How to send your comments to IBM	xix
If you have a technical problem	
Summary of Changes	XX
SC24-6242-02, z/VM Version 6 Release 2	XX
IPv6 Support for FTP Server and Client	XX
IPv6 Support for SMTP Server and Client	XX
GSKKYMAN	
MPROUTE Enhancements and Upgrade to z/OS 1.12 Equivalency	
LDAP Enhancements	
Query OSA Address Table	
Support Withdrawal	XX
SC24-6242-01, z/VM Version 6 Release 1 (Updated Edition)	xxi
z/VM SSL Server Enhancements	xxi
Support for IBM zEnterprise System Networks	
SC24-6240-00, z/VM Version 6 Release 1	XXi
GSKKYMAN and GSKTRACE	
NSLOOKUP	XXI
Chapter 1. Introducing Computer Networks and Protocols	
Computer Networks	
Internet Environment	
Internet Protocol Version 4 and Internet Protocol Version 6	
TCP/IP Protocols and Functions	
Link Protocols	
Network Protocols	
Transport Protocols	
Applications and Protocols	
Routing	
Internet Addressing	
IPv4 Addressing	
IPv6 Addressing	15
Chapter 2. Transferring Files Using FTP	
FTP Command	
The NETRC DATA File	
The FTP DATA File	
Statement Syntax	
FTP DATA File Statements	
CCONNTIME Statement	31
DATACL DIVID SIZIEDIEDI	.5/

About This Document

This document describes the functions of and explains how to use the applications available in TCP/IP running on the IBM® z/VM® V6.2 operating system (TCP/IP level 620). These applications include:

- · Transferring files
- · Sending electronic mail
- · Logging on to a foreign host
- · Monitoring the network
- Authenticating network users
- Remote printing
- Managing network resources
- · Using the Domain Name System

This document also describes how to use the Network File System (NFS), REXEC command, and GDDMXD with the X Window System.

For information about how to set up, initialize, and customize your TCP/IP, see *z/VM: TCP/IP Planning and Customization* and *z/VM: TCP/IP Programmer's Reference*. For information about error messages that may appear while using TCP/IP, see *z/VM: TCP/IP Messages and Codes*.

Intended Audience

This document is intended for an end-user and describes how to use level 620 after it has been installed and customized on your network. You should read this document when you want to use the applications that are available in level 620.

Before using this document, you should be familiar with the CP and CMS components of z/VM.

In addition, TCP/IP should already be installed and customized for your network.

Conventions and Terminology

This topic describes important style conventions and terminology used in this document.

How the Term "internet" Is Used in This Document

In this document, an internet is a logical collection of networks supported by routers, gateways, bridges, hosts, and various layers of protocols, which permit the network to function as a large, virtual network.

Note: The term "internet" is used as a generic term for a TCP/IP network, and should not be confused with the Internet, which consists of large national backbone networks (such as MILNET, NSFNet, and CREN) and a myriad of regional and local campus networks worldwide.

How Numbers Are Used in This Document

In this document, numbers over four digits are represented in metric style. A space is used rather than a comma to separate groups of three digits. For example, the number sixteen thousand, one hundred forty-seven is written 16 147.

How to Read Syntax Diagrams

This document uses diagrams (often called *railroad tracks*) to show the syntax of external interfaces.

To read a syntax diagram, follow the path of the line. Read from left to right and top to bottom.

- The ►►— symbol indicates the beginning of the syntax diagram.
- The → symbol, at the end of a line, indicates that the syntax diagram is continued on the next line.
- The ►— symbol, at the beginning of a line, indicates that the syntax diagram is continued from the previous line.
- The → symbol indicates the end of the syntax diagram.

Within the syntax diagram, items on the line are required, items below the line are optional, and items above the line are defaults. See the following examples.

Syntax Diagram Convention Example **Keywords and Constants:** ►►-KEYWORD-A keyword or constant appears in uppercase letters. In this example, you must specify the item KEYWORD as shown. In most cases, you can specify a keyword or constant in uppercase letters, lowercase letters, or any combination. However, some applications may have additional conventions for using all-uppercase or all-lowercase. **Abbreviations:** ►►-KFYWOrd-Uppercase letters denote the shortest acceptable abbreviation of an item, and lowercase letters denote the part that can be omitted. If an item appears entirely in uppercase letters, it cannot be abbreviated. In this example, you can specify KEYWO, KEYWOR, or KEYWORD. Symbols: Asterisk Colon You must specify these symbols exactly as they Comma appear in the syntax diagram. Equal Sign Hyphen () Parentheses Period Variables: ►►—KEYWOrd—var_name— A variable appears in highlighted lowercase, usually In this example, var_name represents a variable that

you must specify following KEYWORD.

Syntax Diagram Convention

Example

Repetitions:

An arrow returning to the left means that the item can be repeated.

A character within the arrow means that you must separate each repetition of the item with that character.

A number (1) by the arrow references a syntax note at the bottom of the diagram. The syntax note tells you how many times the item can be repeated.

Syntax notes may also be used to explain other special aspects of the syntax.

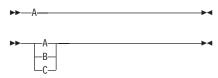

Notes:

Specify *repeat* up to 5 times.

Required Item or Choice:

When an item is on the line, it is required. In this example, you must specify A.

When two or more items are in a stack and one of them is on the line, you must specify one item. In this example, you must choose A, B, or C.

Optional Item or Choice:

When an item is below the line, it is optional. In this example, you can choose A or nothing at all.

When two or more items are in a stack below the line, all of them are optional. In this example, you can choose A, B, C, or nothing at all.

Defaults:

When an item is above the line, it is the default. The system will use the default unless you override it. You can override the default by specifying an option from the stack below the line.

In this example, A is the default. You can override A by choosing B or C.

Repeatable Choice:

A stack of items followed by an arrow returning to the left means that you can select more than one item or, in some cases, repeat a single item.

In this example, you can choose any combination of A, B, or C.

Syntax Diagram Convention

Example

Syntax Fragment:

Some diagrams, because of their length, must fragment the syntax. The fragment name appears between vertical bars in the diagram. The expanded fragment appears in the diagram after a heading with the same fragment name.

▶► A Fragment ⊢

A Fragment:

In this example, the fragment is named "A Fragment."

Message and Response Notation

This document might include examples of messages or responses. Although most examples are shown exactly as they would appear, some content may depend on the specific situation. The following notation is used to show variable, optional, or alternative content:

- Highlighted text (usually italics) indicates a variable that represents the data XXX that will be displayed.
- Brackets enclose an optional item that might be displayed. []
- {} Braces enclose alternative items, one of which will be displayed.
- The vertical bar separates items within brackets or braces.
- The ellipsis indicates that the preceding item might be repeated. A vertical ellipsis indicates that the preceding line, or a variation of that line, might be repeated.

Where to Find More Information

Appendix H, "Abbreviations and Acronyms," on page 475, lists the abbreviations and acronyms that are used throughout this document.

The "Glossary" on page 487, defines terms that are used throughout this document associated with TCP/IP communication in an internet environment.

For more information about related publications, see "Bibliography" on page 489.

Links to Other Online Documents

The online version of this document contains links to other online documents. These links are to editions that were current when this document was published. However, due to the nature of some links, if a new edition of a linked document has been published since the publication of this document, the linked document might not be the latest edition. Also, a link from this document to another document works only when both documents are in the same directory.

How to send your comments to IBM

We appreciate your input on this publication. Feel free to comment on the clarity, accuracy, and completeness of the information or give us any other feedback that you might have.

Use one of the following methods to send us your comments:

- 1. Send an email to mhyrcfs@us.ibm.com.
- 2. Go to IBM z/VM Reader's Comments (www.ibm.com/systems/z/os/zvm/zvmforms/webqs.html).
- 3. Mail the comments to the following address:

IBM Corporation

Attention: MHVRCFS Reader Comments

Department H6MA, Building 707

2455 South Road

Poughkeepsie, NY 12601-5400

U.S.A.

4. Fax the comments to us as follows:

From the United States and Canada: 1+845+432-9405

From all other countries: Your international access code +1+845+432-9405

Include the following information:

- Your name and address
- · Your email address
- · Your telephone or fax number
- The publication title and order number:

z/VM V6R2 TCP/IP User's Guide SC24-6240-02

- · The topic name or page number related to your comment
- · The text of your comment

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate without incurring any obligation to you.

IBM or any other organizations will use the personal information that you supply only to contact you about the issues that you submit to IBM.

If you have a technical problem

Do not use the feedback methods listed above. Instead, do one of the following:

- · Contact your IBM service representative.
- Contact IBM technical support.
- See IBM: z/VM Service Resources (www.ibm.com/vm/service/).
- Go to IBM Support Portal (www.ibm.com/support/entry/portal/Overview/).

Summary of Changes

This document contains terminology, maintenance, and editorial changes. Technical changes are indicated by a vertical line to the left of the change. Some product changes might be provided through service and might be available for some prior releases.

SC24-6242-02, z/VM Version 6 Release 2

This edition includes changes to support the general availability of z/VM V6.2.

IPv6 Support for FTP Server and Client

Provide support for IPv6 in the zVM FTP client and server.

The following changes have been made as a result of this support:

- · FTP command.
- · NETRC DATA file.
- · OPEN command.
- PASSIVE command.
- · SENDPORT command.

IPv6 Support for SMTP Server and Client

Provide support for IPv6 in the zVM SMTP client and server.

GSKKYMAN

Added information for FIPS support. See Chapter 7, "SSL Certificate/Key Management and SSL Tracing Information," on page 215.

MPROUTE Enhancements and Upgrade to z/OS 1.12 Equivalency

The following information has changed to support the upgrade of MPROUTE to z/OS 1.12 equivalency.

- The NETSTAT command now includes the ROUTERADV option. See "NETSTAT Command" on page 166 and "ROUTERADV" on page 188.
- The NETSTAT GATE command and the NETSTAT CONFIG HELP command now include new output fields. See "NETSTAT Command" on page 166.

LDAP Enhancements

A new utility, LDAPCHPW (Idapchangepwd) has been added to Chapter 5, "Using the LDAP Client Utilities," on page 123.

Query OSA Address Table

This support provides TCP/IP with the capability to display the content of the OSA Address Table (OAT) via the QDIO interface for both OSA cards and VSWITCH controllers. The NETSTAT command now includes the OSAINFO option.

Support Withdrawal

The z/VM Kerberos servers (VMKERB and ADMSERV) and the z/VM Domain Name System server (NAMESRV) have been removed from TCP/IP for z/VM, Level

© Copyright IBM Corp. 1987, 2011

620. The Kerberos protocol is no longer supported. The Domain Name System (DNS) protocol is still supported using non-z/VM servers.

SC24-6242-01, z/VM Version 6 Release 1 (Updated Edition)

This edition includes changes to support product changes provided or announced after the general availability of z/VM V6.1.

z/VM SSL Server Enhancements

These enhancements improve the SSL server's ability to provide concurrent secure connectivity by increasing its overall performance and decreasing the amount of system resources it requires.

Changes have been made in Chapter 6, "Monitoring the TCP/IP Network," on page

- A new SSL option was added on the NETSTAT IDENTIFY command.
- The NETSTAT CONFIG SSL command has been updated.

Support for IBM zEnterprise System Networks

Networking support for the IBM zEnterprise Unified Resource Manager enhances z/VM's virtual and real networking components to provide integrated management of these resources within an ensemble. z/VM's hypervisor provides the foundation for this management for both the intraensemble data network (IEDN) and the intranode management networks (INMN).

The NETSTAT command includes the new CONTROLLER option, which displays the current VSWITCH CONTROLLER settings. See "NETSTAT Command" on page 166 and "CONTROLLER" on page 186.

The NETSTAT CONFIG HELP output includes the new CONTROLLER option. See "HELP" on page 190.

The NETSTAT DEVLINKS command now returns two additional values in the TYPE field: IEDN (for an intra ensemble data network) and INMN (for an intra node management network). See "DEVLINKS" on page 192.

SC24-6240-00, z/VM Version 6 Release 1

This edition includes changes or additions to support the general availability of z/VM V6.1.

GSKKYMAN and GSKTRACE

Information about the GSKKYMAN and GSKTRACE commands has been moved to this document. See Chapter 7, "SSL Certificate/Key Management and SSL Tracing Information," on page 215.

NSLOOKUP

Enhanced NSLOOKUP documentation.

Chapter 1. Introducing Computer Networks and Protocols

This chapter introduces the concepts of computer networks and an internet environment. The protocols used by TCP/IP are listed by layer and then described. Routing and addressing guidelines are also described.

Computer Networks

A computer network is a group of connected nodes that are used for data communication. A computer network configuration consists of data processing devices, software, and transmission media that are linked for information interchange.

Nodes are the functional units, located at the points of connection among the data circuits. A node, or end point, can be a host computer, a communication controller, a cluster controller, a video display terminal, or another peripheral device.

Computer networks can be local area networks (LANs), which provide direct communication among data stations on the user's local premises, or wide area networks (WANs), which provide communication services to a geographic area larger than that served by a LAN. Typically, WANs operate at a slower rate of speed than LANs.

Different types of networks provide different functions. Network configurations vary, depending on the functions required by the organization. Different organizations implement different types of networks. The technology used by these networks varies not only from organization to organization, but often varies within the same company.

Networks can differ at any or all layers. At the physical layer, networks can run over various network interfaces, such as Ethernet. Networks can also vary in the architectures they use to implement network strategies. Some of the more common architectures used today are Open Systems Interconnection (OSI), Transmission Control Protocol/Internet Protocol (TCP/IP), Systems Network Architecture (SNA), and Integrated Services Digital Network (ISDN). Networks use different protocols (rules) to communicate over the different physical interfaces available. In addition to these differences, networks can use different software packages to implement various functions.

To exchange information among these different networks, the concept of an internet emerged.

Internet Environment

An internet is a logical collection of networks supported by gateways, routers, bridges, hosts, and various layers of protocols. An internet permits different physical networks to function as a single, large, virtual network, and permits dissimilar computers to communicate with each other, regardless of their physical connections. Processes within gateways, routers, and hosts originate and receive packet information. Protocols specify a set of rules and formats required to exchange these packets of information.

Protocols are used to accomplish different tasks in TCP/IP software. To understand TCP/IP, you should be familiar with the following terms and relationships.

© Copyright IBM Corp. 1987, 2011

Introduction

A *client* is a computer or process that requests services on the network. A *server* is a computer or process that responds to a request for service from a client. A user accesses a service, which allows the use of data or some other resource.

A datagram is a basic unit of information, consisting of one or more data packets that are passed across an internet at the transport level.

A gateway is a functional unit that connects two computer networks of different network architectures. A *router* is a device that connects networks at the ISO Network Layer. A router is protocol-dependent and connects only networks operating the same protocol. Routers do more than transmit data; they also select the best transmission paths and optimum sizes for packets. A bridge is a router that connects two or more networks and forwards packets among them. The operations carried out by a bridge are done at the physical layer and are transparent to TCP/IP and TCP/IP routing.

A *host* is a computer, connected to a network, that provides an access point to that network. A host can be a client, a server, or a client and server simultaneously. In a communication network, computers are both the sources and destinations of the packets. The *local host* is the computer to which a user's terminal is directly connected without the use of an internet. A foreign host is any machine on a network that can be interconnected. A remote host is any machine on a network that requires a physical link to interconnect with the network.

An internet address is a unique address identifying each node in an internet. Internet addresses are used to route packets through the network. Currently, there are two versions used for internet addressing: Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6). For more on internet addressing, see "Internet Addressing" on page 13.

Mapping relates internet addresses to physical hardware addresses in the network. For example, in IPv4, the Address Resolution Protocol (ARP) is used to map internet addresses to Ethernet physical hardware addresses. In IPv6, Internet Control Message Protocol Version 6 (ICMPv6) is used to map internet addresses to physical hardware addresses.

A *network* is the combination of two or more nodes and the connecting branches among them. A *physical network* is the hardware that makes up a network. A logical network is the abstract organization overlaid on one or more physical networks. An internet is an example of a logical network.

Packet refers to the unit or block of data of one transaction between a host and its network. A packet usually contains a network header, at least one high-level protocol header, and data blocks. Generally, the format of the data blocks does not affect how packets are handled. Packets are the exchange medium used at the internetwork layer to send and receive data through the network.

A port is an end point for communication between applications, generally referring to a logical connection. A port provides queues for sending and receiving data. Each port has a port number for identification. When the port number is combined with an internet address, a **socket** address results.

Protocol refers to a set of rules for achieving communication on a network.

Internet Protocol Version 4 and Internet Protocol Version 6

Internet Protocol version 4 (IPv4) is the set of protocols that most TCP/IP networks use. A new generation of protocols has been developed called Internet Protocol version 6 (IPv6). IPv4 is now approximately 20 years old and beginning to exhibit problems. The most significant issue surrounding IPv4 is the growing shortage of IPv4 addresses, which are needed by all machines attached to the Internet. IPv4 uses 32-bit addresses. In theory, 32 bits allows over 4 billion nodes, each with a globally-unique address. In practice, the interaction between routing and addressing makes it impossible to exploit more than a small fraction of that many nodes. Consequently, there is a growing concern that the continued growth of the Internet will lead to the exhaustion of IPv4 addresses early in the 21st century.

IPv6 fixes a number of problems in IPv4, such as the limited number of available IPv4 addresses. IPv6 uses 128-bit addresses, an address space large enough to last for the foreseeable future. It also adds many improvements to IPv4 in areas such as routing and network autoconfiguration. IPv6 is expected to gradually replace IPv4, with the two coexisting for a number of years during a transition period.

For general IPv6 information, see ONLamp.com: Introduction to IPv6 (www.onlamp.com/lpt/a//onlamp/2001/05/24/ipv6_tutorial.html).

Also available is a description of IPv6 in *TCP/IP Tutorial and Technical Overview*, GG24-3376, at IBM Redbooks (www.ibm.com/redbooks/).

The TCP/IP for z/VM IPv6 support improves the guest LAN support for the OSA-Express simulation in QDIO mode and for HiperSockets[™] simulation. Virtual machines (z/VM and other guest operating systems) in the guest LAN environment are able to define and to use simulated devices that support both the IPv4 and IPv6 protocols. The IP Assist Simulation for QDIO-based and HiperSockets-base network adapters has been updated to allow virtual machines to detect that their OSA-Express devices support both IPv4 and IPv6 and interact with these devices according to the IP Assists architecture.

The current IPv6 support in TCP/IP for z/VM is at the network (IP) layer. (For more information about TCP/IP functions grouped by layer, see "TCP/IP Protocols and Functions" on page 4.) The TCP/IP for z/VM stack allows routing IPv6 traffic in the guest LAN environment. Operationally, a single TCP/IP for z/VM stack provides support for static routing of IPv6 traffic and provides the existing IPv4 support. The TCP/IP for z/VM stack does not support IPv6 security or IPv6 in the upper application layers, such as FTP, and SMTP. An exception to upper application layer support is Telnet: a telnet client that supports IPv6 can connect to the telnet server in the TCP/IP for z/VM stack.

Additionally, programming interfaces for the sockets library now support IPv6. The support includes updates to the sockets interfaces for the TCP/IP for z/VM stack, the Byte File System, and Language Environment[®]. For more information on the programming interfaces, see:

- z/VM: TCP/IP Programmer's Reference, SC24-6239
- z/VM: OpenExtensions Callable Services Reference, SC24-6203
- XL C/C++ for z/VM: Runtime Library Reference, SC09-7624

TCP/IP for z/VM currently supports the following IPv6-related RFCs:

• RFC 2460, Internet Protocol, Version 6 (IPv6), Specification

The IPv6 specification defines the basic IPv6 header and the IPv6 extension headers and options. The specification also discusses packet size issues, the semantics of flow labels and traffic classes, and the effects of IPv6 on upper-layer protocols.

- RFC 3513, Internet Protocol Version 6 (IPv6) Addressing Architecture
 The IPv6 Addressing Architecture specification defines the addressing architecture of the IPv6 protocol. It includes a detailed description of the currently defined address formats for IPv6.
- RFC 2461, Neighbor Discovery for IP Version 6 (IPv6)

The neighbor discovery specification defines how to do address resolution for neighboring nodes (similar to ARP for IPv4), as well as how to locate neighboring routers (this is called *router discovery*). For IPv4, the OSA-Express adapter provides the offload function of maintaining the ARP cache. For IPv6, the address resolution function of neighbor discovery is not offloaded to the OSA-Express adapter and is implemented in the TCP/IP for z/VM stack.

The TCP/IP for z/VM stack implements both the host and router parts of the neighbor discovery protocol. When configured as a router, router advertisements can be sent to provide autoconfiguration information for other hosts-prefixes, parameters and default routes.

Restriction: The TCP/IP for z/VM stack cannot be configured as a tunnel endpoint for tunneling IPv6 traffic over IPv4 networks.

- RFC 2462, IPv6 Stateless Address Autoconfiguration
 The specification defines the steps a host takes in deciding how to autoconfigure its interfaces in IPv6.
- RFC 2710, Multicast Listener Discovery (MLD) for IPv6
 The specification defines the protocol used by an IPv6 router to discover the presence of multicast listeners (that is, nodes wishing to receive multicast packets) on its directly-attached links, and to discover specifically which multicast addresses are of interest to those neighboring nodes.

Restriction: The TCP/IP for z/VM stack participates in multicast listener discovery performing the host function of registering multicast addresses needed for neighbor discovery. However, the TCP/IP for z/VM stack is not a router of IPv6 multicast traffic (a multicast router).

- RFC 2463, Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification
 - The ICMPv6 specification defines the packet formats and processing rules for ICMP for IPv6.
- RFC 3484, Default Address Selection for Internet Protocol version 6 (IPv6)
 The specification describes two algorithms; one for source address selection and one for destination address selection.

 $\mbox{\bf Restriction:}$ The TCP/IP for z/VM stack uses the source address selection algorithm only.

Copies of these RFCs are available at IP Version 6 Working Group (ipv6) - Charter (datatracker.ietf.org/ipv6/charter/)

TCP/IP Protocols and Functions

This section categorizes the TCP/IP protocols and functions by their functional group link (physical) layer, network layer, transport layer, and application layer). Table 1 on page 5 shows the functional groups and their related protocols and functions.

TCP/IP Protocols and Functions

Table 1. Functional Groups

Group	Protocols and Functions					
Link (physical) layer	Ethernet Others	6				
Network Layer	Internet Protocol (IP) Internet Control Message Protocol (ICMP) Address Resolution Protocol (ARP) Internet Group Management Protocol (IGMP) Internet Protocol version 6 (IPv6) Internet Control Message Protocol Version 6 (ICMPv6) Neighbor Discovery Stateless Address Autoconfiguration Multicast Listener Discovery					
Transport Layer	Transmission Control Protocol (TCP) User Datagram Protocol (UDP)	8				
Application Layer	Telnet File Transfer Protocol (FTP) Internet Message Access Protocol (IMAP) Simple Mail Transfer Protocol (SMTP) Domain Name System (DNS) Simple Network Management Protocol (SNMP) Remote Printing (LPR and LPD) MPRoute X Window System X Toolkit GDDMXD Remote Procedure Call (RPC) Network File System (NFS) Remote Execution Protocol (REXEC) Dynamic Host Configuration Protocol (DHCP) Socket Interfaces Secure Socket Layer (SSL)	9 - 12				

Figure 1 on page 6 shows the relationship of these protocols and functions within the TCP/IP layered architecture for VM.

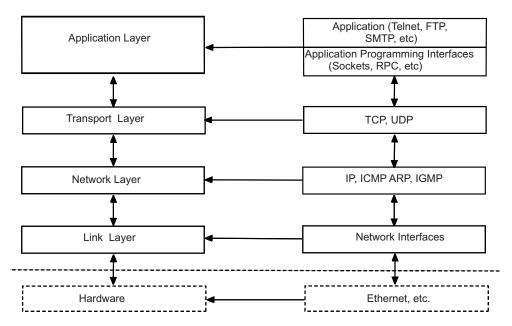

Figure 1. The TCP/IP Layered Architecture

Link Protocols

Various network protocols compose the network layer available in TCP/IP. Network protocols define how data is transported over a physical network. These network protocols are not defined by TCP/IP. After a TCP/IP packet is created, the network protocol adds a transport-dependent network header before the packet is sent out on the network.

Network Protocols

Protocols in the internetwork layer provide connection services for TCP/IP. These protocols connect physical networks and transport protocols. This section describes the internetwork protocols in TCP/IP.

For more information about TCP/IP in general, see RFCs 1118, 1180, 1206, 1207, and 1208. For a list of other related RFCs, see Appendix G, "Related Protocol Specifications."

Internet Protocol (IP)

The Internet Protocol (IP) provides the interface from the transport layer (host-to-host, TCP, or UDP) protocols to the physical-level protocols. IP is the basic transport mechanism for routing IP packets to the next gateway, router, or destination host.

IP provides the means to transmit blocks of data (or packets of bits) from sources to destinations. Sources and destinations are hosts identified by fixed-length internet addresses. Outgoing packets automatically have an IP header prefixed to them, and incoming packets have their IP header removed before being sent to the higher-level protocols. This protocol provides for the universal addressing of hosts in an internet network.

IP does not ensure a reliable communication, because it does not require acknowledgments from the sending host, receiving host, or intermediate hosts. IP

does not provide error control for data; it provides only a header checksum. IP treats each packet as an independent entity unrelated to any other packet. IP does not perform retransmissions or flow control. A higher-level protocol that uses IP must implement its own reliability procedures.

For more information about IP, see RFC 791.

Internet Control Message Protocol (ICMP)

The Internet Control Message Protocol (ICMP) passes control messages between hosts, gateways, and routers. For example, ICMP messages can be sent in any of the following situations:

- When a host checks to see if another host is available (with a PING command)
- When a packet cannot reach its destination
- When a gateway or router can direct a host to send traffic on a shorter route
- When a host requests a netmask or a time stamp
- When a gateway or router does not have the buffering capacity to forward a packet

ICMP provides feedback about problems in the communication environment; it does not make IP reliable. ICMP does not guarantee that an IP packet is delivered reliably or that an ICMP message is returned to the source host when an IP packet is not delivered or is incorrectly delivered.

For more information about ICMP, see RFC 792.

Address Resolution Protocol (ARP)

The Address Resolution Protocol (ARP) maps internet addresses to hardware addresses. TCP/IP uses ARP to collect and distribute the information for mapping tables.

ARP is not directly available to users or applications. When an application sends an internet packet, IP requests the appropriate address mapping. If the mapping is not in the mapping table, an ARP broadcast packet is sent to all the hosts on the network requesting the physical hardware address for the host.

For more information about ARP, see RFC 826.

Internet Group Management Protocol (IGMP)

The Internet Group Management Protocol (IGMP) is used to communicate multicast group information. It lets all systems on a physical network know which hosts belong to which multicast groups. Multicast routers use IGMP messages to determine which multicast datagrams to forward onto which interfaces.

There are two types of IGMP messages — reports and gueries. IGMP report messages are sent out to notify others when a multicast group has been joined, and to respond to an IGMP query that was received. IGMP query messages are sent out by multicast routers to see which multicast groups still have members.

For more information about IGMP, see RFC 1112.

Internet Control Message Protocol Version 6 (ICMPv6)

In addition to the functions carried out by ICMP for IPv4, ICMPv6 conveys multicast group membership information, a function previously performed by IGMP, and address resolution, a function previously performed by ARP.

TCP/IP Protocols and Functions

For more information about ICMPv6, see RFC 2463.

Neighbor Discovery

Neighbor discovery is an ICMPv6 function that enables a node to identify other hosts and routers on its links. The node needs to know at least one router in order to forward packets to a target node not on its local link. Neighbor discovery also allows a router to tell a node to use a more appropriate router if that node has initially made an incorrect choice.

For more information on neighbor discovery, see RFC 2461.

Stateless Address Autoconfiguration

Although the 128-bit address field of IPv6 solves a number of problems inherent in IPv4, the size of the IPv6 address space represents a potential problem to the TCP/IP administrator. Due to this potential problem, IPv6 has the capability, through stateless address autoconfiguration, to assign an address to an interface automatically at initialization time, with minimal or no action by the TCP/IP administrator.

For more information on stateless address autoconfiguration, see RFC 2462.

Multicast Listener Discovery

Multicast listener discovery (MLD) is a process used by a router to discover the members of a multicast group. MLD is a subset of ICMPv6 and provides the equivalent function in IGMP for IPv4. Through MLD, information is provided by the router to whichever multicast routing protocol is being used, so that multicast packets are correctly delivered to all links where there are nodes listening for the appropriate multicast address.

For more information on multicast listener discovery, see RFC 2710.

Transport Protocols

The transport layer of TCP/IP consists of transport protocols, which allow communication between application programs. This section describes the transport protocols in TCP/IP.

Transmission Control Protocol (TCP)

The Transmission Control Protocol (TCP) provides a reliable vehicle for delivering packets between hosts on an internet. TCP takes a stream of data, breaks it into datagrams, sends each one individually using IP, and reassembles the datagrams at the destination node. If any datagrams are lost or damaged during transmission, TCP detects this and resends the missing datagrams. The received data stream is a reliable copy of the transmitted data stream.

For more information about TCP, see RFC 793.

User Datagram Protocol (UDP)

The User Datagram Protocol (UDP) provides an unreliable mode of communication between source and destination hosts. UDP is a datagram-level protocol built directly on the IP layer. UDP is used for application-to-application programs between TCP/IP hosts.

Like IP, UDP does not offer a guarantee of datagram delivery or duplication protection. UDP does provide checksums for both the header and data portions of a datagram. However, applications that require reliable delivery of streams of data should use TCP.

For more information about UDP, see RFC 768.

Applications and Protocols

Applications are provided with TCP/IP that allow users to use network services. These applications are included in the application layer of TCP/IP. The application layer is built on the services of the transport layer. This section describes the applications, functions, and protocols in TCP/IP.

Telnet Protocol

The Telnet Protocol provides a standard method to interface terminal devices and terminal-oriented processes with each other. Telnet is built on the services of TCP in the transport layer. Telnet provides duplex communication and sends data either as ASCII characters or as binary data.

Telnet is commonly used to establish a logon session on a foreign host. Telnet can also be used for terminal-to-terminal communication and interprocess communication.

For more information about the Telnet Protocol, see RFCs 854, 856, 857, 885, and 1091.

File Transfer Protocol (FTP)

The File Transfer Protocol (FTP) allows you to transfer data between local and foreign hosts or between two foreign hosts. FTP is built on the services of TCP in the transport layer. FTP transfers files as either ASCII characters or as binary data. ASCII characters are used to transfer files that contain only text characters.

FTP provides functions, such as listing remote directories, changing the current remote directory, creating and removing remote directories, and transferring one or more files in a single request. Security is handled by passing user and account passwords to the foreign hosts.

For more information about FTP, see RFC 959.

Internet Message Access Protocol (IMAP)

The Internet Message Access Protocol (IMAP) is a mail protocol with both client (sender) and server (receiver) functions.

IMAP provides the processing that allows a client to access electronic mail that is kept in an IMAP Mailstore server. It permits a "client" email program to access remote message folders called "mailboxes", as if they were local.

For more information about IMAP, see RFC 2060.

Simple Mail Transfer Protocol (SMTP)

The Simple Mail Transfer Protocol (SMTP) is an electronic mail protocol with both client (sender) and server (receiver) functions.

SMTP is implemented with the CMS NOTE and CMS SENDFILE EXECs in a VM environment. You do not interface directly with SMTP. Instead, electronic mail software is used to create mail, which in turn uses SMTP to send the mail to its destination.

For more information about SMTP, see RFCs 821, 822, 974, 1413, and 1440.

Domain Name System (DNS)

The Domain Name System (DNS) uses a hierarchical-naming system for naming hosts. Each host name is composed of domain labels separated by periods. Local network administrators have the authority to name local domains within an internet. Each label represents an increasingly higher domain level within an internet. The fully qualified domain name of a host connected to one of the larger internets generally has one or more subdomains.

For example:

host.subdomain.subdomain.rootdomain
or
host.subdomain.rootdomain

For more information about the Domain Name System, see RFCs 1034 and 1035.

Simple Network Management Protocol (SNMP)

The Simple Network Management Protocol (SNMP) provides a means for managing an internet environment. SNMP allows network management by elements, such as gateways, routers, and hosts. Network elements act as servers and contain management agents, which perform the management functions requested. Network management stations act as clients; they run the management applications, which monitor the network. SNMP provides a means of communicating between these elements and stations to send and receive information about network resources.

For more information about Network Management, see RFCs 1155, 1157, 1187, and 1213.

Remote Printing (LPR and LPD)

TCP/IP provides both client and server support for remote printing. This application allows you to spool files remotely to a line printer daemon (LPD). The line printer client (LPR) sends the file to be printed to a specified print server host and to a specified printer.

For more information about LPR and LPD, see RFC 1179.

MPRoute

MPRoute uses the Routing Information Protocol (RIP) and Open Shortest Path First (OSPF) protocol to create and maintain network routing tables dynamically. RIP and OSPF arrange to have gateways and routers periodically broadcast their routing tables to neighbors. Using this information, an MPRoute server can update a host's routing tables. For example, MPRoute determines if a new route has been created, if a route is temporarily unavailable, or if a more efficient route exists.

For more information about RIP, see RFCs 1058 and 1723. For more information about OSPF, see RFC 1583.

X Window System

The X Window System Protocol is designed to support network transparent windowing and graphics. TCP/IP for z/VM provides client support for the X Window System application program interface.

For more information about the X Window System Protocol, see RFC 1013.

X Toolkit

X toolkit is a collection of basic C language routines for developing a variety of application environments.

Intrinsics: Intrinsics are a collection of C language routines for building and using widgets.

Widgets: Widgets are a set of routines that create a graphic interface.

· Athena Widgets

The widget set developed by MIT's Project Athena is generally known as the Athena Widget set. It enables application programmers to include standard graphic elements in their applications.

OSF/Motif

OSF/Motif** is an X Window System toolkit defined by Open Software Foundation, Inc. (OSF**), which enables the application programmer to include standard graphic elements that have a three-dimensional appearance. Performance of the graphic elements is increased with gadgets and windowless widgets.

GDDMXD

GDDMXD is an interface that allows graphics from the IBM Graphical Data Display Manager/VM to be displayed on workstations that support the X Window System.

When GDDMXD is installed and activated, the data stream created by GDDM® is translated to the X Window System protocol and transmitted by TCP/IP to the X Window System server for the display. If GDDMXD is installed and not activated, or has been made inactive, GDDM transmits data to its supported display device as if GDDMXD was not present.

Remote Procedure Call (RPC)

The Remote Procedure Call Protocol (RPC) is a programming interface that calls subroutines to be executed on a foreign host. RPCs are high-level program calls, which can be used in place of the lower-level calls that are based on sockets.

For more information about RPC, see RFC 1057.

Network File System (NFS)

The Network File System (NFS) allows you to manipulate files on different TCP/IP hosts as if they reside on your host. NFS is based on the NFS protocol, and uses the Remote Procedure Call (RPC) protocol to communicate between the client and the server. The files to be accessed reside on the server host and are made available to the user on the client host.

The Network File System supports the hierarchical file structure used by the UNIX operating system. The directory and subdirectory structure can be different for individual client systems.

For more information about NFS, see RFC 1094 and 1813.

Remote Execution Protocol (REXEC)

The Remote Execution Protocol (REXEC) allows you to execute a command on a foreign host and receive the results on the local host. Remote Execution Protocol provides automatic logon and user authentication, depending on the parameters set by the user.

Dynamic Host Configuration Protocol (DHCP)

The Dynamic Host Configuration Protocol (DHCP) provides a framework for passing configuration information to hosts on a TCPIP network. DHCP is based on the Bootstrap Protocol (BootP), adding the capability of automatic allocation of reusable

TCP/IP Protocols and Functions

network addresses and additional configuration options. DHCP captures the behavior of BootP relay agents; DHCP participants can interoperate with BootP participants.

For more information about DHCP, see RFC 2131 and z/VM: TCP/IP Planning and Customization.

Socket Interfaces

Socket interfaces allow you to write your own applications to supplement those supplied by TCP/IP. Most of these additional applications communicate with either TCP or UDP. Some applications are written to communicate directly with IP. To write applications that use the socket interfaces of TCP/IP for z/VM, you must be able to compile and link the programs.

Sockets are duplex, which means that data can be transmitted and received simultaneously. Sockets allow you to send to, and receive from, the socket as if you are writing to and reading from any other network device. For more information on sockets, see z/VM: TCP/IP Programmer's Reference.

Secure Socket Layer (SSL)

The Secure Socket Layer (SSL) protocol provides privacy between two communicating applications — a client and a server. In SSL, a server is always authenticated and must provide a certificate to prove its identity. In addition to authentication, both the client and the server participate in a handshake protocol that produces the cryptographic parameters for the session.

The processing required for SSL is provided by a TCP/IP security server. An installation identifies the ports that are secure and specifies the certificates to be used. Any VM TCP/IP server listening on a secure port can participate in an SSL session with any external client that supports SSL. The SSL session consists of two connections — the connection from the remote client to the security server and the connection from the security server to the real (application) server.

For more information about configuring the SSL Server, see z/VM: TCP/IP Planning and Customization. For information about managing SSL certificates and obtaining SSL diagnostic information, see Chapter 7, "SSL Certificate/Key Management and SSL Tracing Information," on page 215.

Routing

The routing functions in an internet are performed at the network layer. Routing is the process of deciding where to send a packet based on its destination address. Two kinds of routing are involved in communication within an internet: direct and indirect.

Direct routing is used when the source and destination nodes are on the same logical network within an internet. The source node maps the destination internet address into a hardware address and sends packets to the destination node through this address. This mapping is normally performed through a translation table. If a match cannot be found for a destination internet address, ARP in IPV4 or neighbor discovery in IPv6 is invoked to determine this address.

Indirect routing is used when the source and destination nodes are on different networks within an internet. The source node sends packets to a gateway or router on the same network using direct routing. From there, the packets are forwarded through intermediate gateways or routers, as required, until they arrive at the

destination network. Direct routing is then used to forward the packets to the destination host on that network. Each gateway, router, and host in an internet has a routing table that defines the address of the next gateway or router to other networks (as well as other nodes on other networks) in an internet.

Internet Addressing

Each internet host is assigned at least one unique internet address. This address is used by the IP and other higher-level protocols. When gateway hosts are used, more than one address may be required. Each interface to an internet is assigned its own unique address. Internet addresses are used to route packets through the network.

Internet addressing differs between IPv4 and IPv6. The next topic covers IPv4 addressing, followed by a topic on IPv6 addressing.

IPv4 Addressing

Addresses within an internet consist of a network number and a local address. The unique network number is assigned to each network when it connects to another internet. If a local network is not going to connect to other internets, any convenient network number is assigned.

Hosts that exchange packets on the same physical network should have the same network number. Hosts on different physical networks might also have the same network number. If hosts have the same network number, part of the local address is used as a subnetwork number. All host interfaces to the same physical network are given the same subnetwork number.

An internet can provide standards for assigning addresses to networks, broadcasts, and subnetworks. Examples of these standard formats are described in the following sections.

Network Address Format

A standard internet address uses a two-part, 32-bit address field. The first part of the address field contains the network address; the second part contains the local address. The four different types of address fields are classified as A, B, C, or D, depending on the bit allocation.

Figure 2 represents a class A address. A class A address has a 7-bit network number and a 24-bit local address. The highest order bit is set to 0.

0	1234567	1 2 3 890123456789012345678901
0	Network	Local Address

Figure 2. Class A Address

Figure 3 on page 14 represents a class B address. A class B address has a 14-bit network number and a 16-bit local address with the highest order bits set to 10.

0 1	1 23456789012345	2 6789012345678901
1 0	Network	Local Address

Figure 3. Class B Address

Figure 4 represents a class C address. A class C address has a 21-bit network number and an 8-bit local address with the three highest order bits set to 110.

012	1 345678901234567890123	45678901
110	Network	Local Address

Figure 4. Class C Address

Figure 5 represents a class D address. A class D network is a multicast address that is sent to selected hosts on the network. The four highest order bits are set to 1110.

Figure 5. Class D Address

Note: Class D addresses are not supported in TCP/IP for z/VM.

A commonly used notation for internet host addresses is the dotted-decimal, which divides the 32-bit address into four 8-bit fields. The value of each field is specified as a decimal number, and the fields are separated by periods (for example, 010.002.000.052 or 10.2.0.52).

Address examples in this book use dotted-decimal notation in the following forms:

Class A nnn.lll.lll.lll Class B nnn.nnn.lll.lll Class C nnn.nnn.nnn.lll

where:

nnn Represents part or all of a network number. IIIRepresents part or all of a local address.

Broadcast Address Format

TCP/IP uses IP broadcasting to send datagrams to all the TCP/IP hosts on a network or subnetwork. A datagram sent to the broadcast address is received by all the hosts on the network and processed as if the datagram was sent directly to the host's IP address. The IP broadcast address is formed by setting all the host bits to ones.

For more information about IP broadcasting, see RFCs 919 and 922.

Multicast Address Format

TCP/IP uses IP multicasting to send datagrams to all the TCP/IP hosts on a network or subnetwork. The multicast datagrams are only received by those TCP/IP hosts that have signed up to listen for the particular IP multicast address (joined the multicast group). If a TCP/IP host has not joined the multicast group, then the datagram is discarded.

For more information on IP multicasting, see RFC 1112.

Subnetwork Address Format

The subnetwork capability of TCP/IP divides a single network into multiple logical networks (subnets). For example, an organization can have a single internet network address that is known to users outside the organization, yet configure its internal network into different departmental subnets. Subnetwork addresses enhance local routing capabilities, while reducing the number of network numbers required. For a subnet, the local address part of an internet address is divided into a subnet number and a host number, for example:

network_number subnet_number host_number

where:

network number Is the network portion of the internet address. Is a field of a constant width for a given network. subnet_number host number Is a field that is at least 1-bit wide.

If the width of the *subnet number* field is 0, the network is not organized into subnets, and addressing to the network is done with an internet network address (network number).

Figure 6 represents a class B address with a 6-bit wide subnet field.

0 1	1 23456789012345	2 678901	2345678901
1 0	Network	Subnet	Host

Figure 6. Class B Address with Subnet

The bits that identify the subnet are specified by a bit mask. A bit mask is a pattern of characters used to assign subnet addresses. The subnet bits are not required to be adjacent in the address. However, the subnet bits generally are contiguous and are the most significant bits of the local address.

For more information about subnetwork addresses, see RFC 950.

IPv6 Addressing

One problem that IPv6 solves is the limited number of addresses available in IPv4. IPv6 uses a 128-bit address space, which has no practical limit on global addressibility and provides 340 282 366 920 938 463 463 374 607 431 768 211 456 addresses. Currently, this is enough addresses so that every person can have a single IPv6 network with as many as 18 000 000 000 000 000 000 nodes on it, and still the address space would be almost completely unused.

There are three conventional forms for representing IPv6 addresses as text strings:

 The preferred form is x:x:x:x:x:x:x:x, where the x's are the hexadecimal values of the eight 16-bit pieces of the address.

Examples:

```
FE80:0000:0000:0000:0001:0800:23e7:f5db
1080:0:0:0:8:800:200C:417A
```

It is not necessary to write the leading zeros in an individual field, but there must be at least one numeral in every field (except for the case described in the following bullet).

Due to some methods of allocating certain styles of IPv6 addresses, it will be common for addresses to contain long strings of zero bits. In order to make writing addresses containing zero bits easier, a special syntax is available to compress the zeros. The use of :: indicates multiple groups of 16 bits of zeros. The :: can only appear once in an address. The :: can also be used to compress both leading and trailing zeros in an address.

Examples: The following are preferred form addresses:

```
1080:0:0:0:8:800:200C:417A a unicast address
FF01:0:0:0:0:0:0:101 a multicast address
0:0:0:0:0:0:0:1
                        the loopback address
                    the unspecified addresses
0:0:0:0:0:0:0:0
```

The corresponding compressed forms are:

```
1080::8:800:200C:417A
                            a unicast address
FF01::101
                            a multicast address
::1
                            the loopback address
                            the unspecified addresses
::
```

An alternative form that is sometimes more convenient when dealing with a mixed environment of IPv4 and IPv6 nodes is x:x:x:x:x:d.d.d.d., where the x's are the hexadecimal values of the 6 high-order 16-bit pieces of the address, and the d's are the decimal values of the 4 low-order 8-bit pieces of the address (standard IPv4 representation). This form is used for IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. These types of addresses are used to hold embedded IPv4 addresses in order to carry IPv6 packets over the IPv4 routing infrastructure.

Examples:

```
0:0:0:0:0:0:13.1.68.3
0:0:0:0:0:FFFF:129.144.52.38
The same addresses in compressed form are:
::13.1.68.3
::FFFF:129.144.52.38
```

Hierarchical Addressing and Routing Infrastructure

As important as the expanded address space is the use of hierarchical address formats. The IPv4 addressing hierarchy includes network, subnet, and host components in an IPv4 address. IPv6, with its 128-bit addresses, provides globally unique and hierarchical addressing based on prefixes rather than address classes, which keeps routing tables small and backbone routing efficient.

The general format is as follows:

global routing prefix	subnet ID	interface ID
n bits	m bits	128-(n+m) bits

Figure 7. IPv6 Address Format

The global routing prefix is a value (typically hierarchically structured) assigned to a site; the subnet ID is an identifier of a link within the site; and the interface ID is a unique identifier for a network device on a given link (usually automatically assigned).

When configured for unicast routing, the TCP/IP for z/VM stack may also be configured to provide autoconfiguration information for other hosts-prefixes, parameters, and default routes, as specified in the *RFC 2461, Neighbor Discovery for IP Version 6 (IPv6)*.

Textual representation of IPv6 prefixes

The text representation of IPv6 address prefixes is similar to the way IPv4 address prefixes are written in Classless Inter-Domain Routing (CIDR) notation. An IPv6 address prefix is represented by the notation:

ipv6-address/prefix-length

Where:

ipv6-address

Is an IPv6 address in any of the notations listed above.

prefix-length

Is a decimal value specifying how many of the leftmost contiguous bits of the address comprise the prefix.

Example: The following are legal representations of the 60-bit prefix 12AB0000000CD3 (hexadecimal):

12AB:0000:0000:CD30:0000:0000:0000:0000/60

12AB::CD30:0:0:0:0/60 12AB:0:0:CD30::/60

When writing both a node address and a prefix of that node address (for example, the node's subnet prefix), the two can be combined as follows:

node address: 12AB:0:0:CD30:123:4567:89AB:CDEF

its subnet number: 12AB:0:0:CD30::/60

combination: 12AB:0:0:CD30:123:4567:89AB:CDEF/60

Types and Categories of IPv6 Addresses

The type of a IPv6 address is identified by the high-order bits of the address, as follows:

Table 2. Types of IPv6 Addresses

Address type	Binary prefix	IPv6 notation
Unspecified	00 0 (128 bits)	::/128
Loopback	00 1 (128 bits)	::1/128
Multicast	11111111	FF00::/8
Link-local unicast	1111111010	FE80::/10
Site-local unicast	1111111011	FEC0::/10
Global unicast	(everything else)	

Three categories of IP addresses are supported in IPv6:

Unicast

An identifier for a single interface. A packet sent to a unicast address is delivered to the interface identified by that address. It can be link-local scope, site-local scope, or global scope.

Multicast

An identifier for a group of interfaces (typically belonging to different nodes). A packet sent to a multicast address is delivered to all interfaces identified by that address.

Anycast

An identifier for a group of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to the closest member of a group, according to the routing protocols' measure of distance.

Anycast addresses are taken from the unicast address spaces (of any scope) and are not syntactically distinguishable from unicast addresses. Anycast is described as a cross between unicast and multicast. Like multicast, multiple nodes may be listening on an anycast address. Like unicast, a packet sent to an anycast address will be delivered to one (and only one) of those nodes. The exact node to which it is delivered is based on the IP routing tables in the network.

There are no broadcast addresses in IPv6. Multicast addresses have superseded this function.

Unicast IPv6 Addresses: IPv6 unicast addresses can be aggregated with prefixes of arbitrary bit-length similar to IPv4 addresses under Classless Interdomain Routing (CIDR).

A unicast address has the following format:

n bits	128-n bits
network prefix	interface ID

Figure 8. Unicast Address Format

There are several types of unicast addresses in IPv6: global unicast, site-local unicast, and link-local unicast. There are also some special-purpose subtypes of global unicast, such as IPv6 addresses with embedded IPv4 addresses. Additional address types or subtypes can be defined in the future.

Global Unicast Addresses: The general format for IPv6 global unicast addresses is:

n bits	m bits	128-n-m bits
global routing prefix	subnet ID	interface ID

Figure 9. Global Unicast Address Format

The global routing prefix is a (typically hierarchically-structured) value assigned to a site (a cluster of subnets/links). The subnet ID is an identifier of a link within the site. The interface ID is used to identify an interface on a link; interface IDs are required to be unique within a subnet prefix.

All global unicast addresses other than those that start with B'000' have a 64-bit interface ID field (that is, n + m = 64). Global unicast addresses that start with B'000' have no such constraint on the size or structure of the interface ID field.

Examples of global unicast addresses that start with B'000' are IPv6 address with embedded IPv4 addresses. These include IPv4-mapped IPv6 addresses and IPv4-compatible IPv6 addresses.

Local Use Address: There are two types of local-use unicast addresses defined: link-local and site-local. The link-local address is for use on a single link and the site-local address is for use in a single site.

Link-local Addresses: Link-local addresses have the following format:

10 bits	54 bits	64 bits
1111111010	0	interface ID

Figure 10. Link-local address format

A link-local address is required on each physical interface. Link-local addresses are designed to be used for addressing on a single link for purposes such as automatic address configuration, neighbor discovery, or in the absence of routers. It also may be used to communicate with other nodes on the same link. A link-local address is automatically assigned.

Routers will not forward any packets with link-local source or destination addresses to other links.

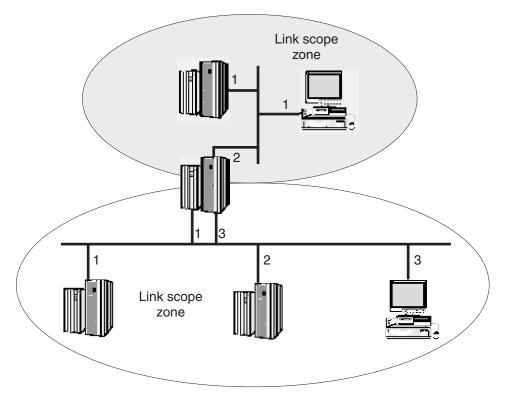

Figure 11. Link-local scope zones

Figure 11 on page 19 depicts two separate link-local scope zones. More than one interface may be connected to the same link for fault tolerance or extra bandwidth. Some nodes may allow the same link-local zone index to be assigned to each interface connected to the same physical link, while others may assign a unique link-local zone index to each interface even when more than one interface is connected to the same physical link. The TCP/IP for z/VM server assigns a unique link-local address to each physical interface.

Site-local Addresses: Site-local addresses have the following format:

10 bits	38 bits	16 bits	64 bits
1111111011	0	subnet ID	interface ID

Figure 12. Site-local address format

Site-local addresses are designed to be used for addressing inside of a site without the need for a global prefix. A site-local address cannot be reached from another site. A site-local address is not automatically assigned to a node. It must be assigned using automatic or manual configuration.

Routers will not forward any packets with site-local source or destination addresses outside of the site.

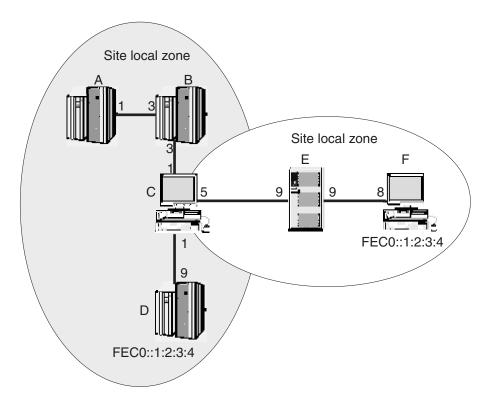

Figure 13. Site-local scope zones

Nodes connected to the same site-local scope zone may communicate with each other using site-local addresses. However, nodes which are not connected to the same site-local scope zone may not communicate using site-local addresses but must instead use global addresses.

Figure 13 on page 20 depicts two site-local scope zones. In this configuration, node A can communicate with node D using site-local addresses since they are both within the same site-local scope zone. However, node A cannot communicate with node F using site-local addresses because the two nodes are not connected to the same site-local scope zone. Instead, node A must use global addresses when communicating with node F. Since node C is connected to both site-local scope zones, it may use the appropriate site-local address when communicating with both node A and node F.

The TCP/IP for z/VM server supports connecting to a single site-local scope zone and cannot be connected to two or more site-local scope zones at the same time. For example, the TCP/IP for z/VM server could be either node A or node F in Figure 13 on page 20, as both are connected to only a single site-local scope zone, but could not be node C, as node C is connected to two site-local scope zones.

Loopback Address: The unicast address 0:0:0:0:0:0:0:0:0:0:0:1 is called the loopback address. It cannot be assigned to any physical interface. It may be thought of as a link-local unicast address assigned to a virtual interface (typically called the loopback interface) that allows local applications to send messages to each other.

The loopback address cannot be used as the source address in IPv6 packets that are sent outside of a node. An IPv6 packet with a destination address of loopback cannot be sent outside of a node and be forwarded by an IPv6 router. A packet received on an interface with destination address of loopback will be dropped.

Unspecified Address: The address 0:0:0:0:0:0:0:0 is called the unspecified address. It will not be assigned to any node. It indicates the absence of an address. One example of its use is in the Source Address field of any IPv6 packets sent by an initializing host before it has learned its own address.

The unspecified address cannot be used as the destination address of IPv6 packets or in IPv6 routing headers. An IPv6 packet with a source address of unspecified cannot be forwarded by an IPv6 router.

IPv4-mapped IPv6 Addresses: These addresses hold an embedded global IPv4 address. They are used to represent the addresses of IPv4 nodes as IPv6 addresses to applications that are enabled for IPv6 and are using AF_INET6 sockets. This allows IPv6 enabled applications always to deal with IP addresses in IPv6 format regardless of whether the TCP/IP communications are occurring over IPv4 or IPv6 networks. The dual-mode TCP/IP stack performs the transformation of the IPv4-mapped addresses to and from native IPv4 format. IPv4-mapped addresses have the following format:

80 bits	16	32 bits
00000000	FFFF	IPv4 address

Figure 14. IPv4-mapped IPv6 address

Examples:

· In IPv6-IPv4 decimal form:

::FFFF:129.144.52.38

In IPv6-compressed form

::FFFF:8190:3426

IPv4-compatible IPv6 Addresses: These addresses hold an embedded global IPv4 address. They are used dynamically to tunnel IPv6 packets over IPv4 networks. IPv6 nodes that use this technique are assigned special IPv6 unicast addresses which hold an IPv4 address in the low-order 32-bits. IPv4-compatible IPv6 addresses have the following format:

80 bits	16	32 bits
00000000	0000	IPv4 address

Figure 15. IPv4-compatible IPv6 address

Examples:

- In IPv6-IPv4 decimal form
 - ::129.144.52.38
- In IPv6-compressed form
 - ::8190:3426

Multicast IPv6 Addresses: An IPv6 multicast address is an identifier for a group of interfaces (typically on different nodes). It is identified with a prefix of 11111111 or FF in hexadecimal notation. It provides a way of sending packets to multiple destinations. An interface may belong to any number of multicast groups.

Multicast address format: Binary 11111111 at the start of the address identifies the address as being a multicast address. Multicast addresses have the following format:

8	4	4	112 bits
111111	11 flags	gs scope	group ID

Figure 16. Multicast address format

| 0 | 0 | 0 | T |

Figure 17. Flags in multicast address

- The 3 high-order flags are reserved, and must be initialized to 0.
- T = 0 indicates a permanently-assigned (well-known) multicast address, assigned by the Internet Assigned Number Authority (IANA).
- T = 1 indicates a non-permanently assigned (transient) multicast address.

Scope is a 4-bit multicast scope value used to limit the scope of the multicast group. Group ID identifies the multicast group, either permanent or transient, within the given scope.

Multicast scope: The scope field indicates the scope of the IPv6 internetwork for which the multicast traffic is intended. The size of this field is 4 bits. In addition to information provided by multicast routing protocols, routers use multicast scope to determine whether multicast traffic can be forwarded. For multicast addresses there are 14 possible scopes (some are still unassigned), ranging from interface-local to global (including both link-local and site-local).

The following table lists the defined values for the scope field:

Table 3. Multicast scope field values

Value	Scope
0	Reserved
1	Interface-local scope (same node)
2	Link-local scope (same link)
3	Subnet-local scope
4	Admin-local scope
5	Site-local scope (same site)
8	Organization-local scope
E	Global scope
F	Reserved
All other scope field values	s are currently undefined.

For example, traffic with the multicast address of FF02::2 has a link-local scope. An IPv6 router never forwards this type of traffic beyond the local link.

Interface-local

The interface-local scope spans a single interface only. A multicast address of interface-local scope is useful only for loopback delivery of multicasts within a node, for example, as a form of interprocess communication within a computer. Unlike the unicast loopback address, interface-local multicast addresses may be joined on any interface.

Link-local

Link-local addresses are used by nodes when communicating with neighboring nodes on the same link. The scope of the link-local address is the local link.

Subnet-local

Subnet-local scope is given a different and larger value than link-local to enable possible support for subnets that span multiple links.

Admin-local

Admin-local scope is the smallest scope that must be administratively configured, that is, not automatically derived from physical connectivity or other, non-multicast-related configuration.

Site-local

The scope of a site-local address is the site or organization internetwork. Addresses must remain within their scope. A router must not forward packets outside of its scope.

Organization-local

This scope is intended to span multiple sites belonging to a single organization.

Global

Global scope is used for uniquely identifying interfaces anywhere in the Internet.

Multicast groups: Group ID identifies the multicast group, either permanent or transient, within the given scope. The size of this field is 112 bits. Permanently assigned groups can use the group ID with any scope value and still refer to the same group. Transient assigned groups can use the group ID in different scopes to refer to different groups. Multicast addresses from FF01:: through FF0F:: are reserved, well-known addresses. Use of these group IDs for any other scope values, with the T flag equal to 0, is not allowed.

All-nodes multicast groups: These groups identify all IPv6 nodes within a given scope. Defined groups include:

- Interface-local all-nodes group (FF01::1)
- Link-local all-nodes group (FF02::1)

All-routers multicast groups: These groups identify all IPv6 routers within a given scope. Defined groups include:

- Interface-local all-routers group (FF01::2)
- Link-local all-routers group (FF02::2)
- Site-local all-routers group (FF05::2)

Solicited-node multicast group: For each unicast address which is assigned to an interface, the associated solicited-node multicast group is joined on that interface. The solicited-node multicast address facilitates the efficient guerying of network nodes during address resolution.

Anycast IPv6 Addresses: An IPv6 anycast address is an identifier for a set of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to one of the interfaces identified by that address (the nearest interface), according to the routing protocols' measure of distance. It uses the same formats as a unicast address, so one cannot differentiate between a unicast and an anycast address simply by examining the address. Instead, anycast addresses are defined administratively.

For more information about IPv6 addressing, see RFC 3513, Internet Protocol Version 6 (IPv6) Addressing Architecture.

Chapter 2. Transferring Files Using FTP

This chapter describes how to use the File Transfer Protocol (FTP) command and its subcommands to transfer files between your local host and a foreign TCP/IP host. The FTP command and its subcommands, allow you to sequentially access multiple foreign hosts without leaving the FTP environment.

When FTP commands are used with a non-z/VM foreign host, you may need to consult documentation specific to that host and its operating system for information about file naming and supported FTP commands and parameters.

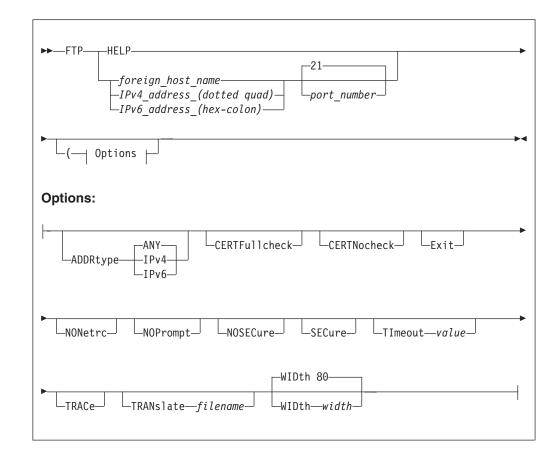

The following table lists general operations and FTP subcommands that correspond to these functions:

Table 4. FTP and Subcommand Functions

FUNCTION	SUBCOMMANDS		
Establish a connection and identify yourself to a foreign host's FTP server	ACCT OPEN USER	NETRC PASS	
Obtain status information about FTP on the foreign host	DEBUG NOOP SYSTEM	STATUS	
List or work with directories belonging to the foreign host	CD or CWD CDUP LS	DIR MKDIR RMDIR PWD	
List or work with directories on the local host	LCD	LPWD	
Prepare the environment prior to transferring files	HANGEUL JIS78KJ KSC5601 TCHINESE	EUCKANJI IBMKANJI JIS83KJ LOCSITE SIZE SJISKANJI SUNIQUE TYPE	
Transfer Parameter Commands	ASCII EBCDIC BINARY MODE PORT PASSIVE	SENDPORT SENDSITE STRUCT	
Perform Special Function	QUOTE	SITE	
Work with and transfer files to and from the foreign host	APPEND GET PUT	DELIMIT MGET MPUT	
Delete or rename files on the foreign host	DELETE RENAME	MDELETE	
Communicate with the underlying operating systems	CMS		
Obtain help about FTP and its subcommands	HELP

FTP Command

Purpose

Т

Use the FTP command to establish an environment, or shell, that allows you to transfer files between your local host and a foreign TCP/IP host.

