlockout=TRUE pwdlockoutduration=0 pwdmaxage=2592000 pwdminage=86400 pwdminlergth=10 pwdsafemodify=FALSE

In the first row of Table 16, the **pwdMinLength**, **pwdGraceloginlimit**, and **pwdInHistory** values are selected from the individual policy as that policy is evaluated first. When the **pwdMinLength** value is selected from the individual policy, the **passwordMinAlphaChars** and **passwordMinOtherChars** values default to 0 because these attributes are interdependent and must come from the same policy. The **pwdExpireWarning**, **pwdCheckSyntax**, **passwordMinAlphaChars**, **passwordMinOtherChars**, and **pwdMaxAge** are selected from the composite group policy because that is evaluated next. The remaining password attribute values are selected from the global password policy.

In the second row of Table 16, the **pwdGraceLoginLimit**, **pwdMaxAge**, and **pwdMinAge** are selected from the individual policy because those policies are evaluated first. When the **pwdMaxAge** and **pwdMinAge** are selected from the

	individual policy, the <b>pwdExpireWarning</b> defaults to 0 because these attributes are interdependent and must come from the same policy. The <b>pwdMinLength</b> , <b>passwordMinDiffChars, passwordMinOtherChars</b> , and <b>pwdInHistory</b> are selected from the composite group because that is evaluated next. The remaining password attribute values are selected from the global password policy.
I	Password policy operational attributes
     	For user entries that are subject to LDAP password policy, there are several operational attributes that contain password policy state information. The password operational attributes in Table 17 are in the critical access class and by default, only the LDAP administrator can query and read them. If other users need access to these attributes, the default ACLs may be changed to allow read access to these attributes. See Chapter 9, "Using access control," on page 135 for more information.
Ι	Table 17. Password policy operational attributes in user entries
Ι	Attribute and description
Ι	pwdChangedTime
 	Specifies the GMT time in Zulu format when the <b>userPassword</b> value was last changed or the <b>ibm-</b> <b>pwdPolicyStartTime</b> attribute value of the effective password policy entry's start time whatever time is later.
I	Example:
I	pwdChangedTime: 20091021182253.188983Z
Ι	pwdAccountLockedTime
   	Specifies the GMT time in Zulu format when the user's account was locked. If the user's account is not locked, this attribute is not present in the user's entry. If the user's password is reset by the LDAP administrator, this attribute is automatically removed from the entry.
I	Example:
I	pwdAccountLockedTime: 20091021183747.488417Z
I	pwdExpirationWarned
I	Specifies the GMT time in Zulu format of the first password expiration warning for this user.
I	Example:
I	pwdExpirationWarned: 20091021181746.852469Z
Ι	pwdFailureTime
   	A multi-valued attribute specifying the GMT times in Zulu format of the previous consecutive authentication failures for this user. The number of consecutive authentication failures by this user is limited by the <b>pwdMaxFailure</b> attribute value in the effective password policy entry. On a successful authentication, all <b>pwdFailureTime</b> attribute values are removed from the user's entry.
Ι	Example:
Ι	pwdFailureTime: 20091021181836.913647Z

Table 17. Password policy operational attributes in user entries (continued)

	Table 17. Tassword policy operational autobules in user entries (continued)
Ι	Attribute and description
Ι	pwdGraceUseTime
     	A multi-valued attribute specifying the GMT times in Zulu format of the previous grace logins for this user. The number of grace logins allowed by this user with an expired password is limited by the <b>pwdGraceLoginLimit</b> attribute value in the effective password policy entry. If grace logins are not allowed by the effective password policy, this attribute is not present in the user's entry. If the user's password is changed before the grace logins limit is exceeded, all <b>pwdGraceUseTime</b> attribute values are removed from the user's entry.
I	Example:
 	pwdGraceUseTime: 20091013183626.310768Z pwdGraceUseTime: 20091021155707.839414Z
Ι	pwdHistory
   	A multi-valued attribute containing the history of previously used passwords for this user entry. The number of previous password values stored for this user is limited by the <b>pwdlnHistory</b> attribute value in the effective password policy entry. When the current <b>userPassword</b> attribute value is changed for this user, the previous password values in the history are compared to ensure that the user does not reuse an old password value.
	The format for this attribute is: pwdHistory: time#syntaxOID#length#data
Ì	Where,
Ι	time is the GMT time in Zulu format when this password value was added to the password history.
I	syntax0ID is the numeric OID that defines the syntax used to store the password value.
Ι	length is the number of octets in the old password data.
 	data is the octet representing the password in the format specified by the syntax0ID. This portion is in the same encryption or hashing format used for the original <b>userPassword</b> attribute value.
I	Example:
 	pwdHistory: 20091021161139.092945Z#1.3.6.1.4.1.1466.115.121.1.40#15#{none}newsecret pwdHistory: 20091021180138.780760Z#1.3.6.1.4.1.1466.115.121.1.40#62#{SSHA}sfuS12Tfj1wVNHhD322vCJVzkK72XvvGeYi2Z7qP4wZghByJc9jFfQ==
I	pwdReset
   	A boolean (true or false) indicating if the user's password is changed or set by another user. When set to true, the password value must be changed by the user after successful authentication before the user is allowed to perform any other operations. If the <b>userPassword</b> value in this entry is changed by the user, this attribute is removed from the user's entry.
I	Example:
Ι	pwdReset: true
I	ibm-pwdAccountLocked
   	A boolean (true or false), if set to true, indicates that the user's account is administratively locked by the LDAP administrator. When a user's account is locked, the user is unable to successfully authenticate to the server. This attribute is not present in the user's entry if the account has never been administratively locked.
I	Example:
	ibm-pwdAccountLocked: true
' I	The LDAP administrator can query these password policy operational attributes for

The LDAP administrator can query these password policy operational attributes for user entries in a particular state. Because these attributes are operational, each attribute name or the special '+' attribute must be specified on the search request so that they are returned on the search response. If the authenticated user has

I

T

I

access to operational attributes, the '+' attribute returns all operational attributes other than the **ibm-allMembers**, **ibm-allGroups**, **ibm-entryCheckSum**, **ibm-entryCheckSumOp**, and **hasSubordinates** attributes.

This example uses the LDAPSRCH utility to retrieve operational attributes. ldapsrch -D adminDn -w adminPw -s sub -b "c=us" objectclass=\* +

The **pwdChangedTime** attribute may be used in a search filter to retrieve a list of candidate users whose passwords may be about to expire. This example assumes that the effective password policy expiration policy is 90 days and searches for all entries of passwords expiring on August 10, 2010. Therefore, this example uses the LDAPSRCH utility to search for all entries when the password was last changed on May 2, 2010:

ldapsrch -D adminDn -w adminPw -s sub -b "c=us" "(!(pwdChangedTime>=20100502000000Z))" dn

The **pwdAccountLockedTime** attribute is used in a search filter to retrieve a list of candidate users that may be locked. Users are not always locked when this attribute is present in their entries because the effective password policy lockout duration might already be exceeded. This example uses the LDAPSRCH utility to search for all entries that have an **pwdAccountLockedTime** attribute value: 1dapsrch -D adminDn -w adminPw -s sub -b "c=us" "(pwdaccountlockedtime=\*)" dn

The **pwdReset** attribute may be used in a search filter to retrieve a list of candidate users whose password must be changed because the password was reset or changed by another user. If the effective password policy does not enforce password reset, then this search does not retrieve all users that need to change or reset their passwords. This example uses the LDAPSRCH utility to search for all entries that have a **pwdReset** attribute value.

ldapsrch -D adminDn -w adminPw -s sub -b "c=us" "(pwdreset=true)" dn

### PasswordPolicy control

L

The **PasswordPolicy** server control is specified on a client request to solicit additional warning and error information related to password policy enforcement, which the server returns in the **PasswordPolicy** response control. For example, during authentication, the **PasswordPolicy** response control can notify the user that the password must be changed, is about to expire, or there are only a few grace logins available before the user's password expires. For add requests, the **PasswordPolicy** response control provides additional error information about the password value syntax. For modify requests, the **PasswordPolicy** response control provides additional error information about the password value syntax, the new password value exists in the password history, or the old password value must be specified.

By default, the LDAP client utilities send the **PasswordPolicy** server control on these requests to obtain additional warning and error information about password policy enforcement. For more information about the LDAP client utilities, see *z/VM: TCP/IP User's Guide*.

Table 18 on page 110 and Table 19 on page 110 contain summaries of the warnings and errors that are returned by the **PasswordPolicy** response control. See "PasswordPolicy" on page 340 for more information.

#### Table 18. PasswordPolicy response control warnings

I	Warnings and description
I	timeBeforeExpiration
I	Indicates the number of seconds before the user's password expires.
I	graceLoginsRemaining
I	Indicates the number of times a user is allowed to authenticate with an expired password.
	Table 19. PasswordPolicy response control errors
I	Errors and description
I	passwordExpired
I	Indicates that the user's password has expired and must be reset by the LDAP administrator
I	accountLocked
 	Indicates the user's account is locked by the LDAP administrator or a user with sufficient authority or the account is locked because of exceeding the maximum number of failed authentications.
I	changeAfterReset
 	Indicates the user's password must be changed before the user is allowed to perform any operation other than authentication and modify requests.
I	passwordModNotAllowed
I	Indicates that the password cannot be changed by the user even if the ACLs allow it to be changed.
I	mustSupplyOldPassword
I	Indicates that the old password value must be supplied when changing the user's password value.
I	insufficientPasswordQuality
I	Indicates that the new password value did not pass the quality standards specified in the effective password policy.
I	passwordTooShort
I	Indicates that the new password value is too short.
I	passwordTooYoung
I	Indicates that the password value is not allowed to be changed because it has been changed too recently.
I	passwordInHistory
I	Indicates that the new password value exists in the password history and cannot be reused again.
	<b>Note:</b> A subset of these <b>PasswordPolicy</b> response control warnings and errors are returned if the user entry is participating in native authentication or is an SDBM user. For more information, see "Binding with SDBM using password policy" on page 66.
Ī	Replicating password policy operational attributes
	If password policy operational attributes in a user's entry are updated during an add, bind, compare, or modify request, these updates are replicated to the configured replica or consumer server. These password policy operational attributes are replicated in an advanced or basic replication environment because: <ul> <li>The <b>pwdChangedTime</b> attribute is replicated to all replica or consumer servers</li> </ul>
	to enable expiration of the user's password on all servers.
	110 z/VM: TCP/IP LDAP Administration Guide

<ul> <li>The pwdReset attribute is replicated to all replica or consumer servers to deny access to operations other than bind and modifying the user's password value.</li> <li>The pwdHistory attribute is replicated to all replica or consumer servers to keep the user's password history synchronized across all servers.</li> <li>The pwdAccountLocked, pwdExpirationWarned, pwdFailureTime, and pwdGraceUseTime attributes are replicated to all replica or consumer servers to enable the password policy to be managed as a whole across the entire replication environment. This allows the number of login failures, the number of grace logins, and the locking of the user's account to be managed as a whole across the entire replication environment.</li> </ul>
• The <b>ibm-pwdAccountLocked</b> attribute is replicated to all replica or consumer servers to lock the user's entry on all servers in the replication environment.
Because these operational attributes are replicated to all consumer or replica servers, use peer-to-peer or read/write replica servers in a replication environment. This allows all servers to keep the password policy operational attribute values for user entries synchronized in all servers in the replication environment. For example, consider a master-replica replication environment with a password policy that allows users three failed logins before the user's account is locked. If users are attempting to authenticate to the read-only replica server in this environment, the user is only locked out from the read-only replica server when the incorrect password has been specified three times. The read-only replica server cannot update the password policy operational attribute values for the entry on the master server. In this example, the user is still allowed to authenticate to the master server although the user is locked out on the replica server. To prevent these types of situations in a replication environment, it is recommended that peer-to-peer replication environments be used when password policy is configured and active. This enables all servers the ability to update the password policy operational attributes during authentication.

# Password policy related extended operations

A set of extended operations is provided to allow the LDAP administrator to query the effective password policy for a user or group and to query the status of a user's account. The LDAPEXOP utility is provided to call these password policy extended operations. Table 20 summarizes the extended operations including the LDAPEXOP operation value. For more information, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

 	LDAPEXOP operation	LDAPEXOP description	Overview
     	acctstatus	Account status extended operation	This extended operation is used to query the status of a user entry that contains a <b>userPassword</b> value. The status returned is if the user's account is opened, locked by the administrator, or the user's password is expired. See "Account status" on page 347 for more information.
   	effectpwdpolicy	Effective password policy extended operation	This extended operation is used to query a user's or group's effective password policy entries and the effective password policy attribute values. See "Effective password policy" on page 357 for more information.
   			cy examples" on page 106 and "Account status on page 117 for examples on using these extended

### Overriding password policy and unlocking accounts

T

1

1

1

1

Т

The LDAP administrator can override typical password policy behavior for specific user entries by modifying the password policy operational attributes. This section shows examples of how the effective password policy is overridden for specific users.

The LDAP administrator can prevent the password for a specific account or user from expiring by setting the **pwdChangedTime** attribute value to a date far in the future. This example uses the LDAPMDFY utility to set the password expiration time to January 1, 2200 at midnight GMT.

ldapmdfy -D adminDn -w adminPw dn: cn=user1,c=us changetype: modify replace: pwdChangedTime pwdChangedTime: 22000101000000Z

The LDAP administrator can unlock an account, that is locked because of excessive login failures, by removing the **pwdAccountLockedTime** and **pwdFailureTime** attributes from the user entry. This example uses the LDAPMDFY utility to perform these modifications.

ldapmdfy -D adminDn -w adminPw
dn: cn=user2,c=us
changetype: modify
delete: pwdAccountLockedTime

delete: pwdFailureTime

The LDAP administrator can unlock an account because the password has expired by setting the **pwdChangedTime** attribute to the current time and removing the **pwdExpirationWarned** and **pwdGraceUseTime** attributes. The **pwdChangedTime** attribute value is set to the current time to avoid the user's password from expiring immediately. This example uses the LDAPMDFY utility to unlock or unexpire the user's account by setting the **pwdChangedTime** attribute to the current time of June 1, 2010 at 1:00 GMT.

ldapmdfy -D adminDn -w adminPw dn: cn=user3,c=us changetype: modify replace: pwdChangedTime pwdChangedTime: 20100601010000Z

replace: pwdExpirationWarned
replace: pwdGraceUseTime

The LDAP administrator can bypass forcing a user to change the password value after a password reset by removing the **pwdReset** attribute. This example uses the LDAPMDFY utility to remove the **pwdReset** attribute.

ldapmdfy -D adminDn -w adminPw
dn: cn=user4,c=us
changetype: modify
delete: pwdReset

The LDAP administrator can force a user to change their password value by setting the **pwdReset** attribute value to true. This example uses the LDAPMDFY utility to set the **pwdReset** attribute value to true.

     	ldapmdfy -D <i>adminDn</i> -w <i>adminPw</i> dn: cn=user5,c=us changetype: modify replace: pwdReset pwdReset: true
               	The LDAP administrator can administratively lock a user's account by setting the <b>ibm-pwdAccountLocked</b> operational attribute to true. This prevents the user from authenticating successfully to the LDAP server. This example uses the LDAPMDFY utility to set the <b>ibm-pwdAccountLocked</b> attribute value to true. 1dapmdfy -D adminDn -w adminPw dn: cn=user6,c=us changetype: modify replace: ibm-pwdAccountLocked
     	The LDAP administrator can administratively unlock a user's account by setting the <b>ibm-pwdAccountLocked</b> operational attribute to false. If a user's account is unlocked in this manner, it does not affect the state of the account with respect to being locked due to excessive password failures or an expired password.
     	<pre>ldapmdfy -D adminDn -w adminPw dn: cn=user7,c=us changetype: modify replace: ibm-pwdAccountLocked ibm-pwdAccountLocked: false</pre>
     	If the <b>Server administration</b> server control is specified (the <b>-k</b> option in the LDAPMDFY utility) when modifying the <b>ibm-pwdAccountLocked</b> attribute from true to false, the <b>pwdAccountLockedTime</b> and <b>pwdFailureTime</b> attribute values are also automatically removed the user's entry. This removes the administrative lock and the lock from excessive password failures. However, it does not affect the state of the account for an expired password.
Unlocking or u	inexpiring the account of the LDAP administrator
     	If the LDAP administrator's password is contained in an entry residing in a CDBM LDBM backend and the account becomes locked or expired under LDAP password policy rules, the LDAP administrator is unable to authenticate to the LDAP server. If this occurs, the LDAP server <b>UNLOCK</b> command is available to unlock or unexpire the account of the LDAP administrator.
I I	To unlock the LDAP administrator, use the following UNLOCK operator command: smsg <i>ldapsrv</i> unlock admin
I	where Idapsrv is the name of the LDAP server virtual machine.
 	If this command is successful, the LDAP administrator's account is unlocked or unexpired and is able to successfully authenticate to the LDAP server.
Password poli	cy examples
   	This section contains examples of configuring global, group, and individual password policy entries and associating them with users and groups. This section also contains examples of using the <b>Effective password policy</b> and <b>Account</b>

status extended operations.

I

# Global password policy example

T

Т

Т

Т

When the global password policy entry, **cn=pwdpolicy,cn=ibmpolicies**, is initially created in the CDBM backend, the policy is not enabled. This example uses the LDAPMDFY utility to activate the global password policy and to change its default values. For more information about the LDAPMDFY utility, see *z/VM: TCP/IP User's Guide*.

```
ldapmdfy -p port -D adminDn -w adminPw
dn: cn=pwdpolicy,cn=ibmpolicies
replace: x
ibm-pwdpolicy: true
pwdmaxage: 7776000
pwdexpirewarning: 5184000
pwdmaxfailure: 5
pwdlockout: true
pwdinhistory: 3
pwdminlength: 5
pwdchecksyntax: 1
```

After these modifications are made to the global password policy entry, the following policy is in effect for all existing entries that have **userPassword** attribute values:

- Passwords must be changed every 90 days (7776000 seconds) and password expiration warnings are sent on the **PasswordPolicy** response control starting 60 days (5184000 seconds) before the password expires.
- There are a maximum of five login failures before the user's account is locked and must be unlocked by the LDAP administrator.
- The previous three password values are kept in the user's password history and the user is unable to reuse these password values.
- · The new password value must have a minimum length of five characters.

# Group password policy example

If there are a number of users that must have a password policy that differs from the global password policy, group password policies are used. These users must be placed in a static, dynamic, or nested group and those groups are updated to refer to a password policy entry. This example uses the LDAPADD utility to add a password policy entry in the CDBM backend to be used as a group password policy. For more information about the LDAPADD client utility, see *z/VM: TCP/IP User's Guide*.

```
ldapadd -p port -D adminDn -w adminPw
dn: cn=group,cn=ibmpolicies
objectclass: pwdpolicy
objectclass: ibm-pwdpolicyext
objectclass: container
pwdminlength: 10
pwdinhistory: 5
pwdchecksyntax: 2
passwordminalphachars: 5
passwordminotherchars: 2
pwdmaxage: 5184000
pwdexpirewarning: 2592000
pwdattribute: userpassword
ibm-pwdpolicy: true
```

The characteristics are:

 Passwords must be changed every 60 days (5184000 seconds) and password expiration warnings are sent on the **PasswordPolicy** response control starting after 30 days (2592000) of last password modification.

- The minimum length of password values is 10 characters, five must be alphabetic characters, and two must be non-alphabetic characters. Password syntax checking is enforced because the **pwdCheckSyntax** attribute is set to two.
- The previous five password values are kept in the user's password history and the user is unable to reuse these password values.

After the password policy entry is created, the group entry that needs to use this special password policy must be modified to set the **ibm-pwdGroupPolicyDN** operational attribute value. This example uses the LDAPMDFY utility to modify the existing cn=group,c=us entry to add an **ibm-pwdGroupPolicyDN** operational attribute value for the cn=group,cn=ibmpolicies password policy entry.

ldapmdfy -p port -D adminDn -w adminPw
dn: cn=group,c=us
add: ibm-pwdgrouppolicydn
ibm-pwdgrouppolicydn: cn=group,cn=ibmpolicies

Although the cn=group,cn=ibmpolicies password policy entry created earlier is enabled by setting the **ibm-pwdPolicy** attribute value to true, the global password policy must be enabled to evaluate additional password policies (if it is not already). Set the **ibm-pwdGroupAndIndividualEnabled** attribute value to true in the global password policy entry. This example uses the LDAPMDFY utility to enable the evaluation of additional password policies in the LDAP server.

ldapmdfy -p port -D adminDn -w adminPw
dn: cn=pwdpolicy,cn=ibmpolicies
replace: x
ibm-pwdgroupandindividualenabled: true

After the global password policy is enabled to evaluate additional password policies, users that are members of the cn=group,c=us group are subject to the password policy specified in the cn=group,cn=ibmpolicies entry.

# Individual password policy example

Т

I

|

L

L

If there are only a few users that must have a password policy that differs from the global password policy, an individual password policy can be created and used. The users that require this special password policy are updated to refer to a password policy entry.

This example uses the LDAPADD utility to add a password policy entry in the CDBM backend to be used as an individual password policy.

```
ldapadd -p port -D adminDn -w adminPw
dn: cn=individual,cn=ibmpolicies
objectclass: pwdpolicy
objectclass: ibm-pwdpolicyext
objectclass: container
pwdminlength: 8
pwdgraceloginlimit: 3
pwdinhistory: 4
pwdchecksyntax: 1
pwdattribute: userpassword
ibm-pwdpolicy: true
```

The characteristics are:

- The minimum length of a password value is eight characters with no restrictions on alphabetic or numeric characters.
- The previous four password values are kept in the user's password history and the user is unable to reuse these password values.

	• There are three grace logins allowed before the user's password expires.
       	After the password policy entry is created, the individual users needed to use this special password policy must be modified to set the <b>ibm-pwdIndividualPolicyDN</b> operational attribute value. This example uses the LDAPMDFY utility to modify the existing cn=user5,c=us entry to add an <b>ibm-pwdIndividualPasswordPolicyDN</b> operational attribute value for the cn=individual,cn=ibmpolicies password policy entry.
     	ldapmdfy -p <i>port -</i> D <i>adminDn -w adminPw</i> dn: cn=user5,c=us add: ibm-pwdIndividualPolicydn ibm-pwdIndividualPolicydn: cn=individual,cn=ibmpolicies
	Although the cn=individual, cn=ibmpolicies password policy entry created earlier is enabled by setting the <b>ibm-pwdPolicy</b> attribute value to true, the global password policy must be enabled to evaluate additional password policies (if it is not already). Set the <b>ibm-pwdGroupAndIndividualEnabled</b> attribute value to true in the global password policy entry. This example uses the LDAPMDFY utility to enable the evaluation of additional password policies in the LDAP server. Idapmdfy -p <i>port</i> -D <i>adminDn</i> -w <i>adminPw</i> dn: cn=pwdpolicy,cn=ibmpolicies replace: x
I	ibm-pwdgroupandindividualenabled: true
   	After the global password policy is enabled to evaluate additional password policies, the cn=user5,c=us entry is subject to the password policy specified in the cn=individual,cn=ibmpolicies entry.
Effective pass	word policy extended operation example
•         	The <b>Effective password policy</b> extended operation in the LDAPEXOP utility is used to query the effective password policy of a user or group. The <b>Effective password policy</b> extended operation displays the password policy attribute values and the password policy entries that have contributed to the effective password policy for the specified user or group. For more information, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .
• 1 1 1 1 1 1 1 1	The <b>Effective password policy</b> extended operation in the LDAPEXOP utility is used to query the effective password policy of a user or group. The <b>Effective password policy</b> extended operation displays the password policy attribute values and the password policy entries that have contributed to the effective password policy for the specified user or group. For more information, see "LDAPEXOP
	The <b>Effective password policy</b> extended operation in the LDAPEXOP utility is used to query the effective password policy of a user or group. The <b>Effective password policy</b> extended operation displays the password policy attribute values and the password policy entries that have contributed to the effective password policy for the specified user or group. For more information, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization.</i> The following example uses the <b>Effective password policy</b> extended operation in the LDAPEXOP utility to query the effective password policy for user cn=user5,c=us Idapexop -p <i>port</i> -D <i>adminDn</i> -w <i>adminPw</i> -op effectpwdpolicy -d "cn=user5,c=us"
	The <b>Effective password policy</b> extended operation in the LDAPEXOP utility is used to query the effective password policy of a user or group. The <b>Effective password policy</b> extended operation displays the password policy attribute values and the password policy entries that have contributed to the effective password policy for the specified user or group. For more information, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization.</i> The following example uses the <b>Effective password policy</b> extended operation in the LDAPEXOP utility to query the effective password policy for user cn=user5,c=us Idapexop -p <i>port</i> -D <i>adminDn</i> -w <i>adminPw</i> -op effectpwdpolicy -d "cn=user5,c=us" The effective password policy is calculated based on the following entries: cn=pwdpolicy,cn=ibmpolicies

pwdmaxage=5184000
pwdmaxfailure=5
pwdminage=0
pwdminlength=8
pwdmustchange=TRUE
pwdsafemodify=FALSE

#### Notes:

- Because cn=user5,c=us has an individual password policy (cn=individual,cn=ibmpolicies) and is a member of a group that has an activated group password policy (cn=group,cn=ibmpolicies), the effective password policy is calculated based on each of these password policy entries.
- 2. The **ibm-pwdPolicyStartTime** attribute value returned in the **Effective password policy** extended operation example is a result of the individual password policy start time because that policy is evaluated first.

# Account status extended operation example

The **Account status** extended operation in the LDAPEXOP utility is used to query if the user's account is opened, locked, or the password has expired.

ldapexop -p port -D adminDn -w adminPw -op acctstatus -d "cn=user1,c=us" acctstatus\_extended\_op: Account is locked.

# Changing password values when pwdsafemodify is set to true

If the **pwdSafeModify** attribute in the effective password policy is set to true, the current and new password value must be provided when changing a user's **userPassword** attribute value.

The LDAPCHPW utility is provided and you must specify the current and new password values when modifying the **userPassword** attribute value. For more information, see *z/VM: TCP/IP User's Guide*.

The following example uses the LDAPCHPW utility to change the **userPassword** attribute value for user cn=user1,c=us from secret to supersecret.

#### For example:

ldapchpw -p port -D cn=user1,c=us -w secret -n supersecret

If changing passwords with a non-z/VM LDAP client, use the LDAPMDFY utility to specify the current and new **userPassword** attribute values as shown in the example. This example changes the password for user cn=user2,c=us from secret to supersecret.

ldapmdfy -p port -D cn=user2,c=us -w secret dn: cn=user2,c=us changetype: modify delete: userpassword userpassword: secret add: userpassword

userpassword: supersecret

# Chapter 7. CRAM-MD5 and DIGEST-MD5 authentication

The z/VM LDAP server allows clients to authenticate using the CRAM-MD5 (Challenge Response Authentication Mechanism) and DIGEST-MD5 SASL bind mechanisms. CRAM-MD5 is defined in RFC 2195: *IMAP/POP AUTHorize Extension for Simple Challenge/Response*. DIGEST-MD5 is defined in RFC 2831: *Using Digest Authentication as a SASL Mechanism*. Both the CRAM-MD5 and DIGEST-MD5 mechanisms are multi-stage binds where the server sends the client a challenge and then the client sends a challenge response back to the server to complete the authentication. The client challenge response contains a hash of the password entered by the user, the username, and other pieces of data encoded to the specifications of either the CRAM-MD5 or DIGEST-MD5 RFCs.

The CRAM-MD5 and DIGEST-MD5 SASL bind mechanisms are more secure than performing simple binds since the credentials are not passed in clear text. Also, the CRAM-MD5 and DIGEST-MD5 bind mechanisms on the z/VM LDAP server do not require any additional products to be installed or configured.

The z/VM LDAP server DIGEST-MD5 bind mechanism supports the integrity and confidentiality options defined in RFC 2831: *Using Digest Authentication as a SASL Mechanism*. Upon the successful completion of a DIGEST-MD5 bind, the negotiated quality of protection (qop) is used for subsequent messages sent over the connection. The negotiated qop continues until the completion of a new SASL bind request. If the new SASL bind request fails, the connection reverts to anonymous authentication with no integrity or confidentiality support.

The DIGEST-MD5 authentication mechanism is more secure than the CRAM-MD5 authentication mechanism because it prevents chosen plaintext password attacks. During a DIGEST-MD5 authentication exchange between a client and the server, there is additional information passed which is used to construct a more robust hashing algorithm when compared against a CRAM-MD5 authentication making it more difficult to decipher.

# DIGEST-MD5 bind mechanism restrictions in the z/VM LDAP server

DIGEST-MD5 restrictions on the LDAP server:

- 1. The unspecified userid form of the authorization identity is not supported; however, the DN version is supported on the z/VM LDAP client and server.
- 2. Subsequent authentication is not supported.

# Considerations for setting up an LDBM or CDBM backend for CRAM-MD5 and DIGEST-MD5 authentication

T

L

The following are considerations for setting up an LDBM or CDBM backend for CRAM-MD5 and DIGEST-MD5 authentication:

- In order to use the CRAM-MD5 bind mechanism on the z/VM LDAP server, the LDBM or CDBM entry that you bind with should contain a **uid** attribute value. The **uid** attribute is always in the LDAP server schema. There are three ways to perform a CRAM-MD5 bind to the z/VM LDAP server:
  - a. Only specifying the bindDN in the bind request in your client application.
     When using the z/VM LDAP client utilities, such as LDAPSRCH (Idapsearch), this is done by only specifying the -D option.

- b. Only specifying the username in the CRAM-MD5 bind mechanism in your client application. The username that is specified must map to one of the uid attribute values in one of the LDBM or CDBM entries. When using the z/VM LDAP client utilities, such as LDAPSRCH, this is done by only specifying the -U option.
- c. Specifying both the bindDN in the bind request and the username in the CRAM-MD5 bind mechanism in your client application. The username that is specified must map to one of the **uid** attribute values in one of the LDBM or CDBM entries. The bindDN specified in the bind request must map to the same distinguished name as the username. When using the z/VM LDAP client utilities, such as LDAPSRCH, this is done by specifying both the **-D** and the **-U** options.

For more information on the z/VM LDAP client utilities, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.

Assuming that the password entered on the client application is correct, the CRAM-MD5 bind is successful, otherwise it returns an LDAP credentials error.

- 2. In order to use the DIGEST-MD5 bind mechanism on the z/VM LDAP server, the LDBM or CDBM entries that you bind with must contain a **uid** attribute value. The **uid** attribute is always present in the server schema. There are two ways to perform a DIGEST-MD5 bind to the z/VM LDAP server:
  - a. Only specifying the username in the DIGEST-MD5 bind mechanism in your client application. The username that is specified must map to one of the uid attribute values in one of the LDBM or CDBM entries. When using the z/VM LDAP client utilities, such as LDAPSRCH, this is done by only specifying the -U option.
  - b. Specifying both the username and the authorization DN in the DIGEST-MD5 bind mechanism in your client application. The username that is specified must map to one of the **uid** attribute values in one of the LDBM or CDBM entries. The authorization DN that is specified must map to the same distinguished name as the username. When using the z/VM LDAP client utilities, such as LDAPSRCH, this is done by specifying both the **-D** and the **-U** options.

For more information on the z/VM LDAP client utilities, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.

Assuming that the password entered on the client application is correct, the DIGEST-MD5 bind will be successful, otherwise it will return an LDAP credentials error.

- It is strongly suggested that the uid attribute values specified on the entries to be used for CRAM-MD5 or DIGEST-MD5 authentication be unique across every LDBM and CDBM backend that is configured on the LDAP server. Authentication can fail if more than one entry has the same uid attribute value.
- 4. In order for the CRAM-MD5 and DIGEST-MD5 binds to work properly, the userPassword attribute values for the entry must be in clear text (not recommended) or encrypted in either DES or AES. DES and AES encryption are recommended since they both encrypt the userPassword and provide clear text decryption. For additional information on AES and DES encryption, refer to "Configuring for Encryption or Hashing" in *z/VM: TCP/IP Planning and Customization*.

LDAP server needs access to the clear text password so that the CRAM-MD5 and DIGEST-MD5 bind mechanisms work properly against that entry.

- 5. CRAM-MD5 and DIGEST-MD5 binds are not supported with entries that are participating in native authentication.
- 6. CRAM-MD5 and DIGEST-MD5 binds are not supported to the SDBM backend.

T

T

T

T

T

T

### CRAM-MD5 and DIGEST-MD5 configuration option

Т

The **digestRealm** option in the LDAP server configuration file allows for the specification of a realm name to be used to help create the CRAM-MD5 and DIGEST-MD5 hashes. The value of this option gets passed on the initial challenge from the server to the client once it has been decided that a CRAM-MD5 or DIGEST-MD5 bind is desired. See the **digestRealm** option in *z/VM: TCP/IP Planning and Customization*. If the **digestRealm** configuration option is not specified, the realm name defaults to the fully qualified hostname of the system where the LDAP server is running assuming that a DNS (Domain Name Server) is available. If the **digestRealm** option is not specified and the fully qualified hostname of the LDAP server can not be determined because of a problem with the DNS (Domain Name Server), any CRAM-MD5 or DIGEST-MD5 binds attempted will fail.

### Example of setting up for CRAM-MD5 and DIGEST-MD5

The following diagram shows an example of how you could set up your entries in your LDBM backend.

**Note:** Because of space limitations in the diagram, the entries in the example do not contain all of the necessary information to make them valid directory entries. For example, object classes and required attributes have been left out of many of the entries.

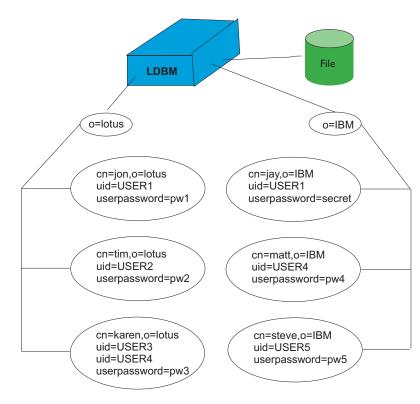

Figure 20. CRAM-MD5 and DIGEST-MD5 authentication example

The following table outlines what happens if you attempt to do a CRAM-MD5 or DIGEST-MD5 bind from a client. The username refers to the **-U** option on the z/VM LDAP client utilities, while the bindDN (CRAM-MD5) or authorization DN

(DIGEST-MD5) is the **-D** option on the z/VM LDAP client utilities. See "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide* for more details on the LDAP client utilities. The following table assumes that native authentication is not turned on under the subtrees: o=lotus and o=IBM.

Table 21. Behavior of CRAM-MD5 and DIGEST-MD5 authentication in example
---

Username	BindDN (CRAM-MD5) or authorization DN (DIGEST-MD5)	Password	Behavior
USER2		pw2	Bind is successful to cn=tim,o=lotus
USER2	cn=tim,o=lotus	pw2	Bind is successful to cn=tim,o=lotus
USER2	cn=jon,o=lotus	pw2	Bind is not successful because the bindDN (CRAM-MD5) or authorization DN (DIGEST-MD5) cn=jon,o=lotus does not equal the username DN cn=tim,o=lotus
USER1		pw1	Bind is not successful, because there are multiple entries with the same username value: cn=jon,o=lotus and cn=jay,o=IBM
USER1	cn=jay,o=IBM	secret	Bind is successful to cn=jay,o=IBM because the username DN cn=jay,o=IBM equals the bindDN (CRAM-MD5) or authorization DN (DIGEST-MD5) cn=jay,o=IBM
USER1	cn=jon,o=lotus	pw1	Bind is successful to cn=jon,o=lotus because the username DN cn=jon,o=lotus equals the bindDN (CRAM-MD5) or authorization DN (DIGEST-MD5) cn=jon,o=lotus
USER3		pw3	Bind is successful to cn=karen,o=lotus
USER4	cn=karen,o=lotus	pw3	Bind is successful to cn=karen,o=lotus
USER4	cn=matt,o=IBM	pw4	Bind is successful to cn=matt,o=IBM
USER3	cn=karen,o=lotus	bad	Bind is not successful to username DN cn=karen,o=lotus and bindDN (CRAM-MD5) or authorization DN (DIGEST-MD5) cn=karen,o=lotus because the password is incorrect.
USER5	cn=nothere,o=lotus	pw5	Bind is not successful because the username DN cn=steve,o=IBM does not equal the non-existent bindDN (CRAM-MD5) or authorization DN (DIGEST-MD5) cn=nothere,o=lotus
BAD		pw1	Bind is not successful because a <b>uid</b> value equal to BAD was not found in any of the entries in the LDBM backend.

# Chapter 8. Static, dynamic, and nested groups

The LDAP server supports group definitions. These group definitions allow for a collection of names to be easily associated for access control checking or in application-specific uses such as a mailing list. See Chapter 9, "Using access control" for additional information on access control checking.

The LDAP server supports static, dynamic, and nested groups. It is possible to query static, dynamic, and nested group memberships with the use of the **ibm-allMembers** and **ibm-allGroups** operational attributes. For a given group entry, the **ibm-allMembers** attribute enumerates all of the members that belong in that group. For a given user entry, the **ibm-allGroups** attribute determines the groups in which the user has membership.

A search request specifying the **ibm-allMembers** or **ibm-allGroups** attribute returns group membership information for just the backend containing the base entry. Access checking is performed for the **member** and **uniqueMember** attributes when obtaining the group membership information. Additional access checking is performed on any of the attributes contained in a dynamic group URL search filter on the **memberURL** attribute. Access checking is not performed on the **memberURL** and **ibm-memberGroup** attributes themselves.

### Static groups

I

L

L

|

L

A static group is defined as a group where the members are defined individually. The **accessGroup**, **accessRole**, **groupOfNames**, and **ibm-staticGroup** object classes each use a multi-valued attribute called **member** to define a list of distinguished names (DNs) that belong to the static group. The **groupOfUniqueNames** object class uses a multi-valued attribute called **uniqueMember** to define a list of distinguished names (DNs) that belong to the static group. The **uniqueMember** attribute type is treated as a distinguished name and not as a distinguished name with an optional unique identifier.

These attributes and object classes are always in the LDAP server schema. Except for the **groupOfNames** and **groupOfUniqueNames** object classes, they cannot be modified. The **groupOfNames** and **groupOfUniqueNames** object classes can be modified in limited ways, as described in "Changing the initial schema" on page 36. One modification you may consider making in these two object classes is to move the **member** or **uniqueMember** attribute from the MUST list to the MAY list. This will allow static group entries using these object classes to be created without any members and also allow all the members to be deleted from existing entries.

A typical static group entry is as follows:

dn: cn=ldap\_team\_static,o=endicott
objectclass: groupOfNames
cn: ldap\_team\_static
member: cn=jon,o=endicott
member: cn=ken,o=endicott
member: cn=jay,o=endicott

### **Dynamic groups**

A dynamic group is defined as a group in which membership is determined using one or more LDAP search expressions. Each time a dynamic group is used by the LDAP server, a user's membership in the group is decided by determining if the user entry matches any of the search expressions. The **ibm-dynamicGroup** and **groupOfURLs** object classes each use the multi-valued attribute called **memberURL** to define the LDAP search expression. These object classes and attribute are always in the LDAP server schema and cannot be modified.

Dynamic groups allow the group administrator to define membership in terms of attributes and allow the directory itself to determine who is or is not a member of the group. For example, members do not need to be manually added or deleted when a person moves to a different project or location.

Alias and referral entries are not processed during the group membership search.

The following simplified LDAP URL syntax must be used as the value of **memberURL** attribute to specify the dynamic group search expression. **1dap:**///baseDN[??[searchScope][?searchFilter]]

where

#### baseDN

Specifies the DN of the entry from which the search begins in the directory. The dynamic URL is not used if the base entry is not within the same backend as the dynamic group entry. This parameter is required.

#### searchScope

Specifies the extent of the search. The default scope is **base**.

- base Returns information only about the baseDN specified in the URL.
- **one** Returns information about entries one level below the *baseDN* specified in the URL. It does not include the *baseDN*.
- **sub** Returns information about entries at all levels below and including the *baseDN*.

#### searchFilter

Is the filter that you want applied to the entries within the scope of the search. See LDAPSRCH in *z/VM: TCP/IP User's Guide* for additional information on LDAP search filters. The default is **"objectclass=**\*".

**Note:** As the format above suggests, the host name must not be present in the syntax. The remaining parameters are just like the normal LDAP URL syntax, defined in RFC 2255: *The LDAP URL Format* (except there is no support for extensions in the URL). Each parameter field must be separated by a ?, even if no parameter is specified. Normally, a list of attributes to return would have been included between the *baseDN* and *searchScope*. An add or modify operation of a dynamic group entry fails if it contains a **memberURL** attribute that is not in the correct format. This prevents introducing an improperly formatted **memberURL** attribute into the LDAP server.

An entry is considered to be a member of the dynamic group if it falls within the search scope and matches the search filter. Alias entries and referral entries are treated as normal entries during the group membership search; no alias dereferencing or referral processing is performed.

A typical dynamic group entry is the following:

dn: cn=ldap\_team\_dynamic,o=endicott
objectclass: groupOfURLs
cn: ldap\_team\_dynamic
memberURL: ldap:///o=endicott??sub?(ibm-group=ldapTeam)

#### Dynamic group search filter examples:

A single entry in which the scope defaults to base and the filter defaults to "objectclass=\*":

ldap:///cn=Ricardo,ou=Endicott,o=ibm,c=us

The "In Flight Systems" team with a scope of one-level and the filter defaults to "objectclass=\*":

ldap:///ou=In Flight Systems,ou=Endicott,o=ibm,c=us??one

A subtree search for all the support staff in Endicott: ldap:///ou=Endicott,o=ibm,c=us??sub?title=\*Support

A subtree search for all the Garcias or Nguyens whose first name begins with an "A":

ldap:///o=ibm,c=us??sub?(&(|(sn=Garcia)(sn=Nguyen))(cn=A\*))

A search filter that includes escaped percent signs, question marks and spaces in the base DN (o=deltawing infosystems) and filter ((&(percent=10 %)(description=huh?))):

ldap:///o=deltawing%20infosystems,c=au??sub?(&(percent=10%25)(description=huh%3f))

### **Nested groups**

I

A nested group is defined as a group that references other group entries, which can be static, dynamic, or nested groups. The **ibm-nestedGroup** object class uses the multi-valued attribute called **ibm-memberGroup** to indicate the DNs of the groups that are referenced by the nested group. This object class and attribute are always in the LDAP server schema and cannot be modified. Nested groups allow LDAP administrators to construct and display group hierarchies that describe both direct and indirect group memberships. A group referenced within the nested group is ignored if it is not in the same backend as the nested group. The group hierarchy established by a nested group cannot loop back to itself. The LDBM or CDBM backend rejects an add or modify operation of a nested group entry if it results in a loop.

Note: The **ibm-nestedGroup** object class is an **AUXILARY** object class and also requires a **STRUCTURAL** object class.

A typical nested group entry is as follows:

dn: cn=ldap\_team\_nested,o=endicott
objectclass: container
objectclass: ibm-nestedGroup
cn: ldap\_team\_nested
ibm-memberGroup: cn=ldap\_team\_static,o=endicott
ibm-memberGroup: cn=ldap\_team\_dynamic,o=endicott
ibm-memberGroup: cn=ldaptest\_team\_nested,o=endicott

# **Determining group membership**

T

Т

The members of a group entry are determined depending on the type of group. Note that a group can be multiple types (for instance, both dynamic and static).

- Static group: the values of the member attribute of the group entry if the object class of the group entry is accessGroup, accessRole, groupOfNames, or ibm-staticGroup, or the values of the uniqueMember attribute if the object class is groupOfUniqueNames.
- 2. Dynamic group: the DN of each entry in this LDBM or CDBM backend that matches the scope and search filter contained in one of the values of the **memberURL** attribute of the group entry. Dynamic group membership is the union of all search expressions that are present on each of the individual **memberURL** attribute values even if the search expressions are contradictory, such as ldap:///o=ibm??sub?cn=bob and ldap:///o=ibm??sub?(!(cn=bob)). A dynamic search filter is ignored if the base in the search filter is not in the same LDBM or CDBM backend as the dynamic group.
- 3. Nested group: the members of each static, dynamic, or nested group for each value of the **ibm-memberGroup** attribute in the nested group entry.

Zero-length values are ignored for the **member**, **uniqueMember** and **ibm-memberGroup** attributes.

# **Displaying group membership**

Two operational attributes can be used for querying aggregate group membership. For a given group entry, the **ibm-allMembers** attribute enumerates the entire set of group membership, including static, dynamic, and nested members as described by the nested group hierarchy. For a given user entry, the **ibm-allGroups** attribute enumerates the entire set of groups within the same backend as the user entry to which that user has membership, including ancestor groups from nested group hierarchy. As with all operational attributes, they are only returned if explicitly requested and can not be specified on a search filter.

The **ibm-allGroups** and **ibm-allMembers** search and comparison operations are supported only on entries within the LDBM or CDBM backend. These operations are not supported against users or groups that are present within the SDBM backend.

### ACL restrictions on displaying group membership

The following ACL restrictions only apply when attempting to query **ibm-allMembers** or **ibm-allGroups** operational attributes. These rules do not apply when groups are gathered from all the backends that are participating in group gathering at authentication time. The entries and attributes used to evaluate **ibm-allMembers** and **ibm-allGroups** have ACL restrictions, against which the bound DN has to be checked. The members of a group are determined from three sources:

- For static groups, the bound DN must have read access on the member or uniqueMember attribute if it is performing an ibm-allMembers or ibm-allGroups search operation, or compare access if performing a comparison operation. The member and uniqueMember attributes are in the normal access class.
- For dynamic groups, the bound DN must have search access on all of the attributes that are present in the dynamic group filter for any of the DNs that are returned. The ACL access to the **memberURL** attribute does not matter when resolving **ibm-allMembers** or **ibm-allGroups** attributes.

 For nested groups, there is no restriction on using the ibm-memberGroup attribute, but the restrictions described above apply to the groups referenced in the nested group entry. A referenced group is ignored if it is not in the same LDBM or CDBM backend as the nested group.

Specifying **ibm-allMembers** or **ibm-allGroups** in a search or compare operation also requires that the bound DN have read or compare access to the **ibm-allMembers** or **ibm-allGroups** attribute. Note that the **ibm-allMembers** and **ibm-allGroups** attributes are in the **system** access class.

For more information about access control permissions, see Chapter 9, "Using access control."

### ACL restrictions on group gathering

	If LDAP password policy is active, the list of the static, dynamic, and nested groups
I	of which the binding user is a member are gathered at authentication time. If LDAP
I	password policy is not active, the list of static, dynamic, and nested groups are not
I	gathered until the next non-bind request is received. No ACL processing is done
I	when reading group entries for group gathering because it is not possible to know
I	what access rights the binding user has to any of the attributes or subtrees in the
	directory until all the groups are fully determined.

### **Group examples**

I

### Examples of adding, modifying, and deleting group entries

Adding group entries: This example creates static group entries using the accessGroup, groupOfUniqueNames, and groupOfNames object classes.

ldapadd -h 127.0.0.1 -D "cn=admin" -w xxxx -f staticGrps.ldif

Where staticGrps.ldif contains:

dn: cn=group1, o=Your Company
objectclass: accessGroup
cn: group1
member: cn=bob, o=Your Company
member: cn=lisa, o=Your Company
member: cn=chris, cn=bob, o=Your Company
member: cn=john, cn=bob, o=Your Company

dn: cn=group2, o=Your Company
objectclass: groupOfUniqueNames
cn: group2
uniquemember: cn=tom, o=Your Company
uniquemember: cn=dan, o=Your Company
uniquemember: cn=sam, o=Your Company
uniquemember: cn=kevin, o=Your Company

dn: cn=group3, o=Your Company
objectclass: groupOfNames
cn: group3
member: cn=david, o=Your Company
member: cn=jake, o=Your Company
member: cn=scott, o=Your Company
member: cn=eric, o=Your Company

This example creates a dynamic group entry that has an object class of **groupOfURLs**:

ldapadd -h 127.0.0.1 -D "cn=admin" -w xxxx -f dynamicGrp.ldif

Where dynamicGrp.ldif contains:

dn: cn=dynamic\_team,o=Your Company
objectclass: groupOfUrls
cn: dynamic\_team
memberurl: ldap:///o=Your Company??sub?(employeeType=ldapTeam)

This example creates a nested group entry with an object class of **ibm-nestedGroup** that references cn=dynamic\_team,o=Your Company and cn=group1,o=Your Company.

ldapadd -h 127.0.0.1 -D "cn=admin" -w xxxx -f nestedGrp.ldif

#### Where nestedGrp.ldif contains:

dn: cn=nested\_grp,o=Your Company
objectclass: ibm-nestedGroup
objectclass: person
cn: nested\_grp
sn: group
ibm-memberGroup: cn=dynamic\_team,o=Your Company
ibm-memberGroup: cn=group1,o=Your Company

*Modifying group entries:* In order to add a member to a static group, add the user's distinguished name as an additional value for the **member** or **uniqueMember** attribute. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modStaticGrp.ldif

Where modStaticGrp.ldif contains:

dn: cn=group1, o=Your Company
changetype: modify
add: member
member: cn=jeff, cn=tim, o=Your Company

dn: cn=group2, o=Your Company
changetype: modify
add: uniqueMember
uniqueMember: cn=joe,o=Your Company

In order to remove a member from a static group, remove the user's distinguished name from the set of **member** or **uniqueMember** attribute values in the static group entry. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modStaticGrp.ldif

Where modStaticGrp.ldif contains:

dn: cn=group1, o=Your Company
changetype: modify
delete: member
member: cn=jeff, cn=tim, o=Your Company

dn: cn=group2, o=Your Company
changetype: modify
delete: uniqueMember
uniqueMember: cn=joe,o=Your Company

In order to add a new search expression to a dynamic group, add the LDAP URL search expression as a value of the **memberURL** attribute. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modDynamicGrp.ldif

Where modDynamicGrp.ldif contains:

dn: cn=dynamic\_team, o=Your Company changetype: modify add: memberURL memberURL: ldap:///o=Your Company??sub?(employeeType=javaTeam)

In order to remove a search expression from a dynamic group entry, the **memberURL** attribute value containing the search expression must be removed from the group entry. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modDynamicGrp.ldif

Where modDynamicGrp.ldif contains:

```
dn: cn=dynamic_team, o=Your Company
changetype: modify
delete: memberURL
memberURL: ldap:///o=Your Company??sub?(employeeType=javaTeam)
```

In order to add a new group reference to an existing nested group entry, add the new group's DN as a value of the **ibm-memberGroup** attribute. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modNestedGrp.ldif

Where modNestedGrp.ldif contains:

dn: cn=nested\_grp, o=Your Company
changetype: modify
add: ibm-memberGroup
ibm-memberGroup: cn=group2,o=Your Company

In order to remove a group reference entry from an existing nested group entry, the **ibm-memberGroup** attribute value containing the group reference DN must be deleted. Following is an example:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modNestedGrp.ldif

Where modNestedGrp.ldif contains:

dn: cn=nested\_grp, o=Your Company
changetype: modify
delete: ibm-memberGroup
ibm-memberGroup: cn=group2,o=Your Company

**Deleting group entries:** In order to delete a static, dynamic, or nested group entry, delete the directory entry that represents the group. The LDAPDLET command can be used to perform this delete operation.

This example deletes the static, dynamic, and nested group entries that were created in the above examples:

ldapdlet -h 127.0.0.1 -D "cn=admin" -w xxx -f deleteGrp.list

Where deleteGrp.list contains:

cn=nested\_grp,o=Your Company cn=group1,o=Your Company cn=group2,o=Your Company cn=group3,o=Your Company cn=dynamic\_team,o=Your Company

## Examples of querying group membership

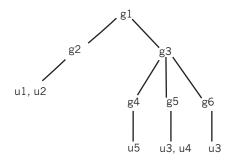

Figure 21. Group hierarchy and membership for the examples

The entries below are used in the following examples: dn: o=ibm objectclass: organization aclEntry: group:CN=ANYBODY:normal:rsc:system:rsc aclPropagate: TRUE o: ibm dn: cn=g1,o=ibm objectclass: container objectclass: ibm-nestedGroup cn: g1 ibm-memberGroup: cn=g2,o=ibm ibm-memberGroup: cn=g3,o=ibm aclEntry: group:CN=ANYBODY:normal:rsc:system:rsc dn: cn=g2,o=ibm objectclass: accessGroup cn: g2 member: cn=u1,o=ibm member: cn=u2,o=ibm aclEntry: group:CN=ANYBODY:normal:rsc:system:rsc aclEntry: access-id:cn=u1,o=ibm:normal:rsc:system:rsc aclEntry: access-id:cn=u2,o=ibm:normal:rsc:system:rsc:at.member:deny:rsc dn: cn=g3,o=ibm objectclass: container objectclass: ibm-nestedGroup cn: g3 ibm-memberGroup: cn=g4,o=ibm ibm-memberGroup: cn=g5,o=ibm ibm-memberGroup: cn=g6,o=ibm dn: cn=g4,o=ibm objectclass: accessGroup cn: g4 aclEntry: group:CN=ANYBODY:normal:rsc:system:rsc aclEntry: access-id:cn=u4,o=ibm:normal:rsc:system:rsc:at.member:deny:c member: cn=u5,o=ibm dn: cn=g5,o=ibm objectclass: container objectclass: ibm-dynamicGroup cn: g5 memberURL: ldap:///o=ibm??sub?(|(cn=u3)(cn=u4)) aclEntry: group:cn=ANYBODY:normal:rsc:system:rsc aclEntry: access-id:cn=u3,o=ibm:normal:rsc:system:rsc:at.ibm-allMembers:deny:rs: at.ibm-allMembers:grant:c dn: cn=g6,o=ibm objectclass: container objectclass: ibm-dynamicGroup cn: g6 memberURL: ldap:///o=ibm??sub?(cn=\*3)

```
dn: cn=u1.o=ibm
objectclass: person
cn: ul
sn: user
userpassword: secret1
dn: cn=u2,o=ibm
objectclass: person
cn: u2
sn: user
userpassword: secret2
dn: cn=u3,o=ibm
objectclass: person
aclEntry: access-id:cn=u1,o=ibm:normal:rsc:system:rsc:at.cn:deny:s
aclEntry: access-id:cn=u2,o=ibm:normal:rsc:system:rsc:at.ibm-allGroups:deny:r
aclEntry: group:cn=ANYBODY:normal:rsc:system:rsc
cn: u3
sn: user
userpassword: secret3
dn: cn=u4,o=ibm
objectclass: person
aclentry: group:cn=ANYBODY:normal:rsc:system:rsc
aclentry: access-id:cn=u3,o=ibm:normal:rsc:system:rsc:at.ibm-allGroups:deny:r
cn: u4
sn: user
userpassword: secret4
dn: cn=u5,o=ibm
objectclass: person
cn: u5
sn: user
userpassword: secret5
dn: cn=u6,o=ibm
objectclass: person
cn: u6
sn: user
userpassword: secret6
```

Note: The **ibm-allMembers** and **ibm-allGroups** attributes are **system** class attributes. The **member** and **cn** attributes are **normal** class attributes.

ibm-allGroups and ibm-allMembers search and comparison examples:

**Example 1:** This example shows an **ibm-allMembers** attribute search on a static group entry.

```
ldapsrch -L -D "cn=u6,o=ibm" -w secret6 -b "cn=g4,o=ibm" "objectclass=*" ibm-allMembers
```

```
dn: cn=g4,o=ibm
ibm-allmembers: cn=u5,o=ibm
```

Access checking done for cn=u6,o=ibm:

- 1. Read access to the **ibm-allMembers** attribute in cn=g4,o=ibm.
- 2. Read access to the **member** attribute in cn=g4,o=ibm.

**Example 2:** This example shows an **ibm-allMembers** attribute search on a dynamic group entry.

ldapsrch -L -D "cn=u6,o=ibm" -w secret6 -b "cn=g5,o=ibm" "objectclass=\*" ibm-allMembers

```
dn: cn=g5,o=ibm
ibm-allmembers: cn=u3,o=ibm
ibm-allmembers: cn=u4,o=ibm
```

Access checking done for cn=u6,o=ibm:

- 1. Read access to the ibm-allMembers attribute in cn=g5,o=ibm.
- Search access to the cn attribute in the returned entries, cn=u3,o=ibm and cn=u4,o=ibm, from the search filter specified in the memberURL attribute.

Note: memberURL attribute access rights do not matter.

**Example 3:** This example shows an **ibm-allMembers** attribute search on a nested group entry.

ldapsrch -L -D "cn=u6,o=ibm" -w secret6 -b "cn=g3,o=ibm" "objectclass=\*" ibm-allMembers

```
dn: cn=g3,o=ibm
ibm-allmembers: cn=g3,o=ibm
ibm-allmembers: cn=u3,o=ibm
ibm-allmembers: cn=u4,o=ibm
ibm-allmembers: cn=u5,o=ibm
```

Access checking done for cn=u6,o=ibm:

- 1. Read access to the **ibm-allMembers** attribute in cn=g3,o=ibm.
- 2. Read access to the **member** attribute in cn=g4,o=ibm.
- Search access to the cn attribute in the returned entries, cn=u3,o=ibm and cn=u4,o=ibm, from the search filter specified in the memberURL attribute of cn=g5,o=ibm.
- Search access to the cn attribute in the returned entries, cn=u3,o=ibm and cn=g3,o=ibm, from the search filter specified in the memberURL attribute of cn=g6,o=ibm.
  - **Note:** Since cn=u3,o=ibm has already been added as an **ibm-allMembers** attribute value, a duplicate value will not be added.

Note: ibm-memberGroup access rights do not matter.

**Example 4:** This example shows an **ibm-allMembers** attribute search on a dynamic group entry when the bound user is not granted read access to the **ibm-allMembers** attribute.

ldapsrch -L -D "cn=u3,o=ibm" -w secret3 -b "cn=g5,o=ibm" "objectclass=\*" ibm-allmembers

dn: cn=g5,o=ibm

Access checking done for cn=u3,o=ibm:

 Read access to the **ibm-allMembers** attribute in cn=g5,o=ibm has been denied. Therefore, no **ibm-allMembers** attribute values will be added.

**Example 5:** This example shows an **ibm-allMembers** attribute search on a static group entry when the bound user does not have read authority on the **member** attribute.

ldapsrch -L -D "cn=u2,o=ibm" -w secret2 -b "cn=g2,o=ibm" "objectclass=\*" ibm-allmembers

dn: cn=g2,o=ibm

Access checking done for cn=u2,o=ibm:

- 1. Read access to the **ibm-allMembers** attribute in cn=g2,o=ibm.
- Read access to the **member** attribute in cn=g2,o=ibm has been denied. Therefore, the **member** attribute value will not be added as an **ibm-allMembers** attribute value.

**Example 6:** This example shows an **ibm-allMembers** attribute search on a dynamic group entry when the bound user does not have search authority in the entries that are to be returned for the attributes that are specified in the dynamic group filter.

ldapsrch -L -D "cn=u1,o=ibm" -w secret1 -b "cn=g5,o=ibm" "objectclass=\*" ibm-allmembers

dn: cn=g5,o=ibm
ibm-allmembers: cn=u4,o=ibm

Access checking done for cn=u1,o=ibm:

- 1. Read access to the **ibm-allMembers** attribute in cn=g5,o=ibm.
- Search access to the **cn** attribute in the returned entries, cn=u3,o=ibm and cn=u4,o=ibm, from the search filter specified in the **memberURL** attribute. However, search access has been denied on the **cn** attribute of cn=u3,o=ibm therefore it is not added as an **ibm-allMembers** attribute value.

**Example 7:** This example shows an **ibm-allMembers** comparison operation on a dynamic group entry.

ldapcmpr -D "cn=u3,o=ibm" -w secret3 "cn=g5,o=ibm" "ibm-allmembers=cn=u3,o=ibm"
ldap\_compare: Compare true

Access checking done for cn=u3,o=ibm:

- 1. Compare access to the **ibm-allMembers** attribute in cn=g5,o=ibm.
- 2. Search access to the **cn** attribute on the returned entries, cn=u3,o=ibm and cn=u4,o=ibm, from the search filter specified in the **memberURL** attribute.