Once an FTP connection has been established with a foreign host, the various subcommands listed in Table 5 on page 39 can be used to transfer files and interact with the remote FTP server.

Operands

```
foreign_host_name
The name of the foreign host to which you are connecting. Specify
foreign_host_name using an internet host name or an internet address. You are
prompted for a host name if this operand is omitted when the FTP command is
issued.

IPv4 addres (dotted auad)
```

```
IPv4_addres_(dotted quad)
    "Old" style IP address in dotted quad notation. For example, "123.45.67.89".

IPv6_address_(hex-colon)
    "New" style IP address in hex-colon notation. For example,
    "1234:5678::ABCD:EF09".

port_number
    the port number of the FTP server on the foreign host. The default is port 21,
    which is considered to be a "well-known" port.
```

Options

1

I

Ι

ADDRtype

ANY

Any target host address allowed.

IPv4

Target host address must be in AF INET (IPv4) address family.

IPv6

Target host address must be in AF_INET6 (IPv6) address family.

CERTFULLCHECK

The remote server certificate and any associated CA certificates are verified for correctness, for control and data connections. If a certificate error is detected, the corresponding connection fails.

A self-signed certificate cannot be used for secure connections unless it has been added to the local certificate database. For more information, see Using Self-Signed Certificates in *z/VM: TCP/IP Planning and Customization*.

CERTNOCHECK

The CERTNOCHECK option is accepted and ignored. All connections are handled as described for the CERTFULLCHECK operand.

Exit

Causes FTP to terminate when an error condition is encountered. Error conditions associated with FTP subcommands will also cause FTP to terminate when this operand is used. For more information about FTP return codes, see "FTP Return Codes" on page 99.

NOSECure

Causes the FTP client not to attempt to secure data and control connections using TLS. The NOSECURE option overrides FTP DATA SECURECONTROL and SECUREDATA statement value of YES. This setting may be overridden while in the FTP session by using the CPROTECT and PRIVATE subcommands.

NONetrc

Suppresses use of the NETRC DATA file. See "The NETRC DATA File" on page 30 for more information.

NOPrompt

Suppresses prompts for the logon user name and password. Use this option when a NETRC DATA file is used and command input is to be obtained through non-interactive means, such as from an exec. See "The NETRC DATA File" on page 30 for more information.

SECure

Causes the FTP client to attempt to secure data and control connections using TLS. The SECURE option overrides FTP DATA SECURECONTROL and SECUREDATA statement value of NO. This setting may be overridden for data connections while in the FTP session by using the CLEAR subcommand.

TImeout seconds

Specifies the number of seconds to be used for **all** of the following timing parameters:

- MyopenTime
- DconnTime
- CconnTime
- InactTime

Transferring Files Using FTP

DataCtTime

The value specified with the TIMEOUT operand is applied to each previously listed timing parameter. If individual timeout values are required, these can be specified in an FTP data file. For more information about this file and timeout parameters and defaults, see "The FTP DATA File" on page 30.

Numeric values between 15 and 720 are accepted for the TIMEOUT parameter.

Note: If the TIMEOUT operand value is not valid, FTP ignores that value and uses the default values established for each timeout parameter.

TRACe

Starts the generation of tracing output. TRACE is used to assist in debugging. Trace data is written to the console.

TRANslate filename

The file name of a translation table file other than a standard table. The file type is TCPXLBIN, and the file mode is an asterisk (*). If this parameter is not specified, the FTP command searches sequentially for FTP TCPXLBIN and STANDARD TCPXLBIN. If neither is found, FTP uses the compiled translation table.

This table provides client side translation. For more information on how to configure the translation performed by the z/VM FTP server, see z/VM: TCP/IP Planning and Customization. You can also control the translation by using the TRANslate operand of the SITE subcommand. For more information, see "SITE" on page 87.

Note: The FTP TCPXLBIN file is not supplied, because the standard translation table is adequate for most uses. You can create your own FTP TCPXLBIN file if your installation needs a translation for FTP that differs from the translation supported by STANDARD TCPXLBIN. For more information on translation tables see Chapter 14, "Using Translation Tables," on page 409.

If LOADDBCSTABLE is specified in FTP DATA, then filename is used to determine which DBCS translation table to load. For information on the loading and customizing of DBCS translation tables, see z/VM: TCP/IP Planning and Customization.

WIDth width

Specifies the maximum width to use for lines written to the console by FTP. Data that is longer than the specified width is wrapped to successive lines, as necessary. The minimum acceptable width is 1, while the maximum is 32767. The default for width is 80. When a FILEDEF is used to control FTP command output, the WIDTH option is ignored.

Usage Notes

- If the specified foreign_host is not accessible, or this operand has not been correctly specified, the FTP subcommand environment is established, but no foreign host connection exists. When this occurrs, the OPEN, USER, PASS, and ACCT subcommands can be used to establish a connection and log in as desired.
- If FTP can establish a connection to the specified foreign host and a valid entry for that host is present in a NETRC DATA file, by default, FTP uses that host's user name and password to logon to that host. Otherwise, you are prompted for this information, unless the NOPROMPT command option has been specified to suppress prompting.

 Once in the FTP environment, FTP subcommands are limited to 130 characters unless line continuation is used. For more information see "Continuing Subcommand Input Strings" on page 41.

Examples

The example that follows shows information that is typically displayed when an FTP connection is successfully established with a foreign z/VM TCP/IP host. In this example GDLVM7 (in the domain ENDICOTT.IBM.COM) is the *foreign_host* to which the connection is made.

```
Ready;
ftp gdlvm7
VM TCP/IP FTP level 620
Connecting to GDLVM7 9.117.32.29, port 21
220-FTPSERVE IBM VM Level 330 at GDLVM7.ENDICOTT.IBM.COM,
10:04:05 EST THURSDAY 2001-12-01
220 Connection will close if idle for more than 5 minutes.
USER (identify yourself to the host):
terix
>>>USER terix
331 Send password please.
Password:
>>>PASS ******
230-TERIX logged in; working directory = TERIX 191 (ReadOnly)
230 write access currently unavailable
Command:
```

The NETRC DATA File

The NETRC DATA file provides an alternative to responding to FTP prompts for logon information when you connect to a foreign host. When a user name and password for a specific host are defined in this file, FTP will use those values instead of prompting for this information.

When the FTP command or the OPEN subcommand is issued, FTP will search the NETRC DATA file for the first valid match on the specified host. If found, that host's user name and password will be used when a connection to that host is attempted. If no match is found for the host in question, you will be prompted for a user name and password, unless the NOPROMPT option has been specified.

For more information on the NETRC DATA File and how it may be used for other applications, see Appendix B, "Using the NETRC DATA File," on page 425.

The FTP DATA File

The FTP DATA configuration file defines operational characteristics that affect FTP connections and DBCS data translation.

A sample FTP data file is provided as FTP SDATA on the TCPMAINT 592 disk.

Notes:

- If the TIMEOUT operand is specified upon invocation of the FTP command, its corresponding value overrides all timing values specified within the FTP DATA file. However, if the TIMEOUT-specified value is not valid, the default timing values identified in the next section are used.
- 2. When DBCS file transfers are performed, both the remote FTP server and the local client must have the appropriate translate tables loaded.

Statement Syntax

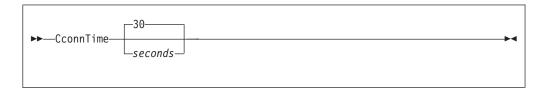

Within FTP DATA, blanks and record boundaries are used to delimit tokens. All characters to the right of (and including) a semicolon are treated as comments.

FTP DATA File Statements

Configuration statements that can be specified in the FTP DATA file are described in this section.

CCONNTIME Statement

The CCONNTIME statement specifies the timeout value used when waiting for a response to a connection close request on a Control connection.

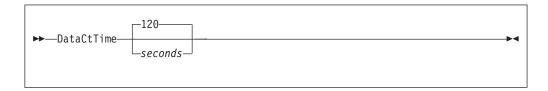

Operands

seconds

The number of seconds to allow before a timeout when waiting for a response to a connection close request on a Control connection. The minimum CCONNTIME value is 15 and the maximum is 720; the default is 30 seconds.

DATACTTIME Statement

The DATACTTIME statement specifies the timeout value used when waiting for a response to a TCP send or TCP receive request.

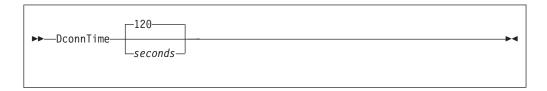

Operands

seconds

The number of seconds to allow before a timeout when waiting for a response to a TCP send or TCP receive request. The minimum DATACTTIME value is 15 and the maximum is 720; the default is 120 seconds.

DCONNTIME Statement

The DCONNTIME statement specifies the timeout value used when waiting for a response to a connection close request on a Data connection.

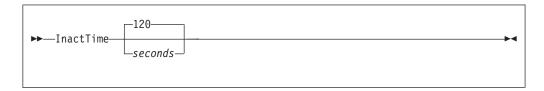

Operands

seconds

The number of seconds to allow before a timeout when waiting for a response to a connection close request on a Data connection. The minimum DCONNTIME value is 15 and the maximum is 720; the default is 120 seconds.

INACTTIME Statement

The INACTTIME statement specifies the timeout value used when attempting to establish a data connection to complete FTP subcommand operations.

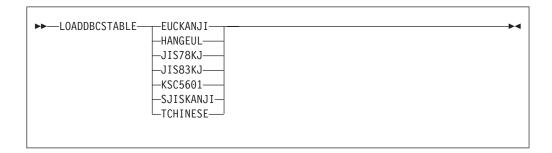

Operands

seconds

The number of seconds to allow before a timeout when attempting to establish a data connection to complete FTP subcommand operations. The minimum INACTTIME value is 15 and the maximum is 720; the default is 120 seconds.

LOADDBCSTABLE Statement

The LOADDBCSTABLE statement indicates to the FTP client which DBCS translate tables should be loaded at initialization time. By using multiple LOADDBCSTABLE parms, any number of translate tables may be selected ranging from none to all of the DBCS translate tables.

Operands

JIS78KJ

Indicates that the JIS 1978 Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table file.

JIS83KJ

Indicates that the JIS 1983 Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table file.

SJISKANJI

Indicates that the Shift JIS Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table file.

EUCKANJI

Indicates that the Extended Unix Code Kanji DBCS translation table should be loaded from the TCPKJBIN binary translate table file.

HANGEUL

Indicates that the Hangeul DBCS translation table should be loaded from the TCPHGBIN binary translate table file.

KSC5601

Indicates that the Korean Standard Code KSC-5601 DBCS translation table should be loaded from the TCPHGBIN binary translate table file.

TCHINESE

Indicates that the Traditional Chinese (5550) DBCS translation table should be loaded from the TCPCHBIN binary translate table file.

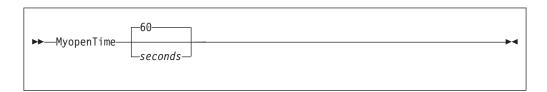

If the LOADDBCSTABLE parameter is not specified, specified incorrectly, or if FTP DATA is not accessible, then no DBCS translate tables will be loaded, and the corresponding FTP client DBCS transfer types will be unavailable.

Additional virtual storage may be required by the FTP client if a large number of translate tables are loaded concurrently.

Note: The IBMKANJI transfer type does not require any translate table to be loaded. For more information on loading and customizing DBCS translate tables, see *z/VM: TCP/IP Planning and Customization*.

MYOPENTIME Statement

The MYOPENTIME statement specifies the timeout value used when attempting to establish a connection.

Operands

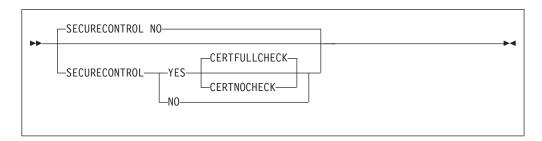

seconds

The number of seconds to allow before a timeout when attempting to establish a connection. The minimum MYOPENTIME value is 15 and the maximum is 720; the default is 60 seconds.

SECURECONTROL Statement

The SECURECONTROL statement specifies if the FTP client will secure control connections using TLS.

Note: In order to secure FTP data connections, the control connection associated with the FTP session must first be secured. See "Transferring Files Using Secure FTP" on page 53 for more information.

Operands

NO Specifies the FTP client will not secure control connections using TLS. This is the default. When NO is specified, the FTP user may optionally override the SECURECONTROL setting at initialization by using the SECURE option to the FTP command or while in the FTP session by using the CPROTECT subcommand.

YES

Specifies the FTP client will secure control connections using TLS. When YES is specified, the FTP user may optionally override the SECURECONTROL setting at initialization by using the NOSECURE option to the FTP command.

CERTFULLCHECK

When specified with YES, the remote server certificate and any associated CA certificates are verified for correctness for control connections. If a certificate error is detected, the corresponding connection fails.

A self-signed certificate cannot be used for secure connections unless it has been added to the local certificate database. For more information, see Using Self-Signed Certificates in *z/VM: TCP/IP Planning and Customization*.

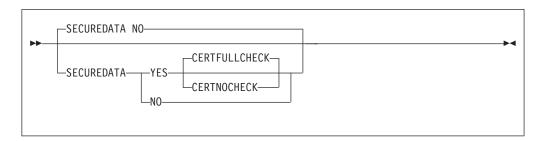

CERTNOCHECK

The CERTNOCHECK option is accepted and ignored. All connections are handled as described for the CERTFULLCHECK operand.

SECUREDATA Statement

The SECUREDATA statement specifies if the FTP client will secure data connections using TLS.

Note: In order to secure FTP data connections, the control connection associated with the FTP session must first be secured. See "Transferring Files Using Secure FTP" on page 53 for more information.

Operands

NO Specifies the FTP client will not secure data connections using TLS. This is the default. When NO is specified, the FTP user may optionally override the SECUREDATA setting at initialization by using the SECURE option to the FTP command or while in the FTP session by using the PRIVATE subcommand.

YES

Specifies the FTP client will secure data connections using TLS. This is the default. When YES is specified, the FTP user may optionally override the SECUREDATA setting at initialization by using the NOSECURE option to the FTP command or while in the FTP session by using the CLEAR subcommand.

CERTFULLCHECK

When specified with YES, the remote server certificate and any associated CA certificates are verified for correctness for data connections. If a certificate error is detected, the corresponding connection fails.

A self-signed certificate cannot be used for secure connections unless it has been added to the local certificate database. For more information, see Using Self-Signed Certificates in *z/VM: TCP/IP Planning and Customization*.

CERTNOCHECK

The CERTNOCHECK option is accepted and ignored. All connections are handled as described for the CERTFULLCHECK operand.

FTP Subcommands

The FTP subcommands listed in Table 5 can be used to perform file transfer operations between your local z/VM host and a foreign TCP/IP host, once an FTP connection (and thus, the FTP subcommand environment) has been established. For information about establishing an FTP connection, see "FTP Command" on page 26.

Table 5 provides a summary of all FTP subcommands that can be used with the z/VM FTP server and client, and shows the shortest abbreviation, a brief description, and a page reference for more information for each subcommand that is supported.

Table 5. FTP Subcommands

Subcommand	Minimum Abbreviation	Description	Page	
ACCT	AC	Sends host-dependent account information.	54	
APPEND	AP	Appends a file on your local host to a file on the foreign host.	54	
ASCII	AS	Sets the transfer type to ASCII.	55	
BINARY	В	Sets the transfer type to IMAGE.	56	
ccc	CCC	Causes the FTP client to clear (stop using TLS on) the control connection.	56	
CD	CD	Changes the working directory. CWD is a synonym for CD.	57	
CDUP	CDU	Changes the working directory to the parent directory on the foreign host. CD is a synonym for CDUP.	60	
CLEAR	CLE	Causes the FTP client to set up for clear data connections when set up for secure data connections using TLS.	57	
CLOSE	CLO	Disconnects from the foreign host.	61	
CMS	CM	Passes a CMS command.	61	
CPROTECT	СР	Causes the FTP client to attempt to secure the control connection using TLS.	57	
CWD	CW	Changes the working directory. CD is a synonym for CWD.	57	
DEBUG	DEB	Toggles internal debug options.	62	
DELETE	DELE	Deletes a single file on the foreign host.	63	
DELIMIT	DELI	Displays the delimiter character between the file name and the file type.	63	
DIR	DI	Lists the directory entries for files on the foreign host. LIST is a synonym for DIR.	64	
EBCDIC	EB	Sets the transfer type to EBCDIC.	65	
EUCKANJI	EU	Sets the transfer type to EUCKANJI.	66	
GET	G	Copies a file from the foreign host to your local host. RETRIEVE is a synonym for GET.	66	
HANGEUL	НА	Sets the transfer type to HANGEUL.	67	
HELP	IELP H Displays help information for FTP.		68	

Table 5. FTP Subcommands (continued)

Subcommand	Minimum Abbreviation	Description	Page	
?	?	Provides information to use FTP.	68	
IBMKANJI	I	Sets the transfer type to IBMKANJI.	68	
JIS78KJ	JIS7	Sets the transfer type to JIS78KJ.	69	
JIS83KJ	JIS8	Sets the transfer type to JIS83KJ.	69	
KSC5601	K	Sets the transfer type to KSC5601.	70	
LCD	LC	Changes the working directory on the local host.	70	
LOCSITE	LOCSI	Changes local site information.	71	
LOCSTAT	LOCST	Displays FTP status information for the local host.	71	
LPWD	LP	Displays the name of the active working directory on the local host.	72	
LS	LS	Lists the names of files on the foreign host. NLST is a synonym for LS.	73	
MDELETE	MD	Deletes multiple files on the foreign host.	74	
MGET	MG	Copies multiple files from the foreign host to your local host.	75	
MKDIR	MK	Creates a new directory on the foreign host.	76	
MODE	MO	Specifies the mode or data format of the transfer.	76	
MPUT	MP	Copies multiple files on your local host to the foreign host.	77	
NETRC	NE	Enables or disables automatic logon capability through use of a NETRC DATA file.		
NOOP	NO	Checks whether the foreign host is still responding.	78	
OPEN	0	Opens a connection to a foreign host. CONNECT is a synonym for OPEN.	79	
PASS	PA	Supplies a password to the foreign host.	80	
PASSIVE	PASSI	Controls whether the client or server establishes connections for data transfers.	80	
PRIVATE	PR	Causes the FTP client to set up for secure data connections using TLS.		
PUT	PU	Copies a file on your local host to the foreign host.		
PWD	PW	Displays the name of the active working directory on the foreign host.		
QUIT	QUI	Leaves the FTP command environment.		
QUOTE	QUO	Sends an uninterpreted string of data.	84	
RENAME	REN	Renames a file on the foreign host.		
RMDIR	RM	Remove a directory from the foreign host.	85	

Table 5. FTP Subcommands (continued)

Subcommand Minimum Abbreviation		Description	Page	
SENDPORT	SENDP	Enables or disables automatic transmission of the FTP server PORT subcommand. TOGLPORT is a synonym for SENDPORT.	86	
SENDSITE	SENDS	Enables or disables automatic transmission of the SITE subcommand.	86	
SITE	SI	Sends information to the foreign host using site-specific commands.	87	
SIZE	SIZE	Retrieves the transfer size (in bytes) for a foreign host file.	89	
SJISKANJI	SJ	Sets the transfer type to SJISKANJI.	90	
STATUS	STA	Displays status information for the foreign host.	90	
STRUCT	STR	Sets the file transfer structure.	91	
SUNIQUE	SU	Toggles the storage methods.	91	
SYSTEM	SY	Displays the name of the foreign host's operating system.	92	
TCHINESE	TC	Sets the transfer type to TCHINESE.	93	
TYPE	TY	Specifies the transfer type.	94	
USER	U	Identifies you to a foreign host. LOGIN is a synonym for USER.	95	

Continuing Subcommand Input Strings

Due to system limitations, FTP subcommand input lines are restricted to 130 characters; subcommand text that is present after 130 characters is ignored. When FTP subcommands are supplied, a continuation operator — a plus sign (+) preceded by a single blank — can be used to continue a string on a subsequent input line. The plus sign and its preceding blank will not be present in the resulting final string; thus, any blanks necessary to delimit multiple tokens for certain FTP subcommands must be explicitly provided as part of the input string(s) that are continued. Delimiting blanks can be included either before the " +" continuation operator, or at the beginning of the next line of continued text. Note that multiple blanks are not significant (that is, are not preserved). The limit for the subcommand input stream continued in this fashion is 200 bytes.

Example of Line Continuation

Suppose the current working directory on the foreign host is:

GPLSRV2:DOC.LIBRARY.PROJECTX

The following MKDIR subcommand is then issued, using two lines:

mkdir gplsrv2:doc.library.projectx. +
worlfiles

The foreign host replies with:

>>>MKD gplsrv2:doc.library.projectx.worlfiles
257 New directory GPLSRV2:DOC.LIBRARY.PROJECTX.WORLFILES has
been created.

FTP Subcommands

After creating several other directories, you realize the worlfiles directory should be workfiles. To correct this, you issue an RMDIR command of the form:

```
rmdir +
```

with the remainder of the command completed by retrieving and using previously entered commands:

```
qplsrv2:doc.library.projectx. +
worlfiles
```

The foreign host replies with:

```
>>>RMD gplsrv2:doc.library.projectx.worlfiles
250 Directory GPLSRV2:DOC.LIBRARY.PROJECTX.WORLFILES has been
    removed.
```

You then correct the directory name, again retrieving and using previously entered commands (with the last one corrected to workfiles):

```
mkdir +
gplsrv2:doc.library.projectx. +
workfiles
```

The response from the foreign host is then:

```
>>>MKD gplsrv2:doc.library.projectx.workfiles
257 New directory GPLSRV2:DOC.LIBRARY.PROJECTX.WORKFILES has
    been created.
```

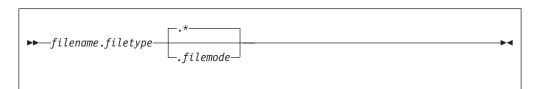

File Name Formats

FTP provides a mechanism to transfer files from one host to another, in which different operating systems (and thus, file systems) may be in use. Therefore, the format used to identify a file is dependent on the host system where that file resides or will reside.

In FTP subcommands used to manipulate files, it is necessary to distinguish files associated with the local host from those on a foreign host. In the FTP subcommand descriptions throughout this chapter, files that are specific to the local host are identified using the term localfile, whereas a file that is specific to a remote (foreign) host is identified using the term foreignfile.

Working with local CMS files

When CMS files are identified for FTP subcommands that require a local file (localfile), use this naming format:

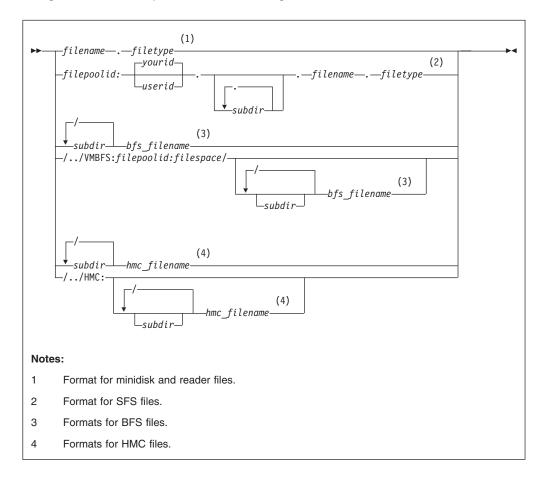

Notes:

- 1. When a specific file mode is provided for a CMS local file, only the resource accessed at that file mode is used to obtain or create the file that has been identified
- 2. When a file mode is not specified, or is specified as an asterisk (*) for a CMS local file, the resources involved in manipulation of the referenced file may vary, based on the FTP subcommand in use. For certain FTP subcommands, a file

mode specified as an asterisk signifies the local working directory *only*, whereas for others, this may imply use of the local working directory *first*, followed by the current CMS search order.

Working with Remote Files: When z/VM is in use on the foreign host and a *foreignfile* name is required, use the naming format that follows:

To reference minidisk or reader files, the appropriate working directory must be established on the foreign VM host. Fully-qualified SFS, BFS, and HMC foreign files can be referenced regardless of whether they reside in the current working directory on the foreign host.

For more information about CMS file names and limitations, see the *z/VM: CMS Commands and Utilities Reference*. For details regarding BFS file-naming conventions, refer to the *z/VM: OpenExtensions User's Guide*.

File Name Pattern Matching

When subcommands are issued that affect multiple CMS files, such as MDELETE, MGET, and MPUT, pattern matching can be used to affect the scope of the set of files affected by these subcommands (as can be done with the CMS LISTFILE command). Pattern matching is accomplished by specifying an asterisk (*) as a portion of, or in place of, *filename* or *filetype* when a file name is specified for these commands.

Pattern matching can also be used with the *name* operand that is used in DIR and LS subcommands. In addition to the pattern matching just described for *filename* and *filetype* (when *name* is specified using the format *filename.filetype*), the *name*

FTP Subcommands

operand itself can be used for pattern matching. Pattern matching based on the name operand is accomplished by specifying an asterisk (*) as a portion of, or in place of, the name operand.

Notes:

1. When the foreign host working directory is a virtual reader, pattern matching characters that are used as a portion of the filename, filetype or name operands must be specified as a leading or trailing character. An asterisk (*) can still be used in place of these operands.

File Name Case Considerations

When FTP operations are performed between hosts that are based on differing file system implementations, it may be necessary to account for differences that can arise due to case sensitive file naming conventions.

For example, when multiple CMS files are identified for MDELETE, MGET, and MPUT operations, the name and type of these files are provided by the z/VM FTP server to a connected client in lowercase, whereas for other subcommands (such as DIR or LS) these same files may be identified using uppercase names. For subcommands that affect only a single file (such as PUT or GET), case is preserved for file naming information that is transmitted.

While these response differences do not adversely affect operations between z/VM hosts, they may affect file-related actions performed on a connected host that is case-sensitive (with respect to naming conventions and the underlying file system implementation of that host).

Note: For minidisks and SFS directories, CMS files are created with names in uppercase. FTP on z/VM does not support mixed-case file naming for these resources.

Working with Non-CMS Files

For detailed information about naming and referencing files on a non-z/VM host, consult the documentation specific to that host and its operating system. The information provided in Appendix A, "Specifying Files and Data Sets," on page 421 may be useful as well.

In general, the z/VM FTP client does not restrict the naming of a foreignfile when such information is supplied to the FTP server on a foreign host. For example, the slash (/) often used in naming Unix files can be used when these files are referenced, even though this is not a valid CMS file name character. However, length restrictions may at times be encountered, due to implementation considerations.

Information about how certain naming conditions and problems are dealt with by FTP on a z/VM host follows.

Many commonly-referenced file systems (Unix is one example) maintain files using a descriptive file name only, and have no underlying support for a file type, as does CMS. When these files are transferred to a z/VM host, and the existing foreign file name cannot be used to adequately produce a CMS file name and file type, that file is stored on CMS minidisks and SFS directories using a CMS file type of SDEFAULT.

For some files, due to their naming, a specific CMS file name or file type must be provided when those files are retrieved from a foreign host. For example, to retrieve a *foreignfile* that begins with a period (.), the *foreignfile* specified with the GET subcommand must include an explicit *filename*. To retrieve a group of such files using an MGET subcommand, use an asterisk (*) as the *foreignfile* file name.

When the remote host is the z/VM FTP server, file identifiers (including directory and file name) for files residing in the HMC removable media are limited to 191 characters.

Quoted Strings and Embedded Spaces (Blanks)

When the need arises to specify an FTP subcommand that includes a foreign file or directory name that requires spacing, that name should be enclosed using single (') quotation marks.

When the z/VM FTP client encounters a subcommand operand string that is enclosed within quotation marks *and* that string contains embedded spaces, it discards the delimiting quotation marks *before* the string is passed to the FTP server on the foreign host.

If quotation marks are encountered that enclose a subcommand string which does *not* contain embedded blanks, the z/VM FTP client assumes the supplied quotation marks are inherent to this string. Thus, the delimiting quotation marks are retained, and are passed on to the FTP server on the foreign host.

Fully-Qualified Pathnames

For certain FTP subcommands, the z/VM FTP server allows a fully-qualified pathname.

For example, assume the SFS directory FPSERV1:TSTUSER.TESTCASES is the working directory, but that information about all **TEST007** files that reside in the FPSERV1:TSTUSER.TESTDATA directory needs to be obtained at a given time. This information can be obtained using the DIR command that follows:

```
dir fpserv1:tstuser.testdata.test007.*
```

If these files reside on the NOTSECUR 191 minidisk (for which a read password of ALL is in effect), this information would be retrieved using this command:

```
dir notsecur.191/test007.*
```

A fully-qualified pathname can be specified for these FTP subcommands:

- APPEND (APPE)
- DELETE (DELE)
- DIR (LIST)
- LS (NLST)
- GET, MGET (RETR)
- SIZE (SIZE)
- PUT, MPUT (STOR)
- PUT, MPUT with SUNIQUE active (STOU)
- RENAME

Note: When fully-qualified path names are used with FTP subcommands, the FTP server temporarily acquires the appropriate z/VM file system resource necessary to satisfy a request. This action by the FTP server does not alter the working directory that has been established through use of either the CD or CWD commands.

Interpretation of Path Information

The z/VM FTP server accepts path information for FTP commands such as CD and GET. The path information can be specified in one of three formats:

- · full qualified path
- absolute path
- · relative path

Because the z/VM FTP server provides access to different file systems (such as SFS and BFS), a fully qualified path is different than an absolute path.

The **full qualified path** specifies the file system and the path. It can address any given file or directory accessible on the system.

For example:

/../VMBFS:SERVT2:TCPBFS4/SUBDIR1/SUBDIR2

The **absolute path** contains an absolute path on the current file system, but not the file system itself. It makes use of the file system of the current working directory (as established by either a CD or CWD subcommand). Hence it can only address files and directories on the current file system.

For example:

/SUBDIR1/SUBDIR2

The **relative path** specifies a path starting with the current working directory on the current file system. It makes use of the file system of the current working directory (as established by either a CD or CWD subcommand). Hence, it can only address files and directories on the current file system.

For example:

SUBDIR1/SUBDIR2

As a practical example consider the following BFS directory structure:

```
SERVT2:TCPBFS4
|- FILE1.BIN
|- SUBDIR1
|- FILE2.BIN
|- SUBDIR2
|- FILE3.BIN
```

Assume you want to retrieve FILE3.BIN:

 Using a full qualified path the file can be retrieved independent from what the current directory is with the command:

```
GET /../VMBFS:SERVT2:TCPBFS4/SUBDIR1/SUBDIR2/FILE3.BIN
```

This command will work no matter what the current file system or path is.

 Using an absolute path you first need to change the working directory to the SERVT2:TCPBFS4 BFS file pool. Note that we directly change into the SUBDIR1 directory:

```
CD /../VMBFS:SERVT2:TCPBFS4/SUBDIR1
```

Now you can retrieve the file using an absolute path with the following command: GET /SUBDIR1/SUBDIR2/FILE3.BIN

This command will work with any current directory on the SERVT2:TCPBFS4 file pool.

 From inside the working directory established using the CD command above you can also specify a relative path to retrieve FILE3.BIN:

GET SUBDIR2/FILE3.BIN

This command does not only require the current working directory to be on the correct file system but is also dependent of the current position within the file system.

Storage Space Requirements for Transferred Files

The information that follows must be considered when files are stored on a z/VM host, especially when minidisk or SFS storage space is constrained, or when attempts are made to minimize the use of such space.

As part of necessary overhead required by the FTP server and by CMS for performing file system management, a number of storage blocks must be reserved and used for other than data storage purposes. For instance, some blocks are used as control blocks to maintain the minidisk file directory (for which additional block space may be required as new files are created), while others are used as pointer blocks to manage file structure.

However, these various *reserved* blocks are not reflected in the output returned for the CMS QUERY DISK or QUERY LIMITS commands. This means the results obtained from these commands must be used only as an *approximation* of storage block usage and availability when determining whether a file can be stored on a z/VM host.

File Transfer Methods

When files are transferred between two hosts, appropriate transmission attributes must be used to ensure the content and structure of any transferred file are preserved. The nature of a file transfer is primarily controlled using two FTP subcommands:

- the MODE subcommand, which determines how the file contents are transmitted. For more information, see "MODE" on page 76.
- the TYPE subcommand, which establishes attributes of the file contents. For more information, see "TYPE" on page 94.

Controlling File Translation

Because z/VM maintains data in EBCDIC format, it is often necessary to be aware of and have control over how EBCDIC-ASCII file translation is performed when files are transferred to or from a remote host.

Table 6 shows recommendations for setting transmission attributes for file transfers that are performed between differing host systems. In this table, IBM host systems (VSE/ESA, z/VM or OS/390 hosts) are referred to as "EBCDIC" hosts. By comparison, a Unix, Windows, or Linux host is considered to be an "ASCII" host. With respect to EBCDIC hosts, text data is considered to be comprised of only standard, displayable characters, whereas for an ASCII host, text data generally contains the carriage return (ASCII X'0D' and EBCDIC X'15'), the line feed (ASCII X'0A' and EBCDIC X'25') and displayable characters.

Table 6. Recommended Methods of File Transfer

Source Host	Intermediate Host	Target Host	Data	TYPE Setting	Mode Setting
EBCDIC	(none)	EBCDIC	binary	E (EBCDIC)	B (Block)
EBCDIC	(none)	EBCDIC	text	E (EBCDIC)	S (Stream)

Source Host	Intermediate Host	Target Host	Data	TYPE Setting	Mode Setting	
EBCDIC	(none)	ASCII	text	A (ASCII)	S (Stream)	
ASCII	(none)	EBCDIC	text	A (ASCII)	S (Stream)	
ASCII	(none)	EBCDIC	binary	I (Image) (1*)	S (Stream)	
ASCII	EBCDIC (2*)	ASCII	binary	I (Image) (1*)	S (Stream)	
EBCDIC	ASCII (2*)	EBCDIC (3*)	binary	I (Image) (1*)	S (Stream)	

Table 6. Recommended Methods of File Transfer (continued)

- 1. The BINARY subcommand can be used to set the transfer type to Image.
- 2. Used only for storage purposes.
- 3. See accompanying notes for more information.

Notes:

- 1. When files are transferred between IBM EBCDIC host systems, the combined use of the MODE B and TYPE E subcommands is generally sufficient to achieve satisfactory results.
- 2. When a CMS file such as a MODULE, (which has an internal format which must be preserved) is transferred using an intermediate ASCII host, that file should first be compressed using the PACK option of the CMS COPYFILE command. This "packed" file should then be handled as a binary file until it is transferred to its final destination. For the z/VM destination host, a SITE (or LOCSITE) FIXRECFM 1024 subcommand must be issued prior to the PUT (or GET) subcommand used to transfer the file — this is necessary to create a file that can then be uncompressed using the UNPACK option of the CMS COPYFILE command.

Automatic File Translation

The z/VM FTP server can be configured by the system administrator to automatically perform EBCDIC-ASCII file translation based on the value of a file extension, which is defined to be the last component of a file name — that is, the characters that follow the last period in a path name. For file extensions, up to eight characters are matched and mixed case is **not** respected.

Automatic file translation, when enabled, is applicable to only the Image (TYPE I) file transfer type. Thus, if the transfer type is changed to other than Image — for example, ASCII — during a session for which automatic file translation is active, automatic translation ceases and files are transferred in accordance with the newly established transfer type. In such a case, automatic file translation can be reinstated by changing back to the **Image** transfer type.

Automatic file translation is recommended when a web browser or graphical FTP client is used to interact with a z/VM FTP server, because these clients often default to using a transfer type of Image (or, binary) and do not offer a way for a different file transfer type to be specified.

The associations between file extensions and file translation are configured by the z/VM system administrator, as is the initial automatic file translation setting for an FTP session. While file extension associations cannot be changed by an FTP client, whether automatic file translation is performed by the server can be controlled by using the AUTOTRANS operand of the SITE subcommand. For more information, see "SITE" on page 87.

File List Formats

After an FTP connection has been established with a z/VM foreign host, the FTP server can be instructed to provide **DIR** subcommand responses (file *lists*) in one of two different *list formats*:

- VM-format (VM), or
- · Unix-format (UNIX), sometimes referred to as Unix long-list format.

These formats are described in more detail in the following sections.

VM-format Lists

The VM-format list response provides file information in a format that — for the minidisk and Shared File System (SFS) directory file groups — closely resembles that produced by the CMS LISTFILE command. A sample VM-format list response follows:

```
Command:
 dir
>>>PORT 9,117,32,30,4,53
200 Port request OK.
 >>>LIST
125 List started OK
                                                 80 1
43 10
 ENDTRACE TCPIP
                                                                                 1 1999-07-28 12:24:01 TCM191
                                                                                 1 1999-11-16 9:05:22 TCM191

                                                                                                          - 'FIRST'
 250 List completed successfully.
 Command:
```

For a z/VM virtual reader (**RDR**), list responses are similar to that produced by the CP QUERY RDR ALL command, but with certain fields removed. A sample VM-format response for a virtual reader follows:

```
Command:
dir
>>>PORT 9,117,32,29,10,213
200 Port request OK.
>>>LIST
125 List started OK
0013 SMTP
             00000011 1999-11-03 12:46:10 CIBULAPR MAIL
0154 RSCS
             00002789 1999-12-29 10:12:46 FL3XSAMP TXT
0116 TCPLVL2 00000170 1999-12-16 11:39:07 TCP-HELP LIST3820
0115 TCPLVL2 00002874 1999-12-16 11:39:06 TCP-OVER LIST3820
             00002825 1999-06-29 10:12:45 FL32SAMP
0153 RSCS
             00000015 2000-01-14 12:50:10 CIBULAMA MAIL
0214 SMTP
250 List completed successfully.
Command:
```

The fields in this type of response are referred to (in order) as the **spoolid**, **origin**, **records**, **date**, **time**, **filename** and **filetype** fields.

For files residing in the removable media of an HMC, the LISTFORMAT setting for an FTP session is ignored because there is no VM-format list for HMC directories. For HMC directories, Unix-format lists are always sent in response to the DIR subcommand.

Unix-format Lists

When a web browser, or other graphical FTP client is used to interact with a z/VM FTP server, the use of Unix-format lists is recommended. This is because these types of clients have, in general, been implemented to work with a Unix file system model and expect Unix-like information to be presented as FTP transactions are performed. If VM-format file lists are supplied when such a client is used, directory and file information may not be correctly displayed or managed by the client; this may then cause FTP processing capabilities to become limited or adversely affected.

The list format initially supplied by an FTP server is configured by the z/VM system administrator. However, the list format used during an FTP session can be controlled by using the **LISTFORMAT** operand of the SITE subcommand. For more information on the SITE subcommand, see "SITE" on page 87.

Unix-format List Fields

Unix-format responses returned by a z/VM FTP server contain the following fields, with each separated by one or more spaces:

mode	a one byte entry type followed by three bytes each of Owner.

Group, and Other permissions

 link count
 a count of the number of symbolic links to a file

 owner
 the login or user name that owns a file or directory

 group
 the group name with which permissions are associated

size the size (in bytes) of a file or directory

date date of last modification (month and day, provided in the form *mmm*

nn)

time time of last modification, provided in the form *hh:mm* (for files

greater than six months old, hh:mm is replaced with the year in

which the file was last modified, provided as *nnnn*)

name the name of a file or directory

An example Unix-format response follows:

Here is a sample Unix-format response for a virtual reader:

```
Command:
dir
>>>PORT 9,117,32,29,10,213
200 Port request OK.
>>>LIST
125 List started OK
-rwx---rwx 1 MIKE - 0 Nov 3 12:46 0013.CIBULAPR.MAIL
-rwx--rwx 1 MIKE - 0 Dec 29 10:12 0154.FL3XSAMP.TXT
-rwx--rwx 1 MIKE - 0 Dec 16 11:39 0116.TCP-HELP.LIST3820
-rwx--rwx 1 MIKE - 0 Dec 16 11:39 0115.TCP-OVER.LIST3820
-rwx--rwx 1 MIKE - 0 Jun 29 1999 0153.FL32SAMP.TXT
-rwx--rwx 1 MIKE - 0 Jun 29 1999 0153.FL32SAMP.TXT
-rwx--rwx 1 MIKE - 0 Jan 1 12:50 0214.CIBULAMA.MAIL
```

Since the z/VM Byte File System (**BFS**) is based on a Unix file system model, all fields of the Unix-format file list are applicable and available when BFS files and directories are listed in response to a DIR subcommand.

When a Unix-format response is returned for z/VM-specific file system groups — **minidisks**, **SFS** directories, or virtual readers (**RDR**) — some of the information associated with this format is not pertinent to these file system groups. Thus, the FTP server substitutes or modifies values for certain Unix-format fields when its response corresponds to one of these file system groups; this is done to allow for correct processing of the response by web browser and graphical FTP clients.

Modifications to Unix-format field values for non-BFS files and directories are applied by the z/VM FTP server as follows:

- An entry type of d is supplied if the response entry is associated with an SFS directory; otherwise, a hyphen (-) is present.
- For SFS and minidisk, owner permissions are always **rwx**, but for RDR files, owner permissions are always hyphens (---).
- Group permissions are supplied as hyphens (---).
- Other permission bits will indicate the authority of the current user. Execute authority (x) is assumed if the login user has read authority for the file in use.

For resources protected by an External Security Manager (ESM), Other permissions are always provided as rwx. Exact file authorizations for these resources may be determined by using the QAUTH operand of the "SITE" subcommand, see "SITE" on page 87.

- · A link count of 1 is always provided.
- If the file owner is a member of an Access Control Interface group (ACIGROUP), that ACIGROUP name is supplied in the group field. If an ACIGROUP is not available, the group name is supplied as a hyphen (-). For more ACIGROUP information, see *z/VM: CP Planning and Administration*.
- For minidisk and SFS files, the size field contains the file size calculated depending on the planned mode. Because the final size depends on the transfer mode (ASCII, BINARY, or EBCDIC), the planned mode can be set with the LISTFORMAT command by specifying LISTFORMAT UNIX [ASCII | BINARY | EBCDIC].
- For virtual reader files, a size of **0** is always indicated.
- For a virtual reader, the spool ID precedes the file name and file type; thus, for these resources, this field is formatted as: spoolid.filename.filetype
- For SFS, a broken alias that points to an SFS file that is already deleted is shown with a file size of 0 and a date of 01/01/1970.

Transferring Files Using a Web Browser

To FTP to a z/VM host using a web browser, use the following FTP address or location format:

ftp://userid:password@host.domain/directory

If a password is not specified as part of the location information you supply (but is required to gain access to the host in question) a password prompt will be issued.

If a *directory* is not specified as part of the location information, the web browser informs the z/VM FTP server to begin at the root directory that is associated with the userid default working directory. If the user ID in question (userid) does not have authorization for the root directory, either proper authorization must be obtained or a suitable directory must be specified as part of the FTP location address (that is, a directory for which access authorization exists).

Also, be aware that the following sequence of events may produce unexpected results when a web browser FTP client is used in conjunction with a z/VM FTP

- 1. FTP operations commence with a root directory that corresponds to a specific type of z/VM file system (BFS, SFS, minidisk, reader) for which no specific directory has been specified as part of the FTP address or location.
- The type of z/VM file system used is overtly changed, by having specified a fully-qualified directory in the FTP address or location.
- 3. A browser operation is performed that requires use of the root directory (and z/VM file system) that was originally established in Step 1, such as backward paging that initiates a file retrieval, store, or delete request.

Problems may arise after such a sequence of events because web browser implementations generally expect to operate with only one type of file system for a given user FTP session; the browsers do not expect the root directory to change for the life of an FTP session. Given this, a browser will not likely send a change directory (CD or CWD) request prior to an operation that requires a z/VM file system type that differs from that currently in use. Because the z/VM FTP server

employs a different root directory for each type of z/VM file system in use, its responses may differ from those expected by the browser.

Under these (and similar) circumstances, unexpected results may be a consequence of discrepancies between the z/VM FTP server and the browser in use, with respect to conventions that concern how files should be referenced using path and directory information, as well as perception as to what constitutes a "working directory".

Transferring Files Using Secure FTP

The FTP client may be configured to use secure control and data connections using the Transport Layer Security (TLS) protocol. RFC 4217 (Securing FTP with TLS) describes the protocol used by the FTP client. Please see this RFC for more detailed information.

By default, the FTP client does not use secure control or data connections. To configure the FTP client to automatically use secure control connections, use the SECURECONTROL statement in the FTP DATA configuration file. To configure the FTP client to automatically use secure data connections, use the SECUREDATA statement in the FTP DATA configuration file.

Note: In order to secure FTP data connections, the control connection associated with the FTP session must first be secured.

To override the FTP SECURECONTROL and SECUREDATA settings at FTP command invocation, use the SECURE or NOSECURE option on the FTP command. This will cause the FTP client to either use or not use secure connections.

Note: The SECURE and NOSECURE options affect both control and data connections.

Once in the FTP session, the control connection may be secured using the CPROTECT subcommand. When the CPROTECT subcommand is issued, a negotiation will take place between the FTP client and the FTP server to secure the control connection. Once the control connection is secure, control connection transmissions are confidentiality and integrity protected by encryption. At this point, you may set up secure data connections by using the PRIVATE subcommand. When the PRIVATE subcommand is issued, a negotiation will take place between the FTP client and the FTP server to secure data connections. Once secure data connections are set up, data connection transmissions are confidentiality and integrity protected by encryption. To return to using non-secure (clear) data connections, the CLEAR subcommand may be used.

When FTP connections are secured, the FTP client always verifies the correctness of the remote server certificate and any associated CA certificates. Such verification is performed whenever a secure control or secure data connection is attempted. If a certificate error is detected, the corresponding connection fails. These operations are the same as when the following FTP DATA configuration file statements are used for the respective control or data connection types:

- SECURECONTROL YES CERTFULLCHECK
- SECUREDATA YES CERTFULLCHECK

ACCT

Purpose

Before you can access files on a foreign host, some hosts require account information. Use the ACCT subcommand to send host-dependent account information.

Operands

account information

Specifies the account information required by the foreign host.

Usage Notes

- Some TCP/IP systems require passwords to gain access to specific resources or for a specific kind of access, such as "read" or "write". For such systems, you can use the ACCT subcommand to supply such passwords.
- If the foreign host is a VM system, the ACCT subcommand can be used to supply minidisk passwords. The password you supply is used by the VM FTP server when CP LINK commands are issued on your behalf.

When access to a VM minidisk is requested and a LINK password is required, the FTP server attempts LINK commands in the following order:

- 1. MR (Multiple Read) mode
- 2. WR (Read/Write) mode
- 3. RR (Read only) mode.

The level of access provided is determined by the first LINK attempt that succeeds. Thus, the minidisk password you supply as the *account_information* parameter should provide a minidisk LINK corresponding to the highest level of access you desire. For many systems, a Multiple Read password is most appropriate.

For more information about the CP LINK command, see the *IBM z/VM: CP Command and Utility Reference*.

APPEND

Purpose

Use the APPEND subcommand to append a local file to a foreign file.

Operands

localfile

The name of the local file to be appended to a file that resides on a foreign host. For information about how to specify *localfile* see "File Name Formats" on page 42.

foreignfile

The foreign host file to which the local file is to be appended. If a foreign file of this name does not already exist, the file is created. For information about how to specify *foreignfile* see "File Name Formats" on page 42.

Usage Notes

- To append to a file on the foreign host, you must have a defined working directory, and you must have write privileges to it. For more information, see the subcommands "ACCT" on page 54 and "CD or CWD" on page 57.
- When the foreign file has a fixed-record format, the file format and record length
 of the foreign file are always preserved. Records from the local file can be
 truncated or padded with blanks when necessary.
- When files are transferred between two hosts, appropriate transmission attributes
 must be used to ensure the content and structure of any transferred file are
 preserved. For more information, please refer to "Controlling File Translation" on
 page 47.

ASCII

Purpose

Use the ASCII subcommand to change the transfer type to ASCII, and at the same time change the record format used to store local files.

Operands

The ASCII subcommand has no parameters.

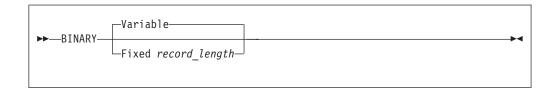

Usage Notes

 The ASCII subcommand is intended for use when text files are transferred to or from an ASCII host. When FTP sessions are established, ASCII is the default transfer type.

Note: The ASCII subcommand causes files transferred to the local host to be stored as variable-record (**V**) format files.

For more information about file transfer methods, see Table 6 on page 47.

BINARY

Purpose

Use the BINARY subcommand to change the file transfer type to Image.

Operands

Variable

Specifies that files are stored as variable-record (V) format files.

Fixed record length

Specifies that files are stored as fixed-record format (F), with records of length record length.

Usage Notes

- To specify how a binary file is stored on the local host, use the BINARY subcommand with the VARIABLE or FIXED operand before a GET (or MGET) subcommand is issued to retrieve a file. Note that when the BINARY subcommand is used in this manner, this has the same effect as issuing separate TYPE IMAGE and LOCSITE subcommands.
- For a z/VM foreign host where the FTP server has been configured to perform automatic file translation, the BINARY subcommand has no effect on file translation — the server continues to determine whether EBCDIC-ASCII translation should occur based only on file extension. However, the VARIABLE and FIXED operands still affect how a transferred file is stored on the local VM system.

To enable or disable automatic file translation for files transferred using the **Image** transfer type, use the AUTOTRANS operand of the SITE subcommand. For information, see "SITE" on page 87.

CCC

Purpose

Use the CCC subcommand to cause the FTP client to clear (stop using TLS on) the control connection. The control connection must already be in a secure state in order for the CCC subcommand to be accepted.

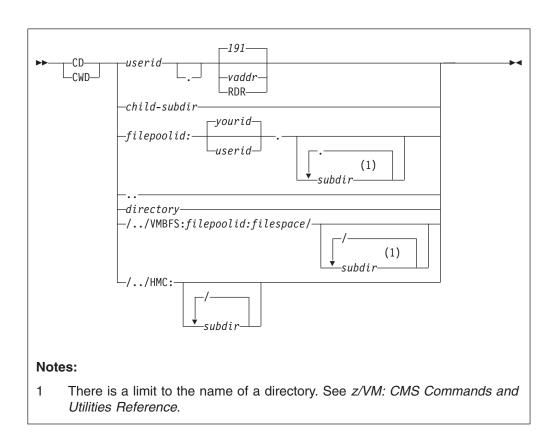

Operands

The CCC subcommand has no parameters.

Usage Notes

- If an error occurs while attempting to secure the control connection and the control connection enters an ambiguous state, the control connection will be aborted.
- If clearing the control connection is unsuccessful and the control connection is still in a secure state, the control connection will not be aborted
- The CCC option overrides an FTP DATA SECURECONTROL statement value of YES (described in FTP DATA File Statements section) and the use of the SECure option on the FTP command.
- Since clearing the control connection potentially allows an attacker to insert commands onto the control connection, some FTP servers may refuse to honor this command.

CD or CWD

Purpose

Use the CD or CWD subcommand to change the working directory or file group on the foreign host.

Operands

userid

The user ID associated with the resource that is to be accessed.

vaddr

A minidisk virtual address. The default virtual address is 191.

FTP Subcommands

RDR

Indicates the virtual reader associated with *userid* is to be accessed.

child-subdir

A subdirectory that is defined under the current working directory.

filepoolid

The name of the Shared File System (SFS) file pool in which the directory to be accessed is defined.

userid

The user ID that owns the SFS directory that is to be accessed. If not specified, the user ID that corresponds to the currently active login user name (as specified with the USER subcommand) is used — signified here as *yourid*.

subdir

The name of a subdirectory that is defined under the top-level directory defined by *filepoolid:userid*.

.. A special operand that changes the working directory to the parent directory on the foreign host. This operand performs the same function as the CDUP subcommand.

directory

The name of a file directory or other system-dependent file group designator on the foreign host.

/../VMBFS:filepoolid:filespace/

The name of the Byte File System (BFS) root. The **VMBFS**, *filepoolid*, and *filespace* tokens are all required and must be specified in **uppercase**.

/../HMC:

A keyword indicating a Hardware Management Console (HMC) removable medium (DVD or flash drive) that has been connected to the logical partition of a remote z/VM FTP server.

Usage Notes

- You can also use the CWD subcommand to change the current working directory. This subcommand is interchangeable with the CD subcommand.
- While in the FTP environment, you can issue a CD command to specify a subdirectory or fully-qualified directory name for access to SFS and BFS.
- To work with SFS directories, TCP/IP V2R3 for VM or later must be in use on the foreign host. To work with BFS directories, TCP/IP V2R4 or later must be in use on the foreign host. To work with VM readers, TCP/IP FL320 or later must be in use on the foreign host. To work with HMC directories, TCP/IP FL540 or later must be in use on the foreign host.
- When CD commands are used with a remote host running z/VM, your use of SFS, BFS, HMC, and virtual reader support can affect how the directory names you supply are used. When support for these resources is available, the VM FTP server will interpret the directory names you supply using the following precedence:
 - 1. If the current working directory is a BFS directory, the supplied directory name is treated as a BFS path name.
 - 2. If the string "/.../VMBFS:" is present, the directory name is treated as a BFS path name.
 - 3. If the current working directory is an HMC directory, the supplied directory name is treated as an HMC directory name.

- 4. If the string /../HMC: is present, the directory name is treated as an HMC directory name.
- 5. If the current working directory is an SFS directory, the supplied directory name is treated as an SFS directory name.
- 6. If a colon (:) is present in the directory name, it is treated as an SFS directory name.
- 7. If the supplied directory name ends with either "RDR" or ".RDR", an attempt is made to change the working directory to a virtual reader.
- 8. If the previously listed attempts fail to result in a successful change of directory, an attempt will be made to acquire a minidisk.

Note: Certain SFS, HMC subdirectories, and BFS path names can present problems when you alternate the use of SFS/HMC/BFS resources and minidisks or virtual readers as working directories. When SFS, HMC subdirectories, or BFS path names exist with names that also conform to the *userid.vaddr* or *userid.*RDR directory format, you might obtain that SFS, HMC, or BFS resource as a working directory instead of an intended *userid* minidisk or virtual reader. This situation is dependent upon the SFS, HMC, or BFS directory hierarchy being referenced, as well as the SFS/HMC/BFS directory that is the current working directory.

- The following restrictions apply to BFS files and directories:
 - When a CD request is for a Byte File System (BFS) directory, only the VM user's primary GID (from the POSIXINFO statement) is used by the FTP server. The user's supplementary GID list (from the POSIXGLIST statement) is not used.
 - When the user ID issuing a CD command has file pool administration authority for the target BFS file pool, that administration authority is not respected by the FTP server. In other words, the user ID must have explicit permission to the object through the UID and GID associated with the user ID.
- The initial working directory you obtain after you logon to a foreign host is dependent upon that host system. For z/VM hosts, the initial working directory established, as well as the type of access to that directory (with regard to "read" versus "write" status), can be affected by several factors, such as:
 - the logon user ID you supply
 - the configuration of the FTP server
 - the use of an External Security Manager (ESM)
 - the release of TCP/IP for VM in use on foreign host.

In many environments, the 191 minidisk of the login user ID is established as the initial working directory, by default. When possible, write access to this resource is obtained. However, these defaults can be influenced and altered by one, or a combination, of the previously cited factors.

- If TCP/IP Function Level 320 or later is in use on the foreign host and native VM minidisk password protection is in use, access to minidisks will be achieved without the need to specify a minidisk password, when one of the following conditions is true:
 - the login user ID owns the target minidisk
 - a minidisk read, write, or multiple password of **ALL** is in effect for the minidisk

For these conditions, write access will be obtained, whenever possible. If none of these conditions is applicable for this kind of environment, the **ACCT** subcommand must be used to provide a suitable minidisk password to gain access to the minidisk.

FTP Subcommands

For this same type of environment, but with a level of VM TCP/IP prior to Function Level 320 in use, minidisk access without the need for a minidisk password will be achieved only when a minidisk read, write, or multiple password of "ALL" is in effect for a minidisk. Otherwise, minidisk access will only be provided when you use the ACCT subcommand to provide a suitable minidisk password.

You can specify the *dev.null directory for testing throughput. If *dev.null is specified, the PUT and MPUT subcommands transfer data to the foreign host, but do not store the data at the foreign host. The GET and MGET subcommands use the working directory that was in effect before the CD *dev.null command.

Examples

CD COOK, 191

where 191 is the default minidisk address.

cd server5:.os2tools

where OS2TOOLS is the SFS directory within the client's filespace in file pool SERVER5.

cd /../VMBFS:SERVER5:ROOT/user/alan

where user/alan is the directory within file space ROOT of file pool SERVER5.

CDUP

Purpose

Use the CDUP subcommand to change the working directory to the parent directory on the foreign host. The CDUP command is a special case of the CD command. It is included to simplify the implementation of programs for transferring files between operating systems that use differing directory naming conventions. The reply codes are identical to the reply codes for the CD command. CDUP works for only one level at a time and is executed only if the current directory is an SFS or a BFS directory.

Note: You can also use the ".." operand of the CD subcommand to change the working directory to the parent directory.

Operands

The CDUP subcommand has no parameters.

CLEAR

Purpose

Use the CLEAR subcommand to cause the FTP client to set up for clear data connections when setup for secure data connections using TLS.

Operands

The CLEAR subcommand has no parameters.

Usage Notes

- CLEAR is not valid when there is no active security mechanism.
- CLEAR overrides an FTP DATA SECUREDATA statement value of YES and the use of the SECURE option on the FTP command.
- If set up for clear data connections is unsuccessful and the session is still setup for secure connections, secure data connections will continue to be used.

CLOSE

Purpose

Use the CLOSE subcommand to disconnect from the foreign host.

Operands

The CLOSE subcommand has no parameters.

Usage Notes

 CLOSE does not end FTP processing, therefore you can use the OPEN subcommand to establish a new session.

CMS

Purpose

Use the CMS subcommand to pass a CP or CMS command to the local z/VM system.

Operands

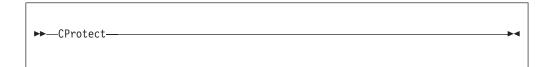

command

Specifies a CMS or CP command.

Usage Notes

- The CMS subcommand can be used to perform regular VM CMS functions such as checking your file list.
- · Running TCP/IP related CMS functions may disrupt operation of the FTP command and cause its termination.

CPROTECT

Purpose

Use the CPROTECT subcommand to cause the FTP client to attempt to secure the control connection using TLS.

Operands

The CPROTECT subcommand has no parameters.

Usage Notes

- Once a CPROTECT subcommand succeeds, control connection transmissions are confidentiality and integrity protected by encryption.
- · CPROTECT is not valid when there is no active security mechanism.
- The CPROTECT option overrides an FTP DATA SECURECONTROL statement value of NO and the use of the NOSECURE option on the FTP command.
- If an error occurs while attempting to secure the control connection and the control connection enters an ambiguous state, the control connection will be aborted.

DEBUG

Purpose

Use the DEBUG subcommand to enable or disable the internal debugging option.

Operands

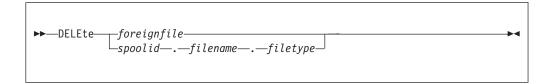

The DEBUG subcommand has no parameters.

Usage Notes

 DEBUG acts as a toggle that turns the debugging option on or off. The DEBUG subcommand is ON, initially, if the TRACE parameter was specified on the FTP command. The DEBUG subcommand is OFF if the TRACE parameter was not specified.

 The DEBUG subcommand is intended to aid in problem diagnosis. When DEBUG is ON, FTP displays tracing information, in addition to the commands sent to the foreign host and the responses received from that host.

DELETE

Purpose

Use the DELETE subcommand to delete a file specified in the path name at the foreign host.

Operands

foreignfile

The foreign host file to be deleted. For information about how to specify *foreignfile* see "File Name Formats" on page 42.

spoolid

The system-assigned number of the spool file to be deleted; *spoolid* is valid only when the working directory on the foreign host is a z/VM virtual reader (**RDR**). When a *spoolid* is specified, the *filename* and *filetype* associated with that spool file can optionally be included, though these values are not used by the FTP server.

DELIMIT

Purpose

Use the DELIMIT subcommand to display the character that is used as the delimiter between the *filename* and the *filetype*.

Operands

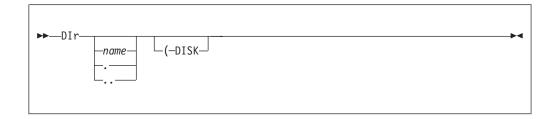

The DELIMIT subcommand has no parameters and should be used for informational purposes only.

Examples

• Response displayed after invoking the DELIMIT subcommand:

```
File delimiter is '.'
Command:
```

DIR

Purpose

Use the DIR subcommand to get a list of directory entries or a list of files in a file group on the foreign host.

Operands

name

The name of the directory or file group on the foreign host for which files should be listed. If name is omitted, all directory entries or files for the current working directory or file group are listed. For information about how to specify name, see the "Usage Notes" for this subcommand and "File Name Formats" on page 42.

To select which directory or file group is current, use the CD subcommand; for more information about this subcommand, see "CD or CWD" on page 57.

- Specifies that list information should be returned for the current working directory. For z/VM hosts, this operand is recognized in this manner only when SFS, HMC, or BFS directories are referenced. For other z/VM resources, responses are returned as if no operand had been specified.
- Specifies that list information should be returned for the parent directory of the current working directory. For z/VM hosts, this operand is recognized in this manner only when SFS, HMC, or BFS directories are referenced. For other z/VM resources, responses are returned as if no operand had been specified.

DISK

Stores the results of the DIR subcommand in file FTP DIROUTP, on the current local working directory. DIR subcommand results are not displayed when this operand is used.

Usage Notes

- For z/VM hosts that support list format selection, the response to the DIR subcommand can differ, based on the list format that is specified for the current session. If a list format of UNIX is specified, the server responds with a Unix-format list; otherwise, the response is a VM-format (VM) list.
 - For more information about VM-format and Unix-format responses to the DIR subcommand, see "File List Formats" on page 23.
 - For more information about controlling the type of list format used for an FTP session, see the description of the "SITE" subcommand, refer to "SITE" on page 87.
- The DIR subcommand provides a complete list of directory and file entries that includes auxiliary information about those entries. To get a list that contains only the names of files present in the directory, use the LS subcommand. For more information, see "LS" on page 73.

- If the DIR subcommand is issued for a BFS directory that contains other than regular BFS files, a vm; foreign host may return an error response that indicates a BFS directory error has occurred.
- For z/VM foreign hosts, pattern matching can be used to specify a subset of files about which information is returned. For more information, see "File Name Pattern Matching" on page 43.
- z/VM hosts do not support pattern matching for BFS files and directories.
- If the working directory on the foreign host is a z/VM virtual reader (RDR) and VM-format lists are in use, pattern matching using the name operand is possible. When used, matching is performed against all reader-specific fields in unison (that is, data is returned for a reader file when a match is found for any field).

Examples

• A sample VM-format (VM) list response for a minidisk working directory follows:

 A sample Unix-format (UNIX) list response, for the same directory as in the previous example, follows:

```
dir
>>>PORT 129,34,128,246,13,134
200 Port request OK
>>>LIST
125 List started OK
-rwx---r-x 1 MIKEW TCPIPDEV
-rwx---r-x 1 MIKEW TCPIPDEV
                                     432 Mar 18 10:28 ALTTEST.EXEC
                                      240 Mar 18 16:13 LASTING.GLOBALV
-rwx---r-x 1 MIKEW TCPIPDEV 3192 Dec 8 1998 PROFILE.EXEC
                                      80 Mar 17 8:57 TEST.DATA
-rwx---r-x 1 MIKEW
-rwx---r-x 1 MIKEW
                        TCPIPDEV
                        TCPIPDEV
                                      432 Mar 17 10:30 TEST.EXEC
-rwx---r-x 1 MIKEW TCPIPDEV 10640 Mar 18 13:28 TEST1.INFO
250 List completed successfully
Command:
```

EBCDIC

Purpose

Use the EBCDIC subcommand to change the file transfer type to EBCDIC.

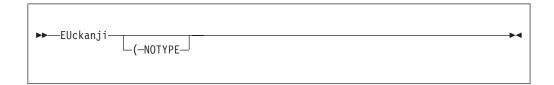

Operands

The EBCDIC subcommand has no parameters.

Usage Notes

• The EBCDIC transfer type is used to transfer files to or from another EBCDIC host. For more information about file transfer methods, see Table 6 on page 47.

EUCKANJI

Purpose

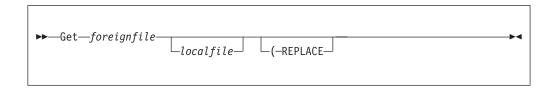

Use the EUCKANJI subcommand to change the file transfer type to Extended UNIX Code (EUC) Kanji.

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

GET

Purpose

Use the GET subcommand to transfer a file from a foreign host to the local host.

Operands

foreignfile

The foreign host file to be retrieved. For information about how to specify *foreignfile* see "File Name Formats" on page 42.

localfile

The name of the local file to be created. For information about how to specify *localfile*, see the "Usage Notes" for this subcommand and "File Name Formats" on page 42.

REPLACE

Causes any *localfile* that already exists to be overwritten with the content of the *foreignfile* that is retrieved. If *localfile* already exists and the REPLACE operand is not specified, FTP does not overwrite the existing file; it instead issues an informational message that identifies the existing file.

Usage Notes

- To retrieve a file from a foreign host, a working directory must be established for which you have at least "read" privilege. For more information, see the description of the subcommands "ACCT" on page 54 and "CD or CWD" on page 57.
- The *localfile* is created at the local working directory by default that is, when a file mode is not specified or is specified as an asterisk (*).
- If *localfile* is not specified, FTP attempts to create a file that is named to match that of the retrieved foreign file (with measures taken to meet z/VM file naming conventions and restrictions). Thus, if *foreignfile* is a BFS file, *localfile* should be explicitly specified, since the default file name produced may not be as expected.
- If the foreign file is named using a Unix or Unix-like format, the *localfile* name and type are derived from that part of the *foreignfile* name that follows the right-most slash (/) that is present.
- The retrieval of a foreign file directly to a BFS directory is not supported by the CMS FTP client. However, this can be accomplished with a two-step process.
 First, use the FTP GET subcommand to retrieve the file to a local SFS directory or minidisk; then, use the CMS OPENVM PUTBFS command to copy that file to its final location.
- When files are transferred between two hosts, appropriate transmission attributes
 must be used to ensure the content and structure of any transferred file are
 preserved. For more information, please refer to "Controlling File Translation" on
 page 47.

HANGEUL

Purpose

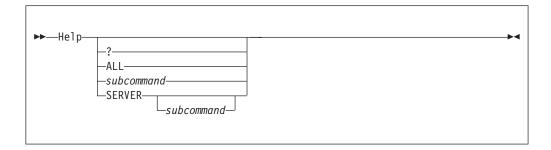

Use the HANGEUL subcommand to change the file transfer type to Hangeul.

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

HELP

Purpose

Use the HELP subcommand to get help with FTP subcommands.

Operands

? Provides information about how to use FTP.

ALL

Displays a description of all subcommands.

subcommand

Specifies the name of the subcommand. The *subcommand* can be abbreviated to its minimum abbreviation.

SERVER

Displays the help offered by the foreign host for the internal FTP commands.

Usage Notes

 If you enter the HELP subcommand without a parameter, you see the HELP FTP MENU, which lists the subcommands and a description of the help information available. If you enter the ? subcommand without a parameter, you see information about how to use the subcommands.

IBMKANJI

Purpose

Use the IBMKANJI subcommand to change the file transfer type to IBM Kanji.

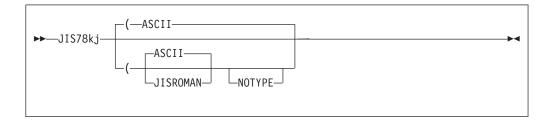

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

This option usually causes *no* conversion to be performed on the transferred file. This option has exactly the same effect as the EBCDIC TYPE command alias.

JIS78KJ

Purpose

Use the JIS78KJ subcommand to change the file transfer type to JIS78KJ (1978 edition).

Operands

ASCII

Use ASCII shift-in escape sequence ESC (B

JISROMAN

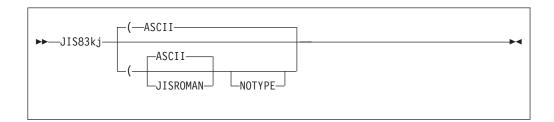

Use JISROMAN shift-in escape sequence ESC (J

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

If neither ASCII nor JISROMAN is specified, then the ASCII shift-in sequence will be used.

JIS83KJ

Purpose

Use the JIS83KJ subcommand to change the file transfer type to JIS83KJ (1983 edition).

Operands

ASCII

Use ASCII shift-in escape sequence ESC (B

JISROMAN

Use JISROMAN shift-in escape sequence ESC (J

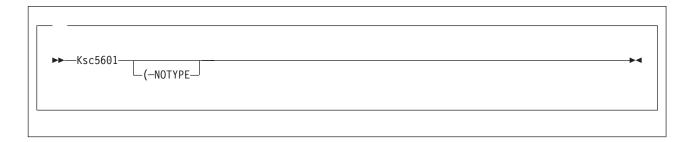

FTP Subcommands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

If neither ASCII nor JISROMAN is specified, then the ASCII shift-in sequence will be used.

KSC5601

Purpose

Use the KSC5601 subcommand to change the file transfer type to KSC-5601.

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

LCD

Purpose

Use the LCD subcommand to change the working directory on the local host.

Operands

directory

The CMS file mode of an accessed minidisk or SFS directory to be used as the current working directory on the local host.

Examples

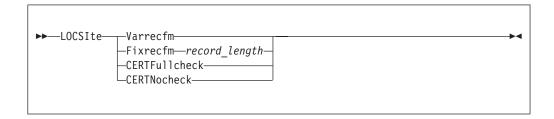

Response displayed after invoking the LCD subcommand:

```
Local directory mode is 'Z' Command:
```

Usage Notes

· LCD to a BFS directory is not supported by TCP/IP.

LOCSITE

Purpose

Use the LOCSITE subcommand to change the record format and record length used for files created on the local host, or to change how secure connections should be handled based certificate verification results.

Operands

Varrecfm

Specifies that the variable record format is to be used.

Fixrecfm record length

Specifies that the fixed-record format is to be used. The parameter *record_length* specifies the record length for fixed records.

CERTFULLCHECK

The remote server certificate and any associated CA certificates are verified for correctness, for control and data connections. If a certificate error is detected, the corresponding connection fails.

A self-signed certificate cannot be used for secure connections unless it has been added to the local certificate database. For more information, see Using Self-Signed Certificates in *z/VM: TCP/IP Planning and Customization*.

CERTNOCHECK

The CERTNOCHECK operand is accepted and ignored. All connections are handled as described for the CERTFULLCHECK operand.

LOCSTAT

Purpose

Use the LOCSTAT subcommand to display local status information.

Operands

The LOCSTAT subcommand has no parameters.

The following status information is displayed:

FTP Subcommands

- Value of the TRACE flag (set using the FTP command or the DEBUG subcommand)
- SENDPORT setting (true or false)
- SENDSITE setting (true or false)
- Name, port number, and logon status of the foreign host
- · Port number of the local host
- FTP data type (ASCII, EBCDIC, or Image) and transfer mode (block or stream)
- Record format (fixed or variable) and record length (for fixed record format)
- · Translate table used by the client
- NETRC DATA file usage setting (true or false)
- Logon prompt setting (true or false)
- · Console Width setting
- Secure control connection setting
- Secure data connection setting

Examples

1

Information displayed after invoking the LOCSTAT subcommand:

```
Trace:FALSE, Send Port:TRUE
Use NETRC DATA File:TRUE, Logon Prompting:TRUE
Send Site with Put command: TRUE
Connected to:YKTVMX, Port:FTP control (21), logged in
Local Port:3452
Data type:a, Transfer mode:s
Record format:V
Secure control connection: TRUE (CERTFULLCHECK)
Secure data connections: TRUE (CERTFULLCHECK)
Translate Table: STANDARD
User Specified Translate Table: POSIX
Console Width: 80
Command:
```

LPWD

Purpose

Use the LPWD subcommand to display the name of the current working directory on the local host.

Operands

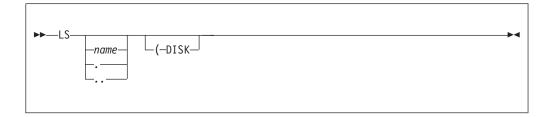

The LPWD subcommand has no parameters.

Examples

The following is an example of the response displayed as the result of the LPWD command.

Local directory is 'Z' Command:

LS

Purpose

Use the LS subcommand to list only the name(s) of a set of foreign files, file group, or directory.

Operands

name

The name of the directory or file group on the foreign host for which files should be listed. If name is omitted, all directory entries or files for the current working directory or file group are listed. For information about how to specify *name*, see the "Usage Notes" for this subcommand and "File Name Formats" on page 42.

To select which directory or file group is current, use the CD subcommand. For more information see "CD or CWD" on page 57.

- Specifies that list information should be returned for the current working directory. For z/VM hosts, this operand is recognized in this manner only when SFS, HMC, or BFS directories are referenced. For other z/VM resources, responses are returned as if no operand had been specified.
- .. Specifies that list information should be returned for the *parent directory* of the current working directory. For z/VM hosts, this operand is recognized in this manner only when SFS, HMC, or BFS directories are referenced. For other z/VM resources, responses are returned as if no operand had been specified.

DISK

Stores the results of the DIR subcommand in file FTP LSOUTPUT, on the current local working directory. DIR subcommand results are not displayed when this operand is used.

Usage Notes

- The LS subcommand provides a list of directory and file names only. To obtain a list of directory and file entries that includes auxiliary information about those entries, use the DIR subcommand. For more information, see "DIR" on page 64.
- For a given z/VM file system group, the response returned for an LS subcommand, regardless of whether VM-format or Unix-format lists are in use, is the same.
- If the LS subcommand is issued for a BFS directory that contains other than regular BFS files, a z/VM foreign host may return an error response that indicates a BFS directory error has occurred.
- For z/VM foreign hosts, pattern matching can be used to specify a subset of files about which information is returned. For more information see "File Name Pattern Matching" on page 43.

FTP Subcommands

Note: z/VM hosts do not support pattern matching for BFS files and directories.

Examples

A sample response to an LS subcommand follows. In this example, pattern matching has been used to obtain a list of only those files for which the file name begins with a "T":

```
Command:
1s t*
>>>PORT 9,117,32,30,4,53
200 Port request OK.
>>>LIST
125 List started OK
TCPIP.DATA
TCPMNT2.NETLOG
TCPMNT2.SYNONYM
TCPSLVL.EXEC
TEST.EXEC
TESTFTPB.EXEC
TRACE2.TCPIP
250 List completed successfully.
Command:
```

A sample LS response for a z/VM virtual reader working directory is shown here:

```
Command:
1 s
>>>PORT 9,117,32,29,10,213
200 Port request OK.
>>>LIST
125 List started OK
0013.CIBULAPR.MAIL
0154.FL3XSAMP.TXT
0116.TCP-HELP.LIST3820
0115.TCP-OVER.LIST3820
0153.FL32SAMP.TXT
0214.CIBULAMA.MAIL
250 List completed successfully.
Command:
```

MDELETE

Purpose

Use the MDELETE subcommand to delete multiple files on the foreign host.

Operands

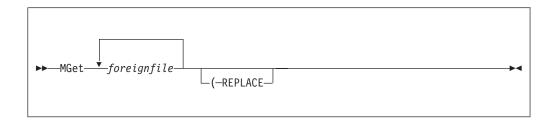

foreignfile

A foreign host file or file group to be deleted. For information about how to specify foreignfile see "File Name Formats" on page 42.

Usage Notes

- For z/VM foreign hosts, pattern matching can be used to specify a subset of files to be deleted. For more information, see "File Name Pattern Matching" on page 43.
- To delete multiple files to which pattern matching cannot be applied, repeat foreignfile as necessary, with each foreignfile specification separated by at least one space.

MGET

Purpose

Use the MGET subcommand to transfer a file or group of files from a foreign host.

Operands

foreignfile

A foreign host file or file group to be retrieved. For information about how to specify *foreignfile* see "File Name Formats" on page 42.

REPLACE

Causes an existing local file of the same name as *foreignfile* to be overwritten with the content of a corresponding *foreignfile* that is retrieved. If the local file already exists and the REPLACE operand is not specified, FTP does not overwrite the existing file; it instead issues an informational message that identifies the existing file.

Usage Notes

- To retrieve files from a foreign host, a working directory must be established for which you have at least "read" privilege. For more information, see the subcommands "ACCT" on page 54 and "CD or CWD" on page 57.
- For z/VM foreign hosts, pattern matching can be used to specify a subset of files to be retrieved. For more information, see "File Name Pattern Matching" on page 43.
- To retrieve multiple files to which pattern matching cannot be applied, repeat *foreignfile* as necessary, with each *foreignfile* specification separated by at least one space.
- The MGET subcommand creates local files in the same manner as those created (on a single-file basis) when the GET subcommand is used. For more information, see the GET subcommand "Usage Notes" on page 67.
- When files are transferred between two hosts, appropriate transmission attributes must be used to ensure the content and structure of any transferred file are preserved. For more information, please refer to "Controlling File Translation" on page 47.

MKDIR

Purpose

Use the MKDIR subcommand to create a new directory on the foreign host.

Operands

directory

The name of the new directory to be created. The directory specified can be a fully-qualified SFS name, just an SFS directory name (without a specified filepool), a fully-qualified BFS name, or a BFS subdirectory name.

Usage Notes

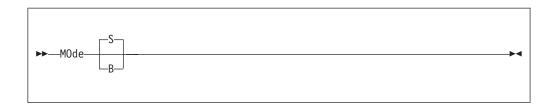

- Because of the way FTP handles searches, avoid naming any SFS or BFS subdirectories with the same name as a CMS minidisk that you might want to access using FTP.
- MKDIR is allowed for the owner of the root directory where the new directory is to be created, or for SFS administrators and BFS super users. The POSIX and SFS permissions associated with the user ID you supply with the USER subcommand determine what directories can be created using the MKDIR command.

General SFS users can create directories only in their own filespace. For BFS users, the POSIX permission checking performed by native BFS support determines whether the MKDIR can be done. An SFS file pool administrator or BFS super user has authorization to create directories for anyone enrolled in a filepool. The FTPSERVE machine is an SFS file pool administrator and a BFS super user, therefore inheriting all of the privileges of the registered user ID. See z/VM: TCP/IP Planning and Customization for more details.

- You must CD to an existing SFS or BFS directory before you can issue MKDIR.
- The VM FTP server initially creates an SFS file control directory. To change the SFS directory to Dircontrol, issue the SITE DIRATTR dirid DIRControl command. See the SITE command for more information.

For more information on SFS naming conventions, see the z/VM: CMS User's Guide or the z/VM: SFS and CRR Planning, Administration, and Operation book.

MODE

Purpose

Use the MODE subcommand to define how bits of data are to be transmitted, setting the mode (data format for the file transfer).

Operands

- Sets stream mode. Stream mode is the default transfer mode. In stream mode, data is transmitted as a stream of bytes. Any representation type can be used with stream mode. Stream mode is more efficient, because data block information is not transferred.
- **B** Sets block mode. In block mode, data is transmitted as a series of data blocks, preceded by one or more header bytes. Block mode allows the transfer of binary data and preserves the logical record boundaries of the file.

See Table 6 on page 47 for more information about file transfer methods.

MPUT

Purpose

Use the MPUT subcommand to transfer a file or group of files to a foreign host.

Operands

localfile

A local file or file group on the local host to be transferred to the foreign host. For information about how to specify *foreignfile* see "File Name Formats" on page 42.

Usage Notes

- To transfer files to a foreign host, a working directory must be established for which you have at least "write" privilege. For more information see the subcommands "ACCT" on page 54 and "CD or CWD" on page 57.
- For z/VM foreign hosts, pattern matching can be used to specify a subset of local files to be transferred. For more information see "File Name Pattern Matching" on page 43.
- To transfer multiple files to which pattern matching cannot be applied, repeat *localfile* as necessary, with each *localfile* specification separated by at least one space or blank.
- The MPUT subcommand creates foreign files in the same manner as those created (on a single file basis) when the PUT subcommand is used. For more information see the Usage Notes for "PUT" on page 81.
- When files are transferred between two hosts, appropriate transmission attributes
 must be used to ensure the content and structure of any transferred file are
 preserved. For more information, please refer to "Controlling File Translation" on
 page 47.

NETRC

Purpose

Use the NETRC subcommand to enable or disable automatic logon capability through use of a NETRC DATA file.

Operands

The NETRC subcommand has no parameters.

Usage Notes

 The NETRC subcommand acts as a toggle that enables or disables FTP's use of a NETRC DATA file. This file allows you to maintain logon user name and password information for specific hosts; when you connect to such a host, login is performed automatically, using the values defined in this file. For more information see "The NETRC DATA File" on page 30.

NOOP

Purpose

Use the NOOP subcommand to determine if the foreign host is still responding.

Operands

The NOOP subcommand has no parameters.

Usage Notes

• If the foreign host is responding, you receive one of the following responses.

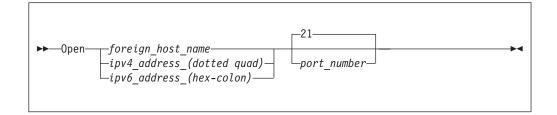

200 OK

or

200 NOOP command successful

You are prompted for the next FTP subcommand after the message is displayed, unless the EXIT parameter of the FTP command is active.

OPEN

Purpose

Use the OPEN subcommand to open a connection to the foreign host's FTP server when:

- You want to open another connection after closing one without leaving the FTP subcommand environment
- You were unable to open a connection after specifying a foreign_host with the FTP command

Operands

I

```
foreign host name
```

The host name or internet address of the foreign host.

```
IPv4_address_(dotted quad)
```

"Old" style IP address in dotted quad notation. For example, "123.45.67.89".

```
IPv6 address (hex-colon)
```

"New" style IP address in hex-colon notation. For example,

"1234:5678::ABCD:EF09"

port_number

A port on the foreign host. The default is port 21, which is also known as a well-known port.

Usage Notes

- If you are already connected to a foreign host, you must disconnect from the foreign host before you can connect to a different host with the OPEN subcommand. For more information about closing a connection, see "CLOSE" on page 61.
- If a NETRC DATA file is in use and a valid match is found for the specified host name, that host's user name and password will be used to automatically logon to that host. If no match is found, or if the use of a NETRC DATA file is suppressed, automatic login will not occur; a subsequent USER subcommand must be issued in order to logon to the foreign host.

Examples

In this example, a CLOSE subcommand is used to terminate the FTP connection that is currently active, and an OPEN subcommand is then used to establish a connection with the GDLVMK4 host.

```
Command:
close
>>>QUIT
221 Quit command received. Goodbye.
Command:
```

FTP Subcommands

open gdlvmk4 Connecting to gdlvmk4 9.130.48.75, port 21 220-FTPSERVE IBM VM Level 420 at GDLVMK4.VMTEST.ENDICOTT.IBM., 15:02:07 EST THURSDAY 2001-12-13 220 Connection will close if idle for more than 5 minutes. USER (identify yourself to the host): teri >>>USER teri 331 Send password please. Password: >>>PASS ******* 230-TERI logged in; working directory = TERI 191 (ReadOnly) 230 write access currently unavailable Command:

PASS

Purpose

Use the PASS subcommand to supply a login password to a foreign host (if one is required by that host) in order to validate the identity of a previously supplied login user name.

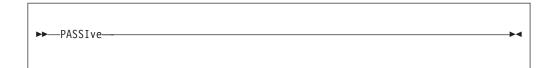

Operands

password

The logon password to be used on the foreign host. If you supply an incorrect password, you are not prompted to enter the password again. You must instead issue a USER subcommand and again identify yourself to the remote host before you can supply the correct password using another PASS subcommand.

Note: If the password contains leading or trailing blanks, or begins with a single quote, it must be surrounded by single quotes and any imbedded single quotes must be doubled. Otherwise, the exact password should be entered. If a password containing leading or trailing blanks is entered without surrounding the password with single quotes, leading and trailing blanks will be removed from the password before sending the password to the FTP server.

PASSIVE

Purpose

Use the PASSIVE command to control whether the client or the server establishes connections for data transfers.

Operands

The PASSIVE subcommand has no parameters.

Usage Notes

• By default, passive data transfers are turned off when you start FTP. Each time you use the PASSIVE subcommand, passive data transfers are turned on and off alternately. If PASSIVE is on, the FTP client sends the server a PASV/EPSV command and uses the response to determine which address and port to use when establishing the data connection with the server. If PASSIVE is off, the client sends the server a PORT/EPRT command (if the SENDPORT subcommand is on) containing the address and port the server should use to establish the data connection with the client.

 Passive data transfer may enable the use of FTP through a firewall that does not allow incoming connections.

PRIVATE

Purpose

Use the PRIVATE subcommand to cause the FTP client to set up for secure data connections using TLS.

Operands

The PRIVATE subcommand has no parameters.

Usage Notes

- Once a PRIVATE subcommand succeeds, data transmissions are confidentiality and integrity protected by encryption.
- PRIVATE is not valid when there is no active security mechanism.
- PRIVATE overrides an FTP DATA SECUREDATA statement value of NO and the use of the NOSECURE option on the FTP command.
- PRIVATE is not allowed if the control connection is not secure
- If set up for secure data connections is unsuccessful, attempts to open a data connection will be rejected. To override this while in FTP session, enter the CLEAR command.

PUT

Purpose

Use the PUT subcommand to transfer a file from the local host to a foreign host.

Operands

localfile

A file on the local host that is to be transferred to and created on the foreign host. For information about how to specify localfile see "File Name Formats" on page 42.

foreignfile

The foreign host file to be created. For information about how to specify foreignfile see "File Name Formats" on page 42.

Usage Notes

- To transfer files to a foreign host, a working directory must be established for which you have at least "write" privilege. For more information, see the subcommands "ACCT" on page 54 and "CD or CWD" on page 57.
- If a file mode is not specified for the *localfile*, the file mode of the local working directory is first searched for this file; if found, this localfile is sent to the foreign host. If the localfile is not found at the local working directory, the first such file present in the CMS search order is transferred.
- · In general, if a foreign host file already exists that matches the name of the transferred localfile, the existing foreign host file is replaced; this is the case for z/VM foreign hosts. For non-z/VM hosts, whether a foreign file is automatically replaced is dependent on the storage method used by that host.
 - The "SUNIQUE" subcommand can be used to avoid overwriting a file that already exists on a foreign host. See "SUNIQUE" on page 91 for more information.
- Attempts to create the same foreign host file at a given time through different FTP connections may produce unexpected results. Some hosts may reply with a message that indicates a PUT or MPUT request should be resubmitted when such a condition is encountered.
- For z/VM hosts, when a transfer type of **Image** is used and the working directory on the foreign host is a minidisk or SFS directory, files are stored as variable-record (V) format files by default. To have files stored as fixed-record (F) format files for an Image mode transfer to these file system groups, do the following:
 - 1. Issue the SENDSITE subcommand to prevent SITE subcommands from being automatically issued for any PUT (or MPUT) subcommands that will be issued.
 - 2. Issue the SITE FIXRECM nn command to set the record length to be used when files are created.
- When an image file is stored on a z/VM foreign host as a fixed-record (F) format file, the last record of that file can be incomplete (that is, data stored using the last record does not consume the entire record). In such a case, this last record is padded with zeros (0).
- The transfer of a local file that resides in a BFS directory is not supported by the CMS FTP client. However, this can be accomplished with a two-step process. First, use the CMS OPENVM GETBFS command to copy that file from the BFS directory where it resides to a local SFS directory or minidisk; then, after this SFS directory or minidisk is established as the current local directory, issue the FTP PUT subcommand to transfer the file to the foreign host.

 When files are transferred between two hosts, appropriate transmission attributes must be used to ensure the content and structure of any transferred file are preserved. For more information, please refer to "Controlling File Translation" on page 47.

PWD

Purpose

Use the PWD subcommand to display the name of the current working directory on the foreign host.

Operands

The PWD subcommand has no parameters.

Examples

 The following is an example of the information displayed after invoking the PWD subcommand if the current working directory is a minidisk.

```
257 'KRASIK1.0191' is working directory Command:
```

 The following is an example of the information displayed after invoking the PWD subcommand if the current working directory is an SFS directory.

```
257 'SERVER1:KRAS1' is working directory Command:
```

• The following is a sample of the information displayed after invoking the PWD subcommand if the current working directory is a BFS directory.

```
257 './.../VMBFS:BFS:KRASIK1/' is working directory Command:
```

 The following is a sample of the information displayed after invoking the PWD subcommand if the current working directory is a VM reader.

```
257 "TERI.RDR" is working directory Command:
```

QUIT

Purpose

Use the QUIT subcommand to disconnect from the foreign host and end FTP processing.

Operands

The QUIT subcommand has no parameters.

QUOTE

Purpose

Use the QUOTE subcommand to send an uninterpreted string of data to the server port on the foreign host. The QUOTE subcommand bypasses the FTP interface of the local user to send commands that the foreign server understands, but the local host does not understand.

Operands

string

Data to be sent verbatim to the port on the foreign host.

Usage Notes

 The QUOTE subcommand allows you to use commands that TCP/IP does not support, such as the FTP ALLOcate subcommand.

Examples

 To send the ALLOcate subcommand to a non-VM foreign host that supports ALLOcate, enter:

QUOTE ALLO bytes

Where:

ALLO Is the FTP standard string for the ALLOcate subcommand.

bytes Is the number of bytes to allocate.

To send a password to the VM FTP server, enter:

QUOTE ACCT password

In this example, the local host implements FTP in a way that does not support the ACCT subcommand, but the foreign host requires a password to obtain a write link to a minidisk.

RENAME

Purpose

Use the RENAME subcommand to rename a file on the foreign host.

Operands

foreignfile

The foreign host file that is to be renamed. For more information about how to specify *foreignfile* see "File Name Formats" on page 42.

newfile

The new name to be given to *foreignfile* For more information about how to specify *newfile* see "File Name Formats" on page 42.

Usage Notes

 For a z/VM foreign host, you cannot use the RENAME subcommand to relocate a file in a different directory; a directory change is not permitted when a file is renamed.

Similarly, you cannot replace an existing CMS file by using this subcommand. For example, if a file named *newfile* already exists, that file, as well as the existing *foreignfile* are maintained without change when a RENAME operation is attempted. In such a case, an error reply is returned that indicates the RENAME operation has failed.

For a non-z/VM foreign host, the RENAME subcommand may cause an existing
file to be deleted. That is, if the files foreignfile and newfile already exist on the
foreign host, the content of the existing newfile file can be lost when its name is
assigned to foreignfile.

RMDIR

Purpose

Use the RMDIR subcommand to remove a directory you own on a foreign host.

Operands

directory

The name of the directory to be removed.

Usage Notes

- Before issuing an RMDIR subcommand, the user ID identified in the USER subcommand must first be using SFS or BFS (have a working directory in some SFS or BFS directory).
- You cannot remove the current working directory. You must first change to a
 different directory, and then issue an RMDIR subcommand to remove the desired
 directory. Note that the usual restrictions regarding non-empty
 directories/subdirectories may prevent an RMDIR from being executed
 successfully. Refer to the CMS User's Guide for further information.
- The directory specified can be a fully-qualified SFS or BFS name or just an SFS or BFS directory name (without a specified file pool).

SENDPORT

Purpose

Use the SENDPORT subcommand to toggle PORT/EPRT commands.

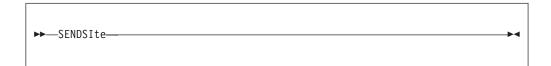

Operands

The SENDPORT subcommand has no parameters.

Usage Notes

- By default, the SENDPORT subcommand is turned on when you start the machine. Each time you use the SENDPORT subcommand, it is turned alternately on and off.
- FTP uses a PORT/EPRT command by default when establishing a connection for each data transfer. FTP does not send PORT/EPRT commands for data transfer when you use the SENDPORT subcommand to disable PORT/EPRT commands.
- SENDPORT is useful for communication with FTP implementations that ignore PORT/EPRT commands, but show (incorrectly) that the PORT/EPRT command has been accepted.
- The SENDPORT setting is ignored when passive data transfer mode is established using the PASSIVE subcommand. This is because no PORT/EPRT command is transmitted by the client in passive mode.

SENDSITE

Purpose

Use the SENDSITE subcommand to toggle the sending of site information.

Operands

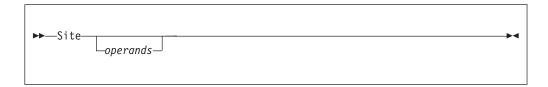

The SENDSITE subcommand has no parameters.

Usage Notes

- By default, the SENDSITE subcommand is turned on when you start FTP. Each time you use the SENDSITE subcommand, it is turned alternately on and off. If SENDSITE is on, site information is sent to the foreign host with the PUT or MPUT subcommands. If SENDSITE is off, no site information is sent.
- By default, FTP sends a SITE subcommand containing record format information, when you issue the PUT or MPUT subcommand. Record format information is used by VM and MVS[™] foreign hosts.

 If the foreign host is non-VM, you can use the SENDSITE subcommand to prevent the record format information from being sent.

SITE

Notes:

- 1. The recognition and validation of operands specified with the SITE subcommand is dependent on the foreign host.
- 2. The handling of incorrect or extraneous operand information may vary from one host to another. Some hosts may respond with an error reply code when a SITE command is considered to be in error, whereas another host may simply ignore such a command.

Purpose

Use the SITE subcommand to send information to a foreign host in order to make use of services which are specific to that system.

Operands

Ι

Ι SITE subcommand operands that are supported by the *current* function level z/VM FTP server are described in this section. Some of these operands may not be supported by vm; hosts on which a prior function level is in use.

AUTOTrans ON | OFF

Specifies whether automatic EBCDIC-ASCII file translation, based on file extensions, is performed by a z/VM FTP server when files are transferred using the **Image** transfer type. Specify AUTOTRANS ON if automatic file translation should be performed, or AUTOTRANS OFF to prevent such translation. For more information about factors that affect file translation, see "Automatic File Translation" on page 48.

DIRATtr dirid **DIRControl** | **FILecontrol** (options

Sets the directory attribute of the SFS directory specified. For a further explanation of available options, see z/VM: CMS User's Guide.

FIXrecfm record length

Specifies that the fixed-record format is to be used. The parameter record length specifies the record length for fixed records.

GRAnt AUTh fn ft dirid **TO** userid (options

Grants authority for a user to a directory or files. userid can be a nickname in the FTP server's NAMES files. See the z/VM: CMS Commands and Utilities Reference for details of the GRANT AUTHORITY command.

LISTFormat VM | UNIX [ASCII | BINARY | EBCDIC]

Specifies the format to be used for file list information that is returned in response to DIR (or, LIST) subcommands. Specify LISTFORMAT VM for VM-format lists to be supplied by the FTP server, or LISTFORMAT UNIX if Unix-format lists should be returned. With LISTFORMAT UNIX, you can optionally specify the transfer mode (ASCII, BINARY, or EBCDIC) whose resulting size should be shown as file size in the output of the DIR (or, LIST)

FTP Subcommands

subcommands. The default transfer mode is ASCII. For more information about VM-format and Unix-format responses, see "File List Formats" on page 49.

PERMit pathname mode string (REPlace | ADD | REMove

Issues an OPENVM PERMIT command to change the permission bits used to control the owner access, group access, and general access to a BFS object. *Pathname* can be specified as a relative pathname or a fully-qualified pathname. To issue the SITE PERMIT command, you must be the owner of the BFS object or have the appropriate privileges. See the *z/VM: OpenExtensions Commands Reference* for details of the OPENVM PERMIT command.

QAUTH fn ft

Queries the authority of the current working directory or files in the directory. The *fn* and *ft* parameters are optional. If *fn* or *ft* is omitted, QAUTH returns the directory authority information. See the *z/VM: CMS Commands and Utilities Reference* for details of the QUERY AUTHORITY command.

ODIRattr dirid

Returns the directory attribute of the SFS directory specified.

QDISK

Returns the disk information for the current working directory. If the current working directory is an SFS subdirectory, the information returned is the result of the CMS QUERY DISK and CMS QUERY LIMITS commands. If the current working directory is a BFS directory, the information returned is the result of the CMS QUERY LIMITS command. See the *z/VM: CMS Commands and Utilities Reference* for details on the QUERY DISK and QUERY LIMITS commands.

QPERMit pathname (OBJ

Returns the output of the OPENVM LISTFILE (OWNERS command for the current working directory, or for the specified *pathname*. If *pathname* is omitted the QPERMIT command returns information for the current working directory. The *Pathname* can be specified as a relative pathname or it can be fully qualified. *OBJ* is optional and if specified, will return the output of OPENVM LISTFILE (OWNERS OBJECT command for the current working directory or pathname. See the *z/VM: OpenExtensions Commands Reference* for details of the OPENVM LISTFILE (OWNERS command.

REVoke AUTh fn ft dirid FROM userid (options

Revokes authority for a user to a directory or files. *userid* can be a nickname in the FTP server's NAMES files. See the *z/VM: CMS Commands and Utilities Reference* for details of the REVOKE AUTHORITY command.

TRANslate filename

XLATe filename

Specifies the name of the translation table to use on the server side. The translation table specifies the name of an EBCDIC-ASCII translation table that is to be used for all subsequent ASCII file transfers. To use the default translation table, issue either a SITE XLATE or a SITE XLATE * command. The specified translation table must be a TCPXLBIN file available on the remote z/VM or OS/390 host. See *z/VM: TCP/IP Planning and Customization* for further information on loading and customizing translation tables, as well as Chapter 14, "Using Translation Tables," on page 409.

The name of translation table to use on the client side is controlled by the TRANslate option on the FTP command. See "FTP Command" on page 26.

VARrecfm

Specifies that the variable-record format is to be used.

Usage Notes

- To obtain information about site-specific operands that are supported by a foreign host, issue the **HELP SERVER SITE** command.
- By default, the z/VM PUT and MPUT subcommands automatically issue a SITE subcommand before a file is transferred. This is done to provide CMS file record format information to the foreign host (under the assumption that the foreign host can make use of this information, which is the case for IBM EBCDIC host systems).
- The SENDSITE subcommand can be used to prevent SITE subcommands from being automatically issued by the PUT or MPUT subcommands. For more information see "SENDSITE" on page 86.
- For the operands that follow, dirid can be specified as a single period (.) to signify the current foreign host working directory:

DIRATTR, GRANT, QDIRATTR, REVOKE

- For SITE operands that require an SFS directory (*dirid*), specify this directory using the same syntax as for other SFS-related CMS commands. For more information about the naming of SFS directories, see the *z/VM: CMS Commands* and Utilities Reference.
- The operands that follow are accepted only when the foreign host working directory is an SFS directory:

DIRATTR, GRANT, QUATH, QDIRATTR, REVOKE

 The operands that follow are accepted only when the foreign host working directory is a BFS directory:

PERMIT, QPERMIT

SIZE

Purpose

Use the SIZE subcommand to retrieve the transfer size (in bytes) for a foreign host file.

Operands

foreignfile

Specifies the foreign host file for which size information is to be retrieved. For more information about how to specify *foreignfile* see "File Name Formats" on page 42.

The returned file transfer size may account for included record delimiter or block header bytes, depending on the current TYPE and MODE settings.

SJISKANJI

Purpose

Use the SJISKANJI subcommand to change the file transfer type to SJISKANJI.

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

Note: JIS is the abbreviation for the Japan Institute of Standards.

STATUS

Purpose

Use the STATUS subcommand to retrieve status information from the foreign host.

Operands

name

Specifies the file or foreign directory for which status information is requested. The *name* parameter is not supported by the VM FTP server.

Usage Notes

 The retrieved status information can be a directory, a file, or general status information, such as a summary of activity. If name is omitted, general status information is retrieved.

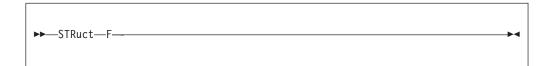

Examples

· Information displayed after invoking the STATUS subcommand:

```
211-Server FTP talking to host 129.34.128.246, port 3452
User: KRASIK1 Working directory: KRASIK1 0191
The control connection has transferred 399 bytes.
There is no current data connection.
The next data connection will be actively opened to host 129.34.128.246, port 3452, using mode Stream, structure File, type ASCII Nonprint, byte-size 8. record format is V, record length 65535
```

List format is UNIX. Automatic file translation is ON. FTPSERVE Translate Table: STANDARD
211 User Specified Translate Table: POSIX
Command:

STRUCT

Purpose

Use the STRUCT subcommand to set the structure of the file.

Operands

F Shows the file structure. The F file structure is the only structure supported. The file structure affects the transfer mode, and the interpretation and storage of the file. With a file structure of F, the file is considered to be a continuous sequence of data bytes.

SUNIQUE

Purpose

Use the SUNIQUE subcommand to toggle the method of storing files.

Operands

The SUNIQUE subcommand has no parameters.

Usage Notes

- By default, SUNIQUE is toggled off, and FTP uses a store command (STOR) with the PUT and MPUT subcommands. If the foreign host already has a file with the name specified by *foreignfile*, the foreign host overwrites the existing file.
- If SUNIQUE is toggled on, FTP uses a store-unique command (STOU) with the PUT and MPUT subcommands, and prevents you from erasing the existing file on the foreign host that is specified by *foreignfile*. The created foreign file is stored with a unique file name. FTP sends the name of the created foreign file to the local host, where the file name is displayed on your terminal.
- To uniquely store files or copies of files when the named foreignfile already exists, the z/VM FTP server generates unique file names by appending a numeric suffix (from 1 to 999, in increments of 1) to the foreignfile name provided as part of a PUT or MPUT command. The foreignfile name is truncated (if necessary) to allow inclusion of this suffix. A maximum of 999 uniquely-named copies of a file can be created on a z/VM host. Note that the foreignfile name is modified only when necessary.

When the "store unique" attribute is in effect, the FTP server identifies file names available for use by first searching the current working directory for the named

FTP Subcommands

file. If the file already exists, the server sequentially checks for similarly-named (and numbered) files until the next available suffix number for constructing a unique file name has been identified.

Notes:

- 1. There is no guarantee that a file with a low suffix number (with respect to the numbering scheme just described) is an older file (with respect to time and date) than a file that has a higher suffix number.
- 2. When uniquely-stored files are selected for deletion, some criteria other than the numeric suffix value should be used. The date and time stamp associated with a file is usually a reasonable compromise choice.
 - For example, if a foreignfile name of UNIQTEST is in use, a file might be stored uniquely with the name UNIQTES9, with an ensuing file stored uniquely as UNIQTE10.
- In rare cases, the file transfers for which the "store unique" attribute is in effect may fail because the foreign host cannot uniquely store a file. For a z/VM host, this would be the case when the z/VM FTP server detects that the named file and all 999 uniquely named copies of the file already exist in the foreign directory. To store a file in this event, one of the following actions may prove successful:
 - Turn off the "store unique" attribute by re-issuing the SUNIQUE subcommand to toggle the setting, then re-attempt the file transfer.
 - Delete one of the uniquely named copies of the file you are attempting to store.

SYSTEM

Note: Information returned in response to the SYSTEM subcommand will vary depending on the foreign host with which an FTP session is established. Other factors, such as configuration parameters or active session attributes, may further affect this response. Note that the SYSTEM subcommand may not be supported by all foreign hosts.

Purpose

Use the SYSTEM subcommand to display information about the operating system that is in use on a foreign host.

Operands

The SYSTEM subcommand has no operands.

Examples

For z/VM hosts that support list format selection, the response to the SYSTEM subcommand can differ, based on the list format in effect for a session.

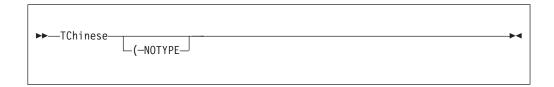

For example, when VM-format lists are in effect, the SYSTEM subcommand response is:

```
215-z/VM Version 3 Release 1.0, service level 0000 (nn-bit) CMS Level 16, Service Level 000 215 VM is the operating system of this server. Command:
```

However, if Unix-format lists are in use, this response is modified to indicate this fact, and the following response is produced:

```
215-z/VM Version 3 Release 1.0, service level 0000 (nn-bit)
CMS Level 16, Service Level 000
215 VM is the operating system of this server. UNIX list format is active.
Command:
```

TCHINESE

Purpose

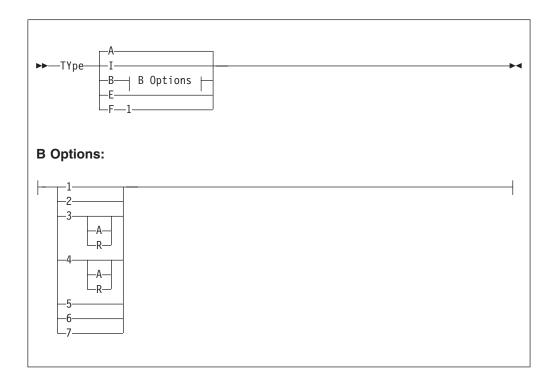

Use the TCHINESE subcommand to change the file transfer type to Traditional Chinese.

Operands

NOTYPE

Used when connecting to an FTP server that does not support the TYPE command generated by this TYPE command alias. See Appendix D, "Using DBCS with FTP and Mail," on page 433 for more information.

TYPE

Purpose

Use the TYPE subcommand to set the file transfer type (the data representation for the transfer). FTP supports the ASCII, EBCDIC, Image (binary), and Kanji file transfer types.

Operands

- Sets the transfer type as ASCII, which is intended for use when text files are transferred to or from an ASCII host. When FTP sessions are established, ASCII is the default transfer type. The TYPE A subcommand has a similar effect as the ASCII subcommand, but it does not alter the record format used to store local files.
- Sets the transfer type as **Image** (or, **binary**), which is intended for use when binary data is transferred or when the efficient storage and retrieval of files is desired. With the Image transfer type, data is sent as contiguous bits, packed into 8-bit bytes. The TYPE I subcommand has a similar effect as the BINARY subcommand, but it does not alter the record format used to store local files.

Note: A transfer type of **Image** must be used when automatic file translation (performed by a z/VM FTP server) is desired.

- Sets the transfer type as DBCS Kanji, Hangeul, or Traditional Chinese. Specifying the B transfer type with the appropriate options has the same effect as using the EUCKANJI, HANGEUL, JIS78KJ, JIS83KJ, KSC5601, SJISKANJI or TCHINESE subcommands. The options provide further DBCS information. For more information about DBCS support for FTP, see Appendix D, "Using DBCS with FTP and Mail," on page 433.
- Sets the transfer type as EBCDIC. Specifying the EBCDIC transfer type has the

- same effect as using the EBCDIC subcommand. The EBCDIC transfer type is intended for efficient transfer between hosts that use EBCDIC for their internal character representation.
- F Sets the transfer type as EBCDIC IBM Kanji. Specifying the IBM Kanji transfer type has the same effect as using the IBMKANJI subcommand. For more information about DBCS support for FTP, see Appendix D, "Using DBCS with FTP and Mail," on page 433.

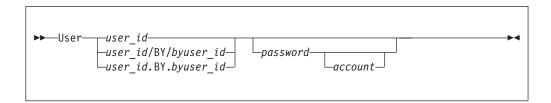

Usage Notes

 For a z/VM foreign host where the FTP server has been configured to perform automatic file translation, the TYPE I subcommand has no effect on file translation — the server continues to determine whether EBCDIC-ASCII translation should occur based only on file extension.

To enable or disable automatic file translation for files transferred using the **Image** transfer type, use the AUTOTRANS operand of the "SITE" subcommand. For more information, see "SITE" on page 87.

• For more information about file transfer methods, see Table 6 on page 47.

USER

Purpose

Use the USER subcommand to identify yourself to a foreign host after an FTP connection has been established.

Operands

user_id

The logon name to be used on the foreign host.

byuser id

An alternate logon name *user_id* to be used by a foreign z/VM host when login authorization is performed.

When the /BY/ or .BY. delimiter and <code>byuser_id</code> are included with <code>user_id</code>, the <code>byuser_id</code> logon password is used for login authorization checking, instead of that for <code>user_id</code>. To be effective, <code>byuser_id</code> must be included in a LOGONBY statement in the <code>user_id</code> CP directory entry. When an External Security Manager (ESM) such as RACF® is installed, its defined authorization criteria may override that defined by CP for the LOGONBY statement. For example, RACF may perform authorization checks for attempts to log on a shared user ID. For further details, refer to the documentation provided by the ESM in use.

password

The logon password to be used on the foreign host. If a password is not included with the USER subcommand, you are prompted to provide a password, if one is required by the foreign host. If you supply an incorrect

FTP Subcommands

password, you are not prompted to enter the password again. You must instead reissue the USER subcommand to supply the correct password.

Note: If the password parameter contains blanks or begins with a single quotation mark, it must be surrounded by single quotation marks, and any imbedded single quotation marks must be doubled. Otherwise, the exact password should be entered. If a password containing blanks is entered without surrounding the password with single quotation marks, leading and trailing blanks will be removed from the password and only the first token of the password will be sent to the FTP server.

account

The host-dependent account information to gain access to specific resources or for a specific kind of access. If the account information contains blanks or begin with a single quotation mark, the account information must be supplied in the same manner described for the password above.

Using FTP Within an EXEC

When the FTP command is used within an exec, FTP subcommands can be supplied by either the program stack or a CMS disk file. Likewise, FTP command results can be directed to either the console, or to a CMS disk file.

Notes:

- 1. FTP supports only DISK and TERMINAL I/O devices when FILEDEF commands are used to manage subcommand input and command results.
- 2. It is recommended that the EXIT option be used when FTP is used within an exec, so that error conditions can be detected and handled, as needed.

Providing FTP Subcommand Input

The program stack is used as the input source for FTP subcommands if the input device DISK has not been defined with a FILEDEF, or if the input device has been defined as TERMINAL.

If subcommand input is to be obtained from a disk file, that file must be identified with the CMS FILEDEF command. When disk file input is obtained by using FILEDEF, the following notes apply:

Notes:

- 1. Only the ddname INPUT is recognized and used by FTP for subcommand input.
- 2. Program stack data is ignored.
- If all FTP subcommands defined in the file complete without incident, and a QUIT was not the last subcommand executed, FTP will supply a QUIT subcommand to end the FTP session.
- 4. When a NETRC DATA file is used to provide logon user name and password values, it is advised that the NOPROMPT option be used to suppress unanticipated prompts for this information; this will cause FTP to return a nonzero return code in the event no NETRC DATA file exists or no entry for the target host is present in this file.
- 5. Because of the processing performed by FTP to obtain login passwords, you must provide the login password with the login name (user ID) when you use FTP within an exec, unless a NETRC DATA file is used to supply these values. (That is, for stack input, the logon password must be queued with the logon name. For disk file input, the password must be part of the same line as the logon name.)

If a foreign host requires account information to be provided, you need to supply values with the ACCT subcommand in this manner as well.

Managing FTP Command Output

By default, FTP dialog output (messages, subcommand reply codes and text) generated during FTP command processing is directed to your terminal. However, FTP command results can be also directed to a disk file. As with subcommand input, the file to receive FTP dialog results must be identified with the CMS FILEDEF command. Only the ddname OUTPUT is recognized and used by FTP for handling FILEDEF command output.

Examples

The following example shows how FTP subcommands could be issued from within a REXX exec. In this example, the CMS program stack is used to supply FTP subcommands. This sample also illustrates a method for checking the return and reply codes from the FTP command.

```
/* FTPSTACK EXEC */
/* Setup variables to hold some commonly-used items. */
/*-----*/
remote host = 'rdrunner.endicott.ibm.com'
login_id = 'coyote'
pass word = 'wileyc'
acct info = 'secretpw'
local_mode = 'A'
remote dir = 'COYOTE.191'
remote_dir = 'COTOTE.191

remote_file = 'ACME' || '.' || 'SURPLUS'

local_file = 'ACME-A1' || '.' || 'CATALOG'

/*-----*/
/* Setup the FTP subcommands to be issued... */
/*----*/
ftpcmd.1 = login id pass word /* USER and PASS responses */
ftpcmd.2 = 'acct' acct_info /* Account info - this will */
                 /* supply the minidisk READ */
                      /* password in this case. */
ftpcmd.3 = 'cd' remote dir
ftpcmd.4 = 'lcd' local mode
/*-----*/
/* Working with another VM host, so set up the transfer */
/* MODE and TYPE for EBCIDIC data -- would do the same for */
/* an MVS host.
/*----*/
ftpcmd.5 = 'mode b'
ftpcmd.6 = 'type e'
/*----*/
ftpcmd.7 = 'get' remote file local file
ftpcmd.8 = 'quit'
ftpcmd.0 = 8
/*----*/
/* Display and queue the FTP subcommands that will be used. */
/*-----*/
'MAKEBUF'
buff num = rc
Say "FTP subcommands being issued are:"
Do ii=1 to ftpcmd.0
 Say ftpcmd.ii
 Queue ftpcmd.ii
End
```

Using FTP Within an EXEC

```
/*----*/
/* Issue the FTP command, and save it's return code. */
/*-----*/
Say ""; Say "Issuing FTP command..."
'FTP' remote_host '(EXIT'
ftprc = rc
'DROPBUF' buff num
/*-----*/
/* Interrogate the FTP command return code, and explain it */
/* to the extent possible.
If (ftprc <> 0)
 Then Do
     fterr = Right(ftprc,3)
     cmdrc = Left(ftprc,(Length(ftprc)-3))
     Say "FTP command code: cmdrc
     Say "FTP Server Reply code:" fterr
     Say "Possible Internal Error code:" fterr
  End
Exit ftprc
```

This next example shows how FTP subcommands could be maintained separately from an exec that makes use of those subcommands. In this example, FTP subcommands to be issued are contained in a CMS file (SPACELY ACCTFTP A), which might contain the following data:

```
jetsong rorge
cd c:\sprocket\accts
lcd a
get sprocket.txt sprocket.acctdata
quit
```

For the data illustrated above, jetsong is the user ID and rorge is the login password. The GET subcommand will cause the file SPROCKET.TXT A to be retrieved as SPROCKET ACCTDATA to the invoking user ID's A disk.

```
/* FTPFILDF EXEC */
/*-----*/
/* Setup variables for host and input/output files. */
/*-----*/
remote host = 'sprocketman.endicott.ibm.com'
input file = 'SPACELY ACCTFTP A'
output_file = 'SPACEFTP RESULTS A'
/*-----*/
/* Check existing FILEDEFS, and account for them as */
/* required. Then establish the desired FILEDEFS.
/*----*/
'PIPE CMS QUERY FILEDEF | Stem filedefs.'
If (filedefs.0 = 0)
 Then Nop
 Else Nop
              /* Add appropriate checking, etc. here */
'ESTATE' input file
If (rc <> 0)
  Then Do
    Say input file "does not exist..."
    Exit 8
   End
  Else 'FILEDEF INPUT DISK' input file
'FILEDEF OUTPUT DISK' output file
/*----*/
/* Issue the FTP command, and save it's return code. */
/*-----*/
Say ""; Say "Issuing FTP command..."
'FTP' remote host '(EXIT'
ftnrc = rc
/* Interrogate the FTP command return code, and explain it */
```

FTP Return Codes

When the FTP command EXIT operand is used, the FTP return code is composed of a command code and a reply code. The following is the format of the FTP EXIT return code:

YYXXX

where:

YY

Is the command code, which is a number from 1 to 99. For a description of the possible FTP command codes, see Table 7.

XXX

Is the reply code that is sent from the foreign host FTP server. The reply code is a 3-digit number. For a description of the possible reply codes, see Table 8 on page 101. At times *XXX* may instead be an FTP internal error code. For a description of possible internal error codes, see Table 9 on page 103. If an FTP server reply code or an internal error code is not available, *XXX* will be zero.

Table 7. FTP Command Codes

Code Number	Command	EXIT_IF_ERROR
1	AMBIGUOUS	true
2	?	false

Table 7. FTP Command Codes (continued)

Code Number	Command	EXIT_IF_ERROR
61	CPROTECT	true
63	PRIVATE	true
64	CLEAR	true
99	UNKNOWN	true

Examples

The following are examples of FTP return codes.

The FTP return code 16550 indicates the following:

16 The GET command failed.

550 The reply code from the FTP server.

The FTP return code 4532 indicates the following:

The APPEND command failed.

532 The reply code from the FTP server.

FTP Reply Codes

When you enter an FTP command, TCP/IP displays the sequence of subcommands, if any, that are sent to the foreign host's FTP server. In addition, the subcommand's response is also displayed as a reply code. These replies ensure the synchronization of requests and actions during file transfer, and guarantee that you always know the state of the foreign host's FTP server. The descriptions of the possible reply codes are listed in Table 8.

Note: In general, the reply code descriptions below will not match the messages received from a foreign host, since reply message text will vary from one server implementation to another. The following descriptions are intended to provide an explanation of the reply codes themselves.

Table 8. FTP Reply Codes

Description
Restart marker reply
Service ready in <i>nnn</i> minutes
Data connection already open; transfer starting

FTP Reply Codes

Table 8. FTP Reply Codes (continued)

Code	Description	
226	Closing data connection; requested file action successful	
227	The FTP server has opened a passive connection for data transfer at the specified IP address and port.	
229	Entering extended passive mode.	
230	User logged on; requested minidisk, BFS, or SFS Directory not available; proceed	
234	Security data exchange complete	
250	Requested file action or directory okay, completed	
255	In target directory already	
257	PATH NAME created or directory status given	
331	Send password please	
332	Supply minidisk password using account	
421	Service not available; closing Telnet connection	
425	Cannot open data connection	
426	Connection closed; transfer ended abnormally	
431	Temporarily unable to process security	
450	Requested action not taken; file busy, minidisks or SFS directory not available	
451	Requested action aborted; local error in processing	
452	Requested action not taken; insufficient storage space in system	
500	Syntax error; command unrecognized	
501	Syntax error in parameters or arguments	
502	Command not implemented	
503	Bad sequence of commands	
504	Command not implemented for that parameter	
521	Data connection cannot be opened with this PROT setting	
522	Unsupported protocol. (1,2)	
530	Not logged on	
532	Need account for storing files	
533	Command protection level denied for policy reasons	
534	Request denied for policy reasons	
550	Requested action not taken; file not found or no access	
551	Requested action aborted; page type unknown	
552	Requested file action ended abnormally; exceeded storage allocation	
553	Requested action not taken; file name not allowed	

1

Internal Error Codes

If an internal error occurs when you enter an FTP command, the reply code is an internal error code rather than an FTP reply code. Table 9 lists the possible internal error codes.

Table 9. Internal Error Codes

Code	Error	EXIT_IF_ERROR
01	NOmoreSLOTS	false
02	TOOfewDOTS	false
03	WOULDclobberFILE	false
04	CMSfileERROR	false
05	CMSfileNOTfound	false
06	CMSdiskFILEid	false
07	CMSinvalidCHAR	false
08	CMSdiskNOTaccessed	false
09	CMSdiskREADonly	false
10	CMSfileNOTaccessed	false
11	BLOCKbutNOTebcdcic	false
12	INITemulationERROR	true
13	OPENwasNOTissued	true
14	NOinputFILE	false
15	CANTwriteTOoutput	false
16	USERwasNOTissued	true
17	FileNOTauthorized	false
18	InvalidRecfm	false
19	InsuffStorage	false
20	AppcVMerror	false
21	SharingConflict	false
22	SysResrcUnavail	false
23	FSOpenError	false
24	InvalidFILEDEFDev	false
25	NoPromptConflict	true
26	InvalidArgString	true
27	NoClosingQuote	true
28	TLSConnAuthFailed	EXIT_IF_ERROR
30	TLSConntrolNotAuth	true
31	TLSConnAlreadyAuth	true
32	TLSConnAlreadyClear	true

For example, the internal error code 13 indicates that an "OPENwasNOTissued" error condition has occurred.

Using FTP with RACF

The Resource Access Control Facility (RACF) allows FTP servers to act as surrogates for other user IDs. This means that the server can access those disks available to that user ID.

The command that allows FTP servers to act as surrogates is provided in a program called FTPPERM EXEC. To use it, enter the command: FTPPERM ADD

If you get an error, contact your system administrator.

You may delete the FTP server's surrogate authority by issuing the command: FTPPERM DELETE

FTPPERM is explained in *z/VM: TCP/IP Planning and Customization*.

Chapter 3. Sending and Receiving Electronic Mail

This chapter describes electronic note and file delivery and also discusses how mail is sent to and from other hosts/users on systems connected through TCP/IP or Remote Spooling Communication Subsystem (RSCS). In addition, this chapter also describes the electronic mail gateway, delivery failures, the OfficeVision® interface, IMAP, and the SMSG interface to the SMTP server.

You can also use SMTP to transfer Kanji mail messages. For more information about using Kanji support with SMTP, see "Using DBCS with Mail" on page 437.

NOTE and SENDFILE Commands

Note: The SENDFILE and NOTE commands are no longer supplied with TCP/IP. You can now use the CMS version of SENDFILE and NOTE to send notes and files to network recipients. For a complete description of the syntax and options for these commands, refer to the *z/VM: CMS Commands and Utilities Reference*.

Electronic Mail Gateway

Electronic mail services are provided in conjunction with the SMTP virtual machine. This virtual machine can be configured by your TCP/IP administrator to operate as a mail gateway between TCP/IP network users and users located on an RSCS network that is attached to the local host. For example, PROFS users then can exchange mail with UNIX users through the VM TCP/IP SMTP gateway. An example of such an environment follows:

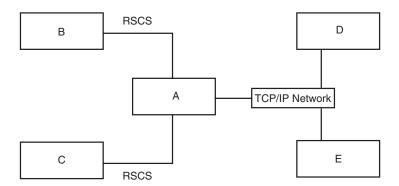

Figure 18. Example SMTP Mail Gateway Environment

Where:

A Is the local VM host, running both TCP/IP and RSCS.
B and C Are hosts attached to host A through an RSCS network.
D and E Are hosts attached to host A through a TCP/IP network.

Users on hosts A, B, and C can send mail or files to users on TCP/IP hosts D and E using the CMS NOTE and SENDFILE commands, or PROFS interface. The users on hosts D and E can send mail to the users on host A using addresses in the following format:

user id@A.domain

Where:

© Copyright IBM Corp. 1987, 2011

Is the user ID of the VM user on host A. user id Is the TCP/IP host name of host A. A.domain

The users on TCP/IP hosts D and E can send mail to users on RSCS hosts B and C using addresses in the following format:

user id%RSCSHost@A.domain

Where:

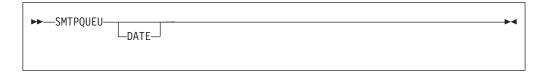

Is the user ID of the user on the host. user id RSCSHost Is the name of the RSCS host (B or C). A.domain Is the TCP/IP host name of host A.

Note and File Delivery

All mail arriving from senders on foreign hosts is delivered to the virtual machine of the VM recipient by the SMTP virtual machine. Normal VM processing places the mail in the virtual reader of the addressee. This mail can be read using OfficeVision or traditional CMS functions such as RDRLIST and PEEK. For information on manipulating electronic mail using CMS, see z/VM: CMS Commands and Utilities Reference.