**Example 8:** This example shows an **ibm-allGroups** attribute search where the user belongs to dynamic and nested group entries.

ldapsrch -L -D "cn=u6,o=ibm" -w secret6 -b "cn=u4,o=ibm" "objectclass=\*" ibm-allGroups

dn: cn=u4,o=ibm ibm-allgroups: cn=g5,o=ibm ibm-allgroups: cn=g3,o=ibm ibm-allgroups: cn=g1,o=ibm

Access checking done for cn=u6,o=ibm:

- 1. Read access to the **ibm-allGroups** attribute in cn=u4,o=ibm.
- Search access on the cn attribute in cn=u4,o=ibm from the search filter specified in the memberURL attribute in cn=g5,o=ibm.

Since cn=g3,o=ibm has cn=g5,o=ibm as an **ibm-memberGroup** attribute value, cn=g3,o=ibm is added as an **ibm-allGroups** attribute also. cn=g1,o=ibm has cn=g3,o=ibm as an **ibm-memberGroup** value, therefore cn=g1,o=ibm is also added as an **ibm-allGroups** attribute value.

**Example 9:** This example shows an **ibm-allGroups** attribute search where the user belongs to static and nested group entries.

ldapsrch -L -D "cn=u1,o=ibm" -w secret1 -b "cn=u2,o=ibm" "objectclass=\*" ibm-allGroups

dn: cn=u2,o=ibm
ibm-allgroups: cn=g2,o=ibm
ibm-allgroups: cn=g1,o=ibm

Access checking done for cn=u1,o=ibm:

- 1. Read access to the ibm-allGroups attribute in cn=u2,o=ibm.
- Read access to the member attribute in cn=g2,o=ibm.

Since cn=g1,o=ibm has an **ibm-memberGroup** attribute value of cn=g2,o=ibm, cn=g1,o=ibm is added as an **ibm-allGroups** attribute value.

**Example 10:** This example shows an **ibm-allGroups** attribute search where the user being searched belongs to static and nested group entries. The bound user has read authority to the **ibm-allGroups** attribute of the user being searched, but does not have read authority on the **member** attribute in the static group entry.

ldapsrch -L -D "cn=u2,o=ibm" -w secret2 -b "cn=u2,o=ibm" "objectclass=\*" ibm-allGroups

dn: cn=u2,o=ibm

Access checking done for cn=u2,o=ibm:

- 1. Read access to the **ibm-allGroups** attribute in cn=u2,o=ibm.
- Read access to the member attribute of cn=g2,o=ibm is denied. Therefore, cn=g2,o=ibm is not added as an ibm-allGroups attribute value.

**Example 11:** This example shows an **ibm-allGroups** search where the bound user does not have read authority on the **ibm-allGroups** attribute.

ldapsrch -L -D "cn=u3,o=ibm" -w secret3 -b "cn=u4,o=ibm" "objectclass=\*" ibm-allGroups

dn: cn=u4,o=ibm

Access checking done for cn=u3,o=ibm:

1. Read access to the **ibm-allGroups** attribute in cn=u4,o=ibm is denied. Therefore, no **ibm-allGroups** attribute values are added.

**Example 12:** This example shows an **ibm-allGroups** comparison operation where the bound user is allowed to determine that a user belongs to a nested group entry. ldapcmpr -D "cn=u2,o=ibm" -w secret2 "cn=u3,o=ibm" "ibm-allGroups=cn=g1,o=ibm" ldap compare: Compare true

Access checking done for cn=u2,o=ibm:

- 1. Compare access to the ibm-allGroups attribute in cn=u3,o=ibm.
- Search access to the cn attribute of cn=u3,o=ibm is granted from the search filter specified in the memberURL attribute in cn=g5,o=ibm.

Since cn=g3,o=ibm has cn=g5,o=ibm as an **ibm-memberGroup** attribute value, cn=g3,o=ibm is added as an **ibm-allGroups** attribute as well. cn=g1,o=group has cn=g3,o=ibm as an **ibm-memberGroup** value, therefore cn=g1,o=group is also added as an **ibm-allGroups** attribute value. Therefore, the compare operation will return an **LDAP\_COMPARE\_TRUE** to the client application.

# Chapter 9. Using access control

T

L

1

Access control of information in the LDAP server is specified by setting up Access Control Lists (ACLs). LDBM, GDBM, or CDBM ACLs provide a means to protect information stored in an LDAP directory. Administrators use ACLs to restrict access to different portions of the directory, or specific directory entries. When using the LDBM, GDBM, or CDBM backend, ACLs are created and managed using the Idap\_add and Idap\_modify APIs.

ACLs are represented by a set of attributes which appear to be a part of the entry. The attributes associated with access control, such as **entryOwner**, **ownerPropagate**, **aclEntry**, and **aclPropagate**, are unusual in that they are logically associated with each entry, but can have values which depend upon other entries higher in the directory hierarchy. Depending upon how they are established, these attribute values can be explicit to an entry, or inherited from an ancestor entry.

Use of LDAP's SDBM backend allows a user to be authenticated to the directory namespace using the RACF ID and password. The RACF identity becomes associated with the user's RACF-style distinguished name that was used on the LDAP bind operation. It is then possible to set up ACLs for entries managed by the LDBM, GDBM, or CDBM backend using RACF-style user and group DNs. This controls access to LDBM, GDBM, or CDBM database directory entries using the RACF user or group identities.

The LDAP server schema entry also has an ACL that can be set to control access to the schema entry.

### **Access control attributes**

Access to LDAP directory entries and attributes is defined by Access Control Lists (ACLs). Each entry in the directory contains a special set of attributes which describe who is allowed to access information within that entry. Table 22 shows the set of attributes which are related to access control. More in-depth information about each attribute is given following the table.

It is possible to specify access control settings for individual attribute types. This is called attribute-level access control. Also, it is possible to explicitly deny access to information.

Table 22. ACL and entry owner attributes

noe annouroe	
aclEntry	This is a multi-valued attribute that contains the names and permissions associated with those names that have access to information in the directory entry (or the entry along with the subtree of information below the entry, depending on the setting of the <b>aclPropagate</b> attribute).
aclPropagate	This is a single-valued boolean attribute which indicates whether the <b>aclEntry</b> information applies only to the directory entry it is associated with or to the entire subtree of information including and below the directory entry it is associated with. Note that propagation does not apply to entries that have an explicit <b>aclEntry</b> defined for the entry and that propagation stops at the next propagating ACL (aclPropagate=TRUE) that is encountered in the directory subtree.

#### ACL attributes

aclSource	This is a single-valued attribute that is managed by the LDAP server and cannot be changed by the LDAPMDFY command. This attribute accessible for any directory entry, indicates the distinguished name of the entry that holds the ACL that applies to the entry. This attribute is useful in determining which propagating ACL is used to control access to information in the directory entry.
Entry owner attributes	
entryOwner	This is a multi-valued attribute that contains the distinguished names of users or groups that are considered owners of the directory entry (or the entry along with the subtree of information below the entry, depending on the setting of the <b>ownerPropagate</b> attribute).
ownerPropagate	This is a single-valued boolean attribute which indicates whether the <b>entryOwner</b> information applies only to the directory entry it is associated with or to the entire subtree of information including and below the directory entry it is associated with. Note that propagation does not apply to entries that have an explicit <b>entryOwner</b> defined for the entry and that propagation stops at the next propagating <b>entryOwner</b> (ownerPropagate=TRUE) that is encountered in the directory subtree.
ownerSource	This is a single-valued attribute that is managed by the LDAP server and cannot be changed by the LDAPMDFY command. This attribute indicates the distinguished name of the entry that holds the <b>entryOwner</b> that applies to the entry. This attribute is useful in determining which propagating <b>entryOwner</b> is used to control access to information in the directory entry.

Table 22. ACL and entry owner attributes (continued)

### aclEntry attribute

 **aclEntry** is a multi-valued attribute which contains information pertaining to the access allowed to the entry and each of its attributes. **aclEntry** lists the following types of information:

- Who has rights to the entry (scope of the protection). Also called the subject.
- What specific attributes and classes of attributes (attribute access classes) that the subject has access to.
- What rights the subject has (permissions to specific attributes and classes of attributes).

#### **Syntax**

Following is the **aclEntry** attribute value syntax:

5 <b>,</b> ,
<pre>aclEntry: aclEntry_value</pre>
where,
aclEntry_value :- [access-id: group: role:]subject_DN[granted_rights]
or,
aclEntry_value :- aclFilter:filter.operation[granted_rights]
subject_DN :- valid DN, the object that privileges are granted to.
<i>filter</i> :- valid search filter, using the following attributes only: <b>ibm-filterSubject</b> , <b>ibm-filterIP</b> , <b>ibm-filterTimeOfDay</b> , <b>ibm-filterDayOfWeek</b> , <b>ibm-filterBindMechanism</b> , and <b>ibm-filterConnectionEncrypted</b> . See ACL filters for more information.
operation :- union   replace   intersect. See ACL filters for more information.
granted_rights :- object_rights   normal_rights   sensitive_rights   critical_rights   restricted_rights   system_rights   attr_rights

I	<pre>object_rights :- :object:[grant: deny:]object_rights_list</pre>
I	object_rights_list :- [ald]
	normal_rights :- :normal:[grant: deny:]attr_rights_list
	sensitive_rights :- :sensitive:[grant: deny:]attr_rights_list
	critical_rights :- :critical:[grant: deny:]attr_rights_list
	restricted_rights :- :restricted:[grant:\deny:]attr_rights_list
	system_rights :- :system:[grant:\deny:]attr_rights_list
	attr_rights :- : <b>at.</b> attr_name:[grant: deny:]attr_rights_list
	attr_name:- any valid attribute name
	attr_rights_list :- [r w s c]
	The <i>subject_DN</i> is any valid DN which represents the object (entry) to which privileges are being granted. The DN ends when the first granted rights keyword is detected.
	The <i>granted_rights</i> is specified as follows where <i>object_rights_list</i> is one or more elements of the set [ <b>ald</b> ], and <i>attr_rights_list</i> is one or more elements of the set [ <b>rlwlslc</b> ].
Ι	See ACL filters for more information about the <i>filter</i> and <i>operation</i> values.
	Multiple specifications for the same access class or attribute type within the same <b>aclEntry</b> attribute value will be merged into a single specification. For example:
	group:cn=Anybody:normal:rs:system:rsc:normal:c:normal:deny:w
	will result this merged access list
	group:cn=Anybody:normal:rsc:normal:deny:w:system:rsc
	Scope of protection The scope of the protection is based on the following three types of privilege attributes:
I	access-id
I	The distinguished name of an entry to set permissions for.
I	group The distinguished name of the group entry to set permissions for.
I	<b>role</b> The distinguished name of the group entry to set permissions for.
I	aclFilter
	The <b>aclEntry</b> filter, that if evaluates to true, reduces, augments, or replaces the set of permissions.
I	Access control groups can be either static, dynamic, or nested groups. The following object classes are evaluated as group entries for the LDBM and CDBM backends: <b>ibm-staticGroup</b> , <b>groupOfNames</b> , <b>groupOfUniqueNames</b> , <b>accessRole</b> , <b>accessGroup</b> , <b>ibm-dynamicGroup</b> , <b>groupOfUrls</b> , and <b>ibm-nestedGroup</b> . For additional information on static, dynamic, and nested groups, see Chapter 8, "Static, dynamic, and nested groups," on page 123.
	When specifying a user or group distinguished name in an <b>aclEntry</b> attribute value, the <b>access-id</b> , <b>group</b> , or <b>role</b> portions of the value are optional and are accepted for compatibility with older levels of the LDAP server. If replicating to non-z/OS IBM TDS, one of these prefixes is required. The distinguished name that is used does

not need to be the name of any entry in the directory. The distinguished name is the name that represents the user that has authenticated to the directory server or the group that the user is a member of.

The access control implementation supports several "pseudo-DNs". These are used to refer to large numbers of subject DNs which, at bind time, share a common characteristic in relation to either the operation being performed or the target object on which the operation is being performed. Currently, three pseudo DNs are defined:

group:cn=anybody
group:cn=authenticated
access-id:cn=this

Т

1

T

T

The group:cn=anybody refers to all subjects, including those that are unauthenticated (considered anonymous users). All users belong to this group automatically. The group:cn=authenticated refers to any DN which has been authenticated to the directory. The method of authentication is not considered. The access-id:cn=this refers to the bind DN which matches the target object's DN on which the operation is performed.

A search filter can be specified after the **aclFilter** component in an **aclEntry** attribute value. When the search filter evaluates to true, it reduces, augments, or replaces the set of permissions specified. See "ACL filters" on page 142 for more information about the search filters that are allowed to be specified.

#### **Examples**

In this example, the DN type is access-id and the DN itself is cn=personA, ou=deptXYZ, o=IBM, c=US.

access-id:cn=personA, ou=deptXYZ, o=IBM, c=US

In this example, the DN type is group and the DN itself is cn=deptXYZRegs, o=IBM, c=US.

group:cn=deptXYZRegs, o=IBM, c=US

This is an example of how to use a RACF identity established with SDBM in an ACL.

access-id:racfid=YourID,profileType=user
group:racfid=YourGroup,profileType=group

#### Attribute access classes

Attributes requiring similar permission for access are grouped together in classes. Attributes are assigned to an attribute access class within the schema definitions. The **IBMAttributeTypes** attribute in the LDAP server schema entry holds the attribute type's access class. The three attribute access classes are:

- normal
- sensitive
- critical

Each of these attribute access classes is discrete. If a user has write permission to **sensitive** attributes, then the user does not automatically have write permission to **normal** attributes. This permission must be explicitly defined.

The default attribute access class for an attribute is **normal**. By default, all users have read access to **normal** attributes. There are two additional attribute access

classes used internally by LDAP for system attributes. These attribute access classes are **restricted** and **system**. You can specify these access classes when granting permissions in ACLs.

For example, a person's name would typically be defined in the **normal** class. Perhaps a social security number would be considered **sensitive**, and any password information for the user would be considered **critical**. Following are some example definitions excerpted from the LDAP server schema. Note that the attribute **userPassword** is defined with access class **critical**.

```
attributetypes: (
 2.5.4.49
 NAME ( 'dn'
              'distinguishedName'
                                    )
 EQUALITY distinguishedNameMatch
 SYNTAX 1.3.6.1.4.1.1466.115.121.1.12
 USAGE userApplications
 )
ibmattributetypes: (
 2.5.4.49
 ACCESS-CLASS normal
 )
attributetypes: (
 2.5.4.35
 NAME 'userPassword'
 DESC 'Defines the user password'
 SYNTAX 1.3.6.1.4.1.1466.115.121.1.40
 USAGE userApplications
ibmattributetypes: (
 2.5.4.35
 ACCESS-CLASS critical
```

It is possible to specify access controls on individual attributes. However, when defining schema an access class is always defined for the attribute type. If not specified, that attribute type is defined to belong to the **normal** class.

Note: The restricted attributes are: aclEntry, aclPropagate, entryOwner, and ownerPropagate. In order to update access control information, you must have permissions to read and write these attributes. The system attributes include aclSource and ownerSource and other attributes for which the server controls the values. In order to update access control information, you must have permission to read and write these attributes. If the system keyword is not specified in an aclEntry attribute value, the system access will be set to 'system:rsc'.

### Access permissions

Following is the set of access permissions.

Table 23. Permissions which apply to an entire entry

Add	Add an entry below this entry
Delete	Delete this entry

Table 24. Permissions which apply to attribute access classes

Read	Read attribute values
Write	Write attribute values
Search	Search filter can contain attribute type

Table 24. Permissions which apply to attribute access classes (continued)CompareCompare attribute values

Following are some examples of valid aclEntry values:
access-id:cn=Tim, o=Your Company:normal:rwsc:sensitive:rsc:object:ad
role:cn=roleGroup, o=Your Company:object:ad:normal:rsc:sensitive:rsc
group:cn=group1, o=Your Company:system:csr:normal:sw
<pre>cn=Lisa, o=Your Company:normal:rwsc:sensitive:rwsc:critical:rwsc:restricted:rwsc:system:rwsc</pre>
cn=Ken, o=Your Company:normal:rsc
group:cn=group2,dc=yourcompany,dc=com:normal:rwsc:at.cn:deny:w:sensitive:grant:rsc
cn=Karen,dc=yourcompany,dc=com:at.cn:grant:rwsc:normal:deny:rwsc
cn=Mary,dc=yourcompany,dc=com:normal:rwsc:sensitive:rwsc:critical:deny:rwsc:at.userpassword:w
group:cn=anybody:normal:rsc
group:cn=authenticated:normal:rwsc:sensitive:rsc
access-id:cn=this:normal:rwsc:sensitive:rwsc:restricted:rwsc
aclFilter: (&(ibm-filterTimeOfDay>=09:00)(ibm-filterTimeOfDay<=17:00)(ibm-filterDayOfWeek>=1) (ibm-filterDayOfWeek<=5)):union:normal:w
aclFilter: ( (ibm-filterSubject=cn=Ken, o=Your Company)(ibm-filterIP=129.176.132.*)) :replace:normal:rwsc:critical:rsc:sensitive:rwsc
See Access determination for information on how the <b>aclEntry</b> values are used to determine access.
The <b>aclEntry</b> attribute value is defined as a directory string.
When the <b>aclFilter</b> scope is not specified, a search using the <b>aclEntry</b> attribute matches against the distinguished name in the value. An <b>aclEntry</b> value in this format is normalized following the matching rules for a distinguished name. Two <b>aclEntry</b> attributes in this format are considered to be the same if they have the same distinguished name.
When the <b>aclFilter</b> scope is specified, a search using the <b>aclEntry</b> attribute matches against the scope, filter, and operation in the search filter. An <b>aclEntry</b> in this format is normalized by normalizing the scope, filter, and the operation. Two <b>aclEntry</b> attributes in this format are considered to be the same if they have the

### aclPropagate attribute

same filter and operation.

T

1

Each entry with an explicit ACL has associated with it an **aclPropagate** attribute. By default, the entry's explicit ACL is inherited down the hierarchy tree, and its **aclPropagate** attribute is set to **TRUE**. If set to **FALSE**, the explicit ACL for the entry becomes an override, pertaining only to the particular entry. The **aclPropagate** syntax is Boolean. See Propagating ACLs for more information.

### aclSource attribute

Each entry has an associated **aclSource**. This reflects the DN with which the ACL is associated. This attribute is kept and managed by the server, but may be retrieved for administrative purposes. This attribute cannot be set, only retrieved.

The derivation of **aclSource** is further explained in Propagating ACLs.

### entryOwner attribute

|

L

L

Т

L

I

I

I

I

I

L

I

I

|

I

T

I

T

|

|

Each entry has an associated **entryOwner** which are, in essence, the administrators for a particular entry. The **entryOwner** is allowed to be a user or a group, like what is allowed within an **aclEntry** attribute.

When specifying a user or group distinguished name in an **entryOwner** attribute value, the **access-id**, **group**, or **role** portions of the value are optional and are accepted for compatibility with older levels of the LDAP server. If replicating to non-z/OS IBM TDS, one of these prefixes is required. The distinguished name that is used does not need to be the name of any entry in the directory. The distinguished name is the name that represents the user that has authenticated to the directory server or the group that the user is a member of.

Entry owners are not constrained by permissions given in the **aclEntry**. They have total access to any entry attribute, and can add and delete entries as they want.

**Note:** Unlike the **aclEntry** attribute, the **entryOwner** attribute cannot reduce permissions for the LDAP administrator.

Entry owners, the administrator DN, and users who have write permission for **restricted** attributes are the only people who are allowed to change the attributes related to access control. If a backend is configured for basic replication as a peer or read-only replica, only the administrator DN and the peerserver DN or masterserver DN can set the access control attributes within the backend directory. If a subtree is configured for advanced replication, only the administrator DN and the **ibm-slapdMasterDN** specified on the replication agreement can set the access control attributes within the configured replication context.

The **entryOwner** attribute value is defined as a directory string.

When the **ownerFilter** scope is not specified, a search using the **entryOwner** attribute matches against the distinguished name in the value. An **entryOwner** value in this format is normalized following the matching rules for a distinguished name. Two **entryOwner** attributes in this format are considered to be the same if they have the same distinguished name.

When the **ownerFilter** scope is specified, a search using the **entryOwner** attribute matches against the scope, filter, and the action (**grantIdeny**) in the search filter. An **entryOwner** in this format is normalized by normalizing the scope, filter, and the action. Two **entryOwner** attributes in this format are considered to be the same if they have the same filter and action.

### **Syntax**

Following is the **entryOwner** attribute value syntax:

entry0wner: entry0wner\_value
where,
entryOwner\_value :- [access-id:|group:|role:]subject\_DN
or,
entryOwner\_value :- ownerFilter:filter:grant|deny
subject\_DN :- valid DN, represents the object that privileges are granted.

   	<i>filter</i> :- valid search filter, using the following attributes only: <b>ibm-filterSubject</b> , <b>ibm-filterIP</b> , <b>ibm-filterTimeOfDay</b> , <b>ibm-filterDayOfWeek</b> , <b>ibm-</b> <i>filterBindMechanism</i> , and <b>ibm-filterConnectionEncrypted</b> . See ACL filters for more information.	
		e of protection ope of the protection is based on the following types of privilege attributes:
	access	-id
I		The distinguished name of an entry to grant administrator rights to.
1	group	The distinguished name of the group entry to grant administrator rights to.
I	role	The distinguished name of the group entry to grant administrator rights to.
	owner	Filter
		The <b>entryOwner</b> filter, that if evaluates to true, grants or denies entry
		owner permissions to the entry.

### ownerPropagate attribute

Owner propagation works exactly the same as ACL propagation. By default, owners are inherited down the hierarchy tree, and their owner propagate attribute is set to **TRUE**. If set to **FALSE**, the owner becomes an override, pertaining only to the particular entry. The **ownerPropagate** syntax is boolean.

# ownerSource attribute

Each entry also has an associated **ownerSource**. This reflects the DN with which the owner values are associated. This attribute is kept and managed by the server, but can be retrieved for administrative purposes. This attribute cannot be set, only retrieved.

# ACL filters

AOL IIIters	
 	The access granted to a subject can be altered by using filters on <b>aclEntry</b> and <b>entryOwner</b> with the <b>aclFilter</b> and <b>ownerFilter</b> scope of protection.
I	The syntax of specifying a filter in an <b>aclEntry</b> attribute is:
I	aclFilter:filter.operation[granted_rights]
I	See aclEntry attribute for more information about granted_rights.
I	The syntax of specifying a filter in an entryOwner attribute is:
I	ownerFilter: filter: action
I	where,
 	<i>filter</i> :- An IETF RFC 2254 (RFC 2254: <i>The String Representation of LDAP Search Filters</i> ) compliant LDAP search filter using the attributes below.
I	operation :- union   replace   intersect
I	action :- grantideny
I	A filter can use only the following attributes:

#### ibm-filterSubject

This attribute is used to filter a distinguished name. It can be a bind DN, an alternate DN, a pseudo DN, or a group DN. The attribute can be used, for example, in a filter to reduce ACL permissions for a specific group.

#### ibm-filterIP

This attribute is used to filter the IPv4 or IPv6 address of a client connection. The value can be any syntactically valid IPv4 or IPv6 address, with or without a trailing wildcard. The supported syntax for IPv6 addresses is defined in IETF RFC 2373 (RFC 2373: *IP Version 6 Addressing Architecture*). The wildcard can be specified within any IPv4 octet or in any IPv6 group, and must be the final character in the string. For example, the following are all valid:

- 124.\*
- 124.153.242\*
- 05DC:0001:0000:0000:0000:0000:2\*
- 5DC:1::2\*
- **Note:** The final two addresses listed above are equivalent. All addresses are normalized to their fully expanded syntax. In other words, insignificant leading zeros are added to each IPv4 octet or IPv6 group to expand it to the maximum number of digits, except for any octet or group with a wildcard is not expanded. If a wildcard is specified with the :: IPv6 syntax, normalization shifts the wildcard to the final group of the address. Following are some examples of normalization:

#### Table 25. ibm-filterIP normalization examples

Not normalized address	Normalized address
1.002.03.4	001.002.003.004
01.02.03*	001.002.03*
1:2:3:4:5:6:7:8	0001:0002:0003:0004:0005:0006:0007:0008
1::8	0001:0000:0000:0000:0000:0000:0008
01:2:30:4:05:6:700:08*	0001:0002:0030:0004:0005:0006:0700:08*
::FFFF:129.100.242.10	0000:0000:0000:0000:0000:FFFF:129.100.242.010
1::*	0001:0000:0000:0000:0000:0000:*

#### ibm-filterTimeOfDay

This attribute is used to filter the time of day that the directory entry is accessed. The value is the hh:mm format of 24 hour time, with hh ranging from 00 to 23 and mm ranging from 00 to 59. This can be used, for example, to grant access only during a certain time of day.

#### ibm-filterDayOfWeek

This attribute is used to filter the day of week that the directory entry is accessed. The value is an integer mapping the days of the week as follows: Sunday = 0, Monday = 1, Tuesday = 2, Wednesday = 3, Thursday = 4, Friday = 5, Saturday = 6. This can be used, for example, to grant access only during certain days of the week.

### ibm-filterBindMechanism

This attribute is used to filter the bind mechanism used to connect to the LDAP server. The following string values can be used to represent bind mechanisms: **SIMPLE**, **EXTERNAL**, **CRAM-MD5**, and **DIGEST-MD5**. This attribute can be used, for example, to deny access for SIMPLE binds.

     	<b>ibm-filterConnectionEncrypted</b> This attribute is used to filter whether encryption is used to access the LDAP server. The valid values are <b>TRUE</b> and <b>FALSE</b> . This can be used, for example, to deny access for non-SSL binds or SSL binds done with no cipher specifications.
1	The <i>operation</i> value is required for <b>aclFilter</b> values, and specifies the way that ACL filters are applied:
   	<b>replace</b> The effective permission is replaced by the ACL filter permission. For example, to grant clients from a given subnetwork a specific set of permissions only, use <b>replace</b> .
   	<b>union</b> The effective permission is joined with the ACL filter permission. This is used to expand permissions when granting, and reduce permissions when denying. For example, to grant clients from a given subnetwork a set of permissions, at a minimum, use <b>union</b> .
     	intersect The effective permission is intersected with the ACL filter permission. This is used to reduce permissions. For example, to grant clients from a given subnetwork a set of permissions, if and only if they already have those permissions, use intersect.
   	The <i>action</i> value is required for <b>ownerFilter</b> values, and must be set to either grant, to grant entry owner access to the entry, or deny, to deny entry owner access when the LDAP search filter evaluates to true.
   	Filters using incorrect filter syntax, filter attributes, or operation values fail when an attempt is made to add or modify the incorrect <b>aclEntry</b> or <b>entryOwner</b> attribute value.
   	Note that unlike the <b>aclEntry</b> attribute, the <b>entryOwner</b> attribute cannot reduce permissions for the administrator DN.

# Initializing ACLs with LDBM

The LDBM backend adds an ACL to each suffix entry if no **aclEntry** value is specified during the add of this entry. This improves performance of future ACL modifications made to an ACL placed on the suffix entry. The ACL that is used is: aclEntry: cn=anybody:normal:rsc:system:rsc

aclPropagate: TRUE

Similarly, if no entry owner is specified when the suffix entry is created, entryOwner is added to the entry with a value set to the administrator DN, along with ownerPropagate TRUE.

# **Default ACLs with LDBM**

Every entry must have an ACL. If there is no ACL explicitly specified in the entry and no parent entry is propagating its ACL, then a default ACL is assigned to the entry. The default ACL is treated differently than a normal aclEntry value. The default value cannot be deleted. If an aclEntry value is later added to the entry, explicitly or by inheritance, the entire default aclEntry value is replaced. The LDAP server sets the value of the aclSource attribute to 'default' when the entry is using the default ACL. The default ACL is:

aclEntry: group:CN=ANYBODY:normal:rsc:system:rsc

Similarly, every entry must have an entry owner. If none is specified or inherited, a default **entryOwner** value set to the administrator DN is assigned to the entry. The default value cannot be deleted. If an **entryOwner** value is later added to the entry, explicitly or by inheritance, the entire default **entryOwner** value is replaced. The LDAP server sets the value of the **ownerSource** attribute to 'default' when the entry is using the default owner.

# Initializing ACLs with GDBM

When the LDAP sever is started with GDBM configured for the first time, the LDAP server creates the change log suffix entry, cn=changelog. The suffix entry is created with an **aclEntry** and **entryOwner** value that allows access only to the LDAP administrator and propagates the **aclEntry** and **entryOwner** values. Only the **aclEntry** and **entryOwner** attributes can be modified. Change log entries cannot be modified to override the inherited ACL values from the change log suffix entry.

Initiali	zing ACLs with CDBM
	When the LDAP server is started with CDBM configured for the first time, the LDAP server creates the following entries:
I	• cn=ibmpolicies
I	<ul> <li>cn=pwdpolicy,cn=ibmpolicies</li> </ul>
I	<ul> <li>cn=configuration</li> </ul>
I	<ul> <li>cn=Replication,cn=configuration</li> </ul>
I	<ul> <li>cn=Log Management,cn=configuration</li> </ul>
I	<ul> <li>cn=Replication,cn=Log Management,cn=configuration</li> </ul>
     	The cn=ibmpolicies suffix entry is created with the same initial ACL as an LDBM suffix, that allows read access to anybody and propagates the <b>aclEntry</b> and <b>entryOwner</b> values. Therefore, only the LDAP administrator can update the cn=ibmpolicies suffix. The <b>aclEntry</b> and <b>entryOwner</b> values can be modified. If the <b>aclEntry</b> and <b>entryOwner</b> values are deleted, the default ACL is used.
   	The cn=configuration suffix entry is created with an <b>aclEntry</b> and <b>entryOwner</b> value that allows access only to the LDAP administrator and propagates the <b>aclEntry</b> and <b>entryOwner</b> values.
   	<b>Note:</b> It is suggested that you do not entirely delete the <b>aclEntry</b> and <b>entryOwner</b> values. The default ACL is used if they are deleted and allows users other than the administrator access to sensitive configuration related data.

# Initializing ACLs with schema entry

When the LDAP sever is started for the first time, the LDAP server creates the LDAP server schema entry, cn=schema. The entry is created with the same initial ACL as an LDBM suffix, which allows read access to anybody. Therefore, only the LDAP administrator can update the schema. The **aclEntry** and **entryOwner** values can be modified.

### **Access determination**

The same bound user may be granted different access permissions to an entry if:

- the user is the LDAP administrator and the server is, or is not, in maintenance mode
- the user is the masterserver DN or peerserver DN
- the user is the entry owner
- the user has specific access permissions set for:
  - the bind DN,

1

Т

- alternate DNs,
- pseudo DNs,
- groups the bind or alternate DNs are members of
- · the user has matching ACL filters

For using the **GetEffectiveACL** extended operation in the LDAPEXOP utility, see Querying effective permissions.

The z/VM LDAP server uses the following algorithm to determine the permissions to grant a bound user:

Note: When you see "additional access information," it refers to:

- · The IP address of the client connection
- The bind mechanism used to bind to the LDAP server
- Whether encryption was used to bind to the LDAP server
- · The time of day that the directory entry was accessed
- The day of week that the directory entry was accessed.

The LDAP administrator, **masterServerDN**, **peerServerDN**, and **entryOwner** matches are first evaluated:

- 1. If the bind DN is the LDAP administrator and the server is in maintenance mode, then
  - Full access is given
  - Then, the algorithm ends and the server continues to process the request.
- 2. If the bind DN is the masterServerDN or peerServerDN, then
  - Full access is given
  - Then, the algorithm ends and the server continues to process the request.
- 3. If the bind DN is the LDAP administrator, then
  - Full access is first applied
  - Then, permissions for all **aclFilter** values matching the LDAP administrator's bind DN and additional access information are applied
  - Finally, the algorithm ends and the server continues to process the request.
- 4. If the bind DN matches a base **entryOwner**, or the bind DN and additional access information match an **ownerFilter**, then
  - Full access is given if no matching **ownerFilter** specify the deny operator
  - Then, the algorithm ends and the server continues to process the request.
- 5. If the alternate DN matches a base **entryOwner**, or the alternate DN and additional access information match an **ownerFilter**, then
  - Full access is given if no matching **ownerFilter** specify the deny operator
  - Then, the algorithm ends and the server continues to process the request.
- If the group DN that the bind or alternate DNs belongs to matches a base entryOwner, or the group DNs and additional access information match an ownerFilter, then:
  - Full access is given if no matching ownerFilter specify the deny operator
  - Then, the algorithm ends and the server continues to process the request.

If a match has not yet been found or an **ownerFilter** denied access above, then **aclEntry** values are evaluated as follows:

- 1. If no **aclEntry** attributes are specified, then the default permissions are applied, or
- If the bind is anonymous, and a base aclEntry matches the cn=anybody pseudo DN, or filter in an aclFilter component match the cn=anybody pseudo DN and additional access information, then:
  - See step a on page 147.
- 3. If a base **aclEntry** value matches the bind DN or filter in an **aclFilter** component matches the bind DN and additional access information, then:
  - See step a on page 147.
- 4. If a base **aclEntry** value matches the alternate DN(s) or filter in an **aclFilter** component matches the alternate DN(s) and additional access information, then:
  - See step b on page 147.
- If the entry DN matches the bind DN, and a base aclEntry matches the cn=this pseudo DN, or filter in an aclFilter component match the cn=this pseudo DN and additional access information, then:
  - See step a on page 147.
- If the entry DN matches an alternate DN, and a base aclEntry matches the cn=this pseudo DN, or filter in an aclFilter component match the cn=this pseudo DN and additional access information, then:
  - See step a on page 147.
- If a base aclEntry value matches the group DN(s) that the bind or alternate DNs belongs to or filter in an aclFilter component match the group DN(s) and additional access information, then:
  - See step b on page 147.
- If the bind DN is authenticated, and a base aclEntry matches the cn=authenticated pseudo DN, or filter in an aclFilter component match the cn=authenticated pseudo DN and additional access information, then:
  - See step a on page 147.
- If the bind is authenticated, and a base aclEntry matches the cn=anybody pseudo DN, or filter in an aclFilter component match the cn=anybody pseudo DN and additional access information, then:
  - See step a on page 147.

I

L

- 10. The bound user does not receive any permissions.
  - Step a: The algorithm applies permissions and ends as follows:
  - Any matching base permissions are first applied
  - Then, any matching aclFilter permissions are applied
  - Finally, the algorithm ends and the server continues to process the request.
  - Step b: The algorithm applies permissions and ends as follows:
  - The union of matching base permissions are first applied
  - Then, any matching aclFilter permissions are applied
  - Finally, the algorithm ends and the server continues to process the request.
- **Note:** In each of these steps, permissions for matching filters can be set if base permissions have already been set or not.

If at least one **aclEntry** matches, access to system attributes are always granted read, search, and compare permissions, unless they are explicitly overridden.

The way **aclFilter** permissions are applied depends on the value specified for the operation (replace, union, and intersect). If there are one or more matching **aclFilters**, up to three temporary ACLs are formed from the union of all permissions for each operation. These are applied to the bound user's effective permission as follows:

- 1. If there are filter permissions for the replace operation, the bound user's base effective ACL is replaced by the replace filter permissions to form a new effective permission.
- If there are any filter permissions for the union operation, the bound user's new effective permission becomes the union of the union filter permissions and the existing effective permission. The existing effective permission is produced by step 1, or if step 1 did not apply, it is the base effective permission.
- 3. If there are any filter permissions for the intersect operation, the bound user's new effective permission becomes the intersect of the intersect filter permissions and the existing effective permission. The existing effective permission is produced by step 2, or if step 2 did not apply, then it is the existing effective permission produced by step 1, or if step 1 did not apply, it is the base effective permission.

When using attribute-level permissions or grant/deny support, the order of evaluation of the separate permissions clauses is important. The access control permissions clauses are evaluated in a precedence order, not in the order in which they are found in the ACL entry value. There are four types of permissions settings: access-class grant permissions, access-class deny permissions, attribute-level grant permissions, and attribute-level deny permissions. The precedence for these types of permissions is as follows (from highest precedence to lowest):

- attribute-level deny permissions
- attribute-level grant permissions
- · access-class deny permissions
- access-class grant permissions

Using this precedence, a deny permission takes priority over a grant permission (for the same item specified) while attribute-level permissions take precedence over access-class permissions.

A similar grant or deny precedence exists for the grant or deny support provided for **ownerFilter**. A deny always takes precedence over a grant of **entryOwner** access.

### Access determination examples

Т

Т

Т

1

Т

I

T

The following are examples that illustrate the permissions that users have for entries and attribute types.

#### Example 1:

aclEntry: group:cn=Anybody:normal:rsc

In this example, unauthenticated (anonymous) users have permission to read, search and compare all attributes within the **normal** attribute access class. ACL entry values for unauthenticated users use pseudoDN cn=Anybody.

#### Example 2:

aclEntry: access-id:cn=personA,ou=deptXYZ,o=IBM,c=US:object:ad:normal:rwsc:sensitive:rwsc:critical:rsc

In this example, the user corresponding to cn=personA, ou=deptXYZ, o=IBM, c=US has permission to add entries below the entry, to delete the entry, to read, write, search, and compare both **normal** and **sensitive** attributes, and to read, search and compare **critical** attributes.

#### Example 3:

aclEntry: group:cn=Authenticated:normal:rwsc:sensitive:rwsc

In this example, users who have authenticated to the directory where a specific **aclEntry** value does not apply, are allowed to read, write, search, and compare, **normal** and **sensitive** attributes in the directory entry.

#### Example 4:

aclEntry: cn=Tim,dc=yourcompany,dc=com:at.cn:deny:w:normal:rwsc

In this example, cn=Tim,dc=yourcompany,dc=com is granted read, write, search, and compare to **normal** attributes except for the **cn** attribute in which write access is denied. Note that the following ACL entry results in the same access:

aclEntry: cn=Tim,dc=yourcompany,dc=com:normal:rwsc:at.cn:deny:w

The evaluation of the permissions clauses is based on precedence, not order in the ACL entry value(s).

#### Example 5:

aclEntry: cn=Karen,dc=yourcompany,dc=com:normal:rwsc:sensitive:rsc:at.userpassword:w: critical:deny:rwsc

In this example, cn=Karen,dc=yourcompany,dc=com is granted read, search, and compare to **normal** and **sensitive** attributes, and write to **normal** attributes and the **userpassword** attribute. All access to **critical** attributes (except for write in **userpassword**) is turned off.

#### Example 6:

aclEntry: group:cn=group1,dc=yourcompany,dc=com:normal:rwsc aclEntry: group:cn=group2,dc=yourcompany,dc=com:sensitive:rwsc:at.cn:deny:w

In this example, a member of group1 is only granted read, write, search, and compare to **normal** attributes. A member of both group1 and group2 is granted read, write, search, and compare to **normal** and **sensitive** attributes, excluding write access to the **cn** attribute. This is an example where a member of both groups is granted access to less information than what is granted to each of the two groups individually.

#### Example 7:

aclEntry: access-id:cn=Tim,dc=yourcompany,dc=com:normal:rwsc:at.cn:rsc

In this example, cn=Tim,dc=yourcompany,dc=com is granted read, write, search, and compare on **normal** attributes and read, search, and compare on the **cn** attribute. Note that cn=Tim,dc=yourcompany,dc=com also has write access to the **cn** attribute by virtue of **cn** having an access class of **normal**.

#### Example 8:

aclEntry: access-id:cn=Tim,dc=yourcompany,dc=com:normal:rwsc:at.cn:deny:rsc

In this example, cn=Tim,dc=yourcompany,dc=com is granted read, write, search, and compare on **normal** attributes and denied read, search, and compare on the **cn** attribute. Note that cn=Tim,dc=yourcompany,dc=com still has write access to the **cn** attribute by virtue of **cn** having an access class of **normal**.

#### Example 9:

Т

Т

```
aclEntry: cn=Ken, o=Your Company:normal:rsc
aclFilter: (&(|(ibm-filterSubject=cn=Ken, o=Your Company)
(ibm-filterIP=129.176.132.*))(ibm-filterTimeOfDay>=09:00)
(ibm-filterTimeOfDay<=17:00)(ibm-filterDayOfWeek>=1)
(ibm-filterDayOfWeek<=5)):union:normal:w</pre>
```

In this example, cn=Ken, o=Your Company is granted read, write, search, and compare access on **normal** attributes when authenticated from any IP address on Monday through Friday from 9:00 AM to 5:00 PM. On any other time or day, cn=Ken, o=Your Company is only granted read, search, and compare access on **normal** attributes.

If another user binds from IP address 129.176.132.28 on Monday through Friday from 9:00 AM to 5:00 PM, they are granted write access on **normal** attributes.

#### Example 10:

```
aclEntry: group:cn=group1, o=Your Company:system:rsc:normal:sw
aclEntry: aclFilter:(&(ibm-filterSubject=cn=group1,
    o=Your Company)(ibm-filterIP=129.176.*)(ibm-filterBindMechanism=CRAM-MD5)
    (ibm-filterConnectionEncrypted=true)):intersect:system:rsc:normal:s
```

In this example, if cn=Ken,o=Your Company is a member of cn=group1,o=Your Company, binds from IP address 129.176.113.76 using a CRAM-MD5 mechanism, over an encrypted SSL connection. cn=Ken,o=Your Company is granted system:rsc and normal:s permissions. Note the intersect operation restricted permissions by disposing of normal:w permissions.

#### Example 11:

```
aclEntry: access-id:cn=Joe,dc=yourcompany,dc=com,o=IBM:normal:r
aclEntry: group:cn=group1,dc=yourcompany,dc=com:normal:rw
aclEntry: group:cn=group2,dc=yourcompany,dc=com:critical:rw
aclEntry:aclFilter:(&(ibm-filterSubject=cn=group1,dc=yourcompany,dc=com)
(ibm-filterIP=129.176.*)):union:normal:sc
```

In this example, if cn=Joe,dc=yourcompany,dc=com,o=IBM is a member of cn=group1,dc=yourcompany,dc=com and binds from IP address 129.176.53.92, cn=Joe,dc=yourcompany,dc=com,o=IBM is only granted read permission on **normal** attributes, for the following reasons:

- There is a specific access-id value for cn=Joe,dc=yourcompany,dc=com,o=IBM, therefore, only that base access-id ACL is granted, and no group ACLs are granted. cn=Joe,dc=yourcompany,dc=com,o=IBM's effective permission, before any filters are applied, is normal:r.
- The resulting subject that is tested for membership in the filter is cn=Joe,dc=yourcompany,dc=com,o=IBM. It does not match, therefore, the ACL filter does not apply.

A member of cn=group1,dc=yourcompany,dc=com that binds from IP address 172.191.214.98 is only granted read and write permissions on **normal** attributes.

A member of both cn=group1,dc=yourcompany,dc=com and cn=group2,dc=yourcompany,dc=com that binds from IP address 129.176.98.112, is

granted read, write, search, and compare access on **normal** attributes (because of the union with the filter), and is granted read and write access on **critical** attributes.

aclEntry: access-id:cn=Mary,dc=yourcompany,dc=com,o=IBM:normal:rw aclEntry: group:cn=group1,dc=yourcompany,dc=com:normal:rwsc aclEntry: aclFilter:(|(ibm-filterSubject=cn=group1,dc=yourcompany,dc=com) (ibm-filterIP=129.176.92.\*)):intersect:normal:rsc:critical:r

In this example, if cn=Mary,dc=yourcompany,dc=com,o=IBM (who is not a member of group1,dc=yourcompany,dc=com) binds from IP 129.176.92.113, cn=Mary,dc=yourcompany,dc=com,o=IBM is granted read permission on **normal** attributes. This is because cn=Mary,dc=yourcompany,dc=com,o=IBM's effective permission is determined by the intersect of normal:rw and the ACL filter. Note the intersect operation restricted permissions by disposing of normal:wsc and critical:r while keeping normal:r permissions.

#### Example 13:

```
aclEntry: group:cn=group1,dc=yourcompany,dc=com:normal:rwsc
aclEntry: aclFilter:(ibm-filterIP=129.176.*):replace:normal:rw
aclEntry: aclFilter:(!(ibm-filterSubject=cn=group1,dc=yourcompany,dc=com))
:replace:normal:deny:w
```

In this example, a member of cn=group1,dc=yourcompany,dc=com that binds from IP address 129.176.29.52 is granted read and write access to **normal** attributes. The base **aclEntry** for cn=group1,dc=yourcompany,dc=com is first applied, and is then replaced by the **aclEntry** with **aclFilter** for ibm-filterIP=129.176.\*.

#### Example 14:

```
aclEntry: aclFilter:(ibm-filterIP=129.176.29.52):intersect:normal:sc
aclEntry: aclFilter:(ibm-filterIP=129.176.*):replace:normal:r
aclEntry: aclFilter:(ibm-filterSubject=cn=group1, o=Your Company)
:union:critical:r
aclEntry: aclFilter:(ibm-filterIP=129.176.29*):union:sensitive:r
aclEntry: aclFilter:(ibm-filterSubject=cn=Mary, o=Your Company)
:intersect:normal:r
aclEntry: group:cn=group1, o=Your Company:normal:rw
aclEntry: aclFilter:(ibm-filterSubject=cn=group1, o=Your Company)
:replace:normal:rwsc
```

In this example, if cn=Mary, o=Your Company, a member of cn=group1, o=Your Company, binds from IP address 129.176.29.52, cn=Mary, o=Your Company's effective permission is determined by all of the **aclEntry** values above, as follows:

- cn=Mary, o=Your Company's base effective permission is granted read and write permissions on normal attributes. This is because cn=Mary, o=Your Company is a member of cn=group1, o=Your Company.
- The replace filters that match for cn=Mary, o=Your Company are then joined together to produce one replace filter with read, write, search, and compare access on **normal** attributes. These permissions now become cn=Mary, o=Your Company's effective permission, replacing her base effective permission.
- 3. The union filters that match for cn=Mary, o=Your Company are then joined together to produce one union ACL with read permissions on **sensitive** and **critical** attributes. These permissions are joined with cn=Mary, o=Your Company's effective permission that was produced in step 2. This produces cn=Mary, o=Your Company's new effective permission, granting read, write, search, and compare permissions on **normal** attributes, and read permissions on **sensitive** and **critical** attributes.

	4. Finally, the intersect filters that match for cn=Mary, o=Your Company are joined together to produce one intersect ACL with read, search, and compare access on <b>normal</b> attributes. These permissions are intersected with the effective permission produced by step 3, to produce cn=Mary, o=Your Company's final effective permission, giving her read, search, and compare access on <b>normal</b> attributes.	
	Example 15:	
	entryOwner: ownerFilter:(&(ibm-filterSubject=cn=Ken, o=Your Company) (ibm-filterIP=129.176.132.*))	
	In this example, cn=Ken, o=Your Company is given owner access only when bound from an IP address within the 129.176.132.* subnetwork.	
	Example 16:	
	entryOwner: access-id:cn=Ken, o=Your Company entryOwner: ownerFilter:(&(ibm-filterSubject=cn=Ken, o=Your Company) (ibm-filterIP=129.176.132.*)):deny	
	In this example, cn=Ken, o=Your Company is granted owner access when bound from an IP address that is not within the 129.176.132.* subnetwork. However, cn=Ken, o=Your Company is denied owner access when bound from an IP address that is within the 129.176.132.* subnetwork.	
Search		
	In order to read an attribute from the directory, the user must have read permission for the specific attribute or for the attribute access class that the attribute belongs.	
Filter		
	In order to use an attribute in a search filter supplied on a search operation, the user must have search permission for the specific attribute or for the attribute access class that the attribute belongs.	
Compare		
Compare	In order to perform a compare operation on an attribute/value combination, the user must have compare permission for the specific attribute or for the attribute class that the attribute belongs.	
Requested attributes		
	If the user has the search permission on all attributes contained in the filter, the server returns as much information as possible. All requested attributes that the user has read permission for are returned.	
	For example, allow the <b>aclEntry</b> be	
	group:cn=Anybody:normal:rsc:sensitive:c:critical:c	
	and allow the client to perform an anonymous search	
	ldapsrch -b "c=US" "cn=LastName" title userpassword telephoneNumber	

where title is a **normal** attribute, telephoneNumber is a **sensitive** attribute, and userpassword is a critical attribute. Users performing anonymous searches are given the permission granted to the cn=Anybody group. In this example, permission exists to the filter because **cn** is in the **normal** attribute access class, and cn=Anybody has s (search) permission to the normal attribute access class.

L I

T

T

T

T

Т

I I

I

I

What is returned however, is only the **title** attribute for any matching entry. The **telephoneNumber** and **userPassword** attributes are not returned because **cn=Anybody** does not have read permissions on the **sensitive** and **critical** attribute access classes.

I	Querying effective permissions		
	When filters are specified in <b>aclEntry</b> or <b>entryOwner</b> attribute values in the directory, it might be difficult to determine the permissions that users or groups have to entries. To ease in the determination of effective ACLs, the LDAPEXOP utility provides the <b>GetEffectiveACL</b> extended operation. For more information, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .		
     	This extended operation in the LDAPEXOP utility allows the specification of search criteria and bound user's information (such as the bind distinguished name, time of day, the day of the week, and IP address where the user is authenticating from). By specifying the search criteria and bound user's information, the LDAP administrator is allowed to simulate the effective ACLs for multiple users in the directory.		
	This extended operation returns the following information for each requested entry:		
I	<ul> <li>the entry DN to which access was requested</li> </ul>		
	<ul> <li>the subject and all of its alternate DNs and group DNs for which access was calculated for</li> </ul>		
 	<ul> <li>the source attribute values (aclEntry, aclPropagate, aclSource, entryOwner, ownerPropagate, and ownerSource) in effect for the entry</li> </ul>		
	<ul> <li>the applicable attribute values (aclEntry and entryOwner) used to form the effective permissions</li> </ul>		
I	<ul> <li>the calculated effective access class permissions</li> </ul>		
I	<ul> <li>the calculated effective attribute permissions</li> </ul>		
	This example performs the <b>GetEffectiveACL</b> extended operation for each entry returned on the subtree search of the dc=yourcompany,dc=com subtree. The requested subtree search uses dc=yourcompany,dc=com as the baseDN, with a filter of "objectclass=*", a search size limit of 100, a search time limit of 10 seconds,		
   	and no alias dereferencing. Based on these returned search entries, the <b>GetEffectiveACL</b> extended operation calculates the effective ACLs for user cn=Joe Shmoe,ou=users,dc=yourcompany,dc=com when a simple bind is done from IP address 129.176.132.92 at 18:30 on a Saturday over a secure SSL connection.		
   	ldapexop -D <i>adminDn -w adminPw</i> -op geteffectiveacl -filter "objectclass=*" -base "dc=yourcompany,dc=com" -s sub -a never -z 100 -l 10 -dn "cn=Joe Shmoe,ou=users,dc=yourcompany,dc=com" -ip 129.176.132.92 -time 18:30 -day 6 -mech SIMPLE -encrypt		
	#ENTRY INFORMATION: dn: dc=yourcompany,dc=com #SUBJECT INFORMATION: #Bind DN: dn: cn=Joe Shmoe,ou=users,dc=yourcompany,dc=com		
	#Alternate DNs: dn: cn=alt_01 dn: cn=alt_02		
   	#Group DNs: dn: cn=group_01 dn: cn=group_02		
	#SOURCE ATTRIBUTE VALUES: aclEntry: group:cn=Anybody:normal:rsc:system:rsc		

aclPropagate: TRUE aclSource: dc=yourcompany,dc=com entryOwner: cn=Admin ownerPropagate: TRUE ownerSource:dc=yourcompany,dc=com

#APPLICABLE ATTRIBUTE VALUES: aclEntry: group:cn=Anybody:normal:rsc:system:rsc

#EFFECTIVE ACCESS-CLASS PERMISSIONS: normal: grant:rsc system: grant:rsc

#ENTRY INFORMATION: dn: ou=users,dc=yourcompany,dc=com

# **Propagating ACLs**

I

I

|

ACLs can be set on any entry in the hierarchy. ACLs (including ACL filters) can propagate through the directory hierarchy. These ACLs, called propagating ACLs, have the **aclPropagate** attribute set to **TRUE**. All descendents of this entry inherit the ACL set at that point, unless overridden. In order to specify an ACL different from that of its parent, a new ACL must be explicitly set.

When setting the new ACL, there is again a choice of whether to propagate the ACL. If set to **TRUE**, the ACL will propagate down to all descendants. If set to **FALSE**, the ACL is not propagated; it instead becomes an override ACL. The ACL is not propagated down through the hierarchy, but instead applies only to the one particular entry that it is associated with within the hierarchy. If unspecified, **aclPropagate** is set to **TRUE**.

An entry without an explicit ACL receives its ACL from the nearest propagating ancestor ACL. If there is no propagating ACL, the entry receives the default ACL. Propagated ACLs do not accumulate as the depth in the tree increases. The scope of a propagated ACL is from the explicitly-set propagating ACL down through the tree until another explicitly-set propagating ACL is found.

The same rules apply to propagating the entry owner permissions (including ACL filters for entry owners) based on the **ownerPropagate** attribute.

### Example of propagation

1

Following is the explicit ACL for entry ou=deptXYZ, o=IBM, c=US :

```
aclPropagate: TRUE
aclEntry: group:cn=deptXYZRegs, o=IBM, c=US:normal:rcs:sensitive:rsc
aclEntry: group:cn=dertscand, ou=deptXYZ, o=IBM, c=US:object:ad:normal:rwsc:sensitive:rwsc:critical:rsc
aclEntry: group:cn=Anybody:normal:rsc
aclSource: ou=deptXYZ, o=IBM, c=US
```

In the absence of an explicit ACL for entry cn=personA, ou=deptXYZ, o=IBM, c=US, the following is the implicit, propagated ACL for the entry:

```
aclPropagate: TRUE
aclEntry: group:cn=deptXYZRegs, o=IBM, c=US:normal:rcs:sensitive:rsc
aclEntry: access-id:cn=personA, ou=deptXYZ, o=IBM, c=US:object:ad:normal:rwsc:sensitive:rwsc:critical:rsc
aclEntry: group:cn=Anybody:normal:rsc
aclSource:ou=deptXYZ, o=IBM, c=US
```

In this example, a propagating ACL has been set on ou=deptXYZ, o=IBM, c=US. No ACL has been set on the descendant cn=personA, ou=deptXYZ, o=IBM, c=US. Therefore, the descendant inherits its ACL value from the nearest ancestor with a propagating ACL. This happens to be ou=deptXYZ, o=IBM, c=US, which is reflected in the **aclSource** attribute value. The **aclEntry** and **aclPropagate** values are identical to those values in the explicit propagating ACL set at ou=deptXYZ, o=IBM, c=US.

### **Examples of overrides**

Following is an explicit ACL for entry o=IBM, c=US:

```
aclPropagate: TRUE
aclEntry: group:cn=IBMRegs, o=IBM, c=US:normal:rcs:sensitive:rsc
aclEntry: group:cn=Anybody:normal:rsc
aclSource: o=IBM, c=US
```

Following is an explicit ACL for entry ou=deptXYZ, o=IBM, c=US:

```
aclPropagate: FALSE
aclEntry: group:cn=deptXYZRegs, o=IBM, c=US:normal:rcs:sensitive:rsc
aclEntry: access-id:cn=personA, ou=deptXYZ, o=IBM, c=US:object:ad:normal:rwsc:sensitive:rwsc:critical:rsc
aclEntry: group:cn=Anybody:normal:rsc
aclSource: ou=deptXYZ, o=IBM, c=US
```

Note that in the explicit ACLs above, **aclSource** is the same as the entry DN. This attribute is generated and managed by the LDAP server; it cannot be set when modifying ACLs.

Following is an implicit ACL for entry cn=personA, ou=deptXYZ, o=IBM, c=US: aclPropagate: TRUE aclEntry: group:cn=IBMRegs, o=IBM, c=US:normal:rcs:sensitive:rsc aclEntry: group:cn=Anybody:normal:rsc aclSource: o=IBM, c=US

In this example, a propagating ACL has been set on o=IBM, c=US. An override ACL has been set (**aclPropagate** is **FALSE**) on the descendant ou=deptXYZ, o=IBM, c=US. Therefore, the ACL set at ou=deptXYZ, o=IBM, c=US pertains only to that particular entry.

The descendant cn=personA, ou=deptXYZ, o=IBM, c=US inherits its ACL value from the nearest ancestor with a propagating ACL (which is o=IBM, c=US as reflected in the **aclSource**). The ACL on ou=deptXYZ, o=IBM, c=US is not used because **aclPropagate** is **FALSE**.

#### Other examples

In these examples, the administrator DN will be cn=admin, c=US.

The following example shows the default ACL:

```
aclPropagate: TRUE
aclEntry: group:cn=Anybody:normal:rsc:system:rsc
aclSource: default
ownerPropagate: TRUE
entryOwner: access-id:cn=admin,c=US
ownerSource: default
```

The following example shows a typical ACL for entry cn=personA, ou=deptXYZ, o=IBM, c=US:

```
aclPropagate: TRUE
aclEntry: group:cn=deptXYZRegs, o=IBM, c=US:normal:rcs:sensitive:rsc
aclEntry: access-id:cn=personA, ou=deptXYZ, o=IBM, c=US:object:ad:normal:rwsc:sensitive:rwsc:critical:rsc
aclEntry: group:cn=Anybody:normal:rsc:system:rsc
aclSource: ou=deptXYZ, o=IBM, c=US
ownerPropagate: TRUE
entryOwner: access-id:cn=deptXYZMgr, ou=deptXYZ, o=IBM, c=US
ownerSource: ou=deptXYZ, o=IBM, c=US
```

This is an inherited ACL and an inherited owner. Both owner properties and ACL properties are inherited from entry ou=deptXYZ, o=IBM, c=US. In this example, members of group cn=deptXYZRegs, o=IBM, c=US have permission to read, search and compare attributes in both the **normal** and **sensitive** attribute access classes. They do not have permission to add or delete entries under this entry. Nor do they have permission to access any information or change any information on attributes in the **critical** attribute access class. Unauthenticated, as well as all other bound users, have permission to read, search, and compare attributes in the **normal** and **system** attribute access classes only. The personA has add and delete permission on the entry; read, write, search, and compare permissions on **normal** and **sensitive** attributes; and read, search, and compare permission on **critical** attributes. The deptXYZMgr had full access to the entry since it is the owner of the entry. As always, the administrator also has unrestricted access to the entry.

## Access control groups

|

|

Access control groups provide a mechanism for applying the same **aclEntry** or **entryOwner** attribute values to an entry for multiple users without having to create an explicit **aclEntry** or **entryOwner** for each user.

For the LDBM and CDBM backends, the following object classes are evaluated as access control group entries: **accessGroup**, **accessRole**, **groupOfNames**, **groupOfUniqueNames**, **ibm-staticGroup**, **groupOfUrls**, **ibm-dynamicGroup**, and **ibm-nestedGroup**. See Chapter 8, "Static, dynamic, and nested groups," on page 123 for more information on static, dynamic, and nested groups.

# Associating DNs, access groups, and additional bind and directory entry access information with a bound user

After a successful bind request, a bind distinguished name is associated with the bound user.

• For a simple bind, the bind DN is the DN specified in the bind request. There must be an entry in LDAP with that DN. The entry can be in an LDBM, SDBM, or CDBM backend, or in a client operation plug-in extension. There are no alternate DNs.

- For a CRAM-MD5 bind, the bind request must specify a DN or a username. If a DN is specified, there must be an entry in LDAP with that DN. If a username is specified, there must be an entry in LDAP that contains the username as a **uid** attribute value. If both a DN and a username are specified, there must be an entry in LDAP with that DN and the username must be a **uid** attribute value in that entry. In all of these cases, the bind DN is the DN of the entry. The entry can be in an LDBM or CDBM backend, or in a client operation plug-in extension. There are no alternate DNs. See Chapter 7, "CRAM-MD5 and DIGEST-MD5 authentication," on page 119 for more information.
- For a DIGEST-MD5 bind, the bind request must specify a username and may optionally contain an authorization DN. If only a username is specified, there must be an entry in LDAP that contains the username as a **uid** attribute value. If both a username and an authorization DN are specified, there must be an entry in LDAP with the authorization DN as its DN and the username must be a **uid** attribute value in that entry. In both cases, the bind DN is the DN of the entry. The entry can be in an LDBM or CDBM backend or in a client operation plug-in extension. See Chapter 7, "CRAM-MD5 and DIGEST-MD5 authentication," on page 119 for more information.
- For a certificate (EXTERNAL) bind, the bind DN is normally the subject DN from the certificate specified in the bind request. There can not be an entry in an LDBM or CDBM backend or in a client operation plug-in extension corresponding to this DN.

After the bind DN is determined, the DNs of the groups the bound user belongs to are added to the bind information. If LDAP password policy is active, groups are determined during authentication time. If LDAP password policy is not active, the groups are determined at the beginning of the next non-bind request. The bind DN and group information are used in access control in LDAP operations from the bound user.

**Note:** Group gathering is not performed if any of the following is true:

- 1. The user binds as the adminDN, peerServerDN, or masterServerDN.
- 2. The **authenticateOnly** server control is specified as part of the bind request.

The groups are gathered in the following manner:

- The backend or client operation plug-in extension that contains the bind DN is contacted to contribute DNs of any group entries that contain the bind DN or any of the alternate DNs. If the bind DN is not in a backend or a client operation plug-in extension, this step is skipped.
- Each LDBM or CDBM backend that has extendedGroupSearching on specified in the LDAP server configuration file is also contacted to contribute the DNs of any group entries in the backend that contain the bind DN or any of the alternate DNs. The client operation plug-in extensions are also contacted to contribute group DNs if they have registered a SLAPI\_TYPE\_GROUPS callback type routine. Note that SDBM does not support extended group searching.

In addition to bind DN and groups, there is additional data added to the bind information and to the directory entry access information that further distinguish the identity of the bound user. This additional information is used when matching ACL filters to determine access control for LDAP operations from the bound user. The following additional data is added to the bound user's bind information:

- · IP address of the bound user's client connection
- · Bind mechanism used to bind to the LDAP server

T

Т

T

T

T

Т

Т

Т

T

Т

Т

Т

Т

T

Т

1

	<ul> <li>Whether a secure, encrypted SSL connection was used to bind to the LDAP server.</li> </ul>
	The following data is added to the bound user's directory entry access information when accessing an entry:
I	<ul> <li>Time of day the bound user accessed the directory entry</li> </ul>
I	<ul> <li>Day of week the bound user accessed the directory entry.</li> </ul>

#### Deleting a user or a group

Deleting a user or a group does not have any cascade effect on any **aclEntry** and **entryOwner** values that include that user or group. The user or group DN is not removed from the ACLs. If another user or group is subsequently created with the same DN, that user or group will be granted the privileges of the former user or group.

## **Retrieving ACL information from the server**

In order to retrieve all of the ACL information in a namespace, use the LDAPSRCH command, as shown in the following example:

ldapsrch -h 127.0.0.1 -D "cn=admin, dc=Your Company,dc=com" -w xxxxxx -b "dc=Your Company,dc=com" "(objectclass=\*)" aclEntry aclPropagate aclSource entryOwner ownerPropagate ownerSource

dn: dc=Your Company, dc=com aclPropagate: TRUE aclEntry: CN=ADMIN:normal:rwsc:sensitive:rwsc:critical:rwsc:object:ad aclEntry: CN=ANYBODY:normal:rsc:system:rsc aclSource: dc=Your Company, dc=com ownerPropagate: TRUE entryOwner: CN=ADMIN ownerSource: default

This command performs a subtree search starting at the root of the tree (assuming the root of the tree is "dc=Your Company, c=com") and returns the six ACL attributes for each entry in the tree. It is necessary to specifically request the six ACL attributes because they are considered as "operational" and, therefore, can only be returned on a search if requested. (See IETF RFC 2251, RFC 2251: *Lightweight Directory Access Protocol (v3)*.)

ACL information (aclEntry, aclPropagate, aclSource, entryOwner, ownerPropagate, and ownerSource) is returned for all entries. For those entries that contain ACLs, the aclSource and ownerSource attributes contain the same DN as the entry DN. For those entries that do not contain ACLs, the aclSource and ownerSource attributes contain distinguished names of the entries that contain the ACL information (aclEntry and entryOwner) that are used for access control checking of information in that entry.

#### Notes:

- 1. It is possible for the **aclSource** and **ownerSource** attributes to contain the value default. This is not a distinguished name but rather represents that the ACL that applies to the entry is the default ACL.
- If the tree is larger than the sizeLimit option in the LDAP server configuration file or on the search command, then not all entries are returned. For more information, see the sizeLimit configuration option in "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.

You can also use the same method to get the ACL information for a portion of the namespace by specifying the **-b** searchbase parameter on the **search** command, where searchbase is the starting point for the search.

#### Creating and managing access controls

To create and update ACLs in LDBM, GDBM, CDBM, or the schema entry, use a tool implementing **Idap\_modify** APIs, such as LDAPMDFY (the **Idapmodify** utility) allows creation, modification, and deletion of any set of attributes that are associated with an entry in the directory. Since access control information is maintained as a set of additional attributes within an entry, LDAPMDFY is a natural choice for administering access control information in LDBM, GDBM, CDBM, or the schema entry.

For details on using the utilities, such as LDAPMDFY, see *z/VM: TCP/IP User's Guide*.

#### Creating an ACL

I

In order to create an ACL, the **aclEntry** and **aclPropagate** attributes must be added to the information stored for an entry. The **aclEntry** and **aclPropagate** attributes are added to an entry by either specifying them as part of the entry information when the entry is added to the directory or by modifying the entry after it exists to contain the **aclEntry** and **aclPropagate** information.

It is possible to create an ACL without specifying the **aclPropagate** attribute. In this case, the **aclPropagate** attribute is assumed to have a value of **TRUE** and is added into the directory entry automatically, along with the **aclEntry** information.

Since LDAPMDFY is very powerful, all the possible ways of adding the **aclEntry** and **aclPropagate** information cannot be shown here. The examples shown here describe the more common uses of LDAPMDFY ato add ACL information.

Figure 22 shows how to add a propagating ACL with three **aclEntry** values to an existing entry replacing any current **aclEntry** value.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f newAcl.ldif

Where newAcl.ldif contains:

dn: cn=tim, o=Your Company changetype: modify replace: aclEntry aclEntry: cn=jeanne, o=Your Company: normal:rsc:sensitive:rsc:critical:rsc aclEntry: cn=jeff, cn=tim, o=Your Company:normal:rsc aclEntry: cn=tim, o=Your Company: normal:rwsc:sensitive:rwsc:critical:rwsc

Figure 22. Example of adding propagating ACL to existing entry in directory

The ACL added in Figure 22 is created as a propagating ACL since the **aclPropagate** attribute is not specified and so assumed to be **TRUE**. This means that the ACL will apply to all entries below cn=tim, o=Your Company that do not already have an ACL associated with them. Note that the first and last **aclEntry** values span two lines in the newAcl.ldif file. In order to do this, the first character on the continued line must be a space character, as shown in the example.

While it is not required that the administrator update all ACL information, the examples in this section all use the administrator when updating ACLs. Further, the use of -h 127.0.0.1 implies that the LDAPMDFY commands are performed from the same system on which the LDAP server is running and that the LDAP server is listening on TCP/IP port 389. For more details on the **-h**, **-p**, **-D**, and **-w** command-line options, refer to the LDAPMDFY command description in *z/VM: TCP/IP User's Guide*. The ACL attributes can be updated from any LDAP client as long as the user performing the updates has the proper authorization to update the ACL information.

The ACL attributes are defined to be in a special access class called **restricted**. Therefore, in order to allow someone other than the LDAP administrator to update the ACL attributes, they must either be the entry owner or have the proper authorization to **restricted** attributes. Figure 23 shows an example of adding an ACL so that cn=jeanne, o=Your Company can update the ACL information:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f newAcl.ldif

Where newAcl.ldif contains:

dn: cn=jeanne, o=Your Company changetype: modify replace: aclEntry aclEntry: cn=jeanne, o=Your Company: normal:rsc:sensitive:rsc:critical:rsc:restricted:rwsc aclEntry: cn=jeff, cn=tim, o=Your Company:normal:rsc aclEntry: cn=tim, o=Your Company: normal:rsc add: aclPropagate aclPropagate: TRUE

Figure 23. Example of adding propagating ACL to existing entry in the directory.

The ACL added in Figure 23 allows cn=jeanne, o=Your Company to update the ACL information for this entry. In addition, since the ACL is a propagating ACL, this allows cn=jeanne, o=Your Company to create new ACL information against any entry that is controlled by this ACL. Care must be taken here, however, since it is possible for cn=jeanne, o=Your Company to set up an ACL which then does not allow cn=jeanne, o=Your Company update capability on the ACL information. If this occurs, a user with sufficient authority (the administrator, for example) must be used in order to reset/change the ACL information.

Figure 24 shows an example of adding a non-propagating ACL. A non-propagating ACL applies only to the entry to which it is attached and not to the subtree of information that might be stored below the entry in the directory.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f newAcl.ldif Where newAcl.ldif contains: dn: cn=jeff, cn=tim, o=Your Company changetype: modify replace: aclEntry aclEntry: cn=tim, o=Your Company:normal:rwsc:sensitive:rwsc: critical:rwsc:restricted:rwsc aclEntry: cn=jeff, cn=tim, o=Your Company:normal:rwsc: sensitive:rwsc:critical:rwsc aclEntry: cn=jeanne, o=Your Company:normal:rsc replace: aclPropagate aclPropagate: FALSE -

Figure 24. Example of setting up a non-propagating ACL

Setting up a non-propagating ACL is similar to setting up a propagating ACL. The difference is that the **aclPropagate** attribute value is set to **FALSE**.

#### Modifying an ACL

Once an ACL exists for an entry in the directory, it may have to be updated. To do this, the LDAPMDFY command is used. The examples in this section use the LDAPMDFY command, however, any LDAP client application issuing LDAP modify operations to the LDAP server may be used. Therefore, modifications to ACL information need not be performed from the same system on which the LDAP server is running.

Modifications to ACLs can be of a number of different types. The most common modifications are to:

- Add an additional aclEntry value to the ACL to allow another person or group access to the entry
- Change an ACL from propagating to non-propagating (not permitted for the GDBM change log suffix, cn=changelog)
- Remove an aclEntry value which exists in the ACL to disallow another person or group access to the entry that they had before.

Figure 25, Figure 26, and Figure 27 show examples of these modifications, respectively.

Access determination shows how an additional **aclEntry** value is added to existing ACL information.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modAcl.ldif

Where modAc1.1dif contains:

```
dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
add: aclEntry
aclEntry: cn=dylan, cn=tim, o=Your Company:
    normal:rwsc:sensitive:rwsc:critical:rwsc:restricted:rwsc
```

Figure 25. Example of adding an aclEntry attribute value

In Figure 25, cn=dylan, cn=tim, o=Your Company is granted permissions against the cn=jeff, cn=tim, o=Your Company entry in the directory. The existing ACL

information remains in the entry; the **aclEntry** attribute value for cn=dylan, cn=tim, o=Your Company is added to this information.

Figure 26 shows how to modify an existing ACL to be non-propagating instead of propagating.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modAcl.ldif

Where modAc1.ldif contains:

dn: cn=tim, o=Your Company
changetype: modify
replace: aclPropagate
aclPropagate: FALSE
-

Figure 26. Example of modifying aclPropagate attribute

In Figure 26, the existing ACL against cn=tim, o=Your Company is modified to be a non-propagating ACL instead of a propagating ACL. This means that the ACL will no longer apply to entries below cn=tim, o=Your Company in the directory tree. Instead, the first propagating ACL that is found in an entry above cn=tim, o=Your Company will be applied to the entries below cn=tim, o=Your Company. If no propagating ACL is found in the entries above cn=tim, o=Your Company, then the default ACL is used.

Figure 27 shows how to remove an **aclEntry** value from existing ACL information:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modAcl.ldif

Where modAcl.ldif contains:

dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
delete: aclEntry
aclEntry: cn=dylan, cn=tim, o=Your Company

Figure 27. Example of removing a single aclEntry attribute value

In Figure 27, the **aclEntry** attribute value for cn=dylan, cn=tim, o=Your Company is removed from the ACL information for entry cn=jeff, cn=tim, o=Your Company. Only the distinguished name part of the **aclEntry** value needs to be specified when deleting the value.

#### **Deleting an ACL**

In order to delete an ACL that is attached to an entry in the directory, the **aclEntry** and **aclPropagate** attributes must be deleted from the entry. To do this, use the LDAPMDFY command to delete the entire attribute (all values) from the entry.

Figure 28 shows an example of deleting an ACL from an entry.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f delAcl.ldif

Where delAcl.ldif contains: dn: cn=jeff, cn=tim, o=Your Company changetype: modify delete: aclEntry delete: aclPropagate

Figure 28. Example of deleting an ACL from an entry

In Figure 28, the existing ACL against cn=jeff, cn=tim, o=Your Company is removed. This means that the ACL will no longer apply to the entry. Instead, the first propagating ACL that is found in an entry above cn=jeff, cn=tim, o=Your Company will be applied to cn=jeff, cn=tim, o=Your Company. If no propagating ACL is found in the entries above cn=jeff, cn=tim, o=Your Company, then the default ACL is used.

#### Creating an owner for an entry

In addition to the access control list control of directory entries, each entry can have assigned to it an entry owner or set of entry owners. As an entry owner, full access is allowed to the entry. Entry owners are granted add and delete permission, as well as read, write, search, and compare for all attribute classes. Entry owners can add and modify ACL information on the entries for which they are specified as the owner.

Entry owners are listed in the **entryOwner** attribute. Just like **aclEntry** information, **entryOwner** information can be propagating or non-propagating based on the setting of the **ownerPropagate** attribute. Like the **aclSource** attribute for **aclEntry** information, the **ownerSource** attribute lists the distinguished name of the entry that contains the **entryOwner** attribute which applies to the entry. The **ownerSource** attribute is set by the server and cannot be directly set when modifying the ACLs.

In order to create an entry owner, the **entryOwner** and **ownerPropagate** attributes must be added to the information stored for an entry. The **entryOwner** and **ownerPropagate** attributes are added to an entry by either specifying them as part of the entry information when the entry is added to the directory or by modifying the entry after it exists to contain the **entryOwner** and **ownerPropagate** information.

It is possible to create an entry owner without specifying the **ownerPropagate** attribute. In this case, the **ownerPropagate** attribute is assumed to have a value of **TRUE** and is added into the directory entry automatically.

Since the LDAPMDFY command is very powerful, all the possible ways of adding the **entryOwner** and **ownerPropagate** information cannot be shown here. The examples shown here describe the more common uses of the LDAPMDFY command to add entry owner information.

Figure 29 shows how to add a propagating entry owner with two **entryOwner** values to an existing entry.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f newOwn.ldif

Where new0wn.ldif contains:

dn: cn=tim, o=Your Company changetype: modify replace: entryOwner entryOwner: cn=joe, o=Your Company entryOwner: cn=carol, o=Your Company

Figure 29. Example of adding a propagating set of entry owners to existing entry in the directory

The entry owners added in Figure 29 are created as a propagating set of entry owners since the **ownerPropagate** attribute is not specified and so assumed to be **TRUE**. This means that the entry owners will apply to all entries below cn=tim, o=Your Company that do not already have an entry owner associated with them.

While it is not required that the LDAP administrator update all entry owner information, the examples in this section all use the administrator as the entry owner updating ACLs. Further, the use of -h 127.0.0.1 implies that the LDAPMDFY commands are performed from the same system on which the LDAP server is running and that the LDAP server is listening on TCP/IP port 389. For more details on the **-h**, **-p**, **-D**, and **-w** command-line options, refer to the LDAPMDFY command description in *z/VM: TCP/IP User's Guide*. The entry owner attributes can be updated from any LDAP client as long as the user performing the update has the proper authorization to update the entry owner information.

The entry owner attributes, like the ACL attributes, are defined to be in a special access class called **restricted**. Therefore, in order to allow someone other than the LDAP administrator to update the entry owner attributes, they must either be the entry owner or have the proper authorization to **restricted** attributes. See Figure 23 for an example of allowing users other than the LDAP administrator the ability to update entry owner information.

Figure 30 shows an example of adding a non-propagating entry owner. A non-propagating entry owner applies only to the entry to which it is attached and not to the subtree of information that might be stored below the entry in the directory.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f newOwn.ldif

Where new0wn.ldif contains:

```
dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
replace: entryOwner
entryOwner: cn=george, o=Your Company
entryOwner: cn=jane, o=Your Company
-
replace: ownerPropagate
ownerPropagate: FALSE
-
```

Figure 30. Example of setting up a non-propagating entry owner

Setting up a non-propagating entry owner is similar to setting up a propagating entry owner. The difference is that the **ownerPropagate** attribute value is set to **FALSE**.

#### Modifying an owner for an entry

Once an entry owner exists for an entry in the directory, it may have to be updated. To do this, the LDAPMDFY command is used. The examples in this section use the LDAPMDFY command, however, any LDAP client application issuing LDAP modify operations to the LDAP server may be used. Therefore, modifications to entry owner information need not be performed from the same system on which the LDAP server is running.

Modifications to entry owners can be of a number of different types. The most common modifications are to:

- Add an additional entryOwner value to the set of entry owners to allow another person or group to control the entry
- Change an entry owner from propagating to non-propagating (not permitted for the GDBM change log suffix, cn=changelog)
- Remove an entryOwner value which exists in the entry owner set to disallow another person or group access to control the entry that they had control over before.

Figure 31, Figure 32, and Figure 33 show examples of these modifications, respectively.

Figure 31 shows how an additional **entryOwner** value is added to existing entry owner information.

```
ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modOwn.ldif
```

Where modOwn.ldif contains:

```
dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
add: entryOwner
entryOwner: cn=george, o=Your Company
```

Figure 31. Example of adding an entryOwner attribute value

In Figure 31, cn=george, o=Your Company is granted entry owner control of the cn=jeff, cn=tim, o=Your Company entry in the directory. The existing entry owner information remains in the entry; the **entryOwner** attribute value for cn=george, o=Your Company is added to this information.

Figure 32 shows how to modify an existing entry owner to be non-propagating instead of propagating.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modOwn.ldif

Where modOwn.ldif contains:

dn: cn=tim, o=Your Company
changetype: modify
replace: ownerPropagate
ownerPropagate: FALSE

Figure 32. Example of modifying the ownerPropagate attribute

In Figure 32, the existing entry owner set for cn=tim, o=Your Company is modified to be non-propagating instead of propagating. This means that the entry owner will no longer apply to entries below cn=tim, o=Your Company in the directory tree. Instead,

the first propagating entry owner set that is found in an entry above cn=tim, o=Your Company will be applied to the entries below cn=tim, o=Your Company. If no propagating entry owner is found in the entries above cn=tim, o=Your Company, then the default entry owner is used.

Figure 33 shows how to remove an **entryOwner** value from existing entry owner information:

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modOwn.ldif

Where modOwn.ldif contains:

dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
delete: entryOwner
entryOwner: cn=george, cn=tim, o=Your Company

Figure 33. Example of removing a single entryOwner Attribute value

In Figure 33, the **entryOwner** attribute value for cn=george, cn=tim, o=Your Company is removed from the entry owner information for entry cn=jeff, cn=tim, o=Your Company. Only the distinguished name part of the **entryOwner** value needs to be specified when deleting the value.

#### Deleting an owner for an entry

In order to delete an entry owner set that is attached to an entry in the directory, the **entryOwner** and **ownerPropagate** attributes must be deleted from the entry. To do this, use the LDAPMDFY command to delete the entire attribute (all values) from the entry.

Figure 34 shows an example of deleting an entry owner set from an entry.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f delOwn.ldif

Where delown.ldif contains:

dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
delete: entryOwner
delete: ownerPropagate

derette. Ownerr

Figure 34. Example of deleting an entry owner set from an entry

In Figure 34, the existing entry owner set against cn=jeff, cn=tim, o=Your Company is removed. This means that the entry owner information will no longer apply to the entry. Instead, the first propagating entry owner set that is found in an entry above cn=jeff, cn=tim, o=Your Company will be applied to cn=jeff, cn=tim, o=Your Company. If no propagating entry owner set is found in the entries above cn=jeff, cn=tim, o=Your Company, then the default entry owner is used.

#### Creating a group for use in ACLs and entry owner settings

Sets of users can be grouped together in the directory by defining them as members of a group in the directory. A directory group, used for access control checking, is just another entry in the directory. A static, dynamic, or nested group entry can be used as a group on the **aclEntry** or **entryOwner** attributes. See Chapter 8, "Static, dynamic, and nested groups" for more information on creating, modifying, and deleting static, dynamic, and nested group entries.

When defining access controls or entry owner sets, names of group entries can be used in the same place as user entry names. When access control decisions are performed, a user's group memberships can be used in determining if a user can perform the action requested.

Groups are added to access control information in just the same way as user entries are added to access control information. Figure 35 shows how a group can be added to the **aclEntry** information in an existing access control specification for an entry. Figure 36 shows how a group can be added as an **entryOwner** to an existing entry owner specification for an entry.

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modAcl.ldif

Where modAc1.ldif contains:

I

dn: cn=jeff, cn=tim, o=Your Company
changetype: modify
add: aclEntry
aclEntry: group:cn=group1, o=Your Company:normal:rwsc:sensitive:rsc

Figure 35. Example of adding a group to access control information

ldapmdfy -h 127.0.0.1 -D "cn=admin" -w xxxx -f modOwn.ldif

Where modOwn.ldif contains:

dn: cn=jeff, cn=tim, o=Your Company changetype: modify add: entryOwner entryOwner: cn=group1, o=Your Company

Figure 36. Example of adding a group to entry owner information

# Chapter 10. Basic replication

Once the z/VM LDAP server is installed and configured, users can access the directory, add entries, delete entries, or perform search operations to retrieve particular sets of information.

Replication is a process which keeps multiple directories in sync. Through replication, a change made to one directory is propagated to one or more additional directories. In effect, a change to one directory shows up on multiple different directories.

There are several benefits realized through replication. The single greatest benefit is providing a means of faster searches. Instead of having all search requests directed at a single server, the search requests can be spread among several different servers. This improves the response time for the request completion.

Additionally, the replica provides a backup to the replicating server. Even if the replicating server crashes, or is unreadable, the replica can still fulfill search requests, and provide access to the data.

There are two types of basic replication:

- In peer to peer replication, each LDAP peer server is a read-write server. Updates processed on one peer server are replicated to all the other peer servers. Peer servers are read-write to all users.
  - **Note:** The basic replication support for peer to peer replication is provided for failover support purposes. With basic peer to peer replication, there is no support for resolving simultaneous updates on multiple peer servers, which can cause a failure of replication. As a result, updates should be targeted to one peer server at a time.
- In basic read-only replication, a single read-write LDAP server (the master) replicates the updates it processes to a set of read-only replica servers.

#### Master

All changes to the directory are made to the master server. The master server is then responsible for propagating the changes to all other directories. It is important to note that while there can be multiple directories representing the same information, only one of those directories can be the master.

Read-only replica

Each of the additional servers which contain a directory replica. These replica directories are identical to the master directory. These servers are read-only to all users and will only accept updates from their master server.

If you need more advanced replication choices, see Chapter 11, "Advanced replication," on page 185.

A basic replication network can contain both peer replica servers and read-only replica servers. In this case, each peer server must act as a master to each read-only replica (in addition to being a peer to all the peer servers), so that updates that occur on any peer server are replicated to all the other peer and read-only replicas in the network.

T

|

   	Basic replication is supported when the servers involved are running in single-server mode. For more information about server operating modes, see "LDAP Server Operational Mode" in <i>z/VM: TCP/IP Planning and Customization</i> .
 	In z/VM LDAP, basic replication is supported in an LDBM backend. Basic replication is not performed for the SDBM or GDBM backends or for the schema entry.

# ibm-entryuuid replication

Basic replication of the **ibm-entryuuid** attribute is performed to any LDAP server that has 1.3.18.0.2.32.3 (the OID for the entry UUID capability) as a value in the **ibm-enabledCapabilities** attribute in the root DSE. z/VM LDAP servers have this capability. If the root DSE of a replica server does not contain the required capability, then the **ibm-entryuuid** attribute will not be replicated to that server, however, the entry and other attributes will be replicated.

# **Complex modify DN replication**

Basic replication of Modify DN new superior operations will be performed to any LDAP server that has 1.3.18.0.2.32.33 (the OID for the subtree move capability) or 1.3.18.0.2.32.34 (the OID for the subtree rename capability) as a value in the **ibm-enabledCapabilities** attribute in the root DSE. z/VM LDAP servers have this capability. If a replica server is not at a supported level, Modify DN new superior operations will fail until the replica is removed from the replica collection.

## Password encryption and basic replication

To ensure data integrity and the correct working of the LDAP servers in the replication environment, the **pwEncryption** option in the configuration files for the servers involved in replication must be the same. If one of the servers involved in replication is a non-z/OS or non-z/VM server, then the administrator must select a **pwEncryption** method that is supported by both servers for correct operation of replication. If no encryption methods are common between the servers, then password encryption should not be used.

When replicating between a z/VM LDAP server and a non-z/OS or non-z/VM LDAP server and using **crypt** for password encryption, specify **pwCryptCompat off** in the backend section of the z/VM LDAP server configuration file. This setting indicates that the LDAP server should use the UTF-8 version of the crypt algorithm to encrypt passwords. When **userPassword** attribute values in **crypt** are replicated between z/VM and non-z/OS or non-z/VM LDAP servers, the password will be the same on both platforms and therefore it will be usable.

If using AES or DES encryption and the key is stored in an LDAPKEYS file and both of the servers involved in replication are z/VM LDAP servers, the same key label and data key must be present in both server's copy of the LDAPKEYS file. The AES or DES key label is specified in the LDAP server configuration files of both of the LDAP servers involved in replication.

#### **Replicating server**

In order for the basic replication process to occur, the following must happen:

• The replicating server (master or peer) must be aware of each replica that is to receive the change information.

 Each read-only and peer server must be aware of the replicating servers for the directory that it serves. See "LDAP update operations on read-only replicas" on page 177 for more information.

The replicating server becomes aware of the existence of the replica servers when entries with an object class of **replicaObject** are added to the directory. Each of these entries represents a particular replica server. The attribute/value pairs within the replica entry provide the information the replicating server needs in order to locate the replica server and send any updates to that server.

# **Replica entries**

The **replicaObject** object class is provided in the initial schema. Like other LDAP object class definitions, the **replicaObject** has mandatory and optional attributes. Each of the **replicaObject** attributes are single-valued. The following is a description of the mandatory attributes of **replicaObject**. Values in a replica entry are recognized at server startup and when a replica entry is added or modified. The internal number of how many replication operations have been set aside (the set aside count) for a replica is not reset when the replica entry is modified. In order to reset the count, either the server needs to be restarted or the replica entry needs to be removed and added. See "Basic replication error log" on page 181 for more information about the set aside count.

Attribute	Description and example
replicaHost	This can be an IPv4 address, IPv6 address, or a hostname of the system where the replica server is running.
	Example:
	replicahost: 9.130.77.27 replicahost: [5f1b:df00:ce3e:e200:20:800:2078:e3e3] replicahost: myMachine.ibm.com
replicaBindDN	Specifies the LDAP distinguished name that the replicating server uses to bind to the replica when sending directory updates. The <b>replicaBindDN</b> and the <b>masterServerDN</b> or <b>peerServerDN</b> in the replica's LDAP server configuration file must have the same value.
	Example:
	replicaBindDN: cn=Master
replicaCredentials	Contains the authentication information needed for the replicating server to authenticate to the replica using the <b>replicaBindDN</b> . The <b>replicaCredentials</b> attribute value will be encrypted if the <b>secretEncryption</b> option is specified in the LDAP server configuration file. This improves directory security because the bind password is no longer stored in the directory in clear text. The <b>secretEncryption</b> option is also used to encrypt pending updates while they are stored in the replication queue.
	Example:
	replicaCredentials: secret
cn	Forms the RDN of the LDAP distinguished name of the replicaObject entry.
	Example:
	cn: myReplica

 Table 26. Replica entry schema definition (mandatory attributes)

In the examples in Table 26, when the replicating server receives and successfully finishes an update request, the update is also sent to myMachine.ibm.com on port 389 (the default port). The replicating server performs a bind operation using the

DN of cn=Master and password of secret. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for more information specifying the replication server DN and password.

In addition, there are several attributes available that provide additional flexibility in configuring a replica server. For instance, an added description might better describe the replica server, and it might listen on a different port then the default port of 389. Examples of adding a description and changing the port to 400 are shown in Table 27, which describes the optional attributes of **replicaObject**.

Table 27. Replica entry schema definition (optional attributes)

Attribute	Description and example
replicaPort	Describes the port number on which the replica is listening for incoming requests. By default, the server listens on port 389.
	Example:
	replicaPort: 400
replicaUpdateTimeInterval	Delays the propagation of additional updates for specified number of seconds. The default is for the replicating server to send updates immediately.
	Example:
	replicaUpdateTimeInterval: 3600
replicaUseSSL	Determines whether the replicating server should replicate over SSL/TLS. The default is to replicate without using SSL/TLS.
	Example:
	replicaUseSSL: TRUE
description	Provides an additional text field for extra information pertaining to the replica entry.
	Example:
	description: Replica machine in the fourth floor lab
seeAlso	Identifies another directory server entry that might contain information related to this entry.
	Example:
	seeAlso: cn=Alternate Code, ou=Software, o=IBM, c=US
replicaBindMethod	Identifies the bind method to be used. If it is specified, it must be set to simple.
	Example:
	replicaBindMethod: simple

Basic replication supports only simple authentication. SASL EXTERNAL, DIGEST-MD5, and CRAM-MD5 bind mechanisms are not supported as valid basic replication bind mechanisms.

There are several additional attributes that affect error handling during basic replication. See "Basic replication error log" on page 181 for more information about error handling. These attributes are not in any object class, therefore, the **extensibleObject** object class must included in the replica entry when adding these attributes to the entry. Table 28 on page 173 describes these attributes.

T

T

T

T

T

Т

Table 28. Additional	optional	replication	attributes
----------------------	----------	-------------	------------

Attribute	Description and example
ibm-slapdLog	Specifies the file name of the basic replication error log. This must be a BFS file. The file name can be fully-qualified or can be relative to the current working directory of the LDAP server. The current working directory is set when the LDAP server is started to the <b>HOME</b> environment variable if specified, or else to /etc/1dap. This format is not recommended. The value must be unique among all the replica entries in this LDAP server. If this attribute is not presen in the replica entry or it has no value, error logging and setting aside will not occur.
	Example:
	<pre>ibm-slapdLog: /home/replog/replical.errlog</pre>
ibm- slapdReplMaxErrors	Specifies the maximum number of basic replication errors that will be set aside in the basic replication error log before replication is allowed to stall. If this attribute is not present in the replica entry or if the value is 0, then no operations are set aside. In this case, errors are still logged and basic replication stalls when the first error occurs. This attribute is not used if a replication log file name has not been specified with the <b>ibm-slapdLog</b> attribute.
	Example:
	ibm-slapdReplMaxErrors: 5

# Adding replica entries in LDBM

I

|
|
|

In LDBM, replica entries can be placed anywhere within the directory tree, although it is recommended that a replica entry be a leaf entry. Placing replica entries in the directory tree then requires that any parent entries of the replica entry be added to the directory before adding the replica entry. These entries must be added to both the replicating server and replica server before addition of the replica entry. This is needed on the replica server because these entries are being added at the replicating server without replication being active. If a replica entry is not placed as a leaf node in the directory tree, the only entries allowed below the replica entry are other replica entries. The LDAP server allows non-replica entries to be placed below replica entries; however, these entries will not be replicated to the replica servers.

The replica entry defines a replica for the backend containing the entry. Any changes made to the directory tree managed by that backend will be replicated to each replica defined for that backend. The replica entry does not define replicas for other backends in the LDAP server, therefore, if changes to all LDBM directory trees managed by the LDAP server are to be replicated, then each backend must contain the appropriate replica entries to define replication for that backend.

The following is an example of a replica entry definition using LDIF format.

dn: cn=myReplica,o=Your Company
objectclass: replicaObject
objectclass: extensibleObject
cn: myReplica
replicaHost: myMachine.ibm.com
replicaBindDn: cn=Master
replicaCredentials: secret
replicaPort: 400

replicaUseSSL: FALSE
description: Replica machine in the fourth floor lab
ibm-slapdLog: ro1.errlog
ibm-slapdReplMaxErrors: 5

## Searching a replica entry

Most of the attributes in a replica entry are operational attributes. When searching a replica entry, the operational attributes are not included in the output unless they are specified in the attributes to be returned. The following command searches for all replica entries in a suffix and returns the complete replica entries in LDIF format:

ldapsrch -h ldaphost -p ldapport -D binddn -w passwd -L -b "suffix"
"objectclass=replicaObject" "\*" replicaHost replicaBindDN replicaCredentials
replicaPort replicaUpdateTimeInterval replicaUseSSL replicaBindMethod

## Displaying basic replication status

The LDAP server DISPLAY REPLICAS operator command can be used to display information about the status of replication to each replica server. See "SMSG Interface to the LDAP Server" in *z/VM: TCP/IP Planning and Customization* for a description of the DISPLAY REPLICAS output.

#### Basic replication maintenance mode

Т

Maintenance mode is the LDAP server setup mode for basic replication. This mode restricts access to the backends in an LDAP server to allow replica backends to be primed for basic replication. Access to the backends is as follows:

- read-only replica backend: The masterServerDN for the replica and the adminDN have unrestricted access
- peer replica backend: The peerServerDN for the replica and the adminDN have unrestricted access
- non-replica backends (including the schema entry): The adminDN has unrestricted access. The masterServerDN and peerServerDN have no access outside of the backends which specify them.

Other users can bind to the LDAP server, but cannot access any entries within the server.

ACL checking is performed during search operations from **masterServerDN** and **peerServerDN** but not during update and compare operations. No ACL checking is done for any operations from **adminDN**. In addition, the **adminDN** has the capability in maintenance mode to modify attributes that are read-only and are typically only set by the LDAP server, such as **ibm-entryuuid**.

**Note:** The LDAP server schema entry is not part of any replica backend. When the LDAP server is not in maintenance mode, **masterServerDN** and **peerServerDN** can only update the LDAP server schema if the schema entry ACL permits them to. When in maintenance mode, they cannot update the LDAP server schema at all. **adminDN** can always update the schema.

Pending replication entries are replicated to the other replica servers, but updates performed when in maintenance mode are not replicated.

Specify the **-m** option on the server startup command (LDAPSRV command) to start the LDAP server in maintenance mode.

You can use the SMSG command to change from maintenance mode to normal mode while the LDAP server is running. The command can also be used to put a running server into maintenance mode. For example:

smsg ldapsrv maintmode on

turns maintenance mode on for the server whose user ID is LDAPSRV, and smsg ldapsrv maintmode off

turns maintenance mode off (and normal mode on) for the same server.

#### **Replica server**

I

|

Initialization, or population, of a replica directory requires several steps.

With basic replication, changes to the LDAP server schema entry on the replicating server are not replicated. A separate update of the LDAP server schema on the replica will be required each time the schema is updated on the replicating server.

Replica servers must support the LDAP Version 3 protocol.

## Populating a replica

- 1. Either start the replica and replicating servers in maintenance mode or on each of these LDAP servers use the SMSG LDAPSRV MAINTMODE ON command to put these servers into maintenance mode.
- Unload the replicating server's directory contents if there are any entries. For LDBM, use DS2LDIF (the **ds2ldif** utility); see "DS2LDIF (ds2ldif utility)" in *z/VM: TCP/IP Planning and Customization*).
- 3. You should make sure the schema for the replica server is the same as the schema for the replicating server.

If the replica and replicating server are both z/VM servers, the schema can be unloaded from the replicating server using DS2LDIF and reloaded into the replica by using the administrator DN to run LDAPMDFY (the **Idapmodify** utility).

 Using the administrator DN, run LDAPADD to add a single replica entry into the backend directory on the replicating server to identify the new replica being populated.

Note that in order to load the replica entry, it is also necessary to load any parent entries in the directory hierarchy in hierarchy order.

- 5. If the replicating server does not contain any entries, go to step 8.
- 6. Transport the LDIF file created in step 2 to the replica server's location.
- 7. Load the LDIF file from step 6 into the replica server. This load can be done using the administrator DN to run LDAPADD to load the LDIF file.
- 8. Configure the replica (see next section).
- 9. Stop the replica server (if it is running) and then restart it in maintenance mode. If it contains a replica entry that defines this server as a replica of itself, use the administrator DN to run LDAPDLET to remove that entry.
- 10. Use the LDAP server SMSG *ldapsrv* MAINTMODE OFF command on the replica server and the replicating server to change these servers to normal mode.

# Configuring the replica

The key to a successful replica configuration rests in ensuring that the values in the replica entry on the replicating server (master or peer) accurately represent the relevant values on the replica server (read-only or peer). Configuring the replica involves specifying appropriate LDAP server configuration file option values to identify:

- the IP address and port on which the replica server should listen for communication from the replicating server
- the type of connection expected by the replicating server when it communicates to the replica server, either over a non-secure or secure connection
- · the DN and password used by the replicating server

The following table identifies the relationship between the attributes in the replica entry on a z/VM LDAP replicating server and the configuration options on an IBM replica server. The values specified for these options must be equivalent. An example of what is meant by equivalent is when the replica server is listening on all of its network interfaces, then **replicaHost** must specify either the corresponding hostname or an IP address of one of the addresses.

Attribute in replica entry on replicating server	Corresponding replica server configuration option or command line parameter
replicaHost	The hostname or IP address specified on the <b>listen</b> configuration option or the <b>-I</b> LDAP server command line parameter.
replicaPort	The port number that is specified on the <b>listen</b> configuration option or the <b>-I</b> LDAP server command line parameter.
replicaUseSSL	Use of <b>Idaps://</b> in the prefix of the <b>listen</b> configuration option or the <b>-I</b> LDAP server command line parameter corresponds to <b>TRUE</b> for <b>replicaUseSSL</b> ; use of <b>Idap://</b> corresponds to <b>FALSE</b> .
replicaBindDn	masterServerDN or peerServerDN configuration option
replicaCredentials	masterServerPW or peerServerPW configuration option

Attribute in replica entry	y on
replicating server	

Corresponding replica server configuration option or command line parameter

#### Notes:

- 1. If the replica server is a non-IBM server, you should consult their documentation for parameters that correspond to the parameters mentioned in the above table.
- The value of the **listen** configuration option or –I command line parameter is an LDAP URL. For additional information about the **listen** option, see "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in *z/VM: TCP/IP Planning and Customization*.
- 3. It is recommended that the **masterServerDN** or **peerServerDN** be a DN that is dedicated specifically to replication. It should not be used for any other operations.
- The masterServer, masterServerDN, masterServerPW, peerServerDN, and peerServerPW options must follow the database option for that backend in the LDAP server configuration file.
- Usage of the masterServerPW or peerServerPW configuration option is strongly discouraged in production environments. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for alternatives.
- 6. The replicaCredentials attribute will be encrypted if the secretEncryption configuration option is specified. This improves directory security because the bind password is no longer stored in the directory in clear text. The secretEncryption configuration option is also used to encrypt pending updates while they are stored in the replication queue.

# LDAP update operations on read-only replicas

Update operations, such as add, delete, modify, and rename, should not be performed against a read-only replica server. Changes must be made to the master server, which then propagates the change to the read-only replica.

If update operations are sent to a read-only replica server, the replica server returns a referral containing the value in the **masterServer** option in the backend section of the LDAP server configuration file on the replica. The client then redirects the request to the master server. After the master server makes the update, it propagates the change to the read-only replica server, binding as the **replicaBindDn** value in the replica entry corresponding to that replica server (the **replicaBindDn** value must match the **masterServerDN** value in the replica server configuration file).

See "SSL/TLS and basic replication" on page 181 for information about securing a directory.

#### Changing a read-only replica to a master

| | | When using read-only basic replication, it might become desirable to change one of the read-only replicas to be the master. Perhaps the machine where the replica server is installed is being upgraded, and you want this replica to now be the master LDAP server.

The following procedure should be followed to change a read-only replica to a master:

 If the read-only replica is out of sync with the master server, use the procedure described in "Recovering from basic replication out-of-sync conditions" on page 183.

- 2. Use the SMSG LDAPSRV MAINTMODE ON command on the master server and on the replica server to put them into maintenance mode.
- 3. Using the administrator DN, unload all the replica entries (entries that describe replica servers) from the master server. Use a search command similar to the one shown in "Searching a replica entry" on page 174 to create LDIF output containing the replica entries for each suffix in the backend. In the LDIF output, remove the replica entry for the read-only replica that is going to become the master. If the master is going to become a read-only replica, add a replica entry for the master in LDIF format to the output.
- 4. Using the administrator DN, run LDAPDLET to remove the replica entries from the master.
- 5. Using the administrator DN, run LDAPADD to add the unloaded replica entries to the replica server.
- 6. Stop the master and replica server.
- 7. Remove the **masterServer, masterServerDN**, and **masterServerPW** options from the LDAP server configuration file on the replica.
- 8. If the original master is being eliminated, the database on the master is no longer needed. Remove all the files in the LDBM database directory. See the description of the **databaseDirectory** option in "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in *z/VM: TCP/IP Planning and Customization* for more information about the location of these files.
- 9. If the original master is going to become a replica, add the masterServer, masterServerDN, and masterServerPW options to the LDAP server configuration file on the original master. The masterServer value must point to the new master. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for more information about alternatives to specifying the masterServerPW option.
- 10. Start the new master server and new replica server (if the original master became a replica server).

#### Basic peer to peer replication

z/VM LDAP peer replication server provides failover support. With this support, if a LDAP server fails, the peer replication server can take over the role of the failing LDAP server and it is then available to process LDAP operations.

A z/VM LDAP peer replication server is a read/write replication server that can send and receive replicated entries. An LDAP server can have both peer replication servers and read-only replication servers defined as **replicaObject** entries.

**Note:** Basic peer to peer replication uses the same replica entry attribute values as shown in "Replica server" on page 175. The instructions in "Adding replica entries in LDBM" on page 173 also apply to peer replicas.

A basic peer to peer replication environment can be as simple as two LDAP servers that are peers to each other, or as complicated as several LDAP servers, where some servers are read-only replication servers and the other servers are peer replication servers. Every peer replication server must replicate to all other peer and read-only replication servers.

#### Server configuration

T

1

1

1

The **peerServerDN** and **peerServerPW** options in the backend section of the LDAP server configuration file are used to configure a basic peer to peer replication

	environment. For more information, see "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in <i>z/VM: TCP/IP Planning and Customization</i> .
   	<b>Note:</b> Usage of the <b>peerServerPW</b> configuration option is strongly discouraged in production environments. See "The Administrator DN and the Replica Server DN and Passwords" in <i>z/VM: TCP/IP Planning and Customization</i> for
I	alternatives.

## Basic replication conflict resolution

I

L

Т

L

|

Minimal conflict resolution is done in a basic peer environment. For example, if peer replication server A receives an update to entry E at the same moment that peer B receives a delete of the same entry, basic replication can stall on server A. Ensure that your peer servers are not receiving conflicting operations. To avoid basic replication stalling, set up a replication error log to set aside replication errors. See "Basic replication error log" on page 181 for more information.

When a conflict occurs, a notification will be sent to the console and server log.

#### Adding a peer replica to an existing server

For failover support, it might be necessary for you to add a peer replica for a backend to an existing server or set of servers. These servers can be stand-alone or already actively replicating.

In order to add a peer replica for a backend to a z/VM LDAP server, you should do the following:

- 1. Start the new peer replica in maintenance mode. The peer replica must have a **peerServerDN** and **peerServerPW** defined in the backend section of the LDAP server configuration file.
- 2. Stop the existing servers. For each existing server that is to become a peer server, update its configuration file to include the **peerServerDN** and **peerServerPW** configuration options. Restart the existing read-write servers in maintenance mode. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for alternatives to specifying the password in the configuration file.
- 3. Prime the new peer replica with all the data from an existing server. You can accomplish this by dumping the existing server's directory (use DS2LDIF) and adding the data to the new peer replica (use LDAPADD). See "Populating a replica" on page 175 for more information.
- 4. Add a replica entry to the existing servers to point to the new peer replica.
- 5. Add a replica entry in the new peer replica pointing to the existing server that was used to prime this server.
  - **Note:** If the existing server was a replicating server with replica entries defined to it, those replica entries might have been copied to the new peer replica in step 3 above. Ensure that this server does not contain a replica entry that defines this server as a replica of itself.
- 6. Turn off maintenance mode on all servers.

The existing servers and the new peer replica are now peer read-write replicas.

## Upgrading a read-only replica to be a peer replica of the master server

It might be necessary for you to upgrade a read-only replica for a backend to a peer of its master, for example, if a peer of the master failed or further failover support is needed.

You should do the following to change a read-only replica for a backend to a peer replica:

- 1. Stop both the master server and the read-only replica.
- 2. Remove the **masterServer, masterServerDN**, and **masterServerPW** options from the backend section of the LDAP server configuration file of the read-only replica.
- 3. Add a **peerServerDN** and **peerServerPW** option to the backend section of each server's configuration file. The two servers will now be peer servers. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for alternatives to specifying the password in the configuration file
- 4. Start both servers in maintenance mode.
- 5. In this backend, on the read-only replica being upgraded:
  - Add a replica entry for each replica that this backend on the master server points to (except the entry that previously pointed to the read-only replica that is being upgraded). This can include both peer servers and read-only replicas. Note that the master server might have other peer servers.
  - · Add a replica entry to point to the master.
- 6. On the master, ensure that the credentials are valid in the replica entry for the read-only replica being upgraded.
- 7. Turn off maintenance mode on both servers.

The read-only replica and the master server are now peer read-write replicas for the backend.

#### Downgrading a peer server to read-only replica

It might be necessary for you to downgrade a backend from a peer server to a read-only replica, for example, if a previously upgraded read-only replica is no longer required to be a peer server, or to prevent out-of-sync conditions between peer servers.

You should do the following to downgrade a peer server to a read-only replica:

- 1. Stop the peer server.
- 2. Remove the **peerServerDN** and **peerServerPW** options from the backend section of the LDAP server configuration file.
- 3. Add **masterServer, masterServerDN**, and **masterServerPW** options to the backend section of the peer replica configuration file. If there are more than one peers, add a **masterServer** option for each one. See "The Administrator DN and the Replica Server DN and Passwords" in *z/VM: TCP/IP Planning and Customization* for alternatives to specifying the password in the configuration file.
- 4. Ensure that the credentials are valid in the replica entry for the newly downgraded peer server on all the replicating servers.
- 5. Start the server.

The peer server is now a read-only replica for the backend.

# SSL/TLS and basic replication

SSL/TLS can be used to communicate between a replicating server (master or peer) and a replica server (read-only or peer).

#### **Replica server with SSL/TLS enablement**

Set the replica server up for SSL/TLS like a typical SSL/TLS server. It needs its own public-private key pair and certificate, and the LDAP server configuration file needs the standard SSL options (**listen, sslKeyRingFile**, and **sslKeyRingFilePW**). See "Setting up for SSL/TLS" in *z/VM: TCP/IP Planning and Customization* for more information.

#### **Replicating server with SSL/TLS enablement**

The replicating server acts as an SSL/TLS client to the replica server.

To set up the replicating server, you must:

- 1. Run the **gskkyman** utility (see *z/VM: TCP/IP User's Guide*), this time as if you were the client. The key database file must contain the replicating server's key pair and certificate. Receive the replica's self-signed certificate and mark it as trusted.
- 2. In the LDAP server configuration file on the replicating server:
  - Set **sslKeyRingFile** to the replica key database file created above.
  - Set sslKeyRingFilePW to the password for the key database file, or set sslKeyRingPWStashFile to the file name where the password is stashed.
- 3. In the replica entry for this replica:
  - Set the replicaPort attribute to the replica's secure port number.
  - Set the replicaUseSSL attribute to TRUE.

See "Setting up for SSL/TLS" in *z/VM: TCP/IP Planning and Customization* for more information.

Because the replicating server acts as an SSL/TLS client to the replica server, the replicating server binds with the replica server. The bind method used is **simple** bind. The SASL external bind method is not supported for basic replication.

## Basic replication error log

L

L

L

Т

|

L

L

L

I

I

I

I

I

L

|

|

A replication error log holds information about each error that occurs during basic replication. To avoid stalling basic replication, the failed replication operation is taken off the replication queue so that replication can continue with the next operation. Depending on the error, the LDIF of the failed operation is set aside (added) to the error log.

There is one error log for each replica of a backend. The file name of the error log for a replica is specified by the **ibm-slapdLog** attribute in the replica entry for that replica within the backend. The file name must be unique across the LDAP server. If the attribute does not exist in the replica entry or the attribute has no value, no errors are logged or replication operations set aside during this backend's replication to that replica. In this case, basic replication to that replica stalls every time a failure occurs. The **ibm-slapdReplMaxErrors** attribute in the replica entry is set to control how many failed replication operations can be set aside each time the LDAP server is started before basic replication stalls for that replica.

The replication error log is used to correct basic replication in two ways:

- · Use the error information to determine why replication failed.
- Use LDAPMDFY to run the error log on the replica server, after resolving the basic replication problems. This performs the modifications that were set aside in the error log, therefore, bringing the backend in the replica to the same level as in the replicating server. You must bind as either the **masterserverDN** or **peerserverDN**, depending on the type of replica.

The following is an example of an error log entry:

sn: Fred Smith

The basic replication error log consists of three messages, each using one or more lines:

- 1. Message one indicates when the error occurred, the entry, and replica server.
- 2. Message two is the error message returned by the replica server.
- 3. Message three indicates what is being done. If the operation is set aside, this message is followed by the LDIF of the operation.

All non-LDIF information is prefixed with the comment character # so that the error log can be run through LDAPMDFY to synchronize the two servers.

Following is an example in which a replication error condition is logged but no set-aside of the modification is needed:

#(070102 03:35:47.003707): delete operation failed for cn=IBMUSER01,

- O=YOUR COMPANY to 9.57.1.198:3389, rc=32
- # R004071 DN 'cn=IBMUSER01,0=YOUR COMPANY' does not exist (ldbm\_process\_request)

# Entry is already deleted, ignoring request.

There is no LDIF. Notice the third message indicates that request is being ignored.

#### Troubleshooting basic replication

If the replica server does not seem to be receiving updates from the replicating server (master or peer), there are several possible reasons. Check the following conditions for a possible quick fix:

- Check for messages from the replicating server.
- Verify that a replica entry for the replica server exists in the backend to be replicated in the replicating server, and was specified correctly to match with the replica server. If cn=localhost is used as the suffix for all replica entries for a backend, use LDAPSRCH with a base of cn=localhost and a filter of objectClass=\*. Otherwise, use LDAPSRCH where the search base is the suffix defined in the backend section of the LDAP server configuration file and the filter is objectClass=replicaObject. If more than one suffix is configured for LDBM, the search must be repeated using each suffix in the search base.

See z/VM: TCP/IP User's Guide for more information about LDAPSRCH.

 Verify that the replicaHost value in the replica entry for that replica specifies the machine on which the replica is running.

- Check that the values listed in the replica entry for that replica match those of the replica server configuration. Specifically, the replicaPort, replicaBindDN, and replicaCredentials should be verified.
- Check that the **replicaUpdateTimeInterval** specified in the replica entry for that replica has been set correctly.
- Verify that the replica server is running by using LDAPSRCH against the replica.
- Check that the default referral specified in the LDAP server configuration file in the replica server points to the replicating server.
- If the replica entry replicaUseSSL attribute is set to TRUE, verify the replicaPort attribute is set to the SSL port configured on the replica server. Verify the sslKeyRingFile, and sslKeyRingFilePW or sslKeyRingPWStashFile values in the LDAP server configuration file on the replica server and on the replicating server are correct.
- When adding a large number of entries, ensure that the region size for the replicating server is sufficient for replicating the entries to the replica. Entries on the replicating server are kept in memory during replication. If the region size is not sufficient, an out of memory condition can occur in the LDAP server. If possible, set the region size on the replicating server to 0M (or unlimited). If that cannot be done, set the region size to 14M (needed to run the LDAP server itself) plus twenty times the size of the largest LDIF file that is to be added to the replicating server.

The **ibm-slapdLog** and **ibm-slapdRepIMaxErrors** attributes in a replica entry can be used to configure a replication error log for this replica. If basic replication fails, the error log holds all errors that occurred during replication and the LDIF for the set aside replication operations.

## Recovering from basic replication out-of-sync conditions

If a replica becomes out-of-sync with its replicating server for any reason, and normal replication processing is not correcting the situation, it might be necessary to reload the replica.

The following procedure should be followed to reload a replica:

- 1. Issue SMSG LDAPSRV MAINTMODE ON on the replicating sever and on each of the replica servers to put them into maintenance mode.
- 2. Using the administrator DN, unload all the replica entries (entries that describe replica servers) from the master server. Use a search command to create LDIF output containing the replica entries for each suffix in the backend.
- 3. Using the administrator DN, run LDAPDLET to remove the replica entries from the master. This resets the replication information in the replicating server.
- 4. Stop all the replica servers.
- 5. Clear out the directory on each replica server. Remove all the files in the LDBM database directory. See the description of the **databaseDirectory** option in "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in *z/VM: TCP/IP Planning and Customization* for more information about the location of these files.
- 6. Run an unload utility on the replicating server. Use DS2LDIF twice, once to unload the schema entry and a second time to unload the LDBM directory entries.
- 7. Start the replica servers in maintenance mode.
- 8. Using an administrator DN, run LDAPMDFY to load the schema unloaded from the replicating server onto each replica.

- 9. On each replica, use LDAPADD to load the directory data retrieved above from the replicating server. LDAPADD must be run using the administrator DN.
- 10. Using an administrator DN, run LDAPADD to add the replica entries unloaded in step 2 back into the replicating server.
- 11. Issue SMSG LDAPSRV MAINTMODE OFF to take the replicating server and each replica out of maintenance mode.

# Chapter 11. Advanced replication

1	Replication keeps data in multiple directory servers synchronized. Advanced replication includes the following function:
   	<ul> <li>Allows specific subtrees within the Directory Information Tree (DIT) to be chosen for participation in advanced replication topologies (in contrast to requiring the entire backend to participate or not participate)</li> </ul>
1	<ul> <li>Allows the subtrees participating in an advanced replication environment to have different roles (for example, supplier or consumer)</li> </ul>
1	<ul> <li>Additional replication topology choices can be combined to serve many different directory information architectures and data redundancy requirements</li> </ul>
	<ul> <li>External error log management using extended operations</li> </ul>
	<ul> <li>Operational attributes to determine the current state of the advanced replication environment</li> </ul>
	<ul> <li>External queue management using extended operations</li> </ul>
	<ul> <li>Password policy updates</li> </ul>
	Schema replication.
	· Schema replication.
Advanced rep	blication terminology
	Cascading replication
	A replication topology with multiple tiers of servers. A peer-master server
1	replicates to a small set of read-only servers that replicate to other servers. Such a topology off-loads replication work from the master servers.
1	Consumer server A server that receives changes from replication from another (supplier)
	server.
	Credentials entry
	An entry that identifies the method and required information that the
	supplier uses in binding to the consumer. For simple binds, it is the
1	distinguished name (DN) and password. This entry is specified in the replication agreement.
	Forwarding server
	A read-only server that replicates all changes sent to it. This contrasts to a
	peer-master server in that a peer-master server does not replicate changes
	sent to it from another peer-master server; it only replicates changes that are originally made on the peer-master server.
	Gateway server
	A server that forwards all replication traffic from the local replication site where it resides to other gateway servers in the replicating network. This
	server also receives replication traffic from other gateway servers within the
	replication network, that it forwards to all servers on its local replication site.
	Gateway servers must be masters (writable).
1	Master server
i	A server that is writable (can be updated) for a given subtree.
	Nested subtree
I	A subtree within another subtree of the directory.
I	Peer server
I	The term used for a master server when there are multiple masters for a

given subtree. A peer server does not replicate changes sent to it from another peer server; it only replicates changes that are originally made on it.

#### **Replica group**

Т

1

The first entry created under a replication context has objectclass **ibm-replicaGroup** and represents a collection of servers participating in replication. It provides a convenient location to set ACLs to protect the replication topology information.

#### **Replica subentry**

Below a replica group entry, one or more entries with objectclass **ibm-replicaSubentry** can be created; one for each server participating in replication as a supplier. The replica subentry identifies the role the server plays in replication: master or read-only. A read-only server might, in turn, have replication agreements to support cascading replication.

#### **Replicated subtree**

A portion of the Directory Information Tree (DIT) that is replicated from one server to another. Under this design, a given subtree can be replicated to some servers and not to others. A subtree can be writable on a given server, while other subtrees might be read-only.

#### **Replicating network**

A network that contains connected replication sites.

#### **Replication agreement**

Information contained in the directory that defines the "connection" or "replication path" between two servers. One server is called the supplier (the one that sends the changes) and the other is the consumer (the one that receives the changes). The agreement contains all the information needed for making a connection from the supplier to the consumer and scheduling replication.

#### **Replication context**

Identifies a portion of the Directory Information Tree (DIT) that is allowed to be replicated from one server to another. The **ibm-replicationContext** auxiliary object class might be added to an entry to mark it as the root of a replicated area. The configuration information related to replication is maintained in a set of entries created below the base of a replication context.

#### **Replication filter**

An entry containing the list of attributes that need to be replicated or excluded from replication corresponding to a particular type of entry. It can exist anywhere in the Directory Information Tree (DIT) but is always associated with an agreement.

#### **Replication site**

A gateway server and any master, peer, or replica servers configured to replicate together.

#### **Replication topology**

The set of entries in a directory that control the type of information that is replicated between LDAP servers and how it is replicated. These objects include:

- Replica groups
- Replica subentries
- Replication agreements

Т

1

I	Theplication contexts
I	<ul> <li>Replication credentials entries</li> </ul>
I	Replication schedule entries
	All LDAP servers in the replicating network must have the same replication topology.
     	<b>Replication schedule</b> Replication can be scheduled to occur at particular times, with changes on the supplier accumulated and sent in a batch. The replication agreement contains the distinguished name (DN) for the entry that supplies the schedule.
	Supplier server A server that sends changes to another (consumer) server.
Replication to	pology
	When advanced replication is configured, specific entries in the directory are identified as the roots of replication subtrees or replication contexts by adding the auxiliary objectclass <b>ibm-replicationContext</b> to them. Each of these replication contexts are replicated independently. The subtree continues down through the Directory Information Tree (DIT) until reaching the leaf entries or other replicated subtrees or contexts. Entries are added below the root of the replicated subtree to contain the replication configuration information. There are one or more replica group entries created directly under each replication context. For each replica group entry, there is a corresponding replica subentry that identifies the role the server plays in the replication environment. Associated with each replica subentry are replication agreements that identify the servers that are supplied (replicated to) by each server and defining the credentials and schedule information.
   	By using advanced replication, a change made to one server is propagated to one or more additional servers. In effect, a change to one server can show up on multiple different LDAP servers. z/VM LDAP supports either basic or advanced replication but not both at the same time. Advanced replication includes:
I	<ul> <li>replication of subtrees of the Directory Information Tree to specific servers</li> </ul>
I	<ul> <li>a multitier topology referred to as cascading replication</li> </ul>
I	<ul> <li>assignment of server role (supplier or consumer) by subtree</li> </ul>
I	<ul> <li>multiple master servers, referred to as peer to peer replication</li> </ul>
I	<ul> <li>gateway servers that replicate across networks</li> </ul>
1	The advantage of replicating by subtrees is that a replica does not need to replicate the entire directory. It can be a replica of a part, or subtree, of the directory.
       	The advanced replication model changes the concept of master and replica servers. These terms no longer apply to servers, but rather to the roles that a server has regarding a particular replicated subtree. A server can act as a master for some subtrees and as a replica for others. The term <i>master</i> is used for a server that accepts client updates for a replicated subtree. The term <i>replica</i> is used for a server that only accepts updates from other servers designated as a supplier for the replicated subtree.
1	The types of directory roles as defined by function are: master-replica, peer-peer, forwarding (cascading), and gateway.

Replication contexts

I

#### Table 29. Server roles

1

Option	Description
Master-replica	A replica is an additional server that contains a copy of the directory information that is replicated from the master server. The replicated data can be the entire DIT or just a portion of the DIT that is replicated to the replica. The replica server provides a read-only backup of the replicated subtree.
Master-peer	The master-peer server contains the master directory information from where updates are propagated to the replicas. All changes are made and occur on the master server, and the master is responsible for propagating these changes to the replicas.
	There can be several servers acting as masters for directory information, with each master responsible for updating other master servers and replica servers. This is referred to as peer replication. Peer replication can improve performance and reliability. Performance is improved by providing a local server to handle updates in a widely distributed network. Reliability is improved by providing a backup master server ready to take over immediately if the primary master fails.
	Notes:
	1. Master servers replicate all client updates, but do not replicate updates received from other masters.
	2. Updates among peer servers can be immediate or scheduled.
Forwarding (Cascading)	A forwarding or cascading server is a replica server that replicates all changes sent to it. This contrasts to a master-peer server in that a master-peer server only replicates changes that are made by clients connected to that server. A cascading server can relieve the replication workload from the master servers in a network that contains many widely dispersed replicas.
Gateway	Gateway replication uses gateway servers to collect and distribute replication information effectively across a replicating network. The primary benefit of gateway replication is the reduction of network traffic.