The following command, issued from the CMS command line, checks any mail that SMTP is delivering or waiting to deliver.

SMTPQUEU Command

Purpose

Use the SMTPQUEU command to instruct the SMTP server to produce and return a batch SMTP response file (BSMTP REPLY) that lists the mail queued for delivery to one or more sites. The response file is spooled to the user that issued the SMTPQUEU command.

Operands

DATE

Specifies that the date and time that a mail item was added to a given site delivery queue should be included in the SMTP server response file.

Usage Notes

1. SMTPQUEU requests are directed to the SMTP server defined by the first SMTPSERVERID statement in the TCPIP DATA file. If no such statement exists, requests are directed to the user ID SMTP.

Examples

This example shows the response of the SMTPQUEU EXEC:

```
220-GDLGCT2.ENDICOTT.IBM.COM running IBM VM SMTP Level 540
on Fri, 23 May 2008 1
220 5:10:42 EDT
050 VERB ON
250 Verbose Mode On
050 OUEU DATE
250-Queues on GDLGCT2.ENDICOTT.IBM.COM at 15:57:01 EDT on 05/23/08
```

```
250-Spool Queue: Empty
250-Queue for Site: 64.233.185.114 RETRY QUEUE Last Tried: 15:55:24
250-Note 00000002 to <user_123@gmail.com> at 05/23/08 15:08:38
250-Undeliverable Queue: Empty
250-Resolution Oueues:
250-Resolver Process Queue: Empty
250-Resolver Send Queue: Empty
250-Resolver Wait Queue: Empty
250-Resolver Retry Queue:
250-00000004 <user_456@hostx.testdomain.com>
250-Resolver Completed Queue: Empty
250-Resolver Error Pending Queue: Empty
250 OK
```

Undelivered Notes

When the SMTP virtual machine cannot deliver a piece of mail, a nondelivery note or an unknown recipient note is forwarded to the sender of the mail explaining the reason for nondelivery. Nondelivery can occur for several reasons. For example, a destination host may not be known, or the recipient may not have a user ID on the destination host.

Nondelivery Note

If a piece of mail cannot be delivered, the body of the original piece of mail is returned as part of the nondelivery notification.

Figure 19 is an example of a nondelivery note.

```
Date: Fri, 8 Jan 93 08:23:54 EST
From: SMTP@VM1.ACME.COM
To: DANIEL@VM1
Subject: Undeliverable Mail
VM1.ACME.COM unable to deliver following mail to recipient(s):
      <MATT@SMTP-GATEWAY.IBM.COM>
VM1.ACME.COM unable to connect for 3 days to host:
      SMTP-GATEWAY.IBM.COM
      ** Text of Mail follows **
Date: Tue, 5 Jan 93 08:22:36 EST
From: <DANIEL@VM1.ACME.COM>
To: <MATT@SMTP-GATEWAY.IBM.COM>
Subject: ACME iron birdseed
Matt,
The shipment of ACME iron birdseed was shipped last Thursday. Please
advise me if you have not received it, and I'll try to track it down.
Also, your ACME giant rock catapult is on back order; another customer
bought the last one yesterday.
Daniel
```

Figure 19. Example of a Nondelivery Note

Unknown Recipient Note

If a recipient is unknown at the destination host, the destination host does not accept the mail for delivery, and a nondelivery notification is forwarded to the sender.

Figure 20 on page 108 is an example of an unknown recipient note.

```
Date: Mon, 15 Feb 93 13:32:12 EST
From: SMTP@VM1.ACME.COM
To: DANIEL@VM1
Subject: Undeliverable Mail
VM1.ACME.COM unable to deliver following mail to recipient(s):
      <GEORGE@SMTP-GATEWAY.IBM.COM>
VM1.ACME.COM received negative reply from host:
     SMTP-GATEWAY.IBM.COM
      ** Text of Mail follows **
Date: Tue, 16 Feb 93 08:22:36 EST
From: <DANIEL@VM1.ACME.COM>
To: <GEORGE@SMTP-GATEWAY.IBM.COM>
Subject:
          Your retirement
George,
I recently learned that you will soon be retiring. I just wanted to
wish you best of luck and thanks for all the great work you have done.
You were a great asset to your company, and I'm sure they will miss you.
Daniel
```

Figure 20. Example of an Unknown Recipient Note

Using OfficeVision Without OfficeVision Extended Mail Installed

PROFS/OfficeVision is an electronic mail interface for VM users. OfficeVision can send and receive electronic mail from users on TCP/IP networks with OfficeVision Extended Mail. For more information about using OfficeVision Extended Mail, see PROFS Extended Mail User's Guide and Installation Manual.

Contact your systems administrator to see if OfficeVision Extended Mail is installed at your site.

Note: Installation of OfficeVision Extended Mail is recommended.

A limited OfficeVision to SMTP interface is provided for sites that do not have PROFS Extended Mail installed. OfficeVision users can prepare mail for TCP/IP network recipients by including the SMTP virtual machine as one of the recipients of the mail. TCP/IP network recipients are specified through a special command within the PROFS note.

Specifying TCP/IP Recipients

When using OfficeVision, you must specify the addresses of RSCS recipients in the following format:

hostname(user id)

Where:

hostname Is the host name of the recipient. Is the user ID of the recipient. user_id

This format conforms to the specifications of local and RSCS network addresses, when you are using OfficeVision directly.

You enter the TCP/IP network address using a .ddn command. The following list describes how to use the .ddn command.

 Specify TCP/IP network addresses using the .ddn command, as shown in the following examples.

Note: The host and user ID pairs may be specified in either one of the following two formats.

```
.ddn TcpHost(TcpUserid)
.ddn TcpUserid@TcpHost
```

- Host names and user IDs can have more than 8 characters. The case (upper or lower) of the TCP/IP network addresses is preserved.
- · Code .ddn commands starting in column 1, like all other OfficeVision dot commands.
- Specify multiple addresses with a single .ddn command. At least one blank space must separate each pair of addresses, as shown in the following example.

```
.ddn TcpHost1(TcpUserid1) TcpUserid2@TcpHost2
```

 Code as many .ddn statements as necessary. The following example shows a group of three .ddn statements.

```
.ddn TcpHost1(TcpUserid1) TcpHost2(TcpUserid2)
.ddn TcpUserid3@TcpHost3 TcpUserid4@TcpHost4
.ddn TcpHost5(TcpUserid5) TcpUserid6@TcpHost6
```

- Do not place text from your note on the same line with a .ddn command in column one. This text would be mistakenly interpreted as additional addresses.
- No embedded blanks can appear within a TCP/IP address.
- PROFS does not convert addresses specified on the .ddn command line to uppercase.
- .ddn commands are not removed from the text of the note, when the note is sent to other PROFS users on the local or RSCS attached systems. The .ddn commands are removed from copies sent to the TCP/IP network recipients.
- · If you resend a note with .ddn commands to SMTP, all of the recipients specified on the .ddn command receive a copy of the mail.
- SMTP ignores .ddn commands in a forwarded note.

Example of Sending a Note Copy to SMTP

OfficeVision does not deliver the mail to the TCP/IP network recipient; you must send a copy of the PROFS note to the SMTP virtual machine. SMTP reads the addresses of the recipients from the OfficeVision note and delivers the note to each recipient. For example,

```
E34
                                     Send A Note
Send to: smtp user2 system3(user1)
From: MyName
Subject: (U)
00001 .ddn yktvmv.watson.ibm.com(user20) user10@ytkvmv.watson.ibm.com
00003 ... Text of note goes here...
00004
00005
00006
```

To verify that SMTP receives a copy of the mail that you send, specify the address of the SMTP virtual machine in the Send To: field of the note, or with a .cc or .ad command.

The address of the SMTP virtual machine is SMTP, unless your system administrator tells you otherwise.

Note Delivery

When SMTP receives a note from a OfficeVision user, the note is rewritten with a SMTP mail header. The note is also placed in batch SMTP format.

If any of the TCP/IP addresses specified are invalid, SMTP sends an error message to the PROFS user. This error message includes the batch SMTP version of the PROFS note. If the TCP/IP addresses are valid, but the mail cannot be delivered, the PROFS user receives an error message of the type described in "Undelivered Notes" on page 107.

Using IMAP to Access Electronic Mail

If you are authorized to access mail from an installation that is utilizing the z/VM IMAP server support, you as a mail user can use an IMAP client to access your mail that is residing in the IMAP mailstore on z/VM. This permits you, (using a "client" email program) to access your mail as if it were local. For example, email stored on the z/VM IMAP server can be manipulated from a desktop computer at home, a workstation at the office, or a laptop computer while away on business without the need to transfer messages back and forth.

In order to access mail from an IMAP server, the following needs to take place:

- · The user (client) must be enrolled into the IMAP Mailstore.
- The client email software must be configured to recognize the IMAP server in order to access the message folders.
- The client email software must connect to the z/VM IMAP server over an IPv4 connection.

You will need to contact your TCP/IP administrator in order to be enrolled as an IMAP user and can read further about IMAP in the *z/VM: TCP/IP Planning and Customization*. You will also need to refer to your particular email client's documentation on how to access your mail folders.

Using Secure SMTP

The SMTP virtual machine may be configured by your TCP/IP administrator for Secure SMTP. This would mean that when sending and receiving mail across a TCP/IP network, SMTP will attempt to use secure connections. The method used for securing SMTP connections is known as Transport Layer Security (TLS) and is documented in RFC 3207 (SMTP Extension for Transport Layer Security). When the server is configured to support TLS, a negotiation will take place between the SMTP client and the SMTP server to secure the connection, and all data that is sent across that connection is encrypted using Secure Socket Layer (SSL). From an end user's perspective, the fact that the mail is flowing across secure connections is transparent.

Using the SMSG Interface to SMTP

The VM Special Message Facility (SMSG) command provides an interactive interface to the SMTP virtual machine to perform general user tasks, such as:

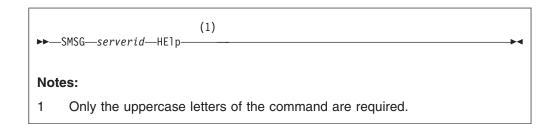

- Querying the SMTP mail delivery queues as well as the operating statistics of the SMTP virtual machine
- Performing privileged system administration tasks, such as rebooting or shutting down the SMTP virtual machine and enabling or disabling various tracing and debugging options.

Note: There is a privileged user SMSG command set designed for system administration tasks which are located in z/VM: TCP/IP Planning and Customization. Responses to commands are sent back to the originator of the command using CP MSG commands (or CP MSGNOH commands if SMTP is running with CP privilege class B).

General User SMSG Commands

The following are SMSG commands that the general user can use.

SMSG HELP Command

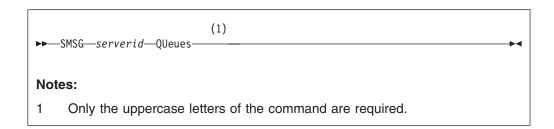

Purpose: Use the SMSG HELP command to provide a list of valid SMSG commands accepted by SMTP.

Operands:

serverid

Specifies the user ID of the virtual machine running the VM SMTP server.

SMSG QUEUES Command

Purpose: Use the SMSG QUEUES command to provide a list of mail queued on the various SMTP mail delivery queues.

Operands:

serverid

Specifies the user ID of the virtual machine running the VM SMTP server.

Example: To get a list of queued mail on the SMTP mail delivery queues, enter:

```
smsg smtp qu
Ready; T=0.01/0.01 10:46:13
* From SMTP: ---- Mail Queues ----
* From SMTP: Spool Queue: 0
* From SMTP: Undeliverable Queue: 0
* From SMTP: --- Resolver Queues ---
* From SMTP: Process Queue: 0
* From SMTP: Send Queue:
                                0
```

```
* From SMTP: Wait Queue:
* From SMTP: Retry Queue:
* From SMTP: Completed Queue:
* From SMTP: Error Queue:
```

SMSG STATS Command

```
(1)
►►—SMSG—serverid—STats
Notes:
     Only the uppercase letters of the command are required.
```

Purpose: Use the SMSG STATS command to provide operating statistics about the SMTP virtual machine. These statistics include:

- · The date that SMTP was last booted
- · The number of spool files in SMTP's RDR
- The number of spool files in SMTP's RDR in HOLD status (these spool files are too big for SMTP to process)
- The number of files on SMTP's 191 minidisk
- · The percent of disk space in use on SMTP's 191 minidisk
- The statistics about mail handled by SMTP over the past two days. These statistics include:
 - The number of pieces of mail that arrived over tcp connections
 - The number of pieces of mail that arrived from spool (from local or RSCS) senders)
 - The number of pieces of mail generated in response to requests to VERBose batch SMTP connections
 - The number of pieces of mail generated to return error mail to the sender
 - The number of pieces of mail delivered to local recipients
 - The number of pieces of mail delivered to recipients on the RSCS network
 - The number of pieces of mail delivered to recipients on the TCP/IP network
 - The number of TCP connections opened through which mail was received
 - The number of TCP connections opened through which mail was delivered

Operands:

Specifies the user ID of the virtual machine running the VM SMTP server.

Example: To obtain statistic information about the SMTP virtual machine, enter:

```
smsg smtp stat
Ready; T=0.01/0.01 10:46:37
* From SMTP: Last Up Time: Mon, 13 Dec 93 09:11:30 EST
* From SMTP: Spool Files: 0 Held:
* From SMTP: Disk Files :
                          6 Full:
                                    01%
* From SMTP: Statistics : 12/23 12/22 12/21 12/20
* From SMTP: From TCP : 23 45
                                    44
                                           50
* From SMTP: From Spool :
                          1
                                             36
* From SMTP: BSMTP Logs : 10 22
                                     22
                                             24
* From SMTP: Error Mail : 2
                                       3
                                              8
```

```
148
* From SMTP: To Local
                             65
                                   153
                                                 166
* From SMTP: To RSCS
                             0
                                     0
                                            0
* From SMTP: To TCP
                                                  30
                             0
                                     1
                                            6
* From SMTP: Passive Opns:
                                                  50
                             22
                                           45
                                    43
* From SMTP: Active Opens:
                                            5
                                                  13
                                     1
```

Receiving Electronic Mail on VM

When a CMS user receives electronic mail transmitted over a TCP/IP network, it is held for the user in their virtual reader until the user acts on it. If the TCPIP DATA file has been set up with SMTPSERVERID definitions for the SMTP server(s), CMS productivity aids that manipulate reader files will recognize the mail's true origin as other than the local SMTP userid. RECEIVE and PEEK will issue messages with the domain name origin of the mail. For RECEIVE, this message is limited to 240 characters and will be truncated if the domain name causes the message text to exceed that limit. For PEEK, this message is limited to the user's defined screen width and will be truncated if the domain name causes the message text to exceed that limit. For electronic mail received with the LOG option, the user's NETLOG file will also contain the domain name of the originator.

The origin of TCP/IP-based e-mail is also identified in the User and Node columns of the RDRLIST panel. Because these fields are each limited to eight characters, this origin information is divided into user and host domain information. Still, truncation of these values is likely, and is performed as described in the next section.

The most widely-used form of an origin address is:

```
user@host.domain
```

The RDRLIST "Node" value is obtained from the *host.domain* portion of the origin address. This information is tokenized using the periods (.) in this information as delimiters, and the displayed "Node" value is the most complete string of unaltered tokens that can be represented using eight characters. If *host* is itself greater than eight characters, its left-most eight characters of are displayed.

The RDRLIST "User" value is obtained from the *user* portion of the origin address that precedes the "@" sign. If *user* is greater than eight characters long, its left-most eight characters are displayed in the "User" field. However, if *user* contains any periods (.), this value is instead tokenized and then displayed in the same fashion as is the *host.domain* information.

If mail is sent using source routing, the origin address contains additional information, and would be similar to:

```
other host. other. domain.: user@host. domain\\
```

If such an address is encountered, data to the left of the last colon (:) present is discarded, and the RDRLIST "User" and "Node" values are obtained from the remaining origin address information, as previously described.

It is also possible for the origin address to include a percent (%) sign, and be of the form:

```
user%host@domain
```

If an address of this kind is encountered, the "@" sign is effectively replaced with a period (.), and the resulting *user* and *host.domain* values are processed to obtain the RDRLIST "User" and "Node" values in the usual way.

Here are some examples of domain name addresses and the resulting "User" and "Node" information that would be displayed on the RDRLIST panel:

```
john.doe%system1@vnet.ibm.com
 becomes User: john.doe
 and
        Node: system1
joneswk@gny1vm.vnet.ibm.com
 becomes User: joneswk
         Node: gny1vm
{\tt Tom\_Duffington@arbitrary\_host.isp.com}
 becomes User: Tom_Duff
 and
          Node: arbitrar
music.marist.edu:urmm@vm.marist.edu
 becomes User: urmm
 and
         Node: vm
pink.floyd@darkside.moon.com
 becomes User: pink
 and Node: darkside
p.t.barnum@big.top.circus.com
 becomes User: p.t
 and
        Node: big.top
```

Chapter 4. Logging On to a Foreign Host

The Telnet and TN3270 protocols provide a standardized interface that allows fullscreen and linemode terminal oriented processes on hosts that support TCP/IP to communicate with each other.

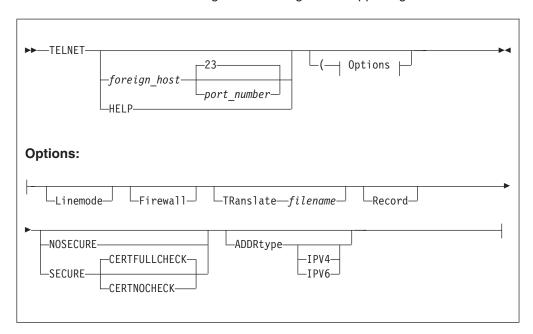

This chapter describes the following subjects:

- Using the TELNET Command
- · Using the TELNET Function Keys
- Using the TELNET Subcommands
- Sending ASCII Control Characters to a Host in Line Mode.

TELNET Command

Purpose

Use the TELNET command to log on to a foreign host supporting TCP/IP.

Operands

foreign host

Specifies the name or internet address of the foreign host. The internet address may be an IPv4 or an IPv6 address.

If you do not specify the name or internet address of the foreign host, you are prompted for the *foreign_host*.

Note: Attempting to specify an IPv6 link local address will produce unpredictable results.

port number

Specifies the port number to which you want to connect on the foreign host. When connecting to a non-TELNET port, the data exchange must follow the protocol recognized by the other port. The default is well-known port 23.

© Copyright IBM Corp. 1987, 2011

TELNET Command

Linemode

Indicates the logon operation. LINEMODE uses the line mode and prevents operation in the transparent (TN3270) mode.

In line mode, the foreign host's output is displayed on your screen one line at a time, without full-screen capabilities. In transparent (TN3270) mode, the foreign host's full-screen capabilities are functional on your local terminal.

Firewall

Specifies that a connection is to be made to a host in transparent (TN3270) mode through a proxy server. TELNET establishes a line-mode connection to the designated foreign host (the proxy server). You conduct a conversation with the proxy server to cause it to establish a connection to the actual destination host. TELNET negotiates the termnial type with that host and will enter 3270 mode if permitted.

TRanslate filename

Specifies a nonstandard translation table file. If this parameter is not specified, TELNET searches sequentially for TELNET TCPXLBIN and STANDARD TCPXLBIN. If neither is found, TELNET uses the compiled translation table. TELNET TCPXLBIN is supplied. The file type is always TCPXLBIN.

A nonstandard translation table is used in line mode only.

Record

Creates a log of interactions with linemode hosts in FILE LOGFILE A. A different file can be selected by issuing a CMS FILEDEF for ddname LOGFILE.

SECURE

A secure telnet connection will be attempted if the telnet server supports secure connections. If the telnet does not support secure connections or if an SSL server is not running on the local system, the telnet command will fail. Specifying the SECURE option overrides a SECURETELNETCLIENT NO statement specified on the TCPIP DATA file.

Note: This option is supported for IPv4 only.

CERTFULLCHECK

The remote server certificate and any associated CA certificates are verified for correctness for the connection. If a certificate error is detected, the corresponding connection fails.

A self-signed certificate cannot be used for secure connections unless it has been added to the local certificate database. For more information, see Using Self-Signed Certificates in *z/VM: TCP/IP Planning and Customization*.

CERTNOCHECK

The CERTNOCHECK option is accepted and ignored. All connections are handled as described for the CERTFULLCHECK operand.

NOSECURE

A clear telnet connection will be attempted. If the telnet server does not support clear connections, the telnet command fails. This is the default taken when neither SECURE or NOSECURE is specified, unless overriden by SECURETELNETCLIENT YES in the TCPIP DATA file. Specifying the NOSECURE option overrides the SECURETELNETCLIENT YES statement specified in the TCPIP DATA file.

ADDRTYPE IPV4 ADDRTYPE IPV6

Specifies which type of internet address Telnet will attempt to resolve a host

name to. If ADDRTYPE is not specified, Telnet will default to IPv4 for secure connections. For connections which are not secure, Telnet will use the first address returned by the resolver whether it is IPv4 or IPv6.

Usage Notes

- The TELNET command can only be used when logged on to VM using a 3270-type display device. It cannot be used from a linemode terminal.
- When you use the TELNET command to connect to a foreign host running TCP/IP, your foreign terminal session resembles a local terminal session.
- When Telnetting to a 2074 controller the Firewall option must be specified. Also, the TN3270E LU name and printer functions cannot be used.

TELNET Function Keys

This section describes the functions that are assigned to Program Function (PF) keys when you invoke TELNET in transparent mode and line mode.

In Transparent (TN3270) Mode

In transparent (TN3270) mode, the only function key that is available is the PA1 attention key. The PA1 key in transparent mode indicates that you want to invoke a TELNET subcommand.

For information about how to send the PA1 keystroke to the foreign session, see "PA1" on page 119.

In Line Mode

Table 10 shows the functions that are assigned to PF keys when you invoke TELNET in line mode.

Table 10. TELNET PF Key Functions

Key	Function	
PF4-PF12, PF16-PF24,	Displays the TELNET subcommand prompt.	
PF1, PF13	Retrieves the previous input line.	
PF2, PF14	Scrolls the screen forward halfway.	
PF3, PF15	Turns off the display of the user information line. Use either of these keys before entering your password.	

Note: When you connect to a VM host from a non-VM host, the following applies:

- If you invoke TELNET from a non-VM host in order to connect to a VM host and your client cannot emulate a 3270 data stream, transparent mode will not be possible. Instead, you will be connected to VM as a line-mode, start-stop terminal.
- When connected to VM as a line-mode, start-stop terminal, two TELNET subcommands have a special meaning:
 - The Abort Output (AO) subcommand causes a single attention to be presented. A single attention displays a VM READ.
 - The Interrupting Process (IP) subcommand causes a double attention to be presented. A double attention displays a CP READ.

TELNET Subcommands

The TELNET subcommands are described in detail on pages 118 through 120.

To invoke a TELNET subcommand while you are logged on to the foreign host, press the designated PF key. For a list of the designated PF keys, see Table 10 on page 117. After you press the PF key, you are prompted to enter the TELNET subcommand. TELNET subcommands can be entered in uppercase or lowercase.

You can use the PA1, AYT, AO, IP, and SYNCH subcommands to communicate with the foreign host while you are logged on with the TELNET command. The following sections describe these subcommands.

AO

Purpose

Use the AO (Abort Output) subcommand to stop displaying output.

The AO subcommand is useful to clear any output that has already been produced but has not been displayed on your terminal.

Operands

The AO subcommand has no parameters.

AYT

Purpose

Use the AYT (Are You There) subcommand to guery the existence of the connection.

Operands

The AYT subcommand has no parameters.

Usage Notes

1. If the connection exists and you are operating in transparent mode, the terminal makes a sound. If you are operating in line mode, you receive a message from the Telnet server.

BRK

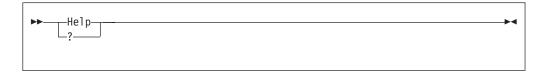

Purpose

Use the BRK subcommand to send a Break or Attention (Attn) keystroke to the remote session.

Operands

The BRK subcommand has no parameters.

HELP

Purpose

Use the HELP or ? subcommand to get help.

Operands

The HELP subcommand has no parameters.

Usage Notes

1. When you invoke the HELP or ? subcommand, a list of TELNET subcommands is displayed.

IP

Purpose

Use the IP (Interrupting Process) subcommand to interrupt the current process running on the foreign host.

Operands

The IP subcommand has no parameters.

Usage Notes

1. The IP subcommand is useful when you want to stop a process that is in a loop, or when you want to stop a process that you inadvertently started.

PA₁

Purpose

Use the PA1 subcommand to send a PA1 keystroke to the remote session in transparent mode.

Operands

The PA1 subcommand has no parameters.

Usage Notes

1. The PA1 subcommand operates only in transparent mode. The PA1 subcommand replaces the PA1 attention key on the foreign host.

QUIT

Purpose

Use the QUIT subcommand to end the TELNET session.

Operands

The QUIT subcommand has no parameters.

Usage Notes

- 1. If you are connected to a foreign host running TCP/IP and you use the QUIT subcommand, you are disconnected but not logged off the foreign host. The Virtual Telecommunication Access Method (VTAM®) application you are accessing determines whether you are also logged off from the foreign host. For example, the Time Sharing Option (TSO) application disconnects you, but does not log you off.
- 2. When you want to end a logon session with the foreign host, use the logoff procedure for the host.

SYNCH

Purpose

Use the SYNCH (Synchronize data path) subcommand to clear the data path.

Operands

The SYNCH subcommand has no parameters.

Usage Notes

1. The SYNCH subcommand clears the data path to the foreign host, except for any TELNET subcommands in the data path.

Sending ASCII Control Characters to a Host in Line Mode

In line mode, use the cent sign (¢) or the grave accent (`) to indicate a control character. For example, to send Ctrl-p, use either ¢p or `p.

Other control characters are shown in Table 11 on page 121.

Table 11. Control Characters

Characters	ASCII Output
`2 - `6	1B-1F
`#	FF (DEL)
`{	5B (left square bracket)
`}	5D (right square bracket)

You use either $\ensuremath{\mathscr{C}}$ or `before pressing the Enter key to suppress the sending of a carriage return and line feed. This function is useful for continuing a line without introducing a new line.

The following is an example of using the ϕ to continue a line.

PURGE RDR 45 78 99 67 69¢Enter 56 44

This function works if the command environment of the foreign host responds to a single non-Enter character, without a carriage return and line feed following it.

Chapter 5. Using the LDAP Client Utilities

The LDAP utilities provide a way to add, compare, modify, search, and delete entries in any server accepting LDAP protocol requests.

Each of the following utilities can be run from CMS:

Idapchangepwd
Idapcompare
Idapdelete
Idapadd
Idapmodify
Idapmodrdn
Idapsearch

I

Each utility accepts many possible parameters. See "Using the Command Line Utilities" on page 124 for a complete explanation of the parameters that can be supplied to each of the client utility programs.

Running the LDAP Client Utilities in CMS

The LDAP client utilities can be run from CMS. In order to do this, you need access to the TCPMAINT 592 disk where the LDAP utility EXECs, load modules, and message catalogs reside.

By default, the LDAP client utilities will access the US English message catalogs. If you want the utilities to access the Japanese message catalogs instead, set the NLSPATH environment variable by executing the following commands from a REXX EXEC:

nlspath = '/usr/lib/nls/msg/Ja_JP.IBM-939/%N' 'globalv select cenv put nlspath'

Running these utilities follows the same syntax as would be used if running them in other systems, except that the program names are invoked using EXECs, so the invocation names are eight characters or less. To run these utilities from CMS, use the following names:

Executable	CMS name
ldapchangepwd	LDAPCHPW
ldapadd	LDAPADD
ldapcompare	LDAPCMPR
ldapdelete	LDAPDLET
ldapmodify	LDAPMDFY
ldapmodrdn	LDAPMRDN
ldapsearch	LDAPSRCH

Throughout this information, whenever an executable is mentioned, it implies that you use the CMS EXEC name to invoke it. For example, whenever the information discusses **Idapcompare**, you should invoke the executable with LDAPCMPR.

If you are using the utilities in interactive mode (for example, reading DNs, changetype lines, and so on, from standard input), you can break out of interactive mode by typing HX and pressing the Enter key. Doing this returns you to CMS. This is similar to pressing Ctrl+C keys in UNIX.

© Copyright IBM Corp. 1987, 2011

Using the Command Line Utilities

The Idapchangepwd, Idapcompare, Idapdelete, Idapmodify, Idapadd, Idapmodrdn, and Idapsearch utilities all perform a bind operation to the LDAP server. When bind is invoked, several results can be returned. Following are bind results using various combinations of user IDs and passwords.

- 1. If a null or zero length DN is specified, the user receives unauthenticated
- 2. If a non-null, non-zero length DN is specified, a password must also be specified.
 - If the DN exists in the database, the entry must have a userpassword value and the password must match the specified value. The user is then bound with that identity.
 - If the DN does not exist in the database, the DN must be the administrator DN specified in the adminDN value in the server configuration file and the password must match the adminPW value in the server configuration file. The administrator DN must not be in the namespace of the LDAP server. The user is then bound as the administrator.

An error is returned when binding with any other combination of user ID and password.

Note: If you are using an LDAP server other than the z/OS or z/VM LDAP server, the bind results might be different.

Using Special Characters with the LDAP Utilities

LDAP utilities often require special characters such as " (double quotation mark) or @ (at). Unless your system administrator has changed them, these characters are also used by CP to perform command line editing. To see which line editing characters you are using, issue the CP QUERY TERMINAL command. If an LDAP utility filter or other operand uses any of the special characters shown in the output of the query, you need to do one of the following:

- Turn off line editing by issuing the CP SET LINEDIT OFF command.
- Disable CP's scan for the special character by issuing the CP TERMINAL xxxxx OFF command, where xxxxx is LINEND, LINEDEL, CHARDEL, or ESCAPE, as
- Use the ESCAPE character as a signal to CP that the character immediately following the escape character is to be used as-is. To determine the ESCAPE character you are using, issue the CP QUERY TERMINAL command.

Example: Your escape character is set to " (double quotation mark) and you want to issue the command:

ldapsrch -h ldap.company.com -b "ou=ldap,o=company.com" "cn=john doe"

You should issue CP TERMINAL ESCAPE OFF prior to issuing the command. If you do not do so, CP removes the double quotation marks before the command executes, resulting in errors. Alternatively, you could issue CP SET LINEDIT OFF.

Specifying a value for a filename

When running the Idapcompare, Idapdelete, Idapmodify, Idapadd, Idapmodrdn, and **Idapsearch** utilities, the file option (-f) value can be specified as follows:

/pathname/filename

Specifies the full path name of a file in the BFS file system.

filename

Specifies a path name that is relative to the current working directory of the LDAP client utility.

//filename.filetype.filemode

Specifies a CMS file. filemode is optional; the default is A.

SSL/TLS information for LDAP utilities

The contents of a client's key database file is managed with GSKKYMAN (the qskkyman utility). For information about GSKKYMAN, see Chapter 7, "SSL Certificate/Key Management and SSL Tracing Information," on page 215. GSKKYMAN is used to define the set of certification authorities (CAs) that are to be trusted by the client. By obtaining certificates from trusted CAs, storing them in the key database file, and marking them as trusted, you can establish a trust relationship with LDAP servers that use certificates issued by one of the CAs that are marked as trusted.

If the LDAP servers accessed by the client use server authentication, it is sufficient to define one or more trusted root certificates in the key database file. With server authentication, the client can be assured that the target LDAP server has been issued a certificate by one of the trusted CAs. In addition, all LDAP transactions that flow over the SSL/TLS connection with the server are encrypted, including the LDAP credentials that are supplied on the bind.

For example, if the LDAP server is using a high-assurance VeriSign certificate, you should obtain a CA certificate from VeriSign, receive it into your key database file, and mark it as trusted. If the LDAP server is using a self-signed GSKKYMAN server certificate, the administrator of the LDAP server can supply you with a copy of the server's certificate request file. Receive the certificate request file into your key database file and mark it as trusted.

Using the LDAP client utilities without the -Z parameter and calling the secure port on an LDAP server (in other words, a non-secure call to a secure port) is not supported. Also, a secure call to a non-secure port is not supported.

SSL/TLS encrypts the key ring file. Either the password must be specified as part of the -P parameter or a file specification of a stash file that was created using GSKKYMAN must be specified (the form is file:// followed immediately—no blanks in between—by the file specification of the stash file).

The file names specified on the -K (SSL key database file) and -P (SSL password stash file) parameters must refer to BFS files. This requirement means that if you want to use a secure connection to the LDAP server, you must have access to a BFS in which to store the SSL key database file, or the SSL password stash file, or both.

Note: If an error occurs when using the LDAP client utilities with the **-Z** parameter. the utility will return a failureReasonCode, which is the SSL reason code. These reason codes are documented in the LDAPSSL H file found on the TCPMAINT 592 disk.

SSL initialization failure

If SSL initialization fails, an error message similar to the following is returned:

ldap_ssl_client_init failed! rc == 113, failureReasonCode == 2 reason text: SSL initialization failed

The failureReasonCode indicates the cause of the SSL failure and is mapped from the return code of various SSL functions. See Table 12 for these values.

Table 12. SSL failure reason codes

Failure reason		
code	SSL return code	Failure reason code description
-1	402	No ciphers matched the server and client lists of acceptable ciphers
-2	403	No client certificate is to be used
-6	405	The certificate type is not supported
-10	406	I/O error communicating with peer application
-11	410	Incorrectly-formatted message received from peer application
-12	411	Message verification failed
-13	412	SSL protocol or certificate type is not supported
-14	413	Certificate signature is not correct for a certificate received from the peer
-15	414	Certificate is not valid
-16	415	Peer application has violated the SSL protocol
-17	416	Not authorized to access key database
-18	417	Self-signed certificate cannot be validated
-20	4	Insufficient storage is available
-21	5	The environment or connection is not in the open state
-22	420	Socket closed by peer
-41	422	V3 cipher is not valid
-99	12 or any other unmapped SSL reason code	Unrecognized error
-1000	none	Failed loading SSL DLL
-1001	none	Failed locating SSL function
1	102	Keyring I/O error
2	202	Keyring open error
4	408	Keyring password is incorrect
12	6, 407	Keyfile label is not valid or certificate is not trusted
106	106	Key database file is corrupted
109	109	Key database does not contain any valid CA certificates
201	201	Key database password or stash filename not set
203	203	Unable to generate temporary RSA key
204	204	Key database password is expired

Table 12. SSL failure reason codes (continued)

Failure reason		
code	SSL return code	Failure reason code description
301	301	Close failed
302	302	Connection has an active write
401	401	Validity time period for the certificate has expired
427	427	Unable to access the LDAP directory
428	428	The client key did not contain a private key
431	431	Certificate has been revoked
432	432	Session renegotiation is not allowed
433	433	Key exceeds allowable export size
434	434	Certificate key is not compatible with the negotiated cipher suite
435	435	Missing CA certificate
436	436	CRL cannot be processed
437	437	A close notification alert has been sent for the connection
438	438	Internal error reported by remote partner
439	439	Unknown alert received from remote partner
501	501	The buffer size is negative or zero
502	502	Operation would block
503	503	Read would be blocked
504	504	Write would be blocked
505	505	Record overflow
602	602	Function identifier is not valid
701	701	Attribute ID is not valid
702	702	Attribute length is not valid
703	703	Attribute enumeration value is not valid
705	705	Attribute value is not valid
706	706	Attribute parameter value is not valid
10001	1	Environment or SSL handle not valid
10003	3	Internal SSL error
10007	7	No certificate received from partner
10008	8	Certificate validation error
10009	9	Error processing cryptography
10010	10	Error validating ASN.1 fields in certificate
10011	11	Error connecting to LDAP server
10103	103	The database is not a key database

Enabling Tracing

You can enable tracing by setting the LDAP_DEBUG environment variable. In CMS, environment variables are set with the GLOBALV SELECT command, specifying the CENV group. For information on the setting environment variables, see "Using Environment Variables" in *z/VM: TCP/IP Programmer's Reference*.

The value for LDAP DEBUG is a mask that you can specify as follows:

- A decimal value (for example, 32).
- A hexadecimal value (for example, x20, X20, 0x20, or 0X20)
- A keyword (for example, FILTER)
- · A construct of those values using plus and minus signs to indicate inclusion or exclusion of a value. If the construct starts with a plus or minus sign, the current trace level is modified. Otherwise, the current trace level is set to 0 before processing the trace values.

Restrictions: To enable or change tracing using this method, the LDAP DEBUG environment variable must be set or changed before the client runtime is first initialized. Later changes to the value of LDAP DEBUG have no effect on the debug level of the client.

Examples: The following are examples of values for LDAP_DEBUG:

- Specifying 32768+8 is the same as specifying 32776, or x8000+x8, or ERROR+CONNS
- Specifying 2146959359 is the same as specifying ANY-STRBUF

The LDAP trace routine uses the IBM-1047 code page when writing text data to the trace data set. The trace output is written to stdout unless the LDAP DEBUG FILENAME environment variable is defined. If the application spawns additional processes, specify % as part of the trace file name. This causes the % to be replaced by the current process identifier, thus generating a unique filename for each process. Failure to do this can cause the trace file to be corrupted because locking is done on a process basis.

Example: The following example shows the use of % in the trace file name. GLOBALV SELECT CENV SET LDAP DEBUG FILENAME myapp.%.trc

Table 13 lists the debug levels and related decimal, hexadecimal and keyword values. Keywords can be abbreviated using the uppercase characters for each keyword.

Table 13. LDAP trace debug levels

Keyword	Decimal	Hexadecimal	Description
0FF	0	0x00000000	No debugging
TRACe	1	0x0000001	Routine entry and exit
PACKets	2	0x00000002	Packet activity
ARGS	4	0x00000004	Data arguments from requests
CONNs	8	0x00000008	Connection activity
BER	16	0x00000010	ASN.1 encoding and decoding
FILTer	32	0x00000020	Search filters
MESSage	64	0x00000040	Message activity and events
ACL	128	0x00000080	Access control list activity

Table 13. LDAP trace debug levels (continued)

Keyword	Decimal	Hexadecimal	Description
STATs	256	0x00000100	Operational statistics
THREad	512	0x00000200	Threading activity
REPLication	1024	0x00000400	Replication activity
PARSe	2048	0x00000800	Parsing activity
PERFormance	4096	0x00001000	Backend performance statistics
SDBM	8192	0x00002000	RACF backend activity
REFErral	16384	0x00004000	Referral activity
ERROr	32768	0x00008000	Error conditions
SYSP1ex	65536	0x00010000	Sysplex/WLM activity
MULTIServer	131072	0x00020000	Multiple server activity
LDAPBE	262144	0x00040000	Frontend-backend connection activity
STRBuf	524288	0x00080000	NLS and UTF-8 activity
TDBM	1048576	0x00100000	Relational backend activity
SCHEma	2097152	0x00200000	Schema activity
BECApabilities	4194304	0x00400000	Backend capabilities
CACHe	8388608	0x00800000	Cache activity
INFO	16777216	0x01000000	Informational messages
LDBM	33554432	0x02000000	File backend activity
ANY	2147483647	0x7FFFFFF	All debug levels
ALL	2147483647	0x7FFFFFF	All debug levels

LDAP URLs and LDAP Filters

Ī

An LDAP URL has the following format:

 $\begin{tabular}{ll} \cite{Align: Constraint of the constraint o$

The URL can optionally be enclosed in angle brackets or prefixed with URL: or both.

Specifies the value 1dap for a non-SSL connection and 1daps for an SSL connection.

host:port

Specifies the location of the LDAP server. The host specification can be a DNS resource name (for example, dcesec4.endicott.ibm.com), a dotted-decimal IPv4 address (for example, 9.130.25.34), or a colon-separated IPv6 address enclosed in square brackets (for example, [1080::8:800:200C:417A]). The port, if specified, must be a decimal number from 1 - 65535. The port defaults to 389 for a non-SSL connection and 636 for an SSL connection.

dn Specifies the distinguished name (DN) for the request. The DN can be used as a filter when the ldap_server_locate() routine should be called to locate the LDAP server.

attributes

Consists of one or more comma-separated search attributes.

scope

Specifies the search scope and can be base, one, or sub.

Specifies the search filter. The search filter as a null-terminated character string in UTF-8 or the local EBCDIC code page, as determined by the LDAP OPT UTF8_IO option for the LDAP handle. If you specify NULL or a zero-length string for this parameter, the search filter is set to "(objectClass=*)".

Search filters can be used in LDAP URLs and LDAPSRCH. Search filters are constructed as defined in RFC 2254: String Representation of LDAP Search Filters. The filter syntax is defined by the rules shown below.

Rules:

```
filter = "(" filtercomp ")"
filtercomp = and / or / not / item
and = "&" filterlist
            = "l" filterlist
or
          = "!" filter
not
filterlist = 1*filter
         = simple/ present / substring / extensible
item
           = attr filtertype value
simple
filtertype = equal / approx / greatereq / lesseq
            = "="
egual
approx
            = "~="
            = ">="
greatereq
            = "<="
lesseq
extensible = attr [":dn"] [":" matchingrule] ":=" value
                / [":dn"] ":" matchingrule ":=" value
          = attr "=*"
present
substring = attr "=" [initial] any [final]
initial
          = value
            = "*" *(value "*")
anv
final
            = value
            = AttributeDescription as defined in RFC 2251
attr
matchingrule = MatchingRuleId as defined in RFC 2251
            = AttributeValue as defined in RFC 2251
value
```

Values inside double quotation marks represent literal values. Items enclosed in square brackets are optional. Items separated by / represent a choice. The notation 1*filter indicates one or more filters. Specifying ":dn" as part of the extensible item indicates that the components of the distinguished name are to be included in the matching as well as the object attributes.

An error is returned if an extensible filter item is specified and the LDAP protocol version is not LDAP_VERSION3.

Leading and trailing whitespace characters are ignored. Embedded whitespace characters are allowed within an attribute value and are retained. Embedded whitespace characters are not allowed within any of the literals in the above rules. Quotation marks have no special meaning within a search filter and are treated as normal characters.

Filter control characters, such as "(", ")", "*", and "\", within an attribute value must be escaped using the format " \xx ", where xx is the hexadecimal representation of the ASCII value of the escaped character. For example, "*" would be represented as "\2a". UTF-8 characters can be represented as a sequence of escaped characters; for example, "(sn=Lu\c4\8di\c4\87)". The case of the hexadecimal characters is not important.

IETF RFC 2254 replaces IETF RFC 1960. However, RFC 1960 specified that filter control characters were escaped by preceding the escaped control character with a reverse slash. For example, "*" would be represented as "*" within an attribute value. In order to provide compatibility with applications written to RFC 1960, filter control characters can be escaped using either format.

Earlier levels of LDAP allowed the outer parentheses to be omitted from the filter. For compatibility, z/VM LDAP allows the outer parentheses to be omitted from the filter. For example, "mail=*"can be specified instead of "(mail=*)".

Examples: The following are some examples of filters:

- (mail=*)
 - This filter matches any entry with the mail attribute and does not match entries without the mail attribute.
- (mail=*@student.of.life.edu)
 - This filter matches any entry whose mail attribute value ends with the string "@student.of.life.edu".
- (&(cn=Jane*)(sn=Doe)(!(uid=jdoe)))

This filter matches any entry whose cn attribute value starts with Jane and whose sn attribute value is Doe and whose uid attribute value is not jdoe.

LDAPCHPW (Idapchangepwd Utility)

-w currentpw

Purpose

I

I

Ī

LDAPCHPW (**Idapchangepwd** utility) allows the **userPassword** attribute value to be changed for the specified entry.

The LDAPCHPW utility opens a connection to an LDAP server, binds, and sends modify password requests to the LDAP server. The input consists of a distinguished name (DN), a current password value, and a new password value. The current password value is deleted from the **userPassword** attribute values for the specified distinguished name and is replaced with the new password value.

Format

Parameters

-D bindDN Use bindDN to bind to the LDAP directory. The bindDN also identifies the DN whose **userPassword** attribute value is to be changed. The bindDN parameter is required and should be a string-represented DN.

If the **-S** or **-m** option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making access checks.

Use *currentpw* as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. This value also specifies the current **userPassword** attribute value that is being changed for the distinguished name (DN) specified by the **-D** option. This value is

LDAPCHPW

replaced by the new password value specified in the **-n** option. Specify? to prompt for the current password value. This option is required. Specify the new userPassword attribute value for the distinguished -n newpw name (DN) specified in the -D option. This value replaces the current password specified in the -w option. Specify ? to prompt for the new password value. This option is required. options Table 14 shows the *options* you can use for the LDAPCHPW utility: Table 14. LDAPCHPW options Option Description -? Print this text. -d debugLevel Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for debuglevel, see Table 13 on page 128. The default is no debug messages. -g realmName Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional. Specify the hostname or IP address on which the -h IdapHost LDAP server is running. The default is the local host. -K keyFile Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL KEYRING environment variable with an associated name. This parameter is ignored if **-Z** is not specified. -m mechanism See the description of the -S option. -M Manage referral objects as normal entries. This requires a protocol level of 3. -N keyFileDN Specify the label associated with the certificate in the SSL key database. This parameter is ignored if -Z is not specified Specify the TCP port where the LDAP server is -p IdapPort listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636. -P keyFilePW Specify either the key database file password or the file specification for a SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/ sslstashfile). This parameter is ignored if -Z is not specified. -R Do not automatically follow referrals.

1	Table 14. LDAPCH	HPW options (continued)
1	Option	Description
1	-S mechanism or	Specify the bind method to use. You can use either -m or -S to indicate the bind method.
 	-m mechanism	Specify EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.
 		The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is no default certificate in the key database file or a certificate other than the default needs to be used, use the -N option to specify the label of the certificate.
1		The CRAM-MD5 method requires a protocol level of 3. The -D or -U option must be specified.
 		The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.
1		If neither -m nor -S is specified, a simple bind is performed.
 	-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication.
 		This option is required if the -S or -m option is set to DIGEST-MD5.
1	-v	Use verbose mode, with many diagnostics written to standard output.
 	-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3 . The default is 3 .
 	-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.
 		The -K keyFile option or equivalent environment variable is required when the -Z option is specified. The -P keyFilePW option is required when the -Z option is specified and the key file specifies a file system key database file. Unless you want to use the default certificate in the key database file, use the -N option to specify the label of the certificate.
Examples		
Lyamples of L	DADCHDM/ oro:	

Examples of LDAPCHPW are:

- The following example changes the userPassword attribute value for entry cn=jon,o=ibm,c=us from a1b2c3d4 to wxyz9876 is: ldapchpw -D "cn=jon,o=ibm,c=us" -w a1b2c3d4 -n wxyz9876
- The following example performs an EXTERNAL bind with the SSL client certificate, clientCert, in the /home/user/client.kdb SSL key database file. The

LDAPCHPW

authenticated user changes the **userPassword** value for entry cn=stanley,o=ibm,c=us from xyz123abc to abc321zyz:

```
ldapchpw -Z -m EXTERNAL -K /home/user/client.kdb -N clientCert -P secret
-D "cn=stanley,o=ibm,c=us" -w xyz123abc -n abc321xyz
```

 The following example performs a simple bind to prompt for the current and new userPassword attribute values for entry cn=yvonne,o=ibm,c=us. At the prompts, the user enters the current and new password values in a non-echoed manner for user cn=yvonne,o=ibm,c=us.

```
ldapchpw -D "cn=yvonne,o=ibm,c=us" -w ? -n ?
Enter current password ==>
Enter new password ==>
```

Usage

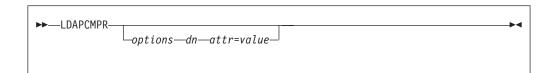

- 1. The LDAP DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 2. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page 129.
- 3. The authenticating user must have the appropriate permissions to update the userPassword attribute for the distinguished name specified in the -D option.
- 4. The routine used to prompt for the password returns at most 255 characters. truncating any additional characters. If the length of the specified password is greater than 255, the password value must be specified on the -w option.

Return codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written. If the errors are caused by the password policy requirements not being met, the Effective password policy extended operation is invoked and the effective password policy entries and attributes values are written to standard output.

LDAPCMPR (Idapcompare Utility)

Format

Purpose

LDAPCMPR (Idapcompare utility) opens a connection to an LDAP server, binds, and does one or more compares for an attribute value in an entry. The input consists of a distinguished name (DN) and an attribute type and value to compare. For each set of input, a comparison is performed for the specified attribute in the entry with that DN. If the DN and attribute type and value are not provided, the input is read from standard input or from file if the -f option is used, and two lines of input are read for each comparison. The first line contains the DN and the second line contains the attribute type and value.

Operands

options

Table 15 shows the options you can use for LDAPCMPR:

Table 15. LDAPCMPR options

Option	Description
-?	Print this text.
-c	Continuous operation mode. Errors are reported, but LDAPCMPR continues with comparisons. The default is to exit after reporting an error.
-d debuglevel	Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for <i>debuglevel</i> , see Table 13 on page 128. The default is no debug messages.
- D binddn	Use <i>binddn</i> to bind to the LDAP directory. The <i>binddn</i> parameter should be a string-represented DN. The default is a NULL string.
	If the -S or -m option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making access checks. This directive is optional when used in this manner.
-f file	Read the compare input from <i>file</i> instead of from standard input or the command line (by specifying <i>dn</i> and <i>attr=value</i>). An LDAP compare is performed for every set of two lines in the file. The first line in the set specifies the DN of the entry to compare. The second line contains the <i>attr=value</i> specification, indicating the attribute and value to compare.
	For more information on specifying files, see "Specifying a value for a filename" on page 124.
-g realmName	Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional.
-h Idaphost	Specify the host on which the LDAP server is running. The default is the local host.
-K keyfile	Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL_KEYRING environment variable with an associated name.
	SSL assumes that the name specifies a key database file. If the name is not a fully-qualified file name, then the current directory is assumed to contain the file.
	For information on SSL key databases, see "SSL/TLS information for LDAP utilities" on page 125.
	This parameter is ignored if -Z is not specified.
-m method	See the description of the -S option.
-M	Manage referral objects as normal entries. This requires a protocol level of 3.

Table 15. LDAPCMPR options (continued)

Option	Description			
-n	Show what would be done, but do not actually compare entries. Useful for debugging in conjunction with -v .			
-N keyfilelabel	Specify the label associated with the key in the SSL key database.			
	This parameter is ignored if -Z is not specified.			
-p Idapport	Specify the TCP port where the LDAP server is listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636.			
-P keyfilepw	Specify either the key database file password or the file specification for a SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/sslstashfile).			
	This parameter is ignored if -Z is not specified.			
-R	Do not automatically follow referrals.			
-S method or method	Specify the bind method to use. You can use either -m or -S to indicate the bind method.			
-m method	The default method is SIMPLE. You can also specify EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.			
	The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is more than one certificate in the key database file, use -N to specify the certificate or the default certificate to be used.			
	The CRAM-MD5 method requires a protocol level of 3. The -D or -U option must be specified. Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.			
	The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.			
-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication.			
	Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.			
	The -U option is required if the -S or -m option is set to DIGEST-MD5.			
-v	Use verbose mode, with many diagnostics written to standard output.			
-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3 . The default is 3 .			

Table 15. LDAPCMPR options (continued)

	Option	Description
	-w passwd	Use <i>passwd</i> as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. The default is a NULL string.
	-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.
		The -K <i>keyfile</i> option or equivalent environment variable is required when the -Z option is specified. The -P <i>keyfilepw</i> option is required when the -Z option is specified and the key file specifies a file system key database file. The -N <i>keyfilelabel</i> option must be specified if you wish to use a certificate that is different than the default specified in the key database.
dn	Specify the D	N of the entry to compare.
attr=value		ttribute type and the value to compare. An error is e entry does not contain the attribute to be compared.

Return Codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written to standard error.

Usage Notes

- 1. If no dn and attr=value arguments are provided and the -f option is not used, the LDAPCMPR command waits to read a list of DNs and attribute types and values from standard input. To break out of the wait, type HX and press the Enter key.
- 2. The LDAP DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 3. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page
- 4. For information about SSL/TLS, see "SSL/TLS information for LDAP utilities" on page 125.

Example

Ι

ı

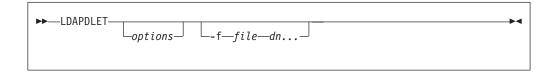

Following is an LDAPCMPR example:

· The following command compares the sn attribute within the entry named cn=Compare Me, o=My Company, c=US. The command returns true if the sn attribute value is Smith and false if it is not.

ldapcmpr "cn=Compare Me, o=My Company, c=US" sn=Smith

LDAPDLET (Idapdelete utility)

Format

Purpose

The LDAPDLET command (Idapdelete utility) opens a connection to an LDAP server, binds, and deletes one or more entries. If one or more dn arguments are provided, entries with those DNs are deleted. If no dn arguments are provided, the input is read from standard input or from file if the -f flag is used. Each line of input contains the DN of an entry to be deleted. Each entry to be deleted must be a leaf entry (an entry with no subordinate entries) or it must become a leaf entry when the previously specified entries are deleted.

Operands

options

Table 16 shows the *options* you can use for LDAPDLET:

Table 16. LDAPDLET options

Option	Description
-?	Print this text.
-c	Continuous operation mode. Errors are reported, but LDAPDLET continues with deletions. The default is to exit after reporting an error.
-d debuglevel	Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for <i>debuglevel</i> , see Table 13 on page 128. The default is no debug messages.
-D binddn	Use binddn to bind to the LDAP directory. The binddn parameter should be a string-represented DN. The default is a NULL string. If the -S or -m option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making
	access checks. This directive is optional when used in this manner.
-f file	Read a series of lines from <i>file</i> , performing one LDAP delete for the DN on each line.
	For more information on specifying files, see "Specifying a value for a filename" on page 124.
-g realmName	Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional.
-h Idaphost	Specify the host on which the LDAP server is running. The default is the local host.

Table 16. LDAPDLET options (continued)

Option	Description
-K keyfile	Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL_KEYRING environment variable with an associated name.
	SSL assumes that the name specifies a key database file. If the name is not a fully-qualified file name, then the current directory is assumed to contain the file.
	For information on SSL key databases, see "SSL/TLS information for LDAP utilities" on page 125.
	This parameter is ignored if -Z is not specified.
-m method	See the description of the -S option.
-M	Manage referral objects as normal entries. This requires a protocol level of 3.
-n	Show what would be done, but do not actually delete entries. Useful for debugging in conjunction with -v.
-N keyfilelabel	Specify the label associated with the key in the SSL key database.
	This parameter is ignored if -Z is not specified.
-p Idapport	Specify the TCP port where the LDAP server is listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636.
-P keyfilepw	Specify either the key database file password or the file specification for a SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/sslstashfile).
	This parameter is ignored if -Z is not specified.
-R	Do not automatically follow referrals.
-S method or	Specify the bind method to use. You can use either -m or -S to indicate the bind method.
-m method	The default method is SIMPLE. EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.
	The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is more than one certificate in the key database file, use -N to specify the certificate or the default certificate to be used.
	The CRAM-MD5 method requires a protocol level of 3. The -D or -U option must be specified. Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.

Table 16. LDAPDLET options (continued)

Option	Description
-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication.
	Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The -U option is required if the -S or -m option is set to DIGEST-MD5.
-v	Use verbose mode, with many diagnostics written to standard output.
-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3 . The default is 3 .
-w passwd	Use <i>passwd</i> as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. The default is a NULL string.
-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.
	The -K <i>keyfile</i> option or equivalent environment variable is required when the -Z option is specified. The -P <i>keyfilepw</i> option is required when the -Z option is specified and the key file specifies a file system key database file. The -N <i>keyfilelabel</i> option must be specified if you wish to use a certificate that is different than the default specified in the key database.

dn

Specify distinguished name (DN) of an entry to delete. You can specify one or more dn arguments. Each dn should be a string-represented DN.

Return Codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written to standard error.

Usage Notes

- 1. If no dn arguments are provided and the -f option is not specified, the LDAPDLET command waits to read a list of DNs from standard input. To break out of the wait, type HX and press the Enter key.
- 2. The LDAP DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 3. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page
- 4. For information about SSL/TLS, see "SSL/TLS information for LDAP utilities" on page 125.

Example

Following is an LDAPDLET example:

• The following command attempts to delete the entry named with commonName Delete Me directly below My Company organizational entry. It might be necessary to supply a binddn and passwd for deletion to be allowed. (See the -D and -w options.)

ldapdlet "cn=Delete Me, o=My Company, c=US"

LDAPMDFY and LDAPADD (Idapmodify and Idapadd Utilities)

Format

Purpose

The LDAPADD (Idapadd utility) command is implemented as a renamed version of LDAPMDFY (Idapmdfy utility). When invoked as LDAPADD, the -a (add new entry) flag is turned on automatically.

LDAPMDFY (Idapmdfy utility) opens a connection to an LDAP server, binds, and modifies or adds entries. The entry information is read from standard input (or an input file redirected to standard input) or from file through the use of the -f option.

Operands

options

Table 17 shows the options you can use for LDAPMDFY and LDAPADD:

Table 17. LDAPMDFY and LDAPADD options

Option	Description
-?	Print this text.
-a	Add new entries. The default for LDAPMDFY is to modify existing entries. If invoked as LDAPADD, this flag is always set.
-b	Assume that any values that start with a slash (/) are binary values and that the actual value is in a file whose path is specified in the place where values normally appear.
-c	Continuous operation mode. Errors are reported, but LDAPMDFY continues with modifications. The default is to exit after reporting an error.
-d debuglevel	Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for <i>debuglevel</i> , see Table 13 on page 128. The default is no debug messages.

Table 17. LDAPMDFY and LDAPADD options (continued)

Option	Description
-D binddn	Use <i>binddn</i> to bind to the LDAP directory. The <i>binddn</i> parameter should be a string-represented DN. The default is a NULL string.
	If the -S or -m option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making access checks. This directive is optional when used in this manner.
-f file	Read the entry modification information from <i>file</i> instead of from standard input.
	For more information on specifying files, see "Specifying a value for a filename" on page 124.
-F	Force application of all changes regardless of the contents of input lines that begin with replica: (by default, replica: lines are compared against the LDAP server host and port in use to decide if a replication log record should actually be applied).
-g realmName	Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional.
-h Idaphost	Specify the host on which the LDAP server is running. The default is the local host.
-K keyfile	Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL_KEYRING environment variable with an associated name.
	SSL assumes that the name specifies a key database file. If the name is not a fully-qualified file name, the current directory is assumed to contain the file.
	For information on SSL key databases, see "SSL/TLS information for LDAP utilities" on page 125.
	This parameter is ignored if -Z is not specified.
-m method	See the description of the -S option.
-M	Manage referral objects as normal entries. This requires a protocol level of 3.
-n	Show what would be done, but do not actually modify entries. Useful for debugging in conjunction with -v .
-N keyfilelabel	Specify the label associated with the key in the SSL key database.
	This parameter is ignored if -Z is not specified.
-p Idapport	Specify the TCP port where the LDAP server is listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636.

Table 17. LDAPMDFY and LDAPADD options (continued)

Option	Description
-P keyfilepw	Specify either the key database file password or the file specification for a SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/sslstashfile).
	This parameter is ignored if -Z is not specified.
-r	Replace existing values by default.
-R	Do not automatically follow referrals.
-S method or -m method	Specify the bind method to use. You can use either -m or -S to indicate the bind method.
	The default method is SIMPLE. EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.
	The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is more than one certificate in the key database file, use -N to specify the certificate or the default certificate to be used.
	The CRAM-MD5 method requires a protocol level of 3. The -D or -U option must be specified. Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.
-u on I off	Specify whether LDAPMDFY sends the SchemaReplaceByValueControl control to the server. This control indicates how a schema modify reacts to a replace modification. If set to off, a schema modification removes all current values for an attribute and replaces them with the set of values in the replace operation. If set to on, an attribute value is updated if some value in the replace operation has the same numeric object identifier as a value that already exists in the schema attribute. An attribute value is added if the numeric object identifier in the replace operation does not exist in the schema attribute. No attribute values are removed.
-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication.
	Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The -U option is required if the -S or -m option is set to DIGEST-MD5.
-V	Use verbose mode, with many diagnostics written to standard output.

Table 17. LDAPMDFY and LDAPADD options (continued)

Option	Description
-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3. The default is 3.
-w passwd	Use <i>passwd</i> as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. The default is a NULL string.
-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.
	The -K <i>keyfile</i> option or equivalent environment variable is required when the -Z option is specified. The -P <i>keyfilepw</i> option is required when the -Z option is specified and the key file specifies a file system key database file. The -N <i>keyfilelabel</i> option must be specified if you wish to use a certificate that is different than the default specified in the key database.

Input modes

The LDAPMDFY and LDAPADD commands accept two forms of input. The type of input is determined by the format of the first input line supplied to LDAPMDFY or LDAPADD.

The first line of input to the LDAPMDFY or LDAPADD command must denote the distinguished name of a directory entry to add or modify. This input line must be of

```
dn:distinguished name
or
distinguished name
```

where dn: is a literal string and distinguished_name is the distinguished name of the directory entry to modify (or add). If dn: is found, the input mode is set to LDIF mode. If it is not found, the input mode is set to modify mode.

Notes:

- 1. The LDAPADD command is equivalent to invoking the 1dapmdfy -a command.
- 2. The LDAPMDFY and LDAPADD commands do not support base64 encoded distinguished names.

LDIF mode

When using LDIF mode style input, attribute types and values are delimited by a single colon (:) or a double colon (::). Furthermore, individual changes to attribute values are delimited with a changetype: input line. The general form of input lines for LDIF mode is:

```
change record
<black line>
change_record
<black line>
```

In LDIF mode style input:

1. A comment line is a line that begins with a number sign (#) in column 1. Comment lines are ignored.

- 2. A continuation line is a line that begins with a space in column 1. The rest of the continuation line, starting in column 2, is appended to the previous line.
- 3. Ensure that there are no extraneous spaces or characters at the end of a line. Even if not viewable in an editor, these characters are part of the modify input and can produce unexpected errors or unusable data.