You can request updates on a replica server, but, the update is forwarded to the master server by returning a referral to the client. If the update is successful, the master server then sends the update to the replicas. Until the master has completed replication of the update, the change is not reflected on the replica server where it was originally requested. If replication fails, it is repeated even if the master is restarted. Changes are replicated in the order that they are made on the master. For more information, see "Recovering from advanced replication errors" on page 243.

If you are no longer using a replica, you must remove the replication agreement entry from the supplier. Leaving the entry causes the server to queue up all updates and uses unnecessary directory space. Also, the supplier continues trying to contact the missing consumer to try sending the data again. When a replication agreement is deleted, replication is halted immediately. That is, any updates in the replication queue are lost.

## Advanced replication overview

This section presents a high-level description of the various advanced replication topologies.

# Master-replica replication

I

1

The basic relationship in advanced replication is that of a master server and its replica server. The master server can contain a directory or a subtree of a directory. The master is writable, which means it can receive updates from clients for a given

subtree. The replica server contains a copy of the directory or a copy of part of the directory of the master server. The replica is read only; it cannot be directly updated by clients. Instead it refers client requests to the master server, that performs the updates and then replicates them to the replica server.

A master server can have several replicas. Each replica can contain a copy of the master's entire directory, or a subtree of the directory. In the following example, Replica 2 contains a copy of the complete directory of Master Server, Replica 1, and Replica 3 each contain a copy of a subtree of the Master Server directory.

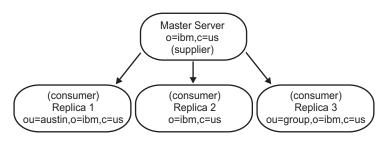

Figure 37. Master-replica replication

The relationship between two servers can also be described in terms of roles, either supplier or consumer. In the previous example, Master Server is a supplier to each of the replicas. Each replica in turn is a consumer of Master Server.

# Forwarding (cascading) replication

Т

L

L

I

T

I

I

T

|

1

L

Forwarding (cascading) replication is a topology that has multiple tiers of servers. A master server replicates to a set of read-only (forwarding) servers that in turn replicate to other servers. Such a topology off-loads replication work from the master server. In the example of this type of topology, the master server is a supplier to the two forwarding servers. The forwarding servers serve two roles. They are consumers of the master server and suppliers to the replica servers associated with them. These replica servers are consumers of their respective forwarding servers. For example:

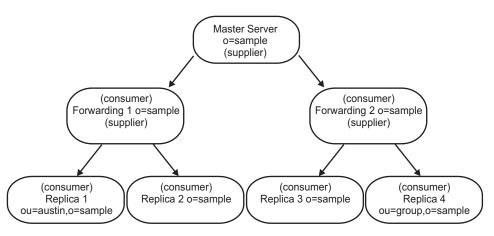

Figure 38. Cascading replication

## Peer-to-peer replication

There can be several servers acting as masters for directory information, with each master responsible for updating other master servers and replica servers. This is referred to as peer replication. Peer replication can improve performance,

availability, and reliability. Performance is improved by providing a local server to handle updates in a widely distributed network. Availability and reliability are improved by providing a backup master server ready to take over immediately if the primary master fails. Peer master servers replicate all client updates to the replicas and to the other peer masters, but do not replicate updates received from other master servers.

**Note:** Conflict resolution for add and modify operations in peer-to-peer replication is based on timestamps of entries. for more information, see "Replication conflict resolution" on page 191.

Figure 39 is an example of peer-to-peer replication:

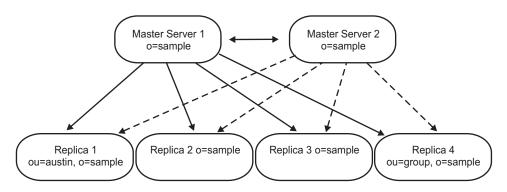

Figure 39. Peer-to-peer replication

#### Gateway replication

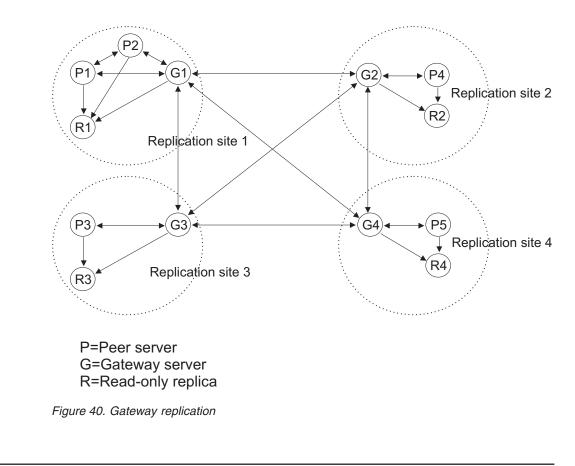

Т

Gateway replication is a more complex adaptation of peer-to-peer replication that extends replication capabilities across networks. The most notable difference is that a gateway server does replicate changes received from other peer servers through the gateway.

A gateway server must be a master server, that is, writable. It acts as a peer server within its own replication site. That is, it can receive and replicate client updates and receive updates from the other peer-master servers within the replication site. It does not replicate the updates received from the other peer-masters to any servers within its own site.

Within the gateway network, the gateway server acts as a two-way forwarding server. In one instance, the peers in its replication site act as the suppliers to the gateway server and the other gateway servers are its consumers. In the other instance, the situation is reversed. The other gateway servers act as suppliers to the gateway server and the other servers within its own replication site are the consumers.

Gateway replication uses gateway servers to collect and distribute replication information effectively across a replicating network. The primary benefit of gateway replication is the reduction of network traffic. For example:

# Advanced replication features

This topic presents a high-level overview of advanced replication features.

## Partial replication

1

I

Partial replication is an advanced replication feature that replicates only the specified entries and a subset of attributes for the specified entries within a subtree. Using partial replication, an LDAP administrator can enhance the replication bandwidth depending on the deployment requirements. The attributes that are to be replicated are specified using a replication filter. For more information about partial replication, see "Partial replication" on page 234.

## Replication scheduling

Replication scheduling is an advanced replication feature that allows updates to be queued and then replicated at a certain time each day or during certain days of the week. Using replication scheduling, an LDAP administrator can schedule advanced replication to occur at optimal times when network traffic is minimal. For more information about replication schedule entries, see "Schedule entries" on page 200.

# **Replication conflict resolution**

If there are replication conflicts involving delete or modifyDN operations, LDAP administrator intervention might be needed to correct the problems. For example, if an entry is renamed on one server while it is being modified on a second server, the modifyDN might arrive at a replica before the modify. Then when the modify arrives, it fails. In this case, the administrator needs to respond to the error by applying the modify to the entry with the new distinguished name (DN). All

information necessary to redo the modify with the correct name is preserved in the replication and error logs. Replication errors are rare occurrences in a correctly configured replication topology, but it is not safe to assume that they never occur.

Conflict resolution for add and modify operations in peer-to-peer replication is based on the **modifyTimeStamp** attribute value. The entry update with the most recent **modifyTimestamp** on any server in a multi-master replication environment is the one that takes precedence. Replicated delete and rename (modify DN) requests are accepted in the order received without conflict resolution. When a replication conflict is detected, the replaced entry is archived for recovery purposes in the lost and found log that is specified in the **ibm-slapdLog** attribute of the **cn=Replication,cn=Log Management,cn=configuration** entry.

Updates to the same entry made by multiple servers might cause inconsistencies in directory data because conflict resolution is based on the **modifyTimestamp** value of the entries. The most recent **modifyTimestamp** value takes precedence. If the data on your servers becomes inconsistent, to resynchronize the servers use the synchronization procedure in "Recovering from advanced replication errors" on page 243.

For advanced replication conflict resolution to work correctly, the supplier server must provide the modified entry's **modifyTimestamp** value before the entry was updated on the supplier. The consumer server uses the **modifyTimestamp** attribute value to determine what to do with a modified entry. If the consumer server receives a **modifyTimestamp** value on an entry that is earlier than the same entry's **modifyTimestamp** in its own server, then the modify request from the supplier server is ignored. However, this same replication conflict resolution does not occur for the schema entry, **cn=schema**. The replicated **cn=schema** entry is always replaced on the consumer server even if the consumer server has a later **modifyTimestamp** value.

## **Enabling advanced replication**

Т

T

Т

1

1

Before advanced replication entries are allowed to be added to the LDBM backend, the CDBM backend must be configured in the LDAP server configuration file and the **useAdvancedReplication** configuration option set to **on** in the CDBM backend. For example:

database CDBM GLDBCD31
databaseDirectory /var/ldap/cdbm
useAdvancedReplication on

#### Notes:

- If useAdvancedReplication on is specified in the CDBM backend and basic replication entries with an objectclass of replicaObject exist in any configured LDBM backend, the server does not start. Entries with an objectclass of replicaObject are not allowed to be added when advanced replication is allowed. Basic and advanced replication environments are not supported at the same time in the z/VM LDAP server. If planning to use an advanced replication environment, all basic replication replicaObject entries must be removed from the LDBM backend.
- If there are advanced replication entries in the LDBM backend and useAdvancedReplication off is specified in the CDBM backend, the server does not start because basic replication is intended to be used. Replication contexts, replica groups, replica subentries, and replication agreement entries are not allowed to be added when basic replication is allowed.

3. The masterServer, masterServerDN, masterServerPW, peerServerDN, and peerServerPW configuration options are not allowed to be specified in any LDBM backend when the CDBM backend is configured and the useAdvancedReplication option is set to on. The masterServer, masterServerDN, masterServerPW, peerServerDN, and peerServerPW options are valid only when the server is configured to run in a basic replication environment.

The **cn=configuration** suffix contains entries that are used to configure advanced replication support. When the server is first started, the following advanced replication configuration entries under the **cn=configuration** suffix are automatically created:

- cn=configuration
- cn=Replication,cn=configuration
- cn=Log Management,cn=Configuration
- cn=Replication,cn=Log Management,cn=Configuration

For more information about these entries and attribute values that affect advanced replication configuration, see "CDBM Backend Configuration and Policy Entries" in *z/VM: TCP/IP Planning and Customization*.

The following sections indicate the entries that must be added or modified in the supplier server to successfully configure advanced replication.

#### **Replication contexts**

A replication context is an entry in the directory with the auxiliary objectclass **ibm-replicationContext** that identifies the root of a replicated subtree. The auxiliary objectclass **ibm-replicationContext** is allowed to be added to any entry in the directory. For the optional attribute value for the **ibm-replicationContext** objectclass, see Table 30. The replication configuration information is maintained in a set of entries created below the base of a replication context. If there is more than one replication context present in the same subtree, the replication configuration information under the child replication context entry is used while the replication configuration under the parent entry is ignored.

If the **ibm-replicationContext** auxiliary objectclass is added to a non-suffix level entry in the directory, explicit **aclEntry** and **entryOwner** attribute values are required. When an **entryOwner** attribute value is required, it must start with an *access-id:*. For more information about protecting the replication topology, see "Protecting replication topology entries" on page 232.

Table 30. ibm-replicationContext objectclass schema definition (optional attribute)

Attribute description and example

#### ibm-replicaReferralURL

A single valued attribute that contains an ordered list of LDAP URLs with server name and optional port numbers separated by spaces. This list contains a list of servers that have update access to this replication context.

| Example:

ibm-replicaReferralURL: ldap://master1.ibm.com:500 ldaps://master2.ibm.com:636

     	For the example in Table 30 on page 193, assume that a replication context of o=ibm is used. When a client attempts an update operation on the consumer server under the o=ibm replication context, the referral list in the <b>ibm-replicaReferralURL</b> attribute value is sent back to the client indicating the supplier servers for the replication context.
Ι	eplica groups
Ι	A replica group entry is created directly under a replication context entry with the
Ι	structural object class ibm-replicaGroup. For the optional and required attributes for
Ι	the <b>ibm-replicaGroup</b> objectclass, see Table 31. A replica group entry represents a
Ι	collection of servers participating in replication for the context. Multiple replica group
Ι	entries are allowed to be created under a replication context. A replica group entry
Ι	provides a convenient location to set ACLs to protect the replication topology
Ι	information; however, these entries do not affect how the replication topology is
Ì	configured. For more information about protecting the replication topology, see
Ì	"Protecting replication topology entries" on page 232.

Table 31. ibm-replicaGroup objectclass schema definition (optional and required attributes)

I	Attribute description and example
I	description
 	An optional attribute that provides a text field for extra information pertaining to the replica group entry. This attribute does not affect advanced replication configuration.
I	Example:
I	description: Replica group 1
I	ibm-replicaGroup
I	A required attribute value that specifies the name of a replica group.
I	Example:
I	ibm-replicaGroup: Group1
I	

# **Replica subentries**

T

T

|

A replica subentry is created directly under a replica group with the structural objectclass **ibm-replicaSubentry**. For the optional and required attributes for the **ibm-replicaSubentry** objectclass, see Table 32. A replica subentry identifies the role the server plays in advanced replication (for example master, peer, forwarding, or gateway server). Do not create the replica subentry if the server's role is a read-only replica server. If the auxiliary objectclass **ibm-replicaGateway** is added to a replica subentry, the server's role is a gateway server. For more information, see "Gateway replication" on page 190. There should be only one replica subentry created for a single server under a given replication context.

Table 32. ibm-replicaSubentry objectclass schema definition (optional and required attributes)

	Attribute description and example
L	cn
	A required attribute that specifies the common name of the replica subentry. This attribute does not affect advanced replication configuration.
I	Example:
	cn: Subentry 1

I I	Table 32. ibm-replicaSubentry	, objectclass	schema definit	ion (ontional	and require	d attributes)	(continued)
1	Table 32. IniteplicaSuberilis	UDJECICIASS	Schema uennin	ισπ (σριισπαι	anu regune	a allibules	(continueu)

	Attribute description and example
	description
	An optional attribute that provides an additional text field for extra information pertaining to the replica subentry. This attribute does not affected advanced replication configuration.
	Example:
	description: Represents the LDAP server (master1) under this replication context
	ibm-replicaServerID
   	A required attribute that specifies the server ID of the server that this entry represents. To determine the ID of a server, search the root DSE entry for the <b>ibm-serverID</b> attribute. This attribute cannot be modified after this entry is created. If this attribute value must be changed, all entries under the replica subentry must be deleted and then readded.
 	A server does not interrogate the replica subentry or any replication agreements beneath it when the <b>ibm-replicaServerID</b> attribute value does not match its own ID. For more information about replication agreement entries, see "Replication agreements."
I	Example:
I	ibm-replicaServerID: supplier1
	ibm-replicationServerIsMaster
	A required boolean (true or false) attribute that indicates whether the server represented by this replica subentry, as determined by the <b>ibm-replicaServerID</b> attribute value, is a master server for the replication context.
   	If set to true, the server represented by this replica subentry, as determined by the <b>ibm-replicaServerID</b> attribute, is a master, peer, or gateway server if there are any replication agreement entries for the replication context under this replica subentry. If set to false, the server represented by this replica subentry, as determined by the <b>ibm-replicaServerID</b> attribute, is a forwarding server if there are any replication agreement entries for the replication context under this replica subentry.
I	Example:
	ibm-replicationServerIsMaster: true

For the examples in Table 32 on page 194, the replica subentry represents a supplier server with a server ID of supplier1. It is also the master server under the replication context (o=ibm) where this replica subentry resides.

# **Replication agreements**

I

L

L

L

I

L

L

I

I

I

L

L

L

T

A replication agreement is an entry in the directory with the structural object class **ibm-replicationAgreement** created directly under a replica subentry to define replication from the server represented by the subentry to another server. For the required attributes for the **ibm-replicationAgreement** objectclass, see Table 33 on page 196. For the optional attributes for the **ibm-replicationAgreement** objectclass, see Table 34 on page 196. A replication agreement entry is like a **replicaObject** entry used in basic replication. This object represents an individual connection from a supplier server to a consumer server. A replica subentry might have any number of replication agreement entries defined under it to specify each supplier agreement this server has under this replication topology.

1 Table 33. ibm-replicationAgreement objectclass schema definition (required attributes)

I	Attribute description and example
I	cn
I	Common name of the replication agreement entry. This attribute does not affect advanced replication configuration.
I	Example:
I	cn: agreement1
I	ibm-replicaConsumerID
   	Identifies the server ID of the consumer server. This value matches the <b>ibm-serverID</b> attribute value in the root DSE entry of the consumer server or a warning message is issued in the LDAP server log when the replication agreement initializes.
I	Example:
I	ibm-replicaConsumerID: consumer1
I	ibm-replicaCredentialsDN
 	Specifies the distinguished name (DN) of the entry containing the credentials entry used to authenticate to the consumer server. For more information about credential entries, see "Credentials entries" on page 198.
I	Example:
I	<pre>ibm-replicaCredentialsDN: cn=consumer1,cn=localhost</pre>
I	ibm-replicaURL
 	Specifies the LDAP URL of the consumer server. The LDAP URL syntax is fully documented in RFC 2255: <i>The LDAP URL Format</i> .
   	The prefix of the LDAP URL indicates whether a non-secure or secure connection is used between the supplier and consumer servers. If the LDAP URL prefix is 1dap://, a non-secure connection is used. If the LDAP URL prefix is 1daps://, a secure connection is used. For more information about using SSL/TLS in an advanced replication environment, see "SSL/TLS and advanced replication" on page 236.
I	Example:
I	ibm-replicaURL: ldaps://consumer1.ibm.com:500
I	
     	For the examples in Table 33, when the replicating server receives and successfully finishes an update request, the update is also sent to the consumer server with an ID of consumer1 that is located on host name consumer1.ibm.com on secure port 500. The replicating server performs a simple or SASL EXTERNAL bind operation using the information provided in the credentials entry cn=consumer1,cn=localhost.
I	Table 34. ibm-replicationAgreement objectclass schema definition (optional attributes)
I	Attribute description and example
I	description
 	Provides an additional text field for extra information pertaining to the replication agreement entry. This attribute does not affect advanced replication configuration.
I	Example:
 	description: Represents the replication agreement from the supplier1 server to the consumer1 server

I	Table 34. ibm-replicationAgreement objectclass schema definition (optional attributes) (continued)
I	Attribute description and example
Ι	ibm-replicaScheduleDN
   	Specifies the DN of a schedule entry that determines when replication updates are sent to this consumer. If a schedule DN is not specified, advanced replication defaults to "immediate" replication mode. For more information about advanced replication scheduling, see "Schedule entries" on page 200.
I	Example:
I	<pre>ibm-replicaScheduleDN: cn=schedule,o=ibm</pre>
I	ibm-replicationCreateMissingEntries
   	A boolean (true or false) indicating whether missing parent entries are to be created on the consumer server. If set to true, the missing parent entries are automatically created by the supplier server and replicated to the consumer server. If set to false or if the attribute is not specified, the missing parent entries are not created on the consumer server.
I	Example:
I	ibm-replicationCreateMissingEntries: true
Ι	ibm-replicationExcludedCapability
   	A multi-valued attribute that lists the OIDs of features that the consumer server does not support. Operations related to these capabilities are excluded from the updates sent to the consumer in this replication agreement. If this attribute is not specified, no capabilities are excluded from being replicated.
L	Only the following capabilities are allowed to be excluded:
I	<ul> <li>1.3.18.0.2.32.4 – IBM filtered ACLs (only supported on non-z/OS IBM Tivoli Directory Servers)</li> </ul>
I	<ul> <li>1.3.18.0.2.32.98 – z/VM LDAP server and z/OS IBM Tivoli Directory Server ACL filters</li> </ul>
I	Example:
Ι	<pre>ibm-replicationExcludedCapability: 1.3.18.0.2.32.4</pre>
I	ibm-replicationFilterDN
   	Specifies the DN of a replication filter entry that contains filters that include or exclude the replication of certain entries or attribute types to the consumer server. For additional information about using partial replication, see "Partial replication" on page 234.
I	Example:
L	ibm-replicationFilterDN: cn=filter,o=ibm
I	ibm-replicationOnHold
   	A boolean (true or false) indicating whether advanced replication from the replication agreement is suspended or not. If set to true, replication updates from the supplier server to the consumer server are queued until this attribute value is set to false. If set to false or this attribute is not specified, replication updates are handled normally.
   	This attribute value is also modified by the <b>Cascading control replication</b> and the <b>Control replication</b> extended operations. For more information about the <b>Cascading control replication</b> extended operation, see "Cascading control replication" on page 348. For more information about the <b>Control replication</b> extended operation, see "Control replication" on page 352.
I	Example:
L	ibm-replicationOnHold: false
Ι	
 	To aid in enforcing the accuracy of the data within the replication agreement entry, when the supplier binds to the consumer, it retrieves the <b>ibm-serverID</b> attribute

   	from the root DSE entry and compares it to the <b>ibm-replicaConsumerID</b> attribute value. A warning is logged in the LDAP server's job log if these server IDs do not match.
   	You can designate that part of a replicated subtree not replicate by adding the <b>ibm-replicationContext</b> auxiliary class to the root of the subtree, without defining any replica subentries.
Ι	Credentials entries
	Because the replication agreement entry can be replicated, a DN to credentials object is used in the <b>ibm-replicaCredentialsDN</b> attribute value. This allows the supplier server credentials entry to be stored in an area of the DIT that is not replicated. Replicating the supplier server credentials entries (where 'clear text' passwords must be obtainable) represents a potential security exposure. The cn=localhost suffix in an LDBM backend is an appropriate location for the creation of supplier server credential entries.
	The objectclass of the entry specified in the <b>ibm-replicaCredentialsDN</b> attribute value in the replication agreement indicates the authentication method used by the supplier to authenticate with the consumer server. If the entry's objectclass is <b>ibm-replicationCredentialsSimple</b> , the supplier server uses a simple bind to authenticate to the consumer. For the required attributes of the <b>ibm-replicationCredentialsSimple</b> objectclass, see Table 35. If the entry's objectclass is <b>ibm-replicationCredentialsExternal</b> , the supplier server performs a SASL EXTERNAL bind to the consumer server. For the optional attributes of the <b>ibm-replicationCredentialsExternal</b> objectclass, see Table 36 on page 199.
   	A consumer server credentials entry is required on the consumer server to identify the distinguished name that the supplier server is using to perform a simple or SASL EXTERNAL bind. For more information about the consumer server credential entries, see "Consumer server entries" on page 211.
T	Table 35. ibm-replicationCredentialsSimple objectclass schema definition (required attributes)
Ι	Attribute description and example
Ι	replicaBindDN
 	Specifies the LDAP distinguished name that the replicating server uses to bind with the consumer server when sending directory updates.
Ι	Example:
Ι	replicaBindDN: cn=supplier,cn=localhost
Ι	replicaCredentials
 	Contains the authentication information needed for the replicating server to authenticate with the consumer server using the distinguished name specified in the <b>replicaBindDN</b> attribute value.
   	This password value is encrypted if it is added or modified when the <b>secretEncryption</b> configuration option is set to <b>AES</b> or <b>DES</b> under the backend containing the replication agreement. If <b>secretEncryption</b> is set to <b>AES</b> or <b>DES</b> , directory security improves because the password is no longer stored in the directory in clear text.
Ι	Example:
	replicaCredentials: secret
	For the examples in Table 35, the replication agreement uses a simple bind to the

For the examples in Table 35, the replication agreement uses a simple bind to the consumer server using a bind DN of cn=supplier,cn=localhost and a bind password of secret.

|

I	Table 36. ibm-replicationCredentialsExternal objectclass schema definition (optional attributes)
I	Attribute description and example
Ι	ibm-replicaKeyFile
   	Specifies the path and file name of the SSL/TLS key database file to be used by the replication agreement to perform an SASL EXTERNAL bind. Specifying a value here overrides the default that comes from the <b>sslKeyRingFile</b> configuration option. For the acceptable formats for this attribute value, see "sslKeyRingFile" in <i>z/VM: TCP/IP Planning and Customization</i> .
   	<b>Note:</b> If a value is specified for this attribute, it must be the same for all replication agreements in the server. The LDAP server supports having only one opened SSL/TLS key database file at a time. It is suggested that all SSL certificates that need to be used by the server be placed in one SSL/TLS key database file.
Ι	Example:
I	<pre>ibm-replicaKeyFile: /home/server1/server1.kdb</pre>
I	ibm-replicaKeyLabel
   	Specifies the label of the certificate that is used for LDAP server-client authentication for the SASL EXTERNAL bind. The certificate label must reside in the SSL/TLS key database file being used for this credentials entry, as specified by the <b>ibm-replicaKeyFile</b> attribute value or the <b>sslKeyRingFile</b> configuration option if <b>ibm-replicaKeyFile</b> is not specified.
     	Specifying a value here, overrides the default that comes from the <b>sslCertificate</b> configuration option. If the <b>sslCertificate</b> configuration option is not specified or is set to <b>none</b> , the default SSL certificate in the <b>ibm-replicaKeyFile</b> attribute value (or the <b>sslKeyRingFile</b> configuration option if <b>ibm-replicaKeyFile</b> is not specified) is used. For more about the <b>sslCertificate</b> option, see "sslcertificate" in <i>z/VM: TCP/IP Planning and Customization</i> .
Ι	Example:
I	ibm-replicaKeyLabel: EXTERNAL1
I	ibm-replicaKeyPwd
   	Specifies the password protecting access to the SSL/TLS key database file. It can also be used to specify a fully qualified file name where the password for the SSL/TLS key database file is stashed. Specify this attribute only if the <b>ibm-replicaKeyFile</b> attribute value (or the <b>sslKeyRingFile</b> configuration option, if <b>ibm-replicaKeyFile</b> is not specified) is an SSL/TLS key database file.
Ι	If using an SSL stash file, it must be specified in the following format:
Ι	file://filename
I	where filename is the fully qualified Byte File System location of the SSL stash file.
'   	This password value is encrypted if it is added or modified when the secretEncryption configuration option is set to <b>AES</b> or <b>DES</b> under the backend containing the replication agreement. If secretEncryption is set to <b>AES</b> or <b>DES</b> , directory security improves because the password is no longer stored in the directory in clear text.
	Example: ibm-replicaKeyPwd: secret
	ואוו-ובאווכמונצו אם. שבנובנ
   	For the examples in Table 36, the replication agreement uses a SASL EXTERNAL bind to the consumer server with the SSL certificate label EXTERNAL1 in SSL key database file /home/server1/server1.kdb that has a password of secret.
     	A SASL EXTERNAL bind requires a secure connection from the replicating server to the replica server. The replication agreement entry must use an <b>ibm-replicaURL</b> attribute value with an LDAP URL prefix of ldaps:// to signify an SSL connection. The replicating server must have read access to the SSL/TLS key database file that is specified in the <b>sslKeyRingFile</b> configuration option or the <b>ibm-replicaKeyFile</b>

	attribute value in the SASL EXTERNAL supplier server credentials entry. If the optional attribute values in Table 36 on page 199 are not specified in the SASL EXTERNAL supplier server credentials entry, the default SSL configuration in the LDAP server configuration file is used. For more information about using SSL/TLS in an advanced replication environment,
	see "SSL/TLS and advanced replication" on page 236.
	Schedule entries
	An LDAP administrator can schedule advanced replication to occur at optimal times when network traffic is minimal for each individual replication agreement. Each replication agreement entry is allowed to have an <b>ibm-replicaScheduleDN</b> attribute value optionally specified. This attribute value identifies the distinguished name (DN) of a weekly schedule entry, that has an object class of <b>ibm-</b> <b>replicationWeeklySchedule</b> . For the schema definition of the <b>ibm-</b> <b>replicationWeeklySchedule</b> objectclass, see Table 37. The weekly schedule entry allows an LDAP administrator to specify the distinguished name (DN) of additional entries that point to one or more daily replication schedule entries. If the distinguished name in the <b>ibm-replicaScheduleDN</b> attribute value cannot be found or is not a weekly schedule entry, advanced replication continues by ignoring the weekly replication schedule.
	Table 37. ibm-replicationWeeklySchedule objectclass schema definition (optional attributes)
	Attribute description and example
	cn
	Common name of the weekly replication schedule entry. This attribute does not affect advanced replication configuration.
	Example:
	cn: myweekly
	description
	Provides an additional text field for extra information pertaining to the weekly schedule entry. This attribute does not affect advanced replication configuration.
	Example:
	description: Weekly schedule for advanced replication
	bm-repIWeeklySchedName
	Descriptive name for the weekly schedule entry. This attribute does not affect advanced replication configuration.
	ibm-replWeeklySchedName: Weekly schedule for agreement 1
	bm-scheduleMonday
	Specifies the distinguished name (DN) of a daily replication schedule entry for Monday.
	Example:
	ibm-scheduleMonday: cn=monday,o=ibm
	bm-scheduleTuesday
	Specifies the distinguished name (DN) of a daily replication schedule entry for Tuesday.
	ibm-scheduleTuesday: cn=tuesday,o=ibm

Ι	Table 37. ibm-replicationWeeklySchedule objectclass schema definition (optional attributes) (continued)
Ι	Attribute description and example
Ι	ibm-scheduleWednesday
I	Specifies the distinguished name (DN) of a daily replication schedule entry for Wednesday.
Ι	Example:
Ι	ibm-scheduleWednesday: cn=wednesday,o=ibm
Ι	ibm-scheduleThursday
I	Specifies the distinguished name (DN) of a daily replication schedule entry for Thursday.
 	Example: ibm-scheduleThursday: cn=thursday,o=ibm
Ι	ibm-scheduleFriday
I	Specifies the distinguished name (DN) of a daily replication schedule entry for Friday.
 	Example: ibm-scheduleFriday: cn=friday,o=ibm
' 	ibm-scheduleSaturday
' I	Specifies the distinguished name (DN) of a daily replication schedule entry for Saturday.
I	Example:
I	ibm-scheduleSaturday: cn=saturday,o=ibm
Ι	ibm-scheduleSunday
Ι	Specifies the distinguished name (DN) of a daily replication schedule entry for Sunday.
Ι	Example:
' I	ibm-scheduleSunday: cn=sunday,o=ibm
Ι	
     	A daily replication schedule entry has an object class of <b>ibm-</b> <b>replicationDailySchedule</b> . For the schema definition of the <b>ibm-</b> <b>replicationDailySchedule</b> objectclass, see Table 38. A daily replication schedule entry allows an LDAP administrator to accomplish the following replication scheduling:
   	<ul> <li>Configure the time each day to start advanced replication for that replication agreement. This is accomplished by using the multi-valued ibm- replicationImmediateStart attribute.</li> </ul>
   	<ul> <li>Allows replication to be turned off by specifying a batch time. This drains the replication queue and replication waits until the next scheduled time once the queue is fully drained. This is done by using the multi-valued ibm-replicationBatchStart attribute.</li> </ul>
Ι	<ul> <li>Advanced replication can be turned on and off multiple times each day.</li> </ul>
I	Table 38. ibm-replicationDailySchedule objectclass schema definition (optional attributes)
Ι	Attribute description and example
Ι	cn
I	Common name of the daily schedule entry. This attribute does not affect advanced replication configuration.
Ι	Example:
L	cn: mydaily

I	Table 38. ibm-replicationDailySchedule objectclass schema definition (optional attributes) (continued)
I	Attribute description and example
Ι	description
 	Provides an additional text field for extra information pertaining to the daily schedule entry. This attribute does not affect advanced replication configuration.
I	Example:
 	description: Each day stops replication at 6:30 AM and then restarts at 9:45 AM and continues for the rest of the day until 6:30 AM the following day.
I	ibm-replDailySchedName
I	Descriptive name for the daily schedule entry. This attribute does not affect advanced replication configuration.
I	Example:
I	ibm-replDailySchedName: Daily schedule for replication agreement 1
Ι	ibm-replicationBatchStart
 	A multi-valued attribute that indicates the time batch replication starts. All updates in the replication queue are replicated at the time specified and then replication waits until the next scheduled time.
	<b>Note:</b> If advanced replication is waiting, it is not allowed to be resumed with either a <b>Cascading control replication</b> extended operation or a <b>Control replication</b> extended operation. However, "replicate now" on a <b>Control replication</b> extended operation can be used to immediately drain the replication queue if replication is waiting. For more information about the <b>Cascading control replication</b> extended operation, see "Cascading control replication" on page 348. For more information about the <b>Control replication</b> extended operation, see "Control replication" on page 352.
I	The attribute value format is: Thhmmss
   	where: hh - Hour based on a 24 hour clock (00 – 23) mm - Minutes (00-59) ss - Seconds (00-59)
I	Example:
I	ibm-replicationBatchStart: T063000
	This value indicates that queued replication updates are replicated at 6:30 AM until the replication queue is drained; then replication waits.

Table 38. ibm-replicationDailySchedule objectclass schema definition (optional attributes) (continued) L L Attribute description and example ibm-replicationImmediateStart L A multi-valued attribute that indicates when advanced replication immediately starts and continues until the next L ibm-replicationBatchStart attribute value or replication is otherwise suspended. L L Advanced replication is allowed to be suspended or resumed with a Cascading control replication extended operation or a **Control replication** extended operation. For more information about the **Cascading control** Т L replication extended operation, see "Cascading control replication" on page 348. For more information about the Control replication extended operation, see "Control replication" on page 352. L L The attribute value format is: Thhmmss where: L hh - Hour based on a 24 hour clock (00 - 23)L mm - Minutes (00-59) L L ss - Seconds (00-59) L Example: L ibm-replicationImmediateStart: T094500 L This value indicates that replication starts at 9:45 AM. L ibm-replicationTimesUTC L A boolean (true or false) indicating whether the time values specified in the **ibm-replicationBatchStart** and L ibm-replicationImmediateStart attributes are in GMT or local time. If set to true, GMT is used for time values. If set to false, or the attribute is not specified, local time is used for time values. L Example: I ibm-replicationTimesUTC: true I Assuming that each daily schedule in the weekly schedule entry uses the examples in Table 38 on page 201, advanced replication occurs daily as follows: Because an ibm-replicationBatchStart attribute value of T06300 is specified, the • replication queue is drained and replication waits at 6:30 AM each day. All future replication updates are queued. • At 9:30 AM each day, advanced replication restarts because an ibm-replicationImmediateStart attribute value has been specified. Replication immediately starts and continues until the next day at 6:30 AM. When the LDAP server starts and there is a weekly replication schedule entry configured, advanced replication inherits the state of the most recent ibm-replicationBatchStart or ibm-replicationImmediate time. If the weekly schedule examples are used in Table 38 on page 201 and the LDAP server starts at 7:00 AM, replication is suspended until 9:30 AM when the next ibm-replicationImmediate time is encountered. This processing occurs even if there is a missing daily schedule in the weekly schedule entry. T T Consumer server entries I If the consumer server is a read only replica server, the only required replication 

If the consumer server is a read only replica server, the only required replication related entry is the consumer server credentials entry. If the consumer server is a peer or forwarding server, a replica subentry and a consumer server credentials entry are required. The consumer server credentials entry must reside under the **cn=configuration** suffix in the CDBM backend.

1

I

L

   	<b>Note:</b> The consumer server credentials entry differs from the supplier server credentials entry. For more information about the supplier server credentials entry, see "Credentials entries" on page 198.
	The consumer server credentials entry is used on the consumer server to verify that it is actually a supplier server performing a simple or SASL EXTERNAL bind. A consumer server only accepts update operations from its supplier server and the LDAP administrator when using the <b>Server Administration</b> control. There are two types of consumer server credential entries that can be used, one that has an objectclass of <b>ibm-slapdReplication</b> and the other has an objectclass of <b>ibm-slapdSupplier</b> .
	When a supplier server replicates updates to its consumer server, a special entry is used to indicate that the supplier server has master level access to the consumer server. Master level access bypasses ACL and entry owner restrictions and allows updates to be made even when the server is a read-only consumer, cascading consumer, or under a quiesced replication context. If the supplier server authenticates to the consumer server with a simple bind, the DN specified by the <b>replicaBindDN</b> attribute value in the replication agreement entry is used as the bind DN. If the supplier server authenticates to the consumer server with a SASL EXTERNAL bind, the bind DN is extracted from the SSL certificate.
	If the <b>ibm-slapdMasterDN</b> attribute value in an <b>ibm-slapdReplication</b> entry matches the bind DN, the supplier server (or user) is allowed master level access to all replication contexts. If the <b>ibm-slapdMasterDN</b> attribute value in an <b>ibm-slapdSupplier</b> entry matches the bind DN, the supplier server (or user) is only allowed master level access to the replication contexts indicated by the multi-valued <b>ibm-replicaSubtree</b> attribute value.
	<b>Note:</b> The consumer server credentials entry must be present on both the consumer and supplier servers and reside under the <b>cn=configuration</b> suffix in the CDBM backend. The topology entries are the only way for the servers to know their roles in the topology as a whole, therefore, are needed on all the servers in the topology.
I	Table 39. ibm-slapdReplication objectclass schema definition (required and optional attributes)
	Attribute description and example
' 1	A required attribute that specifies the common name of the consumer server credentials entry.
1	Example:
	cn: master server
Ι	ibm-slapdMasterDN
Ι	Specifies the distinguished name (DN) that the supplier server uses to authenticate with the consumer server.
   	If the supplier server authenticates to the consumer server with a simple bind, this value matches the <b>replicaBindDN</b> attribute value in the simple bind supplier server credentials entry used by the replication agreement entry. If the supplier server authenticates to the consumer server with a SASL EXTERNAL bind, this value matches the bind DN extracted from the SSL certificate.
Ι	Example:
Ι	<pre>ibm-slapdMasterDN: cn=supplier,cn=localhost</pre>

	Table 39. ibm-slapdReplica	ation objectclass	s schema definition	(required and o	optional attributes)	(continued)
	Table 00. Ion Stapanephot	unon objecticiase		(icquired and c		(continucu)

I	Attribute description and example
Ι	ibm-slapdMasterPW
   	Contains the simple bind authentication information needed for the replicating server to authenticate with the consumer server using the <b>ibm-slapdMasterDN</b> . This password value matches the <b>replicaCredentials</b> attribute value in the simple bind supplier server credentials entry used by the replication agreement entry.
   	This password value is encrypted if it is added or modified when the <b>secretEncryption</b> configuration option is set to <b>AES</b> or <b>DES</b> in the CDBM backend. If <b>secretEncryption</b> is set to <b>AES</b> or <b>DES</b> , directory security improves because the password is no longer stored in the directory in clear text.
I	If a SASL EXTERNAL bind is used, this attribute value is not specified.
 	<b>Note:</b> This value is only used if the entry specified in the <b>ibm-slapdMasterDN</b> attribute value does not reside under a configured suffix in the LDAP server.
	Example: ibm-slapdMasterPW: secret
I	ibm-slapdMasterReferral
 	A single valued attribute that contains the LDAP URL of the supplier server. The LDAP URL syntax is documented in RFC 2255: The LDAP URL Format.
 	If an update operation is done by a user other than the supplier server or the LDAP administrator with <b>Server Administration</b> control, this value is returned as one of the referral values.
Ι	For more information about referrals with advanced replication, see "Replication topology hints and tips" on page 230.
Ι	Example:
Ι	ibm-slapdMasterReferral: ldap://master1.ibm.com:500
Ι	ibm-slapdNoRepIConflictResolution
   	A boolean (true or false) indicating whether the consumer server participates in replication conflict resolution. If set to true, the consumer server does not participate in conflict resolution. If set to false, or the attribute is not specified, the consumer server does participate in conflict resolution.
   	Conflict resolution is used to attempt automatically to resolve conflicts with entries that are no longer synchronized between a supplier and consumer server. The <b>modifyTimestamp</b> attribute value of the entry is used to detect a conflict between the two servers.
Ι	Example:
	ibm-slapdNoReplConflictResolution: true
     	For the examples in Table 39 on page 204, the supplier server located at master1.ibm.com on non-secure port 500 does a simple bind to the consumer server by binding with the cn=supplier,cn=localhost entry and specifying a password of secret. The consumer server is not configured for conflict resolution.
I	Table 40. ibm-slapdSupplier objectclass schema definition (required and optional attributes)
Ι	Attribute description and example
Ι	cn
I	A required attribute that specifies the common name of the consumer server credentials entry.
Ι	Example:
I	cn: master server

I	Table 40. ibm-slapdSupplier objectclass schema definition (required and optional attributes) (continued)
I	Attribute description and example
I	ibm-slapdMasterDN
I	Specifies the distinguished name (DN) that the supplier server uses to authenticate with the consumer server.
 	If the supplier server authenticates to the consumer server with a simple bind, this value matches the <b>replicaBindDN</b> attribute value in the simple bind supplier server credentials entry used by the replication agreement entry.
 	If the supplier server authenticates to the consumer server with a SASL EXTERNAL bind, this value matches the bind DN extracted from the SSL certificate.
I	Example:
I	<pre>ibm-slapdMasterDN: cn=supplier,cn=localhost</pre>
I	ibm-slapdMasterPW
   	Contains the simple bind authentication information needed for the replicating server to authenticate with the consumer server using the <b>ibm-slapdMasterDN</b> . This password value matches the <b>replicaCredentials</b> attribute value in the simple bind supplier server credentials entry used by the replication agreement entry.
   	This password value is encrypted if it is added or modified when the <b>secretEncryption</b> configuration option is set to <b>AES</b> or <b>DES</b> in the CDBM backend. If <b>secretEncryption</b> is set to <b>AES</b> or <b>DES</b> , directory security improves because the password is no longer stored in the directory in clear text.
I	If a SASL EXTERNAL bind is used, this attribute value is not specified.
 	<b>Note:</b> This value is only used if the entry specified in the <b>ibm-slapdMasterDN</b> attribute value does not reside under a configured suffix in the LDAP server.
I	Example:
I	ibm-slapdMasterPW: secret
I	ibm-slapdReplicaSubtree
 	A multi-valued attribute that specifies the distinguished names of replication contexts that are subject to this consumer server credentials entry.
I	The bound user has master server level access to the replication contexts that are specified for this attribute.
I	Example:
I	<pre>ibm-slapdReplicaSubtree: o=ibm</pre>
I	
	For the examples in Table 40 on page 205, when the supplier server replicates updates to the o=ibm replication context on the consumer server, the supplier server performs a simple bind using the cn=supplier,cn=localhost entry and specifying a password of secret.
I	Things to consider before configuring advanced replication
I	Before setting up an advanced replication configuration, there are some

Before setting up an advanced replication configuration, there are some administrative responsibilities that must be considered. In order to ensure that replication is operating smoothly and that your replicas are staying up-to-date, the administrator needs to take some periodic actions to monitor the replication status. After advanced replication is correctly configured, it continues to automatically propagate updates to all defined replica servers. However, if errors occur, human intervention might be required to fully correct the problem.

Detailed status and error information is available to the LDAP administrator by querying the operational attributes in the replication agreement entries. For a

T

T

T

T

T

T

Т

T

description of the information available, see "Monitoring and diagnosing advanced replication problems" on page 240. Configuring multiple master servers adds to the potential error cases that an LDAP administrator must be aware of. If the same entry is updated at two different master servers at approximately the same time, those updates are likely to conflict when they are replicated to other servers in the advanced replication topology. The advanced replication conflict resolution support is designed to detect and resolve conflicts that might occur. For more information about replication conflict resolution, see "Replication conflict resolution" on page 191.

Consider the following when planning an advanced replication environment:

- Determine if an existing Directory Information Tree (DIT) subtree is to be introduced into a replication topology or if a new subtree is to be added to the server after the replication topology is established. It is suggested that all servers that serve as a supplier server are put into maintenance mode until the replication topology entries are loaded on all servers. This ensures that external updates to the subtree are not lost while configuring advanced replication. For more information, see "Advanced replication maintenance mode" on page 233.
  - a. If using an existing subtree for advanced replication:

Т

L

L

L

- Modify the subtree to add the auxiliary objectclass ibmreplicationContext. If the ibm-replicationContext auxiliary objectclass is added to a non-suffix level entry in the directory, explicit aclEntry and entryOwner attribute values are required. The entryOwner attribute value must start with an access-id:.
- 2) Unload the entire subtree to an LDIF file by using the DS2LDIF utility. For additional information about the DS2LDIF utility, see "DS2LDIF (ds2ldif utility)" in *z/VM: TCP/IP Planning and Customization*).
- 3) For each server participating in the replication topology, add the unloaded entries to the server by using the LDAPADD utility. For more information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.
- b. If using a new subtree for advanced replication, verify that the subtree has an auxiliary objectclass of **ibm-replicationContext**. For each server participating in the replication topology, add the same entries to all servers by using the LDAPADD utility. For more information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.
- 2. For each consumer server in the replication topology, load master bind and referral information under the cn=configuration suffix in the CDBM backend. Consumer server credential entries with an objectclass of ibm-slapdSupplier or ibm-slapdReplication must be added. If using a consumer server credentials entry with an objectclass of ibm-slapdSupplier, the replication context must be added to the ibm-slapdReplicaSubtree attribute value. For more information, see "Consumer server entries" on page 211.
- 3. For each supplier server in the replication topology, supplier server credential entries must be added for each unique consumer server in the replication context. A supplier server credential entry enables the supplier server to authenticate with the consumer server by using a simple or SASL EXTERNAL bind. If the objectclass of the supplier server credentials entry is **ibm-replicationCredentialsSimple**, a simple bind is used. If the objectclass of the supplier server credentials entry is **ibm-replicationCredentials** entry is **ibm-replicationCredentials**.
- **Note:** There are no requirements for placing supplier server credential entries within a specific subtree. If supplier server credential entries are not

       	replicated, use the <b>cn=localhost</b> subtree that does not allow the replication of entries. If supplier server credential entries are replicated outside the scope of the replication context being configured, consider using the <b>cn=ibmpolicies</b> subtree. When the <b>cn=ibmpolicies</b> subtree is configured for advanced replication, schema modifications are also replicated. For more information about schema replication, see "Replication of schema and password policy updates" on page 231.		
і Т	he following steps are used to deploy the replication topology on all servers:		
	. On a supplier server in the topology, use the LDAPADD utility with the <b>Server</b> <b>Administration</b> and the <b>Do Not Replicate</b> controls to add the replication topology entries. The replication topology entries are the following:		
	<ul> <li>Replication context with an objectclass of ibm-replicationContext. For more information, see "Replication contexts" on page 193.</li> </ul>		
	<ul> <li>Replica group with an objectclass of <b>ibm-replicaGroup</b>. For more information, see "Replica groups" on page 194.</li> </ul>		
 	<ul> <li>Replica subentry with an objectclass of <b>ibm-replicaSubentry</b>. For more information, see "Replica subentries" on page 194.</li> </ul>		
 	<ul> <li>Replication agreement with an objectclass of <b>ibm-replicationAgreement</b>.</li> <li>For more information, see "Replication agreements" on page 195.</li> </ul>		
2     	. On the replication context added in the previous step, use the <b>Replication topology</b> extended operation in the LDAPEXOP utility. This synchronizes all replication topology entries for each consumer server in the replication context. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .		
	When these steps are complete, the supplier servers are moved out of maintenance node.		
Advanced replication configuration examples			
l c	his topic provides examples of the different replication topologies that can be onfigured. It provides example LDIF data that includes the host names, IP ddresses, ports, server IDs, and passwords.		

## Suppliers and consumers

I

1

In advanced replication, updates are propagated from one LDAP server to another through a replication queue. The server that enters updates into the replication queue is called a supplier. The server that absorbs these changes is called the consumer. The queue is maintained on the supplier. • Host names and ports: Provide the supplier with enough information to connect to the consumer. • Server IDs: Strings that enable one LDAP server to identify other LDAP servers in the topology. Bind DNs and passwords: The supplier connects to the consumer using the • LDAP protocol. In LDAP terminology, this is called a bind. The bind requires a bind Distinguished Name (DN) and a password. The following examples demonstrate setup for a topology consisting of a maximum of three servers. Note: The host name of the consumer resolves correctly from the supplier. If not, the supplier cannot connect to the consumer and advanced replication fails.

Table 41. Topology setup

Server	Host name
Server 1	server1.us.ibm.com
Server 2	server2.us.ibm.com
Server 3	server3.us.ibm.com

Each LDAP server in Table 41 is listening on port 389, which is the default LDAP port.

These examples assume that a simple bind is being done from the supplier server to the consumer server. Each example assumes the following bind DN and password for all supplier-consumer agreements.

• **DN:** cn=bindtoconsumer

• **Password:** iamsupplier

In the examples, the server ID of each server is the role of that server in the topology. That is, in the Master-Replica topology, the master identifies the server ID as Master and the replica is identified as Replica. In the Peer-to-Peer topology, one peer is Peer1 and the other is Peer2. In the Master-Forwarder-Replica topology, the master is Master, the forwarder is Forwarder, and the replica is Replica. In the Gateway topology, the gateway servers are Gateway1 and the other is Gateway2 and the replica is Replica.

Do not change the server ID for a server. When the LDAP server is first configured with a CDBM backend, the server ID is generated as an IBM entry UUID value in the **ibm-slapdServerID** attribute value in the **cn=configuration** entry. For convenience, the server ID is published in the rootDSE entry's attribute **ibm-serverID**. The server ID is only allowed to be modified when there are no replica subentries defined in the server. For more information about the **ibm-slapdServerID** attribute value, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*.

## Advanced replication related entries summary

For convenience, this section quickly summarizes the various types of entries that are used to build an advanced replication topology.

#### Supplier server entries

• **Replication context:** This is the root entry for the subtree that is to be replicated. It must have an auxiliary objectclass of **ibm-replicationContext.** To replicate a subtree o=ibm,c=us, the replication context might be:

```
dn: o=ibm,c=us
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm
```

All other replication entries except for the credential and schedule entries must be under the replication context. The credential and schedule entries can be anywhere in the DIT. • **Replica group:** This entry is not important apart from the fact that all the advanced replication related entries exist under this entry. It must have the **ibm-replicaGroup** objectclass. For example:

```
dn: ibm-replicaGroup=default, o=ibm,c=us
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default
```

Т

Т

• **Replica subentry:** These types of entries declare the servers that are taking part in the advanced replication topology. Each server participating in the topology has one subentry. If a server is represented by more than one subentry under a replication context, unexpected behavior might result. This is done by having more than one subentry under a replication context containing the same **ibm-replicaServerID** attribute value. This entry has the **ibm-replicaSubentry** objectclass. For example:

```
dn: ibm-replicaServerId=Peer1,ibm-replicaGroup=default, o=ibm,c=us
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Peer1
ibm-replicationServerIsMaster: true
cn: Peer1
description: Peer1
```

As shown in the replica subentry example, the entry has the server ID of the participating server, Peer1. It has an attribute called **ibm-replicationServerIsMaster**. When this attribute is set to true, the server is a read-write copy.

• **Replication agreements:** These types of entries occur under replica subentries. When these entries appear under a specific server's replica subentry, they define a replication agreement from that server to some other server in the topology. For example:

```
dn: cn=Peer2, ibm-replicaServerId=Peer1,ibm-replicaGroup=default,o=ibm,c=us
objectclass: top
objectclass: ibm-replicationAgreement
cn: Peer2
ibm-replicaConsumerId: Peer2
ibm-replicaUrl: ldap://server2.us.ibm.com:389
ibm-replicaCredentialsDN: cn=Peer1BindCredentials, cn=localhost
description: Replication agreement from Peer1 to Peer2
```

The replication agreement example is from Peer1 to Peer2. The supplier is Peer1 as the agreement occurs under the subentry for Peer1. The consumer is Peer2. The server Peer2 is on server2.us.ibm.com and is listening on port 389. Peer1 binds to Peer2 using the credentials defined in the entry (cn=Peer1BindCredentials,cn=localhost).

Replication credentials: If a simple bind is used by the supplier server to authenticate with the consumer server, this entry defines the bind DN and password that is used. This credential entry uses the ibm-replicationCredentialsSimple objectclass. If a SASL EXTERNAL bind is used by the supplier server to authenticate with the consumer server, for information about the ibm-replicationCredentialsExternal objectclass, see "Credentials entries" on page 198. For example:

```
dn: cn=Peer1BindCredentials, cn=localhost
objectclass: ibm-replicationCredentialsSimple
cn: ReplicaBindCredentials
replicaBindDN: cn=bindtoconsumer
replicaCredentials: iamsupplier
description: Bind Credentials on Peer1 to be used to bind to other servers.
```

The replication credential example defines the **replicaBindDN** as cn=bindtoconsumer and the password as iamsupplier. Take note of the description. The same credentials entry can be used for multiple replication agreements.

#### **Consumer server entries**

If the consumer server is a read only replica server, the only required replication related entry is the consumer server credentials entry. If the consumer server is a peer or forwarding server, a replica subentry and a consumer server credentials entry are required. The consumer server credentials entry identifies the distinguished name and optionally the password value that the supplier server uses to authenticate with the consumer server. There are two types of credential entries that can be used on the consumer.

Type 1 example:

dn: cn=Master server,cn=configuration
objectclass: ibm-slapdReplication
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://localhost:1389

#### Type 2 example:

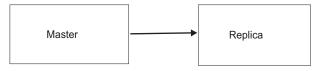

dn: cn=Supplier s1,cn=configuration
objectclass: ibm-slapdSupplier
cn: Supplier s1
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdReplicaSubtree: o=ibm,c=us

The use of the credential established by type 2 is limited to the **ibm-slapdReplicaSubtree** only. Therefore, suppliers binding with bind DN as cn=bindtoconsumer and password as iamsupplier supplies only to the o=ibm,c=us subtree, unless another credential entry gives rights to another subtree. The type 1 credential entry is global across the LDAP server. When a type 2 entry is defined in the **cn=configuration** suffix in the CDBM backend, any subtree can be supplied to if a supplier authenticates with bind DN of cn=bindtoconsumer and password of iamsupplier.

**Note:** The consumer server credentials entry must be present on both the consumer and supplier servers and reside under the **cn=configuration** suffix in the CDBM backend. The topology entries are the only way for the servers to know their roles in the topology as a whole, therefore, are needed on all the servers in the topology.

# Creating a master-replica topology

This example describes deploying the most basic of all the topologies, the master-replica topology. It has one read-write server and one read-only server.

- Figure 41. Master-replica topology
- The first step when building a topology is to define:

1. **Replication context:** o=ibm,c=us

Т

- Supplier(s): LDAP server on server1.us.ibm.com:389 is the only supplier. The server ID is Master. It supplies updates to the LDAP server on server2.us.ibm.com:389.
- 3. **Consumer(s):** LDAP server on server2.us.ibm.com:389 is the only consumer. The server ID is Replica. It consumes updates from the LDAP server on server1.us.ibm.com:389.
- 4. **Read-write server(s):** LDAP server on server1.us.ibm.com:389, with ID Master is the only read-write server.
- 5. **Read-only server(s):** LDAP server on server2.us.ibm.com:389, with ID Replica is the only read-only server.

**Configuration changes:** Because of these examples, some CDBM changes are needed for the master and the replica server for replication to work correctly.

**Note:** These are done here for this example ONLY. The server ID is only allowed to be modified when there are no replica subentries defined in the server. For more information about the **ibm-slapdServerID** attribute value, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*.

#### 1. Server IDs:

 On the master server, apply the following modify using the LDAPMDFY utility. For additional information about the LDAPMDFY utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Master

- On the replica server, apply the following modify:

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Replica

 Consumer server credentials entry: Add this entry to the replica server using the LDAPADD utility. For additional information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.For example:

```
dn: cn=Master server,cn=configuration
changetype: add
objectclass: ibm-slapdReplication
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server1.us.ibm.com:389
```

 The next step is to build the LDIF file for the topology. This LDIF file is called masterreplica.ldif. Copy each of these entries to masterreplica.ldif with the necessary changes in the subtree, server IDs, host names, and ports.

#### 1. Replication context:

 If the subtree entry exists, use the LDAPMDFY utility to modify the existing entry. For example:

dn: o=ibm,c=us
changetype: modify
add: objectclass
objectclass: ibm-replicationContext

 If the subtree entry does not exist, add the entry with the ibm-replicationContext auxiliary objectclass by using the LDAPADD utility. For example:

```
dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm
```

Т

|

1

I

I

I

I

T

Т

|

L

|

1

Т

I

L

|

L

Т

L

Т

|

2. Add the replica group entry using the LDAPADD utility. For example:

```
dn: ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default
```

3. **Replica subentries:** Because this topology is using a master and a read-only replica server, a replica subentry is only needed for the master server. Read-only replicas do not need a replica subentry. For example, for a subentry for the master:

dn: ibm-replicaServerId=Master,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Master
ibm-replicationServerIsMaster: true
cn: Master
description: Master server of the topology

Take note of the master subentry carefully. The subentry for the master uses the server ID Master and has the server declared as a master server. This server receives updates from clients.

- **Note:** The number of subentries is not dependent on the number of physical servers in the topology. Rather, it is dependent on the number and role of the LDAP servers in the topology.
- 4. **Supplier server credentials entry:** This step defines the credentials that the master uses to bind to the replica. Add an entry with the LDAPADD utility. For example:

dn: cn=ReplicaBindCredentials, o=ibm,c=us
changetype: add
objectclass: ibm-replicationCredentialsSimple
cn: ReplicaBindCredentials
replicaBindDN: cn=bindtoconsumer
replicaCredentials: iamsupplier
description: Bind Credentials on master to bind to replica

Note the DN and password are the same as the pair that was added in the consumer server credentials entry section above. Add the entry with the LDAPADD utility. As a result, updates to this object results in the server attempting to replicate.

5. Replication agreements: There is one supplier-consumer relationship in this advanced replication topology. The master supplies updates to the o=ibm, c=us subtree to the replica that consumes the changes. Therefore, there is only one agreement: From the master to the replica. Note the number of agreements is dependent upon the number of supplier-consumer relationships in the topology. For example:

dn: cn=Replica, ibm-replicaServerId=Master,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Replica
ibm-replicaConsumerId: Replica
ibm-replicaUrl: ldap://server2.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from master to replica

The entry above is under the subentry for the master. It supplies to a consumer with an ID as Replica. The replica URL is ldap:// server2.us.ibm.com:389 meaning that the replica is listening on server2.us.ibm.com on port 389. This agreement uses the credentials that were created in the last step for the master to bind to the replica. That means the master binds to the replica with a bind DN cn=bindtoconsumer and the password iamsupplier. Note there is no agreement under the subentry for the replica. This is natural as the replica is a read-only copy and cannot receive any client updates, therefore, there is no point in having an agreement, because there are no updates to propagate.

 Now that the replication entries have been added, the masterreplica.ldif file is as follows:

dn: o=ibm,c=us changetype: add objectclass: top objectclass: organization objectclass: ibm-replicationContext o: ibm dn: ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaGroup ibm-replicaGroup: default dn: ibm-replicaServerId=Master,ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaSubentry ibm-replicaServerId: Master ibm-replicationServerIsMaster: true cn: Master description: Master server of the topology. dn: cn=ReplicaBindCredentials. o=ibm.c=us changetype: add objectclass: ibm-replicationCredentialsSimple cn: ReplicaBindCredentials replicaBindDN: cn=bindtoconsumer replicaCredentials: iamsupplier description: Bind Credentials on master to bind to replica. dn: cn=Replica, ibm-replicaServerId=Master,ibm-replicaGroup=default,o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicationAgreement cn: Replica ibm-replicaConsumerId: Replica ibm-replicaUrl: ldap://server2.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from master to replica.

The LDIF is different if the replication context exists. Rather than:

dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm

I	it is:
   	dn: o=ibm,c=us changetype: modify add: objectclass
	objectclass: ibm-replicationContext
 	For the sake of simplicity, it is assumed that the subtree entry does not exist at all.
•	Next, add the <b>masterreplica.ldif</b> file on the master server. Use the LDAPADD utility on the master where the <b>masterreplica.ldif</b> file was created. For example:
	ldapadd -h server1.us.ibm.com -p 389 -D <i>adminDN</i> -w <i>adminPW</i> -f masterreplica.ldif -k -L
I	The -L option on the LDAPADD utility sends the <b>Do Not Replicate</b> control to the
1	server that indicates not to replicate the topology now. The <b>-k</b> option sends the
	Server Administration control to the server so that the addition of entries continues even when the subtree becomes read-only because of a server ID
	mismatch.
•	Next add the replication topology to the replica also. Use the LDAPEXOP utility. For example:
1	<pre>ldapexop -h server1.us.ibm.com -p 389 -D adminDN -w adminPW -op repltopology -rc o=ibm,c=us</pre>
I	This is an example of the Replication topology extended operation. It
1	propagates the advanced replication topology to all the consumers defined under the o=ibm,c=us replication context. For additional information about the
1	LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning</i>
	and Customization.
•	After the LDAPADD and LDAPEXOP commands are performed successfully, the master-replica topology is ready. The master accepts updates on the o=ibm,c=us
1	subtree and propagates them to the replica. The replica does not accept
l I	updates. It returns a referral to the master in case a client tries to update it, however, it can handle searches.
Creating a peer-	to-peer replication topology

The peer-to-peer replication topology does not differ much from the master-replica topology. It also has two servers, but, both the servers are now read-write servers. They both supply changes to each other.

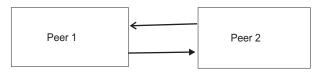

Figure 42. Peer-to-peer topology

I

L

I

T

Т

- The first step when building a topology is to define:
  - 1. **Replication context:** o=ibm,c=us
  - 2. **Supplier(s):** LDAP server on server1.us.ibm.com:389 with server ID Peer1 supplies updates to the LDAP server with server ID Peer2 on server2.us.ibm.com:389. LDAP server on server2.us.ibm.com:389 with server ID Peer2 supplies updates to the LDAP server with server ID Peer1 on server1.us.ibm.com:389.
  - 3. Consumer(s): LDAP server with server ID Peer2 on server2.us.ibm.com: 389 consumes updates from LDAP server with server ID Peer1 on

server1.us.ibm.com:389. LDAP server with Server ID Peer1 on server1.us.ibm.com:389 consumes updates from LDAP server with server ID Peer2 on server2.us.ibm.com:389.

- 4. **Read-write server(s):** LDAP servers Peer1 and Peer2 on server1.us.ibm.com and server2.us.ibm.com are read-write servers.
- 5. Read-only server(s): There are no read-only servers in this topology.

**Configuration changes:** Some CDBM changes need to be done to both the Peer1 and Peer2 servers for replication to work correctly. Configured servers are current. If you are using the same servers that you used for the Master-Replica setup, undo the changes that you made in "Creating a master-replica topology" on page 211.

- **Note:** These are done here for this example only. The server ID is only allowed to be modified when there are no replica subentries defined in the server. For more information about the **ibm-slapdServerID** attribute value, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization.*
- 1. Server IDs:

Т

Т

 On the Peer1 server (server1.us.ibm.com), apply the following modify using the LDAPMDFY utility. For additional information about the LDAPMDFY utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP* User's Guide.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Peer1

 On the Peer2 server (server2.us.ibm.com), apply the following modify using the LDAPMDFY utility.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Peer2

2. **Consumer server credentials entry:** Add this first entry to the Peer1 server and the second entry to the Peer2 server using the LDAPADD utility. For additional information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.

# **Note:** An alternative is to add entries with an **ibm-slapdSupplier** objectclass. Also, each peer uses the other peer as the referral. This is useful if a peer must become a read only replica or a forwarding server.

For example, for a consumer side credentials entry for the Peer1:

dn: cn=Master server,cn=configuration
changetype: add
objectclass: ibm-slapdReplication
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server2.us.ibm.com:389

For example, for a credential subentry for the Peer2:

dn: cn=Master server,cn=configuration
changetype: add
objectclass: ibm-slapdReplication
cn: master server

```
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server1.us.ibm.com:389
```

- The next step is to build the LDIF file for the replication topology. This LDIF file is called **peer2peer.Idif**. Copy each of these entries to **peer2peer.Idif** with the necessary changes in the subtree, server IDs, host names, and ports.
  - 1. Replication context:

I

I

Т

L

 If the subtree entry exists, use the LDAPMDFY utility to modify the existing entry. For example:

```
dn: o=ibm,c=us
changetype: modify
add: objectclass
objectclass: ibm-replicationContext
```

 If the subtree entry does not exist, add the entry with the ibm-replicationContext auxiliary objectclass by using the LDAPADD utility. For example:

```
dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm
```

2. Add the replica group entry using the LDAPADD utility. For example:

dn: ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default

3. **Replica subentries:** Because there are two LDAP servers in the topology, you need to add two replica subentries; one for Peer1 and another one for the Peer2 server by using the LDAPADD utility. For example, for a subentry for Peer1:

dn: ibm-replicaServerId=Peer1,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Peer1
ibm-replicationServerIsMaster: true
cn: Peer1
description: Subentry for Peer1

For example, for a subentry for Peer2:

```
dn: ibm-replicaServerId=Peer2,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Peer2
ibm-replicationServerIsMaster: true
cn: Peer2
description: Subentry for Peer2
```

The subentry for Peer1 identifies the server ID as Peer1 and has the server declared as a master server. The server can receive updates from clients. The subentry for the Peer2 identifies the server ID as Peer2, and it also has the server declared as a master server. This server can also receive updates from LDAP clients that bind to it.

4. **Supplier server credentials entry:** This step defines the credentials that Peer1 and Peer2 use to bind to each other. Add the entry with the LDAPADD utility. For example:

dn: cn=ReplicaBindCredentials, o=ibm,c=us
changetype: add
objectclass: ibm-replicationCredentialsSimple
cn: ReplicaBindCredentials
replicaBindDN: cn=bindtoconsumer
replicaCredentials: iamsupplier
description: Bind Credentials on Peer1 and Peer2 to bind to each other.

- 5. **Replication agreements:** There are two supplier-consumer relationships in this topology. Peer1 supplies updates made to the o=ibm,c=us subtree to Peer2, that consumes the changes. Peer2 also accepts updates from clients on the o=ibm,c=us subtree and sends them to Peer1, that consumes the changes. Therefore, there are two agreements:
  - a. from Peer1 to Peer2

b. from Peer2 to Peer1

**Note:** The number of agreements is dependent upon the number of supplier-consumer relationships in the topology.

For example, a replication agreement from Peer1 to Peer2:

dn: cn=Peer2, ibm-replicaServerId=Peer1,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Peer2
ibm-replicaConsumerId: Peer2
ibm-replicaUrl: ldap://server2.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Peer1 to Peer2

For example, a replication agreement from Peer2 to Peer1:

```
dn: cn=Peer1, ibm-replicaServerId=Peer2,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Peer1
ibm-replicaConsumerId: Peer1
ibm-replicaUrl: ldap://server1.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Peer2 to Peer1
```

The two agreements for this topology are shown above. The first one is the agreement from Peer1 to Peer2. It is under the Peer1 subentry. The second one is from Peer2 to Peer1 and it is under the Peer2 subentry. Note the use of the same credentials entry for both agreements. This is acceptable. The credentials entry is added to both Peer1 and Peer2.

 Now that the replication entries have been added, the peer2peer.ldif file is as follows:

```
dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm
dn: ibm-replicaGroup=default. o=ibm.c=us
changetype: add
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default
dn: ibm-replicaServerId=Peer1,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Peer1
```

1	ihm und institut Commute Markey, kuns
	ibm-replicationServerIsMaster: true cn: Peerl
	description: Subentry for Peer1.
	<pre>dn: ibm-replicaServerId=Peer2,ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaSubentry ibm-replicaServerId: Peer2 ibm-replicationServerIsMaster: true</pre>
	cn: Peer2
	description: Subentry for Peer2.
	<pre>dn: cn=ReplicaBindCredentials, o=ibm,c=us changetype: add objectclass: ibm-replicationCredentialsSimple cn: ReplicaBindCredentials replicaBindDN: cn=bindtoconsumer replicaCredentials: iamsupplier description: Bind Credentials on Peer1 and Peer2 to bind to each other.</pre>
	dn: cn=Peer2, ibm-replicaServerId=Peer1,ibm-replicaGroup=default,o=ibm,c=us
	changetype: add objectclass: top objectclass: ibm-replicationAgreement
	cn: Peer2 ibm-replicaConsumerId: Peer2
	ibm-replicaUrl: ldap://server2.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
	description: Replication agreement from Peer1 to Peer2.
	dn: cn=Peer1, ibm-replicaServerId=Peer2,ibm-replicaGroup=default,o=ibm,c=us changetype: add
	objectclass: top objectclass: ibm-replicationAgreement cn: Peer1
	ibm-replicaConsumerId: Peerl
	ibm-replicaUrl: ldap://serverl.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Peer2 to Peer1
•	Next, add the <b>peer2peer.Idif</b> file on the Peer1 server. Use the LDAPADD utility on the Peer1 where the <b>peer2peer.Idif</b> file was created. For example:
I	ldapadd -h server1.us.ibm.com -p 389 -D <i>adminDN</i> -w <i>adminPW</i> -f peer2peer.ldif -k -L
	The <b>–L</b> option on the LDAPADD utility sends the <b>Do Not Replicate</b> control to the server that indicates not to replicate the topology now. The <b>-k</b> option sends the <b>Server Administration</b> control to the server so that the addition of entries continues even when the subtree becomes read-only because of a server ID mismatch.
•	Next add the replication topology to the Peer2 also. Use the LDAPEXOP utility.
	For example:
1	<pre>ldapexop -h server1.us.ibm.com -p 389 -D adminDN -w adminPW -op repltopology -rc o=ibm,c=us</pre>
     	This is an example of the <b>Replication topology</b> extended operation. It propagates the advanced replication topology to all the consumers defined under the o=ibm,c=us replication context. For additional information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .
• •	After the LDAPADD and LDAPEXOP commands are performed successfully, the peer-to-peer topology is ready. Both peers accept updates on and send them to the other peer.
⊢ Creating a maet	er-forwarder-replica (cascading) topology
-	
	nother advanced replication topology is the master-forwarder-replica or cascading eplication topology.

I L

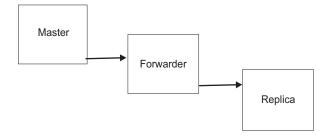

Figure 43. Master-forwarder-replica topology

The forwarder server is a specialized replica server. As previously stated, replica servers are read-only as is a forwarder server. Replica servers do not transmit changes that are consumed by them. However, forwarder servers replicate changes that they have consumed. To supply changes further down the topology, forwarders have agreements under their subentries.

**Note:** Gateway replication topologies are similar, however, forwarders are specialized replicas while gateways are specialized masters.

This topology needs to have one more server included: server3.us.ibm.com

- The first step when building a topology is to define:
  - 1. Replication context: o=ibm,c=us
  - Supplier(s): LDAP server on server1.us.ibm.com:389 with server ID Master supplies updates to the LDAP server with server ID Forwarder on server2.us.ibm.com:389. LDAP server on server2.us.ibm.com:389 with server ID Forwarder supplies updates to the LDAP server with server ID Replica on server3.us.ibm.com:389.
  - Consumer(s): LDAP server with server ID Forwarder on server2.us.ibm.com:389 consumes updates from LDAP server with server ID Master working on server1.us.ibm.com:389. LDAP server with server ID Replica on server3.us.ibm.com:389 consumes updates from the LDAP server with server ID Forwarder working on server2.us.ibm.com:389.
  - 4. **Read-write server(s):** LDAP server on server1.us.ibm.com:389, with ID Master is the only read-write server.
  - 5. **Read-only server(s):** LDAP server on server1.us.ibm.com:389, with IDs, Forwarder and Replica are read-only.

**Configuration changes:** Some configuration changes need to be made to the Master, Forwarder, and Replica servers for replication to work correctly. Configured servers are current. If reusing the same servers that were used for the Master-Replica setup, undo the changes that were made in "Creating a master-replica topology" on page 211. If reusing the same servers that were used for the Peer-Peer setup, undo the changes that were made in "Creating a peer-to-peer replication topology" on page 215.

- **Note:** These are done here for this example only. The server ID is only allowed to be modified when there are no replica subentries defined in the server. For more information about the **ibm-slapdServerID** attribute value, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*.
- 1. Server IDs:

 On the Master server (server1.us.ibm.com), apply the following modify using the LDAPMDFY utility. For additional information about the LDAPMDFY utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP* User's Guide.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Master

L

Т

L

 On the Forwarder server (server2.us.ibm.com), apply the following modify using the LDAPMDFY utility.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Forwarder

 On the Replica server (server3.us.ibm.com), apply the following modify using the LDAPMDFY utility.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Replica

2. **Consumer server credentials entry:** Add this first entry to the Forwarder server and the second entry to the Replica server using the LDAPADD utility. For additional information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide*.

Note: An alternative is to add entries with an **ibm-slapdSupplier** objectclass.

For example, for a consumer server credentials entry for the Forwarder:

dn: cn=Master server,cn=configuration
changetype: add
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server1.us.ibm.com:389
objectclass: ibm-slapdReplication

For example, for a consumer server credentials entry for the Replica:

dn: cn=Master server,cn=configuration
changetype: add
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server1.us.ibm.com:389
objectclass: ibm-slapdReplication

- The next step is to build the LDIF file for the replication topology. This LDIF file is called **mfr.ldif**. Copy each of these entries to **mfr.ldif** with the necessary changes in the subtree, server IDs, host names, and ports.
  - 1. Replication context:
    - If the subtree entry exists, use the LDAPMDFY utility to modify the existing entry. For example:

dn: o=ibm,c=us
changetype: modify
add: objectclass
objectclass: ibm-replicationContext

 If the subtree entry does not exist, add the entry with the ibm-replicationContext auxiliary objectclass by using the LDAPADD utility. For example:

```
dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm
```

2. Add the replica group entry using the LDAPADD utility. For example:

dn: ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default

3. **Replica subentries:** Because this topology is using a master, a forwarding, and a read-only replica server, replica subentries are only needed for the Master and for the Forwarder servers. The read-only Replica server does not need a replica subentry. The following entries can be added using the LDAPADD utility.

For example, for a subentry for Master:

dn: ibm-replicaServerId=Master,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Master
ibm-replicationServerIsMaster: true
cn: Master
description: Subentry for Master

For example, for a subentry for Forwarder:

dn: ibm-replicaServerId=Forwarder,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
ibm-replicaServerId: Forwarder
ibm-replicationServerIsMaster: false
cn: Forwarder
description: Subentry for the Forwarder

The subentry for Master identifies the server ID as Master and has the server declared as a master server. The server can receive updates from clients. The subentry for the Forwarder identifies the server ID as Forwarder, and is declared as a non-master server. It cannot get updates from clients.

4. **Supplier server credentials entry:** This step defines the credentials that the Master uses to bind to the Forwarder. Add the entry with the LDAPADD utility. For example:

```
dn: cn=ReplicaBindCredentials, o=ibm,c=us
changetype: add
objectclass: ibm-replicationCredentialsSimple
cn: ReplicaBindCredentials
replicaBindDN: cn=bindtoconsumer
replicaCredentials: iamsupplier
description: Bind Credentials on master to bind to forwarder
```

- 5. **Replication agreements:** There are two supplier-consumer relationships in this topology. Master supplies updates made to the o=ibm,c=us subtree to Forwarder, that consumes the changes and then supplies these changes to the Replica. Therefore, there are two agreements:
  - a. from Master to Forwarder
  - b. from Forwarder to Replica

Т

I

Т

# **Note:** The number of replication agreements is dependent upon the number of supplier-consumer relationships in the topology.

For example, a replication agreement from Master to Forwarder:

1

1

dn: cn=Forwarder, ibm-replicaServerId=Master,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Forwarder
ibm-replicaConsumerId: Forwarder
ibm-replicaUrl: ldap://server2.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Master to Forwarder

#### For example, a replication agreement from Forwarder to Replica:

dn: cn=Replica, ibm-replicaServerId=Forwarder,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Replica
ibm-replicaConsumerId: Replica
ibm-replicaConsumerId: Replica
ibm-replicaUrl: ldap://server3.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Forwarder to Replica

The two agreements for this topology are shown above. The first one is the agreement from Master to Forwarder. It is under the Master subentry. The second one is from Forwarder to Replica and it is under the Forwarder subentry. Note the use of the same credentials entry for both agreements. This is acceptable. The consumer server credentials entry is added to both Master and Forwarder servers.

Now that the replication entries have been added, the mfr.ldif file is as follows:

dn: o=ibm,c=us changetype: add objectclass: top objectclass: organization objectclass: ibm-replicationContext o: ibm dn: ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaGroup ibm-replicaGroup: default dn: ibm-replicaServerId=Master,ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaSubentry ibm-replicaServerId: Master ibm-replicationServerIsMaster: true cn: Master description: Subentry for Master. dn: ibm-replicaServerId=Forwarder, ibm-replicaGroup=default, o=ibm, c=us changetype: add

changetype: add objectclass: top objectclass: ibm-replicaSubentry ibm-replicaServerId: Forwarder ibm-replicationServerIsMaster: false cn: Forwarder description: Subentry for the Forwarder. dn: cn=ReplicaBindCredentials, o=ibm,c=us

changetype: add objectclass: ibm-replicationCredentialsSimple cn: ReplicaBindCredentials replicaBindDN: cn=bindtoconsumer replicaCredentials: iamsupplier description: Bind Credentials on master to bind to forwarder.

dn: cn=Forwarder, ibm-replicaServerId=Master,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top

	objectclass: ibm-replicationAgreement cn: Forwarder ibm-replicaConsumerId: Forwarder ibm-replicaUrl: ldap://server2.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Master to Forwarder
	<pre>dn: cn=Replica, ibm-replicaServerId=Forwarder,ibm-replicaGroup=default,o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicationAgreement cn: Replica ibm-replicaConsumerId: Replica ibm-replicaUrl: ldap://server3.us.ibm.com:389 ibm-replicaCredentialSDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Forwarder to Replica</pre>
•	Next, add the <b>mfr.ldif</b> file on the Master server. Use the LDAPADD utility on the Master where the <b>mfr.ldif</b> file was created. For example:
1	ldapadd -h server1.us.ibm.com -p 389 -D <i>adminDN -</i> w <i>adminPW</i> -f mfr.ldif -k -L
•	Next, add the <b>mfr.ldif</b> file on the Forwarder server. Use the LDAPADD utility on the Master server and target the Forwarder server. For example:
l	ldapadd -h server2.us.ibm.com -p 389 -D <i>adminDN -w adminPW</i> -f mfr.ldif -k -L
     	The <b>-L</b> option on the LDAPADD utility sends the <b>Do Not Replicate</b> control to the server that indicates not to replicate the topology now. The <b>-k</b> option sends the <b>Server Administration</b> control to the server so that the addition of entries continues even when the subtree becomes read-only because of a server ID mismatch.
•	Next, add the replication topology to the Replica also. Use the LDAPEXOP utility. For example:
	ldapexop -h server2.us.ibm.com -p 389 -D <i>adminDN -w adminPW</i> -op repltopology -rc o=ibm,c=us
     	This is an example of the <b>Replication topology</b> extended operation. It propagates the advanced replication topology to the Replica defined under the o=ibm,c=us replication context. For additional information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .
• • •	After the LDAPADD and LDAPEXOP commands are performed successfully, the master-forwarder-replica topology is ready. The Master accepts updates, that go to the Forwarder and then to the Replica. If you intend to add another replica to the topology, under the forwarder, you need to add another subentry for the replica, and add an agreement from the forwarder to that replica.
Creating a gatew	vay topology
l Cr	gateway topology requires at least two gateway servers. Gateway topologies are reated in a similar manner to a master-forwarder-replica (cascading) topology. A ateway topology includes gateway master servers that forward all replication traffic

from the local replication site where it resides to other gateway servers in the replicating network. A gateway server also receives replication traffic from other gateway servers within the replication network and forwards updates to all servers on its local replication site.

Т

Т

L I

L

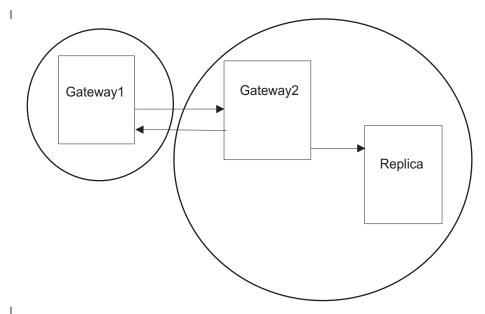

Figure 44. Gateway topology

1

T

1

1

T

T

L

In a gateway topology, gateway servers are distinguished from normal master servers by including the **ibm-replicaGateway** objectclass for the replica subentry in the replication context. As previously stated, a server is a master if the server ID in the replica subentry within the replication context equals the server's server ID and the subentry's **ibm-replicationServerIsMaster** attribute is set to true. For more information about replica subentries, see "Replica subentries" on page 194.

- The first step when building a topology is to define:
  - 1. Replication context: o=ibm,c=us
  - 2. **Supplier(s):** LDAP server on server1.us.ibm.com:389 with server ID Gateway1 supplies updates to the LDAP server with server ID Gateway2 on server2.us.ibm.com:389. LDAP server on server2.us.ibm.com:389 with server ID Gateway2 supplies updates to the LDAP server with server ID Gateway1 on server1.us.ibm.com:389 and to the LDAP server with server ID Replica on server3.us.ibm.com:389.
  - 3. Consumer(s): LDAP server with server ID Gateway2 on server2.us.ibm.com:389 consumes updates from LDAP server with server ID Gateway1 on server1.us.ibm.com:389. LDAP server with Server ID Gateway1 on server1.us.ibm.com:389 consumes updates from LDAP server with server ID Gateway2 on server2.us.ibm.com:389. LDAP server with server ID Replica on server3.us.ibm.com:389 consumes updates from LDAP server with server ID Gateway2 on server2.us.ibm.com:389.
  - 4. **Read-write server(s):** LDAP servers Gateway1 and Gateway2 on server1.us.ibm.com and server2.us.ibm.com are read-write servers.
  - 5. **Read-only server(s):** LDAP server Replica on server3.us.ibm.com is a read-only server.

**Configuration changes:** Some configuration changes need to be made to the Gateway1, Gateway2, and Replica servers for replication to work correctly. Configured servers should be current. If reusing the same servers that were used for the Master-Replica setup, undo the changes that were made in "Creating a master-replica topology" on page 211. If reusing the same servers that were used for the Peer-Peer setup, undo the changes that were made in "Creating a peer-to-peer replication topology" on page 215. If reusing the same servers that

were used for the Master-forwarder-replica setup, undo the changes that were made in "Creating a master-forwarder-replica (cascading) topology" on page 219.

- **Note:** These are done here for this example only. The server ID is only allowed to be modified when there are no replica subentries defined in the server. For more information about the **ibm-slapdServerID** attribute value, see "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization.*
- 1. Server IDs:

1

Т

 On the Gateway1 server (server1.us.ibm.com), apply the following modify using the LDAPMDFY utility. For additional information about the LDAPMDFY utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP* User's Guide.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Gateway1

 On the Gateway2 server (server2.us.ibm.com), apply the following modify using the LDAPMDFY utility.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
bm-slapdserverid: Gateway2

 On the Replica server (server3.us.ibm.com), apply the following modify using the LDAPMDFY utility.

dn: cn=configuration
changetype: modify
replace: ibm-slapdserverid
ibm-slapdserverid: Replica

2. **Consumer server credentials entry:** Add the first entry to the Gateway1 server, the second entry to the Gateway2 server, and the third entry to the Replica server using the LDAPADD utility. For additional information about the LDAPADD utility, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP* User's Guide.

Note: An alternative is to add entries with an **ibm-slapdSupplier** objectclass.

For example, for a consumer server credentials entry for Gateway1:

dn: cn=Master server,cn=configuration
changetype: add
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server2.us.ibm.com:389
objectclass: ibm-slapdReplication

For example, for a consumer server credentials entry for Gateway2:

dn: cn=Master server,cn=configuration
changetype: add
cn: master server
ibm-slapdMasterDN: cn=bindtoconsumer
ibm-slapdMasterPW: iamsupplier
ibm-slapdMasterReferral: ldap://server1.us.ibm.com:389
objectclass: ibm-slapdReplication

For example, for a consumer server credentials entry for Replica:

dn: cn=Master server,cn=configuration
changetype: add
cn: master server

ibm-slapdMasterDN: cn=bindtoconsumer ibm-slapdMasterPW: iamsupplier ibm-slapdMasterReferral: ldap://server2.us.ibm.com:389 objectclass: ibm-slapdReplication

- The next step is to build the LDIF file for the replication topology. This LDIF file is called gateway.ldif. Copy each of these entries to gateway.ldif with the necessary changes in the subtree, server IDs, host names, and ports.
  - 1. Replication context:

I

1

I

T

I

T

1

1

T

|

1

1

1

1

I

1

1

T

L

Т

 If the subtree entry exists, use the LDAPMDFY utility to modify the existing entry. For example:

```
dn: o=ibm,c=us
changetype: modify
add: objectclass
objectclass: ibm-replicationContext
```

 If the subtree entry does not exist, add the entry with the ibm-replicationContext auxiliary objectclass by using the LDAPADD utility. For example:

dn: o=ibm,c=us
changetype: add
objectclass: top
objectclass: organization
objectclass: ibm-replicationContext
o: ibm

2. Add the replica group entry using the LDAPADD utility. For example:

```
dn: ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaGroup
ibm-replicaGroup: default
```

3. **Replica subentries:** Because this topology is using two gateways and a read-only replica server, replica subentries are only needed for the Gateway1 and for the Gateway2 servers. The read-only Replica server does not need a replica subentry. The following entries can be added using the LDAPADD utility.

For example, for a subentry for Gateway1 (note that an objectclass of **ibm-replicaGateway** has been added to this entry to indicate that it is a gateway server):

dn: ibm-replicaServerId=Gateway1,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
objectclass: ibm-replicaGateway
ibm-replicaServerId: Gateway1
ibm-replicationServerIsMaster: true
cn: Gateway1
description: Subentry for Gateway1.

For example, for a subentry for Gateway2 (note that an objectclass of **ibm-replicaGateway** has been added to this entry to indicate that it is a gateway server):

dn: ibm-replicaServerId=Gateway2,ibm-replicaGroup=default, o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicaSubentry
objectclass: ibm-replicaGateway
ibm-replicaServerId: Gateway2
ibm-replicationServerIsMaster: true
cn: Gateway2
description: Subentry for Gateway2.

The subentry for Gateway1 identifies the server ID as Gateway1 and has the server declared as a gateway server. The Gateway1 server can receive updates from clients. The subentry for Gateway2 identifies the server ID as Gateway2 and has the server declared as a gateway server. The Gateway2 server can receive updates from clients.

4. **Supplier server credentials entry:** This step defines the credentials that Gateway1 uses to bind to Gateway2, Gateway2 uses to bind to Gateway1, and Gateway2 uses to bind to Replica. Add the entry with the LDAPADD utility. For example:

```
dn: cn=ReplicaBindCredentials, o=ibm,c=us
changetype: add
objectclass: ibm-replicationCredentialsSimple
cn: ReplicaBindCredentials
replicaBindDN: cn=bindtoconsumer
replicaCredentials: iamsupplier
description: Bind Credentials used on the gateway servers.
```

- 5. Replication agreements: There are three supplier-consumer relationships in this topology. Gateway1 supplies updates made to the o=ibm,c=us subtree to Gateway2. Gateway2 supplies updates made to the o=ibm,c=us subtree to Gateway1 and to Replica. Therefore, there are three agreements:
  - a. from Gateway1 to Gateway2
  - b. from Gateway2 to Gateway1
  - c. from Gateway2 to Replica
  - **Note:** The number of replication agreements is dependent upon the number of supplier-consumer relationships in the topology.

For example, a replication agreement from Gateway1 to Gateway2:

dn: cn=Gateway2,ibm-replicaServerId=Gateway1,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Gateway2
ibm-replicaConsumerId: Gateway2
ibm-replicaConsumerId: Gateway2
ibm-replicaCredentialSDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Gateway1 to Gateway2.
Ear oxample, a replication agreement from Cateway2 to Cateway1;

#### For example, a replication agreement from Gateway2 to Gateway1:

dn: cn=Gateway1,ibm-replicaServerId=Gateway2,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Gateway1
ibm-replicaConsumerId: Gateway1
ibm-replicaUrl: ldap://server1.us.ibm.com:389
ibm-replicaCredentialSDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Gateway2 to Gateway1.

#### For example, a replication agreement from Gateway2 to Replica:

dn: cn=Replica, ibm-replicaServerId=Gateway2,ibm-replicaGroup=default,o=ibm,c=us
changetype: add
objectclass: top
objectclass: ibm-replicationAgreement
cn: Replica
ibm-replicaConsumerId: Replica
ibm-replicaUrl: ldap://server3.us.ibm.com:389
ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us
description: Replication agreement from Gateway2 to Replica.

The three agreements for this topology are shown above. The first one is the agreement from Gateway1 to Gateway2. It is under the Gateway1 subentry. The second one is from Gateway2 to Gateway1 and it is under the Gateway2 subentry. The third one is from Gateway2 to Replica and it is also under the

1

Gateway2 subentry. Note the use of the same credentials entry for all three agreements. This is acceptable. The consumer server credentials entry is added to Gateway1, Gateway2, and Replica servers.

 Now that the replication entries have been added, the gateway.ldif file is as follows:

T

I

L

dn: o=ibm,c=us changetype: add objectclass: top objectclass: organization objectclass: ibm-replicationContext o: ibm dn: ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaGroup ibm-replicaGroup: default dn: ibm-replicaServerId=Gateway1,ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaSubentry objectclass: ibm-replicaGateway ibm-replicaServerId: Gateway1 ibm-replicationServerIsMaster: true cn: Gateway1 description: Subentry for Gateway1. dn: ibm-replicaServerId=Gateway2,ibm-replicaGroup=default, o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicaSubentry objectclass: ibm-replicaGateway ibm-replicaServerId: Gateway2 ibm-replicationServerIsMaster: true cn: Gateway2 description: Subentry for Gateway2. dn: cn=replicaBindCredentials, o=ibm,c=us changetype: add objectclass: ibm-replicationCredentialsSimple cn: replicaBindCredentials replicaBindDN: cn=bindtoconsumer replicaCredentials: iamsupplier description: Bind Credentials used on the gateway servers. dn: cn=Gateway2,ibm-replicaServerId=Gateway1,ibm-replicaGroup=default,o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicationAgreement cn: Gateway2 ibm-replicaConsumerId: Gateway2 ibm-replicaUrl: ldap://server2.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Gateway1 to Gateway2. dn: cn=Gateway1,ibm-replicaServerId=Gateway2,ibm-replicaGroup=default,o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicationAgreement cn: Gateway1 ibm-replicaConsumerId: Gateway1 ibm-replicaUrl: ldap://server1.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Gateway2 to Gateway1. dn: cn=Replica, ibm-replicaServerId=Gateway2,ibm-replicaGroup=default,o=ibm,c=us changetype: add objectclass: top objectclass: ibm-replicationAgreement cn: Replica ibm-replicaConsumerId: Replica

	ibm-replicaUrl: ldap://server3.us.ibm.com:389 ibm-replicaCredentialsDN: cn=ReplicaBindCredentials, o=ibm,c=us description: Replication agreement from Gateway2 to Replica.
	Next, add the <b>gateway.Idif</b> file on the Gateway2 server. Use the LDAPADD utility on Gateway2 where the <b>gateway.Idif</b> file was created. For example:
	ldapadd -h server2.us.ibm.com -p 389 -D <i>adminDN -w adminPW</i> -f gateway.ldif -k -L
:	The <b>-L</b> option on the LDAPADD utility sends the <b>Do Not Replicate</b> control to the server that indicates not to replicate the topology now. The <b>-k</b> option sends the <b>Server Administration</b> control to the server so that the addition of entries continues even when the subtree becomes read-only because of a server ID
•	nismatch. Next, add the replication topology to the Gateway1 and Replica servers. Use the
	_DAPEXOP utility. For example: Idapexop -h server2.us.ibm.com -p 389 -D adminDN -w adminPW -op repltopology
	-rc o=ibm,c=us This is an example of the <b>Replication topology</b> extended operation. It propagates the advanced replication topology to the Gateway1 and Replica servers defined under the o=ibm,c=us replication context. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP</i> <i>Planning and Customization</i> .
(	After the LDAPADD and LDAPEXOP commands are performed successfully, the gateway topology is ready. The Gateway1 server accepts updates that go to the Gateway2 server. The Gateway2 server also accepts updates which then forwards them to the Gateway1 and Replica servers.
Replication topol	ogy hints and tips
The	e following is helpful information about replication topologies.
	When setting up the advanced replication topologies, all master servers are in maintenance mode until all the topology entries have been loaded on all servers participating in the topology. The <b>Do Not Replicate</b> and <b>Server Administration</b> controls are also used when adding entries for configuring advanced replication topologies. This precludes updates to master servers that would be lost if they are received before all server responsibilities (replica, master, forwarder, gateway) and relationships (replication agreement) being established.
2.	All peers in a topology need to supply to every other server in the topology unless they are separated by gateways. If they are separated by gateways, all the peers under a gateway need to supply to all other servers including the gateway. This is because peers do not replicate changes supplied by other peers. That leads to peers receiving the updates they initiated.
3.	All gateways in a topology need to supply to each other. There has to be at least two gateways in a topology for them to be useful.
4.	Read-only servers do not accept updates that clients send. When an update is attempted against a read-only server, the referral list returned to the client is established from the following:
	a. The <b>ibm-replicationContext</b> objectclass allows for an optional attribute, <b>ibm-replicaReferralURL</b> . As stated previously, the <b>ibm-replicationContext</b> auxiliary objectclass must be added to the root of the subtree. This objectclass identifies the subtrees that are replication contexts. The <b>ibm-replicaReferralURL</b> attribute can hold a space delimited list of LDAP

1

 b. The cn=configuration subtree in the CDBM backend allows a consumer server credentials entry with an objectclass of ibm-slapdReplication to be stored. If this object exists and contains a value for the ibm-slapdMasterReferral attribute, the value is appended to referral list set by the replication context. If the replication context does not define a referral list with the ibm-replicaReferralURL attribute, this is the only value sent to the client. For more information about consumer server entries, see "Consumer server entries" on page 203.

c. If the LDAP server configuration file has a referral configuration option specified and there are no consumer server credentials entries in the cn=configuration subtree with an ibm-slapdMasterReferral value, the referral option values are appended to the referral list set by the replication context. If the replication context does not have a referral list specified with the ibm-replicaReferralURL attribute and the consumer server credentials entry is not providing a referral list, the referral option is the only value sent to the client. For more information about the referral configuration option, see "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in z/VM: TCP/IP Planning and Customization.

# Replication of schema and password policy updates

Advanced replication allows the replication of schema, password policy entries, and other entries under the **cn=ibmpolicies** suffix. Schema, password policy, and other updates can be replicated by configuring a replication topology under the **cn=ibmpolicies** suffix in the CDBM backend. By default, schema and password policy updates are not replicated unless a replication topology is configured in the **cn=ibmpolicies** suffix.

Before configuring schema replication, verify that the schema between the servers are already synchronized.

**Note:** The **Idapdiff** utility available on z/OS and other platforms facilitates the synchronization of schema and directory trees between servers. You can use the utility to synchronize the schema between z/VM LDAP servers. For more information about this utility, see *z/OS IBM Tivoli Directory Server Administration and Use* 

Before configuring replication of password policy and other entries in the **cn=ibmpolicies** suffix, verify that the entries are already synchronized. You can use the **Idapdiff** utility to synchronize the entries. If LDAP password policy is active on both servers, make sure that each server is configured to use the same password policy rules.

Schema replication and replication of entries in the **cn=ibmpolicies** suffix is the same as configuring advanced replication in the LDBM backend. For information about configuring advanced replication, see "Advanced replication configuration examples" on page 208; however, change the suffix used in those examples with **cn=ibmpolicies**. When the advanced replication entries are properly configured in the CDBM backend, the server performs schema replication and replication of entries in the **cn=ibmpolicies** suffix.

# Protecting replication topology entries

Т

1

The default propagating ACLs inherited from a suffix or root entry might be inappropriate for controlling access to the replication topology entries. To protect access to all replication topology entries in the server, make sure the **ibm-slapdReplRestrictedAccess** attribute value is set to true in the **cn=replication,cn=configuration** entry. When the **ibm-slapdReplRestrictedAccess** attribute is true, only the LDAP administrator and the master server DN for the replication context is allowed access to the replication topology entries. For more information about the **ibm-slapdReplRestrictedAccess** attribute, "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*.

# Unconfiguring advanced replication

If advanced replication is no longer needed, perform the following steps on the supplier server to remove the replication topology entries:

- 1. Ensure that the supplier server is in maintenance mode. For more information about advanced replication maintenance mode, see "Advanced replication maintenance mode" on page 233.
- 2. Bind to the supplier server as the LDAP administrator.
- 3. Delete the replication agreement entry.
- 4. Delete the replica subentry.
- 5. Delete the replica group.
- 6. Delete the **ibm-replicationContext** attribute value from the objectclass attribute type from the replication context.
- Move the supplier server out of maintenance mode. For more information about advanced replication maintenance mode, see "Advanced replication maintenance mode" on page 233.

On the consumer server, perform the following steps to remove the replication topology entries:

- 1. Ensure that the consumer server is in maintenance mode. For more information about advanced replication maintenance mode, see "Advanced replication maintenance mode" on page 233.
- 2. Bind to the consumer server as the LDAP administrator.
- 3. Delete the replication agreement entry.
- 4. Delete the replica subentry.
- 5. Delete the replica group.
- 6. Delete the **ibm-replicaReferralURL** attribute from the replication context.
- 7. Delete the **ibm-replicationContext** attribute value from the objectclass attribute type from the replication context.
- 8. If the server is no longer a consumer server for any other replication contexts, delete the consumer server credentials entry with an objectclass of **ibm-slapdReplication**.
- 9. If there are any consumer server credentials entries with an objectclass of ibm-slapdSupplier that have only one ibm-slapdReplicaSubtree attribute value equal to the replication context that is being deleted, the entry can be deleted, or else, delete the ibm-slapdReplicaSubtree attribute value from the consumer server credentials entry.

10. Move the consumer server out of maintenance mode. For more information about advanced replication maintenance mode, see "Advanced replication maintenance mode."

Once all replication topology entries are removed from the supplier and consumer servers, the **useAdvancedReplication** configuration option in the CDBM backend is set to **off** in both servers.

At this point, advanced replication is no longer configured between these two servers and each server is distinctly managing the data in the subtree that made up the replication context.

Maintenance mode allows the LDAP administrator to set up the server for advanced replication. This mode restricts access to all entries in an LDAP server. This allows the advanced replication topology to be fully configured on all servers participating in advanced replication.

While an LDAP server is in maintenance mode, the **adminDN** has unrestricted access to all entries in the server and can update operational attributes, such as **ibm-entryuuid** and **modifyTimestamp**, in the server. The operational attribute values in the **replicateOperationalAttributes** control are allowed to be updated when bound as the **adminDN** in maintenance mode. When the server is not in maintenance mode, the **adminDN** must specify the **Server Administration** control for the server to honor the operational attribute values in the **replicateOperationalAttributes** control. For more information about the **replicateOperationalAttributes** and **Server Administration** controls, see Appendix B, "Supported server controls," on page 337.

Consumer servers under maintenance mode continues to accept updates from supplier servers.

Pending replication entries are replicated to consumer servers, but, updates performed when in maintenance mode are not replicated.

Other users can bind to the LDAP server, but cannot access any entries within the server.

Specify the **-m** option on the server startup command (LDAPSRV command) to start the LDAP server in maintenance mode. The LDAP server MAINTMODE operator command can be used to change from maintenance mode to normal mode while the LDAP server is running. It can also be used to put a running server into maintenance mode.

- The following command can be sent to the LDAP server:
- smsg ldapsrv maintmode state

where state can be **on** to turn maintenance mode on or **off** to turn maintenance mode off (and turn on normal mode).

# **Partial replication**

Partial replication is an advanced replication feature that replicates only the specified entries and a subset of attributes for the specified entries within a subtree. The entries and attributes that are to be replicated are specified by the LDAP administrator. Using partial replication, an administrator can enhance the replication bandwidth depending on the deployment requirements. With partial replication support, the LDAP administrator can allow entries that have certain object class values to be replicated to a consumer server. For example, entries that have an objectclass of **person** and only the **cn, sn, userPassword** attributes are allowed to be replicated but not the **description** attribute.

The replication filter entry can be specified in each individual replication agreement entry in the **ibm-replicationFilterDN** attribute value. For more information, see "Replication agreements" on page 195. A replication filter entry has a structural objectclass of **ibm-replicationFilter**. For the required attribute values for the **ibm-replicationFilter** objectclass., see Table 42. If an **ibm-replicationFilterDN** attribute value is not a valid replication filter entry or does not exist, replication for the replication agreement is suspended. If replication from the replication agreement is suspended, the replication filter entry must be added to the directory or the **ibm-replicationFilterDN** attribute value must be removed from the replication agreement entry. When replication is suspended for the replication agreement, it can be resumed by using the **Control replication** extended operation in the LDAPEXOP utility. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

The attributes that are to be replicated are specified using a replication filter in the **ibm-replicationFilterAttr** attribute. A set of attributes pertaining to an object class constitutes a replication filter. The list of attributes selected for an object class can either be a part of an inclusion list or an exclusion list. An inclusion list is list of attributes that are selected for replication while an exclusion list is list of attributes that are not selected for replication. For the required attribute values for the format of the **ibm-replicationFilterAttr** attribute values, see Table 42.

Table 42. ibm-replicationFilter objectclass schema definition (required attributes)

I	Attribute description and example
I	cn
I	Common name of the replication filter entry. This attribute does not affect advanced replication configuration.
I	Example:
I	cn: filter1

Ι	Table 42. Ibm-replication-liter object class schema definition (required attributes) (continued)		
Ι	Attribute description and example		
Ι	ibm-replicationFilterAttr		
 	A multi-valued attribute that specifies a replication filter. A replication filter is based on the object class values of entries that are replicated. The filter can be an inclusion or exclusion filter.		
 	The following is the replication filter format: ( <b>objectclass</b> =objclass):[!](attr1[,attr2])		
I	where,		
   	objclass Specifies a valid objectclass in the server's schema. If an * is specified, then all other objectclasses not specified by other <b>ibm-replicationFilterAttr</b> attribute values (if any) in the replication filter entry, are subject to this replication filter.		
I	! If specified, indicates that the attribute type list is an exclusion list, otherwise, it is an inclusion list.		
   	attr1, attr2 Specifies a list of valid attribute types in the server's schema. If an exclusion list, the attribute types in this list are not replicated for entries that have an objectclass value of objclass. If an inclusion list, the attribute types in this list are replicated for entries that have an objectclass value of objclass. An * can be specified to indicate all attribute types for the objclass.		
   	<ul> <li>The following attributes are always replicated, irrespective of their presence in the exclusion list:</li> <li>Object class attributes of an entry</li> <li>Naming attribute</li> <li>All operational attributes (for example, <b>ibm-entryuuid</b> attribute values)</li> </ul>		
Ι	Notes:		
ï	<ol> <li>If an attribute type is present in both an inclusion and an exclusion list, the exclusion takes precedence.</li> </ol>		
   	<ol> <li>If there is not an <b>ibm-replicationFilterAttr</b> attribute value with objclass equal to *, no replication with entries that have an objectclass other than the ones explicitly specified is done. This acts as if an <b>ibm-replicationFilterAttr</b> attribute value of (objectclass=*):!(*) is specified on the replication filter entry.</li> </ol>		
Ι	Example:		
I	<pre>ibm-replicationFilterAttr: (objectclass=person):(cn,sn)</pre>		
1	The example in Table 42 on page 234 allows the following replication to occur:		
1	<ul> <li>Entries with an objectclass of person only have their cn and sn attribute values</li> </ul>		
	replicated.		
I	<ul> <li>Entries with other objectclasses are not replicated.</li> </ul>		
I	Replication filter examples		
Ι	The following are examples that explain the usages of replication filters:		
I	Example 1		
   	<pre>dn: cn=replicationfilter, cn=localhost objectclass: ibm-replicationFilter ibm-replicationFilterAttr: (objectclass=person):(*) ibm-replicationFilterAttr: (objectclass=*): !(*)</pre>		
Ι	The first ibm-replicationFilterAttr filter value indicates entries with an objectclass		

The first **ibm-replicationFilterAttr** filter value indicates entries with an objectclass of person have all their attributes replicated. The second ibm-replicationFilterAttr filter value indicates entries with an objectclass other than person are not replicated. This means that only entries with an objectclass of person are replicated and no other entries are replicated.

L

L

#### Example 2

Т

1

```
dn: cn=replicationfilter, cn=localhost
objectclass: ibm-replicationFilter
ibm-replicationFilterAttr: (objectclass=javaObject):(javaClassName,description)
ibm-replicationFilterAttr: (objectclass=javaNamingReference):(javaReferenceAddress)
ibm-replicationFilterAttr: (objectclass=*): !(javaReferenceAddress)
```

The first **ibm-replicationFilterAttr** filter value indicates entries with an objectclass of **javaObject** has their **javaClassName** and **description** attributes replicated. The second **ibm-replicationFilterAttr** filter value indicates entries with an objectclass of **javaNamingReference** has the **javaReferenceAddress** attribute replicated. The third **ibm-replicationFilterAttr** filter value indicates the **javaReferenceAddress** attribute is not replicated for any entries other than **javaObject** and **javaNamingReference**.

Therefore, if an entry has an objectclass of **javaObject**, the **javaClassName** and **description** attributes are replicated. If an entry has an objectclass of **javaObject** and an auxiliary objectclass of **javaNamingReference**, the **javaClassName**, description, and **javaReferenceAddress** attributes are replicated. If an entry has an objectclass other than **javaObject** or **javaNamingReference**, all attributes except **javaReferenceAddress** are replicated.

Example 3

```
dn: cn=replicationfilter, cn=localhost
objectclass: ibm-replicationFilter
ibm-replicationFilterAttr: (objectclass=person):(cn,sn,userPassword)
ibm-replicationFilterAttr: (objectclass=inetOrgPerson):!(userPassword,employeeNumber)
ibm-replicationFilterAttr: (objectclass=*): !(*)
```

The first **ibm-replicationFilterAttr** filter value indicates entries with an objectclass of **person** have their **cn**, **sn**, and **userPassword** attribute values replicated. The second **ibm-replicationFilterAttr** filter value indicates that entries with an objectclass of **inetOrgPerson** do not have their **userPassword** and **employeeNumber** attribute values replicated. The third **ibm-replicationFilterAttr** filter value indicates are replicated if the objectclass is something other than **person** or **inetOrgPerson**.

Therefore, if an entry has an objectclass of **person**, the attributes **cn**, **sn**, and **userPassword** are replicated. If an entry has objectclasses of **person** and **inetOrgPerson**, only the **cn** and **sn** attributes are replicated. Because the **userPassword** attribute is present in both the inclusion and exclusion list, the **userPassword** attribute is eliminated because exclusion takes precedence over inclusion. If any other entry has an objectclass other than **person** or **inetOrgPerson**, no attributes are replicated.

# SSL/TLS and advanced replication

SSL/TLS can be used to communicate between a replicating server (supplier, gateway, forwarder, or peer) and a replica server (consumer, gateway, forwarder, or peer).

# **Replica server with SSL/TLS enablement**

Set up the replica server for SSL/TLS by updating the LDAP server configuration file if it is not already configured for SSL/TLS. An LDAP URL with a prefix of 1daps:// is required in the **listen** configuration option in the replica server so that a secure connection can be configured.

If a SASL EXTERNAL bind is performed between the replicating and replica servers, the replica server must be configured to use server and client authentication. The **sslAuth** configuration option must be set to **serverClientAuth**. The replica server must have the replicating server's certificate in its key database file.

For more information, see "Setting up for SSL/TLS" in *z/VM: TCP/IP Planning and Customization*.

# Replicating server with SSL/TLS enablement

The replicating server acts as an SSL/TLS client to the replica server. To set up the replicating server to use simple binds, you must:

- 1. Run the **gskkyman** utility as if you were the client. For more information on the **gskkyman** utility, see SSL Certificate Management in *z/VM: TCP/IP User's Guide*. Receive the replica's self-signed certificate and mark it as trusted.
- 2. In the LDAP server configuration file on the replicating server:
  - Set the **sslKeyRingFile** configuration option to the replica key database file.
  - If a key database file is used, set sslKeyRingFilePW to the password for the key database file, or set sslKeyRingPWStashFile to the file name where the password is stashed.
- 3. The **ibm-replicaURL** attribute value in the replication agreement entry must use an LDAP URL with a prefix of ldaps://. This indicates that an SSL connection is used between the replicating and replica servers. For information about the **ibm-replicaURL** attribute value, see Table 33 on page 196.

The above procedure can also be used to set up the replicating server to use SASL EXTERNAL binds. The SSL-related configuration options in the LDAP server configuration file, if specified, represent the default values for the related optional attributes in **ibm-replicationCredentialsExternal** objects. These defaults can be overridden by specifying the optional attributes. For more information about SASL EXTERNAL credentials entries, see Table 36 on page 199.

Because the replicating server acts as an SSL/TLS client to the replica server, the replicating server binds with the replica server.

# Displaying advanced replication configuration

Because many replication topologies can be configured in the LDAP server at one time, the LDAP server **DISPLAY REPLICAS** operator command is used to allow the LDAP administrator to easily query the current state of all configured replication contexts and replication agreements in the LDAP server. This command allows the LDAP administrator to verify that the advanced replication topologies are configured properly and are working as expected. For more information about the LDAP server **DISPLAY REPLICAS** operator command, see "SMSG Interface to the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.

If the LDAP server **DISPLAY REPLICAS** operator command output indicates that there are problems in a replication agreement entry, LDAP search requests can be used to query the replication agreement entry's operational attributes to determine the replication problems. For more information, see "Monitoring and diagnosing advanced replication problems" on page 240.

Comman	d line tasks for managing replication
	This topic discusses the use of the tools that are at your disposal to check the current advanced replication status for each of your configured replication agreements. These procedures can be used to recover from out of sync conditions between servers participating in advanced replication.
Advance	d replication related extended operations
	A set of extended operations is provided to allow administrators the opportunity to manage all aspects of advanced replication. Specifically, the extended operations allow an administrator to do the following:
	<ul> <li>Propagate any replication topology entries to all consumers</li> </ul>
	<ul> <li>Manage the replication queue, especially in the context of replication scheduling</li> </ul>
	<ul> <li>Manage any replication related errors</li> </ul>
	<ul> <li>Manage the quiesce state of the replication context</li> </ul>
	Suspend or resume replication processing
	The extended operations also allow for an administrator to manage a specific serv and then have the server cascade the management operation to any of its consumers. These extended operations require the user to bind with the LDAP server administrator's DN and password. The LDAPEXOP utility is provided to invoke the advanced replication extended operations. This utility provides a command-line interface to all the advanced replication extended operations. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" <i>z/VM: TCP/IP Planning and Customization</i> .
	Table 43 summarizes the extended operations with their LDAPEXOP operation value.

**Note:** The term, **cascade**, is used to describe the process of a supplier server issuing an extended operation it processed to one or all of its consumers.

LDAPEXOP operation	LDAPEXOP description	Overview
cascrepl	Cascading control replication extended operation	This extended operation can quiesce, unquiesce, or force immediate replication of all pending changes (even if scheduling is dictated another way). When the extended operation is performed on the supplier that this extended operation was issued against, it proceeds to cascade the extended operation to one or all of its consumers. If forcing immediate replication of all pending changes, two variants of the extended operation can be issued. If the replication of all pending changes must complete before the cascade step, the administrator can use the <b>wait</b> option. If there are no dependencies on the completion of the replication operations before cascading, the <b>replnow</b> option can be used. For more information about the <b>Cascading</b> <b>control replication</b> " on page 348.
controlqueue	Control replication queue extended operation	This extended operation can skip one or all pending changes in the advanced replication queue. For more information about the <b>Control replication queue</b> extended operation, see "Control replication queue" on page 355.

LDAPEXOP operation	LDAPEXOP description	Overview
controlrepl	Control replication extended operation	This extended operation suspends or resumes all advanced replication-related activity.
		Also, given any replication schedule objects that might exist resuming replication does not necessarily cause the immediate replication of any pending changes. Instead, in addition to resume, this extended operation can be used to begin the immediate replication of any pending changes, even if replication schedule objects have deferred replication For more information about the <b>Control replication</b> extended operation, see "Control replication" on page 352.
controlreplerr	Control replication error log extended operation	This extended operation can delete, retry, or show, any replication operations that resulted in an unsuccessful return code returned to the supplier from the consumer.
		The show options returns an LDIF representation of the unsuccessful replication operation. For more information about the <b>Control replication error log</b> extended operation see "Control replication error log" on page 354.
quiesce	Quiesce or unquiesce context extended operation	This extended operation can quiesce or unquiesce a replication context.
		A quiesced replication context typically cannot accept any LDAP update operations. To perform LDAP update operations on a quiesced context the update operations musbe done by the administrator with the <b>Server Administratio</b> control. for more information about the <b>Quiesce or unquiesce context</b> extended operation, see "Quiesce or unquiesce context" on page 358.
repltopology	Replication topology extended operation	This extended operation propagates advanced replication topology-related entries to all consumers. It then cascades this extended operation to all the consumers. This results in a cascading of the topology-related entries to all servers tha participate in replication for a given replication context. For more information about the <b>Replication topology</b> extended operation, see "Replication topology" on page 359.

# Viewing replication configuration information

A great deal of information related to replication activity is available using searches. To see the replication topology information related to a particular replicated subtree, you can do a subtree search with the base set to the DN of the subtree and the filter set as (**objectclass=ibm-repl**\*) to find the subentry that is the base of the topology information.

ldapsrch -p port -D adminDN -w adminPW -b baseDn objectclass=ibm-repl\*

The objects returned includes the replica group itself, plus the following:

- Entries with an objectclass of **ibm-replicaSubentry** for each server that replicates data within this replication context. These entries are replica subentries that contain a server ID attribute and the role that servers plays in the replication topology. For more information about replica subentries, see "Replica subentries" on page 194.
- For each replica subentry, there is a replication agreement entry for each consumer server that receives replication updates from the server described by

the replica subentry. For more information about replication agreement entries, see "Replication agreements" on page 195.

# Monitoring and diagnosing advanced replication problems

An LDAP administrator can monitor the state of advanced replication processing and troubleshoot problems by using LDAP search requests to retrieve operational attributes available for the roots of the replication contexts (entries with an objectclass of **ibm-replicationContext**) and replication agreements (entries with an objectclass of **ibm-replicationAgreement**). Because these are operational attributes, either the + attribute or each individual attribute must be requested on a search request in order to be returned. Also, operational attributes cannot be used in search filters.

The following tables describe the operational attributes for the replication context and replication agreement entries. Replication context entries use the auxiliary objectclass of **ibm-replicationContext** and replication agreement entries use the structural objectclass **ibm-replicationAgreement**. For the operational attributes for the **ibm-replicationContext** objectclass, see Table 44. For the operational attributes for the **ibm-replicationAgreement** objectclass, see Table 45 on page 241.

When retrieved for a replication context or replication agreement entry, the operational attributes provide information concerning that entry. It is important to take notice of attributes that have values that contain *failureld* or *changeld* values. The *failureld* and *changeld* numbers increase sequentially. However, some numbers might be skipped by the server for various reasons. For example, if DB2<sup>®</sup> is restarted while the server is running, the *changeld* might skip numbers. These IDs are often required when working with the **Control replication error log** and the **Control replication queue** extended operations with the LDAPEXOP utility. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

Table 44. ibm-replicationContext operational attributes

### Attribute and description

ibm-replicationThisSeverIsMaster

A boolean (true or false) indicating whether the server is the master of the replication context. If set to true, the server is the master of the replication context. If set to false, the server is a not the master of the replication context.

### ibm-replicationIsQuiesced

A boolean (true or false) indicating whether the replication context is quiesced. If set to true, the replication context is quiesced. If set to false, the replication context is not quiesced.

Updates under a quiesced replication context are restricted to the LDAP administrator, if using the **Server Administration** control (OID 1.3.18.0.2.10.15), and any replication master DNs with authority under this context. Advanced replication continues for a quiesced context. If the server is restarted, all replication contexts are then unquiesced.

T

Т

1

Т

T

For the optional non-operational attribute for the **ibm-replicationContext** objectclass, see Table 30 on page 193.

I	Table 45. ibm-replicationAgreement operational attributes
I	Attribute and description
I	ibm-replicationChangeLDIF
 	The LDIF representation of the next pending change that has not yet been replicated and has resulted in advanced replication being stalled to the consumer server. If there is not a stalled replication change, the value is N/A.
I	Examples of when an advanced replication queue might be stalled include:
I	1. A replication change failed because of an LDAP_TIMEOUT return code.
     	<ol> <li>The backend replication table has reached the maximum number of errors allowed on the supplier server within this backend while attempting to replicate a change to a consumer server. For more information about the ibm-slapdRepIMaxErrors attribute value, "CDBM backend configuration and policy entries" in <i>z/VM: TCP/IP</i> <i>Planning and Customization.</i></li> </ol>
I	ibm-replicationFailedChangeCount
     	Specifies the number of advanced replication operations that have failed in this replication agreement. This number is shared among all replication agreement entries on the backend level by the <b>ibm-slapdReplMaxErrors</b> attribute in the CDBM backend configuration entry <b>cn=Replication</b> , <b>cn=Configuration</b> . For more information about the <b>ibm-slapdReplMaxErrors</b> attribute value, "CDBM backend configuration and policy entries" in <i>z/VM: TCP/IP Planning and Customization</i> .
I	ibm-replicationFailedChanges
     	A multi-valued attribute that lists all the logged replication operations that have failed. The number of attribute values is shared among all replication agreement entries on the backend level by the <b>ibm-slapdReplMaxErrors</b> attribute in the CDBM backend configuration entry <b>cn=Replication</b> , <b>cn=Configuration</b> . For more information about the <b>ibm-slapdReplMaxErrors</b> attribute value, "CDBM backend configuration and policy entries" in <i>z/VM: TCP/IP Planning and Customization</i> .
I	A string value of the form: <i>failureld timestamp returnCode numOfAttempts changeld operation entryDn</i>
   	The <i>failureld</i> identifies the update that has failed to replicate to the consumer server. The <i>failureld</i> is used with the <b>Control replication error log</b> extended operation to display, delete, or retry the failing replication update. The LDAPEXOP utility supports the <b>Control replication error log</b> extended operation. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in <i>z/VM: TCP/IP Planning and Customization</i> .
 	The <i>timestamp</i> is the time in Zulu format when this operation was last attempted to be replicated to the consumer server.
I	The returnCode is the LDAP return code from the consumer server.
I	The <i>numOfAttempts</i> is the number of times the error has been tried again on the consumer server.
I	The changeld is the ID that this failureld had when it was in the pending replication queue.
 	The <i>operation</i> indicates the update operation that encountered the failure. It has one of the following values: <b>add</b> , <b>delete</b> , <b>modify</b> , or <b>modifydn</b>
I	The <i>entryDn</i> indicates the distinguished name of the entry that caused the failure.
I	Example:
	<pre>ibm-replicationfailedchanges: 1 20050407202221Z 68 1 170814 add cn=entry-85,o=IBM,c=US failureId: 1 timestamp: 20050407202221Z returnCode: 68 numOfAttempts: 1 changeId: 170814 operation: add operation: add</pre>
I I	<pre>entryDn: cn=entry-85,o=IBM,c=US</pre>

I	Table 45. ibm-replicationAgreement operational attributes (continued)
I	Attribute and description
I	ibm-replicationLastActivationTime
Ι	Specifies the Zulu format timestamp when advanced replication actively began replicating queued updates.
I	ibm-replicationLastChangelD
Ι	Specifies the replication change ID of the last successfully completed advanced replication update.
Ι	ibm-replicationLastFinishTime
   	Specifies the Zulu format timestamp when advanced replication updates in the queue were all attempted and the server awaits a new scheduled start time or more operations to appear in the advanced replication queue. For more information about replication schedule entries, see "Schedule entries" on page 200.
Ι	ibm-replicationLastResult
I	A description of the result from the last advanced replication operation or connection attempt to a consumer server.
I	A string value of the form: timestamp changeld returnCode operation entryDn
 	The <i>timestamp</i> is the time in Zulu format when this operation was last attempted to be replicated to the consumer server.
I	The <i>changeld</i> is the ID of the last replication update.
I	The <i>returnCode</i> is the LDAP return code from the consumer server.
 	The <i>operation</i> indicates the last LDAP operation. It has one of the following values: <b>add</b> , <b>connect</b> , <b>delete</b> , <b>modify</b> , or <b>modifydn</b>
 	The <i>entryDn</i> indicates the distinguished name of the entry that was last added, deleted, modified, or renamed. If <i>operation</i> is <b>connect</b> , <i>entryDn</i> is set to <b>NULL</b> .
Ι	Example:
	ibm-replicationLastResult: 20050412140436Z 19 81 add cn=testpendingchange,o=ibm,c=us
     	<pre>timestamp: 20050412140436Z changeId: 19 returnCode: 81 operation: add entryDn: cn=testpendingchange,o=ibm,c=us</pre>
Ι	ibm-replicationLastResultAdditional
 	The descriptive reason code message text that supplements the return code message with the purpose of providing additional information from the last replication attempt.
Ι	ibm-replicationNextTime
   	Specifies the Zulu format timestamp of the next time advanced replication would begin if pending changes existed. When this value is set to <b>19000101000000z</b> , replication begins immediately once a change is ready to be replicated if the <b>ibm-replicationState</b> operational attribute is set to <b>active</b> .
I	ibm-replicationPendingChangeCount
I	The number of replication operations that are waiting to be replicated to a consumer server.