An input file in LDIF mode consists of one or more change_record sets of lines that are separated by one or more blank lines. Each change_record has the following form:

```
dn:distinguished name
[changetype: {modify | add | modrdn | delete}]
{change clause
```

Thus, a *change record* consists of a line indicating the distinguished name of the directory entry to be modified, an optional line indicating the type of modification to be performed against the directory entry, and one or more change clause sets of lines. If the changetype: line is omitted, the change type is assumed to be modify unless the command invocation was 1dapmdfy -a or 1dapadd, in which case the changetype is assumed to be add.

When the change type is modify, each change_clause is defined as a set of lines of the form:

```
add:x
{attrtype}{sep}{value}
or
replace:x
{attrtype}{sep}{value}
delete:{attrtype}
[{attrtype}{sep}{value}]
or
{attrtype}{sep}{value}
```

Specifying replace replaces all existing values for the attribute with the specified set of attribute values except when modifying a schema entry using the -u option with SchemaReplaceByValueControl enabled. (See the description of the -u option in Table 17 on page 141.) Specifying add adds to the existing set of attribute values. Specifying delete without any attribute-value pair records removes all the values for the specified attribute. Specifying delete followed by one or more attribute-value pair records removes only those values specified in the attribute-value pair records.

If an add:x, replace:x, or delete: attrtype line (a change indicator) is specified, a line containing a hyphen (-) is expected as a closing delimiter for the changes. Attribute-value pairs are expected on the input lines that are found between the

LDAPMDFY, LDAPADD

change indicator and hyphen line. If the change indicator line is omitted, the change is assumed to be add for the attribute values specified. However, if the -r option is specified on LDAPMDFY, the change_clause is assumed to be replace. The separator, sep, can be either a single colon (:) or a double colon (::). Any whitespace characters between the separator and the attribute value are ignored. If a double colon is used as the separator, the input is expected to be in base64 format. This format is an encoding that represents every three binary bytes with four text characters. Refer to the **base64encode()** function in /usr/lpp/ldap/examples/ line64.c for an implementation of this encoding.

Multiple attribute values are specified using multiple {attrtype} {sep} {value} specifications.

When the change type is add, each change_clause is defined as a set of lines of the form:

```
{attrtype}{sep}{value}
```

As with change type of **modify**, the separator, sep, can be either a single colon (:) or a double colon (::). Any whitespace characters between the separator and the attribute value are ignored. Attribute values can be continued across multiple lines by using a single space character as the first character of the next line of input. If a double colon is used as the separator, the input is expected to be in base64 format.

When the change type is modrdn, each change_clause is defined as a set of lines of the form:

```
newrdn:value
deleteoldrdn: {0 | 1}
```

These are the parameters you can specify on a modify RDN LDAP operation. The value for the newrdn setting is the new RDN to be used when performing the modify RDN operation. Specify 0 for the value of the deleteoldrdn setting in order to save the attribute in the old RDN and specify 1 to remove the attribute values in the old RDN.

When the change type is **delete**, no *change_clause* is specified.

LDIF Mode Examples

Here are some examples of valid input for the LDAPMDFY command using LDIF mode.

Adding a new entry: The following example adds a new entry into the directory using name cn=Tim Doe, ou=Your Department, o=Your Company, c=US, assuming ldapadd or ldapmdfy -a is invoked:

```
dn:cn=Tim Doe, ou=Your Department, o=Your Company, c=US
changetype:add
cn: Tim Doe
sn: Doe
objectclass: organizationalperson
objectclass: person
objectclass: top
```

Adding attribute types: The following example adds two new attribute types to the existing entry. Note that the registeredaddress attribute is assigned two values:

```
dn:cn=Tim Doe, ou=Your Department, o=Your Company, c=US
changetype:modify
add:x
```

```
telephonenumber: 888 555 1234
registeredaddress: td@yourcompany.com
registeredaddress: ttd@yourcompany.com
```

Changing the entry name: The following example changes the name of the existing entry to cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US. The old RDN, cn=Tim Doe, is retained as an additional attribute value of the cn attribute. The new RDN, cn=Tim Tom Doe, is added automatically by the LDAP server to the values of the cn attribute in the entry:

```
dn: cn=Tim Doe, ou=Your Department, o=Your Company, c=US
changetype:modrdn
newrdn: cn=Tim Tom Doe
deleteoldrdn: 0
```

Replacing attribute values: The following example replaces the attribute values for the telephonenumber and registeredaddress attributes with the specified attribute values.

```
dn: cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US
changetype:modify
replace:x
telephonenumber: 888 555 4321
registeredaddress: tim@yourcompany.com
registeredaddress: timtd@yourcompany.com
```

Deleting and adding attributes: The following example deletes the telephonenumber attribute, deletes a single registeredaddress attribute value, and adds a description attribute:

```
dn:cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US
changetype:modify
add:x
description: This is a very long attribute
 value that is continued on a second line.
  Note the spacing at the beginning of the
  continued lines in order to signify that
  the line is continued.
delete: telephonenumber
delete: registeredaddress
registeredaddress: tim@yourcompany.com
```

Modifying multiple entries: The following example adds the postal Code attribute and replaces the description attribute in the directory entry with name cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US and adds a new directory entry with name cn=Ken Smith, ou=Your Department, o=Your Company, c=US.

Note: A line containing only a dash is used to separate different types of changes within an entry and a blank line (a line containing no characters) is used to separate the changes to different entries.

```
dn: cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US
changetype: modify
add: x
postalcode: 12345
replace: x
description: This is a short description.
```

LDAPMDFY, LDAPADD

```
dn: cn=Ken Smith, ou=Your Department, o=Your Company, c=US
changetype: add
cn: Ken Smith
sn: Smith
objectclass: organizationalperson
```

Deleting an entry: The following example deletes the directory entry with name cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US:

```
dn:cn=Tim Tom Doe, ou=Your Department, o=Your Company, c=US
changetype:delete
```

Modify Mode

The modify mode of input to the LDAPMDFY or LDAPADD commands is not as flexible as the LDIF mode. However, it is sometimes easier to use than the LDIF mode.

When using modify mode style input, attribute types and values are delimited by an equal sign (=). The general form of input lines for modify mode is:

```
change record
<black line>
change_record
<black line>
```

In modify mode style input:

- 1. A comment line is a line that begins with a number sign (#) in column 1. Comment lines are ignored.
- 2. A line can be continued by specifying a backslash (\) as the last character of the line. If a line is continued, the backslash character is removed and the succeeding line is appended directly after the character preceding the backslash character.

An input file in modify mode consists of one or more change_record sets of lines separated by a single blank line. Each *change_record* has the following form:

```
distinguished name
[+|-]{attrtype} = {value\_line1[}
value line2[\
...value_lineN]]}
```

Thus, a change_record consists of a line indicating the distinguished name of the directory entry to be modified along with one or more attribute modification lines. Each attribute modification line consists of an optional add or delete indicator (+ or -), an attribute type, and an attribute value. If a plus sign (+) is specified, the modification type is set to add. If a hyphen (-) is specified, the modification type is set to delete. For a delete modification, the equal sign (=) and value should be omitted to remove an entire attribute. If the add or delete indicator is not specified, the modification type is set to add unless the -r option is used, in which case the modification type is set to replace. Any leading or trailing whitespace characters are removed from attribute values. If trailing whitespace characters are required for attribute values, the LDIF mode of input must be used. The new-line character at the end of the input line is not retained as part of the attribute value.

Multiple attribute values are specified using multiple attrtype=value specifications.

Modify Mode Examples

Here are some examples of valid input for the LDAPMDFY command using modify mode.

Adding a new entry: The following example adds a new entry into the directory using name cn=Tim Doe, ou=Your Department, o=Your Company, c=US:

```
cn=Tim Doe, ou=Your Department, o=Your Company, c=US
cn=Tim Doe
sn=Doe
objectclass=organizationalperson
objectclass=person
objectclass=top
```

Adding a new attribute type: The following example adds two new attribute types to the existing entry. Note that the registeredaddress attribute is assigned two values:

```
cn=Tim Doe, ou=Your Department, o=Your Company, c=US
+telephonenumber=888 555 1234
+registeredaddress=td@yourcompany.com
+registeredaddress=ttd@yourcompany.com
```

Replacing attribute values: Assuming that the command invocation was:

```
ldapmdfy -r ...
```

the following example replaces the attribute values for the telephonenumber and registeredaddress attributes with the specified attribute values. If the -r command line option was not specified, the attribute values are added to the existing set of attribute values.

```
cn=Tim Doe, ou=Your Department, o=Your Company, c=US
telephonenumber=888 555 4321
registeredaddress: tim@yourcompany.com
registeredaddress: timtd@yourcompany.com
```

Deleting an attribute type: The following example deletes a single registeredaddress attribute value from the existing entry.

```
cn=Tim Doe, ou=Your Department, o=Your Company, c=US
-registeredaddress=tim@yourcompany.com
```

Adding an attribute: The following example adds a description attribute. The description attribute value spans multiple lines:

```
cn=Tim Doe, ou=Your Department, o=Your Company, c=US
+description=This is a very long attribute \
value that is continued on a second line. \
Note the backslash at the end of the line to \
be continued in order to signify that \
the line is continued.
```

Changing the numeric object identifier: A special input file is required to change the numeric object identifier (OID) of an attribute or an object class in the z/VM LDAP server schema. This input file must contain a delete of the existing attribute or object class (with the old OID) followed by an add of the new version of the attribute or object class (with the new OID). The value for NAME within the attribute or object class must be identical in the delete and add modifications.

For example, to change the OID for the userHomeAddr attribute from 1.3.21.7777 to 2.5.44.3.9999 in the schema, the input file for LDAPMDFY should contain:

LDAPMDFY, LDAPADD

```
cn=schema
-attributetypes=( 1.3.21.7777 NAME 'userHomeAddr' \
DESC 'The home address' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 \
USAGE userApplications )
+attributetypes=( 2.5.44.3.9999 NAME 'userHomeAddr' \
DESC 'The home address' SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 \
USAGE userApplications )
```

Return Codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written to standard error.

Usage Notes

- 1. The LDAP_DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 2. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page
- 3. For information about SSL/TLS, see "SSL/TLS information for LDAP utilities" on page 125.

Examples

1

Following are some LDAPMDFY and LDAPADD examples. Tailor them for use at your installation by replacing the bind DN (binddn) and bind password (bindpw) values to those of an identity with appropriate authority.

1. Assume that the /tmp/entrymods file exists and has the following contents:

```
dn: cn=Modify Me, o=My Company, c=US
changetype: modify
replace: mail
mail: modme@MyCompany.com
add: title
title: Vice President
add: jpegPhoto
jpegPhoto: /tmp/modme.jpeg
delete: description
```

The following command replaces the contents of the Modify Me entry's mail attribute with the value modme@MyCompany.com, adds a title of Vice President, adds the contents of the file /tmp/modme.jpeg as the jpegPhoto value, and completely removes the description attribute.

```
ldapmdfy -b -r -f /tmp/entrymods
```

The same modifications as above can be performed using the older LDAPMDFY input format:

```
cn=Modify Me, o=My Company, c=US
mail=modme@MyCompany.com
+title=Vice President
+jpegPhoto=/tmp/modme.jpeg
-description
```

Assume that the /tmp/newentry file exists and has the following contents:

```
dn: cn=Joe Smith, o=My Company, c=US
objectClass: person
cn: Joseph Smith
```

```
cn: Joe Smith
sn: Smith
title: Manager
mail: jsmith@jsmith.MyCompany.com
uid: jsmith
```

The following command adds a new entry for Joe Smith, using the values from the /tmp/newentry file.

```
ldapadd -f /tmp/newentry
```

3. Assume that the /tmp/newentry file exists and has the following contents:

```
dn: cn=Joe Smith, o=My Company, c=US
changetype: delete
```

The following command removes Joe Smith's entry.

```
ldapmdfy -f /tmp/newentry
```

4. Assume that hostA contains the referral object:

```
dn: o=ABC,c=US
ref: ldap://hostB:390/o=ABC,c=US
objectclass: referral
```

and hostB contains the organization object:

```
dn: o=ABC,c=US
o: ABC
objectclass: organization
telephoneNumber: 123-4567
```

and the /tmp/refmods file has the following contents:

```
dn: o=ABC,c=US
changetype: modify
replace: ref
ref: ldap://hostB:391/o=ABC,c=US
```

and the /tmp/ABCmods file has the following contents:

```
dn: o=ABC,c=US
changetype: modify
add: telephoneNumber
telephoneNumber: 123-1111
```

The following command replaces the ref attribute value of the referral object o=ABC, c=US in hostA, changing the TCP port address in the URL from 390 to 391.

```
ldapmdfy -h hostA -r -M -f /tmp/refmods
```

The following command adds the telephoneNumber attribute value 123-1111 to o=ABC,c=US in hostB.

```
ldapmdfy -h hostB -p 391 -f /tmp/ABCmods
```

5. Assume that the /tmp/schemamods file exists and has the following contents:

```
dn: cn=schema
-attributetypes=( 1.2.1 NAME 'attr1' \
   DESC 'attribute type' EQUALITY caseIgnoreMatch \
   SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
+attributetypes=( 1.2.1 NAME 'attr1' \
   DESC 'attribute type - obsoleted' OBSOLETE \
   EQUALITY caseIgnoreMatch SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
+attributetypes=( 1.2.2 NAME 'attr2' DESC 'new attribute type' \
   EQUALITY caseIgnoreMatch SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 )
+ibmattributetypes=( 1.2.2 ACCESS-CLASS normal )
```

LDAPMDFY, LDAPADD

```
-objectclasses=( 4.5.6 NAME 'oc1' DESC 'sample object class' \
  STRUCTURAL MUST ( cn ) )
+objectclasses=( 4.5.6 NAME 'oc1' DESC 'sample object class' \
  STRUCTURAL MUST ( cn ) MAY ( attr2 ) )
```

The following command obsoletes the attr1 attribute type definition by specifying the OBSOLETE keyword in the definition, adds the attr2 attribute type definition and the associated IBM attribute type information, and modifies the oc1 object class definition by adding the attr2 attribute type as a MAY attribute.

ldapmdfy -f /tmp/schemamods -h hostA -D binddn -w bindpw

6. Assume that the /tmp/modentry file contains the following attributes.

Note: In the following LDIF, the x on the replace: x line is a placeholder for the attribute name and allows multiple attribute names and values to be replaced in a single operation.

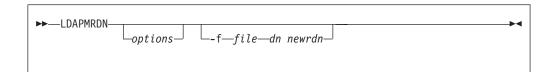

```
dn: racfid=u1,profiletype=user
changetype: modify
replace: x
racfattributes: OPERATIONS
racfconnectgroupUACC: update
```

The following command adds OPERATIONS to racfattributes and changes the racfconnectgroupUACC value to update.

```
ldapmdfy -D racfid=admin1,profiletype=user -w bindpw \
-f /tmp/modentry
```

LDAPMRDN (Idapmodrdn Utility)

Format

Purpose

The LDAPMRDN command (Idapmodrdn utility) opens a connection to an LDAP server, binds, and modifies the DN of entries. The input consists of a distinguished name (DN) and a new relative distinguished name (RDN). The new RDN replaces the existing RDN in the entry specified by the DN. If no dn and newrdn arguments are provided, the input is read from standard input or from file if the -f flag is used, and two lines are read for each rename. The first line contains the DN and the second line contains the new RDN. One or more blank lines must separate each DN and RDN pair.

The entries being renamed can be either leaf entries or non-leaf entries, and entire subtrees can be relocated in the directory with the **-s** option.

LDAPMRDN is not supported for RACF access on z/VM LDAP.

Operands

options Table 18 on page 153 shows the *options* you can use for LDAPMRDN:

Table 18. LDAPMRDN options

Option	Description
-?	Print this text.
-a	Sends an IBMModifyDNRealignDNAttributesControl control with the operation request. The control criticality is set to TRUE. There is no control value. For a description of this control, see <i>z/VM: TCP/IP LDAP Administration Guide</i> .
-c	Continuous operation mode. Errors are reported, but LDAPMRDN continues with modifications. The default is to exit after reporting an error.
-d debuglevel	Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for <i>debuglevel</i> , see Table 13 on page 128. The default is no debug messages.
- D binddn	Use <i>binddn</i> to bind to the LDAP directory. The <i>binddn</i> parameter should be a string-represented DN. The default is a NULL string.
	If the -S or -m option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making access checks. This directive is optional when used in this manner.
-f file	Read the entry rename information from <i>file</i> instead of from standard input or the command line (by specifying <i>dn</i> and <i>newrdn</i>). Multiple pairs of <i>dn</i> and <i>newrdn</i> can be specified in the input file or standard input. The pairs must be separated by one or more blank lines. The <i>newSuperior</i> option cannot be included in <i>file</i> ; this option is only accepted as a command-line option. If the <i>newSuperior</i> option (-s) is specified, each entry specified in the file will have its RDN updated and be moved under the new superior entry's DN. If the IBMModifyDNRealignDNAttributesControl option (-a) is specified, it is sent on each rename operation that is specified in the file.
	For more information on specifying files, see "Specifying a value for a filename" on page 124.
-g realmName	Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional.
-h Idaphost	Specify the host on which the LDAP server is running. The default is the local host.

Table 18. LDAPMRDN options (continued)

Option	Description
-K keyfile	Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL_KEYRING environment variable with an associated name.
	SSL assumes that the name specifies a key database file. If the name is not a fully-qualified file name, the current directory is assumed to contain the file.
	For information on SSL key databases, see "SSL/TLS information for LDAP utilities" on page 125.
	This parameter is ignored if -Z is not specified.
-I seconds	Sends an IBMModifyDNTimelimitControl control with the operation request, substituting <i>seconds</i> as the control value. The control criticality is set to TRUE. For a description of this control, see <i>z/VM: TCP/IP LDAP Administration Guide</i> .
-m method	See the description of the -S option.
-M	Manage referral objects as normal entries. This requires a protocol level of 3.
-n	Show what would be done, but do not actually change entries. Useful for debugging in conjunction with -v .
-N keyfilelabel	Specify the label associated with the key in the SSL key database.
-p Idapport	Specify the TCP port where the LDAP server is listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636.
-P keyfilepw	Specify either the key database file password or the file specification for a SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/sslstashfile).
	This parameter is ignored if -Z is not specified.
-r	Remove old RDN values from the entry. Default is to keep old values.
-R	Do not automatically follow referrals.
-s newSuperior	Specify the DN of the new superior entry under which the renamed entry will be relocated. The <i>newSuperior</i> argument can be the zero-length string (-s ""), if the destination server accepts zero-length string <i>newSuperior</i> arguments on an LDAP Modify DN operation.

Table 18. LDAPMRDN options (continued)

Option	Description
-S method or -m method	Specify the bind method to use. You can use either -m or -S to indicate the bind method.
	The default method is SIMPLE. EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.
	The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is more than one certificate in the key database file, use -N to specify the certificate or the default certificate is used.
	The CRAM-MD5 method requires a protocol level of 3. The -or -U option must be specified. Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.
-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication
	Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.
	The -U option is required if the -S or -m option is set to DIGEST-MD5.
-v	Use verbose mode, with many diagnostics written to standard output.
-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3 . The default is 3 .
-w passwd	Use <i>passwd</i> as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. The default is a NULL string.
-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.
	The -K <i>keyfile</i> option or equivalent environment variable is required when the -Z option is specified. The -P <i>keyfilepw</i> option is required when the -Z option is specified and the key file specifies a file system key database file. The -N <i>keyfilelabel</i> option must be specified if you wish to use a certificate that is different than the default specified in the key database.

Specify the DN of the entry to change. dn Specify the new RDN for the entry. newrdn

Return Codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written to standard error.

Usage Notes

1

- 1. The LDAP DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 2. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page 129.
- 3. For clients using authenticated binds, the DNs in their identity mappings might change as a result of a Modify DN operation which is performed concurrently with their session to the server, and this might affect ACL processing which results in permission to access, or denial of access to, directory entries for which they previously were permitted or denied access. The resolution for this situation is to unbind and rebind, so that identity processing uses the latest
- 4. For information about SSL/TLS, see "SSL/TLS information for LDAP utilities" on page 125.

Examples

The following are LDAPMRDN examples.

1. Assume that the /tmp/entrymods file exists and has the following contents: cn=Modify Me, o=My Company, c=US cn=The New Me

The following command changes the RDN from cn=Modify Me to cn=The New Me and removes the old RDN cn=Modify Me from the entry. The DN of the entry is cn=The New Me, o=My Company, c=US.

```
ldapmrdn -r -f /tmp/entrymods
```

2. The following command is another way to accomplish the same change as Example 1. An IBMModifyDNTimelimitControl control accompanies the operation request, specifying a time limit of 30 seconds.

```
ldapmrdn -r -1 30 "cn=Modify Me, o=My Company, c=US" "cn=The New Me"
```

3. The following command changes the RDN from cn=Modify Me to cn=The New Me and removes the old RDN cn=Modify Me from the entry. The renamed entry is relocated beneath the new superior entry o=Some Other Company, c=US. The DN of the entry is changed to cn=The New Me, o=Some Other Company, c=US. If the renamed entry is a non-leaf node, its subordinate entries are also moved and renamed to reflect their new locations in the directory hierarchy. An IBMModifyDNTimelimitControl control accompanies the operation request, specifying a time limit of 30 seconds, and an IBMModifyDNRealignDNAttributesControl control accompanies the operation request.

```
ldapmrdn -1 30 -a -s "o=Some Other Company, c=US" \
 "cn=Modify Me, o=My Company, c=US" "cn=The New Me"
```

LDAPSRCH (Idapsearch Utility)

Format

Purpose

The LDAPSRCH command (Idapsearch utility) opens a connection to an LDAP server, binds, and performs a search using the specified filter. If LDAPSRCH finds one or more entries, the specified attributes are retrieved and the entries and values are printed to standard output.

Restriction: Use of the approximate filter (\sim =) is not supported on a z/VM LDAP Server. This filter is processed like an equality (=) filter.

Operands

options

Table 19 shows the *options* you can use for LDAPSRCH:

Table 19. LDAPSRCH options

Option	Description		
-?	Print this text.		
-a deref	Specify how alias dereferencing is done. The <i>deref</i> should be one of never, always, search, or find to specify that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when locating the base object for the search. The default is to never dereference aliases.		
-A	Retrieve attributes only (no values). This is useful when you just want to see if an attribute is present in an entry and are not interested in the specific values.		
-b searchbase	Use <i>searchbase</i> as the starting point for the search instead of the default. If -b is not specified, this utility examines the LDAP_BASEDN environment variable for a <i>searchbase</i> definition.		
	Set the LDAP_BASEDN environment variable using the _CEE_ENVFILE LE runtime environment variable. For more information, see <i>z/OS: XL C/C++ Programming Guide</i> .		
	In CMS, environment variables are set with the GLOBALV SELECT command, specifying the CENV group. For information on the GLOBALV command, see <i>z/VM: CMS Commands and Utilities Reference</i> .		
-B	Do not suppress display of non-printable values. This is useful when dealing with values that appear in alternate character sets such as ISO8859.1. This option is implied by the -L option.		

Table 19. LDAPSRCH options (continued)

	(
Option	Description		
-c	Do not suppress display of printable non-ASCII values (similar to the -B option). Values are displayed in the local code page. The LANG environment variable must be set appropriately in the shell so that the desired characters print. Note that the default LANG value of C causes the desired characters not to print.		
-d debuglevel	Specify the level of debug messages to be created. The debug level is specified in the same fashion as the debug level for the LDAP server. For the possible values for <i>debuglevel</i> , see Table 13 on page 128. The default is no debug messages.		
-D binddn	Use <i>binddn</i> to bind to the LDAP directory. The <i>binddn</i> parameter should be a string-represented DN. The default is a NULL string.		
	If the -S or -m option is equal to DIGEST-MD5 or CRAM-MD5, this option is the authorization DN that is used for making access checks. This directive is optional when used in this manner.		
-f file	Read a series of lines from <i>file</i> , performing one LDAP search for each line. In this case, the <i>filter</i> given on the command line is treated as a pattern where the first occurrence of %s is replaced with a line from <i>file</i> . If <i>file</i> is a single hyphen (-) character, then the lines are read from standard input.		
	For more information on specifying files, see "Specifying a value for a filename" on page 124.		
-F sep	Use <i>sep</i> as the field separator between attribute names and values. The default separator is an equal sign (=), unless the -L flag has been specified, in which case this option is ignored.		
-g realmName	Specify the realm name to use when doing a DIGEST-MD5 bind. This option is required when multiple realms are passed from an LDAP server to a client as part of a DIGEST-MD5 challenge; otherwise, it is optional.		
-h Idaphost	Specify the host on which the LDAP server is running. The default is the local host.		
-K keyfile	Specify the name of the SSL key database file. If this option is not specified, this utility looks for the presence of the SSL_KEYRING environment variable with an associated name.		
	SSL assumes that the name specifies a key database file. If the name is not a fully-qualified file name, the current directory is assumed to contain the file.		
	For information on SSL key databases, see "SSL/TLS information for LDAP utilities" on page 125.		
	This parameter is ignored if -Z is not specified.		

Table 19. LDAPSRCH options (continued)

Option	Description		
-I timelimit	Limit the maximum wait time for the search request, overriding the value of LDAP_OPT_TIMELIMIT in the LDAP handle. Specify NULL for this parameter if there is no time limit for the request. Otherwise, set the <i>timeout</i> value to the maximum time in seconds.		
	The LDAP server can also provide a limit on the search time. For information on the server's search time limit and how it interacts with the client time limit, see the documentation for your LDAP server. For the z/VM LDAP server, see the description of the timeLimit configuration file option in z/VM: TCP/IP Planning and Customization. The default time limit for the client, specified by a value of 0, indicates that there is no client time limit and that the maximum number of seconds is limited only by the LDAP server limit.		
-L	Display search results in LDIF format. This option also turns on the -B option, and causes the -F option to be ignored.		
-m method	See the description of the -S option.		
-M	Manage referral objects as normal entries. This requires a protocol level of 3.		
-n	Show what would be done, but do not actually perform the search. Useful for debugging in conjunction with -v .		
-N keyfiledn	Specify the label associated with the key in the SSL key database.		
-p Idapport	Specify the TCP port where the LDAP server is listening. The default LDAP non-secure port is 389 and the default LDAP secure port is 636.		
-P keyfilepw	Specify either the key database file password or the file specification for an SSL password stash file. When the stash file is used, it must be in the form file:// followed immediately (no blanks) by the file system file specification (for example, file:///etc/ldap/sslstashfile).		
	This parameter is ignored if -Z is not specified.		
-R	Do not automatically follow referrals.		
-s scope	Specify the scope of the search. The <i>scope</i> should be one of base, one, or sub to specify a base object, one-level, or subtree search. The default is sub.		

Table 19. LDAPSRCH options (continued)

Table To. LB/II	Table 13. LDAI OHOLI Options (continued)				
Option	Description				
-S method or -m method	Specify the bind method to use. You can use either -m or -S to indicate the bind method.				
	The default method is SIMPLE. EXTERNAL to indicate that a certificate (SASL external) bind is requested, CRAM-MD5 to indicate that a SASL Challenge Response Authentication Mechanism bind is requested, or DIGEST-MD5 to indicate a SASL digest hash bind is requested.				
	The EXTERNAL method requires a protocol level of 3. You must also specify -Z , -K , and -P to use certificate bind. If there is more than one certificate in the key database file, use -N to specify the certificate or the default certificate is used.				
	The CRAM-MD5 method requires a protocol level of 3. The -D or -U option must be specified. Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.				
	The DIGEST-MD5 method requires a protocol level of 3. The -U option must be specified. Optionally, the -D option can be used to specify the authorization DN.				
-t	Write retrieved values to a set of files in the /tmp directory, using file names similar to /tmp/ldapsearch-objectclass-bbeFxQ. This option assumes values are non-textual (binary), such as jpegPhoto or audio. There is no character set translation performed on the values.				
-U userName	Specify the user name for CRAM-MD5 or DIGEST-MD5 binds. The <i>userName</i> is a short name (for example, the <i>uid</i> attribute value) that is used to perform bind authentication.				
	Do not specify the -U option for a CRAM-MD5 bind to a non-z/OS implementation of the IBM Tivoli Directory Server.				
	The -U option is required if the -S or -m option is set to DIGEST-MD5.				
-v	Run in verbose mode, with many diagnostics written to standard output.				
-V version	Specify the LDAP protocol level the client should use. The value for <i>version</i> can be 2 or 3 . The default is 3 .				
-w passwd	Use <i>bind passwd</i> as the password for simple, CRAM-MD5, and DIGEST-MD5 authentication. The default is a NULL string.				

Table 19. LDAPSRCH options (continued)

	Option -z sizelimit	Description	
		Limit the number of entries that can be returned, overriding the value of LDAP_OPT_SIZELIMIT in the LDAP handle. A value of 0 indicates that there is no limit.	
		The LDAP server can also provide a size limit on the number of entries returned. For information on the server's size limit and how it interacts with the client size limit, see the documentation for your LDAP server. For the z/VM LDAP server, see the description of the sizeLimit configuration file option in z/VM: TCP/IP Planning and Customization. The default size limit for the client, specified by a value of 0, indicates that the maximum number of entries is limited only by the LDAP server limit.	
	-Z	Use a secure connection to communicate with the LDAP server. Secure connections expect the communication to begin with the SSL/TLS handshake.	
		The -K keyfile option or equivalent environment variable is required when the -Z option is specified. The -P keyfilepw option is required when the -Z option is specified and the key file specifies a file system key database file. The -N keyfilelabel option must be specified if you wish to use a certificate that is different than the default specified in the key database.	
filter	Specify an IETF RFC 1558-compliant LDAP search filter.		
attributes	Specify a space-separated list of attributes to retrieve. If no attributes list is given, all are retrieved.		

Output format

If one or more entries are found, each entry is written to standard output in the form:

Distinguished Name (DN) attributename=value attributename=value attributename=value

Multiple entries are separated with a single blank line. If the -F option is used to specify a separator character, it is used instead of the equal sign (=). If the -t option is used, the name of a temporary file is used in place of the actual value. If the -A option is given, only the attributename part is written.

Searching a Server's Root DSE

The command:

ldapsrch -h ushost -s base -b "" "objectclass=*"

provides the root DSE (DSA-specific entry, where a DSA is a directory server) information for a server. This request can be directed to servers supporting LDAP Version 3 protocol to obtain information about support available in the server. See IETF RFC 2251: Lightweight Directory Access Protocol (v3) for a description of the information provided by the server. For more information about root DSE and what the z/VM LDAP server returns, see z/VM: TCP/IP LDAP Administration Guide.

Note: the scope option (-s) must be specified when specifying -b "" to search a server's root DSE.

Return Codes

Exit status is 0 if no errors occur. Errors result in a nonzero exit status and a diagnostic message being written to standard error.

Usage Notes

- 1. The LDAP DEBUG environment variable can be used to set the debug level. For more information on specifying the debug level using keywords, decimal, hexadecimal, and plus and minus syntax, see "Enabling Tracing" on page 128.
- 2. You can specify an LDAP URL for *Idaphost* on the **-h** parameter. For information about the syntax of LDAP URLs, see "LDAP URLs and LDAP Filters" on page 129.
- 3. For information about SSL/TLS, see "SSL/TLS information for LDAP utilities" on page 125.

Examples

Following are some LDAPSRCH examples. Each example makes the assumption that the LDAP server is running on the local host and listening on the default LDAP port (389).

· The command:

ldapsrch -b "o=IBM University,c=US" "cn=karen smith" cn telephoneNumber performs a subtree search using the search base "o=IBM University,c=US" for entries with a commonName of karen smith. The commonName and telephoneNumber values are retrieved and printed to standard output. The output might look something like this if two entries are found:

```
cn=Karen G Smith, ou=College of Engineering, o=IBM University, c=US
cn=Karen Smith
cn=Karen Grace Smith
cn=Karen G Smith
telephoneNumber=+1 313 555-9489
cn=Karen D Smith, ou=Information Technology Division, o=IBM University,
c=US
cn=Karen Smith
cn=Karen Diane Smith
cn=Karen D Smith
telephoneNumber=+1 313 555-2277
```

The command:

```
ldapsrch -b "o=IBM University,c=US" -t "uid=kds" jpegPhoto audio
```

performs a subtree search using the search base "o=IBM University,c=US" for entries with user ID of kds. The jpegPhoto and audio values are retrieved and written to temporary files. The output might look like this if one entry with one value for each of the requested attributes is found:

```
cn=Karen D Smith, ou=Information Technology Division, o=IBM University,
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

The command:

```
ldapsrch -L -s one -b "c=US" "o=university*" o description
performs a one-level search at the c=US level for all organizations whose
organizationName begins with university. Search results are displayed in the
```

LDIF format. The organizationName and description attribute values are retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=University of Alaska Fairbanks, c=US
o: University of Alaska Fairbanks
description: Preparing Alaska for a brave new tomorrow
description: leaf node only
dn: o=University of Colorado at Boulder, c=US
o: University of Colorado at Boulder
description: No personnel information
description: Institution of education and research
dn: o=University of Colorado at Denver, c=US
o: University of Colorado at Denver
o: UCD
o: CU/Denver
o: CU-Denver
description: Institute for Higher Learning and Research
dn: o=University of Florida, c=US
o: University of Florida
o: UF1
description: Shaper of young minds
```

· The command:

```
ldapsrch -h ushost -M -b "c=US" "objectclass=referral"
```

performs a subtree search for the c=US subtree within the server at host ushost (TCP port 389) and returns all referral objects. Note that the search is limited to the single server. No referrals are followed to other servers to find additional referral objects. The output might look something like this if two referral objects are found:

```
o=IBM,c=US
objectclass=referral
ref=ldap://ibmhost:389/o=IBM,c=US
o=XYZ Company,c=US
objectclass=referral
ref=ldap://XYZhost:390/o=XYZ%20Company,c=US
```

The command:

```
ldapsrch -D racfid=admin1,profiletype=user -w passwd
-b "profiletype=user" "racfid=G*"
```

performs a search in the user subtree of the z/VM LDAP support for RACF access for the RACF users whose names begin with G. Only the DN of each matching entry is displayed. The output might look like:

```
racfid=G\#126,profiletype=USER racfid=GDCEBLD,profiletype=USER racfid=GKUPERM,profiletype=USER racfid=GLDSRV,profiletype=USER
```

To then retrieve the entire entry for one of the matching users, use the command:

```
ldapserch -D racfid=admin1,profiletype=user -w passwd
-b "racfid=gkuperm,profiletype=user" "objectclass=*"
```

The results might look like:

racfid=GKUPERM,profiletype=USER
objectclass=racfUser
objectclass=racfBaseCommon
racfid=GKUPERM

```
racfprogrammername=UNKNOWN
racfowner=racfid=SUSET1,profiletype=USER
racfauthorizationdate=01.017
\verb|racfdefau|| tgroup=\verb|racfid=SYS1, profiletype=GROUP| \\
racfpasswordchangedate=00.000
racfpasswordinterval=186
racfattributes=NONE
racfrevokedate=NONE
racfresumedate=NONE
```

The following examples use file input to perform multiple searches with the same search base and scope, but with different filters. Each line in the file is used to replace the first occurrence of %s in the filter. The %s can be anywhere in the filter, and can be the entire filter.

Assume file /tmp/searchFile has the following contents:

Jones Doe

The command:

```
ldapsrch -f /tmp/searchFile -L -s sub -b "o=My Company"
   "(&(cn=John)(sn=%s*))"
```

replaces the %s in the filter value with each line of the input file. This is equivalent to issuing these search commands:

```
\label{localization} $$ \lab
  ldapsrch -L -s sub -b "o=My Company" "(&(cn=John)(sn=Doe*))"
```

Assume file /tmp/searchFile has the following contents:

```
o=university*
cn=Karen Smith
```

The command:

```
ldapsrch -f /tmp/searchFile -s one -b "c=US" "%s" description
```

replaces the entire filter with each line of the input file. This is equivalent to issuing these search commands:

```
ldapsrch -s one -b "c=US" "o=university*" description
ldapsrch -s one -b "c=US" "cn=Karen Smith" description
```

Chapter 6. Monitoring the TCP/IP Network

This chapter describes how to use the NETSTAT, RPCINFO, TRACERTE, and PING commands to obtain information from the network.

- · The NETSTAT command displays information about the status of the local host.
- The RPCINFO command displays the servers that are registered and operational with any portmapper on your network.
- · The TRACERTE command helps you debug network problems.
- The PING command determines the accessibility of a foreign node.

NETSTAT Displaying Local Host Information

The NETSTAT command displays the network status of the local host. NETSTAT displays information about TCP/IP configuration, connections, network clients, gateways, devices, and the Telnet server. NETSTAT also drops connections and executes commands for users in the TCPIP virtual machine's OBEY list. For more information about the OBEY list, see *z/VM: TCP/IP Planning and Customization*.

This section describes the NETSTAT parameters and contains examples of the responses that are displayed as a result of issuing the NETSTAT command with a specified parameter.

Note: For inverse name resolution, the NETSTAT command uses the ETC HOSTS file rather than the domain name server. If ETC HOSTS does not exist, the HOSTS ADDRINFO file is used.

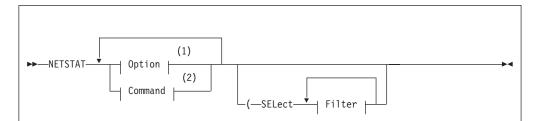

NETSTAT Command Address Interpretation

The NETSTAT command interprets and displays internet addresses symbolically, if possible. If an address cannot be interpreted, it is displayed in dotted decimal notation. Unspecified addresses are displayed as an asterisk (*).

Known port numbers are symbolically displayed. Port numbers that are not known to the network are displayed numerically. A socket is displayed as an internet address, followed by two periods (..) and a port number.

© Copyright IBM Corp. 1987, 2011

NETSTAT Command

Notes:

- If multiple options are specified, NETSTAT may not display the output in the sequence as the options were specified on the command line.
- 2 Only user IDs with TCP/IP OBEY command authorization can use command operands.

Option: (1) (2) -COnn-(2) -ALL-(1) (2)-ALLConn--ALL-–ARp --ipv4_address--CLients--PARMS-TRACE--CONFIG--ACCESS--CONTROLLER--OBEY -PARMS--PORT--ROUTERADV--SSL--TRACE--TRANSLATE--ALL--HELP-__?_ —DEvlinks-└─DETails─ -DOS--FILTers -Gate (3) -ROUTERADV-HE1p-—H0me (4) -IDENTify-L_{SSL}_ └ipv4 address (1) (2) -20--Interval--seconds--LEVe1--NEighbor ipv6_address \sqcup /prefixlength--OSAInfo-L_DETails_ └_P00Lsize-

Notes:

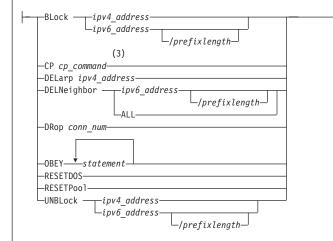

I

- 1 Only ALLCON, CONN and TCP are valid with INTERVAL.
- 2 The userid filter is valid with ALL, ALLCONN, CONN, and INTERVAL.
- 3 The *ipv4_address* and *ipv6_address* filters are valid with GATE only.
- 4 The IDENTIFY option cannot be specified with other options (except TCP).

Option (continued):

```
-SOCKets
-SSL-START userid
(1)
-TCp serverid
(2)
-TELnet
Up
```

Command:

Filter:

(4)

-ipv4_address(4)

-ipv6_address(2)

-ldev
(5)

-userid
(6)

-devicename
(6)

Notes:

- 1 Only ALLCON, CONN and TCP are valid with INTERVAL.
- 2 The *Idev* filter is valid with TELNET only.
- 3 All data that follows the CP keyword is used as CP command input.
- 4 The *ipv4_address* and *ipv6_address* filters are valid with GATE only.
- 5 The *userid* filter is valid with ALL, ALLCONN, CONN, and INTERVAL.
- 6 The *devicename* and * filters are valid with OSAINFO only.

Purpose

Use the NETSTAT command to display network status of the local host.

Note: The minimum abbreviation for each parameter is shown in uppercase letters.

Operands

ALL

Displays information about all TCP/IP connections. This option is useful for debugging the TCPIP virtual machine. For more information about maintaining the TCPIP virtual machine, see *z/VM: TCP/IP Planning and Customization*.

Displays the following information for UDP sockets being used for:

- Outgoing Multicast Data
 - the time-to-live value
 - whether datagrams are sent to loopback
 - the IP address of the link on which the datagrams are sent
- Incoming Multicast Data
 - the multicast groups (by IP addresses) for which data is being received.
 - the IP address of the associated link

ALLConn

Specifies that information about connections in either the "closed" or "time-wait" state should be provided, in addition to that for active TCP/IP connections (that is, connections that are not in either of these states).

ARp ipv4 address

Displays the ARP cache entry for the designated IPv4 address or set of IPv4 addresses. To display entries for multiple IPv4 addresses, specify the last token of the IPv4 address as an asterisk (*).

Example: An *ipv4_address* value of 9.130.48.* displays ARP cache entries for IPv4 addresses from 9.130.48.0 through 9.130.48.255, whereas 9.* displays ARP cache entries for network 9. Specifying **ALL** or a single asterisk (*) displays all ARP cache entries.

Notes:

- 1. Entries for network adapters that maintain their own ARP cache are displayed after those that are maintained within the TCP/IP server. The time at which TCP/IP last obtained adapter-maintained data precedes these types of entries.
- 2. The TCP/IP server requests adapter-maintained ARP data upon each NETSTAT ARP invocation. This data is not displayed for an initial NETSTAT ARP command. To display current adapter-maintained ARP data, issue at least two NETSTAT ARP commands, in sequence.

ARp ALL

Displays the ARP cache entry for all IPv4 addresses and also the arp age value. An asterisk (*) can be used for this purpose as well.

BLock ipv4 address

Ignores incoming traffic from the designated IPv4 address or set of IPv4 addresses. To block traffic from multiple IPv4 addresses, specify the last token of the IPv4 address as an asterisk (*).

Example: An ipv4_address value of 9.130.48.* blocks traffic from IP addresses 9.130.48.0 through 9.130.48.255, whereas 9.* blocks traffic from network 9.

Note: You should exercise care when selecting IP addresses that are to be blocked. It is possible to block one's own IP address, resulting in unpredictable behavior.

BLock ipv6 address

Ignores incoming traffic from the designated IPv6 address. The IPv6 address is specified in full or compressed form.

BLock ipv6 address/prefixlength

Ignores incoming traffic from the designated set of IPv6 addresses. To block traffic from multiple IPv6 addresses, specify a prefix by putting a slash (/) immediately after the IPv6 address followed by a prefixlength.

Example: Specifying **NETSTAT BLOCK** with an *ipv6_address/prefixlength* value of 1080:5F00:AA:BB:CC::/80 blocks traffic from IP addresses 1080:5F00:AA:BB:CC:0:0:0 through 1080:5F00:AA:BB:CC:FFFF:FFFF.

CLients

Displays the following information about each client:

• Authorization, as known by the TCP/IP server; possible values are:

Client is listed in the AUTOLOG list, so can Autologged

be autologged by the TCP/IP server.

Informed Client is listed in the TCP/IP INFORM list; it

may receive error notifications.

Monitor Client is listed in the TCP/IP OBEY list; it can

issue TCP/IP monitor command requests that

should be obeyed.

Probed Client supports connection probe notices. No-garbage-collect Resources in use by this client will not be

affected by TCP/IP "garbage collection"

activity.

- Notes handled by the client
- Elapsed time since the client was last used
- Elapsed time since the client was last forced (applies only to clients in the **AUTOLOG list)**
- VMCF error count

CONFIG

Displays configuration information about the TCP/IP server virtual machine. The following operands can be specified in any order following CONFIG, except the ALL operand, which must be specified alone. If no operands are specified, the default is PARMS TRACE.

ACCESS

Displays the users that have access to TCP/IP services. A list of users permitted to use the system, or a list of users restricted from using the system will be displayed. The list displayed is dependent on whether the PermittedUsersOnly option is specified on the AssortedParms statement in the TCP/IP configuration file.

CONTROLLER

Displays the current VSWITCH CONTROLLER settings.

OBEY

Displays the list of users that have access to privileged TCP/IP services.

PARMS

Displays the current AssortedParms and InternalClientParms settings.

AssortedParms and InternalClientParms settings displayed may not match those specified in the TCP/IP configuration file. In some cases, the TCP/IP server enables or disables features based on other environmental factors, and the display reflects the parameters as the TCP/IP server currently views them.

PORT

Displays the list of ports that have been configured via the PORT statement.

ROUTERADV

Displays the router advertisement configuration parameters of your TCP/IP stack. For more information, see the ROUTERADV statement and the ROUTERADVPREFIX statement in z/VM: TCP/IP Planning and Customization.

SSL

Displays the user IDs of the SSL servers (if any) associated with the subject TCP/IP virtual machine, and the status of these servers (such as whether TCP/IP currently is using a given SSL server to provide secure connection services). For an SSL server that currently is active, the number of connections managed by that server also are displayed.

The possible states cited for the **Status** field in the command response are:

Active

The server is logged on and has established appropriate connections with the TCP/IP server; dependent upon the current configuration and connection activity, the server may or may not be able to accept new connections.

Eligible

The server is one that has been defined for use, but does not meet the criteria for an active server. It could be that the server currently is not logged on, or the server has not initialized and established the necessary connections with the TCP/IP server. The TCP/IP server will make attempts to employ such a server when a new secure connection request cannot be accommodated by the currently active server(s). A server in this state cannot respond to SSLADMIN administrative commands or accept any connections.

Starting

The server has been started by the TCP/IP server as part of its own initialization, or by a NETSTAT SSL START or SSLADMIN START command. The server currently is progressing through the initialization process. A server in this state is not fully initialized, so cannot respond to SSLADMIN administrative commands or accept any connections.

Stopped

A stopped server is one that has been overtly stopped via an SSLADMIN STOP command. As such, the TCP/IP server will not attempt to employ this server to accommodate a new secure connection request that cannot be handled by the currently active server(s). A server in this state is not logged on, so cannot respond to SSLADMIN administrative commands or accept any connections.

TRACE

Displays the current status of TCP/IP tracing. Information includes the destination of trace data, items currently being traced, as well as the users, devices, and IP addresses that have been configured for selective tracing.

TRANSLATE

Displays information on internet address to MAC address translations that have been configured via the TRANSLATE statement.

ALL

Displays all of the above reports.

HELP

Displays NETSTAT CONFIG usage information.

C₀nn

Displays the following information about each *active* TCP/IP connection:

- User ID
- Connection number
- · Local socket
- Foreign socket
- · Connection state

TCP/IP considers a connection to be active if it is not in a "closed" or "time-wait" state.

CONN is the default parameter.

Note: In a Secure Socket Layer (SSL) session, there are two connections the connection from the remote client to the security server and the connection from the security server to the application server. For each of these connections, the connection number for the partner connection of the secure session is displayed on the next line.

CP cp command

Specifies a CP command to be issued by the TCP/IP server; all data that follows the CP parameter is construed to be part of the CP command.

Example: To close the console of the TCPIP virtual machine and send this output to a specific user ID, use this NETSTAT command:

netstat cp spool cons close to userid

Up to 32767 bytes of the CP command response are displayed by the NETSTAT command.

Note: CP commands can be used only by privileged TCP/IP users, as identified by the TCP/IP server's OBEY statement. For more information about listing user IDs with the OBEY statement, see z/VM: TCP/IP Planning and Customization.

DELarp *ipv4* address

Deletes the ARP cache entry for the designated IPv4 address or set of IPv4 addresses. To delete entries for multiple IPv4 addresses, specify the last token of the IPv4 address as an asterisk (*).

Example: An *ipv4_address* value of 9.130.48.* deletes ARP cache entries for IP addresses from 9.130.48.0 through 9.130.48.255, whereas 9.* deletes ARP cache entries for network 9, and * deletes all ARP cache entries.

Notes:

- 1. The DELARP command can be used by privileged TCP/IP users only. For more information about listing user IDs with the OBEY statement, see z/VM: TCP/IP Planning and Customization.
- 2. Adapter-maintained ARP entries cannot be deleted using the NETSTAT DELARP command.

DELNeighbor *ipv6* address

Deletes the neighbor cache entry for the designated IPv6 address. The ipv6_address is specified in full or compressed form.

DELNeighbor *ipv6* address/prefixlength

Deletes the neighbor cache entry for the designated set of IPv6 addresses. To delete entries for multiple IPv6 addresses, specify an IPv6 address that is immediately followed by a slash (/) and a prefix length. Specifying ALL or a single asterisk (*) will delete the entire NEIGHBOR cache.

Example: Specifying **NETSTAT DELNEIGHBOR** with an *ipv6_address*/ prefixlength value of 1080:5F00:AA:BB:CC::/80 will delete the neighbor cache entries for all of the IP addresses from 1080:5F00:AA:BB:CC:0:0:0 through 1080:5F00:AA:BB:CC:FFFF:FFFF.

DELNeighbor ALL

Deletes all neighbor cache entries. An asterisk (*) can be used for this purpose as well.

DEvlinks

Displays the following information about the devices and links defined for the TCP/IP virtual machine:

- Address
- ARP query capability
- Broadcast capability
- Byte counts
- CLAW interface information
- CPU number
- · Device name
- Device type
- HiperSockets[™] port name
- GVRP status
- IPv4 VLAN ID
- IPv6 status
- IPv6 VLAN ID
- Link name
- Link type
- · Maximum frame size
- · MTU size
- · Multicast specific information
- Net number
- Packet forwarding status
- Path MTU discovery status
- Port number
- QDIO port name and router type
- Queue size
- Status
- VLAN ID

The Multicast Specific field is significant only for multicast-capable links. If a link is being used to receive multicast data, then all the multicast groups, and the counts of receivers for each multicast group are displayed.

Special devices and links are described in the output. These are not created as a result of user-specified DEVICE and LINK statements. When a z/VM TCP/IP stack is defined as eligible to be a controller for an OSA-Express device assigned to a virtual switch, a device with type 'VSWITCH-IUCV' shows in the output. For each virtual switch with an active OSA-Express device, a device with type 'VSWITCH-OSD' is described. These devices and links are not

explicitly defined in a z/VM TCP/IP configuration file. They are created as a result of the CP DEFINE VSWITCH command that defines a virtual switch's interface to a network using an OSA-Express device.

Some fields of the DEVLINKS display are device-dependent. These exceptions are described in the list that follows.

Address The base address is displayed for all devices.

ARP query capability Whether or not support for querying ARP

address information is shown only for OSD or

Hipersockets devices.

Byte counts Some device drivers do not provide counts.

This is not displayed for a device type of

VSWITCH-OSD.

GVRP status Indicates whether GVRP initialization completed

> successfully. This is displayed only for QDIO Ethernet links that requested GVRP Support. through explicit specification on the LINK

statement or by taking the default.

IPv6 status Reports whether IPv6 support is enabled or

> disabled for the link. This field is shown only for OSD type devices with the QDIOETHERNET link type and HIPERS type devices with the

QDIOIP link type.

IPv4 VLAN ID

IPv6 VLAN ID A QDIO Ethernet link can be defined to be a

> member of two Virtual Local Area Networks (VLANs) by configuring one VLAN ID for IPv4 and one for IPv6. This is displayed only for

QDIO Ethernet links.

MAC macaddr Displays the MAC address assigned. This is

displayed only for QDIO Ethernet links

operating in layer 2 mode.

Maximum frame size The maximum frame size in use. This field is

displayed for HiperSockets only.

MTU size The MTU size associated with the link that was

either specified as an MTU operand on the LINK statement or was an intelligent default assigned by TCP/IP. This field is shown for all

devices except virtual devices.

Net number This is an integer that identifies the relative

adapter number of a network adapter within an LCS device, for which a link is defined. The value is 0 for the first adapter in the LCS. 1 for the second adapter, and so on. This field is significant only for links defined for LCS

devices.

Reports whether IP forwarding is enabled or Packet forwarding status

disabled for the link.

Path MTU discovery status

Indicates whether path MTU discovery is

enabled or disabled. It is displayed for all

non-VIPA devices.

Port number

This is an integer that identifies the OSA-Express hardware port number within a

QDIO OSD device. This field is significant only

for links defined for OSD devices.

Status Some device drivers do not provide

device-specific status. For these devices,

possible status values are:

Active The device is started. Inactive The device is not started.

Transport Type IP

ETHERNET Indicates the transport type specified. IP

transport operates at a layer 3 level of the OSI model while ETHERNET operates at a laver 2 level. This is displayed only for QDIO Ethernet

links.

VLAN ID A QDIO Ethernet or QDIO IP link can be

> defined to be a member of a single Virtual Local Area Network (VLAN). This is displayed only for QDIO Ethernet and QDIO IP links.

DETails

Displays detailed packet statistics in addition to normal NETSTAT DEVLINKS output.

DOS

Displays information about Denial-of-Service attacks. For each attack detected, it displays the following information:

- · The name of the attack
- · Up to seven IP addresses from which the attack was launched. (For Fraggle, Smurf-IC, Smurf-OB, and Smurf-RP, the IP address is spoofed to be the address of the victim of the attack. Other denial-of-service attacks may also spoof the source IP address to be the address to be something other than the address of where the attack originated.)
- An IP address of * to represent any additional IP addresses that are not already displayed.
- The number of attacks detected per IP address.
- The elapsed time since the first attack was detected.
- · The duration of the attacks.
- The maximum number of half-open connections that are allowed. See the "PENDINGCONNECTIONLIMIT" configuration statement in z/VM: TCP/IP Planning and Customization for more information.
- The maximum number of persist connections that are allowed. See the "PERSISTCONNECTIONLIMIT" configuration statement in z/VM: TCP/IP Planning and Customization for more information.
- The maximum number of connections that a foreign IP address is allowed to have open at the same time. See the "FOREIGNIPCONLIMIT" configuration statement in *z/VM: TCP/IP Planning and Customization* for more information.

DRop conn num

Drops the TCP/IP connection specified by conn_num. You determine the connection number to be dropped from the CONN column of the NETSTAT

I Ι Ι

CONN or NETSTAT TELNET display. If you drop the "passive open" connection for a server, that server will immediately reissue an "open" request.

Note: The DROP command can be used only by privileged TCP/IP users. For more information about listing user IDs with the OBEY statement, see *z/VM: TCP/IP Planning and Customization.*

FILTers

Displays information about blocked IP addresses. For each blocked address or set of addresses, it provides the following information:

- · The IP address
- The number of packets discarded
- How long the block has been in effect
- · How long ago the last packet from the IP address was discarded

Gate

Displays information about gateways (dynamic routes) known by the TCP/IP server.

Note: If the TCP/IP server knows IPv6 routes from router advertisements which indicated route preference values, then the TCP/IP server only makes use of a subset of these IPv6 routes; that is, all reachable IPv6 routes with the best preference value advertised. NETSTAT GATE displays only this subset of routes. For example, the subset used and displayed might get dropped and replaced by a subset of less favorable IPv6 routes if all other IPv6 routes with a more favorable route preference value have been deleted or have become unreachable. The TCP/IP server supports only IPv6 route preference values for default routes. (This is support for a type B host as defined in RFC 4191).

The following information is displayed for each gateway:

- · Address of the network
- The prefix length (for IPv6)
- · First hop address
- Flags
 - Α The route was created dynamically by a Router Advertisement (IPv6 only).
 - C The route was created dynamically by a redirect.
 - G The route is to a gateway
 - Н The route is to a host rather than to a network.
 - M The route was modified dynamically by a redirect.
 - Р The route has been created by path MTU discovery.
 - Q The packet size used by the route has been modified by path MTU discovery.
 - S The route is a static route. Only routes defined using the GATEWAY configuration statement are flagged as static.
 - Т The route was generated automatically based on the TCP/IP stack configuration and is replaced if a matching route (either static or dynamic) is added.
 - U The route is up.

- Link name used by the first hop
- Packet size used by the first hop

Note: If the MTU option is specified on the LINK statement, the MTU shown by NETSTAT GATE matches the MTU shown by NETSTAT DEVLINKS and the ifMtu fields in the TCP/IP APPLMON Monitor Records. Otherwise, these values might differ.

- Subnet mask and subnet value (IPv4 only)
- Route metric:
 - If the route is an OSPF inter-area or intra-area route, this is the OSPF cost of the route.
 - If the route is an OSPF External type 1, this is the OSPF cost to the AS Boundary Router or Forwarding address that is used to reach the destination, plus the external cost.
 - If the route is an OSPF External type 2, this is the external cost.
 - If the route is RIP, this is the RIP metric.
 - If this is a router advertisment route, this is the route preference (IPv6) only):
 - 1 If the router advertisement indicated a preference of high.
 - 2 If the router advertisement indicated a preference of medium.
 - 3 If the router advertisement indicated a preference of low.
 - If the route is static, this value is:
 - 0 if the route is direct (no first hop).
 - 1 if the route is indirect.

ROUTERADV

Displays information about all IPv6 gateways (dynamic routes) known from Router Advertisements by the TCP/IP server. The information displayed for each IPv6 gateway is similar to the respective output of the NETSTAT GATE command, except for Route Metric, which is not displayed. Instead the following information is shown:

· Route preference advertised by the first hop:

The first-hop router has advertised a preference of low. Low

Medium

The first-hop router has advertised a preference of medium

High The first-hop router has advertised a preference of high.

Route reachability (default routers only):

Yes The first-hop router is assumed to be reachable.

No The first-hop router is assumed to be unreachable.

Probing

The first-hop router is assumed to be unreachable and is being probed.

HE1p

?

1

Displays brief help information about the NETSTAT command and its operands and parameters.

H₀me

Displays the HOME list known by the TCP/IP server; an internet address, link name, and subnet mask column are displayed for each entry of the HOME list. When the IP address is a virtual switch management address, the VSWITCH name is also displayed. For more information about the HOME list (and the HOME statement), see *z/VM: TCP/IP Planning and Customization*.

PΙ

IDENTify ipv4 address IDENTify ipv4 address SSL

> Produces information identifying the connections associated with a given IPv4 address or set of IPv4 addresses. To select a set of IPv4 addresses, specify the last token of the IPv4 address as an asterisk (*).

Example: To produce information about all IPv4 addresses that begin with 9.148.134, use the operand 9.148.134.*.

The output from IDENTIFY is intended for programmable use and as such is delimited with blanks rather than formatted in columns.

The following information is given for each connection:

- Local IP address
- · Local port
- · Foreign IP address
- · Foreign port
- Client name
- Logical device status (for Telnet connections only; not included when the SSL operand is also used.)

When the SSL operand is included, information is produced for only secure connections. In addition to the previously described information (up to, and including the client name), the following information (in order) is added for connections that can be categorized as a secure session:

- Connection type identifier; E represents an explicit (TLS-negotiated) connection; I represents an implicit (non-negotiated) connection.
- SSL Server ID
- Certificate Label. For a connection associated with a z/VM client, the string <None> appears in this field.
- · Cipher Details
 - Class (Null, SSLV2, SSLV3, TLS)
 - Hash (Null, SHA1, MD5)
 - Algorithm (Null, RC2, RC4, DES, DES3, FIPSDES, FIPS3DES)
- Keyring (if it exists). When keyring information is present, a semicolon (;) delimits this from previously listed values.

- Because secure session information is established and maintained differently for explicit (E) and implicit (I) connections, two entries are present in the command output for an implicitly secured session:
 - one entry that identifies the SSL server as a participant, for which security details are included, and
 - one entry that identifies the local client participant of the secure session (for which security details are not repeated)

For a secure session established by explicit means, only one entry exists, which identifies both of the participants of the session, as well as its security details.

- The above-listed security details are not included for subordinate connections, which jointly comprise a secure session — that is, the remote host-to-SSL server and SSL server-to-local application connections.
- 3. If an explicit secure connection is changed to one that is not secure (as can be done with the FTP CCC command), that connection still is identified as an explicit (E) connection, but without additional security details.

PI end

Interval seconds

Initiates a full screen display of TCP/IP connections. The screen is updated every seconds seconds; the default is 20 seconds. Information may be sorted by idle time (the default), foreign socket, user ID, bytes out, bytes in, or by (connection) state.

The following information is given for each connection:

- User ID
- · Bytes sent on the connection
- · Bytes received on the connection
- Local port
- · Connection State
- Idle time (hh:mm:ss)
- · Foreign socket

The number of TCBs in use is displayed at the bottom of the screen.

There are two sets of PF keys for the Interval display screen. The initial set of PF keys are defined as follows:

```
PF 1 Usr
               Sort by user ID.
PF 2 Sock
               Sort by foreign socket.
PF 3 Quit
               Exit.
PF 4 BOut
               Sort by bytes out (bytes sent on a connection).
PF 5 BIn
               Sort by bytes in (bytes received on a connection).
PF 6 PFSet2 Show PF key set number 2.
               Scroll up (backward) — when more than one screen of
PF 7 Up
               information is available for display.
PF 8 Dwn
               Scroll down (forward) — when more than one screen of
               information is available for display.
PF 9 T/B
               Scroll to top / bottom of data.
PF 10 Rgtleft Shift screen data to the right or left (back to the original
               position).
PF 11 Ip@
               Locate function; the line at which the cursor is positioned
               becomes the first line of displayed information.
PF 12 Rfsh
               Refresh connection information.
```

If you press PF 6 while the first PF key set is displayed, you see the second set of PF keys:

```
PF 1 St
```

Sort by connection state.

Save data in a file (NETSTAT DATA) and exit.

PF 3 Ouit

Exit.

PF 4 Unused

Not set.

PF 5 Unused

Not set.

PF 6 PFSet1

Show PF key set number 1.

PF 7 Up

Scroll up (backward) — when more than one screen of information is available for display.