	Table 45.	ibm-replicationAgreem	ent operational	attributes	(continued)	)

	Table 43. Ibin-replicationAgreement operational autobiles (continued)	
Ι	Attribute and description	
Ι	ibm-replicationPendingChanges	
I	A multi-valued attribute that lists all changes waiting to be replication to a consumer server.	
I	A string value of the form: <i>changeld operation entryDn</i>	
	The <i>changeld</i> is the ID of the pending replication update.	
 	The <i>operation</i> indicates the LDAP operation that is pending. It has one of the following values: <b>add</b> , <b>delete</b> , <b>modify</b> , or <b>modifydn</b>	
I	The <i>entryDn</i> indicates the distinguished name of the entry that is to be added, deleted, modified, or renamed.	
I	Example:	
	<pre>ibm-replicationpendingchanges: 19 add cn=test1,o=ibm,c=us</pre>	
i	changeId: 19	
	<pre>operation: add entryDn: cn=test1,o=ibm,c=us</pre>	
1	ibm-replicationState	
1	Identifies the current state of the advanced replication queue. It has one of the following values:	
	• active - Indicates that advanced replication is occurring from this replication agreement.	
	• <b>binding</b> - Indicates that the replication agreement is in the process of authenticating with the consumer server.	
1	• <b>connecting</b> - Indicates that the replication agreement is attempting to contact the consumer server.	
 	• <b>on hold</b> - Indicates that the replication agreement is on hold. Replication updates to the consumer server are queued until the replication agreement is resumed.	
I	• ready - Indicates immediate replication mode, ready to send updates as they occur.	
     	• <b>retrying</b> - Indicates that the server retries the current change every 60 seconds until it succeeds. The retrying state occurs when a consumer server is restarted, the replication backend table is full, the current replicated update is failing, or when there is an <b>LDAP_TIMEOUT</b> return code from the consumer server. Retrying is a likely symptom that advanced replication might be stalled and LDAP administrator intervention is required to get it running again. For the steps on how to recover from out of sync conditions between supplier and consumer servers, see "Recovering from advanced replication errors."	
 	• <b>suspended</b> - Indicates that the replication agreement is suspended. No additional replication updates are sent to the consumer server by this agreement (until it returns to the ready state).	
	• <b>waiting</b> - Indicates that the replication agreement is currently waiting for the next scheduled replication to occur. For more information about replication schedule entries, see "Schedule entries" on page 200.	
   	For the required non-operational attributes for the <b>ibm-replicationAgreement</b> objectclass, see Table 33 on page 196. For the optional non-operational attributes for the <b>ibm-replicationAgreement</b> objectclass, see Table 34 on page 196.	
Ι	Recovering from advanced replication errors	
       	Replication errors can be handled proactively, before they are allowed to accumulate, or reactively, after replication has already stalled. Replication stalls occur when the number of failures reaches the limit as specified by the <b>ibm-slapdRepIMaxErrors</b> attribute value in the <b>cn=Replication,cn=configuration</b> entry. For more information about the <b>cn=Replication,cn=configuration</b> entry, "CDBM backend configuration and policy entries" in <i>z/VM: TCP/IP Planning and Customization</i> .	

When replication is stalled, the latest failed change occupies the beginning of the pending changes queue. The latest failed change gets retried every minute until it

Ι

L

succeeds or the failed change is removed from the queue by the LDAP administrator. When this failed change occupies the lead position in the pending replication queue, all other replication updates are blocked and replication is stalled.

The options for handling stalled replication are:

Т

T

Т

- Increase the size of the ibm-slapdRepIMaxErrors attribute in the cn=Replication,cn=configuration entry. This allows more replication failures to be stored in the backend where the replication agreement entry resides.
- 2. Delete or retry one or more failed replication changes.
- 3. Skip the latest failed replication change.
- 4. If the stalled replication problem is severe enough, the entire replication context where the replication agreement entry resides might need to be resynchronized. In order to do this, you must:
  - a. Quiesce the replication context
  - b. Suspend replication for all replication agreements
  - c. Delete all failed replication changes for all replication agreements
  - d. Skip all pending changes for all replication agreements
  - e. Resynchronize the replication context
  - f. Resume replication for the suspended replication agreements
  - g. Unquiesce the replication context

The following operational attributes in the replication agreement entry can be queried to determine what to do:

- 1. The **ibm-replicationChangeLdif** operational attribute in the replication agreement entry shows the LDIF representation of the latest failure. The **ibm-replicationLastResult** and **ibm-replicationLastResultAdditional** operational attributes in the replication agreement have further detail for the reason the change failed.
- 2. The ibm-replicationPendingChanges operational attribute in the replication agreement shows the change ID, the operation type, and the target DN of the next changes to be replicated. The number of pending changes that are displayed is limited by the ibm-slapdMaxPendingChangesDisplayed attribute in the cn=Replication,cn=configuration entry. For more information about the ibm-slapdMaxPendingChangesDisplayed attribute, "CDBM backend configuration and policy entries" in *z/VM: TCP/IP Planning and Customization*. For more information about the ibm-replicationPendingChanges operational attribute, see Table 45 on page 241.
- The ibm-replicationFailedChanges operational attribute in the replication agreement shows each of the failed changes, including the failure ID. For more information about the ibm-replicationFailedChanges operational attribute, see Table 45 on page 241.
- 4. The Control replication error log extended operation can be used to display information about a failure by providing the *failureld* obtained from the ibm-replicationFailedChanges operational attribute. The controlreplerr extended operation -show option in the LDAPEXOP utility can be used to display the latest failure. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

When the latest and all previous failures are understood, the LDAP administrator must decide whether to fix the replication failures individually or resynchronize the entire replication context. The options are:

1

Т

Т

 Increase the size of the ibm-slapdRepIMaxErrors attribute in the cn=Replication,cn=configuration entry. This allows more replication failures to be stored in the backend where the replication agreement entry resides. For more information about the ibm-slapdRepIMaxErrors attribute, "CDBM backend configuration and policy entries" in z/VM: TCP/IP Planning and Customization.

I

- 2. Delete or retry one or more failed changes for the replication agreement by using the Control replication error log extended operation with the LDAPEXOP utility. The -retry option on the control replerr extended operation in the LDAPEXOP utility allows a single failure (identified by its *failureId*) to be retried or all failures to be retried. The ability to retry all failures is especially useful when you have corrected the problem that caused a change to fail the first time. When a failed change is retried successfully, it is removed from the list of failed changes and there is space for a new one. The -delete option on the **controlrepler** extended operation in the LDAPEXOP utility allows a single failure (identified by its failureId) to be deleted or all failures to be deleted. This delete option is especially useful when a change is deemed to be unnecessary, the problem has been fixed manually, or a synchronization tool such as the Idapdiff utility has been used to resynchronize the directories. Deleting a failed change frees space in the list of failed changes so that a new failure can be added. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in z/VM: TCP/IP Planning and Customization.
- 3. Skip the latest failure for the replication agreement by using the Control replication queue extended operation. The LDAPEXOP utility supports the Control replication queue extended operation that allows the next pending change (identified by its *changeld*) or all pending changes to be skipped. This extended operation is useful when the ibm-slapdReplMaxErrors attribute in the cn=Replication,cn=configuration entry is set to 0 in which case the replication failure is not allowed and replication is useful when replication failure. Also, the Control replication queue extended operation is useful when replication failures are not deleted, the ibm-slapdReplMaxErrors attribute value is increased, or after using the Idapdiff utility to resynchronize the replication context. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.
- 4. If there are multiple failed and pending replication changes, the entire replication context where the replication agreement entry resides might need to be resynchronized. In order to do this, you must:
  - a. Quiesce the replication context on all servers in the replication topology by using the Cascading control replication extended operation on the LDAPEXOP utility. The Cascading control replication extended operation is targeted against the master server which in turn quiesces the replication context on all consumer servers. A quiesced replication context only accepts updates from the LDAP administrator when using the Server Administration control and replica master servers. For more information about the Cascading control replication extended operation, see "Cascading control replication" on page 348. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.
  - b. Suspend replication for all replication agreements in the replication context by using the **Control replication** extended operation on the LDAPEXOP utility. A suspended replication agreement queues all replication changes updates until it is resumed. For more information about the **Control replication** extended operation, see "Control replication" on page 352.

   	d	Delete all failed replication changes for all replication agreements by using the <b>Control replication error log</b> extended operation on the LDAPEXOP utility. For more information about the <b>Control replication error log</b> extended operation, see "Control replication error log" on page 354.
   	e.	Skip all pending replication changes by using the <b>Control replication</b> <b>queue</b> extended operation on the LDAPEXOP utility. For more information about the <b>Control replication queue</b> extended operation, see "Control replication queue" on page 355.
 	f.	Resynchronize the replication context manually or by using the <b>Idapdiff</b> utility.
 	g	Resume replication for all suspended replication agreements by using the <b>Control replication</b> extended operation on the LDAPEXOP utility.
   	h.	<ul> <li>Unquiesce the replication context on all servers in the replication topology by using the <b>Cascading control replication</b> extended operation on the LDAPEXOP utility.</li> </ul>
	preve and r The L opera opera	other methodology for handling replication failures is to take a proactive, entive approach. The LDAP administrator monitors the replication failure queue esolves problems before the queue reaches capacity and replication stalls. LDAP administrator can use the <b>Control replication error log</b> extended ation and the <b>ibm-replicationFailedChanges</b> and <b>ibm-replicationState</b> ational attributes in the replication agreement entry to monitor the current ation status.
I	Advanced replicati	on error recovery example
   	that h exam	advanced replication error recovery example uses the master-replica topology has been configured in "Creating a master-replica topology" on page 211. This ple assumes the <b>ibm-slapdReplMaxErrors</b> attribute value in the <b>replication,cn=configuration</b> entry is set to one.
   	agree agree	DAP administrator periodically monitors the replication status of the replication ement in the o=ibm,c=us replication context by querying the replication ement operational attribute values. For more information about the replication ement operational attributes, see Table 45 on page 241.
 	Note	: Operational attributes are only returned on search requests when either the + attribute is specified or each operational attribute is requested.
   	using entry.	current replication status from the master to the replica can be determined by the following LDAPSRCH command to retrieve the replication agreement For more information about the LDAPSRCH utility, see "Using the LDAP t Utilities" in <i>z/VM: TCP/IP User's Guide</i> .
	"(obj ibm-r ibm-r ibm-r	ch -p 389 —h server1.us.ibm.com -D <i>adminDn -w adminPw</i> -b o=ibm,c=us ectclass=ibm-replicationAgreement)" "*" ibm-replicationChangeLdif eplicationFailedChangeCount ibm-replicationFailedChanges ibm-replicationLastActivationTime eplicationLastChangeID ibm-replicationLastFinishTime ibm-replicationLastResult eplicationLastResultAdditional ibm-replicationNextTime ibm-replicationPendingChangeCount eplicationPendingChanges ibm-replicationState
I	The L	DAPSRCH command returns the following entry:
	object object ibm-re	lica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us class=top class=ibm-replicationAgreement plicaconsumerid=Replica plicaurl=ldap://server1.us.ibm.com:389

c. Use the **Idapdiff** utility or manually compare the replication contexts on each of the servers within the replication context.

```

The following analysis of the replication agreement entry can be performed:

- The ibm-replicationState operational attribute value is set to retrying which indicates replication is currently stalled. Replication is stalled because the number of replication failures exceeds one. (The ibm-slapdMaxReplErrors attribute value has been set to one in the cn=Replication,cn=configuration entry).
- 2. The ibm-replicationChangeLdif operational attribute in the replication agreement shows the LDIF representation of the latest failure. The LDIF shows the last failure is a modify of the ou=sub,o=ibm,c=us entry on the consumer server. The ibm-replicationLastResult and ibm-replicationLastResultAdditional operational attributes in the replication agreement indicate that the modify failed on the consumer server because the ou=sub,o=ibm,c=us entry does not exist.
- 3. The ibm-replicationPendingChanges operational attribute in the replication agreement shows the *changeld* of the next pending update is 46. The next pending change is also the same modify operation of the ou=sub,o=ibm,c=us entry. It will be replicated to the consumer server after the add failure in the ibm-replicationFailedChanges operational attribute is resolved.

I

I

I

I

Т

|

1

4. The **ibm-replicationFailedChanges** operational attribute in the replication agreement shows one failed replication update. The attribute value indicates that the *failureld* is 12, the LDAP return code from the consumer server is 32, it is an add operation of the cn=entry,ou=sub,o=ibm,c=us entry, and the supplier server has tried once to replicate the update.

To determine why the addition of the cn=entry,ou=sub,o=ibm,c=us entry failed, the LDAPEXOP utility can be used to perform a **Control replication error log** extended operation to show the failed replication change. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

The following LDAPEXOP command can be used to show the LDIF representation of failed replication change that has a *failureld* of 12.

```
ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op controlreplerr
  -ra "cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default,
  o=ibm,c=us" -show 12
```

#### The LDAPEXOP command returns the following:

dn: cn=entry,ou=sub,o=ibm,c=us control: 2.16.840.1.113730.3.4.2 true control: 1.3.18.0.2.10.19 false:: MIGnMDAKAQAwKwQPbW9kaWZ5dGltZXN0YWlwMRgEFjI wMDkwMjA2MTQ0MzU0LjY1NzcwMFowIA0BADAbBA1tb2RpZmllcnNuYW11MQoECGNuPWFkbWluMDA KAQAwKwQPY3J1YXRldGltZXN0YWlwMRgEFjIwMDkwMjA2MTQ0MzU0LjY1NzcwMFowHwoBADAaBAx jcmVhdG9yc25hbWUxCgQIY249YWRtaW4= changetype: add cn: entry ibm-entryuuid: A091A000-4CAA-198C-8D7D-402084027431 sn: entry objectclass: person objectclass: top

The LDAP administrator can either fix the replication differences manually or use the **Idapdiff** utility to resynchronize the replication contexts on all servers in the replication topology. The **Idapdiff** utility is a useful tool for comparing and verifying that the entries within a replication context on supplier and consumer server are synchronized. For the purposes of this example, the LDAP administrator has chosen to resynchronize the replication context manually.

Before you compare or fix entries within a replication context, quiesce the replication context on all servers within the replication topology by using the **Cascading control replication** extended operation quiesce option on the LDAPEXOP utility. For more information about the LDAPEXOP utility, see "LDAPEXOP (Idapexop utility)" in *z/VM: TCP/IP Planning and Customization*.

The following LDAPEXOP command quiesces the o=ibm,c=us replication context on the master and replica server in the replication topology:

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op cascrepl -action
quiesce -rc "o=ibm,c=us"

After the replication context is quiesced on all servers, the **Control replication** extended operation can be used to suspend replication for all replication agreements within the replication context.

The following LDAPEXOP command suspends replication for all replication agreements in the replication context o=ibm,c=us. The cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us is the only replication agreement within the o=ibm,c=us replication context so that it is the only agreement that is suspended.

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op controlrepl -action suspend -rc "o=ibm,c=us"

Use LDAPSRCH against both servers using a baseDN of o=ibm,c=us. This action should verify that ou=sub,o=ibm,c=us does not exist on the consumer server, explaining why the addition of the child entry cn=entry,ou=sub,o=ibm,c=us failed on the consumer server.

Before synchronizing entries within a replication context on the master and replica servers, all replication failures are deleted and all pending replication changes are skipped. Replication failures are deleted by using the **Control replication error log** extended operation on the LDAPEXOP utility. Pending replication changes are skipped by using the **Control replication queue** extended operation on the LDAPEXOP utility.

The following LDAPEXOP command deletes all failed replication failures from the backend replication table, cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us:

Т

Т

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op controlreplerr -delete all -ra "cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us"

I

1

Т

1

L

I

T

I

Т

L

I

I

Т

I

|

I

T

1

1

The following LDAPEXOP command skips (deletes) all pending replication changes from the replication queue:

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op controlqueue -skip all -ra "cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us"

To synchronize the o=ibm,c=us replication context on the master and replica servers, run DS2LDIF against the supplier server specifying a subtree (-s option) of ou=sub,o=ibm,c=us, and then run LDAPMDFY against the consumer server using the output LDIF file from DS2LDIF. The LDAPMDFY -k option is required to allow updates because the server is quiesced.

Because the master and replica servers are now synchronized, the replication agreement can now be resumed and the replication context unquiesced. The replication agreement is resumed by using the **Control replication** extended operation on the LDAPEXOP utility. The replication context is unquiesced on all servers in the replication topology by using the **Cascading control replication** extended operation on the LDAPEXOP utility.

The following LDAPEXOP command resumes replication for the replication agreement, cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us:

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op controlrepl -action resume -ra "cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us"

The following LDAPEXOP command unquiesces the replication context o=ibm,c=us on all servers in the replication topology:

ldapexop -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -op cascrepl -action unquiesce -rc "o=ibm,c=us"

The current replication status from the master to the replica can be determined by using the following LDAPSRCH command to retrieve the replication agreement entry:

```
ldapsrch -p 389 -h server1.us.ibm.com -D adminDn -w adminPw -b "o=ibm,c=us"
    "(objectclass=ibm-replicationAgreement)" "*" ibm-replicationChangeLdif
    ibm-replicationFailedChangeCount ibm-replicationFailedChanges ibm-replicationLastActivationTime
    ibm-replicationLastChangeID ibm-replicationLastFinishTime ibm-replicationLastResult
    ibm-replicationLastResultAdditional ibm-replicationNextTime ibm-replicationPendingChangeCount
    ibm-replicationState
```

#### The LDAPSRCH command returns the following entry:

cn=Replica, ibm-replicaServerId=Master, ibm-replicaGroup=default, o=ibm, c=us objectclass=top objectclass=ibm-replicationAgreement ibm-replicaconsumerid=Replica ibm-replicaurl=ldap://server2.us.ibm.com:389 ibm-replicacredentialsdn=cn=ReplicaBindCredentials,o=ibm, c=us description=Replication agreement from master to replica cn=Replica ibm-replicationonhold=FALSE ibm-replicationstate=ready ibm-replicationpendingchangecount=0 ibm-replicationnexttime=19000101000000 ibm-replicationlastfinishtime=20090206165454Z ibm-replicationlastchangeid=46 ibm-replicationlastactivationtime=20090206144354Z ibm-replicationfailedchangecount=0 ibm-replicationchangeldif=N/A

Because the **ibm-replicationState** operational attribute value in the replication agreement entry is set to ready, replication from the master to the replica is now no longer stalled.

# Chapter 12. Alias

I

Alias support provides a means for an LDBM or CDBM directory entry to point to another entry in the same directory. An alias entry can also be used to create a convenient public name for an entry or subtree, hiding the more complex actual name of the entry or subtree.

Alias support involves:

- · Creating an alias entry which points to another entry
- Dereferencing during search: when a distinguished name contains an alias, the alias is replaced by the value it points to and search continues using the new distinguished name.

For example, you can create an alias entry to provide a simple name for the LDAP department:

"ou=LDAPZOS,o=IBM"

The alias entry points to the actual LDAP department:

"ou=DEPTC8NG,ou=Poughkeepsie,o=IBM\_US,o=IBM"

This provides easier access to the entries of the LDAP developers, using public names such as:

"cn=kmorg,ou=LDAPZOS,o=IBM"

This name is dereferenced during search to: "cn=kmorg,ou=DeptC8NG,ou=Poughkeepsie,o=IBM\_US,o=IBM

and the information for that entry is returned.

## Impact of aliasing on search performance

Usage of aliases in a directory can cause a large increase in the amount of processing that takes place during search, even if no alias entries are actually involved in the particular search that was requested. To minimize the impact to search performance:

- Do not add aliases to the directory if they are not needed. There is no impact on search if there are no aliases in the directory.
- Only perform a search with dereferencing when aliases are involved in the search. Again, the impact on search is avoided if no dereferencing is requested.
  - **Note:** The search request from the LDAP client specifies whether to do dereferencing. The default value for dereferencing varies between different LDAP clients. If the default is to do dereferencing (this is the case with some Java clients), make sure to specifically reset this value to do no dereferencing when you issue search requests for which you do not want to do dereferencing.
- If you do want to use aliases in a directory, use them efficiently to minimize the number of alias entries. For example, use an alias entry for the root of a subtree (such as the alias for a department entry in the example above) rather than creating an alias entry for each individual entry within the subtree.

### Alias entry

An alias entry contains:

- · one of two object classes:
  - aliasObject AUXILIARY object class
  - alias STRUCTURAL object class

Note: This requires an object class such as **extensibleObject** to allow the naming attributes for the entry.

- aliasedObjectName attribute
  - its value is the distinguished name that the alias points to

These object classes and attributes are always part of the LDAP server schema.

Below is an example of an alias entry:

```
dn: ou=LDAPZOS,o=IBM
objectclass: organizationalUnit
objectclass: aliasObject
ou: LDAPZOS
aliasedobjectname: ou=DeptC8NG,ou=Poughkeepsie,o=IBM US,o=IBM
```

or

```
dn: ou=LDAPZOS,o=IBM
objectclass: alias
objectclass: extensibleobject
ou: LDAPZOS
aliasedobjectname: ou=DeptC8NG,ou=Poughkeepsie,o=IBM US,o=IBM
```

### Alias entry rules

An alias is a directory entry containing either the **alias** structural object class or the **aliasObject** auxiliary object class. Both of these object classes require the **aliasedObjectName** attribute (the **aliasedEntryName** alternate name can also be used). The **extensibleObject** object class should also be specified if the **alias** object class is used in order to add the RDN attributes for the alias entry.

An alias entry must be a leaf entry. This means that no ancestor of an entry can be an alias entry. In addition, an alias entry cannot also be a referral entry. A suffix entry can be an alias entry. In this case, the suffix will have no entries below it.

The value of the **aliasedObjectName** attribute does not have to be an existing entry. However, an error will be returned when dereferencing the alias if the value of the **aliasedObjectName** attribute does not refer to an entry in the same backend as the alias entry. The value cannot be the distinguished name of the alias entry; in other words, an alias entry cannot dereference to itself.

### **Dereferencing an alias**

All or part of a distinguished name (DN) can be an alias. Dereferencing a DN consists of the systematic replacement of an alias within the DN by the value of the **aliasedObjectName** attribute of the alias. This creates a new DN that must then be checked to see if it contains an alias that needs to be dereferenced. This process continues until the final dereferenced DN contains no alias within its name. An error will be returned if a circular chain is detected, that is, when a particular alias entry is

encountered more than once. The final dereferenced DN must be the DN of an entry in the same backend as the original DN. This entry must either exist or be under a referral entry.

Alias dereferencing is performed only during search operations. Alias entries are not dereferenced for any other LDAP operation.

Aliases are not dereferenced when performing a null-based subtree search since all entries in all LDBM backends are included in the search scope.

Duplicate objects will not be returned by a search operation. Duplicate objects can be encountered during a search if an alias points to an entry higher in the tree or if two aliases point to the same entry.

Dereferencing is only used to determine the entries that will be included in the search. The entries actually returned as search results must match the search filter. The DN of returned entries is the dereferenced DN. Using the above example, a search for "cn=John Doe, ou=LDAPZOS,o=IBM" will return an entry with DN "cn=John Doe,ou=DeptC8NG,ou=Poughkeepsie,o=IBM,c=US" if the "cn=John Doe,ou=DeptC8NG,ou=Poughkeepsie,o=IBM,c=US" entry matches the search filter.

Access checking is not performed when dereferencing an alias entry. Normal access checking will be performed for the dereferenced entry. Therefore, a search can dereference aliases even though the requester might not have any permissions to those alias entries.

### **Dereferencing during search**

### **Dereference options**

A flag value controls what alias dereferencing will be done during a search operation. This flag is sent by the client on the search request. The flag can have one of four values:

### LDAP\_DEREF\_NEVER (0)

do not dereference any alias entries. Alias entries encountered during the search operation are processed as 'normal' entries and are returned if they match the search filter.

#### LDAP\_DEREF\_SEARCHING (1)

dereference alias entries within the scope of the search but do not dereference the search base entry (if it contains an alias). The search base is processed as a 'normal' entry (even if it is an alias entry) and is returned if it matches the search filter and is in the search scope.

### LDAP\_DEREF\_FINDING (2)

dereference the search base entry (if it contains an alias) but do not dereference any other alias entries within the search scope. Alias entries within the search scope of the dereferenceed base are processed as 'normal' entries and are returned if they match the search filter.

### LDAP\_DEREF\_ALWAYS (3)

dereference the search base entry (if it contains an alias) and dereference alias entries within the scope of the search. All alias entries encountered during the search operation are dereferenced.

### Dereferencing during finding the search base

In a search request with **LDAP\_DEREF\_FINDING** or **LDAP\_DEREF\_ALWAYS**, dereferencing the search base just establishes a new search base. The results are equivalent to those from a search request that specifies the new base is its base.

### Dereferencing during searching in subtree searches

In a search request with LDAP\_DEREF\_SEARCHING or LDAP\_DEREF\_ALWAYS and subtree scope, dereferencing each entry under the base produces additional bases of subtrees to be searched. The aliases under each additional base are also dereferenced during search to find yet more subtree bases, and so on. When all the additional subtrees have been identified, the search filter is applied to all the non-alias entries in all the subtrees and the entries that match the filter are returned.

### Dereferencing during searching in one-level searches

In a search request with **LDAP\_DEREF\_SEARCHING** or **LDAP\_DEREF\_ALWAYS** and one-level scope, dereferencing each alias entry that is one level below the search base yields additional entries to search (even though they are no longer one level below the search base). The search filter is then applied to these additional entries and to the non-alias entries that are one level below the search base and the entries that match the filter are returned.

### Dereferencing and root DSE subtree search

Aliases are never dereferenced when performing a subtree search starting at the root DSE (this is also known as a null-based subtree search). All alias entries are processed like 'normal' entries, as if **LDAP\_DEREF\_NEVER** was specified.

### Errors during dereferencing

The common dereferencing errors and the resulting return codes are:

- loop detected during dereferencing: LDAP\_ALIAS\_PROBLEM (x'21')
- no entry in this backend for dereferenced DN: LDAP\_ALIAS\_DEREF\_PROBLEM (x'24')

### **Alias examples**

The following figure shows the directory structure used in the examples. The dashed lines indicate aliases. The dashed oval indicates the position of an aliased entry in the directory hierarchy, but the aliased entry does not actually exist.

Note: Fictitious attributetypes are used in the figure.

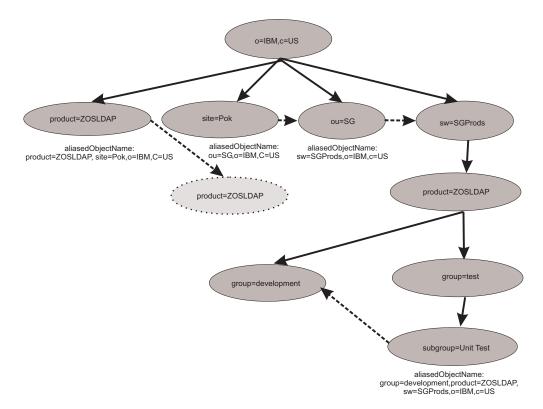

Figure 45. Alias example

The following search examples show the entries that are returned for various combinations of search base, search scope, and dereference option. The filter in each example is "objectclass=\*". Cases that are affected by alias dereferencing are indicated with an "\*".

Example 1: Perform a search from the base "sw=SGProds, o=IBM, c=US".

scope = base

• Returned entries with LDAP\_DEREF\_NEVER, LDAP\_DEREF\_SEARCHING, LDAP\_DEREF\_FINDING, or LDAP\_DEREF\_ALWAYS specified:

"sw=SGProds, o=IBM, c=US"

scope = one-level

• Returned entries with LDAP\_DEREF\_NEVER, LDAP\_DEREF\_SEARCHING, LDAP\_DEREF\_FINDING, or LDAP\_DEREF\_ALWAYS specified:

"product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

scope = subtree

- Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_FINDING specified:
  - "sw=SGProds, o=IBM, c=US"
  - 2. "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 3. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 4. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 5. "subgroup=Unit Test, group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- Returned entries with LDAP\_DEREF\_SEARCHING or LDAP\_DEREF\_ALWAYS specified:
  - 1. "sw=SGProds, o=IBM, c=US"
  - 2. "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 3. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 4. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US" (returned only once)

**Example 2:** Perform a search from the base "site=Pok, o=IBM, c=US".

#### scope = base

 Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_SEARCHING specified:

"site=Pok, o=IBM, c=US"

 Returned entries with LDAP DEREF FINDING or LDAP DEREF ALWAYS specified:

"sw=SGProds, o=IBM, c=US"

#### scope = one-level

 Returned entries with LDAP DEREF NEVER or LDAP DEREF SEARCHING specified:

No entries returned

 Returned entries with LDAP\_DEREF\_FINDING or LDAP\_DEREF\_ALWAYS specified:

"product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

scope = subtree

 Returned entries with LDAP DEREF NEVER or LDAP DEREF SEARCHING specified:

"site=Pok, o=IBM, c=US"

- Returned entries with LDAP\_DEREF\_FINDING specified:
  - 1. "sw=SGProds, o=IBM, c=US"
  - "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

  - "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
     "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 5. "subgroup=Unit Test, group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- Returned entries with LDAP DEREF ALWAYS specified:
  - 1. "sw=SGProds, o=IBM, c=US"

  - "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
     "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 4. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US" (returned only once)

**Example 3:** Perform a search from the base "product=ZOSLDAP, o=IBM, c=US". scope = base

 Returned entries with LDAP DEREF NEVER or LDAP DEREF SEARCHING specified:

"product=ZOSLDAP, o=IBM, c=US"

 Returned entries with LDAP\_DEREF\_FINDING or LDAP\_DEREF\_ALWAYS specified:

"product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

scope = one-level

 Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_SEARCHING specified:

No entries returned

- Returned entries with LDAP\_DEREF\_FINDING or LDAP\_DEREF\_ALWAYS specified:
  - 1. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 2. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- scope = subtree
- Returned entries with LDAP DEREF NEVER or LDAP DEREF SEARCHING specified:

"product=ZOSLDAP, o=IBM, c=US"

- Returned entries with LDAP\_DEREF\_FINDING specified:
  - "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 2. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 3. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 4. "subgroup=Unit Test, group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- · Returned entries with LDAP DEREF ALWAYS specified:
  - "product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 2. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 3. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US" (returned only once)

**Example 4:** Perform a search from the base "group=test, product=ZOSLDAP, o=IBM, c=US".

scope = base

Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_SEARCHING specified:

Error - LDAP NO SUCH OBJECT

 Returned entries with LDAP\_DEREF\_FINDING or LDAP\_DEREF\_ALWAYS specified:

"group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

- scope = one-level
- Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_SEARCHING specified:
  - Error LDAP\_NO\_SUCH\_OBJECT
- Returned entries with LDAP\_DEREF\_FINDING specified:
  - "subgroup=Unit Test, group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- Returned entries with LDAP\_DEREF\_ALWAYS specified:

"group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

- scope = subtree
- Returned entries with LDAP\_DEREF\_NEVER or LDAP\_DEREF\_SEARCHING specified:

Error - LDAP\_NO\_SUCH\_OBJECT

- Returned entries with LDAP\_DEREF\_FINDING specified:
  - 1. "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 2. "subgroup=Unit Test, group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
- Returned entries with LDAP\_DEREF\_ALWAYS specified:
  - "group=test, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"
  - 2. "group=development, product=ZOSLDAP, sw=SGProds, o=IBM, c=US"

# Chapter 13. Change logging

I

|

|

L

I

L

The change log is a set of entries in the directory that contain information about changes to objects. Depending on configuration options, information about a change to an LDBM or CDBM entry, to the LDAP server schema entry (cn=schema), or to an object controlled by an application (for example, a RACF user, group, user-group connection, or general resource profile) can be saved in a change log entry. An LDAP search operation can be used to retrieve change log entries to obtain information about what changes have taken place.

Each LDAP server contains one change log. The change log entries are created in the same order as the changes are made and each change log entry is identified by a change number value, beginning with 1, that is incremented each time a change number is assigned to a change log entry. Therefore, the change number of a new change log entry is always greater than all the change numbers in the existing change log entries.

The change log is implemented in the GDBM backend. The change log uses a hard-coded suffix, cn=changelog. This suffix is a semi-reserved name when the GDBM backend is configured. The change log root (cn=changelog) must not overlap any suffix in any SDBM or LDBM backend and the change log suffix cannot be the source or target of a rename operation. If GDBM is not configured, the user can use cn=changelog as a 'normal' suffix in an SDBM or LDBM backend; however, we do not recommend this because that suffix will have to be renamed to avoid an overlap if GDBM is configured in the future.

Change logging is enabled by configuring GDBM in the LDAP server configuration file. Change log processing is controlled by configuration options in the GDBM backend. The **changeLogging** configuration option turns change logging on or off. The **changeLogMaxEntries** and **changeLogMaxAge** configuration options determine when removal of old change log entries takes place. For more information, see "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization*. If none of these configuration options is specified in the GDBM section, the default is to start change logging with no limits on the size of the change log.

The **changeLoggingParticipant** configuration option can be used to specify if an LDBM or CDBM backend wants change log entries to be created for changes to entries in its backend. Similarly, the configuration option can be specified in the GDBM backend to determine if a change log entry should be created for a change to the LDAP server schema. If the option is not specified for an LDBM, GDBM, or CDBM backend, the default is to create change log entries for changes to that LDBM or CDBM backend, or to the LDAP server schema.

If the GDBM backend is configured and the cn=changelog root entry does not exist in the GDBM backend when the server is started, the LDAP server generates the root entry. The root entry is created with an ACL that allows only the administrator to access the change log. The ACL is propagated to the change log entries. The user needs to use an LDAP modify operation to change this ACL to an appropriate ACL for his usage of the change log. The **aclEntry** and **entryOwner** attributes are the only attributes that can be modified. The **aclPropagate** and **ownerPropagate** attributes will always be TRUE. Modifications to the change log are not logged. This means that no change sequence number will be returned for a persistent search request issued for the change log (cn=changelog).

# Configuring the GDBM backend

Т

Т

T

In a GDBM configuration:

- 1. There can be at most one GDBM backend in the configuration file.
- 2. The suffix option can not be specified in the GDBM backend.
- 3. If the **changeLoggingParticipant** option is specified, it controls whether a change log entry is created for a change to the LDAP server schema. Change log entries are never created for any changes to GDBM entries, including the suffix entry.

# Configuring a file-based GDBM backend

When configuring a file-based GDBM backend, the following configuration file options are required:

database GDBM GLDBGD31 [name]

The commitCheckpointEntries, commitCheckpointTOD, databaseDirectory, fileTerminate, filterCacheBypassLimit, filterCacheSize, include, persistentSearch, readOnly, sizeLimit, and timeLimit are options can also be specified in the GDBM configuration section. The changeLogging, changeLoggingParticipant, changeLogMaxAge, and changeLogMaxEntries configuration options can be specified to control change logging activity. For more information on these options, see "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.

The GDBM database is identical to an LDBM database and is created in the same way.

If you do not want to create change log entries for changes to entries within an LDBM, add the following configuration option to that backend section. You can add the same option to the GDBM section of the configuration file to stop the creation of change log entries for changes to the LDAP server schema entry: changeLoggingParticipant off

# Additional required configuration

	Additional configuration is required for RACF to be able to log changes to a RACF user, group, connection, or resource profile:
	• The SDBM backend must be configured. The SDBM suffix is needed to create a DN for the change log entry for a modification to a RACF user, group, connection, or resource profile. SDBM is also needed to retrieve the RACF user's new password or other changed fields. The following option must be specified in the SDBM section of the configuration file to allow change log entries to be created for changes to resource profiles:
I	enableResources on
	<ul> <li>LDAP Program Call support must be enabled in the LDAP server containing the change log. To do this, add the following option to either the global section of the configuration file or to the command used to start the LDAP server: listen ldap://:pc</li> </ul>

**Note:** This listen parameter for LDAP Program Call support is in addition to any other listen parameters you have specified.

There is no additional configuration needed to log changes to an LDBM or CDBM entry or to the LDAP server schema entry. If you do not want to create change log entries for changes to entries within an LDBM or CDBM backend, add the following configuration option to that backend section. You can add the same option to the GDBM section of the configuration file to stop the creation of change log entries for changes to the LDAP server schema entry:

changeLoggingParticipant off

# When changes are logged

Change log records can be created when the change logging is activated and the GDBM backend is not in read-only mode.

## **RACF** changes

I

I

I

L

I

I

I

Т

L

L

I

An extended operation, **changeLogAddEntry**, is provided to allow an application to log changes to data that it controls. The initial use of this interface is by RACF to log changes to a RACF user, group, user-group connection, or general resource profile when the profile is added, modified, or deleted. The RACF changes can be driven through the LDAP server or be made directly to RACF. For a user password or password phrase change, RACF includes information that the password or password phrase changed in the change log entry. For other user changes, RACF does not provide specific field information at this time.

The creation of a change log entry when using this interface is entirely separate from the change to RACF, even if the RACF change is made using LDAP. The result is that a RACF change can occur without a change log entry being created (for example, if the LDAP server is not running or if the change log entry creation fails).

# LDBM, CDBM, and schema changes

If change logging is activated, each add, modify, delete, or modify DN operation of an entry in any LDBM or CDBM backend or modify of the LDAP server schema entry results in the creation of a change log entry. An exception is if the **changeLoggingParticipant off** option in the LDAP server configuration file is specified for this backend, then no changes in this backend are logged. The option can be specified for the GDBM backend to stop logging changes to the LDAP server schema entry.

The change log entry is created after the change to the LDBM or CDBM backend entry or the LDAP server schema has been committed. This change is not rolled back if the change log record can not be created.

## Change log schema

The following object classes and their attributes define a change log entry. These object classes and attributes are always in the LDAP server schema.

• objectclass: changeLogEntry

changenumber

an integer assigned to this change log entry

#### targetDN

Т

T

T

Т

T

T

the DN to which the change was applied. For RACF, this DN is created from a user, group, class, and/or resource name passed in by RACF and the SDBM suffix.

#### changeType

#### add | modify | delete | modrdn

### changeTime

the time stamp of when the change is made (not when this entry is created)

#### changes

the added entry or the modifications, in LDIF format. This is fully supported for change log entries created by LDBM CDBM, and the LDAP server schema. However, the values for the **userPassword**, **secretKey**, **replicaCredentials**, **ibm-slapdMasterPw**, and **ibm-replicaKeyPwd** attributes are replaced with \*ComeAndGetIt\* in the change log entry. For change log entries created by RACF, this attribute is only present when a RACF user password or password phrase is changed, and contains either \*ComeAndGetIt\* or \*NoEnvelope\*, for example:

replace: racfPassword
racfPassword: \*ComeAndGetIt\*

#### newRDN

the new RDN specified in an LDBM or CDBM modify DN operation

#### delete01dRdn

a boolean indicating if the old RDN was deleted in an LDBM or CDBM modify DN operation

#### newSuperior

the new superior distinguished name specified in an LDBM modify DN operation

· objectclass: ibm-changelog

#### ibm-changeInitiatorsName

the DN of the entity that initiated the change. For RACF, this DN is created from a userid passed in by RACF and the SDBM suffix.

**Note:** If a RACF user's password or password phrase is changed using the *currentvalue/newvalue* support on a bind to the SDBM backend or on a bind using native authentication, the **ibm-changeInitiatorsName** value is created from the userid under which the LDAP server is running (and not the bound user).

The change log root entry and change log entries also have the standard operational attributes: the ACL attributes, **creatorsname**, **createtimestamp**, **modifiersname**, **modifytimestamp**, and **ibm-entryuuid** (change log root only).

### Change log entries

The change log consists of:

- One root (suffix) entry, named cn=changelog
- One or more leaf entries, named changenumber=nnn,cn=changelog

#### root entry

The change log root entry is generated by the LDAP server, when change logging is first enabled. The root entry cannot be created, renamed, or

deleted by the user. The generated root entry contains a propagated ACL that allows only the administrator to access the change log. An appropriately authorized user can modify the root entry to change the ACL. Operations on the change log root are not replicated and do not result in the creation of a change log entry.

The generated root entry is:

dn: cn=changelog
objectclass: container
cn: changelog
aclentry: group:cn=Anybody
aclPropagate: TRUE
entryowner: access-id:adminDN
ownerProgagate: TRUE

The change log root entry should be modified using the modify operation to set access control for the change log. Only the **aclEntry** and **entryOwner** attributes can be modified. The **aclEntry** and **entryOwner** attributes can be entirely deleted, in which case the default ACL is used. For more information, see "Default ACLs with LDBM" on page 144.

### leaf entry

Each change log entry is created as a leaf entry directly under the change log root entry, using the **changeLogEntry** and **ibm-changelog** objectclasses and attributes as described above.

- Change log entries are only created by the LDAP server. The user cannot directly add a change log entry. Also, the user cannot modify or rename a change log entry. Change log entries inherit the ACL of the change log root entry.
- Change log entries are deleted by the LDAP server when the change log is trimmed due to reaching a limit specified by the **changeLogMaxEntries** and **changeLogMaxAge** options in the configuration file. Change log entries can also be deleted by the user through a normal delete operation.
- User operations (search, compare, delete) on change log entries are allowed as long as change logging is enabled (the GDBM backend is configured), even if change logging is off. Add and trim operations by the LDAP server are not performed when change logging is off.
- If the GDBM backend is in read-only mode, delete and modify operations are not allowed. Add and trim operations by the LDAP server are not performed.
- Operations on change log entries are not replicated and do not result in the creation of change log entries.

The following is an example of a change log entry created by RACF:

```
dn: CHANGENUMBER=1815,CN=CHANGELOG
objectclass: CHANGELOGENTRY
objectclass: IBM-CHANGELOG
objectclass: TOP
changenumber: 1815
targetdn: RACFID=KEN,PROFILETYPE=USER,CN=MYRACF
changetime: 20030611161820.374472Z
changetype: MODIFY
changes: replace: racfPassPhrase
racfPassPhrase: *ComeAndGetIt*
-
```

ibm-changeinitiatorsname: RACFID=SUADMIN,PROFILETYPE=USER,CN=MYRACF

# Searching the change log

The change log can be searched using the standard LDAP search facilities.

- You can use any attribute in the search filter. A common search is with a "changenumber >= nnn" filter, where nnn is the largest changenumber value that was retrieved the previous time the search was done (the changenumber=nnn entry is retrieved again to ensure that the next part of the change log has not been trimmed).
- The change log entries matching the search filter are returned in increasing changenumber order.
- You cannot depend on there being change log entries for all consecutive change numbers. Some change numbers might be skipped.
- The change log (including the root entry) can be searched as long as change logging is enabled (the GDBM backend is configured), even if change logging is off.

# Passwords in change log entries

To avoid including passwords in the **changes** attribute of a change log entry, the values of the **userpassword**, **secretkey**, **replicacredentials**, **ibm-replicakeypwd**, **ibm-slapdmasterpw**, **racfpassword**, and **racfpassphrase** attributes are replaced by \*ComeAndGetIt\*. You can use a search command to retrieve the password. For a RACF password or password phrase, see Chapter 5, "Accessing RACF information," on page 65 for more information.

# Unloading and loading the change log

DS2LDIF (the unload utility **ds2ldif**) cannot be used to unload the contents of the change log. You should use the search operation to do this. Change log entries cannot be loaded into the change log. Add operations fail when processing change log entries.

# Trimming the change log

1

When change logging is on, the LDAP server periodically trims the change log based on the limits set in the LDAP server configuration file.

If a change log entry exceeds the age limit set using the **changeLogMaxAge** configuration option, it is removed from the log.

If the number of change log entries exceeds the limit set using the **changeLogMaxEntries** configuration option, the change log entries with the lowest changenumber values are removed. The number of entries that are removed depends on how GDBM is configured.

Entries are removed until the number of entries remaining is at the limit.

### Change log information in the root DSE entry

The following attributes in the root DSE entry allow applications to determine the location of the change log and effectively use it. The attributes appear whenever change logging is enabled (the GDBM backend is configured), whether or not change logging is currently on.

#### changelog=cn=changelog

the location of the change log

#### firstchangenumber=nnn

the lowest change number currently in use in the change log. A zero indicates no change log entries.

#### lastchangenumber=nnn

|

I

L

L

Т

L

|

I

the highest change number currently in use in the change log. A zero indicates no change log entries.

#### How to set up and use the LDAP server for logging changes

1. Update the LDAP server configuration file:

- a. Add the GDBM backend section, including a change log size and age limit if desired.
- b. If you plan to log changes to RACF users, groups, user-group connections, and general resource profiles, you must also:

Add the SDBM backend section, including the **suffix** and, optionally, the **enableResources** configuration options. The **enableResources** configuration option is needed only when logging changes to resource profiles. Following is an example:

database sdbm GLDBSD31 suffix cn=myRacf enableResources on

Enable the PC Callable support (used by RACF to add change log entries to the LDAP server) by specifying the following option in the global section of the configuration file:

listen ldap://:pc

c. If you do not want to log changes to entries in an LDBM or CDBM backend or to the LDAP server schema entry, add the following option to the LDBM, GDBM, or CDBMbackend section (the GDBM backend controls change logging for the schema entry):

changeLoggingParticipant off

- 2. If you plan to log changes to RACF users, groups, connections, and resource profiles, perform the RACF configuration required to support creation of an LDAP change log entry for RACF changes to those profiles. If you plan to retrieve RACF password or password phrase envelopes, you need to perform the RACF configuration required to support creation and retrieval of the password or password phrase envelopes. See *z/VM: RACF Security Server Security Administrator's Guide*
- 3. Restart the LDAP directory server. You will see the GDBM configuration options are displayed.

For a file-based GDBM backend, this will look similar to:

database GDBM GLDBGD31 GDBM-0002 changeLogging: on changeLogMaxAge: 86400 changeLogMaxEntries: 1000 changeLoggingParticipant: on commitCheckpointEntries: 10000 commitCheckpointTOD: 00:00 databaseDirectory: /var/ldap/gdbm fileTerminate: recover persistentSearch: off readOnly: off sizeLimit: 1000 suffix 1: CN=CHANGELOG timeLimit: 3600

Т

T

Т

Т

If GDBM fails to start, the following message is issued:

GLD1106E GDBM-0002 backend initialization failed.

- 4. At this point, change logging is started. Depending on your configuration, a change to a RACF user, group, connection, or resource profile, or to an LDBM or CDBM entry, or to the LDAP server schema entry will result in the creation of a change log entry in the LDAP server.
- 5. If desired, modify the ACL on the change log root entry, cn=changelog, for your usage of the change log. The initial ACL restricts client access to the change log to the LDAP administrator.

For example, to give read access to the change log to RACF user CLREADER, create an ldif file, cl.ldif, similar to the following:

```
dn: cn=changelog
changetype: modify
add: aclentry
aclentry:access-id:racfid=clreader,profiletype=user,cn=myRacf:normal:rsc:
    sensitive:rsc:critical:rsc:system:rsc
```

You should then modify the change log ACL by issuing a modify command similar to the following:

ldapmdfy -h ldaphost -p ldapport -D adminDn -w adminPw -f cl.ldif

6. You can search, delete, and compare change log entries using the LDAP client interfaces and command line utilities. In particular, all change log entries can be viewed using a search similar to the following:

ldapsrch -h ldaphost -p ldapport -D adminDn -w adminPw -b "cn=changelog" "objectclass=\*"

Part of the output from this search would look like:

cn=changelog
objectclass=top
objectclass=container
cn=changelog

```
CHANGENUMBER=1,CN=CHANGELOG
objectclass=CHANGELOGENTRY
objectclass=IBM-CHANGELOG
objectclass=TOP
changenumber=1
targetdn=RACFID=U2,PROFILETYPE=USER,cn=myRacf
changetime=20030611204814.257756Z
changetype=MODIFY
changes=replace: racfPassword
racfPassword: *ComeAndGetIt*
```

ibm-changeinitiatorsname=RACFID=SUSET3, PROFILETYPE=USER, cn=myRacf

7. If the **changes** attribute of a change log entry contains any of the following lines:

```
racfPassword: *NoEnvelope*
racfPassword: *ComeAndGetIt*
racfPassPhrase: *NoEnvelope*
racfPassPhrase: *ComeAndGetIt*
userpassword: *ComeAndGetIt*
replicacredentials: *ComeAndGetIt*
secretkey: *ComeAndGetIt*
ibm-slapdmasterpw: *ComeAndGetIt*
ibm-replicakeypwd: *ComeAndGetIt*
```

then a password in the RACF user profile, LDBM or CDBM entry was changed. If the value is \*ComeAndGetIt\*, then you can try to retrieve the actual password value. See "Passwords in change log entries" on page 264 for information on retrieving passwords.

8. The LDAP root DSE entry contains useful information about the LDAP change log, including its suffix, and the lowest and highest change numbers currently in use. A command similar to the following one obtains this information:

ldapsrch -h ldaphost -p ldapport -D adminDn -w adminPw -s base -b "" "objectclass=\*"
Part of the output from this search would look like:

changelog=cn=changelog firstchangenumber=1 lastchangenumber=202

L

**Note:** The LDAP server occasionally skips one or more change numbers, so it cannot be assumed that there is a change log entry for every number between 1 and 202. In addition, skips are created if you delete a change log entry that does not have the lowest number. Change numbers that are generated by the LDAP server are not guaranteed to be consecutive, but will always increase.

# **Chapter 14. Referrals**

Referrals provide a way for servers to refer clients to additional directory servers. With referrals you can:

- · Distribute namespace information among multiple servers
- Provide knowledge of where data resides within a set of interrelated servers
- Route client requests to the appropriate server

Following are some of the advantages of using referrals:

- · Distribute processing overhead, providing primitive load balancing
- Distribute administration of data along organizational boundaries
- Provide potential for widespread interconnection, beyond an organization's own boundaries.

This topic describes how to create referral entries in an LDBM backend and how to configure a default referral for the LDAP server.

A referral entry can be added to an LDBM backend to indicate that the backend does not contain that entry or any entries below it and to identify another LDAP server that may contain those entries. A referral entry returns referral information to the LDAP client if the target of a client operation is at or below the referral entry or if a search operation includes the referral entry within its search scope.

A default referral can be added to the LDAP server configuration file to identify another LDAP server that might contain entries that do not fall within any of the suffixes in this LDAP server. If the target of an operation is not at or below any suffix defined in the LDAP server, the LDAP server returns the default referral to the client.

This topic also discusses how to associate multiple servers using referrals, an example of associating a set of servers through referrals, basic replication (see Chapter 10, "Basic replication," on page 169), and advanced replication (see Chapter 11, "Advanced replication," on page 185).

### Using the referral object class and the ref attribute

The **referral** object class and the **ref** attribute are used to facilitate distributed name resolution or to search across multiple servers. The **ref** attribute appears in an entry in the referencing server. The value of the **ref** attribute points to the corresponding entry maintained in the referenced server. While the distinguished name (DN) in a value of the **ref** attribute is typically that of an entry in a naming context below the naming context held by the referencing server, it is permitted to be the distinguished name of any entry. A multi-valued **ref** attribute may be used to indicate different locations for the same resource. If the **ref** attribute is multi-valued, all the DNs in the values of the **ref** attribute should have the same value.

A referral entry must be a leaf entry. This means that no ancestor of an entry can be a referral entry. In addition, a referral entry cannot also be an alias entry.

# **Creating referral entries**

Following is an example configuration that illustrates the use of the **ref** attribute.

I

1

I

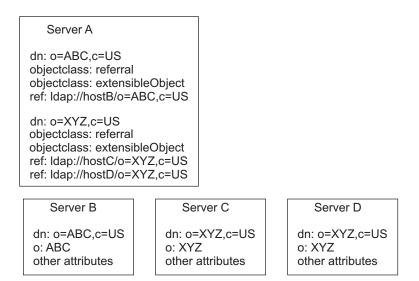

Figure 46. Example using ref attribute

In the example, Server A holds references to two entries: o=ABC,c=US and o=XYZ,c=US. For the o=ABC,c=US entry, Server A holds a reference to Server B and for the o=XYZ,c=US entry, Server A holds references to two equivalent servers, Server C and Server D.

The recommended setup of referrals is to structure the servers into a hierarchy based on the subtrees they manage. Then, provide "forward" referrals from servers that hold higher information and set the default referral to point back to its parent server.

#### Associating servers with referrals

In order to associate servers through referrals:

- · Use referral entries to point to other servers for subordinate references
- Define the default referral to point somewhere else, typically to the parent server

These steps are defined below.

#### Pointing to other servers

Use referral entries to point to the other servers for subordinate references which are portions of the namespace below this server which are not serviced directly.

Referral entries are created in LDBM backends. Referral entries consist of:

**dn** Specifies the distinguished name. It is the portion of the namespace served by the referenced server.

#### objectclass

Specifies referral. Also include the object class extensibleObject.

ref

Specifies the location of the referenced server. There is no required format for the value, however, the z/VM LDAP client can only follow a **ref** value which is in LDAP URL format. A LDAP URL has one of the following formats:

ldap://hostname:port/DN
ldaps://hostname:port/DN

The default port (389 for a non-SSL connection or 636 for an SSL connection) is used if a port is not specified as part of the LDAP URL. The DN of the referral entry is used if a DN is not specified as part of the LDAP URL. The **Idap://** form is for a non-SSL connection while the **Idaps://** form is for an SSL connection. The **Idaps://** form is required if you are using non-standard ports and want to allow SSL connections to the referenced server. The DN value in the LDAP URL should match the DN of the referral entry. The **ref** attribute may be multi-valued, with each value specifying the LDAP URL of a different server. When multiple values are used, each LDAP URL should contain the same DN, and each server should hold equivalent information for the portion of the namespace represented by the DN. Note that you cannot specify a 0-length value for the **ref** attribute.

The z/VM LDAP server automatically adds the **extensibleObject** object class to a referral entry if it is not specified. This allows the RDN attributes to be added to the referral entry.

Following is an example:

dn:	o=IBM,c=US
objectclass:	referral
objectclass:	extensibleObject
ref:	ldap://Host1:389/o=IBM,c=US
ref:	<pre>ldap://Host2:389/o=IBM,c=US</pre>
ref:	<pre>ldap://Host3:1389/o=IBM,c=US</pre>

An LDBM backend can contain any number of referral entries in its directory.

## Defining the default referral

Define the default referral to point to another server which services other portions of the namespace unknown to the referencing server. The default referral can be used to point to:

- The immediate parent of this server (in a hierarchy)
- A "more knowledgeable" server, such as the uppermost server in the hierarchy
- A "more knowledgeable" server which possibly serves a disjoint portion of the namespace.

The default referral is specified using the **referral** option in the LDAP server configuration file and applies to all backends in the LDAP server. The value of the option must be an LDAP URL. Multiple default referrals may be specified. However, each one specified is considered equivalent; that is, each server referenced by a default referral should present the same view of the namespace to its clients.

The default referral LDAP URL does not include the DN portion and a DN, if specified, is ignored. The default port (389 for a non-SSL connection or 636 for an SSL connection) is used if a port is not specified as part of the LDAP URL. The **Idap://** form is for a non-SSL connection while the **Idaps://** form is for an SSL connection. The **Idaps://** form is required if you are using non-standard ports and want to allow SSL connections to the referenced server. Following is an example: referral ldap://host3.ibm.com:999

**SSL/TLS note:** A non-secure client referral to a secure port is not supported. Also, a secure client referral to a non-secure port is not supported.

#### **Processing referrals**

 When LDAP clients request information from LDAP servers that do not hold the needed data, servers can pass back referral URLs, which indicate one or more other servers to contact. The clients can then request the information from the referenced server. By default, z/VM client utilities chase referrals returned from servers.

Servers present the referral URLs differently depending on the LDAP protocol version being used by the client. Referrals are presented to LDAP Version 2 clients in the error string, as the protocol does not provide a specific mechanism for indicating referrals. In LDAP Version 3, protocol elements are specifically defined to allow servers to present referral information to clients.

## **Using LDAP Version 2 referrals**

Referrals are not supported by the LDAP Version 2 protocol. In order to provide referral information to LDAP Version 2 clients, the referral information is returned as part of the error string in the result message. Since clients do not generally examine the error string for results indicating LDAP\_SUCCESS, the LDAP server returns LDAP\_PARTIAL\_RESULTS instead of LDAP\_SUCCESS if referral information is present in the error string. Referral information may be present for any result other than LDAP\_SUCCESS.

The referral information in the error string is returned as follows, where '\n' indicates a newline character:

```
Referral:\n
ldap://hostname:port/DN\n
...
```

where Referral: is followed by a new line character (\n) and ldap:// hostname:port/DN\n is an LDAP URL followed by a new line character. The ellipses (...) indicate a list of multiple referrals; that is, more LDAP URLs followed by new line characters.

#### Limitations with LDAP Version 2 referrals

Multiple referrals are only presented for partial search results when it is necessary to contact more than one additional server to complete the entire request. This would indicate that multiple referral entries were found in the referencing server that matched the search criteria. If chasing referrals, the client contacts every server presented in the list to continue the search request. For referral entries that have multi-valued **ref** attributes, the server sends only one of the LDAP URLs to a client using LDAP Version 2 protocol. This is because there is no provision for distinguishing between equivalent servers to contact (as indicated by multi-valued **ref** attributes) and multiple servers which must be contacted to complete a search request.

A second limitation of referrals in LDAP Version 2 is that operations can sometimes be ambiguous in their intent regarding whether the operation was targeted for "real" entries in the namespace, as opposed to the referral entries themselves. For searches, referral entries are only presented as referrals, since the usual intent of a search is to look at the real entries in the namespace. Server administrators must therefore use other means to examine existing referral entries, such as examining the database, or reviewing DS2LDIF output. For update operations, default referrals for upward references are presented as referrals, so that read-only replica servers can forward update operations to the master replica. However, subordinate references indicated by a referral entry are not followed for update operations, rather they operate on the referral entry itself. This is necessary to allow an administrator the ability to delete or modify existing referral entries. Erroneous changes caused by misdirected update operations are generally avoided through access protection and schema rules.

## **Using LDAP Version 3 referrals**

In LDAP Version 3, referrals are defined as part of the protocol. The LDAP Version 2 limitations mentioned above are overcome by elements of the protocol and extensions to the protocol. There are two methods of passing back referral information in the LDAP Version 3 protocol: referrals and search continuation references.

If the target of a request is a referral entry or is below a referral entry, or if the target does not fall within any of the suffixes in the LDAP server and a default referral is configured, then a result code of **LDAP\_REFERRAL** is presented by the server to indicate that the contacted server does not hold the target entry of the request. The referral field is present in the result message and indicates another server (or set of servers) to contact. Referrals can be returned in response to any operation request except unbind and abandon which do not have responses. When multiple URLs are present in a given referral response, each one must be equally capable of being used to progress the operation.

If the target of a search is found in the directory but a referral entry is encountered during the rest of a one-level or subtree search, a referral is not returned. Instead, one or more search continuation references are returned. Search continuation references are intermixed with returned search entries. Each one contains a URL to another server (or set of servers) to contact, and represents an unexplored subtree of the namespace which potentially satisfies the search criteria. When multiple URLs are present in a given search continuation reference, each one must be equally capable of being used to progress the operation.

As mentioned earlier, the other limitation in LDAP Version 2 referral processing is related to the inability of a client to specify whether a request was targeted for a normal entry or a referral entry. For LDAP Version 3, this difficulty is overcome with a protocol extension in the form of the manageDsalT control. (Appendix B, "Supported server controls," on page 337 describes manageDsalT in detail.) For typical client requests where the control is absent, whenever the server encounters an applicable referral entry while processing the request, either a referral or search continuation reference is presented. When the client request includes this control, the server does not present any referrals or search continuation references, but instead treats the referral entries as normal entries. In this case, even superior references through the use of default referrals are suppressed. The z/VM LDAP client utilities support the -M option to indicate that the requester is managing the namespace, and therefore wishes to examine and manipulate referral entries as if they were normal entries. For more information, see z/VM: TCP/IP User's Guide. An exception to the processing described above is that referral entries are always treated as normal entries during the second phase of a persistent search, even if the manageDsalT control is not specified on the persistent search request. See "PersistentSearch" on page 341 for more information.

# Bind considerations for referrals

When LDAP clients chase referrals from one server to another, they typically need to bind to the referenced server before redirecting the original request. If you distribute your directory across multiple servers connected by referrals, you must

consider the capabilities of the applications which access your directory, how they chase referrals, and how they can bind to the referenced servers.

For example, the LDAP client utilities such as LDAPSRCH (**Idapsearch**) and LDAPMDFY (**Idapmodify**) use the bind DN and password specified on the utility invocation, both when binding to the original target server and also when chasing referrals to other servers. If you want the LDAP client utilities to chase referrals across servers automatically, then the same bind DN and password must be accepted on each of the servers connected by referrals.

If you use an approach where there are no common bind identities, then your applications will either be limited to unauthenticated access or they will require the ability to bind appropriately to each server when chasing referrals.

Consider the following approaches:

- 1. Use unauthenticated access for reading information to avoid the need to bind with a common identity. This makes sense if the data in the directory is general reference information that does not need to be protected.
- 2. Establish an 'authentication' backend for identity information that is the same on each server. This could be an SDBM backend, where the common authentication identities are in RACF, or an LDBM backend that is the same on each server (replication could be used to ensure this). Access control over the other entries in the referral servers uses the distinguished names from the authentication backend to control access to the entries.
- 3. If you use the LDAP administrator DN to access the entries, configure the administrator DN and password identically in each of the referral servers.

#### Example: associating servers through referrals and basic replication

Following are the steps involved in distributing the namespace using referrals.

1. Plan your namespace hierarchy.

```
country - US
company - IBM, Lotus
```

organizationalUnit - IBM Austin, IBM Endicott, IBM HQ

2. Set up multiple servers, each containing portions of the namespace.

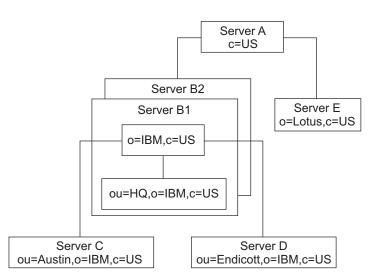

Figure 47. Setting up the servers

Following is a description of each server:

```
Server A
```

Perhaps just a server used to locate other servers in the US. With no other knowledge, clients can come here first to locate information for anyone in the US.

```
Server B1
```

A hub for all data pertaining to IBM in the US. Holds all HQ information directly. Holds all knowledge (referrals) of where other IBM data resides.

Server B2

A replica of Server B1.

Server C

Holds all IBM Austin information.

```
Server D
```

Holds all IBM Endicott information.

```
Server E
```

Holds all Lotus<sup>®</sup> information.

3. Set up referral entries to point to the descendents in other servers.

dn: o=IBM,c=US objectClass: referral objectClass: extensibleObject ref: Idap://ibm.com:389/o=IBM,c=US ref: Idap://ibm.com:390/o=IBM,c=US	← Pointer to Servers B1 and B2
dn: o=Lotus,c=US objectClass: referral objectClass: extensibleObject ref: ldap://lotus.com:389/o=Lotus,c=US	Pointer to Server E

Figure 48. Server A database (LDIF input)

4. Servers can also define one or more default referrals which point to "more knowledgeable" servers for anything that is not underneath them in the namespace.

The default referrals go in the configuration file, not the backend.

Note: The default referral LDAP URLs do not include the DN portion.

```
# General Section
referral ldap://ibm.com:389
referral ldap://ibm.com:390
listen ldap://:789
# ldbm database definitions
database ldbm GLDBLD31
suffix "ou=Endicott,o=IBM,c=US"
```

Figure 49. Server D configuration file

5. Putting it all together.

Figure 50 on page 276, Figure 51 on page 277, and Figure 53 on page 279 show these same six servers, showing the referral entries in the database as well as the default referrals which are used for superior references. Also

included in Servers B1 and B2 are sample definitions for replication, setting up Server B2 as a replica of Server B1. This ensures that these two servers remains identical. Servers B1 and B2 are located on the same system, but use different ports.

Server A: Services "c=US" host name "US.white.pages.com" **Configuration File** listen ldap://:1234 database 1dbm GLDBLD31 suffix "c=US" Directory dn: c=US objectClass: country dn: o=IBM,c=US objectClass: referral objectClass: extensibleObject ref: ldap://ibm.com:389/o=IBM,c=US ref: ldap://ibm.com:390/o=IBM,c=US dn: o=Lotus,c=US objectClass: referral objectClass: extensibleObject ref: ldap://lotus.com:389/o=Lotus,c=US Server E: Services "o=Lotus,c=US" host name "lotus.com" **Configuration File** referral ldap://US.white.pages.com:1234 listen ldap://:389 database 1dbm GLDBLD31 suffix "o=Lotus,c=US" Directory dn: o=Lotus,c=US objectClass: organization

# Chapter 15. Organizing the directory namespace

Directory services are meant to help organize the computing environment of the enterprise. To do this, directory services are meant to be used to help find all the resources at one's disposal. Information that is typically found in a directory consists of configuration information for services offered in the enterprise, locating information for people, places, and things in the enterprise, as well as descriptive information about services and resources available in the enterprise. The directory service should be thought of as the spot that can be queried to find whatever is desired in the enterprise.

When designing the format and organization of the directory service for an enterprise, the intended usage scenarios should be considered. These usage characteristics can have an impact on how the directory namespace should be organized so as to offer reasonable performance.

There are two general areas of directory namespace design to be considered. First, the types of information and the layout of where that information will be placed in the directory namespace must be determined. Additional information types can be added at a later date, but there should be some overall design of where in the directory namespace these types of information should be placed. Second, based on the usage characteristics of the users in the enterprise, the number of distinct directory servers and the namespace subtree or subtrees that they support must be considered.

As an example, consider an enterprise that consisted of two physical locations, one in Los Angeles, CA and one in New York City, NY. People in New York City access information about people, places, and things in Los Angeles often, while the people in Los Angeles rarely access information items in New York City. To offer good performance for both locations, a separate directory server could be installed and run in each location. These LDAP servers would manage information about the people, places, and things that reside in their respective locations. In addition, because the New York City personnel access information about things in the Los Angeles location, the information from the Los Angeles LDAP server could be replicated to an additional LDAP server at the New York City LDAP server. This would allow the New York City personnel to access information about the Los Angeles location by contacting a local server. In Los Angeles, however, directory requests about items in the New York City portion of the enterprise namespace are redirected (that is, referred) to the New York City LDAP server for the information. This would save managing a replicated set of information at the expense of slightly longer access times on the less-requested information.

The next two sections discuss information layout in the namespace and partitioning an enterprise namespace across multiple LDAP servers. These sections are followed by a small example.

# **Information layout**

A directory is meant to provide information about people, places, and things in the enterprise. The most direct use of a directory is to hold information on how to contact other people in the enterprise. This has commonly been known as the *internal phone book*. With the widespread enhancements in technology, people are now more accessible than ever. We have pagers, answering machines, cellular phones, and e-mail. In trying to communicate with someone we might need to know about all of this information. Modeling a person object class based on the attributes

about a person that are important to others in the enterprise is an easy way to support an online *internal phone book* using an LDAP directory service. In addition to people, different organizations within an enterprise can also be modeled by creating new object classes and attribute types. This would allow storage in the LDAP directory of locating information for useful services in the organization like benefits, travel reservations, and human resources.

Another application of directory services is the ability to model or store information about places. A place could be a conference room, which might have attributes of **numberOfSeats**, **projectorType**, **phoneNumber**, **calendarLocation**, **dataPortType**, **officeNumber**, and **buildingNumber**. Using this method, different conference rooms within a company could be located and compared. Another example of a place would be the whole site in which employees work. An object class for a site LDAP directory entry might be made up of **streetAddress**, **generalManagerDN**, **siteMap**, and **cafeteriaLocation**.

Things abound within the enterprise. Under this category falls computers, copiers, FAX machines, printers, and computer software, as well as configuration information for servers that use an LDAP directory service. Each of these can be modeled with attribute types used inside object classes specific to the device or program.

In laying out where entries should appear in the directory hierarchy, by far the most common method of naming things is to start with the country in which the company is organized, followed by the name of the company, treated as an organization attribute type. Thus, the top level suffix for LDAP directory service names for entries within the company sometimes follows the form: o=CompanyName, c=US (for US-based companies). Alternately, the top level suffix may follow the domain form, for example: dc=CompanyName, dc=com. Below this suffix it is common for organizational unit object classes to be used to represent departments or sites within an organization. Below these organizational entries the actual entry representing a person, place, or thing would be defined. When organizing the information layout for the namespace, the intended usage should be considered to ensure the best performance.

#### Example of building an enterprise directory namespace

Let us look at an example configuration that exhibits the features available with the LDAP server. To set the stage, we will consider a moderately sized company that has personnel working in three locations across the United States. Big Company, Inc. has corporate headquarters in Chicago, IL, and two satellite facilities, one in Los Angeles, CA and the other in New York City, NY. The information technology staff would like to make available information about all of the company's computing and office services using an LDAP directory. In order to facilitate local modifications as necessary of the information in the directory, as well as provide improved response time for accessing local information, each site will have an LDAP server running. The server running at each site will be responsible for managing the directory information that pertains to that site.

The first thing to do is determine the name of the root of the directory namespace for Big Company, Inc. Typically, the name for the company will consist of the country of origin along with the company's given name. In LDAP directory terminology, the company is an organization. In this example, we chose: o=Big Company, c=US as the company's name is Big Company and is located in the United States. Choosing a name of this format helps ensure that when a global namespace coordinator is established, the company's chosen *root* will fit nicely into the overall directory namespace.

Next to choose are the names of the three locations under which the directory information is stored. At this point, the namespace could be organized in a number of ways. One way would be to organize by functional unit (regardless of location). This model is useful if individuals (or computers, or other equipment or services) typically remain with the functional unit as opposed to being tied to the individual or physical location. Another way would be to organize based on the physical locations of the parts of the organization. This is useful if the people, places, and things to be stored in the directory typically do not move between locations. This latter approach will be used in the example. So, with three locations, three names are defined below the overall company distinguished name:

ou=Los Angeles, o=Big Company, c=US ou=Chicago, o=Big Company, c=US ou=New York City, o=Big Company, c=US

Since separate LDAP servers will be established at each location, these names represent the root of the subtree stored and managed by the directory server at each location.

For administration, each site will have a different directory administrator. To define this administrator, an administrator distinguished name and password need to be defined for each location. To start, the following names will be used:

AdminDN "cn=Administrator, ou=Los Angeles, o=Big Company, c=US"

AdminDN "cn=Administrator, ou=Chicago, o=Big Company, c=US"

AdminDN "cn=Administrator, ou=New York City, o=Big Company, c=US"

Since the Chicago location is also the corporate headquarters, the LDAP directory at this location will be used to store information about the entire company as well as information about the Chicago site.

We now have enough information to set up the base configuration files for each of the three LDAP servers that will be used to supply this information. Following are the files needed to set up the LDAP servers on each site. Note that what is shown is the minimal setup required. Other options could be specified in addition to these. For configuration options, see "Creating the DS CONF File" in *z/VM: TCP/IP Planning and Customization*.

# Configuration file for the Chicago LDAP server adminDN "cn=Administrator, ou=Chicago, o=Big Company, c=US" database ldbm GLDBLD31 suffix "o=Big Company, c=US" # end of configuration file

Figure 54. Chicago base configuration

```
# Configuration file for the Los Angeles LDAP server
referral ldap://ldap.chicago.bigcompany.com
adminDN "cn=Administrator, ou=Los Angeles, o=Big Company, c=US"
database ldbm GLDBLD31
suffix "ou=Los Angeles, o=Big Company, c=US"
# end of configuration file
```

Figure 55. Los Angeles base configuration

```
# Configuration file for the New York City LDAP server
referral ldap://ldap.chicago.bigcompany.com
adminDN "cn=Administrator, ou=New York City, o=Big Company, c=US"
database ldbm GLDBLD31
suffix "ou=New York City, o=Big Company, c=US"
# end of configuration file
```

Figure 56. New York City base configuration

The referral line indicates the default place to refer connecting clients when the LDAP server does not contain the information requested by the client. It is called the *default referral*. It is in the form of an LDAP URL. After the scheme name (1dap), the LDAP URL contains a TCP/IP DNS host name for another LDAP server. In this example, it is assumed that the TCP/IP host on which the Chicago LDAP server is running is 1dap.chicago.bigcompany.com. The Chicago LDAP server does not have a default referral defined. This keeps directory searches from inadvertently going over the Internet from within the company.

The adminDN line indicates the distinguished name that should be used to connect to the LDAP server in order to have complete control over the data content held by the LDAP server.

The database line indicates that all following lines pertain to the LDBM storage method. The suffix line indicates what part of the namespace is contained in this server.

After these files have been created, one or more of the LDAP servers can be started. However, there will be no initial data in the LDBM database. The next section tells you how to load entries into the LDAP server.

#### Priming the directory servers with information

Add entries to an LDBM (file-based) backend in the LDAP server by using LDAPADD and LDAPMDFY (the **Idapadd** and **Idapmodify** utilities) or by using the LDAP C language API and the LDAP protocol. It is recommended that at least the top levels of directory information be loaded first into the database. This provides a base from which to add more entries into the directory namespace.

## Using LDIF format to represent LDAP entries

The LDAP Data Interchange Format (LDIF) is used to represent LDAP entries in a simple text format. An LDIF file contains groups of attribute information which will be treated as an entry to be added to the directory. The general format of an LDIF entry is:

dn: distinguished name
attrtype1: attrvalue1
attrtype2: attrvalue2
...

Each line in the LDIF file must begin in column 1. However, to continue a line, start the next line with a single space or tab character. For example:

dn: ou=departments, ou=New York City, o=Big Co
mpany, c=US

Multiple attribute values are specified on separate lines. For example:

objectclass: organizationalunit
ou: departments

#### Note about editing LDIF files

Be aware that some editors place blank spaces at ends of all empty lines within a file. A blank space at the beginning of a line signifies continuation of the entry. The blank lines used to separate entries may be treated as continuations of an attribute value instead of separators if an editor has modified the LDIF file. Also, be aware that some editors delete blanks at the end of a line that is not empty. This can change the value of an attribute, especially if that value is continued on the next line.

If an *attrvalue* contains a nonprinting character, or begins with a space or a colon (:), the *attrtype* is followed by a double colon (::) and the value is encoded in base64 notation. For example, the value:

" begins with a space"

would be encoded like this:

cn:: IGJ1Z21ucyB3aXRoIGEgc3BhY2U=

Multiple entries within the same LDIF file are separated by blank lines. Here is an example of an LDIF file containing three entries.

dn: ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: New York City
dn: ou=fax machines, ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: fax machines
dn: ou=computers, ou=New York City, o=Big Company, c=US

objectclass: organizationalunit ou: computers

**Note:** Trailing spaces are not trimmed from values in an LDIF file. Also, multiple internal spaces are not compressed. If you do not want them in your data, do not put them there.

Multiple attribute values for the same attribute type are specified on multiple lines within the specification of a directory entry. For example:

```
dn: cn=John Doe, ou=New York City, o=Big Company, c=US
objectclass: person
cn: John Doe
phonenumber: 555-1111
phonenumber: 555-2222
sn: Doe
```

#### Generating the file

A file is typically generated using an existing source of information and some tools to format the data into the LDIF format. Note that the order of entries in the LDIF file is important. In order for an entry specified in the LDIF file to be successfully added to the directory, its parent entry must first exist in the directory namespace. For this reason, the top level entries in the directory namespace subtree that the particular LDAP server will support must be first in the LDIF file.

For our example, we will define just a minimal set of entries to get the directory server useful at each location. This will include two referral entries for the Chicago location. The meaning of these entries will be discussed in more detail in the following sections.

Here is the base set of LDIF files to set up the directory namespace at each location. For the Los Angeles location:

dn: ou=Los Angeles, o=Big Company, c=US
objectclass: organizationalunit
ou: Los Angeles
dn: cn=Administrator, ou=LosAngeles, o=Big Company, c=US
objectclass: person
cn: Administrator
sn: Administrator
userpassword: xxxxx

dn: ou=fax machines, ou=Los Angeles, o=Big Company, c=US
objectclass: organizationalunit
ou: fax machines

dn: ou=computers, ou=Los Angeles, o=Big Company, c=US
objectclass: organizationalunit
ou: computers

dn: ou=departments, ou=Los Angeles, o=Big Company, c=US
objectclass: organizationalunit
ou: departments

#### For the New York City location:

dn: ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: New York City

dn: cn=Administrator, ou=New York City, o=Big Company, c=US
objectclass: person
cn: Administrator
sn: Administrator
userpassword: xxxxx

dn: ou=fax machines, ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: fax machines

dn: ou=computers, ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: computers

```
dn: ou=departments, ou=New York City, o=Big Company, c=US
objectclass: organizationalunit
ou: departments
For the Chicago location:
dn: o=Big Company, c=US
objectclass: organization
o: Big Company
dn: ou=Los Angeles, o=Big Company, c=US
objectclass: referral
objectclass: extensibleObject
ref: ldap://ldap.losangeles.bigcompany.com/ou=Los Angeles,o=Big Company,c=US
dn: ou=New York City, o=Big Company, c=US
objectclass: referral
objectclass: extensibleObject
ref: ldap://ldap.newyorkcity.bigcompany.com/ou=New York City,o=Big Company,c=US
dn: ou=Chicago, o=Big Company, c=US
objectclass: organizationalunit
ou: Chicago
dn: cn=Administrator, ou=Chicago, o=Big Company, c=US
objectclass: person
cn: Administrator
sn: Administrator
userpassword: xxxxx
dn: ou=fax machines, ou=Chicago, o=Big Company, c=US
objectclass: organizationalunit
ou: fax machines
dn: ou=computers, ou=Chicago, o=Big Company, c=US
objectclass: organizationalunit
ou: computers
dn: ou=departments, ou=Chicago, o=Big Company, c=US
objectclass: organizationalunit
ou: departments
```

These files will now be used with a load facility. After loading these files on each respective directory server system, the directory namespace will be formed and the servers can now be used to hold and supply information.

Two entries added to the Chicago location directory server database deserve some special attention. These are the referral objects that were in the LDIF file for the Chicago location. Notice that the referral objects have the identical distinguished name as the root of the LDAP directory namespace that is served by the Los Angeles and New York City servers. These entries, coupled with the default referral specification in the configuration file for the directory servers in Los Angeles and New York City, enable searches of the Big Company namespace to originate at any of the three directory servers and resolve to the correct server to obtain the information.

A referral redirects a client request to a different LDAP server that can presumably handle the request (or refer the client to another server that can handle the request). In our example, if a client connects to the New York City server requesting a name that is under the Los Angeles portion of the namespace, the New York City server will send back a referral to the client based on the default referral. This will point the client at the Chicago directory server. The Chicago server will resolve the

request down to the referral object for distinguished name ou=Los Angeles, o=Big Company, c=US and refer the client to the Los Angeles server. Finally, the client will contact the Los Angeles server and obtain the information requested.

# Setting up for replication

As people start using the directory service in their daily routines at Big Company, Inc., the information technology staff notices that the people in New York City are doing a lot of work with the people in Los Angeles. So much, in fact, that an analysis of the TCP/IP traffic between New York City and Los Angeles shows that much of the traffic is directory access requests, presumably to look up phone numbers or FAX numbers for people in Los Angeles. The information technology staff decides to improve directory lookup response time, as well as lessen the directory lookup traffic between New York City and Los Angeles, by creating a replica of the Los Angeles directory server's information in New York City. This will allow local access to this information by the New York City users and cut down on the amount of requests from New York that must travel to Los Angeles to be completed.

#### Defining another LDAP server

To set up a replica of the LDAP server information in Los Angeles, a second LDAP server must be defined and started in New York City. This server can reside on the same system as the first LDAP server, though if this is chosen, the TCP/IP port that this replica server listens on must be different from the other LDAP server running on the system. As an alternative, the replica server could run on a different system, allowing it to listen on the default LDAP port. The configuration file for the replica server in New York City will be very similar to the configuration files for the New York City server and the Los Angeles server. This configuration file must contain some additional items that pertain to replication. Here is what the contents of the New York City Los Angeles replica server should contain:

```
# Configuration file for the New York City Los Angeles replica LDAP server
referral ldap://ldap.chicago.bigcompany.com
listen ldap://:2001
adminDN "cn=Administrator, ou=Los Angeles, o=Big Company, c=US"
database ldbm GLDBLD31
suffix "ou=Los Angeles, o=Big Company, c=US"
masterServer ldap://ldap.losangeles.bigcompany.com
masterServerDN "cn=Replicator, ou=Los Angeles, o=Big Company, c=US"
# end of configuration file
```

The additional lines at the end of the configuration file specify the only "user" that can update entries in the replica LDAP server. The values here must match the values entered at the "source" location when the replica is defined.

## Preparing the replica

The next step is to get the LDAP replica primed with the existing information in the Los Angeles server and set up the Los Angeles server to replicate to the New York City replica. The set of steps to perform (described in Populating a replica) ensures that the replicas are in sync and that no update is lost during this synchronization. Once the replica is defined at the source location, updates to the directory information will be logged to be sent to the replica server when possible.

To initially synchronize the data between the LDAP master server and the LDAP replica server, perform the steps in Populating a replica.

While there are a number of manual steps to perform, there is a small consolation that the steps at different locations are not interleaved. All work can be done at the source location and then all work can be performed at the target (replica) location.

#### Resynching the replica and master servers

If it is noticed that a replica's contents are out of sync with the information at the master server, the information can be resynched by following the steps shown in Recovering from basic replication out-of-sync conditions.

#### Notifying users of the replica

At this point, the New York City users can be notified that a second LDAP server is now available for their use. The notification should contain either the LDAP URL of the new LDAP replica server or the host name and port number of the LDAP replica server, as well as the base of the LDAP subtree that is published by the replica. As updates are made to the Los Angeles LDAP server, these updates will be propagated to the replica server in New York City. See Chapter 10, "Basic replication" for more details on replication.

What Big Company, Inc. now has in place is an Enterprise Directory service that can be used by whatever enterprise distributed processing tasks require lookup or configuration information. These enterprise distributed processing tasks and applications may require some changes to make use of the directory service, but the result will be the ability to view, find, and modify the configuration of the enterprise by looking at and modifying the contents of the LDAP directory.

# **Chapter 16. Client considerations**

When an LDAP application is communicating with an LDAP server, you should consider the following special topics:

- Root DSE
- Monitor Support
- CRAM-MD5 authentication support
- UTF-8 data over the LDAP Version 2 protocol
- · Attribute types stored and retrieved in lowercase
- Abandon behavior
- Changed return codes
- Reason codes.

#### Root DSE

The root DSE is the entry at the top of the LDAP server directory information tree. All the **namingcontexts** (suffixes) in the LDAP server are directly below the root DSE. The root DSE contains information about the LDAP server, including the **namingcontexts** that are configured and the capabilities of the server.

The root DSE can be searched by specifying a zero-length base distinguished name. The search scope can be either base or subtree (the one-level scope is not supported).

#### Root DSE search with base scope

A root DSE search with base scope returns the contents of the root DSE. The root DSE attributes describe the LDAP server. The only search filter supported is **objectclass=**\*. There is no access control checking for the root DSE, but an anonymous bind will fail if **allowAnonymousBinds off** is specified in the LDAP server configuration file. The **supportedcontrol**, **supportedextension**, and **namingcontexts** attributes may contain values that are contributed by plug-in extensions configured in the LDAP server.

The following example uses LDAPSRCH (the **Idapsearch** utility) to request a base search of the root DSE and shows sample output for the search:

ldapsrch -h ldaphost -p ldapport -s base -b "" "objectclass=\*"

Following is an example of the information that the LDAP server will report on a search of the root DSE. A subset of these values may appear in your root DSE based on the server configuration choices you have made.

ibm-sasldigestrealmname=MYHOST.IBM.COM changelog=cn=changelog firstchangenumber=24213 lastchangenumber=24322

Following are Object Identifiers (OIDs) for supported and enabled capabilities:

OID assigned	Short name	Description
1.3.6.1.4.1.4203.1.5.1	Retrieval of operational attributes	Indicates that this server supports the + attribute on search requests to return operational attributes.
1.3.18.0.2.32.1	Advanced replication	Identifies that this server supports advanced replication which includes subtree and cascading replication.
1.3.18.0.2.32.2	Entry Checksum	Indicates that this server supports the <b>ibm-entryCheckSum</b> and <b>ibm-entryCheckSumOp</b> operational attributes.
1.3.18.0.2.32.3	Entry UUID	Identifies that this server supports the <b>ibm-entryuuid</b> operational attribute.
1.3.18.0.2.32.5	Password policy	Indicates that this server supports password policies.
1.3.18.0.2.32.7	System restricted ACL support	Indicates that the server supports specification and evaluation of ACLs on system and restricted attributes.
1.3.18.0.2.32.18	<b>cn=ibmpolicies</b> advanced replication subtree	Indicates that this server supports the replication of the <b>cn=ibmpolicies</b> subtree. This support is only available when advanced replication is configured.
1.3.18.0.2.32.19	Max age ChangeLog entries	Specifies that the server is capable of retaining changelog entries based on age.
1.3.18.0.2.32.24	Monitor operation counts	The server provides new monitor operation counts for initiated and completed operation types.
1.3.18.0.2.32.26	Null-based subtree search	Indicates that the server supports null-based subtree search operations, which search all the LDBM or CDBM entries in the server.
1.3.18.0.2.32.28	TLS capabilities	Specifies that the server is capable of performing Transport Layer Security (TLS).

| |

| | |

OID assigned	Short name	Description
1.3.18.0.2.32.29	Non-blocking advanced replication	Indicates that this server is capable of ignoring some errors received from a consumer (replica) server that would normally cause an update to be retransmitted periodically until a successful return code is received.
1.3.18.0.2.32.31	ibm-allMembers and ibm-allGroups operational attributes	Indicates that a backend supports searching on the <b>ibm-allGroups</b> and <b>ibm-allMembers</b> operational attributes. The members of a static, dynamic or nested group can be obtained by performing a search on the <b>ibm-allMembers</b> operational attribute. The static, dynamic and nested groups that a member DN belongs to can be obtained by performing a search on the <b>ibm-allGroups</b> operational attribute.
1.3.18.0.2.32.33	Modify DN (subtree move)	Indicates that a subtree can be moved to another subtree, within a backend. This move uses a new superior. It can also use a new RDN.
1.3.18.0.2.32.34	Modify DN (subtree rename)	Indicates that a subtree can be renamed. The DN of each entry under the subtree will also be changed. This rename uses a new RDN but not a new superior.
1.3.18.0.2.32.43	Advanced replication configuration	Indicates that this server supports configuration of supplier servers in an advanced replication environment.
1.3.18.0.2.32.44	Global updates support	Indicates that this server supports the advanced replication of global updates using the replication topology in the <b>cn=ibmpolicies</b> subtree in the CDBM backend.
1.3.18.0.2.32.51	Advanced replication conflict resolution maximum entry size	Indicates that this server supports the ibm- slapdReplConflictMaxEntrySize attribute on an CDBM entry with an objectclass of ibm- slapdReplicationConfiguration. This attribute value indicates the maximum number of bytes that an entry can contain and still be resent to a target server as a result of advanced replication conflict resolution.

Table 46. Object Identifiers (OIDs) for supported and enabled capabilities (continued)

**OID** assigned Short name Description Indicates that this server supports 1.3.18.0.2.32.52 Lost and found log the lost and found log for archiving replaced entries as a result of the advanced replication conflict resolution. Indicates that this server supports 1.3.18.0.2.32.54 Password policy account lockout the password policy account lockout feature. Updated ibm-1.3.18.0.2.32.56 Indicates that this server supports entryCheckSumOp operational an updated algorithm for the checksum calculation of the attribute calculation ibm-entryCheckSumOp operational attribute. 1.3.18.0.2.32.57 LDAP password global start Indicates that the server supports time the ibm-pwdPolicyStartTime attribute in the cn=pwdpolicy,cn=ibmpolicies entry. 1.3.18.0.2.32.63 Salted SHA (SSHA) Indicates that this server supports the Salted SHA hashing of password values. Identifies that this server supports 1.3.18.0.2.32.65 Filter replication filtered replication which allows only required entries and a subset of attributes to be replicated. This support is only available when advanced replication is configured. Multiple password policies Indicates that this server allows 1.3.18.0.2.32.77 multiple password policy entries to be defined and used. 1.3.18.0.2.32.88 Password policy max Indicates that this server supports consecutive repeated characters password policies that restrict the maximum number of consecutive repeated characters in password values. Fine grained timestamps Indicates that this server supports 1.3.18.0.2.32.94 advanced replication with fine grained timestamps that include microseconds. Indicates that this server supports 1.3.18.0.2.32.95 ibmreplicationWaitOnDependency the replication of the attribute replication ibmreplicationWaitOnDependency attribute from the advanced replication agreement entry. Indicates that this server supports 1.3.18.0.2.32.98 ACL filter support specifying a filter in the access control attributes to further control access to an object.

# Root DSE search with subtree scope (null-based subtree search)

A root DSE search with subtree scope returns all the entries that match the search filter in the LDBM and CDBM backends configured in the LDAP server. This search is commonly referred to as a null-based subtree search. Note that the search does not include the root DSE itself, the LDAP server schema entry, SDBM entries, and GDBM entries (change log records). Alias entries are not dereferenced during the search; they are processed like normal entries and returned if they match the search filter. Referral entries in LDBM and CDBM return referrals to the client. Any filter can be specified for the subtree search.

A null-based subtree is implemented as a series of searches to each LDBM and CDBM suffix. These individual searches are each limited by the **timelimit** and **sizelimit** options specified in the LDAP server configuration file. If a time limit or size limit is specified on the root DSE search request, then the individual searches are also limited by the amount of time remaining and the number of entries left to return when that individual search is started. For more information, see the descriptions of the **sizelimit** and **timelimit** options in "Step 6. Create and Customize the LDAP Configuration File (DS CONF)" in *z/VM: TCP/IP Planning and Customization*. Each individual LDBM and CDBM search is subject to the normal LDBM and CDBM access control checking.

The following example uses LDAPSRCH to request a subtree search of the root DSE for entries that have a cn value that begins with ken and shows sample output for the search.

ldapsrch -h ldaphost -p ldapport -D binddn -w passwd -s sub -b "" "cn=ken\*"

```
cn=ken,o=ldbm
objectclass=person
objectclass=top
cn=ken
sn=smith
```

#### Monitor support

I

1

Т

1

Т

You can retrieve statistics from the server by issuing a search request with a search base of **cn=monitor** and a filter of (**objectclass=**\*). For details, see Monitoring performance with cn=monitor.

#### **CRAM-MD5** authentication support

CRAM-MD5 authentication is supported on the IBM Tivoli Directory Server client utilities on other platforms, such as AIX<sup>®</sup>, Windows, and Linux. However, the manner in which it has been implemented on the IBM Tivoli Directory Server on other platforms varies from the support that is available on the LDAP server.

In order to perform a CRAM-MD5 authentication bind with the IBM Tivoli Directory Server client utilities on other platforms to the LDAP server, you must specify the bindDN with the **-D** option. The IBM Tivoli Directory Server client utilities on other platforms do not support the specification of the username on a CRAM-MD5 bind.

#### UTF-8 data over the LDAP Version 2 protocol

The LDAP Version 3 Protocol allows UTF-8 attribute values outside of the IA5 character set to be stored in the directory. This information must be able to be returned in some format to LDAP Version 2 clients. An additional LDAP server configuration file option, **sendV3stringsoverV2as**, which has the possible values

**ISO8859-1** or **UTF-8**, can be used to indicate which format to use when sending this information over the Version 2 protocol.

**Note:** Different clients treat non-IA5 data differently over the Version 2 protocol. Refer to the documentation for the client APIs you are using for more information.

## Attribute types stored and returned in lowercase

The LDAP server stores and returns attribute types in lowercase (normalized). For example, the attribute type "productName" is returned as "productname".

#### Abandon behavior

The LDAP server reads additional operations as they arrive as long as the connection is not a secure connection and the previous operation is not bind, unbind, or extended operation. This allows the LDAP server to process abandon operations as they are received and affect previously submitted operations.

# Chapter 17. SSL Certificate/Key Management and SSL Tracing Information

SSL connections make use of public/private key mechanisms for authenticating each side of the SSL session and agreeing on bulk encryption keys to be used for the SSL session. To use public/private key mechanisms (termed PKI), public/private key pairs must be generated. In addition, X.509 certificates (which contain public keys) may need to be created, or certificates must be requested, received, and managed.

SSL uses the **gskkyman** utility to manage PKI private keys and certificates. Invoke the **gskkyman** utility with the CMS GSKKYMAN command. **gskkyman** creates, fills in, and manages a file that contains PKI private keys, certificate requests, and certificates. This file is called a **key database** and, by convention, has a file extension of **.kdb**.

SSL uses the GSK\_KEYRING\_FILE environment variable to specify the locations of the PKI private keys and certificates. The key database file name is passed in this environment variable.

## **Key Database Files**

Key database files are password protected because they contain the private keys that are associated with some of the certificates that are contained in the key database. Private keys, as their name implies, should be protected because their value is used in verifying the authenticity of requests made during PKI operations.

It is recommended that key database files be set with the following string of file permissions:

rw- --- (600) (read-write for only the owner of the key database)

The owner of the key database should be the user who manages the key database. The user ID that runs the LDAP server must have at least read permission to the key database file at runtime. If the LDAP server user ID is a server program that runs under a different user ID than the administrator of the key database file, it is recommended that a group be setup to control access to the key database file. In this case, it is recommended that you set the permissions on the key database file to the following:

rw- r-- (640) (read-write for owner and read-only for group)

The owner of the key database file is set to the administrator user ID and the group owner of the key database file is set to the group that contains the server that will be using the key database file.

For more information about **gskkyman** and setting up the key database and its permissions, see "SSL Certificate Management" in *z/VM: TCP/IP User's Guide*.

# **SSL Tracing Information**

SSL tracing techniques are for use primarily by IBM service personnel in determining the cause of an SSL problem. If you encounter a problem and call the IBM Support Center, you may be asked to obtain trace information or enable one or more of the diagnostic messages described below.

Use the **gsktrace** utility to create a readable copy of SSL trace information. For information about **gsktrace**, see "SSL Tracing Information" in *z/VM: TCP/IP User's Guide*.

gsktrace is not intended for use in a production environment and is used for diagnostic purposes only.

# **Chapter 18. Performance tuning**

Several server configuration options and facilities significantly affect the performance of the server. In addition, specific LDAP server backends operate in conjunction with other products that may require tuning to accommodate the LDAP server. For example, the SDBM backend provides access to the RACF database, that has its own product specific tuning options. This topic describes some of the things to consider when configuring your server for optimal performance.

### General LDAP server performance considerations

### Threads

The **commThreads** configuration option specifies the number of communication threads that handle requests from clients to the LDAP server. However, the primary role of each of these threads is to serve as a worker thread for processing client requests to the directory.

Each communication thread is shared among client connections and is used to process requests as they occur. Therefore, this option does not need to be set nearly as large as the expected number of concurrently connected clients.

Each communication thread requires some resources of its own, including low storage, and other system resources associated with threads. Therefore, you may want to avoid making this option larger than is needed.

It is recommended that **commThreads** be set to approximately two times the number of processors that are running in your LPAR. However, this is a general rule depending upon the activity that your LDAP server experiences.

## **Debug settings**

Activating the LDAP server debug trace facility impacts performance. If optimal performance is desired, debug should only be activated when it is necessary to capture diagnostic information.

## Storage in the LDAP virtual machine

The LDAP server generally requires a minimum of 96 megabytes to run. This storage is required for maintaining server-wide information and for processing client requests.

**Note:** These are estimates only, and the need for storage can increase depending on the size of any LDBM directories configured, and the size of the caches.

## LDAP server cache tuning

The LDAP server implements many caches to help reduce processing time and to avoid access to the database. These caches are beneficial when most accesses to the directory are read operations. Tuning these caches involves monitoring their effectiveness and adjusting their size to increase the percent hit rate.

**Note:** Increasing cache sizes may increase the amount of storage required by the server.

Some caches are invalidated by update activities. If this is a frequent occurrence, increasing the cache size may be of little or no benefit. If the cache hit rate is never any higher than zero for a particular cache, the cache can be disabled by setting its size to 0. However, even caches with seemingly low cache hit rates might provide some benefit, therefore, you should generally avoid disabling them unless close monitoring is done to ensure they are not beneficial.

Most caches in the LDAP server are enabled by default, and the default sizes generally provide some benefit to most installations. However, many installations might benefit from additional tuning. The following approach can be used to evaluate the cache sizes:

- Monitor the cache performance during typical workloads: You can use either the cn=monitor search or the SMSG *ldapsrv* DISPLAY MONITOR command to retrieve current cache statistics. These are described later in this topic.
  - **Note:** The monitor search must be used with a scope of subtree or one-level to retrieve the cache statistics, since the caches are backend specific.
- Examine the cache hit rate, the current number of entries, and the maximum allowed entries (configured size). Also, note the number of cache refreshes and the average size of the cache at refresh.
- If the cache hit rate is well below 100% and the cache is frequently fully populated, consider increasing the cache size. Since this is a configuration option, you must change the server configuration file and restart the server to affect the change.

The following caches are implemented in the LDAP server:

#### **DN cache**

This cache holds information related to the mapping of distinguished names between their raw form and their canonical form. Retrieval of information from this cache reduces processing required to locate entries in the database. This is a server-wide cache, and is implemented in the internal schema backend. To alter its setting from the default, adjust the **dnCacheSize** configuration option in the global section of the LDAP server configuration file.

#### filter cache

This cache holds information related to the mapping of search request inputs and the result set. This cache is implemented in the LDBM, CDBM, and GDBM backends. For LDBM, CDBM, and file-based GDBM, retrieval of information from this cache avoids database read operations when processing search requests.

### **Operations monitor**

T

If the operations monitor is enabled, the LDAP server monitors search statistics for the types of search patterns that are configured and stores search statistics for each search pattern. The operations monitor supports two types of search patterns, **searchStats** and **searchIPStats**. A **searchStats** pattern consists of the search parameters (search base, scope, filter, and attributes to be returned) and status (success or failure). The **searchStats** pattern is useful for evaluating the performance of search patterns. A **searchIPStats** pattern consists of the same elements as **searchStats** pattern does, but also includes the client IP address. The **searchIPStats** pattern is useful in determining if there are any specific clients spamming the LDAP server. The **operationsMonitor** configuration option determines which types of search patterns are monitored. See "Monitoring performance with cn=monitor" on page 305 for more information about the operations monitor.

A new search pattern is added to the operations monitor whenever the search pattern of an incoming search does not match one of the existing operations monitor search patterns. When the number of search patterns exceeds the value of the **operationsMonitorSize** configuration option (the **cachesize** attribute in the **cn=operations,cn=monitor** entry), the least recently used search patterns are trimmed. The total number of trimmed search patterns is stored in the **numtrimmed** attribute of the **cn=operations,cn=monitor** entry. Typically, trimmed search patterns are not a cause for concern because they are infrequently executed search patterns. If there is a high volume of trimmed data, you should consider increasing the value of the **operationsMonitorSize** configuration option or possibly monitoring only **searchStats** patterns. Note that **searchIPStats** search patterns produce more search pattern for each unique client IP address even if the rest of the search pattern is the same. See Table 50 on page 309 for more information about the **cn=operations,cn=monitor** entry and its attributes.

If password policy is enabled, additional cost is incurred during authentication to enforce the policy and to update operational attributes within the user entry. Generally, authentications do not incur much additional overhead with password policy enabled unless updates to the user entry occur.

Failed authentications require updates to the user entry to record the failed attempt, and to conditionally lock the account. Most successful authentications do not cause updates. However, the first expiration warning for a given user entry requires an update to record the event. Also, the first successful authentication which follows a failed authentication for the given user entry requires an update to clear operational attributes related to preceding failed attempts.

The operational attributes that might be updated during authentication are:

- pwdAccountLockedTime
- pwdExpirationWarned
- pwdFailureTime
- pwdGraceUseTime
- ibm-pwdAccountLocked

For more details about these attributes, see "Password policy operational attributes" on page 107.

Use of multiple policies might cause additional cost during authentication and during password change by the user because of group membership determination. In both cases, the effective password policy must be evaluated to apply password policy rules.

To evaluate a user's effective password policy, the LDAP server considers all the password policies associated with a user. This means that the LDAP server evaluates the individual, group, and global password policies to determine a user's effective password policy. If you have defined individual and group password policies, the user's group membership must be resolved to properly apply group password policies.

# LDBM performance considerations

The LDAP server LDBM backend uses the BFS file system for its persistent storage of the directory entry data. When the LDAP server is executing, the entire directory contents are held in virtual storage, including index structures for quick access.

Holding the entire directory contents in virtual storage provides extremely fast access to the directory data. LDAP operations that read directory data involve no DASD I/O during the operation. LDAP operations that update the directory generally perform DASD I/O only to write the changed information to the LDBM checkpoint file. The index updates occur only within the LDAP server virtual storage, and are not stored on DASD.

However, LDBM has inherent scalability limitations. The following resources are affected by the size of the directory, and are generally proportional to the LDBM directory size:

- · The storage required within the LDAP server virtual machine
- · The LDAP server initialization time, both elapsed time and processor time
- · The time required to commit the directory
- The DASD space required for the directory, including space for commit processing.

### Storage in the LDAP virtual machine for LDBM data

Since the entire LDBM directory is kept in storage in the LDAP virtual machine, you need to plan accordingly. The amount of storage required can be estimated from the size of the LDIF data used to load the directory. The storage needed to contain the data is about 7 to 10 times the size of the LDIF file.

These are estimates only. Furthermore, these estimates pertain only to the storage required to hold the LDBM directory representation. You must plan for additional storage for running the server as mentioned in "Storage in the LDAP virtual machine" on page 301.

## LDAP server initialization time with LDBM

Whenever the LDAP server is restarted, it reads the entire LDBM directory into storage and builds the necessary index structures for efficient search processing. This can take several minutes depending on the speed of the processor, the speed of the DASD that holds the data, and the competition for resources because of other workloads. Generally, the initialization elapsed time and the consumed processor time during initialization are proportional to the size of the directory.

### Database commit processing

The LDBM directory contents are kept on DASD in the database files and the checkpoint file. There is one checkpoint file for the backend, and a separate database file for each suffix defined in the backend. The database files contain the overall contents of each entry in the database at the last database commit point. The checkpoint file contains individual entry updates that occurred since the last database commit point, recorded as sequential changes beyond the contents of the database file.

To avoid unbounded growth of the checkpoint file, the database is periodically committed. Commit processing writes new copies of the database and checkpoint files such that the new database files contain the up-to-date contents of each entry in the directory, and the checkpoint file contains no individual file update information. Database commits occur at the following times:

- When the number of checkpoint entries exceeds the value of the **commitCheckpointEntries** option in the LDAP server configuration file.
- When the time of day reaches the commitCheckpointTOD option in the LDAP server configuration file.
- When the LDAP server COMMIT operator command is invoked.
- When the LDAP server is shut down normally.
- · When the LDAP server is restarted and uncommitted updates exist in the checkpoint file after an abnormal termination of the LDAP server.

Commit processing requires both processor and DASD resources, and the resources needed increase as the size of the directory increases. For large directories, commit processing may take a minute or more depending on competition for resources.

When commit processing occurs, a new copy of each directory file is created in its entirety before deleting the old copy and before deleting the previous checkpoint file. Therefore, you should plan enough DASD space to accommodate two copies of each directory file plus the maximum size of your checkpoint file. The amount of DASD space needed for the checkpoint file is highly dependent on the nature of the updates performed, and is best determined by experimentation.

During commit processing, no update requests are processed. Therefore, you should consider avoiding unplanned commits caused by the configuration option commitCheckpointEntries. Instead, consider using commitCheckpointTOD, automated methods of using the LDAP server COMMIT operator command, or planned shutdowns of the LDAP server to control when commit processing occurs.

### DASD space for LDBM data

The amount of space needed to store an LDBM backend in a BFS file system is approximately four to six times the size of the expected input LDIF data. Generally, the space required to hold the LDBM backend data is two to three times the size of the expected input LDIF data. However, during the LDBM commit process each of the LDBM database files is copied, therefore, resulting in occasionally needing twice the amount of file system space.

### **CDBM** performance considerations

1	If the CDBM backend is used only to store configuration entries, then no tuning is
1	necessary. However, if the CDBM backend is used to store user defined entries, for
1	more information about CDBM tuning, see "LDBM performance considerations" on
1	page 304.

### Monitoring performance with cn=monitor

You can retrieve statistics from the server by issuing a search request with a search base of **cn=monitor** and a filter of (**objectclass=**\*). These are the only values accepted for search base and filter on the monitor search. However, any of the possible scope values are accepted.

The LDAP server presents monitor data in multiple entries:

Server-wide statistics are contained in an entry whose distinguished name is cn=monitor.

- Each configured backend has statistics contained in its own entry named cn=backendXXXX,cn=monitor, where XXXX is the backend name specified on the database configuration option in the server configuration file. If no backend name is specified on the database configuration option, the LDAP server generates a name. The naming contexts pertaining to the specific backend are also included in the entry to identify which server backend is being reported.
- Several entries contain statistics for backends that are created by the LDAP server:
  - cn=backendMonitor,cn=monitor Statistics for the backend handling cn=monitor searches
  - cn=backendSchema,cn=monitor Statistics for the backend managing the schema
  - cn=backendRootDSE,cn=monitor Statistics for the backend handling root **DSE** searches
- · If the operations monitor is on (the operationsMonitorSize configuration option is not set to zero), the **cn=operations,cn=monitor** entry contains statistics on search patterns.

For a scope of:

base Only the **cn=monitor** entry is returned containing server-wide statistics

#### one (one-level search)

All backend-specific entries are returned and the operations monitor entry is returned (if configured)

### sub (subtree search)

All entries are returned, including the operations monitor entry (if configured).

The statistics reported on the **cn=monitor** subtree search can also be displayed by using the SMSG command. The command is:

smsg server id display monitor

where *server\_id* is the LDAP virtual machine user ID.

Statistics generally reflect data gathered since the LDAP server was started. However, many of the counters can be reset by using the SMSG command. The command is:

smsg server id reset monitor

where *server\_id* is the LDAP virtual machine user ID. In this case, the values reflect data gathered since the last reset.

The monitor search returns the following attributes:

Table 47. Server statistics	
currentconnections	Current <sup>®</sup> number of client connections
currenttime	Current date and time on the server
livethreads	Configured number of communication threads (commThreads)
maxconnections	Configured maximum number of connections (maxConnections)
maxreachedconnections	High water mark for concurrent client connections
resets	Number of times statistics were reset
resettime	Date and time statistics were last reset

Table 47. Server statistics (continued) starttime sysmaxconnections totalconnections version

Date and time the server was started System defined maximum number of connections Number of client connections made to the server Version of the LDAP server

The statistics reported for the **maxconnections**, **sysmaxconnections**, **totalconnections**, **currentconnections**, and **maxreachedconnections** attribute values only contain information for network connections. PC connection statistics are not included in these attribute values.

The **sysmaxconnections** value may be lower than the **maxconnections** value because of system limits. If the value for the **maxConnections** configuration option is not valid, the **maxconnections** attribute value on **cn=monitor** search reflects the system maximum connection limit. For information about how the maximum number of client connections is set in the LDAP server, see the **maxConnections** configuration option at "maxConnections" in *z/VM: TCP/IP Planning and Customization*.

When statistics are reset, **resettime** is set to the value of **currenttime**, **resets** is incremented, and **maxreachedconnections** is set to the value of **currentconnections**. None of the other server statistics listed above are affected by a reset.

Table 48. Server and backend specific statistics	Table 48.	Server a	and backend	specific	statistics
--	-----------	----------	-------------	----------	------------

abandonsrequested Number of abandon operations requested abandonscompleted Number of abandon operations completed addsrequested Number of add operations requested addscompleted Number of add operations completed bindsrequested Number of bind operations requested bindscompleted Number of bind operations completed bytessent Number of bytes of data sent Number of compare operations requested comparesrequested comparescompleted Number of compare operations completed Number of delete operations requested deletesrequested deletescomplketed Number of delete operations completed entriessent Number of search entries sent Number of extended operations requested extopsrequested extopscompleted Number of extended operations completed modifiesrequested Number of modify operations requested modifiescompleted Number of modify operations completed modifydnsrequested Number of modifyDn operations requested Number of modifyDn operations completed modifydnscompleted opscompleted Number of operations completed opsinitiated Number of operations initiated searchreferencessent Number of search references sent searchesrequested Number of search operations requested searchescompleted Number of search operations completed unbindsrequested Number of unbind operations requested unbindscompleted Number of unbind operations completed unknownopsrequested Number of unrecognized operations completed unknownopscompleted Number of unrecognized operations completed

When statistics are reset, all of the server and backend specific statistics listed above are set to zero.

Table 49. Backend specific statistics	
acl_source_cache_size	Configured maximum size (in entries) of the ACL Source cache ( <b>aclSourceCacheSize</b> )
acl_source_cache_current	Current size (in entries) of the ACL Source cache
acl_source_cache_hit	Number of lookups that have hit the ACL Source cache
acl_source_cache_miss	Number of lookups that have missed the ACL Source cache
acl_source_cache_percent_hit	Percent of lookups that have hit the ACL Source cache
acl_source_cache_refresh	Number of times the ACL Source cache was invalidated
acl_source_cache_refresh_avgsize	Average number of entries in the ACL Source cache at invalidation
dn_cache_size	Configured maximum size (in entries) of the DN cache ( <b>dnCacheSize</b> )
dn_cache_current	Current size (in entries) of the DN cache
dn_cache_hit	Number of lookups that have hit the DN cache
dn_cache_miss	Number of lookups that have missed the DN cache
dn_cache_percent_hit	Percent of lookups that have hit the DN cache
dn_cache_refresh	Number of times the DN cache was invalidated
dn_cache_refresh_avgsize	Average number of entries in the DN cache at invalidation
dn_to_eid_cache_size	Configured maximum size (in entries) of the DN to Entry ID cache ( <b>dnToEidCacheSize</b> )
dn_to_eid_cache_current	Current size (in entries) of the DN to Entry ID cache
dn_to_eid_cache_hit	Number of lookups that have hit the DN to Entry ID cache
dn_to_eid_cache_miss	Number of lookups that have missed the DN to Entry ID cache
dn_to_eid_cache_percent_hit	Percent of lookups that have hit the DN to Entry ID cache
dn_to_eid_cache_refresh	Number of times the DN to Entry ID cache was invalidated
dn_to_eid_cache_refresh_avgsize	Average number of entries in the DN to Entry ID cache at invalidation
entry_cache_size	Configured maximum size (in entries) of the Entry cache (entryCacheSize)
entry_cache_current	Current size (in entries) of the Entry cache
entry_cache_hit	Number of lookups that have hit the Entry cache
entry_cache_miss	Number of lookups that have missed the Entry cache
entry_cache_percent_hit	Percent of lookups that have hit the Entry cache
entry_cache_refresh	Number of times the Entry cache was invalidated
entry_cache_refresh_avgsize	Average number of entries in the Entry cache at invalidation
entry_owner_cache_size	Configured maximum size (in entries) of the Entry Owner cache (entryOwnerCacheSize)
entry_owner_cache_current	Current size (in entries) of the Entry Owner cache
entry_owner_cache_hit	Number of lookups that have hit the Entry Owner cache
entry_owner_cache_miss	Number of lookups that have missed the Entry Owner cache
entry_owner_cache_percent_hit	Percent of lookups that have hit the Entry Owner cache

Table 49. Backend specific statistics (con	tinued)
entry_owner_cache_refresh	Number of times the Entry Owner cache was invalidated
entry_owner_cache_refresh_avgsize	Average number of entries in the Entry Owner cache at invalidation
filter_cache_size	Configured maximum size (in entries) of the Filter cache ( <b>filterCacheSize</b> )
filter_cache_current	Current size (in entries) of the Filter cache
filter_cache_hit	Number of lookups that have hit the Filter cache
filter_cache_miss	Percent of lookups that have hit the Filter cache
filter_cache_percent_hit	Percent of lookups that have hit the Filter cache
filter_cache_refresh	Number of times the Filter cache was invalidated
filter_cache_refresh_avgsize	Average number of entries in the Filter cache at invalidation
filter_cache_bypass_limit	Configured Filter cache bypass limit (filterCacheBypassLimit)
namingcontexts	Suffixes managed by this backend

Note that not all cache statistics shown above appears for each backend. A backend reports statistics for those caches that it supports. The schema backend reports **dn\_cache** statistics. The LDBM and CDBM backend report **filter\_cache** statistics. A file-based GDBM backend reports **filter\_cache** statistics.

When statistics are reset, the **cache\_hit**, **cache\_miss**, **cache\_percent\_hit**, **cache\_refresh**, and **cache\_refresh\_avgsize** for each cache are reset to zero. Resetting the statistics has no effect on the **cache\_size** for each cache, nor on the **filter\_cache\_bypass\_limit**, since these are configured values. Resetting the statistics also has no effect on the **cache\_current** for each cache, since the contents of the caches are not altered by a reset of statistics. Some caches may get invalidated and refreshed because of directory update operations. When this occurs, **cache\_refresh** is incremented and **cache\_current** is set to zero to reflect the refreshed (empty) cache. The **cache\_hit**, **cache\_miss**, and values **cache\_percent\_hit** are accumulated across cache invalidation and refresh until a RESET MONITOR command is issued or the server ends.

Table 50. Operations monitor statistics

L

cachesize	Configured maximum number of search patterns in the operations monitor ( <b>operationsMonitorSize</b> )
currenttimestamp	Current date and time in Zulu time stamp format
entries	Total number of search patterns in the operations monitor entry
numtrimmed	Number of search patterns trimmed from the operations monitor
resets	Number of times the operations monitor statistics were reset
resettimestamp	Date and time in Zulu time stamp format of last reset or server start up if the reset command was never issued
searchStats	Search statistics for search patterns based on the search parameters (search base, scope, filter, and attributes to be returned) and status (success or failure)
searchIPStats	Search statistics for search patterns consisting of the same elements as the <b>searchStats</b> pattern, but also including the client IP address

When statistics are reset, **resetTimestamp** is set to **currentTimestamp**, **resets** is incremented by one, **entries** is set to zero, **numtrimmed** is set to zero, and all search patterns are deleted.

The Zulu time stamp format used in the **currenttimestamp** and **resettimestamp** attribute values is: yyyymmddhhiiss.uuuuuuZ

Where,

*yyyy* is year, *mm* is month, *dd* is day, *hh* is hour, *ii* is minutes, *ss* is seconds, *uuuuuu* is microseconds, Z is a character constant meaning that this time is based on Zulu time, also known as GMT.

The **searchIPStats** and **searchStats** attribute values contain search rates and other search activity that are being monitored. Depending upon the LDAP server configuration, there can be **searchIPStats** and **searchStats** attribute values returned in the **cn=operations,cn=monitor** entry for each search executed against the LDAP server. The **searchStats** attribute values contain the total of all data collected for all searches matching this search pattern no matter the client's IP address.

The format of the searchIPStats and searchStats attribute values is:

ldap://clientIP/baseDN?attributes?scope?filter-string?status,numpOps=numOps,avg=avg, rate=rate,maxRate=maxRate,maxRateTimeStamp=maxRateTimeStamp, createTimeStamp=createTimeStamp

The following describes the LDAP search pattern parts:

#### attributes

List of attributes to be returned.

*avg* Average elapsed time for each occurrence of search pattern in microseconds.

#### baseDN

Distinguished name of the base of the search, with v substituted for attribute values.

#### clientIP

Client IP address (omitted for searchStats search patterns).

#### createTimeStamp

Date and time this search pattern was first added, in Zulu time stamp format.

#### filter-string

Search filter with substitutions for literal attribute values. Excluding the \* character, all strings in values are substituted with \_v. For example: (cn=\*bob\*bah\*) would be  $(cn=*_v*_v*)$ . There is no substitution on **objectclass** equality values when the **objectclass** is defined in the schema.

#### maxRate

The highest rate on this entry.

### maxRateTimeStamp

Date and time **maxRate** was last set, in Zulu time stamp format.

numOps

I

T

Total number of times this search pattern has occurred.

- *opid* A unique integer value that distinguishes each operations monitor search pattern.
- *rate* Number of search operations processed in the previous one minute interval. Starting with server startup or the last reset command, rate is recalculated for each search pattern every 60 seconds.
- *scope* **base** for base object searches, **one** for one-level searches, and **sub** for subtree searches.
- status success for any search operation that results in return code LDAP\_SUCCESS, LDAP\_PARTIAL\_RESULTS, or LDAP\_REFERRAL. Any other return codes result in status being set to failure.

See Table 50 on page 309 for the time stamp format.

- In addition to the above syntax, the following character escaping is performed: comma = %2C percent = %25 question mark = %3F space = %20
- **Note:** The comma, percent, and question mark characters are not escaped when they are used as metacharacters in the search pattern.

For information about monitoring performance with the LDAP server SMSG DISPLAY MONITOR command, see "SMSG Interface to the LDAP Server" in *z/VM: TCP/IP Planning and Customization*.

Note: DISPLAY MONITOR output does not display **cn=operations,cn=monitor** data.

### Monitor search examples

Following is an example of a monitor search using scope=base. This returns only statistics related to the entire server:

ldapsrch -h ldaphost -p ldapport -b cn=monitor -s base objectclass=\*
cn=monitor
version=z/VM Version 6 Release 2 IBM LDAP Server

livethreads=10 maxconnections=24982 sysmaxconnections=25000 totalconnections=20709 currentconnections=1 maxreachedconnections=15 opsinitiated=62126 opscompleted=62125 abandonsrequested=0 abandonscompleted=0 addsrequested=2318 addscompleted=2318 bindsrequested=20709 bindscompleted=20709 comparesrequested=0 comparescompleted=0 deletesrequested=2228 deletescompleted=2228 extopsrequested=0 extopscompleted=0 modifiesrequested=11501 modifiescompleted=11501 modifvdnsrequested=440

```

unbindscompleted=20708
unknownopscompleted=0
entriessent=4221
bytessent=1564656734
searchreferencessent=0
currenttime=Thu Sep 25 16:33:00.187846 2008
starttime=Thu Sep 25 15:52:21.693392 2008
resets=0
```

Following is an example of output of a monitor search with scope=one for a server configured with an LDBM backend. This example shows backend-specific statistics and operations monitor statistics. The cache statistics shown would be included only for LDBM, CDBM, GDBM, and schema backends, because the other backend types do not implement caches. Operations monitor statistics are included for all backends.

Note that not all operational statistics for each backend are shown in the example below. They have been omitted from the example only, and appear in full for a **cn=monitor** search.

```
ldapsrch -L -h ldaphost -p ldapport -b cn=monitor -s one objectclass=*

### Large access groups considerations

I

1

Users with large access groups in z/VM LDAP may experience performance problems and increased storage usage in the LDAP server as access groups grow in size.

Some scenarios that require substantial amounts of processing and storage within the LDAP server, are:

- A search operation that returns all the members of a large access group. This
  includes either a search that returns the many values with the **member** or
  uniqueMember attribute, or a search that returns the many values in the
  ibm-allMembers operational attribute.
- A search operation that requests all the members of a large access group, but the members are not returned because ACL read permissions prevent the requester from seeing the data.
- Update requests that touch a large access group entry when **persistentSearch on** is configured for an LDBM backend that contains the large entry.

These scenarios are also susceptible to the affects of LE HEAPPOOL usage as described below.

The addressability limits of the LDAP server may become a factor when there are hundreds of thousands or millions of members in a single access group.

In this case, consider the following corrective actions:

- Increase the LDAP server's virtual storage size, if possible.
- Limit the number of members placed within a single access group and partition the users into separate access groups. The number of members for each access group that can be managed successfully depends on many factors, such as the size of the member values, the amount of virtual storage defined for the LDAP server, and the level of concurrent activity within the server.