PF 8 Dwn

Scroll down (forward) — when more than one screen of information is available for display.

PF 9 T/B

Scroll to top / bottom of data.

PF 10 Rgtleft

Shift screen data to the right or left (back to the original position).

PF 11 Unused

Not set.

PF 12 Rfsh

Refresh connection information.

Note: The Enter key performs the same function as PF 3 (Quit).

LEVe1

Displays the processor type, z/VM system level, and TCP/IP system level and identifies the stack MODULE (filename, filetype, and filemode) being executed by the TCP/IP server the date when the MODULE was generated and where in storage it is loaded.

NEighbor ipv6 address

Displays the neighbor cache entry for the designated IPv6 address. The ipv6 address is specified in full or compressed form.

See Note on the NEIGHBOR option.

NEighbor *ipv6* address/prefixlength

Displays the neighbor cache entry for the designated set of IPv6 addresses. To display entries for multiple IPv6 addresses, specify an IPv6 address that is immediately followed by a slash (/) and a prefix length.

Example: Specifying **NETSTAT NEIGHBOR** with an *ipv6_address/prefixlength* value of 1080:5F00:AA:BB:CC::/80 will display the neighbor cache entries for all of the IP addresses from 1080:5F00:AA:BB:CC:0:0:0 through 1080:5F00:AA:BB:CC:FFFF:FFFF.

See "Note on the NEIGHBOR option."

NEighbor ALL

Displays the neighbor cache entry for all IPv6 addresses. An asterisk (*) can be used for this purpose as well.

Note on the NEIGHBOR option: The TCP/IP server does not maintain neighbor data for a HiperSockets link. Instead, it requests information from the adapter and creates a NETSTAT NEIGHBOR command display. To display current adapter-maintained neighbor data, issue at least two NETSTAT NEIGHBOR commands in sequence. The TCP/IP server requests adapter-maintained neighbor data upon each NETSTAT NEIGHBOR invocation. This data is not displayed for an initial NETSTAT NEIGHBOR command.

OBEY statement

Processes one or more TCP/IP server configuration statements or VSWITCH controller configuration statements as if they had been entered in a file and

used as the object of an OBEYFILE command. All data that follows the OBEY parameter is processed as part of the statement string. The OBEY command is subject to the considerations described in z/VM: TCP/IP Planning and Customization for use of the OBEYFILE command. In addition, the length of the OBEY command operand is limited to roughly 240 characters, so not all configuration changes can be made using this command.

Whenever you add or change a configuration statement using the OBEY command, be aware that the existing statement is replaced. Therefore, you must supply the entire statement, not just the new or changed portions.

When there is a problem with OBEY, file PROFILE TCPERROR is sent to your reader containing a description of the error and the following error message is displayed:

Configuration error. Details are in PROFILE TCPERROR.

Notes:

- 1. The OBEY command can be used only by privileged TCP/IP users, as identified by the TCP/IP server's OBEY statement. For more information about this facility, see *z/VM: TCP/IP Planning and Customization*.
- 2. Because the OBEY commands are processed asynchronously, you must wait for completion of a command before invoking any subsequent command that depends on a prior command. This is especially important when invoking commands to limit or turn on tracing.

OSAInfo

Displays basic information such as IP and MAC addresses from the OSA Address Table (OAT) for the devices defined for the TCP/IP virtual machine on OSA-Express cards that support the OSAINFO function. The SELECT filter can be used to chose information for a specific device. If no filter is used, the content of the OAT for all connected devices will be displayed.

DETails

Displays all content of the OAT available.

Notes:

1. The OSAINFO command can be used by privileged TCP/IP users only. For more information about listing user IDs with the OBEY statement, see *z/VM*: TCP/IP Planning and Customization.

P00Lsize

Displays information about free pool control block and data buffer pools. The following information is displayed for each free pool element:

- Name of the free pool element.
- Number of elements allocated at server initialization.
- · Number of elements available for use.
- "Low water mark" for this element pool; this is the fewest number of elements that have been available since TCP/IP was started.
- · Permit size calculated for this element. If the number of elements for a pool drops below the permit size, TCP/IP considers the pool to be running low.

For more information about the free pool, see z/VM: TCP/IP Planning and Customization.

RESETDOS

Resets the data displayed for the Denial-of-Service (DOS) attacks.

ı

ı

Notes:

1. The RESETDOS command can be used only by privileged TCP/IP users. Such users are identified with the TCP/IP OBEY statement. For more information about listing user IDs with the OBEY statement, see z/VM: TCP/IP Planning and Customization.

RESETPoo1

Resets the "informed" message flags for all free pool element pools. This allows pool-related notification messages and mail to again be sent.

When the number of elements for a particular pool drops below its permit size, the TCP/IP server sends a message and mail to all users listed in the INFORM list, and then sets an "informed" flag for that pool. This flag blocks further notifications for the pool, even its number of elements rises above, and then again drops below, the permit size.

Note: The RESETPOOL command can be used only by privileged TCP/IP users. Such users are identified with the TCP/IP OBEY statement. For more information about listing user IDs with the OBEY statement, see z/VM: TCP/IP Planning and Customization.

SELect filter

Specifies a character string that is used to limit response information to entries associated with one of the following:

- Client or server user ID (userid)
- IPv4 address (ipv4 address)
- IPv6 address (ipv6 address)
- IPv6 address with prefix (ipv6_address|prefixlength)
- Logical device number (*Idev*)
- Specifies a character string that is used to limit response information to entries associated with one of the following:

```
'*' or 'Device Names'
```

The value specified for *filter* can be a complete string, or a partial string terminated by an asterisk (*), which selects information about multiple entries that all begin with filter.

Example: To select information that corresponds to only the "default" gateway route known by TCP/IP, specify the filter value default for a NETSTAT GATE command, as follows:

```
netstat gate (select default
```

You can specify up to six unique filter values, each of which can be up to 40 characters long. If specified, the SELECT operand and its filter value(s) must be the last parameters of the NETSTAT command.

SOCKets

Displays information about each client using the socket interface.

Each set of one or more sockets is preceded in the response by a socket descriptor. The descriptor contains the following information:

Name: The virtual machine User id of the socket set owner.

Subtask: Identifies the client application

Path id: The IUCV path identifier

Pending call: The name of the active socket function, if any.

The following information is displayed for each socket:

Sock Is the socket number.

Indicates the socket type, such as stream (TCP) sockets, Type

datagram (UDP) sockets, raw sockets, or the special SNMP

DPI socket type used only by SNMP agents.

Bound to Shows the address and port to which the socket is bound.

> Unbound TCP and UDP sockets are not displayed by the NETSTAT CONN or NETSTAT INTERVAL commands.

Shows the address and port to which the socket is connected. Connected to

State Displays the TCP connection state for TCP sockets. For raw

sockets, the IP protocol number is displayed as well. If the

State field is blank, the Conn field is also blank.

Flgs Connection flag (displayed for TCP sockets only); possible

values are:

Α Indicates a connection on the almost accept queue.

C Indicates a connection on the accept queue.

L Indicates a listening socket.

Conn Displays the internal TCP control block (TCB) number used by

the TCP/IP server for this connection. Conn applies only to TCP sockets. If this field is blank, the flag for this connection will be an L; this indicates this is a listening socket for which the accept queue is full, or for which the TCP/IP server is temporarily unable to allocate resources to put a TCB in a "Listen" state. Attempts to connect to the port (displayed in the

Bound to field) are ignored; this allows TCP to retry the

connection.

SSL START userid

Initiates the controlled initialization of an SSL server, or all such servers that are members of a defined server pool.

When multiple NETSTAT SSL START commands are used (or userid is specified as ALL), the start up of all servers — other than the first identified server — is delayed, to avoid contention for common resources that are shared among the various pool servers.

TCp server

Identifies the TCP/IP stack server or the VSWITCH controller server for which status information is to be displayed, or to which commands are to be directed.

TELnet

1

Displays the status of the internal Telnet server.

UNBLock ipv4 address

Allows incoming traffic from the designated IPv4 address or set of IPv4 addresses by removing a previously defined filter. The specification must match the original definition.

UNBLock ipv6 address

Allows incoming traffic from the designated IPv6 address. The specification must match the original definition.

UNBLock ipv6 address/prefixlength

Allows incoming traffic from the designated set of IP addresses by removing a previously defined filter. The specification must match the original definition.

Up Displays the date and time that TCP/IP was started.

Return codes

The following is a list of the return codes generated by NETSTAT:

Code Description

- 0 Normal completion; no errors encountered.
- 1 Syntax error.
- 4 NETSTAT command error.
- 8 Execution error-runtime error.
- TCP/IP error. 12
- 20 User is not authorized to issue command.
- Command line is too long. 100

1nnnn nnnn is a CP return code from NETSTAT CP.

Examples

This section shows sample responses for various NETSTAT commands, issued with a specific operand or set of operands.

ALL

The following is a sample of the information that is displayed, in this case for two clients after entering NETSTAT ALL.

BLOCK

The following is a sample of the information that is displayed after entering NETSTAT BLOCK 9.130.48.*

```
VM TCP/IP Netstat level 620
                                   TCP/IP Server Name: TCPIP
Function performed
Ready;
```

CLIENTS

The following are examples of the information that is displayed for a client after entering NETSTAT CLIENTS.

For a client with notes handled:

```
VM TCP/IP Netstat level 620
                                  TCP/IP Server Name: TCPIP
Current clients:
Client: FTPSERVE
                                      Authorization: Autologged
Notes Handled: Buffer space available, Connection state changed, Data delivered,
Urgent pending, Other external interrupt received, Timer expired,
FSend response
FReceive erro, IUCV interrupt
                                      Last Forced: 2:36:59
Last Touched: 2:20:07
Vmcf error count: 0
Ready;
```

For a client with no notes handled:

```
VM TCP/IP Netstat level 620
                                 TCP/IP Server Name: TCPIP
Current clients:
Client: OPERATOR
                                      Authorization: Monitor, Informed
Notes Handled: none
Last Touched: 2:17:43
                                      Last Forced: 2:34:23
Vmcf error count: 0
Ready;
```

CONFIG Statement

ACCESS: The following is a sample of the information that is displayed after entering NETSTAT CONFIG ACCESS:

```
netstat config access
                                  TCP/IP Server Name: TCPIP

 Port(s):
                      23
Ready;
```

PORT: The following is a sample of the information that is displayed after entering **NETSTAT CONFIG PORT:**

```
netstat config port
VM TCP/IP Netstat level 620
                                TCP/IP Server Name: TCPIP
Configured Port Information:
Port: 5000
                  Protocol: TCP
IP Address: *
Monitor: Yes
User ID: MIGUELD
                  Certificate: MDCERT
Port: 520
                  Protocol: UDP
IP Address: *
Monitor: No
User ID: MPROUT06 Certificate: <none>
Port: TELNET
                  Protocol: TCP
IP Address: *
Monitor: Yes
User ID: IntClien Certificate: <none>
Port: 80
                  Protocol: TCP
IP Address: 24C:4562::2222:F009
Monitor: No
User ID: REDHAT1
                  Certificate: <none>
Port: 2000 - 2050 Protocol: TCP
IP Address: *
Monitor: Yes
User ID: Reserved Certificate: <none>
Port: 8080 Protocol: UDP
IP Address: 9.60.59.6
Monitor: No
User ID: TCPIP Certificate: <none>
Ready;
```

In the preceding sample NETSTAT CONFIG PORT output, the following are definitions for the related fields:

IP Address

IP address which will be used for the port(s). Asterisk (*) means that any IP address may bind to the port(s).

Monitor

This value relates to the NOAUTOLOG parameter of the PORT statement. Value is NO if NOAUTOLOG was specified.

User ID

The user for which this (these) port(s) are reserved. "Reserved" means that no user can listen on the given port(s). IntClien means the port(s) is/are reserved for the TELNET client. Asterisk (*) means any user may listen on the port(s).

ROUTERADV: The following is a sample of the information that is displayed after entering NETSTAT CONFIG ROUTERADV:

```
netstat config routeradv
VM TCP/IP Netstat level 620
                               TCP/IP Server Name: TCPIP
IPv6 Router Advertisement Information:
Link TOVSL2SWA6
 Send Router Advertisements: On
 Max Multicast Adv Interval: 600
 Min Multicast Adv Interval: 200
 Stateful Autoconfig Address: Off
 Stateful Autoconfig Other: Off
 Route Preference Value:
                            Medium
 MTU Size:
 Reachable Time:
 Message Retransmission Time: 0
 Current Hop Limit: 64
 Router Lifetime:
                             3
 Include source link address: On
 Prefix 5C6:C2C1::/64
  On-Link Determination:
  Auto Address Determination: On
  Valid Lifetime: 2592000
Preferred Lifetime: 604800
             5C7:C2C1::/64
 Prefix
  On-Link Determination: On
  Auto Address Determination: On
  Valid Lifetime: 2592000
                          604800
  Preferred Lifetime:
 Ready;
```

If z/VM is configured to send router advertisement messages (using the ROUTERADV configuration option, the configuration for all ROUTERADV options and for all ROUTERADVPREFIX options is displayed. If z/VM is not configured to send router advertisement messages, the following output will occur:

```
netstat config routeradv
                                  TCP/IP Server Name: TCPIP
VM TCP/IP Netstat level 620
IPv6 Router Advertisement Information: None
Ready:
```

SSL: The following is a sample of the information that is displayed after entering **NETSTAT CONFIG SSL:**

```
netstat config ssl
VM TCP/IP Netstat level 620
                                     TCP/IP Server Name: TCPIP01
SSL Server User ID: SSL00001 Status: Active Connections: 600
SSL Server User ID: SSL00002
SSL Server User ID: SSL00003
                                  Status: Active Connections: 600 Status: Active Connections: 300
SSL Server User ID: SSL00004
                                  Status: Eligible
SSL Server User ID: SSL00005 Status: Stopped
Maximum Session System Limit: 3000
Maximum Session Server Limit: 600
SSL Session High-Water Mark 1500
Ready;
```

TRACE: The following is a sample of the information that is displayed after entering NETSTAT CONFIG TRACE:

```
netstat config trace
VM TCP/IP Netstat level 620
                                 TCP/IP Server Name: TCPIP
Trace Destination: CONSOLE
Tracing enabled for:
  ARP, A220 handler, Claw interrupt handler, Claw wait scan,
 *CCS CP System Service, TCP congestion control, Consistency checker,
 CTC handler, Device driver, External interrupt handler, From-1822,
 HIPPI handler, A220 trace routine, ICMP, Internal Telnet server,
 Internal Telnet timeout handler, Ioctl for routing,
 I/O interrupt handler, IP-down, IP-request, IP-up,
 DDN1822 I/O interrupt handler, 1822-Status, 1822-Timer,
 IUCV-API-greeter, IUCV handler, Monitor, Notify,
 Common Packet handler, Parse-Tcp, PCCA handler, PCCA3 handler,
 Ping process, RAWIP-request, RAWIP-up, Retransmit-datagram,
 Roundtrip, Shutdown, SNMP DPI sub-agent, Sock-request, Status-in,
 Status-out, TCP-down, TCP-request, TCP-up, A220 common routine,
 To-CETI, CTC common routine, To-CLAW, HIPPI common routine,
 To-IUCV, To-IUCV signon, PCCA common routine, PCCA3 common routine,
 To-1822, UDP-request, UDP-up,
 ATM handler, ATM common routine, IGMP, Multicast, Dynamic Routing,
 OSD handler, OSD common routine, FPSM process, QDIO process, SSL,
 Denial of Service, IUCV interrupt director, Trace Table, Security,
 Neighbor Discovery
Detailed Tracing enabled for:
Selective Tracing enabled for the following users/devices/IP addresses:
 TCPMAINT
Ready;
```

TRANSLATE: The following is a sample of the information that is displayed after entering NETSTAT CONFIG TRANSLATE:

```
netstat config translate
VM TCP/IP Netstat level 620

HELP: The following is a sample of the information that is displayed after entering **NETSTAT CONFIG HELP:**

```
netstat config help
VM TCP/IP Netstat level 620 TCP/IP Server Name: TCPIP
Usage: NETSTAT CONFIG options
Options:
ACCESS
         - Query users with access to TCP/IP services
CONTROLLER - Query the Controller status of the virtual switch
OBEY - Query users with access to privileged TCP/IP operations
      - Query current AssortedParms and InternalClientParms
PARMS
PORT
         - Query reserved and secure port information
ROUTERADV - Query current ROUTERADV settings
SSL - Query SSL server user ID information
        - Query currently active TCP/IP tracing
TRACE
TRANSLATE - Query IP address to MAC address translations
ALL - Displays all of the above information
HELP or ? - Displays this help text
Note: If no options are specified, the default is PARMS TRACE
Ready;
```

In the preceding example, the first device indicated is TOTCP2, which is a device of type CTC (a Channel-to-Channel device) that has a base virtual address of 03F8 and whose device driver runs on CPU 0. There is one link defined for this device, named VCTC2. This link has LAN broadcast and multicast capabilities.

The second device indicated is LCS1, which is a device of type LCS (a LAN Channel Station device) that has a base virtual address of 09E0 and whose device driver runs on CPU 0. There are two links defined for this device — ETH1, an Ethernet link. The Net number (or, relative adapter number) for each device is 0; this indicates that this is the first link for this device. The ETH1 link has LAN broadcast and multicast capabilities. There are 3 members in the multicast group 224.67.113.10 and 5 members in the multicast group 225.36.12.9.

The status of these devices is "Ready", which indicates they are operational. Also, the Queue Size of zero for each indicates that no envelopes are queued for output.

```

In the preceding example, the first device in this example is DEVHS0, which is a device type of HIPERS (a HiperSocket device). This device has a device driver that runs on virtual CPU 0, a base virtual address of 0520, a port name of HSA0PORT, a IPv4 router type of NonRouter, and with ARP query capability. There is one link defined for this device, named LINKHS0, which is a device type of QDIOIP (Queued Direct I/O Internet Protocol) that has LAN broadcast capabilities and is multicast-capable. There is one member in the multicast group 224.0.0.1.

The second device indicated is DEVOSD0, which is a device type of OSD (indicating it is an OSA-Express Adapter using the QDIO Hardware Facility) at base virtual address 0540 with a port name of OSD0PORT and whose device driver runs on virtual CPU 0. This device is also an IPv4 and IPv6 NonRouter type with ARP query capability. One link is defined for this device, named LINKOSDO, which is a QDIOETHERNET device type that has LAN broadcast capabilities and is multicast-capable. IPv4 VIPA ARP indicates that this device is responsible for handling Address Resolution Protocol (ARP) requests for IPv4 VIPA addresses and Proxied IP addresses on this network. IPv6 VIPA ND indicates that this device is responsible for handling Neighbor Discovery requests for IPv6 VIPA addresses on this network. IPv4 VIPA ARP and IPv6 VIPA ND may be displayed even when VIPA addresses have not been configured on this system. In this case, they indicate the interface which would be responsible for VIPA addresses should they be added at a later time. There is one member in the IPv4 multicast group (224.0.0.1) and one member in each of the IPv6 multicast groups (FF02::1:FF00:1F and FF02::1). LINKOSD0 is enabled for IPv6 support.

In the preceding example, the first device is DEV4000, which is an IEDN (intraensemble data network) device at base address 4000. An IEDN device is a special type of OSA-Express device (CHPID type OSX) used when the z/VM system is managed by the Unified Resource Manager. This device has the same characteristics as an OSD (QDIO) device.

The second device indicated is DEV6096, which is an INMN (intranode management network) device at base address 6096. As with the IEDN device, an INMN device (CHPID type OSM) is used when the system is managed by the Unified Resource Manager, and it is, essentially, another type of an OSD (QDIO) device.

Address: FE80::200:0:D:4040
Flags: Autoconfigured
DAD State: Address Passed DAD
Origin: Link-local Link:

In the preceding sample NETSTAT HOME output, the following are definitions for the IPv6 related fields:

Link: The name of the link associated with this IPv6 HOME entry.

Address: The IPv6 address for this IPv6 HOME entry.

Flags: Possible values for Flags are:

Ready;

Autoconfigured

This IPv6 address was automatically created by TCP/IP as a result of a received prefix in a Router Advertisement, a

prefix on a HOME statement, a prefix on a

ROUTERADVPREFIX statement, or the IPv6 address is a

link local address.

Autoconfigured, Deprecated

The preferred lifetime of the autoconfigured IPv6 address has expired.

DAD State: The status of Duplicate Address Detection (DAD) processing for this

IPv6 Home entry. Values for DAD State are:

Pending Start of Link

The link is not active.

In Progress

Duplicate Address Detection is in progress.

Address Passed DAD

This address has passed Duplicate Address Detection.

Interface ID Passed DAD

The Interface Identifier in this IPv6 address had previously passed Duplicate Address Detection.

Address Failed DAD

This address has failed Duplicate Address Detection.

Interface ID Failed DAD

The Interface Identifier in this IPv6 address had previously failed Duplicate Address Detection.

DAD Bypassed; Device IP table update successful

Duplicate Address Detection has been bypassed for this IPv6 address. The IPv6 address was successfully added to the IP table for the device.

DAD Bypassed; Device IP table update failed

Duplicate Address Detection has been bypassed for this IPv6 address. The IPv6 address could not be added to the IP table for the device. See the messages on the TCP/IP stack console for the reason why this address got this failure.

Unknown DAD state; IPv6 disabled

The link local address for this link failed Duplicate Address Detection, so IPv6 is disabled on this link.

Origin:

The origin for this IPv6 address. Values for Origin are:

HOME statement

This IPv6 address was created by specifying the address or prefix on a HOME statement.

Received Router Advertisement

This IPv6 address was created as a result of receiving a prefix in a Router Advertisement.

ROUTERADVPREFIX statement

This IPv6 address was created as a result of specifying this prefix on a ROUTERADVPREFIX statement.

Link-local

This IPv6 address is the link local address that is automatically created by TCP/IP.

IDENTIFY

The following is a sample of the information that is displayed after entering NETSTAT IDENTIFY 9.130.57.*:

```
VM TCP/IP Netstat level 620
                                 TCP/IP Server Name: TCPIP
9.117.32.29 23 9.130.57.37 1081 INTCLIEN LOOE6 DIALED TO YVETTE 0200
9.117.32.29 23 9.130.57.37 1082 INTCLIEN LOODS DIALED TO PVM 050C
9.117.32.29 23 9.130.57.37 1081 INTCLIEN LOOOB ENABLED
9.117.32.29 23 9.130.57.37 1081 INTCLIEN L0027 LOGON AS M1GR2S 0009
9.117.32.29 1501 9.130.57.110 2538 DSOSERV
9.117.32.29 1501 9.130.57.54 1465 DSOSERV
9.117.32.29 1501 9.130.57.81 1764 DSOSERV
```

The following is a sample of the information that is displayed after entering **NETSTAT IDENTIFY SSL:**

```
TCP/IP Server Name: TCPIP
VM TCP/IP Netstat level 620
9.117.32.29 990 9.60.67.161 2676 FTPSERVE E SSL00001 TSTCERT1 SSLV3 SHA1 RC4 RSA
9.117.32.29 992 9.60.67.161 2658 INTCLIEN I SSL00001
9.117.32.29 23 9.60.67.161 2663 INTCLIEN E SSL00001 TSTCERT1 SSLV3 SHA1 RC4 RSA
9.117.32.29 1024 9.60.67.161 2658 SSL00001 I SSL00001 TSTCERT2 SSLV3 SHA1 RC4 RSA
    ; /etc/gskadm/keyring data/system01
9.117.32.29 1058 9.117.32.29 23 SSL00001
9.117.32.29 1024 9.60.67.161 2663 SSL00001
9.117.32.29 1059 9.117.32.29 990 SSL00001
9.117.32.29 1024 9.60.67.161 2676 SSL00001
```

Note: In the preceding example, the data for the connection authenticated using the TSTCERT2 certificate spans two lines, due to formatting restrictions. For actual command results, this line and the subsequent line that contains the /etc/gskadm/keyring data/system01 text, instead would be a single line of

INTERVAL

The following is a sample of the information that is displayed after entering NETSTAT INTERVAL. The INTERVAL parameter can be used on an IBM 3278 or 3279 display station, or at a terminal or workstation that is emulating an IBM 3278 or 3279 display station.

Notes:

- 1. The Enter key performs the same function as PF 3 (Quit).
- The INTERVAL option provides a full-screen interface for its output as opposed to line-mode.

   9.100.200.125
   IPv4 Multicast Address:
                                             MAC Address
   224.0.0.1
                                             02-09-57-60-00-63
   224.0.0.5
                                             02-09-57-60-00-63
Device DEVB101:
 Data not available yet. Reissue the NETSTAT OSAINFO command.
Device DEVB102: data as of 06/06/10 08:45:20 *BUFFERED*
  Laver 2
    VMAC address:
                                             02-09-57-60-00-63
   VLAN ID:
                          1
  Layer 3
   IPv4 Address:
   9.100.200.123
    9.100.200.124
    9.100.200.125
```

```
IPv4 Multicast Address:
                                      MAC Address
                                      02-09-57-60-00-65
224.0.0.2
224.0.0.4
                                      02-09-57-60-00-65
```

For Layer 2:

```
NETSTAT OSAINFO (SELECT DEVB100
VM TCP/IP Netstat Level 620 TCP/IP Server Name: TCPIPBX
Device DEVB100: data as of 06/06/10 09:49:28
   VMAC address:
                                             02-09-57-60-00-63
   VLAN ID:
                                             1
```

For Layer 3:

```
NETSTAT OSAINFO (SELECT DEVB100
VM TCP/IP Netstat Level 620 TCP/IP Server Name: TCPIPBX
Device DEVB100: data as of 06/06/10 09:49:28
 IPv4 Address:
 9.100.200.123
 9.100.200.124
 9.100.200.125
 IPv4 Multicast Address: ..... MAC Address
```

..... 224.0.0.1 02-09-57-60-00-63 224.0.0.5

In this example, data is displayed for devices DEVB100 and DEVB102. Data displayed consists of layer 2 and layer 3 information, giving IP, IP multicast and MAC addresses.

Note that only data for device DEVB100 could be retrieved with the OSAINFO command, while data for DEVB101 and DEVB102 was not returned in time from the OSA device. However, buffered data was available for DEVB102, visible by string '*BUFFERED*' in the output. For DEVB101, no buffered data was available as apparently the OSA Address Table (OAT) for this device was not requested yet.

POOLSIZE

The following is a sample of the information that is displayed after entering NETSTAT POOLSIZE.

Ready;
```

RPCINFO Command

Purpose

Use the RPCINFO command to display the servers that are registered and operational with any portmapper on your network. The RPCINFO command makes a Remote Procedure Call (RPC) to an RPC server and displays the results.

Operands

-p host

Queries the portmapper on the specified host and prints a list of all registered RPC programs. If host is not specified, the system defaults to the local host name.

-n portnum

Specifies the port number to be used for the -t and -u options in place of the port number that is given by the portmapper.

-u host prognum versnum

Sends an RPC call to procedure 0 of prognum on the specified host using UDP, and reports whether a response is received. The variable prognum is the name or number of the RPC program.

-t host prognum versnum

Sends an RPC call to procedure 0 of prognum on the specified host using TCP, and reports whether a response is received.

-b prognum versnum

Sends an RPC broadcast to procedure 0 of the specified prognum and versnum using UDP, and reports all hosts that respond.

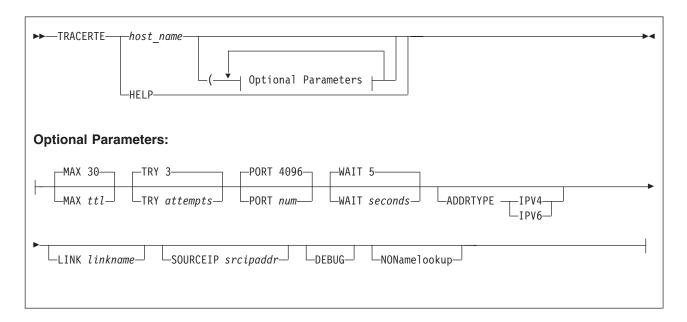

If you specify versnum (the version number), RPCINFO attempts to call that version of the specified program. If you do not specify a version, RPCINFO prints error information.

Note: The version number is required for the -b parameter.

Usage Notes

1. RPCINFO requires SCEERUN LOADLIB to be globally available. You should ensure the IBM Language Environment® can be accessed. It is included in the z/VM base.

TRACERTE Command

Purpose

Use the TRACERTE command to debug network problems. The Traceroute function sends UDP requests with varying Time-to-live (TTL) and listens for TTL-exceeded messages from the routers between the local host and the foreign host.

Operands

host name

Specifies the internet host name used to route packets.

Specifies the maximum TTL. The range for valid values is 1 to 255. The default is 30.

TRY attempts

Specifies the number of attempts. The range for valid values is 1 to 20. The default is three.

PORT num

Specifies the starting port number. The range for valid values is 2048 to 60000. The default is 4096.

WAIT seconds

Specifies the number of seconds to wait for a response. The range for valid values is 1 to 255. The default is five.

ADDRTYPE IPV4

Indicates that TRACERTE is to attempt to resolve the specified host name to an IPv4 type address. If the ADDRTYPE option is not specified, TRACERTE will attempt to determine the address type to which the host name should be resolved based on a LINK option being specified, or on a SOURCEIP option being specified. If none of these options are specified, TRACERTE will first try to resolve the host name to an IPv6 address, and, if unsuccessful, will attempt to resolve the host name to an IPv4 address.

ADDRTYPE IPV6

Indicates that TRACERTE is to attempt to resolve the specified host name to an IPv6 type address. If the ADDRTYPE option is not specified, TRACERTE will attempt to determine the address type to which the host name should be resolved based on a LINK option being specified, or on a SOURCEIP option being specified. If none of these options are specified, TRACERTE will first try to resolve the host name to an IPv6 address, and, if unsuccessful, will attempt to resolve the host name to an IPv4 address.

LINK linkname

Allows you to specify the link on which to send out the packet. The LINK parameter is valid for tracing IPv6 targets only.

When issuing TRACERTE to a link-local address, the LINK option **must** be specified or the TRACERTE will fail. This is due to the fact that all IPv6 link-local addresses have the same prefix (FE80::Interface_ID), so, depending on how the Interface_ID is generated, hosts on different links could have the same link-local address. If the LINK option is not specified, the link to be used is determined from the routing table.

SOURCEIP *srcipaddr*

Allows you to specify the source IP address that is placed in the IP header when the packet is sent out. This is needed because IPv6 can have multiple IP addresses (link-local, site-local, and global) associated with a single link, and you need to verify that the TTL-exceeded error is returned to a specific address. If the SOURCEIP option is not specified, it is determined from the home list.

DEBUG

Specifies that extra messages are to be printed.

NONamelookup

Specifies that TRACERTE should print hop addresses numerically rather than both symbolically and numerically. This eliminates a name server query at each hop along the path.

Usage Notes

1. You can enter an optional parameter multiple times, but only the last instance is used.

Example: In the following example, MAX is used twice, which is valid, but the program uses the last one (MAX 15):

tracerte 9.60.67.166 (MAX 25 MAX 15

- 2. The ADDRTYPE option allows you to specify the address type that should be returned when resolving the destination host name that was specified on the TRACERTE command. If the ADDRTYPE option is not specified, TRACERTE will attempt to determine the address type to which the host name should be resolved based on a LINK option being specified, or on a SOURCEIP option being specified. If none of these options are specified, TRACERTE will first try to resolve the host name to an IPv6 address, and, if unsuccessful, TRACERTE will attempt to resolve the host name to an IPv4 address.
- 3. The range of port numbers that the TRACERTE command uses are normally invalid; however you can change the starting port number for this range if the target host is using a nonstandard UDP port.
- 4. The TRACERTE function will give unpredictable results if the TCP/IP stack is configured to use equal-cost multipath support. With this support, there may be multiple paths to a single destination. When TRACERTE is invoked, it will send the UDP requests out through the different paths. Since the packets will be traveling different paths to the same destination, the responses returned will not be for a single path.
- 5. TRACERTE uses the domain name server for inverse name resolution. If a host name is returned from the domain name server, it is printed along with its IP address. For more information about using domain name servers, see *z/VM*: TCP/IP Planning and Customization, SC24-6238.
- If TRACERTE receives an ICMP destination unreachable code other than "Port Unreachable," the TRACERTE command issues one of the following flags and stops processing:

Code	Meaning
!H	Destination address is not reachable
!N	Destination network is not reachable
!P	Destination protocol is not accessible
!S	Destination address is administratively blocked
!F	Fragmentation is needed

Return codes

- 0 Command Successful
- 8 Syntax Error
- Socket Error 16
- 100 Command line is too long

Examples

The following are examples using the TRACERTE command:

 The second hop does not send TTL (Time-to-live) exceeded messages. Sometimes packets are lost (hops 6, 7, and 10).

```
tracerte cyst.watson.ibm.com
Trace route to CYST.WATSON.IBM.COM (9.2.91.34)
1 (9.67.22.2) 67 ms 53 ms 60 ms
2 * * *

    (50c6:c2c1:dfec:abcd:9:60:28:216) 2 ms 3 ms 2 ms
```

PING Command

Purpose

Use the PING command to send an echo request to a foreign node to determine if the node is accessible. PING uses ICMP as its underlying protocol.

Operands

host name

Specifies the foreign host to which you want to send the echo request. If you omit the host name, the system prompts you for a host name. The host name is either a character-string name or the internet address in the standard format of the foreign host (dotted-decimal format for IPv4 addresses, and either full or compressed format for IPv6 addresses).

He1p

Provides help information about the PING command. You cannot place the HELP parameter on the PING command line with other parameters.

Length bytes

Sets the number of bytes of the echo request. If you do not specify the operand, the default is 256. The number of bytes must be between 8 and the maximum value determined by large envelope size (Irg env size). For more information about large_env_size, see z/VM: TCP/IP Planning and Customization.

Count echo

Sets the number of echo requests that are sent to the foreign host. If you do not specify the operand, the default is 1. The number echo must be between 1 and 2³¹ –1 (2 147 483 647). If *echo* is 0, the PING command sends echo requests continually.

Timeout seconds

Sets the number of seconds that the PING command waits for a response. If you do not specify the operand, the default is 10. The number for seconds must be between 1 and 100.

ADDRTYPE IPV4

Indicates that PING is to attempt to resolve the specified host name to an IPv4 type address. If the ADDRTYPE option is not specified, PING will attempt to determine the address type to which the host name should be resolved based on a LINK option being specified, or on a SOURCEIP option being specified. If none of these options are specified, PING will first try to resolve the host name to an IPv6 address, and, if unsuccessful, it will attempt to resolve it to an IPv4 address.

ADDRTYPE IPV6

Indicates that PING is to attempt to resolve the specified host name to an IPv6 type address. If the ADDRTYPE option is not specified, PING will attempt to determine the address type to which the host name should be resolved based on a LINK option being specified, or on a SOURCEIP option being specified. If none of these options are specified, PING will first try to resolve the host name to an IPv6 address, and, if unsuccessful, it will attempt to resolve it to an IPv4 address.

LINK linkname

Allows you to specify which link to send the packet out on. The LINK parameter is valid for pinging IPv6 targets only.

If the LINK option is not specified, the link to be used is determined from the routing table. When issuing PING to a link-local address, the LINK option must be specified or the PING will fail. This is due to the fact that all IPv6 link-local

addresses have the same prefix (FE80::Interface ID), so, depending on how the Interface ID is generated, hosts on different links could have the same link-local address.

SOURCEIP *srcipaddr*

Allows you to specify the source IP address that is placed in the IP header when the packet is sent out. This is needed because IPv6 can have multiple IP addresses (link-local, site-local, and global) associated with a single link, and you need to verify that the PING is returned to a specific address. If the SOURCEIP option is not specified, it is determined from the home list.

DEBUG

Displays more detailed information about the packets being sent and received by the PING program.

Usage Notes

- 1. More than one option can be placed on the PING command line; however, the HELP parameter is an exception and cannot be placed on the PING command line with other parameters.
- 2. You can enter an optional parameter multiple times, but only the last instance is

Example: In the following example, LENGTH is used twice, which is valid, but the program uses the last one (LENGTH 1000):

```
ping 9.60.67.166 ( LENGTH 900 LENGTH 1000
```

3. When the TCP/IP stack is configured to use equal-cost multipath support, and there are multiple equal-cost paths to the destination being pinged, the ping results may seem inconsistent because the echo requests will be sent out through different interfaces. In the example below, If you ping 10.2.1.3 twice (or once with a COUNT 2 specified), the first echo request will be sent out through LINK1, and the second echo request will be sent out through LINK2.

```
GATFWAY
10.2.1.3
                   LINK1
                              4000
                                       HOST
10.2.1.3
                   LINK2
                              4000
                                       HOST
```

- 4. PING does not support CMS subset mode.
- 5. If you issue HX while PING is running, the only valid command at the VM READ is BEGIN. Any other CMS command issued will be treated as if it is the BEGIN command. You will only see the Ready; message.

Return codes

- 0 Command Successful.
- 4 One or more of the PING attempts timed out.
- A communication error between PING and the TCP/IP stack occurred.
- Socket Error. 16
- 100 A PING command was issued with invalid syntax.

Examples

The following are examples of using the PING command:

PING to an IPv4 destination:

```
ping gdlvm7
  Ping level 620: Pinging host GDLVM7 (9.56.212.11).
                   Enter #CP EXT to interrupt.
  PING: Ping #1 response took 0.024 seconds. Successes so far 1.
  Ready; T=0.04/0.06 12:48:12

    PING to an IPv6 destination:

  ping linuxipv62.tcp (addrtype ipv6
  Ping level 620: Pinging host LINUXIPV62.TCP.raleigh.ibm.com
  (fec0:0:0:1:9:67:114:44)
                 Enter #CP EXT to interrupt.
  PING: Ping #1 response took 0.002 seconds. Successes so far 1.
  Ready; T=0.04/0.06 12:48:12
· PING to an IPv6 address:
  ping 50C6:C2C1::9:60:28:215
  Ping Level 510: Pinging host 50C6:C2C1::9:60:28:215.
                   Enter #CP EXT to interrupt.
  PING: Ping #1 response took 0.004 seconds. Successes so far 1.
  Ready;
```

Chapter 7. SSL Certificate/Key Management and SSL Tracing Information

This topic discusses

- How to use the GSKKYMAN command to manage private SSL keys and certificates. In addition, detailed examples using the GSKKYMAN command are shown in this topic (see "GSKKYMAN Interactive Mode Examples" on page 226).
- · How to set up SSL tracing.

SSL Certificate Management

SSL connections make use of public/private key mechanisms for authenticating each side of the SSL session and agreeing on bulk encryption keys to be used for the SSL session. To use public/private key mechanisms (termed PKI), public/private key pairs must be generated. In addition, X.509 certificates (which contain public keys) may need to be created, or certificates must be requested, received, and managed.

SSL support uses the **gskkyman** utility to manage PKI private keys and certificates. Invoke the **gskkyman** utility with the CMS GSKKYMAN command. GSKKYMAN creates, fills in, and manages a file that contains PKI private keys, certificate requests, and certificates. This file is called a **key database** and, by convention, has a file extension of **.kdb**.

SSL uses the GSK_KEYRING_FILE environment variable to specify the locations of the PKI private keys and certificates. The key database file name is passed in this environment variable.

gskkyman Overview

gskkyman is a program that creates, fills in, and manages a file that contains PKI private keys, certificate requests, and certificates. This file is called a **key database** and, by convention, has a file extension of **.kdb**.

The interface to **gskkyman**, while command-line based, is an interactive dialog between you (the user) and the program. At each step, the interactive **gskkyman** program prompts you with one or more lines of output and expects a numeric choice to be supplied as input at the prompt. Once a choice has been made, the **gskkyman** program prompts you for the individual pieces of information needed to fulfill the request. You are prompted for each piece of information. Many times there is a default choice that is listed between parentheses at the end of the command prompt. If the default choice is acceptable, press the space bar, then Enter, to select the default. If a choice other than the default is desired, enter the value at the prompt and press Enter. If a value is entered that is outside of the acceptable range of inputs, you will be re-prompted for the information.

Note: For a description of command line mode functions and options, see "GSKKYMAN Command Line Mode Syntax" on page 260.

Run **gskkyman** from CMS. You need access to the TCPMAINT 591 and 592 disks where the GSKKYMAN EXEC, load module, SSL code, and message catalogs reside. By default, **gskkyman** accesses the US English message catalogs. If you

© Copyright IBM Corp. 1987, 2011 215

want **gskkyman** to access the Japanese message catalogs instead, set the NLSPATH environment variable by executing the following commands from a REXX EXEC:

```
nlspath = '/usr/lib/nls/msg/Ja_JP.IBM-939/%N'
'globalv select cenv put nlspath'
```

Key Database Files

Key database files are password protected because they contain the private keys that are associated with some of the certificates that are contained in the key database. Private keys, as their name implies, should be protected because their value is used in verifying the authenticity of requests made during PKI operations.

It is recommended that key database files be set with the following string of file permissions:

```
rw- --- (600) (read-write for only the owner of the key database)
```

The owner of the key database should be the user who will be managing the key database. The user ID that runs the program using the key database (LDAP or SSL server) must have at least read permission to the key database file at runtime. If the program runs under a different user ID than the administrator of the key database file, it is recommended that a group be setup to control access to the key database file. In this case, it is recommended that you set the permissions on the key database file to the following:

```
rw- r-- --- (640) (read-write for owner and read-only for group)
```

The owner of the key database file is set to the administrator user ID and the group owner of the key database file is set to the group that contains the server that will be using the key database file.

A key database that is created as a FIPS mode database, can only be updated by gskkyman or by using the CMS APIs executing in FIPS mode. Such a database, however, may be opened as read-only when executing in non-FIPS mode. Key databases created while in non-FIPS mode cannot be opened when executing in FIPS mode.

gskkyman Interactive Mode Descriptions

Interactive mode is entered when the GSKKYMAN command is entered without any parameters. A series of menus will be presented to allow you to select the database functions to be performed. Leading and trailing blanks will be removed from data entries but imbedded blanks will be retained. Blanks will not be removed from passwords.

Database Menu

This is the top-level menu and is displayed when the GSKKYMAN command starts:

Database Menu

- 1 Create new database
- 2 Open database
- 3 Change database password
- 4 Change database record length
- 5 Delete database
- 6 Create key parameter file
- 7 Display certificate file (Binary or Base64 ASN.1 DER)
- 0 Exit program

Enter option number:

Figure 21. Database Menu

Create new database

This option will create a new key database and the associated request database. You will be prompted to enter the key database name, the database password, the password expiration interval, and the database record length and choose either a FIPS or non-FIPS database (see "Key Database Files" on page 216 for a discussion of FIPS mode databases).

The fully-qualified key database name must be 2 to 251 characters. The file can contain an extension consisting of 1 to 3 characters. The recommended extension is ".kdb". If the name does not end with an extension to allow for the addition of an extension when creating the request database or the password stash file, the maximum database name is 247 characters. The key database name may not end with '.rdb' or '.sth' as these extensions are reserved for the request database and the password stash file.

The database password must be between 1 and 128 characters. A password exceeding 128 characters will be truncated to 128 characters.

The password expiration interval must be between 0 and 9999 days (a value of 0 indicates the password does not expire).

The record length must be large enough to contain the largest certificate to be stored in the database and must be between 2500 and 65536.

Two files will be created: the key database and the request database with an extension of '.rdb'. The file access permissions will be set so only the owner has access to the files.

Open database

This option will open an existing database. You will be prompted to enter the key database name and the database password.

The fully-qualified key database name must be between 2 and 251 characters and should either have no extension or an extension of '.kdb' (the maximum database name is 247 characters if the name does not end with an extension of 1-3 characters to allow for the addition of an extension when accessing the request database or the password stash file). The key database name may not end with '.rdb' or '.sth' as these extensions are reserved for the request database and the password stash file.

Change database password

This option will change the database password. You can change the password at any time but you must change it once it has expired in order to access the database once more. You will be prompted to enter the key

database name, the current database password, the new database password, and the new password expiration interval.

The fully-qualified key database name must be between 2 and 251 characters and should either have no extension or an extension of '.kdb' (the maximum database name is 247 characters if the name does not end with an extension of 1-3 characters to allow for the addition of an extension when accessing the request database or the password stash file). The key database name may not end with '.rdb' or '.sth' as these extensions are reserved for the request database and the password stash file.

The new database password must be between 1 and 128 characters.

The password expiration interval must be between 0 and 9999 days (a value of 0 indicates the password does not expire).

Change database record length

This option will change the database record length. All database records have the same length and database entries cannot span records. You can increase the record length if you find it is too small to store a new certificate. You can decrease the record length to reduce the database size if the original record length is too large. You cannot reduce the record length to a value smaller than the largest certificate currently in the database. You will be prompted to enter the key database name, the database password, and the new record length.

The fully-qualified key database name must be between 2 and 251 characters and should either have no extension or an extension of '.kdb' (the maximum database name is 247 characters if the name does not end with an extension of 1-3 characters to allow for the addition of an extension when accessing the request database or the password stash file). The key database name may not end with '.rdb' or '.sth' as these extensions are reserved for the request database and the password stash file.

The new record length must be between 2500 and 65536.

Delete database

This option will delete the key database, the associated request database, and the database password stash file. You will be prompted to enter the key database name.

The fully-qualified key database name must be between 2 and 251 characters and should either have no extension or an extension of '.kdb' (the maximum database name is 247 characters if the name does not end with an extension of 1-3 characters to allow for the addition of an extension when accessing the request database or the password stash file). The key database name may not end with '.rdb' or '.sth' as these extensions are reserved for the request database and the password stash file.

Create key parameter file

This option will create a file containing a set of key generation parameters. Key generation parameters are used when generating Digital Signature Standard (DSS) and Diffie-Hellman (DH) keys. The parameters will be stored in the specified file as an ASN.1-encoded sequence in Base64 format. This file can then be used when creating a signed certificate. The same key generation parameters can be used to generate multiple public/private key pairs. Using the same key generation parameters significantly reduces the time required to generate a public/private key pair. In addition, the Diffie-Hellman key agreement method requires both sides to use the same group parameters in order to compute the key exchange value. Refer to FIPS 186-2 (Digital Signature Standard) and RFC 2631 (Diffie-Hellman Key Agreement Method) for more information on the key generation parameters. The key parameter generation process can take from 1 to 10 minutes depending upon key size, processor speed and system load.

Display certificate file (Binary or Base64 ASN.1 DER)

This option displays information about an X.509 certificate file. You will be prompted to enter the certificate filename. The fully-qualified certificate filename must be between 2 and 251 characters. The specified file must contain either a binary ASN.1 DER-encoded certificate or the Base64-encoding of a binary ASN.1 stream. A Base64-encoded certificate must be in the local code page.

Key Management Menu

The Key Management Menu is displayed once the key database has been created or opened. The key database and the associated request database are opened for update and remain open until you return to the Database Menu.

```
Key Management Menu
      Database: Database name
      Expiration: Expiration date
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
```

Figure 22. Key Management Menu

Manage Keys and Certificates: This option manages certificates with private keys. A list of key labels is displayed. Pressing the ENTER key without making a selection will display the next set of labels. Selecting one of the label numbers will display the following menu:

```
Key and Certificate Menu
       Label: Certificate label name
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate and key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
```

Figure 23. Key and Certificate Menu

Show certificate information

This option displays information about the X.509 certificate associated with the private key.

Show key information

This option displays information about the private key.

Set key as default

This option makes the current key the default key for the database.

Set certificate trust status

This option sets or resets the trusted status for the X.509 certificate. A certificate cannot be used for authentication unless it is trusted.

Copy certificate and key to another database

This option copies the certificate and key to another database. An error will be returned if the certificate is already in the database or if the label is not unique. A certificate and key may only be copied from a FIPS mode database to another FIPS mode database. A certificate and key may not be copied from a non-FIPS mode database to a FIPS mode database.

Export certificate to a file

This option exports just the X.509 certificate to a file. The supported export formats are ASN.1 Distinguished Encoding Rules (DER) and PKCS #7 (Cryptographic Message Syntax)

Export certificate and key to a file

This option exports the X.509 certificate and its private key to a file. The private key is encrypted when it is written to the file. The password you select will be needed when you import the file. The supported export formats are PKCS #12 Version 1 and PKCS #12 Version 3. The PKCS #12 Version 1 format is obsolete but is the only format supported by some SSL implementations. For FIPS mode databases, the export format supported is PKCS #12 Version 3. The strong encryption option uses Triple DES to encrypt the private key while the export encryption option uses 40-bit RC2. Strong encryption is the only supported option when exporting from a FIPS database. The export file will contain the requested certificate and its certification chain.

Delete certificate and key

The certificate and its associated private key are deleted.

Change label

This option will change the label for the database record.

Create a signed certificate and key

This option will create a new certificate and associated public/private key pair. The new certificate will be signed using the certificate in the current database record and then stored in the key database. You will be prompted for the name of the file containing the key generation parameters when creating a certificate with a Digital Signature Standard (DSS) or Diffie-Hellman (DH) key (key generation parameters are not used when generating an RSA public/private key pair). The key generation parameters must be compatible with the requested key type and key size. Keys are in the same domain if they have the same set of key generation parameters. Refer to FIPS 186-2 (Digital Signature Standard) and RFC 2631 (Diffie-Hellman Key Agreement Method) for more information on the key generation parameters. The subject name and one or more subject alternate names can be specified for the new certificate.

The signature algorithm used when signing the certificate is derived from the key algorithm of the signing certificate and the following digest type:

- For RSA signatures, the digest type matches that used in the signature algorithm of the signing certificate. If the digest type is not a SHA-based digest, then SHA-1 will be used.
- · For DSA signatures, the digest type will be SHA-1.

The subject name is always an X.500 directory name while a subject alternate name can be an X.500 directory name, a domain name, an e-mail address, an IP address, or a uniform resource identifier. An X.500 directory name consists of common name, organization, and country attributes with optional organizational unit, city/locality, and state/province attributes. A domain name is one or more tokens separated by periods. An e-mail address consists of a user name and a domain name separated by '@'. An IP address is an IPv4 address (nnn.nnn.nnn) or an IPv6 address (nnnn:nnnn:nnnn:nnnn:nnnn:nnnn:nnnn). A uniform resource identifier consists of a scheme name, a domain name, and a scheme-specific portion.

The signature algorithm used when signing the certificate is derived from the key algorithm of the signing certificate. The digest type used when signing the certificate will match the digest type used in the signature algorithm of the signing certificate. If the signing certificate's key algorithm is DSA, or the digest type used by the signing certificate is not a SHA-based digest, then the digest type used will be SHA-1. Possible signature algorithms are:

- x509_alg_sha1WithRsaEncryption
- x509 alg sha224WithRsaEncryption
- x509 alg sha256WithRsaEncryption
- x509 alg sha384WithRsaEncryption
- x509_alg_sha512WithRsaEncryption
- x509 alg dsaWithSha1.

Create a certificate renewal request

This option will create a certification request using the subject name and public/private key pair from an existing certificate. The certificate request will

be exported to a file in Base64 format. This file can then be sent to a certification authority for processing. The certificate returned by the certification authority can then be processed using option 5 (Receive requested certificate or a renewal certificate) on the Key Management **Menu**. The new certificate will replace the existing certificate in the key database.

Manage Certificates: This option manages certificates without private keys. A list of key labels is displayed. Pressing the ENTER key without making a selection will display the next set of labels. Selecting one of the label numbers will display the following menu:

```
Certificate Menu
       Label: Certificate label name
  1 - Show certificate information
  2 - Set certificate trust status
  3 - Copy certificate to another database
  4 - Export certificate to a file
  5 - Delete certificate
  6 - Change label
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
```

Figure 24. Certificate Menu

Show certificate information

This option displays information about the X.509 certificate.

Set certificate trust status

This option sets or resets the trusted status for the X.509 certificate. A certificate cannot be used for authentication unless it is trusted.

Copy certificate to another database

This option copies the certificate to another database. An error will be returned if the certificate is already in the database or if the label is not unique. A certificate and key may only be copied from a FIPS mode database to another FIPS database. A certificate and key may not be copied from a non-FIPS mode database to a FIPS mode database.

Export certificate to a file

This option exports the X.509 certificate to a file. The supported export formats are ASN.1 DER (Distinguished Encoding Rules) and PKCS #7 (Cryptographic Message Syntax). The export file will contain just the requested certificate when the DER format is selected. The export file will contain the requested certificate and its certification chain when the PKCS #7 format is selected.

Delete certificate

The certificate is deleted.

Change label

This option will change the label for the database record.

Manage Certificate Requests: This option manages certificate requests. A list of request labels is displayed. Pressing the ENTER key without making a selection will display the next set of labels. Selecting one of the label numbers will display the

following menu:

```
Request Menu

Label: label_name

1 - Show key information
2 - Export certificate request to a file
3 - Delete certificate request and key
4 - Change label

0 - Exit program

Enter option number (press ENTER to return to previous menu):
```

Figure 25. Request Menu

Show key information

This option displays information about the private key associated with the certificate request.

Export certificate request to a file

This option exports the certificate request to a file in Base64 format. This file can then be sent to a certification authority for processing.

Delete certificate request and key

The certificate request and its associated private key are deleted.

Change label

This option will change the label for the database record.

Create New Certificate Request: This option will create a certificate request using either RSA encryption or DSA for the public and private keys. The certificate request will be exported to a file in Base64 format. This file can then be sent to a certification authority for processing.

The label has a maximum length of 127 characters and is used to reference the certificate in the request database. The label will also be used when the certificate is received, so it must be unique in both the request and key databases. It must consist of characters which can be represented as 7-bit ASCII characters (letters, numbers, and punctuation) in the ISO8859-1 code page.

The subject name and one or more subject alternate names can be specified for the new certificate. The subject name is always an X.500 directory name while a subject alternate name can be an X.500 directory name, a domain name, an e-mail address, an IP address, or a uniform resource identifier. An X.500 directory name consists of common name, organization, and country attributes with optional organizational unit, city/locality, and state/province attributes. A domain name is one or more tokens separated by periods. An e-mail address consists of a user name and a domain name separated by '@'. An IP address is an IPv4 address (nnn.nnn.nnn) or an IPv6 address

(nnnn:nnnn:nnnn:nnnn:nnnn:nnnn:nnnn). A uniform resource identifier consists of a scheme name, a domain name, and a scheme-specific portion (for example, http://www.endicott.ibm.com/main.html).

Receive Requested Certificate or a Renewal Certificate: This option will receive the signed certificate returned by the certification authority. The certificate can be either a new or renewal certificate issued in response to a certificate request or a renewal of an existing certificate without a corresponding certificate request. If the

certificate was issued in response to a certificate request, the certificate request must still be in the request database. If this is a renewal certificate without a certificate request, the old certificate must still be in the key database and must have the same issuer name, subject name, and public key.

The certificate file must contain either an ASN.1 DER-encoded sequence as defined in RFC 2459 (X.509 Public Key Infrastructure) or a signed data message as defined in PKCS #7 (Cryptographic Message Syntax). The data can either be the binary value or the Base64 encoding of the binary value.

If the import file is in PKCS #7 format, the first certificate in the file must be the request certificate, otherwise the request will fail with 'unable to locate matching request'. The certification chain will be imported if it is contained in the import file. The certificate subject name will be used as the label for certificates added from the certification chain. A chain certificate will not be added to the database if the label is not unique or if the certificate is already in the database.

Base64 data is in the local code page. A DER-encoded sequence must start with the encoding header '-----BEGIN CERTIFICATE-----' and end with the encoding footer '----END CERTIFICATE-----'. A PKCS #7 signed data message must start with the encoding header '----BEGIN CERTIFICATE-----' and end with the encoding footer '-----END CERTIFICATE-----' or start with the encoding header '-----BEGIN PKCS #7 SIGNED DATA----- and end with the encoding footer '----END PKCS #7 SIGNED DATA----'.

An intermediate certificate is a certificate signed by another entity. The key database must already contain a certificate for the issuer. The certificate will not be imported if the certificate authenticity cannot be validated or if the database already contains the certificate.

The request database entry will be deleted once the certificate has been received.

Create a Self-Signed Certificate: This option will create a self-signed certificate using either RSA or DSA encryption for the public and private keys and a certificate signature based on a SHA digest algorithm of the user's choice (if an RSA certificate is requested). Possible signature algorithms are:

- x509 alg sha1WithRsaEncryption
- x509 alg sha224WithRsaEncryption
- x509_alg_sha256WithRsaEncryption
- x509 alg sha384WithRsaEncryption
- x509 alg sha512WithRsaEncryption
- x509_alg_dsaWithSha1.

The label has a maximum length of 127 characters and is used to reference the certificate in the key database. It must consist of characters which can be represented as 7-bit ASCII characters (letters, numbers, and punctuation) in the ISO8859-1 code page.

The number of days until the certificate expires must be between 1 and 9999.

The subject name and one or more subject alternate names can be specified for the new certificate. The subject name is always an X.500 directory name while a subject alternate name can be an X.500 directory name, a domain name, an e-mail address, an IP address, or a uniform resource identifier. An X.500 directory name consists of common name, organization, and country attributes with optional

organizational unit, city/locality, and state/province attributes. A domain name is one or more tokens separated by periods. An e-mail address consists of a user name and a domain name separated by '@'. An IP address is an IPv4 address (nnn.nnn.nnn) or an IPv6 address

(nnnn:nnnn:nnnn:nnnn:nnnn:nnnn:nnnn). A uniform resource identifier consists of a scheme name, a domain name, and a scheme-specific portion (for example, http://www.endicott.ibm.com/main.html).

Import a Certificate: This option imports a certificate and adds it to the key database. The import file contains a certificate without a private key. The certificate will be marked as trusted when it is added to the database. When importing a certificate, the expiration date cannot exceed February 6, 2106.

When adding certificates from the import file to a FIPS key database file only certificates signed with FIPS signature algorithms using FIPS-approved key sizes may be imported. When processing a chain of certificates, processing of the chain will terminate if a non-FIPS certificate is encountered. Certificates processed prior to the failing certificates will be added to the key database file. It is the responsibility of the importer to ensure that the file came from a FIPS source in order to maintain meeting FIPS 140-2 criteria.

The import file must contain either an ASN.1 DER-encoded sequence as defined in RFC 2459 (X.509 Public Key Infrastructure), RFC 3280 (Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile) or a signed data message as defined in PKCS #7 (Cryptographic Message Syntax). The data can either be the binary value or the Base64 encoding of the binary value.

If the import file is in PKCS #7 format, only the first certificate and its certification chain will be imported. The certificate subject name will be used as the label for certificates added from the certification chain. A certification chain certificate will not be added to the database if the label is not unique or if the certificate is already in the database.

Base64 data is in the local code page. A DER-encoded sequence must start with the encoding header '----BEGIN CERTIFICATE----' and end with the encoding footer '-----END CERTIFICATE-----'. A PKCS #7 signed data message must start with the encoding header '----BEGIN CERTIFICATE-----' and end with the encoding footer '-----END CERTIFICATE-----' or start with the encoding header '-----BEGIN PKCS #7 SIGNED DATA-----' and end with the encoding footer '----END PKCS #7 SIGNED DATA----'.

A root certificate is a self-signed certificate and will be imported as long as the certificate is not already in the key database.

An intermediate certificate is a certificate signed by another entity. The key database must already contain a certificate for the issuer. The certificate will not be imported if the certificate authenticity cannot be validated or if the database already contains the certificate.

An existing certificate can be replaced by specifying the label of the existing certificate. The issuer name, subject name, and subject public key in the new certificate must be the same as the existing certificate. If the existing certificate has a private key, the private key is not changed when the certificate is replaced.

Import a Certificate and a Private Key: This option imports a certificate and the associated private key and adds it to the key database. The certificate will be

marked as trusted when it is added to the database. When importing a certificate, the expiration date cannot exceed February 6, 2106.

The import file must contain an ASN.1 DER-encoded sequence as defined in PKCS #12 (Personal Information Exchange Syntax). The data can be either the binary value or the Base64 encoding of the binary value. Base64 data is in the local code page and must start with the encoding header '----BEGIN CERTIFICATE----' and end with the encoding footer '-----END CERTIFICATE-----'.

A root certificate is a self-signed certificate and will be imported as long as the certificate is not already in the key database.

An intermediate CA or end entity certificate is a certificate signed by another entity. The key database must already contain a certificate for the issuer. The certificate will not be imported if the certificate authenticity cannot be validated or if the database already contains the certificate.

Each certificate in the certification chain will be imported if it is present in the import file. The certificate subject name will be used as the label for certificates added from the certification chain. A certification chain certificate will not be added to the database if the label is not unique or if the certificate is already in the database.

Only certificates and keys encoded according to PKCS #12 Version 3 and protected with strong encryption can be imported into a FIPS database. Furthermore, only certificates and keys comprising FIPS signature algorithms and using FIPS-approved key sizes may be imported into a FIPS database.

Show the Default Key: The private key information for the default key is displayed.

Store Database Password: The database password is masked and written to the key stash file. The file name is the same as the key database file name but has an extension of '.sth'.

Show Database Record Length: The database record length is displayed. All records in the database have the same length and a database entry cannot span a database record.

GSKKYMAN Interactive Mode Examples

gskkyman can be run from CMS. The following tasks will be performed in this section:

- · Creating, opening and deleting a key database file
- · Changing a key database password
- Storing an encrypted key database password
- · Creating a self-signed server or client certificate
- · Creating a certificate request and processing the signed request
- Creating a certificate to be used with Diffie-Hellman key exchange
- · Managing keys and certificates:
 - Show certificate/key information
 - Marking a certificate (and private key) as the default certificate for the key database
 - Copying a certificate (and private key) to a different key database:
 - Copying a certificate without its private key

- Copying a certificate with its private key
- Copying a certificate with its private key to a key database on the same system
- Removing a certificate (and private key) from a key database
- Changing a certificate label
- Importing a certificate from a file as a trusted CA certificate
- Importing a certificate from a file with its private key
- Using GSKKYMAN to be your own certificate authority (CA)

Starting GSKKYMAN

To start **gskkyman**, enter gskkyman at the command prompt (see Figure 26).