 If possible, avoid configuring persistentSearch on for an LDBM backend that contains large entries. Some applications that exploit persistent search may only do so with the changelog, and only need persistentSearch on configured for the GDBM backend.

## LE heap pools considerations

By default, the z/VM LDAP server uses LE heap pools to improve performance. This facility reduces the processor consumption and allows better parallelism of concurrent requests within the LDAP server. However, overall storage consumption is typically larger with the use of LE heap pools as compared to running without the facility enabled. Also, once storage is allocated to a given LE heap pool, it remains allocated to that heap pool and can only be used for future storage requests that are eligible (based on size) for the given heap pool. For example, when the LDAP server must process a large access group entry in storage, the following may occur:

- While the request is processing, the LDAP server may use all available storage in its virtual machine, causing a failure of the request, a failure of other concurrent requests, or a failure and abnormal termination of the server.
- because of the sudden, large demand for storage to process the large group, most or all of the storage available to the LDAP server may be allocated and reserved to specific heap pools. Although the LDAP server may appear to be available and able to process a variety of requests, many subsequent requests may fail because of insufficient storage, particularly those for entries with large or numerous attributes. In the absence of any failures, this large increase in storage use by the LDAP server may be detectable by system resource monitoring products, such as the VM Performance Toolkit.

If these problems occur, consider either tuning the heap pool sizes or disabling the heap pools for the LDAP server.

Tuning the heap pool sizes optimizes storage usage for the data within the LDAP server. See *z/OS: Language Environment Programming Guide* for details on how to tune the heap pool settings. Note that the procedure for tuning heap pool settings requires a controlled environment with representative workloads. In this case, the workload should include the scenarios described earlier that cause the large demands for storage. Note that it is recommended that the storage reports needed for the tuning procedure be gathered in a non-production environment because tracking the storage statistics significantly impacts performance.

Disabling heap pools reduces the total heap storage requirements of the LDAP server, at the cost of increased processing.

Overriding the heap pool settings for the LDAP server can be done by specifying the LE run-time option 'HEAPPOOLS'. This option can be specified on the :parms. tag in the DTCPARMS file. For more details on setting this parameter, see *z/OS: Language Environment Programming Reference* and *z/VM: Language Environment User's Guide*.

## GDBM (Changelog) performance considerations

The GDBM database is used only for the changelog function. By its very nature, this function tends to have a high intensity of update activity compared to read activity. Since update activity is generally more costly than read activity, this function should only be enabled when its use is actually needed.

The following should be noted:

- The distinguished names (DNs) of entries and the searchable attributes within entries in GDBM tend to be well bounded in size and content. As such, the default sizes for the DN\_TRUNC column in the DIR\_ENTRY table and the VALUE column in the DIR\_SEARCH table do not require adjustment.
- Since most GDBM requests are update operations, the search filter cache is disabled by default. You may enable the cache, if desired, but if this is done, it is recommended that the cache is monitored to ensure it is providing a benefit.
- When the **changeLogMaxAge** or **changeLogMaxEntries** option is specified in the GDBM section of the LDAP server configuration file, the change log is periodically trimmed, based on the limits set in the configuration file. For more information about these configuration options, see "Configuration File Options" in *z/VM: TCP/IP Planning and Customization*.

### SDBM performance considerations

The z/VM LDAP server SDBM backend allows access to the RACF database. Most tuning that affects performance in this area is within the RACF product.

Also, see "SDBM operational behavior" on page 74 for details regarding different types of LDAP requests supported, and the RACF operations issued by these requests. This information can also be helpful when assessing RACF tuning considerations.

When writing applications that only require authentication to the SDBM backend by using LDAP bind requests, performance can be improved by specifying the **authenticateOnly** control on the bind request within the application. See authenticateOnly for more information.

# Appendix A. Initial LDAP server schema

This appendix shows the initial schema established when the LDAP server is first started. The initial schema is always part of the LDAP server schema and the elements in the initial schema cannot be deleted. With several exceptions, the initial schema cannot be modified. See Updating the schema for more information.

objectclass=ibmSubschema objectclass=subentry objectclass=subschema objectclass=top subtreespecification=NULL subtreespecification=NULL ldapsyntaxes=(1.3.18.0.2.8.1 DESC 'IBM attribute type description') ldapsyntaxes=(1.3.18.0.2.8.3 DESC 'IBM entry UUID') ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.10 DESC 'Certificate pair') ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.11 DESC 'Country string') ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.12 DESC 'Distinguished name' ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.12 DESC 'Distinguished name' ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.15 DESC 'Directory string') ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.15 DESC 'Directory string') ldapsyntaxes=(1.3.6.1.4.1.1466.115.121.1.15 DESC 'Directory string')

## Appendix B. Supported server controls

The sections that follow describe the supported server controls. For information about ASN.1 (Abstract Syntax Notation One) and BER (Basic Encoding Rules), go to the following Web site:

ftp://ftp.rsa.com/pub/pkcs/ascii/layman.asc

### authenticateOnly

- Name: authenticateOnly
- **Description:** Used on an LDAP bind operation to indicate to the LDAP server that it should not attempt to find any group membership information for the client's bind DN.
- Assigned object identifier: 1.3.18.0.2.10.2
- Target of control: Server
- Control criticality: Critical at client's option
- Values: There is no value; the controlValue field is absent.
- **Detailed description:** This control is valid when sent on an LDAP client's bind request to the LDAP server. The presence of this control on the bind request overrides alternate DN look-ups, extended group searching, and default group membership gathering, and causes the LDAP server to only authenticate the client's bind DN and not gather group information at all. This control is intended for a client who does not care about group memberships and subsequent complete authorization checking using groups, but is using the bind only for authentication to the LDAP server and fast bind processing.

I	Not Replicate
I	Name: Do Not Replicate
   	<ul> <li>Description: Used by a client to indicate that an add, delete, modify, or modify DN request is not to be replicated to a consumer or forwarding server in an advanced replication environment.</li> </ul>
I	Assigned object identifier: 1.3.18.0.2.10.23
I	Target of control: Server
I	Control criticality: Never
I	<ul> <li>Values: There is no value; the controlValue field is absent.</li> </ul>
   	<ul> <li>Detailed description: This control is valid when sent on a client's add, delete, modify, or modify DN request. The presence of this control indicates that the supplier server in an advanced replication environment should not replicate the update to a consumer or forwarding server.</li> </ul>
	<b>Note:</b> The LDAPADD, LDAPMDFY, LDAPMDRN, and LDAPDLET utilities have a <b>-L</b> option to add this control to LDAP server requests. For more information about the LDAPADD, LDAPMDFY, LDAPMDRN, and LDAPDLET utilities, see "Using the LDAP Client Utilities" in <i>z/VM: TCP/IP User's Guide</i> .
I.	

### IBMModifyDNRealignDNAttributesControl

Name: IBMModifyDNRealignDNAttributesControl

•	<b>Description:</b> Used by a client to request that a Modify DN operation be extended to realign attribute values for attributes with <b>Distinguished Name</b> syntax, and other specified attribute types known to contain distinguished names, with the new DN values established by the Modify DN operation for those DNs.
•	Assigned object identifier: 1.3.18.0.2.10.11
•	Target of control: Server
•	Control criticality: Critical at client's option
•	Values: There is no value; the controlValue field is absent.
	<b>Detailed description:</b> This control is valid when sent on a client's Modify DN request. Distinguished names which are renamed might be embedded in DN-syntax attributes throughout the directory contents. You might want to replace the embedded values with their renamed counterparts (realignment). The presence of this control on the Modify DN request causes the server to realign matching attribute values in all attribute types whose syntax is <b>Distinguished Name</b> (OID 1.3.6.1.4.1.1466.115.121.1.12), and in the attribute types of <b>aclEntry</b> and <b>entryOwner</b> , which are known to contain distinguished names. The server will evaluate whether the bound user has permission to modify the candidate attribute values, as determined by the appropriate access controls and the permissions granted to the bound DN are sufficient to modify the candidate attribute values, those values will be realigned to match their respective new DN values. If any single access check fails, the entire Modify DN operation fails, and all changes to the directory associated with the current Modify DN operation are undone. The scope for realignment is the backend containing the base DN for the Modify DN request. DN references in other backends or other LDAP servers are not updated. If there are <b>aclFilter</b> or <b>ownerFilter</b> components in <b>aclEntry</b> or <b>entryOwner</b> attribute values, the DN references in those filters are not updated.

### **IBMModifyDNTimelimitControl**

Т

- Name: IBMModifyDNTimelimitControl
- **Description:** Used by a client to request that a Modify DN operation be abandoned if the specified time limit for that operation has been exceeded.
- Assigned object identifier: 1.3.18.0.2.10.10
- · Target of control: Server
- Control criticality: Critical at client's option
- Values: The following ANSI.1 (Abstract Syntax Notation One) syntax describes the BER (Basic Encoding Rules) encoding of the control value.

```
ControlValue ::= SEQUENCE {
Time Limit INTEGER
```

• **Detailed description:** This control is valid when sent on a client's Modify DN request. Modify DN operations might be long-running operations if they affect many entries in the directory (for example, if they rename an entry with a subtree containing many subordinate entries), therefore, you might want to limit the duration of the operation. The presence of this control on the Modify DN request causes the operation to be abandoned by the server if the number of seconds specified in the control value is exceeded. When the operation is abandoned, all changes to the directory associated with the Modify DN operation are undone. A time limit of zero will cause the control to be ignored. The last time limit value will be used if this control is specified more than once.

### **IBMSchemaReplaceByValueControl**

- Name: IBMSchemaReplaceByValueControl
- **Description:** Used on a schema modify request to tell the LDAP server that a replace operation will either replace all schema values or just matching values.
- Assigned object identifier: 1.3.18.0.2.10.20
- Target of control: Server
- Control criticality: Critical at client's option
- **Values:** The following ASN.1 (Abstract Syntax Notation One) statements describe the BER (Basic Encoding Rules) for encoding the control value using implicit tagging:

```
ControlValue ::= SEQUENCE {
replaceByValue BOOLEAN
```

• Detailed description: This control is valid when sent on a client's modify request and has meaning only when performing a modify replace operation of an attribute in the LDAP server schema. If the control value is set to TRUE, then each replace value in the modify operation either replaces the existing value (if there is one with the same object identifier) or is added to the schema (if there is no existing value with the same object identifier). All other values in the schema remain as they are. If the control is set to FALSE, all the values for that attribute in the schema are replaced by the ones specified in the modify operation. See Updating the schema for more information about how LDAP processes a schema modify with replace operation. In all cases, the values of the attributes that are in the initial LDAP server schema cannot be deleted and can be modified only in very limited ways. See Updating the schema for more information.

**IBMschemaReplaceByValueControl** overrides the **schemaReplaceByValue** server configuration option for the current modify request. The last value will be used if this control is specified more than once.

### manageDsalT

|

L

L

- Name: manageDsalT
- **Description:** Used on a request to suppress referral processing, thereby allowing the client to manipulate referral objects.
- Assigned object identifier: 2.16.840.1.113730.3.4.2
- Target of control: Server
- Control criticality: Critical
- Values: There is no value; the controlValue field is absent.
- Detailed description: This control is valid when sent on a client's search, compare, add, delete, modify, or modify DN request. The presence of the control indicates that the server should not return referrals or search continuation references to the client. This allows the client to read or modify referral objects. The LDAP server will not return a referral even if the requested object is not included in any suffix within the LDAP server and a global referral is defined using the referral option in the LDAP server configuration file.

### No Replication Conflict Resolution

- Name: No Replication Conflict Resolution
  - **Description:** Used on an update request from a supplier server to a consumer server in an advanced replication environment to indicate that the consumer server should not resolve any replication conflicts that might occur.

•	Assigned object identifier: 1.3.18.0.2.10.27
•	Target of control: Server
•	Control criticality: Never critical
•	Values: There is no value; the controlValue field is absent.
• •	<b>Detailed description:</b> This control is valid when sent by a supplier server to a consumer server on an add, delete, modify, or modify DN request in an advanced replication environment. The presence of the control indicates that the consumer server does not attempt to resolve any replication conflicts that might
   	occur, such as rejecting an add request because it has an older <b>createtimestamp</b> value. In this scenario, the consumer server always accepts the replicated updates and attempts to apply them to the targeted backend.

### **PasswordPolicy**

T

Т

Name: PasswordPolicy	
<ul> <li>Description: Used by client applications on add, requests to obtain additional warning or error info password value.</li> </ul>	
Assigned object identifier: 1.3.6.1.4.1.42.2.27.8	3.5.1
Target of control: Server	
Control criticality: Never critical	
Request values: There is no value; the control	<b>/alue</b> field is absent.
<ul> <li>Response values: The following ASN.1 (Abstract describes the BER (Basic Encoding Rules) encoded</li> </ul>	
<pre>ControlValue ::= SEQUENCE {    warning [0] CHOICE OPTIONAL {      timeBeforeExpiration [0] INTEGER (0 max      graceLoginsRemaining [1] INTEGER (0 max      error [1] ENUMERATED OPTIONAL {      passwordExpired (0),      accountLocked (1),      changeAfterReset (2),      passwordModNotAllowed (3),      mustSupplyOldPassword (4),      insufficientPasswordQuality (5),      passwordTooShort (6),      passwordInHistory (8) } }</pre>	

#### Where,

- warning ::= An optional field that indicates the password policy warning code. If timeBeforeExpiration is set, the integer indicates the number of seconds before the bound user's password expires. If graceLoginsRemaining is specified, it indicates the remaining number of log ins the bound user has before the password expires.
- error ::= An optional field that indicates the password policy error code.
- Detailed description: This control is valid when sent on an LDAP client's add, bind, compare, or modify request to the LDAP server. The LDAP server returns the PasswordPolicy response control to the client that contains additional warning and error information about a user's password value. For example, on bind and compare requests, the LDAP server may send a PasswordPolicy response control to the client that indicates that the bound user's password is about to expire, has expired, or must be changed after being reset by the LDAP administrator. While on add and modify requests of password values, the LDAP

server may send a **PasswordPolicy** response control that indicates the password is too short, does not meet password policy quality standards, or the password value already exists in the password history of the entry being modified. This information is sent to the client on the add, bind, compare, or modify response.

**Note:** The LDAP client utilities automatically send the **PasswordPolicy** control as a noncritical control on add, bind, compare, and modify requests to the targeted LDAP server. For more information, see *z/VM: TCP/IP User's Guide*.

#### PersistentSearch

T

|

L

I

|

- Name: PersistentSearch
- **Description:** Used on a search request to request not only the current contents of the directory that match the search request but also any entries that match the search specification in the future.
- Assigned object identifier: 2.16.840.1.113730.3.4.3
- Target of control: Server
- · Control criticality: Critical at client's option
- Values: The following ASN.1 (Abstract Syntax Notation One) syntax describes the BER (Basic Encoding Rules) encoding of the control value.

```
ControlValue ::= SEQUENCE {
   changeTypes INTEGER,
   changesOnly BOOLEAN,
   returnECs BOOLEAN
}
EntryChangeNotification ::= SEQUENCE {
   changeType ENUMERATED {
      add (1),
      delete (2),
      modify (4),
      moddn (8) },
   previousDN LDAPDN OPTIONAL,
   changeNumber INTEGER OPTIONAL
}
```

Where,

- changeTypes ::= A bit field that specifies one or more types of changes the client is interested in: 0x01 for add changes, 0x02 for delete changes, 0x04 for modify changes, and 0x08 for modify DN changes.
- changes0n1y ::= A flag that, if TRUE, only changed entries that match the search are returned. If set to FALSE, existing entries matching the search are returned, in addition to changed entries that match the search.
- returnECs ::= A flag that, if TRUE, an entryChangeNotification control is included when returning a changed entry that matches the search. If set to FALSE, the control is not included.
- changeType ::= Indicates the type of change made to the entry.
- previousDN ::= For a moddn changeType, the DN of the entry before it was renamed.
- changeNumber ::= The changeNumber of the change log entry, if any, that was created for this change.

• Detailed description: The control is valid when sent on a client's search request. Support is provided in the client to create this control and parse the resultant entries. See Idap\_create\_persistentsearch\_control() for more information.

A persistent search consists of two phases. The first phase is optional (it is done if changesOnly is **FALSE**), and consists of searching the directory for entries matching the search specification. The second phase consists of executing the search specification against any modifications that occur in the directory and, if found matching, then sending the search results to the waiting client.

Persistent search is supported in the LDBM, CDBM, and GDBM backends. In addition, the schema entry (cn=schema) and the rootDSE (zero-length DN) support persistent searches. The **persistentSearch** configuration option can be used in the backend section of the configuration file to enable or disable persistent search for that backend. See "Configuring the LDAP Server" in *z/VM: TCP/IP Planning and Customization* for more information about the **persistentSearch** configuration option.

- Server behavior: The server behaves as described in the specification found at http://www.mozilla.org/directory/ietf-docs/draft-smith-psearch-ldap-01.txt, with the following exceptions:
  - 1. An error is returned if an error occurs during processing of the persistent search request. Section 4.b of the specification indicates that SearchResultsDone message is not returned if a persistent search is requested. This is not recognized in the case of an error.
  - 2. If more than one **PersistentSearchControl** is received per search request, **LDAP\_PROTOCOL\_ERROR** is returned.
  - 3. If the requesting client is not bound as adminDN, LDAP\_UNWILLING\_TO\_PERFORM is returned.
  - 4. If persistent search is requested and the dereference option was set to something other than LDAP\_DEREF\_NEVER or LDAP\_DEREF\_FINDING, LDAP\_PROTOCOL\_ERROR is returned. If LDAP\_DEREF\_FINDING is specified, alias dereferencing is performed when the persistent search is issued to determine the real base entry. The dereferenced base entry is then used to determine if modified entries are within the scope of the persistent search request.
  - 5. If a persistent search request is specified for a suffix that does not exist in the LDAP server configuration file, **LDAP\_NO\_SUCH\_OBJECT** is returned.
  - 6. If a persistent search request is specified for a suffix that is configured but for a search base that does not exist, no search results are returned until the object is added.
  - 7. The search filter and scope are matched before a delete is done, all other operations are matched afterward. No search results are returned for entries moved out of the search filter or scope because of modification or rename.
  - 8. For a persistent search of the root DSE, the search scope must be LDAP\_SCOPE\_SUBTREE. Backends that do not support persistent search or do not have persistent search enabled will be skipped if a null-based subtree search is used and the persistent search control is marked as critical, otherwise a typical search will be performed for those backends.
  - 9. If a **PersistentSearch** control is included in a search request for an LDBM, CDBM, or GDBM backend that has not enabled persistent search, the search request is rejected with

**LDAP\_UNAVAILABLE\_CRITICAL\_EXTENTION** (0x35) if the control is critical. If the control is not critical, a 'typical' search is performed (even if changesOnly is **TRUE**).

L

Т

- Change log entries trimmed by the LDAP server because of the changeLogMaxAge or changeLogMaxEntries configuration options are not returned to a persistent search of the change log directory.
- 11. If the **manageDsalT** control is not specified with the **PersistentSearch** control and phase one of the search finds a referral, the referral is returned to the client. If the base of the search is equal to or below a referral, the referral is returned and the persistent search second phase does not occur. During the second phase of persistent search, referral entries are always processed such as typical entries, even if the **manageDsalT** control is not specified on the persistent search.
- 12. Idle connection time out also affects persistent search connections. See the description of the **idleConnectionTimeout** configuration option in "Step 7. Create and Customize the LDAP Configuration File (DS CONF)" in *z/VM: TCP/IP Planning and Customization* for more information.
- 13. **sizeLimit** and **timeLimit** parameters and configuration options are respected only during the first phase of persistent search, when existing entries are searched. An error is returned if either limit is exceeded and the persistent search ends. During the second phase, when changed entries are searched, **sizeLimit** and **timeLimit** are ignored.
- 14. Only the entry specified in a modify DN request (the target of the rename operation) can be returned during the second phase of the persistent search. Subentries or entries modified as part of the realignment process are not returned.
- 15. The SDBM backend does not support persistent search. To be notified of changes to a RACF user (including password changes), group, user-group connection, or general resource profile, request a persistent search of the change log directory. If configured, RACF creates a change log entry when a modification is made to a RACF user, group, connection, or resource profile.
- 16. Operational attributes are returned on persistent searches except the following: aclSource, hasSubordinates, ibm-allGroups, ibm-allMembers, ibm-entryChecksum, ibm-entryChecksumOp, ibm-replicationChangeLdif, ibm-replicationFailedChangeCount, ibm-replicationFailedChanges, ibm-replicationLastChangeld, ibm-replicationLastActivationTime, ibm-replicationLastChangeld, ibm-replicationLastFinishTime, ibm-replicationLastResult, ibm-replicationPendingChangeCount, ibm-replicationPendingChangeCount, ibm-replicationPendingChangeCount, ibm-replicationPendingChangeCount, ibm-replicationPendingChanges, ibm-replicationPendingChangeCount, ibm-replicationPendingChanges, ibm-replicationPendingChangeCount, ibm-replicationPendingChanges, ibm-replicationThisServerIsMaster, ownerSource, and pwdChangedTime. The aclEntry, aclPropagate, entryOwner, and ownerPropagate attributes are returned only if they are defined for the entry and are not inherited from a superior entry.

### **Refresh Entry**

L

L

T

I

I

I

|

I

I

I

|

- Name: Refresh Entry
- **Description:** Used by a consumer server in an advanced replication environment to notify a supplier server that a replication conflict has occurred during a modify request.
- Assigned object identifier: 1.3.18.0.2.10.24
- Target of control: Server
- Control criticality: Never critical

- Values: There is no value; the controlValue field is absent.
- Detailed description: This control is valid when sent on an LDAP modify response from a consumer to a supplier in an advanced replication environment when a replication conflict is detected in an entry on a consumer server. When the supplier server receives this control along with an LDAP\_OTHER return code from the consumer server, the supplier sends its copy of the modified entry to the consumer with the intention of bringing the consumer server back in sync.

### replicateOperationalAttributes

Т

T

Т

1

1

1

- Name: replicateOperationalAttributes
- **Description:** Used to pass the values of operational attributes that are typically set by the server during an add, modify, or modify DN operation.
- Assigned object identifier: 1.3.18.0.2.10.19
- · Target of control: Server
- · Control criticality: Critical at client's option
- Values: The values in this control identify the operational attributes and values to be set. The following ASN.1 (Abstract Syntax Notation One) syntax describes the BER (Basic Encoding Rules) encoding of the control value.

```
ControlValue ::= SEQUENCE OF SEQUENCE {
   operation ENUMERATED {
        add (0),
        delete (1),
        replace (2) },
   modification AttributeTypeAndValues
}
AttributeTypeAndValues ::= SEQUENCE {
   type OCTET STRING,
   vals SET OF OCTET STRING
}
```

where:

- operation ::= Indicates whether the operational attribute value should be added to the entry, should be deleted from the entry, or should replace the current value in the entry.
- type ::= Specifies the name of the operational attribute.
- vals ::= Specifies the values of the operational attribute.
- Detailed description: This control is intended to be used to pass values to the server for operational attributes that are typically set by the server, not by the client. For example, a master server might use this control to pass the **modifiersName** and **modifyTimestamp** values on a replication request because the entry on the replica will have the same values as on the master.
- Server behavior:
  - The control is supported only on an add, modify, or modify DN request on a basic replication peer or read-only replica server or an advanced replication consumer server. If the control is specified on another request and the control is critical, the server returns LDAP\_UNAVAILABLE\_CRITICAL\_EXTENSION.
  - 2. If using basic replication, the requester must be bound as the master server DN or peer server DN for the backend processing the request, as specified by the masterServerDN or peerServerDN configuration option in the backend section of the LDAP server configuration file. If using advanced replication, the requester must be bound as the DN specified as the ibm-replicaCredentialsDN attribute value in the replication agreement. If the

S			Each attribute type specified in the control must be defined in the LDAP server schema. If it is not, the server returns <b>LDAP_UNDEFINED_TYPE</b> if the control is critical, otherwise it ignores the attribute.
4		4.	There is no ACL checking performed for the changes to the entry resulting from the control. The server does perform schema checking to assure the attributes are allowed in the entry.
		5.	If more than one <b>replicateOperationalAttributes</b> control is specified in a request, the server returns <b>LDAP_PROTOCOL_ERROR</b> .
Ι	<b>Replication Supp</b>	olie	er ID Bind
Ι	•	Na	me: Replication Supplier ID Bind
 	•		<b>scription:</b> Used by supplier gateway server when it binds to a consumer ver in an advanced replication environment.
I	•	As	signed object identifier: 1.3.18.0.2.10.18
I	•	Tar	rget of control: Server
I	•	Со	ntrol criticality: Never critical
 	•		lues: The following ASN.1 (Abstract Syntax Notation One) syntax describes BER (Basic Encoding Rules) encoding of the control value.
   			trolValue ::= SEQUENCE { upplierServerId OCTET STRING
I		wh	ere,
 			pplierServerId ::= A string containing the advanced replication supplier server
		whi rec ser ser suc sup <b>Se</b> rep	tailed description: This control is used by a gateway server to determine ich servers to replicate to. Gateway servers only replicate updates that are served from other gateway servers to their own local servers (servers that side in the same site as the gateway server, including peer and forwarding overs). When a gateway server binds to its consumer servers, this control is not with its own server ID as the control value. When a gateway server receives ch a control in a bind request, it knows that a gateway server is bound as a oplier and that only local servers should receive replicated updates. <b>rver behavior:</b> This control is sent only by a gateway server in an advanced blication environment when bound as the master server distinguished name ecified in the replication agreement entry. If this control is sent by a user who
I		doe	es not have access, an LDAP_UNWILLING_TO_PERFORM error is returned.

requester is not bound in any of these manners and the control is critical, the

server returns LDAP\_UNAVAILABLE\_CRITICAL\_EXTENSION.

### **Server Administration**

|

- Name: Server Administration
- **Description:** Used by the LDAP administrator on an add, delete, modify, or modify DN operation under conditions where the operation is typically refused. This control forces the operation to occur.
- Assigned object identifier: 1.3.18.0.2.10.15
- · Target of control: Server
- · Control criticality: Critical at client's option
- Values: There is no value; the controlValue field is absent.

- **Detailed description:** In an advanced replication environment, this control allows an add, delete, modify, or modify DN operation sent by the LDAP administrator to be processed by a server that typically refuses the operation, such as a quiesced forwarding server or a read-only replica server. The processed operation is then replicated as any other update.
  - **Note:** This control must be used with discretion because entry updates are allowed under unusual circumstances. Therefore, it is the user's responsibility to ensure the server being updated ends up in a state consistent with the other servers in an advanced replication environment. For example, in an advanced replication environment, the entry's **modifyTimestamp** attribute value, which is used as the base for conflict resolution, might be different on different servers if the entry gets updated individually on those servers with this control.
- Server behavior: This control can only be specified by a user bound as the LDAP administrator. If user is not bound as the LDAP administrator, the server returns an LDAP\_UNWILLING\_TO\_PERFORM error. If the server is a supplier or consumer server and is quiesced in an advanced replication environment, the control must be specified in order to allow the update to occur.
  - **Note:** The LDAPADD, LDAPMDFY, LDAPMDRN, and LDAPDLET utilities have a **-k** option to add this control to LDAP server requests. For more information about the LDAPADD, LDAPMDFY, LDAPMDRN, and LDAPDLET utilities, see "Using the LDAP Client Utilities" in *z/VM: TCP/IP User's Guide.*

### **Cascading control replication**

- Name: Cascading control replication
- **Description:** Performs the requested action to the specified server and passes it along to all replicas of the given replication context. If any of these are forwarding replicas or gateway servers, they pass the extended operation along to their replicas. The operation cascades over the entire advanced replication topology. This extended operation should be targeted against a master server.
- Assigned Object Identifier: 1.3.18.0.2.12.15
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {
  action INTEGER {
    quiesce (0),
    unquiesce (1),
    replicateNow (2),
    wait (3) },
  contextDN LDAPDN,
  timeout INTEGER
}
```

#### where,

action ::= An integer value indicating the operation to be performed on the specified server.

- If set to quiesce, updates under the replication context contextDN are restricted to the LDAP administrator, if using the Server Administration control (OID 1.3.18.0.2.10.15), and any replication master DNs with authority under this context. Advanced replication continues for a quiesced context. If the server is restarted, all replication contexts are then unquiesced.
- If set to unquiesce, updates under the replication context contextDN are allowed and normal operation resumes.
- If set to replicateNow, all queued updates for each replication agreement under contextDN are immediately replicated, regardless of schedule. After queued replication updates have been replicated, each replication agreement follows its normal schedule. If there are any suspended replication agreements, they are skipped and any queued updates remain queued for those replication agreements. Unlike wait, this extended operation is propagated to the consumer server of each replication agreement without waiting for all queued updates to be applied.
- If set to wait, all queued updates for each replication agreement under contextDN are immediately replicated, regardless of schedule. After queued replication updates have been replicated, each replication agreement follows its normal schedule. If there are any suspended replication agreements, they

are skipped and any queued updates remain queued for those replication agreements. Unlike **replicateNow**, this extended operation is not propagated to the consumer server of each replication agreement until that agreement is finished replicating.

contextDN ::= A distinguished name (DN) containing the replication context that this operation affects.

timeout ::= An integer value indicating the number of seconds that the extended operation has to successfully complete. If not present, or 0, the operation has an indefinite amount of time to complete.

- **Detailed description:** The **Cascading control replication** extended operation returns when one of the following conditions occurs:
  - The request is complete on all servers.
  - A failure has occurred on one of the servers in the replication topology.
  - The timeout value is exceeded.

The **Cascading control replication** extended operation is allowed only when the bound user has update authority to all replication agreements in the specified contextDN or is authenticated as a master server for the specified contextDN.

- Response object identifier: 1.3.18.0.2.12.15
- Response description: This extended operation response is used to return error information when a problem is encountered with performing the Cascading control replication extended operation.
- Response values: The following describes the response value.

```
ResponseValue ::= SEQUENCE {
  resultCode
                              INTEGER.
                              OCTET STRING.
  msq
  supplier
                              OCTET STRING,
  consumer
                              OCTET STRING,
  additionalResultCode[1]
                              INTEGER OPTIONAL {
       LDAP_REPLICATION_SUCCESS (0),
       LDAP REPLICATION RETRYING (2) },
                              LDAPDN OPTIONAL
  agreementDN[2]
}
```

where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

supplier ::= A string containing the shortened hostname and advanced replication server ID of the supplier server targeted by the extended operation. The format is '*shortenedHostName*:*serverID*'. If the shortened hostname cannot be determined, the format is 'server ID:*serverID*'.

consumer ::= A string containing the *host:port* of the consumer server that is reporting an error. This is only returned when the consumer has a problem performing the requested operation.

additionalResultCode ::= An integer value that is returned when the resultCode is set to **LDAP\_TIMEOUT**.

agreementDN ::= A distinguished name (DN) containing the replication agreement that is in error.

Response detailed description:

The following table summarizes some different error scenarios and the **Cascading control replication response** returned for such scenarios.

Error scenario	Cascading control replication response
contextDN does not exist or is not a replication context	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform operation	Returns an LDAP_INSUFFICIENT_ACCESS return code
Operation did not complete within the specified time	Returns an LDAP_TIMEOUT return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Value for the input option is not valid	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

When a **Cascading control replication response** returns an **LDAP\_TIMEOUT** return code, the additionalResultCode field in the **Cascading control replication response** is set to either 0 or **LDAP\_REPLICATION\_RETRYING** to indicate the replication update is being retried. The **LDAP\_REPLICATION\_RETRYING** error is only returned when action is set to wait.

### changeLogAddEntry

- Name: changeLogAddEntryRequest
- **Description:** Causes the LDAP server to create a change log entry in the change log using information passed to the extended operation. All input values must be in UTF8.
- Assigned Object Identifier: 1.3.18.0.2.12.48
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

RequestValue ::= SEQUE version applicationID userid group	INTEGER, INTEGER, OCTET STRING, OCTET STRING,
class	OCTET STRING,
resource	OCTET STRING,
<pre>changeType add (0), delete (1), modify (2), rename (3) },</pre>	INTEGER {
changeTime	OCTET STRING,
initiator	OCTET STRING,
changes SEQUENCE OF	changeAttributeList OPTIONAL}

#### Where,

version ::= Identifies which version of the interface is being used. Currently the only value supported is 2. If the interface is extended in the future then other values will be supported.

applicationID ::= 1 for RACF. Other applications will have different identifiers. The identifier informs the LDAP server which (if any) translations of the data should be done.

userid ::= A string containing the userid that is created, modified, deleted, or renamed. This string is used to form the value of the **targetDN** attribute in the change log entry.

group ::= For the RACF application, a string containing the group that is created, modified, deleted, or renamed. The RACF application can specify a value for both userid and group to indicate that the change is to the connection of that user to that group. This string is used to form the value of the **targetDN** attribute in the change log entry.

class::= A string containing the class of the resource profile that is created, modified, deleted, or renamed. This string is used along with the resource string to form a resource profile DN as the value of the **targetDN** attribute in the change log entry.

resource::= A string containing the resource profile that is created, modified, deleted, or renamed. This string is used along with the class string to form a resource profile DN as the value of the **targetDN** attribute in the change log entry.

changeType ::= An integer value indicating the type of change. This is used to form the value of the **changeType** attribute in the change log entry.

changeTime::= A string of decimal numbers, used to form the **changeTime** attribute in the change log entry. The format of the string is:*yyyymmddhhiiss.uuuuuu*Z

Where,

*yyyy* is year, *mm* is month, *dd* is day, *hh* is hour, *ii* is minutes, *ss* is seconds, *uuuuuu* is micro seconds, Z is a character constant meaning that this time is based on Zulu time, also known as GMT.

initiator ::= A string containing the userid that made the change. This string is used to form the value of the **ibm-changeInitiatorsName** attribute in the change log entry.

```
changeAttributeList ::= SEQUENCE {
  field attributeDescription,
  vals SEQUENCE OF AttributeValue,
  action ENUMERATED {
    add (0),
    replace (1),
    delete (2) },
  requestValue Boolean }
```

Where,

field ::= is the name of the attribute that has been changed. For RACF, this consists of the segment name followed by a period followed by the field name. LDAP maps the RACF segment and field name to an LDAP attribute name.

vals ::= is a ber representation (length and data) of the new attribute value.

action ::= describes what has happened to the attribute (value add, replace, or delete). To indicate that an entire attribute is deleted, specify an action of delete with no value in the vals field.

requestValue ::= is a flag that, if TRUE, indicates that the attribute value in the vals field is not present and should be requested from the application.

The changeAttributeList values are used to form the **changes** attribute in the change log entry. If changeAttributeList is not specified, a change log entry is created without a **changes** attribute. This acts as a notification to the user of the change log that it should read the entire entry out of the directory tree.

- **Detailed description:** Class and resource cannot be specified with userid or group. Both class and resource must be specified if either one is specified. In this case, SDBM must be configured to support RACF resources, by specifying **enableResources on** in the SDBM section of the LDAP server configuration file.
- Response object identifier: 1.3.18.0.2.12.49
- **Response description:** This response is used to return error information if an incorrect **changeLogAddEntryRequest** is passed to the LDAP server. If no errors are encountered, then an indication of success is returned to the caller. All output is in UTF8.
- **Response values:** The following describes the response value.

ResponseValue	::= SEQUENCE	{ 4
5 5		
success		(0),
loggingFail	ed	(1),
invalidCrea	lentials	(2),
remoteNotSu	upported	(3),
notConfigur	(4),	
notActive		(5),
decodeFaile	ed	(6),
valueOutOfF	Range	(7),
dnConvertFa	ailed	(8)
}		
msg	OCTET STRING	
}		

Response detailed description:

The following table summarizes some different error scenarios and the **changeLogAddEntryRequest** response returned for such scenarios.

Error scenario	changeLogAddEntryRequest's response	
An internal error prevents the logging operation from completing	Returns a loggingFailed return code	
The caller is not in supervisor state	Returns an invalidCredentials return code	
Change log is not configured	Returns a notConfigured return code	
Change log is not active	Returns a notActive return code	
LDAP server is unable to parse the request	Returns a decodeFailed return code	
Value is outside the range of allowable values	Returns a valueOutOfRange return code	
LDAP server is unable to convert a RACF userid to an LDAP DN	Returns a <b>dnConvertFailed</b> return code	

### **Control replication**

- Name: Control replication
- **Description:** Used to suspend replication, resume replication, or force immediate replication by a supplier server in an advanced replication environment. When a replication agreement is suspended, updates under the context are allowed but the agreement queues the updates to its replica server until advanced replication is resumed for the agreement. This extended operation should be targeted against a master server.
- Assigned Object Identifier: 1.3.18.0.2.12.16

• Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {
   action INTEGER {
      suspend (0),
      resume (1),
      replicateNow (2) },
   scope INTEGER {
      singleAgreement (0),
      allAgreements (1) },
   entryDN LDAPDN
}
```

Where,

action ::= An integer value indicating the operation to be performed on the supplier server. If set to **suspend**, the replication agreement queues the updates to its replica server until advanced replication is resumed for the agreement. If set to **resume**, advanced replication for the replication agreement continues. If set to **replicateNow** and the replication agreement is waiting for scheduled replication to occur, any outstanding updates are immediately replicated. **replicateNow** has no effect on a suspended replication agreement.

scope ::= An integer value indicating the extent of the action that is to be performed. If set to **singleAgreement**, the request applies to a single replication agreement. If set to **allAgreements**, the request applies to all replication agreements within a replication context. This parameter indicates whether the entryDN is a replication agreement or context entry.

entryDN ::= A distinguished name (DN) containing the replication context or agreement that this operation affects. If scope is set to **singleAgreement**, this specifies the distinguished name of the replication agreement that this extended operation is acting on. If scope is set to **allAgreements**, this specifies the distinguished name of the replication context and indicates that all agreements within the context are to be acted on.

- Response object identifier: 1.3.18.0.2.12.16
- **Response description:** This extended operation response is used to return error information when a problem is encountered with performing the **Control replication** extended operation.
- Response values: The following ASN.1 syntax describes the BER encoding of the response value.

ResponseValue	::	=	SEQUENCE	Ξ {
resultCode			INTEG	ER,
msg			OCTET	STRING,
consumer			OCTET	STRING
}				

Where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

consumer ::= A string containing the *host:port* of the consumer server that is reporting an error. This is returned when the consumer has certain problems performing the requested operation.

Response detailed description:

The following table summarizes some different error scenarios and the **Control replication response** returned for such scenarios.

Error scenario	Control replication response
entryDN does not exist or is not a replication context or agreement	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform operation	Returns an LDAP_INSUFFICIENT_ACCESS return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Value for the input option is not valid	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

### **Control replication error log**

- Name: Control replication error log
- **Description:** Used to display advanced replication errors in the error log and correct any advanced replication problems that occur.
- Assigned Object Identifier: 1.3.18.0.2.12.56
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {
  errorOption INTEGER {
    retry (1),
    display (2),
    delete (3) },
  failureId OCTET STRING,
  agreementDN LDAPDN
}
```

#### Where,

errorOption ::= An integer value indicating the operation to be performed on the advanced replication error log. If set to **retry**, tries to reprocess one or all failed replication updates. If set to **delete**, deletes one or all failed replication updates. If set to **show**, shows the failed update specified by the failureId. The failureId cannot be set to **0** when errorOption is set to **show**.

failureId ::= A string indicating the target of the operation. If set to **0**, then all advanced replication errors in the error log are either retried or deleted based on the errorOption setting. Otherwise, this value specifies the failure ID in the advanced replication error log that is to be retried, displayed, or deleted based on the errorOption setting. The failure ID can be determined by searching the agreementDN for the **ibm-replicationFailedChanges** operational attribute. The failure ID must be in the range 1 - 4294967295.

agreementDN ::= A distinguished name (DN) containing the replication agreement that this operation affects.

- Response object identifier: 1.3.18.0.2.12.57
- **Response description:** This extended operation response is used to return error information when a problem is encountered with performing the **Control replication error log** extended operation.
- **Response values:** The following ASN.1 syntax describes the BER encoding of the response value.

```
ResponseValue ::= SEQUENCE {
resultCode INTEGER,
countEffected OCTET STRING,
msg OCTET STRING
}
```

Where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

countEffected ::= A string containing the number of error log failures retried, deleted, or displayed.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

#### Response detailed description:

The following table summarizes some different error scenarios and the **Control replication error log** response returned for such scenarios.

Error scenario	Control replication error log response
agreementDN does not exist or is not a replication agreement	Returns an LDAP_NO_SUCH_OBJECT return code
failureId does not exist for any agreement in this backend	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code
failureId is not logged to this agreementDN	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform operation	Returns an LDAP_INSUFFICIENT_ACCESS return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Value for the input option is not valid	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

### **Control replication queue**

- Name: Control replication queue
- **Description:** Used to indicate which pending changes in the advanced replication queue for a replication agreement ought to be skipped (deleted) and not replicated to the consumer server.
- Assigned Object Identifier: 1.3.18.0.2.12.17
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
requestValue ::= SEQUENCE {
  action INTEGER {
    skipAll (0),
    skipSingle (1) },
  agreementDN LDAPDN,
  changeId OCTET STRING
}
```

Where,

action ::= An integer value indicating the operation that is to be performed on the advanced replication queue. If set to **skipAll**, the server skips (deletes) all updates that have not yet been replicated from the replication agreement. If set to **skipSingle**, the server skips (deletes) the specified changeId. Only the next change to be replicated can be skipped in this manner. If the changeId that is specified is not the first one in the list of pending changes, the extended operation fails. This ensures that the operation only affects the entry that is preventing advanced replication from occurring.

agreementDN ::= A distinguished name (DN) containing the replication agreement that this operation affects.

changeID ::= A string that identifies the change ID of a pending operation in the replication agreement that is to be skipped (deleted). The changeId that is specified must be in the range 1 - 4294967295. Change IDs can be determined by searching the agreementDN for the **ibm-replicationPendingChanges** operational attribute. The changeId is required when action is set to **skipSingle** and ignored when action is set to **skipAll**.

- Response object identifier: 1.3.18.0.2.12.17
- **Response description:** This extended operation response is used to return error information when a problem is encountered with performing the **Control replication queue** extended operation. If action is set to **skipAll** and there are no pending updates in the advanced replication queue, the extended operation is considered successful.
- Response values: The following ASN.1 syntax describes the BER encoding of the response value.

ResponseValue ::=	SEQUENCE {
resultCode	INTEGER,
msg	OCTET STRING,
changesSkipped	INTEGER
}	

Where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

changesSkipped ::= An integer value indicating the number of pending updates in the advanced replication queue that have been skipped (deleted).

#### Response detailed description:

The following table summarizes some different error scenarios and the **Control replication queue response** returned for such scenarios.

Error scenario	Control replication queue response
agreementDN does not exist or is not a replication agreement	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code
The specified changeId is not the next change to be replicated	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform the requested operation	Returns an LDAP_INSUFFICIENT_ACCESS return code

Error scenario	Control replication queue response
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Value for the input option is not valid	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

#### Effective password policy

I

I

I

- · Name: Effective password policy
- **Description:** Used to query the effective password policy for a user or group entry and lists the policies used in determining its effective password policy.
- Assigned Object Identifier: 1.3.18.0.2.12.75
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {
  entryDN LDAPDN
}
```

where,

entryDN ::= A distinguished name (DN) containing the entry whose effective password policies and password policy attribute values are being queried.

- Detailed description: The Effective password policy extended operation can only be executed by the LDAP administrator or a user querying their own effective password policy. The LDAP administrator is allowed to query the effective password policy of users and groups in the directory. When a user entry is queried, this extended operation shows the effective password policy entries and values that are used to control the user's authentication and password modifications. When a group entry is queried, this extended operation provides the effective password policy that is a combination of the group's password policy attributes and the global password policy entry, cn=pwdpolicy,cn=ibmpolicies.
- Response object identifier: 1.3.18.0.2.12.77
- Response description: When a user entry is queried, this extended response shows the effective password entries and values used to control the user's authentication and password modifications. When a group entry is queried, this extended operation provides the effective password policy that is a combination of the group's password policy attributes and the global password policy entry, cn=pwdpolicy,cn=ibmpolicies. If a user is querying their own effective password policy, the objectNames are not returned.
- Response values: The following describes the response value.

ResponseValue	::= SEQUENCE {	
attributes	SEQUENCE OF SEQUENCE	{
	attributeType	AttributeDescription,
	values	SET OF AttributeValue
}		
objectNames	[0] SEQUENCE {	
	objectName	LDAPDN OPTIONAL
}		
}		

Where,

attributes ::= The password policy attribute types and values that are contained in the user's or group's effective password policy.

objectName ::= The distinguished names of all password policy entries from where the effective password policy attribute values are derived. The objectName field is only returned in the extended operation response when bound as the LDAP administrator. It is not returned when bound as a normal user.

#### Response detailed description:

The following table summarizes some different error scenarios and the **Effective password policy** response returned for such scenarios.

Error scenario	Effective password policy response
An unauthorized user tries to perform the extended operation	Returns an LDAP_INSUFFICIENT ACCESS return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Insufficient memory to perform the operation	Returns an LDAP_NO_MEMORY return code
entryDN does not exist	Returns an LDAP_NO_SUCH_OBJECT return code
Internal server error	Returns an LDAP_OPERATIONS_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_PROTOCOL_ERROR return code
Returned for errors not covered by previously documented return codes. Check the corresponding error message for further details.	Returns an LDAP_OTHER return code

### Quiesce or unquiesce context

Т

Т

Т

#### · Name: Quiesce or unquiesce context

- **Description:** Used to change an advanced replication context to or from a quiesced state. In a quiesced state, the entire subtree starting from the context does not accept client updates except from the LDAP administrator, if using the **Server Administration** control (OID 1.3.18.0.2.10.15), and any replication master DNs with authority under this context. Advanced replication continues for a quiesced context. If the server is restarted, all replication contexts are then unquiesced.
- Assigned Object Identifier: 1.3.18.0.2.12.19
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {
quiesce BOOLEAN,
contextDN LDAPDN
}
```

Where,

quiesce ::= A boolean indicating whether to quiesce (TRUE) or unquiesce (FALSE) an advanced replication context.

contextDN ::= A distinguished name (DN) containing the replication context that this operation affects.

- Response object identifier: 1.3.18.0.2.12.19
- **Response description:** This extended operation response is used to return error information when a problem is encountered with performing the **Quiesce or unquiesce context** extended operation.

• **Response values:** The following ASN.1 syntax describes the BER encoding of the response value.

```
ResponseValue ::= SEQUENCE {
  resultCode INTEGER,
  msg OCTET STRING
}
```

Where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

#### • Response detailed description:

The following table summarizes some different error scenarios and the **Quiesce** or **unquiesce context** response returned for such scenarios.

Error scenario	Quiesce or unquiesce context response
contextDN does not exist or is not a replication context	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform operation	Returns an LDAP_INSUFFICIENT_ACCESS return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Unable to find the request data	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

#### **Replication topology**

- Name: Replication topology
- Description: Used to synchronize replication topology related entries across the replication topology. A replication topology entry is an entry that contains an objectclass whose name begins with ibm-replica, such as ibm-replicationContext, ibm-replicaGroup, ibm-replicaSubentry, ibm-replicationAgreement, and ibm-replicationCredentialsSimple. This extended operation is cascaded through all forwarding and gateway servers if agreementDN is not specified. If agreementDN is specified, then the extended operation only synchronizes the replication topology entries in the consumer server defined by the replication agreement.
  - **Note:** Replication topology entries containing credentials are also replicated if they are located under the replication context. These entries should be located instead under the cn=localhost suffix.
- Assigned Object Identifier: 1.3.18.0.2.12.54
- Values: The following ASN.1 syntax describes the BER encoding of the request value.

```
RequestValue ::= SEQUENCE {

contextDN LDAPDN,

timeout INTEGER,

agreementDN LDAPDN OPTIONAL

}
```

Where,

contextDN ::= A distinguished name (DN) containing the replication context on the supplier server that the advanced replication topology related entries are synchronized.

timeout ::= An integer value indicating the number of seconds that the extended operation has to successfully complete. If not present, or 0, the operation has an indefinite amount of time to complete.

agreementDN ::= A distinguished name (DN) containing the replication agreement used to connect to a consumer server. If a value is specified, only the consumer server defined in the agreementDN is synchronized. The extended operation is not cascaded to any consumers of that server.

- Response object identifier: 1.3.18.0.2.12.55
- Response description: This extended operation response is used to return error information when a problem is encountered with performing the Replication topology extended operation.
- **Response values:** The following ASN.1 syntax describes the BER encoding of the response value.

ResponseValue	::=	SEQUEN	CE {
resultCode		INTEG	ER,
msg		OCTET	STRING,
supplier		OCTET	STRING,
consumer		OCTET	STRING
}			

Where,

resultCode ::= An integer value indicating whether the extended operation is successful. Standard LDAP return codes are returned as values within this portion of the extended operation response.

msg ::= A string containing a reason code message. In most cases, it is an error message indicating why the extended operation failed. In some cases, it can be an informational or warning message.

supplier ::= A string containing the shortened hostname and advanced replication server ID of the supplier server targeted by the extended operation. The format is '*shortenedHostName*:*serverID*'. If the shortened hostname cannot be determined, the format is 'server ID:*serverID*'.

consumer ::= A string containing the *host:port* of the consumer server that is reporting an error. This is returned when the consumer has certain problems performing the requested operation.

#### Response detailed description:

The following table summarizes some different error scenarios and the **Replication topology response** returned for such scenarios.

Error scenario	Replication topology response
contextDN does not exist or is not a replication context	Returns an LDAP_NO_SUCH_OBJECT return code
agreementDN does not exist or is not a replication agreement	Returns an LDAP_NO_SUCH_OBJECT return code
Backend does not support advanced replication	Returns an LDAP_UNWILLING_TO_PERFORM return code

Error scenario	Replication topology response
agreementDN is not under a replication context	Returns an LDAP_UNWILLING_TO_PERFORM return code
Not authorized to perform operation	Returns an LDAP_INSUFFICIENT_ACCESS return code
Operation did not complete with specified time	Returns an LDAP_TIMEOUT return code
Syntax of DN specified is not correct	Returns an LDAP_INVALID_DN_SYNTAX return code
Value for the input option is not valid	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to decode the request	Returns an LDAP_DECODING_ERROR return code

### Start TLS

- Name: Start TLS Extended Request
- Description: Causes a non-secure connection to change to a secure connection.
- Assigned Object Identifier: 1.3.6.1.4.1.1466.20037
- · Values: None.
- Detailed description: The client may send the Start TLS extended request at any time after establishing an LDAP directory association, except in the following cases:
  - If a secure connection is already established, or
  - During a multi-stage SASL negotiation, or
  - If there are any outstanding LDAP directory operations on the connection.

The LDAP server responds with an indication of whether the change to a secure connection is allowed. If accepted, the client is expected to immediately begin the secure protocol handshake.

The secure connection might be ended and a non-secure connection resumed by having the client cause a TLS closure alert to be sent to the server. Communication after receiving the TLS closure alert is over a non-secure connection. The client is considered to be in an anonymous authentication state.

- Response object identifier: 1.3.6.1.4.1.1466.20037
- Response description: Upon receiving the Start TLS extended request, the server returns an extended response containing a response code indicating success or failure.
- **Response values:** For the successful response, no response value is returned. For an error response, a response message indicating the cause of the error is returned.
- Response detailed description:

The following table summarizes some different error scenarios and the server's response returned for such scenarios.

Error scenario	Server response
Server accepts connection and can handle the request	Returns an LDAP_SUCCESS return code
SSL/TLS is not configured	Returns an LDAP_UNAVAILABLE return code

Error scenario	Server response
A secure connection is already established	Returns an LDAP_OPERATIONS_ERROR return code
Secure connections are not supported by the server	Returns an LDAP_PROTOCOL_ERROR return code
There are outstanding operations on the connection	Returns an LDAP_OPERATIONS_ERROR return code
A multi-stage SASL negotiation is in progress	Returns an LDAP_OPERATIONS_ERROR return code

#### unloadRequest

- Name: unloadRequest
- Description: Causes the LDAP server to unload entries from a directory into a file in LDIF format. This extended operation is used by the DS2LDIF utility. For more information, see "DS2LDIF (ds2ldif utility)" in z/VM: TCP/IP Planning and Customization.
- Assigned Object Identifier: 1.3.18.0.2.12.62
- Values: The following ASN.1 syntax describes the BER encoding of the request value:

```
RequestValue ::= SEQUENCE {
   tagOption
   outputFileName
   subtreeDN
   backendName
   genealogicalOrder
   filterDN
   noControlValues
   unloadLocalhost
```

BOOLEAN, OCTET STRING. [0] LDAPDN OPTIONAL, [1] OCTET STRING OPT [2] BOOLEAN OPTIONAL OCTET STRING OPTIONAL, BOOLEAN OPTIONAL, [3] LDAPDN OPTIONAL, BOOLEAN OPTIONAL.

[4] [5] BOOLEAN OPTIONAL

}

Where,

tag0ption ::= A boolean indicating whether the encryption tag of **userPassword** attribute values should be displayed in the clear when directory data is unloaded. This value corresponds to the -t option of the ds2ldif utility.

outputFileName ::= A string containing the fully qualified file name or dataset name that the server writes the unloaded directory entries in LDIF format. This value corresponds to the -o option of the ds2ldif utility.

subtreeDN ::= A distinguished name (DN) containing the name of the top entry to unload. This entry and all of the entries below it in the directory hierarchy are unloaded. The value must be the DN of an entry in an LDBM or CDBM backend or of the LDAP server schema entry, cn=schema. This value corresponds to the -s option of the ds2ldif utility.

backendName ::= A string containing the name of an LDBM or CDBM backend. All the entries in the backend are unloaded. The value is either the optional fourth parameter of the database option in the LDAP server configuration file or the name generated for the backend by the LDAP server if the parameter is not specified in the configuration file. This value corresponds to the **-n** option of the ds2ldif utility.

genealogicalOrder ::= A boolean value that specifies how the entries are unloaded. If set to TRUE, entries in each subtree are unloaded together, doing a depth-first traversal of the directory. If set to FALSE or if not specified, there is no guaranteed order of unloaded entries, other than parent entries are always unloaded before child entries. This value corresponds to the **-g** option of the **ds2ldif** utility.

filterDN ::= A distinguished name (DN) of a replication filter entry that contains **ibm-replicationFilterAttr** attribute values. These values are filters used to skip entire entries or attributes within entries while unloading the directory. See Partial replication for more information about replication filter entries. Advanced replication must be enabled in the LDAP server with the CDBM backend configured and **useAdvancedReplication on** specified in the CDBM backend section of the server configuration file. This value corresponds to the **-q** option of the **ds2ldif** utility.

noControlValues ::= A boolean indicating whether the

**replicateOperationalAttributes** control value is unloaded for each entry. If set to TRUE, the **replicateOperationlAttributes** control is not unloaded for each entry. If set to FALSE or if not specified, the **replicateOperationalAttributes** control is unloaded for each entry. The **replicateOperationalAttributes** control value contains the **modifyTimestamp, createTimestamp, creatorsName**, and **modifiersName** attribute types and values for the entry base64 encoded. This value corresponds to the **-j** option of the **ds2ldif** utility.

unloadLocalHost ::= A boolean indicating whether the **cn=localhost** subtree is unloaded if it exists on the targeted LDAP server. This boolean can only be set to TRUE when subtreeDN is not specified. This value corresponds to the **-I** option of the **ds2ldif** utility.

• **Detailed description:** The **unloadRequest** extended operation is rejected if the requester is not bound as the LDAP administrator, as specified by the **adminDN** option in the LDAP server configuration file. subtreeDN and backendName cannot both be specified in the request. If neither is specified and there is only one LDBM or CDBM backend configured, then that backend is unloaded; otherwise, an error is returned.

The aclEntry, aclPropagate, entryOwner, and ownerPropagate attributes are included in an unloaded entry if these attributes have been explicitly set for that entry. The unloaded entry also includes the **ibm-entryuuid** attribute. The **replicateOperationalAttributes** control value is written to the output LDIF file if noControlValues is set to FALSE.

The **ds2ldif** utility uses this extended operation to unload the selected directory data if it encounters a problem starting the backend that is to be unloaded or if the **-r** command-line option is specified. For additional details about the operation of the **ds2ldif** utility, see "ds2ldif Utility" in *z/VM: TCP/IP Planning and Customization*.

- Response object identifier: 1.3.18.0.2.12.63
- Response description: The response indicates the number of entries that were successfully unloaded by the LDAP server as a result of the unloadRequest extended operation.
- **Response values:** The following ASN.1 syntax describes the BER encoding of the response value.

```
ResponseValue :== SEQUENCE {
entryCount INTEGER
```

Response detailed description:

The following table summarizes some different error scenarios and the **unloadRequest response** returned for such scenarios:

Error scenario	unloadRequest's response
Not bound as the LDAP administrator DN	Returns an LDAP_OTHER return code
Multiple LDBM or CDBM backends are active in the server but a subtreeDN or backendName is not specified	Returns an LDAP_OTHER return code
A non-existent subtreeDN, filterDN, or backendName is specified	Returns an LDAP_OTHER return code
Error opening or writing the output LDIF file	Returns an LDAP_OTHER return code
Both subtreeDN and backendName are specified	Returns an LDAP_PROTOCOL_ERROR return code
A zero-length value is specified for subtreeDN, filterDN, or backendName	Returns an LDAP_PROTOCOL_ERROR return code
LDAP server is unable to parse the request	Returns an LDAP_PROTOCOL_ERROR return code
A subtreeDN is specified when unloadLocalHost is set to TRUE	Returns an LDAP_PROTOCOL_ERROR return code
filterDN specified when CDBM backend is not configured or <b>useAdvancedReplication</b> <b>off</b> is specified in the CDBM backend section of the server configuration file	Returns an LDAP_UNWILLING_TO_PERFORM return code

## **Appendix D. Related Protocol Specifications**

IBM is committed to industry standards. The internet protocol suite is still evolving through Requests for Comments (RFC). New protocols are being designed and implemented by researchers, and are brought to the attention of the internet community in the form of RFCs. Some of these are so useful that they become a recommended protocol. That is, all future implementations for TCP/IP are recommended to implement this particular function or protocol. These become the *de facto* standards, on which the TCP/IP protocol suite is built.

RFC	Title	Author

#### Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing IBM Corporation North Castle Drive Armonk, NY 10504-1785 U.S.A.

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing Legal and Intellectual Property Law IBM Japan Ltd. 1623-14, Shimotsurama, Yamato-shi Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

Site Counsel IBM Corporation 2455 South Road Poughkeepsie, NY 12601-5400 U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information may contain examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

#### COPYRIGHT LICENSE:

This information may contain sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

#### **Programming Interface Information**

This book primarily documents information that is NOT intended to be used as Programming Interfaces of z/VM.

This book also documents intended Programming Interfaces that allow the customer to write programs to obtain services of z/VM. This information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking:

#### PI

<....Programming Interface information....>

#### PI end

#### Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at IBM copyright and trademark information - United States (www.ibm.com/legal/us/en/copytrade.shtml).

Adobe and PostScript are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft and Windows are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java is a trademark or registered trademark of Oracle and/or its affiliates.

## Glossary

For a list of z/VM terms and their definitions, see z/VM: Glossary.

The z/VM glossary is also available through the online z/VM HELP Facility. For example, to display the definition of the term "dedicated device", issue the following HELP command:

help glossary dedicated device

While you are in the glossary help file, you can do additional searches:

• To display the definition of a new term, type a new HELP command on the command line:

help glossary newterm

This command opens a new help file inside the previous help file. You can repeat this process many times. The status area in the lower right corner of the screen shows how many help files you have open. To close the current file, press the Quit key (PF3/F3). To exit from the HELP Facility, press the Return key (PF4/F4).

• To search for a word, phrase, or character string, type it on the command line and press the Clocate key (PF5/F5). To find other occurrences, press the key multiple times.

The Clocate function searches from the current location to the end of the file. It does not wrap. To search the whole file, press the Top key (PF2/F2) to go to the top of the file before using Clocate.

## Bibliography

See the following publications for additional information about z/VM. For abstracts of the z/VM publications, see *z/VM: General Information*.

## Where to Get z/VM Information

z/VM product information is available from the following sources:

- z/VM V6R2 Information Center (publib.boulder.ibm.com/infocenter/zvm/v6r2/)
- IBM: z/VM Internet Library (www.ibm.com/vm/library/)
- IBM Publications Center (www.ibm.com/ebusiness/linkweb/publications/servlet/pbi.wss)
- IBM Online Library: z/VM Collection, SK5T-7054