Note: In the examples that follow, your input is shown in bold, and places where you press the Enter key are noted with <enter>.

Figure 26 shows the GSKKYMAN start menu.

```
gskkyman <enter>
      Database Menu
  1 - Create new database
  2 - Open database
  3 - Change database password
  4 - Change database record length
  5 - Delete database
  6 - Create key parameter file
  7 - Display certificate file (Binary or Base64 ASN.1 DER)
  0 - Exit program
Enter option number:
```

Figure 26. Starting Menu for GSKKYMAN

From the **Database Menu** for GSKKYMAN, you can create a new key database, open an existing key database, display the contents of a certificate file, change a database password, change a database record length, delete a database, or exit GSKKYMAN.

Creating, Opening and Deleting a Key Database File

To create a new key database, enter 1 at the command prompt on the Database Menu:

```
Database Menu
  1 - Create new database
  2 - Open database
  3 - Change database password
  4 - Change database record length
  5 - Delete database
  6 - Create key parameter file
  7 - Display certificate file (Binary or Base64 ASN.1 DER)
  0 - Exit program
Enter option number:
1 <enter>
Enter key database name (press ENTER to return to menu):
mykey.kdb <enter>
Enter database password (press ENTER to return to menu):
<enter password>
Re-enter database password:
<enter password>
Enter password expiration in days (press ENTER for no expiration):
35 <enter>
Enter database record length (press ENTER to use 5000):
Enter 1 for FIPS mode database or 0 to continue:
1 <enter>
Key database /home/RACFU01/mykey.kdb created.
Press ENTER to continue.
```

Figure 27. Creating a New Key Database

Figure 27 shows the input prompts that GSKKYMAN produces when you choose 1 to create a new key database. As you can see, default choices are listed in parentheses. In the example, by pressing the Enter key at the Enter database record length prompt, the default of 5000 was chosen.

Notes:

- 1. When dealing with certificates that might be large in size or have large key sizes, for example 2,048 or 4,096, an initial key record length of 5,000 might be required.
- 2. The maximum length of the password specified for a key database file is 128 characters.

After entering the database record length, a message displays confirming that your database was created (see Figure 27). You are prompted to press Enter to continue. Doing so displays the Key Management Menu for the database you have created:

```
Key Management Menu
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
```

Figure 28. Key Management Menu for GSKKYMAN

Figure 28 shows the **Key Management Menu**. Entering **0** at this prompt exits GSKKYMAN. Pressing Enter at the prompt returns you to the **Database Menu**.

To open an existing key database file, on the Database Menu, enter option number 2 (see Figure 29). You are then prompted for the key database name and password.

Note: Do not lose the key database password. There is no method to reset this password if you lose or forget the password. If the password is lost, the private keys stored in the key database are inaccessible, therefore, unusable.

```
Database Menu
  1 - Create new database
  2 - Open database
  3 - Change database password
  4 - Change database record length
  5 - Delete database
  6 - Create key parameter file
  7 - Display certificate file (Binary or Base64 ASN.1 DER)
  0 - Exit program
Enter option number:
2 <enter>
Enter key database name (press ENTER to return to menu):
mykey.kdb <enter>
Enter database password (press ENTER to return to menu):
<enter password>
```

Figure 29. Opening an Existing Key Database File

The key database name is the file name of the key database. The input file name is interpreted relative to the current directory when GSKKYMAN is invoked. You may also specify a fully qualified key database name.

After you enter the key database name and password, the Key Management Menu displays for the database you have selected to open, (see Figure 30).

```
Key Management Menu
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
```

Figure 30. Key Management Menu

To delete an existing database, from the Database Menu, select option 5 (see Figure 31):

```
Database Menu
   1 - Create new database
  2 - Open database
  3 - Change database password
  4 - Change database record length
  5 - Delete database
  6 - Create key parameter file
  7 - Display certificate file (Binary or Base64 ASN.1 DER)
  0 - Exit program
Enter option number:
5 <enter>
Enter key database name (press ENTER to return to menu):
mykey.kdb <enter>
Enter 1 to confirm delete, 0 to cancel delete:
1 <enter>
Key database /home/RACFU01/mykey.kdb deleted.
Press ENTER to continue.
```

Figure 31. Deleting an Existing Key Database

You are prompted to enter the key database name that you wish to delete. Then you must enter 1 to confirm the delete, or 0 to cancel the delete. If you choose 1, a message displays to confirm the file has been deleted.

Note: If you delete an existing key database, the associated request database and database password stash file (if existent) will also be deleted. It's important to note that anyone with write access to a key database can delete that database either by removing it with the rm command or by using GSKKYMAN subcommand.

Changing a Key Database Password

You can change a key database password. From the Database Menu, select option

```
Database Menu
   1 - Create new database
   2 - Open database
   3 - Change database password
  4 - Change database record length
  5 - Delete database
   6 - Create key parameter file
   7 - Display certificate file (Binary or Base64 ASN.1 DER)
   0 - Exit program
Enter option number:
3 <enter>
Enter key database name (press ENTER to return to menu):
mykey.kdb <enter>
Enter database password (press ENTER to return to menu):
<enter current password>
Enter new database password (press ENTER to return to menu):
<enter new password>
Re-enter database password:
<enter new password>
Enter password expiration in days (press ENTER for no expiration):
<enter>
Database password changed.
Press ENTER to continue.
```

Figure 32. Changing a Key Database Password

Figure 32 displays the prompts you are given. You first enter your current password. Then you select a new password, and enter it again to confirm. You can choose your password expiration in days or press Enter to have no expiration. A message displays to confirm the transaction.

Storing an Encrypted Key Database Password

In order for applications to use the key database file, the application must specify both the file name as well as its associated password. The password can either be specified directly or through a stash file containing the encrypted password. The stash file provides a level of security where the password does not have to be explicitly specified. To save the encrypted key database password, enter option 10 from the **Key Management Menu**:

Note: In the following task descriptions, it is assumed that you have opened the key database and are displaying the **Key Management Menu** panel.

```
Key Management Menu
       Database: /home/RACFU01/mykey.kdb
       Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
10 <enter>
Database password stored in /home/RACFU01/mykey.sth.
Press ENTER to continue.
```

Figure 33. Storing a Database Password in a Stash File

Figure 33 shows the message you receive after entering option 10 to store the database password. In this example, the database password was stored in a file called mykey.sth.

Creating a Self-Signed Server or Client Certificate

If your organization does not use a certificate authority (within the organization or outside the organization), a self-signed certificate can be generated for use by the program acting as an SSL server or client. In addition, since root CA certificates are also self signed certificates that are permitted to be used to sign other certificates (certificate requests), these procedures can also be used to create a root CA certificate. See "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245.

Programs acting as SSL servers (i.e. acting as the server side of the SSL handshake protocol) must have a certificate to use during the handshake protocol. A program acting as an SSL client requires a certificate when the SSL server requests client authentication as part of the SSL handshake.

Note: This is not recommended for production environments and should only be used to facilitate test environments prior to production. Self-signed certificates do not imply any level of security or authenticity of the certificate because, as their name implies, they are signed by the same key that is contained in the certificate. On the other hand, certificates that are signed by a certificate authority indicate that, at least at the time of signature, the certificate authority approved the information contained in the certificate.

Note: GSKKYMAN supports the creation of X.509 Version 3 certificates.

When creating a self-signed certificate to be used to identify a server or client, from the Key Management Menu, enter 6. You will be prompted for a number of items

to define the certificate. First you will be asked to select the type of certificate to be created.

```
Key Management Menu
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
6 <enter>
```

Figure 34. Select 6 to Create a Self-Signed Certificate

Certificates that are intended to be used directly by a server or client are considered to be end-user certificates. Certificates intended to be used to sign other certificates are considered to be CA certificates. RSA key certificates are the most common. DSA key certificates represent certificates that follow the FIPS-186 government standard. The larger the key size, the more secure the generated key will be. The most commonly used size is 1024. Note that CPU usage increases as the key size increases. For example, CPU usage will increase by a factor of 6 when the key size is doubled.

If an RSA-based certificate is selected, you will be prompted to select the digest type for the signature algorithm from a list of SHA-based digest types.

Once the certificate type is determined, you will be prompted to enter:

- a label to uniquely identify the key and certificate within the key database
- the individual fields within the subject name
- · certificate expiration. The valid expiration range is 1 to 9999 days. The default value is 365 days.
- the subject alternate names (optional)

Figure 35 on page 234 shows the creation of a signed certificate to be used as a server or client certificate.

```
Certificate Type
   1 - CA certificate with 1024-bit RSA key
   2 - CA certificate with 2048-bit RSA key
   3 - CA certificate with 4096-bit RSA key
  4 - CA certificate with 1024-bit DSA key
   5 - User or server certificate with 1024-bit RSA key
   6 - User or server certificate with 2048-bit RSA key
   7 - User or server certificate with 4096-bit RSA key
  8 - User or server certificate with 1024-bit DSA key
Select certificate type (press ENTER to return to menu):
5 <enter>
       Signature Digest Type
   1 - SHA-1
  2 - SHA-224
  3 - SHA-256
  4 - SHA-384
  5 - SHA-512
Select digest type (default SHA-1):
1 <enter>
Enter label (press ENTER to return to menu):
Server Cert <enter>
Enter subject name for certificate
  Common name (required):
My Server Certificate <enter>
  Organizational unit (optional):
ID <enter>
  Organization (required):
IBM <enter>
  City/Locality (optional):
Endicott <enter>
  State/Province (optional):
NY <enter>
  Country/Region (2 characters - required):
US <enter>
Enter number of days certificate will be valid (default 365):
244 <enter>
Enter 1 to specify subject alternate names or 0 to continue:
Please wait .....
Certificate created.
Press ENTER to continue.
```

Figure 35. Creating a Signed Certificate

Once the certificate is created, the next step is to determine whether the certificate should be marked as the database's default certificate. Setting the certificate as the default certificate allows the certificate to be used by SSL without having to specify

its label. For more information on setting the default certificate, see "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245.

In order for the SSL handshake to successfully validate the use of the self-signed certificates, the partner application needs to know about the signer of the certificate. For self-signed certificates, this means the self-signed certificate must be imported into the partner's database. For more information on importing certificates, see "Importing a Certificate from a File as a Trusted CA Certificate" on page 255.

Creating a Certificate Request

A program may require a certificate, associated with itself, depending on what side of the SSL connection the program is running. This requirement also depends on whether *client authentication* is requested as part of the SSL handshake. Programs acting as SSL servers (act as the server side of the SSL handshake protocol) must have a certificate to use during the handshake protocol. A program acting as an SSL client requires a certificate in the key database if the SSL server requests *client authentication* as part of the SSL handshake operation. The way in which certificates are used within an organization will determine whether you need to create a certificate request. If the organization chooses to use a certificate authority (within the organization or outside of the organization), then you must generate a certificate request.

To create a certificate request, enter 4 from the Key Management Menu.

```
Key Management Menu
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
4 <enter>
```

Figure 36. Select 4 to Create a New Certificate Request

When creating a certificate request, you are first prompted for the type of certificate to be requested. RSA key certificates are the most common. DSA key certificates represent certificates that follow the FIPS-186 government standard. The larger the key size, the more secure the encryption/decryption generated key will be. The most commonly used size is 1024.

After the certificate type is determined, you will be prompted to enter:

· a request file name to store the certificate request

- · a label to uniquely identify the certificate request within the key database
- · the individual fields within the subject name
- the individual fields within the subject alternate name (optional).

The Certificate Type menu appears:

```
Certificate Type
  1 - Certificate with 1024-bit RSA key
  2 - Certificate with 2048-bit RSA key
  3 - Certificate with 4096-bit RSA key
  4 - Certificate with 1024-bit DSA key
Enter certificate type (press ENTER to return to menu):
1 <enter>
Enter request file name (press ENTER to return to menu):
certreq.arm <enter>
Enter label (press ENTER to return to menu):
Test Server Cert <enter>
Enter subject name for certificate
 Common name (required):
Test Server <enter>
 Organizational unit (optional):
ID <enter>
 Organization (required):
IBM <enter>
 City/Locality (optional):
Endicott <enter>
 State/Province (optional):
NY <enter>
 Country/Region (2 characters - required):
US <enter>
Enter 1 to specify subject alternate names or 0 to continue:
Please wait .....
Certificate request created.
Press ENTER to continue.
```

Figure 37. Creating a Certificate Request

Press option 0 to continue or option 1 to specify the subject alternate names. If option 1 is selected, the Subject Alternate Name Type menu appears:

```
Subject Alternate Name Type
   1 - Directory name (DN)
   2 - Domain name (DNS)
   3 - E-mail address (SMTP)
   4 - Network address (IP)
   5 - Uniform resource identifier (URI)
Select subject alternate name type (press ENTER if name is complete):
1 <enter>
Enter subject name for certificate
 Common name (required):
Test server <enter>
  Organizational unit (optional):
IBM <enter>
  Organization (required):
IBM <enter>
  City/Locality (optional):
Endicott <enter>
  State/Province (optional):
NY <enter>
  Country/Region (2 characters - required):
US <enter>
       Subject Alternate Name Type
   1 - Directory name (DN)
  2 - Domain name (DNS)
   3 - E-mail address (SMTP)
   4 - Network address (IP)
   5 - Uniform resource identifier (URI)
Select subject alternate name type (press ENTER if name is complete):
<enter>
Please wait .....
```

Figure 38. Subject Alternate Name Type

When specifying subject alternate names, you are prompted for the type of the alternate name. After the alternate name type is determined, you will be prompted to enter:

the individual fields within the subject name.

After the individual fields are completed, press enter to continue or select one of the subject alternate name types. Repeat the process.

Once the certificate request (and associated subject alternate names) is created, a file with the name you specified will exist in the current working directory or directory specified in the filename. If you choose to exit GSKKYMAN, the program ends. Otherwise, the Key Management Menu (see Figure 30 on page 230) displays, allowing additional operations to be performed.

The certificate request created is stored in a file that is in base64-encoded format. This format is what is typically required by certificate authorities that create

certificates. The following is the contents of the file created by the steps performed in Figure 37 on page 236:

```
$ cat certreq.arm <enter>
----BEGIN NEW CERTIFICATE REOUEST----
MIIBnjCCAQcCAQAwXjELMAkGA1UEBhMCVVMxCzAJBgNVBAgTAk5ZMREwDwYDVQQH
EwhFbmRpY290dDEMMAoGA1UEChMDSUJNMQswCQYDVQQLEwJJRDEUMBIGA1UEAxML

9eVzgQ1FkD9z73NHNz6aJAJMAY/cDU2Yqb+xcfh94/uvHA==
----END NEW CERTIFICATE REQUEST----
```

Figure 39. Contents of certreq.arm after Certificate Request Generation

Creating a certificate to be used with a fixed Diffie-Hellman key exchange

Create a server certificate to be used during an SSL handshake using a fixed Diffie-Hellman key exchange. Fixed Diffie-Hellman requires both sides of the exchange to be based off of the same generation parameters. In order for each side to use the same generation parameters, a key parameter file must be created to be used as input to the certificate being signed.

To create a key parameter file, from the **Database Menu**, enter **6**. First you will be asked to select the key type. Only the key types of 1024-bit DSA key or 2048-bit fixed Diffie-Hellman key are valid for use in a FIPS database. Once the key type is determined, you will be prompted to enter a key parameter file name. The file name is interpreted relative to the current directory when GSKKYMAN is invoked. You may also specify a fully qualified file name.

```
Database Menu
       Database: /home/RACFU01/mykey.kdb
       Expiration: 2008/04/02 05:24:13
  1 - Create new database
  2 - Open database
  3 - Change database password
  4 - Change database record length
  5 - Delete database
  6 - Create key parameter file
  7 - Display certificate file (Binary or Base64 ASN.1 DER)
  0 - Exit program
Enter option number:
6 <enter>
```

```
Key Type
   1 - 1024-bit DSA key
  2 - 1024-bit Diffie-Hellman key
  3 - 2048-bit Diffie-Hellman key
Select key type (press ENTER to return to menu):
2 <enter>
Enter key parameter file name (press ENTER to return to menu):
dh_key_1024.keyfile <enter>
Please wait .....
Key parameter file created.
Press ENTER to continue
```

Figure 40. Creating a key parameter file to be used with Diffie-Hellman

After the key parameter file has been created, the next step is to create the signed certificate using an existing certificate in the key database file to sign the server certificate. From the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. In the Key and Certificate Menu, choose option 10 to create a signed certificate and key. This requires the displayed certificate to contain an RSA or a DSA key and to have signing capability.

Select the certificate type by choosing either option 9 or 10, user or server certificate with a Diffie-Hellman key from the Certificate Type Menu. The Diffie-Hellman key size must match the key size of the key parameters called previously.

Once the certificate type is determined, you will be prompted to enter:

- · key parameter file created earlier
- · a label to uniquely identify the key and certificate within the key database
- · the individual fields within the subject name
- · certificate expiration (Valid expiration range is 1 to 9999 days. Default value is 365 days)
- · the subject alternate names (optional).

```
Certificate Type Menu
  1 - CA certificate with 1024-bit RSA key
  2 - CA certificate with 2048-bit RSA key
  3 - CA certificate with 4096-bit RSA key
  4 - CA certificate with 1024-bit DSA key
   5 - User or server certificate with 1024-bit RSA key
   6 - User or server certificate with 2048-bit RSA key
  7 - User or server certificate with 4096-bit RSA key
  8 - User or server certificate with 1024-bit DSA key
  9 - User or server certificate with 1024-bit Diffie-Hellman key
 10 - User or server certificate with 2048-bit Diffie-Hellman key
Select certificate type (press ENTER to return to menu):
9 <enter>
Enter key parameter file name (press ENTER to return to menu):
dh_key_1024.keyfile <enter>
Enter label (press ENTER to return to menu):
DSA cert with DH 1024 key <enter>
Enter subject name for certificate:
       Common name (required):
DSA cert with DH 1024 key <enter>
       Organizational unit (optional):
Test <enter>
       Organization (required):
Test <enter>
       City/Locality (optional):
Poughkeepsie <enter>
      State/Province (optional):
NY <enter>
       Country/Region (2 characters - required):
US <enter>
Enter number of days certificate will be valid (default 365):
5000 <enter>
Enter 1 to specify subject alternate names or 0 to continue:
0 <enter>
Please wait .....
Certificate created.
Press ENTER to continue.
```

Figure 41. Creating a certificate to be used with Diffie_Hellman

Once the certificate is created, the next step is to determine whether the certificate should be marked as the database's default certificate. Setting the certificate as the default certificate allows the certificate to be used by SSL without having to specify its label. For more information on setting the default certificate, see "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245.

Sending the Certificate Request

The certificate request file can either be transferred to another system (for example, ftp as an ASCII text file) and then transferred to the certificate authority or placed directly into a mail message sent to a certificate authority using cut-and-paste methods.

In addition to the certificate request file that is generated, a request database (.rdb) file is also created or altered. The request database file will be named the same as the key database file, except it will have an extension of .rdb. For example, a key database file of key.kdb will cause a request database file of key.rdb to be created. This request database file must be saved along with the key database in order for the response for the certificate request to be successfully processed.

Receiving the Signed Certificate or Renewal Certificate

Once a certificate is signed by the certificate authority in response to the certificate request, you must received it into the key database. This is for new certificates and renewal certificates.

To receive the certificate, you must store the Base64-encoded certificate in a file on the system to be read in by the GSKKYMAN command. This file should be in the current working directory when GSKKYMAN is started. If this file is on another working directory you will have to specify the fully qualified name.

Note: In order to receive the certificate the CA certificate must also exist in the key database. To store a CA certificate, refer to "Importing a Certificate from a File as a Trusted CA Certificate" on page 255.

To receive a certificate issued on your behalf, from the **Key Management Menu**, see Figure 30 on page 230 and enter option 5.

```
Key Management Menu
       Database: /home/RACFU01/mykey.kdb
       Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
5 <enter>
Enter certificate file name (press ENTER to return to menu):
signed.arm <enter>
Certificate received.
Press ENTER to continue.
```

Figure 42. Receiving a Certificate Issued for your Request

You are prompted for the name of the file that contains the Base64-encoded certificate that was returned to you by the certificate authority in response to a previously submitted certificate request (See "Creating a Certificate Request" on page 235). After receiving the certificate, you press Enter to continue working with the **Key Management Menu**. Upon completion of this step and prior to SSL using the certificate during the SSL handshake processing, you need to determine whether the certificate should be marked as the database's default certificate. Setting the certificate as the default certificate allows the certificate to be used by SSL without having to specify its label. For more information on setting the default certificate, see "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245.

Managing Keys and Certificates

Once certificates are added to the key database, the following are some common operations that can be performed with the certificates.

- Show certificate/key information
- · Mark a certificate (and private key) as the default certificate for the key database
- · Export a certificate to a file or key database
- Remove a certificate (and private key) from a key database
- Change a certificate label
- Create a signed certificate and key
- Create a certificate renewal request.

Showing Certificate/Key Information: It is sometimes useful to display the information contained in the certificates that are stored in the key database. The information displayed includes, among others, the label, issuer/subject name, the version number of the certificate, the key size for the public/private key pair, and the expiration date.

To list information about certificates that contain private keys, from the **Key** Management Menu (see Figure 30 on page 230) select 1. (Manage keys and certificates). This displays the Key and Certificate List.

```
Key and Certificate List
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Test Server Cert
  2 - Server Cert
  0 - Return to selection menu
Enter label number (ENTER to return to selection menu, p for previous list):
2 <enter>
```

Figure 43. Key and Certificate List

Select the number corresponding to the label for which you would like to display certificate/key information. The Key and Certificate Menu for the label you chose displays next (see Figure 44).

```
Key and Certificate Menu
       Label: Server Cert
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate and key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
1 <enter>
```

Figure 44. Key and Certificate Menu

On the Database Menu, you could choose 1 to display certificate information. This accesses the **Certificate Information** menu (see Figure 45 on page 244):

```
Certificate Information
                 Label: Server Cert
             Record ID: 13
      Issuer Record ID: 13
               Trusted: Yes
               Version: 3
         Serial number: 3c73c6d0000e8076
           Issuer name: My Server Certificate
                        ID
                        IBM
                        Endicott
                        NY
                        US
          Subject name: My Server Certificate
                        TD
                        IBM
                        Endicott
                        NY
                        US
        Effective date: 2002/02/20
       Expiration date: 2002/10/22
   Signature algorithm: shalWithRsaEncryption
      Issuer unique ID: None
     Subject unique ID: None

                        31 AA EE A3 67 DA DB 02 03 01 00 01
 Number of extensions: 4
Enter 1 to display extensions, 0 to return to menu:
1 <enter>
```

Figure 45. Certificate Information

From the Certificate Information screen, you can also enter 1 to display certificate extensions:

```
Certificate Extensions List
   1 - subjectKeyIdentifier
  2 - authorityKeyIdentifier
  3 - keyUsage (critical)
   4 - basicConstraints (critical)
Enter extension number (press ENTER to return to previous menu):
3 <enter>
```

Figure 46. Certificate Extensions List

Enter 3 on the Certificate Extensions List to show key usage information:

```
Certificate signature
CRL signature
Press ENTER to continue.
```

Figure 47. Key Usage Information

To display key information, from the **Key and Certificate Menu**, choose **2**, **Show** Key Information. This accesses the Key Information menu (see Figure 48):

```
Key Information
                 Label: Server Cert
             Record ID: 13
      Issuer Record ID: 13
           Default key: Yes
 Private key algorithm: rsaEncryption
      Private key size: 1024
          Subject name: My Server Certificate
                        ID
                        IBM
                        Endicott
                        NY
                        US
 Public key algorithm: rsaEncryption
       Public key size: 1024

                        31 AA EE A3 67 DA DB 02 03 01 00 01
Press ENTER to continue.
```

Figure 48. Key Information menu

Marking a Certificate (and Private Key) as the Default Certificate for the Key Database: Once a certificate has been added to the key database through either a certificate request or as a self-signed certificate, it can be marked as the default certificate for the key database. Marking a certificate as the default certificate allows it to be used by the programs calling SSL without having to explicitly supply the certificate's label.

To mark a certificate as the default certificate for the key database, from the **Key** Management Menu (see Figure 30 on page 230), choose 1, (Manage keys and certificates), and on the **Key and Certificate List** (see Figure 43 on page 243, choose the label number you want to work with. The Key and Certificate Menu displays:

```
Key and Certificate Menu
       Label: My Server Certificate
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate and key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
3 <enter>
Default key set.
Press ENTER to continue.
```

Figure 49. Marking a Certificate (and Private Key) as the Default Certificate

Choose 3 to set the certificate and private key as the default certificate for the key database.

Copying a Certificate (and Private Key) to a Different Key Database: After you have populated your key database file with certificates, it may be necessary for you to transfer a certificate to another key database on your system or a remote system. This transfer maybe necessary for the following reasons:

- The remote system or key database requires the signing certificate to be in its key database file for validation purposes. The certificate does not need to contain the private key information. These certificates are normally certificate authority (CA) certificates but may also be a self-signed certificate.
- The server or client certificate is being used by another application in a separate key database file.

Note: The source key database file and the target key database file must exist before the certificate can be copied to the target key database file. If the target is a FIPS database, then only a FIPS database can be the source.

Copying a Certificate Without its Private Key: To copy a certificate to a different key database format or to a different system without its private key (certificate validation), from the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. Find the label of the certificate to be copied and enter the number associated with the label. In the Key and Certificate Menu, enter option 6 to export the certificate to a file. The Export File Format menu appears:

```
Export File Format
  1 - Binary ASN.1 DER
  2 - Base64 ASN.1 DER
  3 - Binary PKCS #7
  4 - Base64 PKCS #7
Select export format (press ENTER to return to menu):
1 <enter>
Enter export file name (press ENTER to return to menu):
expfile.der <enter>
Certificate exported.
Press ENTER to continue.
```

Figure 50. Copying a Certificate Without its Private Key

You are then prompted for what file format you would like for the exported certificate information. The file format is determined by the support on the receiving system.

After selecting the export format, you will be asked for a file name. You then will receive a message indicating that the certificate was exported. You can now transfer this file to the system and import the certificate into the key database file. If copying to a remote system, this file can now be transferred (in binary if option 1 or 3 has been selected or in ASCII (TEXT) if option 2 or 4 has been selected) to the remote system. For information on receiving the certificate into the key database file, see "Importing a Certificate from a File as a Trusted CA Certificate" on page 255). Upon successfully receiving the certificate, the certificate can now be used to validate the SSL's partner certificate. When the partner is the client, this means that the client can now validate the server's certificate and if the partner is the server, the server can validate the client's certificate when client authentication is requested.

You will also need to determine whether the certificate should be marked as the database's default certificate. Setting the certificate as the default certificate allows the certificate to be used by SSL without having to specify its label. For more information on setting the default certificate, see "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245.

Copying a Certificate with its Private Key: To copy a certificate to a different key database format or to a different system with its private key, the certificate must be exported to a PKCS #12 formatted file. PKCS #12 files are password-protected to allow encryption of the private key information, from the **Key Management Menu**, select 1 - Manage keys and certificates to display the Key and Certificate Menu. Find the label of the certificate to be copied and enter the number associated with the label. In the **Key and Certificate Menu**, enter option **7** to export the certificate and private key to a file.

The **Export File Format** menu appears:

```
Export File Format
     1 - Binary PKCS #12 Version 1
    2 - Base64 PKCS #12 Version 1
     3 - Binary PKCS #12 Version 3
     4 - Base64 PKCS #12 Version 3
Select export format (press ENTER to return to menu):
1 <enter>
Enter export file name (press ENTER to return to menu):
expfile.p12
Enter export file password (press ENTER to return to menu):
Re-enter export file password:
Enter 1 for strong encryption, 0 for export encryption:
1 <enter>
Certificate and key exported.
Press ENTER to continue.
```

Figure 51. Copying a Certificate and Private key to a Different Key Database

You will then be prompted for what file format you would like for the exported certificate information.

The file format is determined by the support on the receiving system. In most cases the format to be used is Binary PKCS #12 Version 3. Export from a FIPS database must be PKCS #12 Version 3 using strong encryption.

After selecting the export format, you will be asked for a file name and password. You then will receive a message indicating that the certificate was exported. You can now transfer this file to the system and import the certificate into the key database file. If copying to a remote system, this file can now be transferred (in binary) to the remote system. For information on receiving the certificate into the key database file, see "Importing a Certificate from a File with its Private Key" on page 257). Upon successfully receiving the certificate, the certificate can now be used to identify the program. For example, the certificate can be used as the SSL server program's certificate or it can be used as the SSL client program's certificate.

Copying a Certificate with its Private Key to a Key Database on the Same System: To copy a certificate and its private key from one key database to another key database on the same system, you will need to know the target key database file name and password. If the source database is a FIPS database, then the target database must also be a FIPS database. If the source database is a non-FIPS database, then the target database must also be a non-FIPS database. From the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. Find the label of the certificate to be copied and enter the number associated with the label. From the Key and Certificate Menu, enter 5 to copy a certificate and key to another database:

```
Key and Certificate Menu
      Label: newimp
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate and key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press Enter to return to previous menu):
Enter key database name (press Enter to return to previous menu):
target.kdb <enter>
Enter database password (press Enter to return to previous menu):
<enter password>
Record copied.
Press ENTER to continue.
```

Figure 52. Copying a Certificate with its Private Key to a Key Database on the Same System

You will then be prompted for the target key database name, and the target key database password. After the certificate is copied to the other key database file, you will receive a message indicating that the certificate has been successfully copied.

Note: When a certificate with a key marked as default is copied from a key database into another database, the certificate is not marked as the default key in that database.

Removing a Certificate (and Private Key) from a Key Database: You may want to remove a certificate from the key database. For example, you may want to remove a certificate after a certificate has expired and is no longer useful. Also, you may want to remove a certificate after a certificate has been exported to a different key database and is no longer needed as part of this key database.

Caution: Once you remove a certificate/private key pair from a key database, you cannot recover it unless it has previously been stored somewhere else (another key database file, a PKCS #12 file for certificate/private key pairs, or a DER-encoded or Base64-encoded file for just certificates). Be sure you no longer require the certificate (and private key if one is associated with the certificate in the key database) before you remove it from the key database.

From the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. Find the label chosen when creating (or receiving) the certificate and enter the number associated with the label. In the Key and Certificate Menu (see Figure 53 on page 250), choose 8 to delete the

certificate and key:

```
Key and Certificate Menu
      Label: newimp
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate and key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
8 <enter>
Enter 1 to confirm delete, 0 to cancel delete:
1 <enter>
Record deleted.
Press ENTER to continue.
```

Figure 53. Delete Certificate and Key

Enter 1 to confirm the deletion of the certificate and key. A message appears, confirming that the record has been deleted. Once the certificate has been removed from the key database, it can no longer be used for identification or verification purposes by SSL during SSL handshake processing.

Changing a Certificate Label: From the Key Management Menu, select 1 -Manage keys and certificates to display the Key and Certificate Menu. Find the label chosen when creating (or receiving) the certificate and enter the number associated with the label. In the Key and Certificate Menu (see Figure 54 on page 251), choose **9** to change the label:

```
Key and Certificate Menu
       Label: cacert
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
9 <enter>
Enter label (press ENTER to return to menu):
cacert2 <enter>
Label changed.
Press ENTER to continue.
```

Figure 54. Changing a Certificate Label

Enter the new label name and press Enter. A message confirms that the label name has been changed.

Creating a Signed Certificate and Key: Creating a signed certificate and key allows for a fastpath method for creating a signed certificate that resides in the same key database file as the displayed signing Certificate Authority certificate. From the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. In the Key and Certificate Menu, choose option 10 to create a signed certificate and key. This requires the displayed certificate to have signing capability.

```
Key and Certificate Menu
       Label: cacert
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
10 <enter>
```

Figure 55. Creating a Signed Certificate and Key

The Certificate Type menu appears. Once the certificate type is determined, you will be prompted to enter:

- · a label to uniquely identify the key and certificate within the key database
- · the individual fields within the subject name
- certificate expiration. The valid range for for a self-signed certificate is 1 to 9999 days. The default is 365 days.

```
Certificate Type
  1 - CA certificate with 1024-bit RSA key
  2 - CA certificate with 2048-bit RSA key
  3 - CA certificate with 4096-bit RSA key
  4 - CA certificate with 1024-bit DSA key
  5 - User or server certificate with 1024-bit RSA key
  6 - User or server certificate with 2048-bit RSA key
  7 - User or server certificate with 4096-bit RSA key
  8 - User or server certificate with 1024-bit DSA key
  9 - User or server certificate with 1024-bit Diffie-Hellman key
 10 - User or server certificate with 2048-bit Diffie-Hellman key
Select certificate type (press ENTER to return to menu):
5 <enter>
Enter label (press ENTER to return to menu):
signedcert <enter>
Enter subject name for certificate
 Common name (required):
My signed Certificate <enter>
 Organizational unit (optional):
ID <enter>
 Organization (required):
IBM <enter>
  City/Locality (optional):
Endicott <enter>
 State/Province (optional):
NY <enter>
 Country/Region (2 characters - required):
Enter number of days certificate will be valid (default 365):
300 <enter>
Enter 1 to specify subject alternate names or 0 to continue:
Please wait .....
```

Figure 56. Certificate Type menu

Press option 0 to continue or option 1 to specify the subject alternate names. If option 1 is selected, the Subject Alternate Name Type menu appears.

```
Subject Alternate Name Type
  1 - Directory name (DN)
  2 - Domain name (DNS)
  3 - E-mail address (SMTP)
  4 - Network address (IP)
  5 - Uniform resource identifier (URI)
Select subject alternate name type (press ENTER if name is complete):
1 <enter>
Enter subject name for certificate
 Common name (required):
Test server <enter>
 Organizational unit (optional):
ID <enter>
 Organization (required):
IBM <enter>
 City/Locality (optional):
Endicott <enter>
 State/Province (optional):
NY <enter>
 Country/Region (2 characters - required):
US <enter>
       Subject Alternate Name Type
  1 - Directory name (DN)
  2 - Domain name (DNS)
  3 - E-mail address (SMTP)
  4 - Network address (IP)
  5 - Uniform resource identifier (URI)
Select subject alternate name type (press ENTER if name is complete):
<enter>
Please wait .....
```

Figure 57. Subject Alternate Name menu

When specifying subject alternate names, you are prompted for the type of the alternate name. After the alternate name type is is determined, you will be prompted to enter:

the individual fields within the subject name.

After the individual fields are completed, select option 0 to continue or option 1 to specify another subject alternate name (repeat the process).

Creating a Certificate Renewal Request: Certificate renewal requests allow for existing signed certificates that have expired or are nearing their expiration dates to be renewed without having to create a brand new certificate request. The renewed certificate continues to contain the same subject name, public/private key pair. From the Key Management Menu, select 1 - Manage keys and certificates to display the Key and Certificate Menu. In the Key and Certificate Menu, choose option 11 to create a certificate renewal request.

```
Key and Certificate Menu
       Label: cacert
  1 - Show certificate information
  2 - Show key information
  3 - Set key as default
  4 - Set certificate trust status
  5 - Copy certificate and key to another database
  6 - Export certificate to a file
  7 - Export certificate and key to a file
  8 - Delete certificate and key
  9 - Change label
 10 - Create a signed certificate key
 11 - Create a certificate renewal request
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
11 <enter>
Enter request filename (press ENTER to return to menu):
renewalcert.arm <enter>
Certificate request created.
Press ENTER to continue.
```

Figure 58. Select 11 to Create a Certificate Renewal Request

Enter the request file name (press ENTER to return to menu). The certificate request is created. Press enter to continue. After creating the certificate renewal request, perform the following steps:

- 1. If you want a certificate authority (CA) to sign the certificate, send the certificate request to the CA. See "Sending the Certificate Request" on page 241. If you are acting as your own CA, use the GSKKYMAN command line interface to sign the certificate. See "Using GSKKYMAN to be Your Own Certificate Authority (CA)" on page 259.
- 2. Receive the renewed certificate into your key database. See "Receiving the Signed Certificate or Renewal Certificate" on page 241.

Importing a Certificate from a File as a Trusted CA Certificate

If you are using a certificate authority for generating your certificates that is not one of the default certificate authorities for which certificates are already stored in the key database, then you must import the certificate authority's certificate into your key database file before you use SSL. If you are using client authentication, then the CA certificate must be imported into the key database of the server program. The client program's key database file must have the CA certificate imported regardless of whether or not the SSL connection uses client authentication.

If you are using a self-signed certificate as the SSL server program's certificate and your SSL client program is also using SSL, then you must import the server's self-signed certificate into the client program 's key database file without a private key.

If you are using a self-signed certificate as the SSL client program's certificate and your SSL server program is also using SSL with client authentication requested, then you must import the client's self-signed certificate into the server program's key database file without a private key.

If the CA certificate being imported was signed by another CA certificate, the complete chain must be present in the key database file prior to the import.

A number of well-known certificate authority's (CA) certificates are stored in the key database when the key database is created. To get a certificate list, select 2 -Manage certificates from the Key Management Menu. Figure 59 and Figure 60 contain lists of CAs for which certificates are stored on key database creation:

```
Certificate List
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - VeriSign Class 1 Public Primary CA
  2 - VeriSign Class 2 Public Primary CA
  3 - VeriSign Class 3 Public Primary CA
  4 - RSA Secure Server CA
  5 - Thawte Server CA
  6 - Thawte Premium Server CA
  7 - Thawte Personal Basic CA
  8 - Thawte Personal Freemail CA
  9 - Thawte Personal Premium CA
  0 - Return to selection menu
Enter label number (ENTER for more labels, p for previous list):
```

Figure 59. Certificate List (part 1)

```
Certificate List
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Equifax Secure Certificate Authority
  2 - Equifax Secure eBusiness CA-1
  3 - Equifax Secure eBusiness CA-2
  4 - Equifax Secure Global eBusiness CA-1
  0 - Return to selection menu
Enter label number (ENTER to return to selection menu, p for previous list):
```

Figure 60. Certificate List (part 2)

To import a certificate without a private key into your key database file, first get the certificate in a file with the file in either Base64-encoded, Binary encoded or PKCS #7 format. From the Key Management Menu enter 7 to import a certificate:

```
Key Management Menu
      Database: /home/RACFU01/mykey.kdb
      Expiration: 2008/04/02 05:24:13
  1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
7 <enter>
Enter import file name (press ENTER to return to menu):
cert.arm <enter>
Enter label (press ENTER to return to menu):
cacert2 <enter>
Certificate imported.
Press ENTER to continue.
```

Figure 61. Importing a Certificate from a File

You will be prompted to enter the certificate file name and unique label to be assigned to the certificate.

Once the certificate is imported, you will receive a message indicating the import was successful. The certificate is treated as "trusted" so that it can be used in verifying incoming certificates. For a program acting as an SSL server, this certificate is used during the verification of a client's certificate. For a program acting as an SSL client, this certificate is used to verify the server's certificate which is sent to the client during SSL handshake processing.

Importing a Certificate from a File with its Private Key

To store a certificate into a different key database format or to a different system with its private key, the certificate must be exported from the source system into a PKCS #12 format file (See Copying a Certificate with its Private Key for more information). PKCS #12 files are password-protected to allow encryption of the private key information. If the CA certificate being imported was signed by another CA certificate, the complete chain must be present in the key database file prior to the import. From the Key Management Menu, enter 8 to import a certificate and a private key:

```
Key Management Menu
       Database: /home/sufwl1/ssl cmd/anne.kdb
       Expiration: 2008/04/02 05:24:13
   1 - Manage keys and certificates
  2 - Manage certificates
  3 - Manage certificate requests
  4 - Create new certificate request
  5 - Receive requested certificate or a renewal certificate
  6 - Create a self-signed certificate
  7 - Import a certificate
  8 - Import a certificate and a private key
  9 - Show the default key
 10 - Store database password
 11 - Show database record length
  0 - Exit program
Enter option number (press ENTER to return to previous menu):
8 <enter>
Enter import file name (press ENTER to return to menu):
cert.p12 <enter>
Enter import file password (press ENTER to return to menu):
<enter password>
Enter label (press ENTER to return to menu):
newcert <enter>
Certificate and key imported.
Press ENTER to continue.
```

Figure 62. Importing a Certificate and Private Key from a File

You will be prompted to enter the certificate file name, password and a unique label to be assigned to the certificate.

Once the certificate is imported, you will receive a message indicating that import was successful. The next step is to determine whether the certificate should be marked as the database's default certificate. Setting the certificate as the default certificate allows the certificate to be used by SSL without having to specify its label. For more information on setting the default certificate, see "Marking a Certificate (and Private Key) as the Default Certificate for the Key Database" on page 245).

A certificate and key can be imported into a FIPS key database providing it is a PKCS #12 Version 3 with strong encryption format. When adding certificates from the import file to a FIPS key database file only certificates signed with FIPS signature algorithms using FIPS-approved key sizes may be imported. When processing a chain of certificates, processing of the chain will terminate if a non-FIPS certificate is encountered. Certificates processed prior to the failing certificate will be added to the key database file. It is the responsibility of the importer to ensure that the file came from a source meeting FIPS 140-2 criteria in order to maintain adherence to the FIPS criteria.

Using GSKKYMAN to be Your Own Certificate Authority (CA)

The GSKKYMAN command provides the capability for you to act as your own Certificate Authority (CA). Being your own CA allows you to sign your own or anyone else's certificate requests. This is very handy if you only need certificates within your private Web network and not for outside Internet commerce.

To be your own CA in a Web network, you must create a CA database and self-signed CA certificate using GSKKYMAN. A server or client that wishes for you to sign a certificate must supply you with their certificate request. After signing the certificate, the server or client must receive the CA certificate and the newly signed certificate. The CA-signed certificate must then be received into either the client or server key database.

The following table describes the steps needed to become your own CA to allow secure communication between a client and a server. This example reflects the steps followed when the CA is on a different system or is a different user than the issuer of the certificate request.

Certificate Authority (System A)	Server or Client (System B)
Step 1 - Create a key database	
Create a key database using the GSKKYMAN command:	Create a key database using the GSKKYMAN command:
 From the Database Menu, select option 1 - Create new database 	From the Database Menu, select option 1 - Create new database
See "Creating, Opening and Deleting a Key Database File" on page 227 for details.	See "Creating, Opening and Deleting a Key Database File" on page 227 for details.
Step 2 - Create a Root Certificate Authority certificate	
Create a Certificate Authority certificate:	No action required.
 From the Key Management Menu, select option 6 - Create a self-signed certificate 	
 From the Certificate Type menu, select one of the CA values for your certificate type 	
See "Creating a Self-Signed Server or Client Certificate" on page 232 for details.	
Step 3 - Create a certificate request	
No action required.	Create a certificate request:
	From the Key Management Menu, select option 4 - Create new certificate request
	From the Certificate Type menu, select one of the certificate types
	See "Creating a Certificate Request" on page 235 for details.
Step 4 - Send the certificate request to the CA	
No action required.	Send the certificate request to the CA:. See "Sending the Certificate Request" on page 241.
Step 5 - Sign the certificate request	

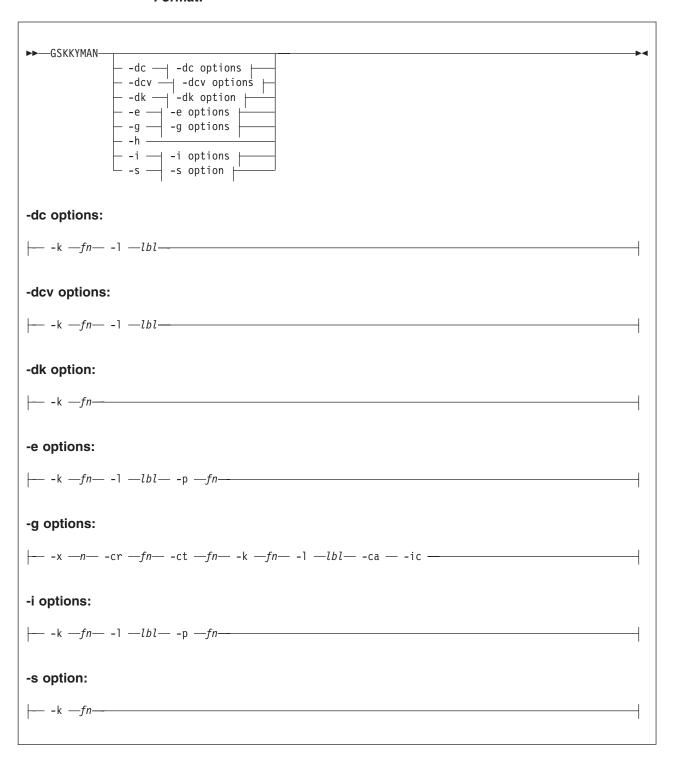

Certificate Authority (System A)	Server or Client (System B)
Before signing a certificate for a client or server, you need to make sure that the requestor has a legitimate claim to request the certificate. After you have verified the claim, you can create a signed certificate. To sign the certificate request, the GSKKYMAN command	No action required.
must be issued using command-line options (see "GSKKYMAN Command Line Mode Syntax" for a description of the options). The GSKKYMAN command must be issued with the following parameters:	
gskkyman -g -x num-of-valid-days -cr certificate-request-file-name -ct signed-certificate-file-name -k CA-key-database-file-name -l label	
Example: The following command will allow you to sign a request certificate and allow the certificate to be valid for 360 days.	
gskkyman -g -x 360 -cr server_request.arm -ct server_signed_cert.arm -k CA.kdb -l labelname	
After you have entered the command, you will be prompted to enter the database password.	
Notes®:	
The signed certificate will be an end user certificate unless the -ca option is specified.	
2. The filename specified on the -ct option is created for you by the utility, and is the actual signed certificate file.	
3. The valid certificate lifetime range is between 1 and 9999 days. The certificate end date will be set to the end date for the CA certificate if the requested certificate lifetime exceeds the CA certificate lifetime.	
Step 6 - Send the signed CA certificate and the newly signed certificate to the requestor	
Export the signed CA certificate (created in Step 2) to a Base64 file (DER or PKCS #7) See "Copying a Certificate Without its Private Key" on page 246. Send (for example, without its private key ftp) the Base64 file and the newly signed certificate (created in Step 4) to the requestor.	No action required.
Step 7 - Import the CA certificate	
No action required.	Import the CA certificate. See "Importing a Certificate from a File as a Trusted CA Certificate" on page 255.
Step 8 - Receive the signed certificate	
No action required.	Receive the signed certificate. See "Receiving the Signed Certificate or Renewal Certificate" on page 241. Note: Depending upon the SSL application, you may need to either send the CA certificate to the client, or the server application may actually present the certificate to the client for them during SSL session setup.

GSKKYMAN Command Line Mode Syntax

This section describes the format and options of the GSKKYMAN command.

GSKKYMAN (gskkyman utility) Command

Format:

Purpose: The GSKKYMAN command is used for key database management.

Functions:

-dc Display certificate details

- -dcv Display certificate verbose details
- Display key database expiration and record length -dk
- Export a certificate and its associated private key -e
- Sign a certificate for a certificate request -g
- -h Display the command syntax
- -i Import a certificate and its associated private key
- Store the database password in the stash file. -s

Options:

-ca

A certification authority certificate will be generated if -ca is specified. An end user certificate will be generated if -ca is not specified.

-cr

Specifies the name (fn) of the certificate request file. You will be prompted for the file name if this option is not specified.

-ct

Specifies the name (fn) of the output generated signed certificate file. You will be prompted for the file name if this option is not specified. You may specify any name. If you specify an existing file name, the file will be overwritten.

-ic

Specifies that the certification chain certificates be included in the certificate file. Otherwise, just the signed certificate will be included in the certificate file.

- -k Specifies the name (fn) of the key database. You will be prompted for the file name if this option is not specified. The length of the fully-qualified file name cannot exceed 251 characters. If the file name does not end with an extension of 1-3 characters, the length of the fully-qualified file name cannot exceed 247 characters. Finally, the key database name cannot end with .rdb or .sth.
 - -е The label of the key to be exported
 - The label associated with the signing certificate -g
 - The label is what you want the certificate to be
- -1 Specifies the certificate label (*lbl*). The label must be enclosed in double quotation marks if it contains one or more spaces. The label for the default key will be used if this option is not specified (export or sign function) or you will be prompted for the label (import function).
- -p Specifies the name (fn) of the PKCS #12 file. You will be prompted for the file name if this option is not specified.
- -x Specifies the number of days (n) until the signed certificate expires and must be between 1 and 9999 days. The certificate will expire in 365 days if this option is not specified.

Usage: The GSKKYMAN command is used to manage a key database and its associated request database. Interactive menus will be displayed if no command options are specified. Otherwise, the requested database function will be performed and the GSKKYMAN command will exit.

The key database contains certificates and private keys and normally has a filename extension of '.kdb'. The request database contains requests for new certificates and always has a filename extension of '.rdb'. The database stash file contains the masked database password and always has a filename extension of '.sth'. Access to these files should be restricted to the database owner.

A certificate or request database consists of fixed-length records. The record length is specified when the database is created and must be large enough to contain the largest certificate entry. A record length of 2500 should be sufficient for most applications. The record length can be increased if necessary after the database has been created.

A temporary database file is created when a database is updated during GSKKYMAN processing. The temporary database file is created using the same name as the database file with ".new" appended to the name. The database file is then rewritten and the temporary database file is deleted upon successful completion of the rewrite operation. The temporary database file will not be deleted if an error occurs while rewriting the database file. If this happens, you can replace the database file with the temporary database file in order to recover from the error. If an error does occur and you do not rename or delete the temporary file, you will get an error on the next database update operation indicating the backup file already exists.

GSKKYMAN Command Line Mode Examples

Command mode is entered when the GSKKYMAN command is entered with parameters. The requested database function will be performed and then the command will exit.

Store the database password in the stash file

```
gskkyman -s -k filename
```

The database password is masked and written to the key stash file. The file name is the same as the key database file name but has an extension of '.sth'. You will be prompted for the key database file name if the '-k' option is not specified.

Export a certificate and the associated private key

```
gskkyman -e -k filename -l label -p filename
```

The certificate and associated private key identified by the record label are exported to a file in PKCS #12 Version 3 format using strong encryption. The default key will be exported if the '-I' option is not specified. You will be prompted for the key database file name if the '-k' option is not specified. You will be prompted for the export file name if the '-p' option is not specified.

Import a certificate and associated private key

```
gskkyman -i -k filename -l label -p filename
```

A certificate and associated private key are imported from a file in PKCS #12 format. You will be prompted for the label if the '-I' option is not specified. You will be prompted for the key database file name if the '-k' option is not specified. You will be prompted for the import file name if the '-p' option is not specified.

· Create a signed certificate for a certificate request

```
gskkyman -g -x days -cr filename -ct filename -k filename -l label -ca -ic
```

The certificate request identified by the -cr parameter is processed and a signed certificate is created and written to the certificate file identified by the -ct parameter. The -x parameter specifies the number of days until the certificate expires and defaults to 365 days. The certificate is signed using the default key if the -I parameter is not specified. You will be prompted for the key database file name if the '-k' option is not specified. You will be prompted for the certificate request file name if the '-cr' option is not specified. You will be prompted for the signed certificate file name if the '-ct' option is not specified.

The signed certificate will be an end user certificate unless the -ca option is specified. A certification authority certificate will have basic constraints and key usage extensions which allow the certificate to be used to sign other certificates and certificate revocation lists. An end user certificate will have basic constraints and key usage extensions which allow the certificate to be used for authentication, digital signatures, and data encryption (a DSA key cannot be used for data encryption).

Any certificate can be used to sign the new certificate as long as the certificate has a private key, the basic constraints certificate extension (if present) has the CA indicator set, and the key usage certificate extension (if present) allows signing certificates. However, depending upon how the new certificate is subsequently used, it may fail the validation checking if the signing certificate is not a valid certification authority certificate.

The signing algorithm that will be used to sign the new certificate is based on the key algorithm of the signing certificate. An RSA signature will use the most secure and compatible SHA-based hash in use in the signature algorithm of either the signing certificate or the certificate request. A DSA signature will use SHA-1. Possible signing algorithms are:

- x509 alg sha1WithRsaEncryption
- x509_alg_sha224WithRsaEncryption
- x509_alg_sha256WithRsaEncryption
- x509_alg_sha384WithRsaEncryption
- x509 alg sha512WithRsaEncryption
- x509_alg_dsaWithSha1.

The certificate file will contain the generated X.509 certificate in DER-encoded Base64 format if the -ic option is not specified. The certificate file will contain the generated X.509 certificate and the certification chain certificates as a PKCS #7 message in Base64 format if the -ic option is specified.

GSKKYMAN Command Line Mode Displays

Command mode is entered when the GSKKYMAN command is entered with parameters. The requested database function will be performed and then the command will exit.

GSKKYMAN command-mode kdb display

When the key database password is correctly entered:

```
Database: /home/sufwl1/ssl cmd/anne.kdb
Epiration Date: 2008/12/02 10:11:12
Record length: 2500
```

GSKKYMAN command-mode certificate display

Output for a single certificate:

```

SSL Tracing Information

The information and techniques described in this topic are for use primarily by IBM® service personnel in determining the cause of an SSL problem. If you encounter a problem and call the IBM Support Center, you may be asked to obtain trace information or enable one or more of the diagnostic messages described below.

The facilities described below are not intended for use in a production environment and are for diagnostic purposes only.

Use the **gsktrace** utility to create a readable copy of SSL trace information. Run **gsktrace** from CMS with the GSKTRACE command. You need access to the TCPMAINT 591 disk where the GSKTRACE EXEC, load module, and message catalogs reside. By default, **gsktrace** accesses the US English message catalogs. If you want **gsktrace** to access the Japanese message catalogs instead, set the NLSPATH environment variable by executing the following commands from a REXX EXEC:

```
nlspath = '/usr/lib/nls/msg/Ja_JP.IBM-939/%N'
'globalv select cenv put nlspath'
```

GSKTRACE (gsktrace utility) command

Purpose

The GSKTRACE command creates a readable copy of SSL trace information.

Note: In order to capture trace information, the trace environment variables GSK_TRACE and GSK_TRACE_FILE must be set prior to starting the server. A single trace file is created, and there is no limit on the size of the trace file. See "Usage Note."

Operands

input trace file

Specifies the file designated by the GSK TRACE FILE environment variable. See "Usage Note."

output trace file

Specifies the name of the output file that will contain the formatted trace information.

Usage Note

In order to capture trace information, you must set the GSK_TRACE and **GSK_TRACE_FILE** prior to starting the server. Specify these environment variables in the CENV group of GLOBALV.

GSK TRACE

Specifies a bit mask enabling SSL trace options. No trace option is enabled if the bit mask is 0 and all trace options are enabled if the bit mask is 0xffff. The bit mask can be specified as a decimal (nnn), octal (0nnnn) or hexadecimal (0xhh) value.

The following trace options are available:

0x01 = Trace function entry

0x02 = Trace function exit

0x04 = Trace errors

0x08 = Include informational messages

0x10 = Include EBCDIC data dumps

0x20 = Include ASCII data dumps

Note: The trace mask can also be set by the GSKTRACE operand on the SSL server VMSSL command. See z/VM: TCP/IP Planning and Customization.

GSK_TRACE_FILE

Specifies the name of the trace file and defaults to /tmp/gskssl.%.trc. The trace file is not used if the GSK_TRACE environment variable is not defined or is set to 0.

The current process identifier is included as part of the trace file name when the name contains a percent sign (%). For example, if GSK_TRACE_FILE is set to /tmp/gskss1.%.trc and the current process identifier is 247, then the trace file name will be /tmp/gskss1.247.trc.

Note: It is recommended that if the default trace file value is not being used, the trace file name always contain a '%' character.

Chapter 8. Using the Network File System Commands

NFS is a TCP/IP protocol that allows heterogeneous systems to share data and files across networks. The NFS protocol is a client/server protocol — an NFS *server* runs on a system that has data and files to share, while an NFS *client* runs on a system where data and files are to be shared from NFS servers.

The VM NFS client allows BFS users and applications transparent access to data on remote systems that have NFS servers supporting the SUN™ NFS Version 2 or Version 3 protocols, or both. These NFS protocols are described in RFCs 1094 and 1813 respectively. z/OS OS/390®, Windows XP, Windows 2000, Windows 95, Windows NT, AIX®, LINUX, UNIX systems, and z/VM are examples of these remote systems.

For VM NFS client information, see the OPENVM MOUNT command in the *z/VM: OpenExtensions Commands Reference*.

VM's NFS Server Support

The following NFS information is described in this chapter:

- Sample remote NFS client commands and PCNFSD User ID Authentication
- · Diagnosing Mount Problems
- · Errors Using Mounted Systems
- · Notes for BFS files and directories
- · Notes for SFS files and directories
- · Notes for minidisk files
- · SMSG VM NFS server commands
- · Name translation file
- NFS Client Problems
- Deleting CMS record-length fields
- · Using NFS with RACF
- BFS All functions defined by the NFS protocol are supported by BFS file systems. For information on special considerations, see "Notes for BFS Files and Directories" on page 285.
- SFS Most functions defined by the NFS protocol are supported by SFS file systems. For information about which functions are not supported, see "Notes for SFS Files and Directories" on page 286.

Minidisk

Some functions that are defined by the NFS protocol are not supported by CMS minidisk file systems. Others are partially supported. For information about which functions are not supported, see "Notes for Minidisk Files" on page 288.

Network File System (NFS) server support for z/VM is available at the Version 2 level (RFC 1094) and at the Version 3 level (RFC 1813). Both User Datagram Protocol (UDP) and Transmission Control Protocol (TCP) transport protocols are supported. If your NFS client can be configured to use NFS Version 3 or the TCP transport protocol, you will be able to select these options.

© Copyright IBM Corp. 1987, 2011 269

NFS Client Commands

The actual format and use of NFS commands in a client system depends on the implementation of the NFS client. In the following descriptions, information is provided for data that is transmitted by the client system to the VM NFS server. For information about other parts of these commands or data that is interpreted by the client system, consult the documentation for the specific NFS client system used.

You can use the following NFS commands from an NFS client machine.

MOUNT Mounts a BFS directory, SFS directory, or CMS minidisk on a local

directory.

MOUNTPW Sends authentication information (user IDs and passwords) to the

VM NFS server to obtain access to protected CMS files, directories,

and file systems.

UMOUNT Removes mounted CMS file systems in the client environment.

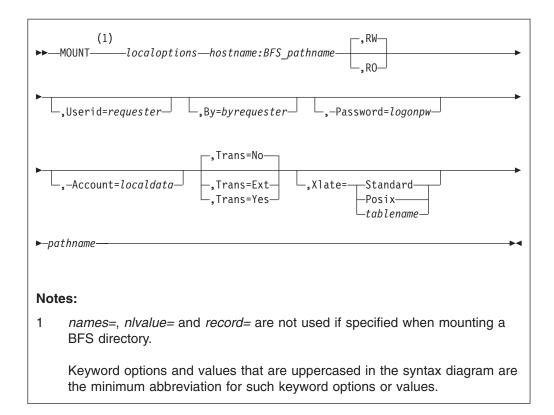

No unique error messages are associated with these commands. The error messages that result from a failed mount attempt depend on the client system, which should provide you with sufficient status information to understand why the failure occurred.

The NFS commands are described in the following sections. In some environments, the command syntax is case-sensitive. The following syntax diagrams are examples only.

MOUNT Command

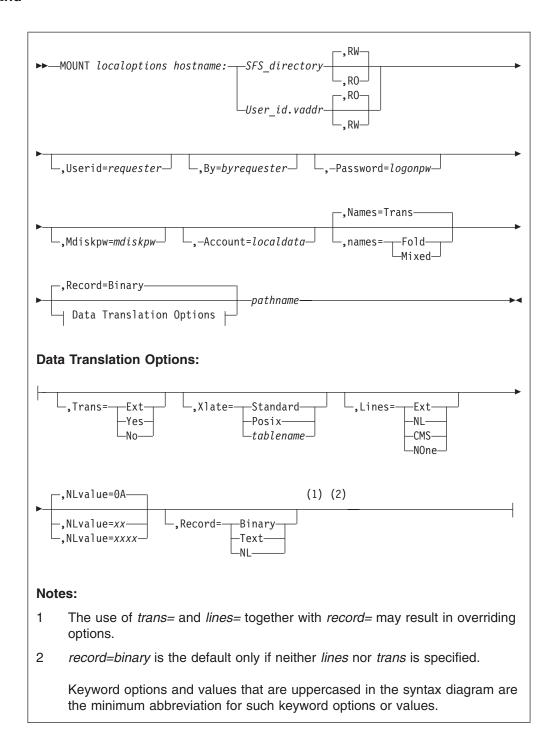

BFS MOUNT Command Syntax

BFS file system protocols are similar to those of NFS.

SFS and Minidisk MOUNT Command Syntax

SFS and minidisk file system protocols are very different from those of NFS in both structure and naming convention. SFS and minidisks files have records; the **lines** and **nlvalue** options allow you to tell NFS how to map records into a data stream. The **names** option tells NFS how to map a CMS file identifier (FILENAME FILETYPE) into the NFS file naming convention.

Purpose

To access a CMS file system, issue the MOUNT command on the NFS client machine in the following format:

MOUNT and MOUNTPW Operands

The specific MOUNT parameters used by an NFS client can vary for different VM systems, based on the access control scheme in use (for example, protecting minidisks using CP LINK passwords versus an external security manager (ESM), such as RACF).

Ensure the appropriate authorizations are in place before issuing a mount request. For example, in the case where an ESM such as RACF is in place to protect minidisks, the owner of a minidisk to be mounted may need to issue RACFPERM or RACFBAT commands to authorize your user ID and/or the VM NFS server to obtain access to that disk. Also, ensure that both the password= and userid= parameters are included in the minidisk mount request.

For BFS and SFS files, authorization checking is done in the file pool server machine when you request access to files in the mounted directory. Your requests for file access are authorized (or not authorized) based on how you are identified to the file pool server. The VM NFS server uses the verified userid= parameter to identify your requests.

Optional parameters can be specified in any order. If an optional parameter is specified more than once, or if overriding parameters such as record= and trans= are used together, the last instance prevails.

localoptions

Specifies the MOUNT options, which vary between different client systems. Some common options for a UNIX client are: intr, soft, retry=n, retrans=n, and timeo=n. When a time-out value is specified, it usually is in units of one-tenth of a second; therefore timeo=20 denotes a time-out value of 2 seconds before a client assumes a network error occurred and retransmits a request to a server.

hostname:

The hostname is the name of the host on which the VM NFS server resides. Some NFS clients use a different syntax to specify the server location in a MOUNT command, rather than placing it as a prefix to the characters that identify the remote file system to be mounted.

BFS pathname

Specifies the fully-qualified name of the BFS directory that contains the files and subdirectories to be accessed by the client.

Use two consecutive commas (,,) to indicate that a BFS directory name contains a comma.

Some NFS clients have difficulties with the special characters required for fully-qualified BFS directory names. You may use slashes (/) in place of the colons (:) that are required before file pool ID and file space ID in a fully-qualified BFS directory name. NFS clients may have other requirements for entering pathnames containing special characters such as blanks.

SFS directory

Specifies the SFS file pool directory that contains the files and subdirectories to be accessed by the client. SFS directory must be fully qualified, except that the file space portion of the directory name can default to requester.

Some NFS clients have difficulties with the special characters required for fully-qualified SFS directory names. You may enter a slash (/) in place of the colon (:) that is required between file pool ID and file space ID in a fully-qualified SFS directory name. You may also enter a slash in place of the period (.) that separates subdirectories.

user id.vaddr

Specifies the minidisk. The user id.vaddr string defines the minidisk that contains the files to be accessed by the client.

- RW Specifies that the type of mount is to be read/write access. This is the default for the mount of a BFS or SFS directory.
- **R0** Specifies that the type of mount is to be read-only. This is the default for a mount of a minidisk.

Userid=requester

Specifies a CP (VM) requester user ID to be associated with the mount request.

The user ID is used as access control for SFS files, and the user ID is translated into UID and GID values which are used as access controls for BFS files. (Additional access controls may be used if an external security manager (ESM) is active for the file pool.) Requester should be enrolled in the file pool containing the BFS or SFS directory, or PUBLIC should be enrolled.

User ID may be used by an external security manager, such as RACF, for deciding whether an NFS client is permitted to access an ESM-protected minidisk.

userid= need not be specified on the MOUNT or MOUNTPW requests if PCNFSD is used.

If **by=** is not specified, the combination of **userid=**requester and password=logonpw is used by the VM NFS server to validate the identity of the client.

When userid= and by= are not provided by PCNFSD, MOUNTPW, or a MOUNT request, the mount will be successful only if anonymous mounts are allowed by the VM NFS server. If anonymous MOUNTs are allowed, the mount may be successful if a user ID of ANONYMOU has authority to use the SFS directory or ESM-protected minidisk. For BFS directories, the mount may be successful if the default user UID or GID values allow permission to use the directory. See z/VM: TCP/IP Planning and Customization for information about allowing anonymous MOUNTs.

By=byrequester

If both userid=requester and by=byrequester are specified, the VM NFS server verifies that **password**=logonpw is the correct logon password for byrequester, and that byrequester has LOGON BY privileges for userid=requester.

Password=logonpw

Specifies the VM logon password of the user ID requesting the mount.

password= need not be specified on the MOUNT or MOUNTPW requests if PCNFSD is used.

The -v option on the OS/2 MOUNT command can be used to have the client prompt you for the password, unless you are mounting a BFS directory.

Mdiskpw=mdiskpw

When no external security manger (ESM) is in use, specifies a CP link password when a password is required to access the minidisk being mounted. If a CMS disk is public (that is, its CP LINK password is ALL), no password needs to be provided with the MOUNT command in order to access files on that disk.

The VM NFS server will not issue a CP LINK for an MW link. If a mount request specifies write access for a minidisk, but a write link to that minidisk already exists, the VM NFS server returns a status code to the NFS client which indicates the CMS minidisk is a read-only file system.

Note: If userid=, by= and mdiskpw= are not specified, the password specified in the password=logonpw parameter is used as a minidisk link password for CMS minidisks. This exception is made because earlier releases of VM NFS did not make a distinction between logon and minidisk link passwords.

Account=local data

Allows additional information to be passed to software such as an ESM in the host. Specifies up to 64 characters of information that can be used by customer-supplied programming in the VM NFS server to further control or record access by NFS clients. The format of this data depends upon the supporting software. If account information is specified by a client and there is no supporting software in the server, the account data is ignored by the VM NFS server.

Names=

Specifies the handling of file names for minidisk, SFS files and directories. The names options are:

Fold File names supplied by the client are translated to uppercase;

file names supplied to the client are translated to lowercase.

Mixed File names are not changed. The client must use valid CMS

names. This mode must be used to refer to CMS files that

contain lowercase letters in their name.

Trans Use default name handling, which is described in the following

paragraph.

If the names parameter is omitted, the default provides translation for names that are too long or contain invalid characters. File names supplied by the client are translated to uppercase; file names supplied to the client are translated to lowercase. Correct CMS file names are generated by the VM NFS server, and these names are used rather than the actual client names. The VM NFS server creates the translation file ##NFS## #NAMES# on the CMS minidisk for minidisk files, and in the top SFS directory of the file space for SFS files. This translation file contains both the original client file names and the corresponding CMS file names. When file names are read by a client, the inverse translation is performed so that the client sees the original name specified when the file was created.

Trans=

defines whether translation should occur for data in files.

EBCDIC-ASCII translation is done based on the value of the file Ext

extension. See Table 20 on page 278.

Yes EBCDIC-ASCII translation is performed.

No No translation is performed.

If neither **record** or **trans** is specified, **trans=no** is the default.

NFS uses translation tables to convert transmitted data between EBCDIC and ASCII. These translation tables can be customized by your TCP/IP administrator. Contact your TCP/IP administrator for information about data translation.

Xlate=

Defines which translation table is to be used for file data translation.

Standard TCP/IP's standard translation table is to be used.

MOUNT Command

Posix This table translates ASCII (ISO 8859-1) to and from EBCDIC

(IBM-1047). The UNIX line terminator (If - X'0A') is translated to

the VM OpenExtensions line-end character NL - X'15').

tablename The name of the translate table to be used. Some examples of

tablename include "Xlate=UK," "Xlate=French," or

"Xlate=10471252."

If xlate is not specified, a system-defined translation table is

used.

tablename may not be abbreviated.

Your TCP/IP administrator may change the list of tables provided, or customize the translation tables in the list. Contact your TCP/IP administrator for information about data translation.

Lines=

defines the way CMS records are converted to an NFS data stream.

Ext The type of conversion done is based on the value of the file extension. See Table 20 on page 278.

NL Line feed characters are inserted at CMS record boundaries.

CMS The CMS file format is maintained. When dealing with CMS variable-length record files, the binary, unsigned, two-byte length field is visible to the client at the beginning of CMS records read from the VM NFS server, and this field must be supplied by the client program in data written to VM.

NOne No linefeed characters are inserted. When dealing with CMS variable-length record files, the two-byte length fields are not visible.

If neither **record** nor **lines** is specified, **lines=none** is the default.

NLvalue=

Specifies two or four hexadecimal characters to be used as the boundary indicating the end of a CMS record. The default is the line feed character.

For example, you can specify *nlvalue=0D0A* for carriage return and line feed.

Record=

The **record** option is supported for compatibility. Use the **trans** and **lines** options to tell NFS how to translate file data.

- Binary is equivalent to trans=no and lines=CMS.
- Text is equivalent to trans=yes and lines=CMS.
- NL is equivalent to trans=yes and lines=NL.

pathname

Specifies the local path name, which identifies where to mount CMS files in the client file name hierarchy.

Figure 63 on page 277 illustrates the MOUNT command.

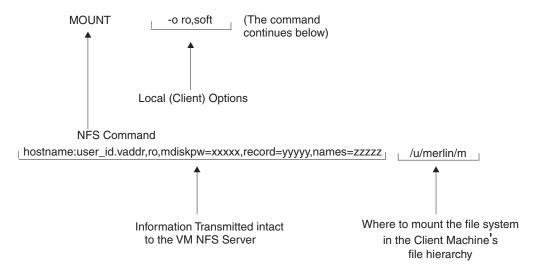

Figure 63. NFS MOUNT Command

NFS File Extension Defaults

Following are the default values used when the trans=ext or lines=ext options are used. The system administrator for your system may change or add to these default values.

File extension is defined to be the last component of a file name, that is, the characters following the last period in the path name. Up to eight characters are matched, and mixed case is not respected.

MOUNT Command

Table 20. File Extension Translation Table

File Extension			trans=ext	lines=ext		
*BIN¹					no	none
\$EXEC	\$REXX	\$XEDIT	AMS	AMSERV		NL

XEDIT						
other or none					no	none

Notes:

- 1. *BIN represents a wildcard, that is, any file extension ending in 'BIN'.
- 2. OFS* represents a wildcard, that is, any file extension starting with 'OFS' unless it also ends in 'BIN'.

PCNFSD User ID Authentication

Many NFS client implementations contain calls to PCNFSD user ID Authentication services. The purpose of these calls is to present a user ID and password to be verified by the host system. Once verified, the UID and GID by which that user is known at the host is returned to the client. For VM, the POSIXINFO and POSIXGLIST CP directory entry statements define the UID and GID(s) associated with a user ID.

Note that a value of -1 is returned for a user ID of ANONYMOU.

When PCNFSD is used, there is no need to send user ID and logon password in the MOUNT or MOUNTPW. If user ID or password are not provided by MOUNTPW or MOUNT, the PCNFSD values are used by the NFS server, as long as the MOUNT request is received by the NFS server immediately following the PCNFSD request. (The NFS client typically sends the MOUNT request immediately following the PCNFSD information.)

Your system administrator has the option of disabling PCNFSD for your NFS server. Contact your system administrator if you receive a message that PCNFSD is not running or is inaccessible.

NFS MOUNT Examples

In the following example, a MOUNT command is issued from an OS/2 command prompt to mount a BFS directory that resides in the root file system in file pool: fpcool. Note that VMBFS, FPCOOL and ROOT must be uppercased when specified in the pathname.

1. Mounting a BFS directory:

```
mount -u4189 -q513 x: qd3vm0:/../VMBFS:FPC00L:R00T/u/jake,
     userid=elwood,password=mypass
```

In the previous command, the user specified his VM uid and gid via the -u and -v options. This indicates to OS/2 what uid and gid are being used. However, the VM NFS server will perform authorization checking based on the verified userid= parameter.

Alternatively, Elwood's VM logon password can be provided via a previous MOUNTPW command.

2. Mounting an SFS directory:

```
mount -v x: gd3vm0:fpcool:jake.mission,trans=ext,lines=ext,
     userid=elwood
```

In the above example, a MOUNT command is issued from an OS/2 command prompt to mount the mission SFS subdirectory owned by the VM user ID, JAKE which resides in file pool fpcool:

After issuing the command above, the user will be prompted for Elwood's user ID password. In response to this prompt, the VM logon (or sign-on) password should be provided.

Alternatively. Elwood's VM logon password can be provided via the password= parameter and no password prompt is issued.

In the following examples, MOUNT commands are issued from an OS/2 command prompt to mount the VM 191 minidisk owned by the VM user ID, JAKE:

1. Accessing a VM minidisk when an External Security Manager (ESM) is in use:

```
mount -v x: gd3vm0:jake.191,ro,trans=yes,lines=NL,
     userid=elwood
```

After issuing the command above, the user will be prompted for Elwood's user ID password. In response to this prompt, the VM logon (or sign-on) password should be provided.

```
mount x: gd3vm0:jake.191,ro,trans=yes,lines=NL,password=harpman,
     userid=elwood
```

In the above command, Elwood's VM logon password harpman is provided via the **password=** parameter; no password prompt is issued.

2. Accessing a VM minidisk when no External Security Manager (ESM) is in use:

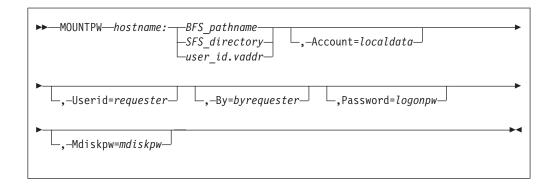

```
mount -v x: gd3vm0:elwood.191,ro,trans=yes,lines=NL
```

After issuing the above command, the user will be prompted for a password. In response to this prompt, a VM minidisk (CP LINK) password should be provided. In this example, read-only access was requested, so the minidisk "Read (R)" password should be provided.

```
mount x: gd3vm0:elwood.191,rw,trans=yes,lines=NL,mdiskpw=whtoast
```

In the above example, read/write access was requested, so the minidisk "Mult (M)" password ("whtoast") was provided via the **mdisk=** parameter.

MOUNTPW Command

Purpose

Use the MOUNTPW command to send authentication information to the VM NFS server to obtain access to protected CMS files, directories and file systems.

Note: If your NFS client is configured to call PCNFSD user ID Authentication services and PCNFSD is available on your VM NFS server, using MOUNTPW is not necessary, because user ID and password information is passed on PCNFSD requests. This applies to mounts for SFS directories, BFS directories, and minidisks protected by ESMs. A minidisk protected by link passwords must still provide the password on the MOUNT or MOUNTPW command.

The MOUNT command can pose a security problem, because NFS client systems often store this command's argument values to respond to a later query asking for information about the mounts that are currently in effect. A password supplied in an argument to a MOUNT command could then be revealed in the query response to someone other than the user who executed the MOUNT command. The MOUNTPW command provides an alternative path for sending passwords, account, and user ID information to the VM NFS server. This information can then be omitted from the subsequent related MOUNT command, and therefore is not present in a display of currently mounted file systems.

A MOUNTPW command precedes the related MOUNT command, which must follow within 5 minutes. After 5 minutes, the VM NFS server discards the information it received in a MOUNTPW command. If a second MOUNTPW command is issued for the same CMS disk or directory before a MOUNT command for that object, the data from the first MOUNTPW command is discarded.

The only MOUNT command options that are recognized on a MOUNTPW command are userid, by, password, mdiskpw and account. All other MOUNT command options are ignored. If user IDs, passwords, or account value are specified on both a MOUNTPW command and a related MOUNT command, the value from the MOUNT command is used.

MOUNT and MOUNTPW Operands

Refer to the "MOUNT Command" on page 270 for a description of the operands.

Usage Note

The MOUNTPW C source file is supplied on TCPMAINT's 592 disk, as are the executable modules built for the IBM client environments listed in Table 21

Table 21. Executables

Operating Environment	MOUNTPW Executable File	
AIX on an IBM RISC System/6000	6000@BIN MOUNTPW	
OS/2	OS2@BIN MOUNTPW	

If none of the executable modules are appropriate, then the MOUNTPW C file must be copied to the client system and compiled into an executable program before you can execute the MOUNTPW command.

Compile the command using a C compiler resident on the client system. The location of header files (.h) in the MOUNTPW source program may not be where your client system expects for a compile. If this is the case, modify the MOUNTPW source program to specify the correct location for your client system. Some platforms may require that you specify libraries to build the MOUNTPW executable. For example, DYNIX/ptx® requires the following: -lsocket, -lnsl, and -lrpc.

Binary files are supplied containing executable MOUNTPW modules for the IBM AIX® environment. These can be used in the NFS client environment AIX Version 4.2.1 and above as an alternative to building executable modules from the source files. Use FTP to copy the files to the AIX environment, renaming the files to the command name and making sure to use the FTP command binary to ensure that a binary copy is performed. Once the files are copied to the AIX environment, use the command chmod a+x mountpw to make the files executable.

UMOUNT Command

Purpose

Use the UMOUNT command to unmount a currently mounted file system.

The format of the UMOUNT command, like the MOUNT command, depends on the client system.

The most common format of the UMOUNT command is shown above.

Operands

pathname

Specifies the local path name that identifies a mounted remote file system in the client environment.

Figure 64 on page 282 illustrates the NFS UMOUNT command.

UMOUNT Command

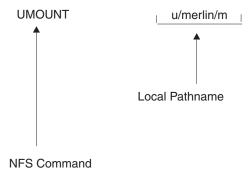

Figure 64. NFS UMOUNT Command

Diagnosing Mount Problems

If your NFS client is having trouble performing a mount, try the following to verify that your VM system is running correctly:

- 1. Verify that the network connections are good. Try to "ping" the VM system, for example: ping gdlvmk1.endicott.ibm.com
- 2. Verify that the PORTMAPPER server is up and running by issuing the "RPCINFO" command. The RPCINFO command can be issued from VM or from another platform that supports it. From VM the command is issued as follows:

```
RPCINFO -p server name
```

For example:

```
RPCINFO -p gdlvmk1.endicott.ibm.com
```

If the portmapper is up, a list of programs, versions, protocols, and port numbers is printed similar to the following:

```
Ready; T=0.04/0.08 16:36:32
rpcinfo -p k321sf01
   program vers proto
                    port
   100000
            2
                udp 111 portmapper
           2
   100000
                       111 portmapper
                tcp
   100005
                      2049 mountd
             1
                udp
   100005
             3
                udp
                      2049 mountd
   100005
             1
                tcp
                      2049 mountd
   100005
             3
                      2049 mountd
                tcp
                      2049 nfs
   100003
                udp
             2
   100003
                udp
                      2049 nfs
   100003
           2
                tcp
                      2049 nfs
   100003
            3
                      2049 nfs
                tcp
   150001
             1
                udp
                      2049 pcnfsd
   150001
             2
                abu
                      2049 pcnfsd
Ready; T=0.04/0.08 16:38:21
```

If a similar response is not returned, contact your system programmer or TCP/IP administrator to start the PORTMAPPER server on your VM system.

- 3. If your mount uses the NFS Version 3 or TCP transport protocol, verify that the output from the RPCINFO -p command lists 3 in the vers column and tcp in the proto column for both the **mountd** and **nfs** programs.
- 4. Verify that the mountd, pcnfsd, portmapper, and nfs services are running on your VM system by entering the following commands from VM:

```
rpcinfo -u server_name mount
rpcinfo -u server_name pcnfsd
rpcinfo -u server name portmapper
rpcinfo -u server name nfs
```

If the services are running on the VM system, the following responses are returned:

```
Ready; T=0.02/0.06 16:45:36
* See if mount is running
rpcinfo -u k321sf01 mount
program 100005 version 1 ready and waiting
program 100005 version 2 ready and waiting
program 100005 version 3 ready and waiting
Ready; T=0.04/0.08 16:45:49
* See if portmapper is running
rpcinfo -u k321sf01 portmapper
program 100000 version 2 ready and waiting
Ready; T=0.04/0.08 16:46:40
* See if nfs is running
rpcinfo -u k321sf01 nfs
program 100003 version 2 ready and waiting
program 100003 version 3 ready and waiting
Ready; T=0.04/0.08 16:47:27
* See if pcnfsd is running
rpcinfo -u k321sf01 pcnfsd
program 150001 version 1 ready and waiting
program 150001 version 2 ready and waiting
Ready; T=0.04/0.08 16:47:53
```

If all of the above verifications look successful, the following can also be verified:

1. Contact your VM NFS server administrator to verify that the EXPORT and EXPORTONLY configuration statements in the VMNFS CONFIG file are set up correctly to allow your NFS client host system to perform the mount.

Errors Using Mounted Systems

Table 22 describes the status values that can be generated by the VM NFS server. Most of these status values are defined in RFC 1094 and RFC 1813. However, there are VM specific status values listed here also and there are status values listed that are defined in the RFCs but never returned.

The actual information that is visible to a program in the client system depends on the specific local file system routine invoked and the design of the NFS client implementation. Some NFS clients may make these error codes visible to the user, some do not.

Table 22. NFS System Return Codes

Code	Description
NFS3ERR_PERM = 1	The caller does not have valid ownership, and the requested operation is not performed.
NFS3ERR_NOENT = 2	The file or directory specified does not exist.
NFS3ERR_IO = 5	I/O error occurred while an operation was in progress.
NFS3ERR_NXIO = 6	Invalid device or address specified.
NFSERR_ENOMEM = 12	The operation caused the server's file system to run out of memory. This status value is specific to the VM NFS server.
NFS3ERR_ACCES = 13	The caller does not have the correct authorization to perform the desired operation.
NFS3ERR_EXIST = 17	The specified file already exists.

Table 22. NFS System Return Codes (continued)

Table 22. IVI & Bystelli Hetalli Code	
Code	Description
NFS3ERR_XDEV = 18	An attempt was made to do a cross-device hard link. This status value is not returned by the VM NFS server.
NFS3ERR_NODEV = 19	Invalid device specified.
NFS3ERR_NOTDIR = 20	A non-directory was specified in a directory operation.
NFS3ERR_ISDIR = 21	A directory was specified in a non-directory operation.
NFS3ERR_INVAL = 22	An invalid argument or unsupported argument for an operation was received. An example is attempting a READLINK on an object other than a symbolic link.
NFS3ERR_FBIG = 27	File too large. The operation caused a file to grow beyond the server's file system limit.
NFS3ERR_NOSPC = 28	The operation caused the server's file system to run out of space.
NFS3ERR_ROFS = 30	Writing attempted on a read-only file system.
NFS3ERR_MLINK = 31	There are too many hard links.
NFS3ERR_NAMETOOLONG = 63	The file name in an operation was too long, or invalid in some other way under the name translation option specified in the MOUNT command.
NFS3ERR_NOTEMPTY = 66	Directory not empty. The caller attempted to remove a directory that was not empty.
NFS3ERR_DQUOT = 69	Disk quota exceeded. The client's disk quota has been exceeded.
NFS3ERR_STALE = 70	Invalid file handle. The file referred to by the file handle no longer exists, or access has been revoked. This access revoked condition also occurs under the following sequence of events.
	1. A client mounts a CMS disk.
	The minidisk link password granting access to that disk is changed.
	3. The VM NFS server is restarted.
	4. The client requests an operation on this disk.
	After it is restarted, the VM NFS server relinks a CMS disk when it first receives a client request referring to that disk. The server restart is not visible to the client. If the minidisk link password has been changed, this link fails and "stale filehandle" status is returned to the client. Similarly, if SFS authorization of BFS permissions change for a mounted directory, and attempts to access the directory fail following a server restart, "stale filehandle" status is returned.
NFS3ERR_REMOTE = 71	Too many levels of remote in the path specified. The file handle given in the arguments referred to a file on a non-local file system on the server.
NFSERR_WFLUSH = 99	Never returned by the VM NFS server.
NFS3ERR_BADHANDLE = 10001	Never returned by the VM NFS server.
NFS3ERR_NOT_SYNC = 10002	Update synchronization mismatch was detected during a SETATTR operation.
NFS3ERR_BAD_COOKIE = 10003	The cookie specified on READDIR or READDIRPLUS is incorrect.

Table 22. NFS System Return Codes (continued)

Code	Description
NFS3ERR_NOTSUPP = 10004	The operation specified is not supported.
NFS3ERR_TOOSMALL = 10005	A buffer or request had an incorrect length.
NFS3ERR_SERVERFAULT = 10006	Never returned by the VM NFS server.
NFS3ERR_BADTYPE = 10007	An attempt was made to create an object of a type not supported by the server. For example, creating a socket using MKNOD is not supported for BFS.
NFS3ERR_JUKEBOX = 10008	Never returned by the VM NFS server.

Notes for BFS Files and Directories

All functions defined by the NFS protocol are supported by BFS file systems.

- 1. By default, NFSERR IO is returned on requests that reference file data for BFS files that have been placed in migrated status.
- 2. The size attribute is ignored on Create Directory.
- 3. All attributes are ignored on Create Link to File and Create Symbolic Link. Attributes for the new link match those of the linked-to file.
- 4. NFSERR_IO or NFS3ERR_INVAL is returned on all requests that attempt to use BFS external links of type CMSEXEC or CMSDATA. This restriction is in place because these types use ddnames and file modes, which will not be defined properly for the VM NFS server.
- 5. NFSERR IO or NFS3ERR INVAL is returned on all requests that attempt to read, write, or perform the set attributes set size function on a BFS FIFO.
- 6. All changes are flushed and committed for a Version 3 Commit request, even when offset and count contain non-zero values.
- 7. Both the VM user's primary GID (from the POSIXINFO statement) and the user's supplementary GID list (from the POSIXGLIST statement) are used for requests.
- 8. The following restrictions apply to the MKNOD procedure:
 - · creation of the block special device file and socket are not supported
 - only 16-bit major and minor device numbers are supported.
- 9. The file mode creation mask that is in effect for the VM NFS server machine will apply to the creation of BFS objects through the VM NFS server. In other words, the NFS client may request the permission values to be associated with the file or directory (based on a local client mask), but these may be overridden by the file mode creation mask on the VM NFS server.
 - The file mode creation mask in effect can be displayed via OPENVM QUERY MASK. Your TCP/IP administrator can change the default by specifying the OPENVM SET MASK command when the VM NFS server starts. For more information on the file mode creation mask, see "Handling Security for Your Files" in the z/VM: OpenExtensions User's Guide, SC24-6206.
- 10. If the requester user ID specified on the mount (or with mountpw or pcnfsd) has file pool administration authority for the target file pool, that administration authority is not respected by VMNFS. In other words, the requester user ID must have explicit permission to the object through the UID and GID associated with the user ID.
- 11. Refer to "VM NFS Server Link Support" on page 298 in this chapter for more notes on BFS symbolic links and external links.

UMOUNT Command

12. If you are able to perform all expected functions for an NFS-mounted Byte File System directory, but ACCESS DENIED or NOT OWNER is displayed when you attempt to create a file, then the UID and GIDs defined for your client may be different from the UID and GIDs defined for the VM user ID used on the MOUNT. For a VM user ID, UID and GIDs are defined by the POSIXINFO, POSIXGROUP, and POSIXGLIST statements in the CP directory entry. Default values of -1 are used if these statements are not used.

The file creation problem is typically seen on systems such as AIX and UNIX. The file is created successfully, but the NFS client then attempts to change the owning UID to match the UID of the VM user ID. This part of the operation fails because it requires super-user capabilities.

Other types of clients tolerate differences in UID/GID definitions more easily. These other NFS clients often use PC-NFS to ask the server: By what UID am I known here? The NFS client then uses that information by recognizing what the owning UID of a new file should be.

How can you correct this problem on a system such as AIX?

- a. The best way to avoid this problem is to have global user ID definitions. The VM user ID is assigned the same UID and GIDs used by the NFS Client system.
- b. If global user ID definitions are not possible, another choice is to create a new user ID on the client system with a UID that matches the VM user ID. Use 'su' to switch to that user ID on the client before creating the file. Also ensure that the GID assigned to the new name is in the list of GIDs assigned to the VM user ID. This may be easier than forcing consistency across all systems, but it is practical only if there is no overlap in the UID definitions for the two systems.
- c. A third choice is to MOUNT using a VM user ID that has super-user authority. This will allow the create request to succeed. In this case, clients that use the mount point have full power to anything under it (because they are considered super-users by the VM NFS server). Access to the mount point must be carefully controlled from the client side.

Notes for SFS Files and Directories

- 1. Most functions defined by the NFS protocol are supported by SFS file systems. Those not supported include:
 - symbolic links

Those partially supported include:

link

Limited support is available for the link NFS request. The intent of this support is to accommodate clients that use link as a temporary step during a file rename or similar operation. A hard link may be created only in the same directory as the source file. Link information is maintained in volatile storage by the VM NFS server, and it is not used when the reply to a read-directory or lookup-file request is constructed.

- · set-attributes
 - Both the time of last modification (mtime) and the time of last access (atime) can be changed. However, SFS maintains only the date, (not time) of last access for SFS files, so when an atime is retrieved, it will show a timestamp that is midnight of the given date.
 - Requests to change file permissions are ignored and *success* status is returned to the client.

- Requests to change mode, uid, or gid are ignored and success status is returned to the client.
- Attempting to increase the size of a variable file generates an error response.
- Only the file space owner may create (mkdir) or remove (rmdir) directories, unless an ESM is used and allows the operation for the requester user ID.
- The file size attribute can be used on Create File to set the size for fixed record format files. The file size attribute is ignored and set to zero for variable record format files.
- 2. Access to SFS file and directories is based on the authorities granted to the requester user ID specified on the MOUNT command, and not UID's. On multiple user systems such as UNIX, all users have the same access to objects in the mounted SFS directory if they have permission to use the mount point. Thus the administrator (super-user) who performs the mount must make sure that appropriate controls are in place for the mount point.
- 3. Each update operation is committed before responding to the client, including Version 3 Write requests. A Version 3 commit request returns a success status to the client.
- 4. CMS users can create SFS files that do not map to NFS file types. The ftype value returned for aliases, erased aliases, revoked aliases, and external objects is NFNON (non-file).
- 5. When names=Trans is specified on the Mount command, NFS provides translation of SFS directory names that are greater than 16 characters or contain invalid characters. There is one restriction: mkdir() or rename() are rejected if the name contains a dot.
 - The mkdir() operation creates FILECONTROL directories and uses the mtime (modification time), if provided by the client.
 - The only date used for SFS directories is mdate.
- 6. A ro (read-only) mount request is similar to the RORESPECT ON setting in a CMS client. If an SFS directory is mounted ro, you may not write to files in that subdirectory structure.
- 7. By default, NFSERR IO is returned on requests that reference file data for SFS files that have been placed in migrated status.
- 8. Files named ##NFS## #VHIST# and ##NFS## #NAMES# may reside in an SFS top directory when files are written using NFS. Do not modify or erase these files. They contain control information needed by NFS. Do not copy the ##NFS## #NAMES# file. If you are using name translation and want to move a file from one file system (such as an SFS directory) to a separate file system (such as a minidisk), NFS mount both file systems and copy the file. This allows the VMNFS file server to proper format.
- 9. Not all file attributes defined by the NFS protocol apply to SFS file systems. In the case of uid and gid, the attribute values are returned as follows:
 - · The uid value returned for an SFS Dircontrol directory will be 1. All other SFS objects will return a uid value of 0.
 - The gid value for an SFS file with fixed record format will be returned as 1. The gid value for an SFS file with variable record format will be returned as 2. All other SFS objects will return a gid value of 0.
 - The record length of an SFS file (LRECL) will be returned in the rdev
- 10. Creation of special files using MKNOD is not supported. Special files are block special device file, character special device file, socket, and named pipe.
- 11. Creation of a regular file with the mode set to EXCLUSIVE is not supported.

UMOUNT Command

- 12. Records in CMS variable files are limited to a length of 65535. If a write request attempts to create a record larger than this, a message is written to the VM NFS server console and an I/O error is returned to the client.
- 13. The NFS READDIR procedure can appear to behave inconsistently with NFS mounted SFS directories, due to native SFS authorization rules. SFS will allow non-directory file system objects to be listed in NFS READDIR output, provided that the NFS client has at least SFS read authorization to the directory containing the objects, but SFS will not allow subdirectories in that directory to be listed in NFS READDIR output, unless the NFS client was also explicitly given at least SFS read authorization to each subdirectory.
 - To ensure that clients will be able to see SFS subdirectories after an NFS READDIR procedure, SFS read authorization should be granted for every directory in a file system hierarchy. Refer to the z/VM: CMS User's Guide, SC24-6173, for more information on SFS authorizations.
- 14. When writing to an existing SFS fixed format file for a mount point created using the lines=nl option, the data must be formatted so that the NLvalue follows every nn bytes of data, where nn is the logical record length for the file. If no **NLvalue** is found where one is expected, an I/O error is returned to the client. One workaround for this restriction is to use the "save as" function in your editor to save the file under a new name. By default, when using the **lines=nl** option, a new file is created in the variable file format.
- 15. If two **NLyalues** are provided in a row when writing to an SFS variable format file, the second **NLvalue** will appear to be at the start of the following record when viewing the file from CMS. Zero-length records are not allowed in the CMS record file system.

Notes for Minidisk Files

1. Some functions that are defined by the NFS protocol are not supported by CMS minidisk file systems. Others are partially supported.

Those not supported include:

- make-directory
- symbolic link
- · remove-directory

Those partially supported include:

- set-attributes
 - Only the time of last data modification (mtime) can be changed.
 - Requests to change file permissions are ignored and *success* status is returned to the client.
 - The size of a file can be changed to zero or to its current size. The size of a fixed record format file can be increased. Other size change requests generate an error response.
 - Requests to change mode, uid, or gid, are ignored and success status is returned to the client.
- link
 - Limited support is available for the link NFS request. The intent of this support is to accommodate clients that use link as a temporary step during a file rename or similar operation. Link information is maintained in volatile storage by the VM NFS server, and it is not used when the reply to a read-directory or lookup-file request is constructed.
- · Access to minidisks is based on the ability of the VM NFS server to link the disk. On multiple user systems such as UNIX**, all users have the same access to files in the mounted minidisk if they have permission to use the

mount point. Thus the administrator (super-user) who performs the mount must make sure that appropriate controls are in place for the mount point.

- A minidisk file size can be changed to zero from an NFS client. To NFS clients it will appear to have a file size of zero; to CMS users the file will appear to have one record, of length one.
- Not all file attributes defined by the NFS protocol apply to minidisk files. In the case of uid and gid, the attribute values returned are as follows:
 - The uid value returned for a minidisk file with either fixed or variable record format will be returned as 0.
 - The gid value for a minidisk file with fixed record format will be returned as 1. The gid value for a minidisk file with variable record format will be returned as 2.
 - The record length of a minidisk file (LRECL) will be returned in the rdev attribute.
- The VM NFS server updates CMS minidisk disk blocks in place, if possible. The advantages of this implementation include:
 - Updates to existing data in a file are immediately visible to a CMS user who accessed the disk before the updates were made.
 - The VM NFS server does not need to keep elaborate data structures in memory, record the current state of a file, or manipulate the CMS allocation and directory information every time a write request is executed.

The disadvantage of this type of implementation is that a time window exists, during which a failure of the VM NFS server could cause a disk block on a CMS disk to be recorded as allocated, when it does not belong to any file.

This time window is of short duration, because, after the block is marked as allocated, the directory or pointer block necessary to record ownership of the block is immediately updated. For this reason, troubles with lost blocks are infrequent.

If a file is open when an update is made, you may not see the update, because CMS buffers the disk block containing the update. CMS only buffers one disk data block for each file, so updates in another data block can be seen, even if the file is open. Closing the file makes the updates visible the next time the file is read.

Updated file data is immediately visible to other NFS clients, subject to the limitations imposed by the buffering performed in those client machines.

Write operations performed by the VM NFS server are similar to the operations that CMS performs to files that have the file mode number 6. The VM NFS server does not distinguish the actual file mode number associated with a file on a CMS disk. New files are always created with the file mode number 1. Files of any file mode number (including zero) can be read by any client that performs a successful mount.

- The file size attribute can be used on Create File to set the size for fixed record format files. The file size attribute is ignored and set to zero for variable record format files.
- 2. All changes are flushed and committed for a Version 3 Write request. A Version 3 Commit request returns a **success** status to the client.
- 3. Creation of special files using MKNOD is not supported. Special files are block special device file, character special device file, socket, and named pipe.
- 4. Creation of a regular file with the mode set to EXCLUSIVE is not supported.

UMOUNT Command

- 5. Records in CMS variable files are limited to a length of 65535. If a write request attempts to create a record larger than this, a message is written to the VM NFS server console and an I/O error is returned to the client.
- 6. When writing to an existing minidisk fixed format file for a mount point created using the lines=nl option, the data must be formatted so that the NLvalue follows every nn bytes of data, where nn is the logical record length for the file. If no **NLvalue** is found where one is expected, an I/O error is returned to the client. One workaround for this restriction is to use the "save as" function in your editor to save the file under a new name. By default, when using the lines=nl option, a new file is created in the variable file format.
- 7. If two **NLvalues** are provided in a row when writing to a minidisk variable format file, the second NLvalue will appear to be at the start of the following record when viewing the file from CMS. Zero-length records are not allowed in the CMS record file system.
- 8. Files named ##NFS## #VHIST and ##NFS## #NAMES# may reside on a minidisk when files are written using NFS. Do not modify or erase these files. They contain control information needed by NFS. Do not copy the ##NFS## #NAMES# file. If you are using name translation and want to move a file from one file system (such as a minidisk) to a separate file system (such as an SFS directory), NFS mount both file systems and copy the file. This allows the VMNFS file server to create a mapping for the client file name in the proper format.

SMSG Interface to VMNFS

The following are the SMSG commands supported by the NFS server.

SMSG DETACH Command

Purpose

Use the SMSG DETACH command to direct the NFS server to detach a minidisk that it has linked.

Note: Some SMSG commands may be restricted by the TCP/IP administrator for use by only authorized VM user IDs.

SMSG command operands are parsed by the NFS server as blank-delimited tokens, and case is not significant. Any tokens present after those recognized by the NFS server are considered to be comments and are ignored.

Operands

server id

The user ID of the NFS server virtual machine, usually VMNFS.

A character string that associates the supplied SMSG command Option with a server response; the replytag prefaces each message issued by the NFS server in response to the given command. Any characters (other than blank and null characters) can be used to form a replytag, and case is not significant.

The replytag also indicates how the NFS server is to deliver its response to a particular SMSG command. The last character of replytag has special meaning and is interpreted by the server as follows:

The following describes how the last character of *replytag* is interpreted.

- respond using the CP SMSG command.
- respond using the CP MSG command. m
- n send no response.

If the replytag does not end with one of these characters, the NFS server chooses a response mode.

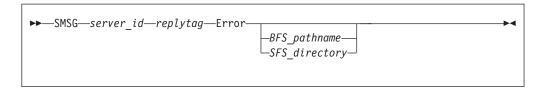

user id

Identifies the VM user ID that owns the minidisk.

vaddr

Is the minidisk virtual address.

SMSG ERROR Command

Purpose

Use the SMSG ERROR command to obtain error information about client requests that pertain to a specific SFS or BFS directory that has been mounted.

Note: Some SMSG commands may be restricted by the TCP/IP administrator for use by only authorized VM user IDs.

SMSG command operands are parsed by the NFS server as blank-delimited tokens, and case is not significant. Any tokens present after those recognized by the NFS server are considered to be comments and are ignored.

Operands

server id

The user ID of the NFS server virtual machine, usually VMNFS.

replytag

A character string that associates the supplied SMSG command Option with a server response; the *replytag* prefaces each message issued by the NFS server in response to the given command. Any characters (other than blank and null characters) can be used to form a *replytag*, and case is not significant.

The replytag also indicates how the NFS server is to deliver its response to a particular SMSG command. The last character of replytag has special meaning and is interpreted by the server as follows:

The following describes how the last character of *replytag* is interpreted.

- respond using the CP SMSG command. S
- respond using the CP MSG command. m
- send no response. n

SMSG Interface to VMNFS

If the replytag does not end with one of these characters, the NFS server chooses a response mode.

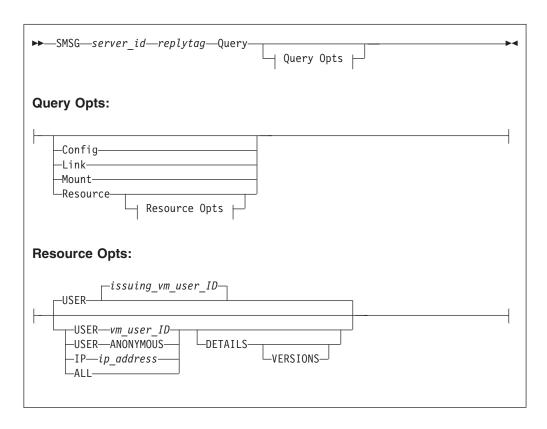

BFS_pathname

The mounted BFS directory for which host error information is requested. Information will only be returned if the VM user ID that originates the error request has permission to the directory in question.

SFS_pathname

The mounted SFS directory for which host error information is requested. Information will only be returned if the VM user ID that originates the error request has authorization for the directory in question.

SMSG QUERY Command

Purpose

Use the SMSG Query command to obtain a summary of NFS server activity.

Note: Some SMSG commands may be restricted by the TCP/IP administrator for use by only authorized VM user IDs.

SMSG command operands are parsed by the NFS server as blank-delimited tokens, and case is not significant. Any tokens present after those recognized by the NFS server are considered to be comments and are ignored.

Operands

server id

The user ID of the NFS server virtual machine, usually VMNFS.

replytag

A character string that associates the supplied SMSG command Option with a

server response; the replytag prefaces each message issued by the NFS server in response to the given command. Any characters (other than blank and null characters) can be used to form a replytag, and case is not significant.

The replytag also indicates how the NFS server is to deliver its response to a particular SMSG command. The last character of replytag has special meaning and is interpreted by the server as follows:

The following describes how the last character of *replytag* is interpreted.

- respond using the CP SMSG command.
- respond using the CP MSG command. m
- n send no response.

If the replytag does not end with one of these characters, the NFS server chooses a response mode.

Ouerv

Requests summary information about NFS server activity. The QUERY command can be further qualified with the CONFIG, LINK, MOUNT or RESOURCE operands to obtain specific information.

Query CONFIG

Requests information about how the NFS server is configured. The server returns the following information in its response:

- The TCP/IP function level of the VMNFS MODULE in use.
- · The status of various configuration parameters, such as whether mounts are restricted to only exported file systems, whether anonymous mounts are allowed, whether PCNFSD is supported, and the time after which PCNFSD information will be discarded.
- The maximum buffer size to be used to satisfy NFS version 3 READ requests.
- The maximum buffer size to be used to satisfy NFS version 3 WRITE requests.
- The maximum number of NFS clients that can concurrently use the TCP transport protocol.
- The number of NFS clients that are concurrently using the TCP transport protocol.

Information returned by the SMSG QUERY CONFIG command can be used to determine if the maximum allowable number of clients which use the TCP transport protocol (controlled by the MAXTCPUSERS server configuration statement) is acceptable.

Query Link

Requests information about minidisks that are linked by the NFS server. Support for the SMSG QUERY LINK command is provided to maintain compatability with prior levels of TCP/IP for VM/ESA®; it is recommended that the SMSG QUERY RESOURCE command be used in place of the SMSG QUERY LINK command.

Query Mount

Requests information about NFS mounts that are active. Support for the SMSG QUERY MOUNT command is provided to maintain compatability with prior levels of TCP/IP for VM/ESA; it is recommended that the SMSG QUERY RESOURCE command be used in place of the SMSG QUERY MOUNT command.

Query Resource

Requests information about specific resources that are actively in use by the NFS server. SFS and BFS directories are considered to be active if they have been used or referenced within the 15 minute period that percedes receipt of an SMSG QUERY RESOURCE command. A minidisk is considered to be active so long as the NFS server has established a link to that minidisk.

If additional operands are not used to qualify a RESOURCE query, information that corresponds to the user ID which originated the SMSG command is returned, as if the USER vm_user_id had been specified.

The information returned in response to an SMSG QUERY RESOURCE command includes:

- · whether a mount is read-write or read-only.
- a one-character mount indicator. This indicator is typically m, meaning the returned resource information corresponds to an explicit client mount. An asterisk (*) indicates the NFS server was restarted and that an implicit mount was performed for a directory that is lower in the hierarchy of the explicitly-mounted directory.
- · the IP address from which a mount was requested.
- the VM user ID under which a mount was requested, or "anonymous" if an anonymous mount was performed.
- · the name of the mounted BFS directory, SFS directory, or minidisk.

The RESOURCE operand can be further qualified with the USER. IP or ALL operands to obtain more specific summary information, as follows:

USER vm_user_id	Limits resource information for directories and minidisks mounted under authority of the specified VM user ID, <i>vm_user_id</i> .
USER ANONYMOUS	Limits resource information for directories and minidisks that have been mounted anonymously.
IP ip_address	Limits resource information for directories and minidisks that have been mounted by the host with the IP address, <i>ip_address</i> .
ALL	Provides resource information for all mounted directories and minidisks. Note that BFS and SFS directory mount information is returned only if the user ID that originates the request has permission (authorization) for those directories. Table 23 shows the information that is displayed when the ALL operand is used.

Table 23. Resource Information

Mount Information	Meaning		
*	The NFS server was restarted and an implicit mount was done for a directory lower in the explicitly-mounted directory's hierarchy.		
m	Information displayed is for an explicit client.		
ro, rw	Indicates whether the mount is read-write or read-only.		
name	The name of the mounted BFS directory, SFS directory, or minidisk.		

Table 23. Resource Information (continued)

Mount Information	Meaning
IP address	The IP address from which the mount was requested.
user ID	The VM user ID under which the mount was requested. This will contain "anonymous" if the mount was made anonymously.

The operands that follow can be used with the USER, IP or ALL operands to obtain additional information, as follows:

DETAILS

Provides counter values for various NFS requests.

VERSIONS

Provides separate request counter values for NFS version 2 requests and NFS version 3 requests.

Examples

The following example asks for a display of NFS server activity.

```
smsg vmnfs m q
```

The reply from this QUERY command is sent by the CP MSG command. The message text (time and origin information added by CP is omitted) that might result from this example is:

```
M VM NFS server start time 18Jan1999 08:50:48.
M 238 RPC (0 duplicate XID), 11 SMSG, 5 *BLOCKIO
M 0 null, 6 getattr, 7 setattr, 98 lookup, 12 read, 4 write
M 4 create, 3 remove, 2 rename, 0 link, 70 readdir, 14 statfs
M 13 mkdir, 1 rmdir, 0 symlink, 0 readlink, 0 access, 0 mknod
M O readdir+, O fsstat, O fsinfo, O pathconf, O commit
M 2 mount, 0 mountpw, 1 mountnull, 0 unmount, 0 unmount-all
M 1 pcnfsd auth, 0 unsupported
M End of reply.
```

SMSG REFRESH user id.vaddr Command

Purpose

Use the SMSG REFRESH user_id.vaddr command to refresh minidisk information after changes have been made to a minidisk that the server has linked in read-only mode; this causes buffered disk block data to be discarded so that subsequent client requests make use of current disk data.

Note: Some SMSG commands may be restricted by the TCP/IP administrator for use by only authorized VM user IDs.

SMSG command operands are parsed by the NFS server as blank-delimited tokens, and case is not significant. Any tokens present after those recognized by the NFS server are considered to be comments and are ignored.

Operands

server id

The user ID of the NFS server virtual machine, usually VMNFS.

SMSG Interface to VMNFS

replytag

A character string that associates the supplied SMSG command Option with a server response; the replytag prefaces each message issued by the NFS server in response to the given command. Any characters (other than blank and null characters) can be used to form a replytag, and case is not significant.

The replytag also indicates how the NFS server is to deliver its response to a particular SMSG command. The last character of replytag has special meaning and is interpreted by the server as follows:

The following describes how the last character of *replytag* is interpreted.

- respond using the CP SMSG command.
- m respond using the CP MSG command.
- n send no response.

If the replytag does not end with one of these characters, the NFS server chooses a response mode.

user id

Identifies the VM user ID that owns the minidisk.

vaddr

Is the minidisk virtual address.

Examples

· The following example instructs the NFS server to discard any disk blocks buffered from the TCPMAINT 592 minidisk.

smsg vmnfs example1m refresh tcpmaint.592

The reply from the SMSG command is sent by the CP MSG command. The message text returned for this command is:

EXAMPLE1M REFRESH TCPMAINT.592 completed.

If a busy reply is sent, the message text is:

EXAMPLE1M REFRESH TCPMAINT.592 busy.

The busy reply is generated if the VM NFS server cannot find a moment when a client request is not using the referenced minidisk. The server tries for 10 seconds before generating a busy reply. If a busy reply is received, you can try the command again.

Name Translation File

The VM NFS server creates the translation file ##NFS## #NAMES# on a:

- CMS minidisk, or
- SFS top directory

that has been mounted read-write with default name processing when the first client request to create an invalid file name for CMS is received. The translation file contains both the original client file names and the corresponding CMS file names that are generated.

The names translation files are hidden from NFS clients. That is, lookup or readdir requests do not return an entry for these files. Please note that these files are only visible to CMS users of the minidisk or directory.

Attention

You can destroy a name translation file by writing incorrect data to the file. This damages the internal structure of the file.

You can also destroy a name translation file by erasing or renaming it using CMS.

Special File Names for VM NFS

The file names (.) and (..) are handled as special cases by the VM NFS file server. No name translation is performed. For minidisk, the file lookup procedure in the server treats each of these file names as a request for the file handle of the directory (the CMS minidisk itself). For SFS and BFS, a file name of (..) is treated as a request for a lookup of the parent directory of the current object. A file name of (.) is treated as a request for a lookup of the current object. This convention supports interpretations that are common in UNIX NFS clients.

Special File Name Considerations

Note for ESM-protected file pools: an NFSERR ACCES error code may indicate that you do not have the correct authorization to perform the desired operation on the target file, or on the name translation file that resides in an SFS top directory.

Note to UNIX users: CMS file rename semantics differ from UNIX. CMS uses file names to denote files, unlike the inode organization that UNIX uses for its files. Changing the name of a file for which some client has a file handle makes that file handle invalid, because there is no longer a file with the name denoted by the file handle. If a new file is created with the old name, or an existing file is renamed to the old name, the old file handle denotes the new file.

UNIX systems avoid a similar problem when reusing inodes, because they maintain an inode generation number which, in combination with the inode number, uniquely identifies a file. A new file with the name that another file used to have is different from the old file, because the inode number and generation number of the new file is different from the old one.

NFS Client Problems

Some client implementations have a particular problem with deleting files from CMS minidisks. The problem results from a discrepancy between assumptions made by the client about how the VM NFS server manages a directory, and the actual mechanism used by CMS to manage the directory on a minidisk. The problem occurs when the PC-DOS client undertakes an operation such as delete *.c. This operation starts with the client reading a buffer of file names (read-directory operation) from the server, and receiving a cookie (file name) that references a particular position in the directory. The client then examines the names, finds one or more that match the specified pattern, and emits erase-file calls for the matching names. Because CMS maintains a compact directory, the hole created by deleting a file is filled by moving the data from the last file in the directory into the hole and shortening the length of the directory itself.

When the client finishes erasing all appropriately named files in this first group of file names, it calls the server (using the previously obtained cookie) to read another group of file names. However, a number of file names (equal to the number of

Using NFS Commands

erased files) can no longer be seen by the client, because the directory is not the same as when the first group of file names was read. In this example, if one of the holes was filled with data for a file that matches the "*.c" pattern, one or more files that should have been erased are retained.

A similar problem between the client and server, again due to a cookie-related discrepancy, can occur with BFS and SFS managed directories, with some NFS client implementations.

You can avoid these problems by making the client application repeat the delete request, if it deletes any files using a wildcard pattern, until it receives a return value indicating that no file names were matched by the pattern. For more specific instructions for particular clients please refer to the VM TCP/IP homepage at IBM: TCP/IP for z/VM and VM/ESA (www.ibm.com/vm/related/tcpip/).

Deleting CMS Record-Length Fields

In the past, the VCMS C sample program was provided to read variable format (V-format) files and delete CMS record-length fields. This sample is no longer provided. Instead the lines option can now be specified on MOUNT requests to prevent CMS record-length fields from being inserted in the NFS data stream (if CMS record-length fields are not needed).

Using NFS with RACF

The Resource Access Control Facility (RACF) allows NFS servers to act as surrogates for other user IDs. This means that the server can access those disks available to a given user ID.

The command that allows NFS servers to act as surrogates is provided in a program called NFSPERM EXEC. To use it, enter the command: NFSPERM ADD

If you get an error, contact your system administrator.

You may delete the NFS server's surrogate authority by issuing the command: NFSPERM DELETE

NFSPERM is explained in the "Using TCP/IP with External Security Manager" section of the *z/VM: TCP/IP Planning and Customization* publication.

VM NFS Server Link Support

Two kinds of links are supported in the NFS protocol, hard links and symbolic links. Hard links are supported by the NFS LINK procedure, and symbolic links are supported by the NFS SYMLINK and READLINK procedures. VM does not natively support hard links and symbolic links for minidisk file systems and SFS, but there is native support for hard links and symbolic links in BFS.

SFS and Minidisk Links

The VM NFS server provides no additional support for symbolic links on minidisk or in SFS, but it does provide limited support for minidisk and SFS hard links. This support is minimal, and is intended to facilitate some NFS clients' intermediate use of hard links during NFS operations such as RENAME.

BFS Links

The VM NFS server fully supports hard links and symbolic links in BFS. A symbolic link may appear in NFS READDIR output, and may be a component of a BFS pathname on an NFS MOUNT command or other NFS client commands.

The VM NFS server provides limited support for BFS external links, even though these fall outside the scope of the NFS protocol. MOUNT external links may appear in NFS READDIR output, may be targets of NFS READLINK procedures, and may be components of BFS pathnames on an NFS MOUNT command or other NFS client commands. NFS READLINK does not support CMSDATA, CMSEXEC, or CODE external links, but they may appear in NFS READDIR output. Creation of external links, and I/O operations on external links, are not supported by the VM NFS server.

Because symbolic links and MOUNT external links may be BFS pathname components, seemingly inconsistent behavior related to pathname parsing can occur during some NFS operations. NFS clients interpret the contents of symbolic links and MOUNT external links when they are encountered as pathname components, and different NFS clients may interpret them differently; this can affect the outcome of NFS READDIR operations and other NFS operations.

- The use of consecutive periods (..) in a BFS pathname can cause problems. UNIX-type implementations interpret this to mean the parent directory of the current directory, and it may be meaningless in non-UNIX-type implementations.
- The VM OpenExtensions fully-qualified BFS prefix "/../VMBFS:" can be a problem if it appears other than at the beginning of a pathname.
- A slash (/) at the beginning of a BFS pathname can imply that the subsequent path is relative to the root of the current file system, and the absence of a slash at the beginning can imply that the subsequent path is relative to the current directory.
- A slash (/) at the end of a pathname can imply that a link should be followed, and the absence of a slash at the end can imply that a link should not be followed.

The following recommendations should thus be observed:

- Consider the run-time perspective of the NFS client when constructing pathnames for symbolic links and MOUNT external links in BFS.
- Do not use consecutive periods (..) in a BFS pathname unless its meaning will be unambiguous at run time.
- Be conscious of whether links are being specified relative to the expected current directory at run time, or relative to the root of the file system.

Refer to the z/VM: OpenExtensions User's Guide and the z/VM: OpenExtensions Commands Reference for more information on BFS symbolic links, external links, and pathname syntax and resolution.

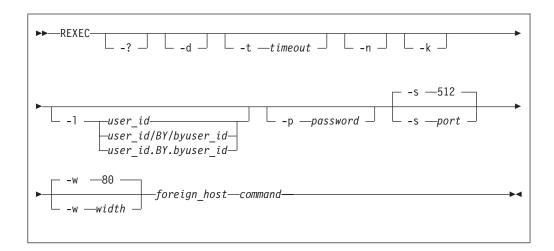

Chapter 9. Using the Remote Execution Protocol

The Remote Execution Protocol (REXEC) is a remote execution client that allows you to execute a command on a foreign host and receive the results on the local host. This chapter describes how to use the REXEC command, and its associated NETRC DATA file.

The REXEC client passes a user name, password, and command to an REXEC daemon on a foreign host, which provides automatic logon and user authentication, depending on the parameters set by the (client) user. If the authentication process succeeds, the command is issued, and any results are returned to the client. If the authentication fails, an error message is displayed on the local host.

An REXEC daemon must be running on the foreign host where your command is to be issued. For information about the TCP/IP REXEC daemon (REXECD), see *z/VM: TCP/IP Planning and Customization*. For information about REXEC daemons on other platforms, see the appropriate documentation associated with the foreign host being used.

REXEC Command

Purpose

Use the REXEC command to execute commands on a foreign host and receive the results on the local host.

Operands

REXEC operands are case-sensitive.

- -? Displays the help message.
- -d Activates debug tracing.
- -t timeout Sets idle time-out. This option specifies the time (in seconds) in which a connection closes if there is no activity. By default, the session will remain active until the remote system closes the connection.
- -n Suppresses use of the NETRC DATA file and hence automatic logon to the foreign host.

Using REXEC

- -k Suppresses prompts for the logon user name and password. Use this option when a NETRC DATA file is used and command input is to be obtained through non-interactive means, such as from an exec.
- -1 user id

Specifies a user ID that is valid on the foreign host. Depending on the type of host, *user_id* may be case sensitive.

- -1 user_id/BY/byuser_id
- -1 user id.BY.byuser id

Specifies an alternate logon name to be used by a foreign z/VM host during authorization. When the /BY/ or .BY. delimiter and the byuser_id parameter are specified with *user_id*, the *byuser_id* logon password is used for authorization checking instead of the *user_id* password.

Any user ID specified in the byuser_id parameter must be included in a LOGONBY statement in the user_id CP directory entry. When an External Security Manager (ESM) such as RACF is installed, its defined authorization criteria may override that defined by CP in the LOGONBY statement. For example, RACF may perform authorization checks for attempts to log on a shared user ID. For further details, refer to the documentation for the ESM in use.

-p password

Specifies the password associated with user id. The password may be case sensitive. If the password contains blanks, it must be surrounded by single quotation marks and any single quotation marks within it must be doubled.

Specifies the TCP port number of the REXEC daemon on the foreign host. The default for port is 512.

Specifies the maximum width to use for lines written by REXEC. The minimum acceptable width is 1, while the maximum is 32767. The default for width is 80. Note that circumstances on the remote host continue to affect or restrict output when the w operand is used.

foreign host

Specifies the name or internet address of the foreign host to which you are sending your command. You can specify the foreign host by its host name or internet address.

command

Specifies the command that is sent to the foreign host. The command can be composed of one or more words. After checking for any prefixed parameters (-I, -p, and -s) and obtaining the foreign host, the remaining REXEC argument string is assigned to command. Depending on the type of foreign host, the command may be case sensitive.

Usage Notes

1. If you omit the user name or password, REXEC prompts you to supply them, unless they are defined in a NETRC DATA file, or unless the -k option has been specified to suppress prompting.

Examples

The following example shows the results obtained for an REXEC command issued against another VM system. In this example, the CP QUERY NAMES command has been executed by an rexec daemon agent (RXAGENT1) on host ODDJOB, as a result of a user specifying a user ID and password of "GUEST".

```
rexec -l guest -p guest -s 512 oddjob cp q names
        - DSC, SMTP
                          -DSC, PORTMAP
LPSERVE - DSC, FTPSERVE -DSC, REXECD SNMPQE - DSC, SNMPD -DSC, RSCS
                                             - DSC
                                             - DSC
         - DSC, PVM
TCPIP
                           -DSC, GCS
                                             - DSC
OPERSYMP - DSC, DISKACNT -DSC, EREP
                                             - DSC
TCPMAINT - DSC, RXAGENT1 -DSC,
         VTAM
VSM
         - TCPIP
Ready;
                                                          RUNNING
                                                                    GDLVM7
```

The NETRC DATA File

The NETRC DATA file provides an alternative for specifying the REXEC *user_id* and *password* parameters. If these parameters are defined within this file for a specific host, they can be omitted when you issue an REXEC command against that host.

For more information on the NETRC DATA File and how it may be used with other applications, see Appendix B, "Using the NETRC DATA File," on page 425.

The following sections should be reviewed before REXEC commands are issued against a VM host running TCP/IP, as they provide important information about the REXEC support provided in the VM environment.

Anonymous Remote Command Execution

TCP/IP provides support for "anonymous" REXEC command execution through the use of one or more REXEC "agent" machines. These machines can be used by specifying either of the following user ID and password combinations:

User IDPasswordANONYMOUANONYMOUGUESTGUEST

Note: Only the first eight characters of the above values are verified. For the case when ANONYMOU is used, longer strings that begin with "ANONYMOU" (such as "ANONYMOUS") may be accepted. Also, note that these values are not case-sensitive.

When an agent machine is used to execute an anonymously-supplied command, the command is passed on to, and executed within, an available agent machine. After the command completes, output is obtained by REXECD via IUCV communications and is passed on to the REXEC client; the agent machine is then made available to process other anonymous REXEC commands. Note that since multiple agent machines may be in use on the remote VM host, there is no guarantee that the same agent will be used to process successive REXEC commands. Also, since a given agent machine handles multiple users' requests, the internal state of that machine may vary as different commands are issued.

Command Execution Using Your Own Virtual Machine

A CMS user's own virtual machine can also be used to execute REXEC-supplied commands. When this is done, command processing is performed in much the same way as that done with RXAGENT machines. The main difference is that your

Using REXEC

virtual machine is autologged following user and password authentication, and then logged off after the given command has completed.

It should be noted that if a client application sends consecutive REXEC commands in quick succession to the VM TCP/IP REXECD server machine, one (or more) of these commands may fail due to errors associated with logging on the intended virtual machine. For example, the message "Unable to autolog user user ID" may be received. Errors such as this may occur due to timing conflicts between the autolog processing and that of the supplied commands. This situation can be avoided by enlisting the use of an RXAGENT machine or by adding an appropriate delay between consecutive commands issued by the client.

In addition to the items listed in the Notes and Restrictions section, the following considerations apply to any CMS user's virtual machine used for REXEC command processing:

- 1. The user machine must not be active when REXEC requests are made against it. If the user's machine is logged on or disconnected, the REXEC request will be rejected.
- 2. Any machine used to process REXEC commands must access the TCP/IP client minidisk TCPMAINT 592, in its PROFILE EXEC. This is necessary so that the RXSNDIU EXEC is available, which is used to process data provided by REXECD after the machine has been autologged.
- 3. Your PROFILE EXEC should not attempt to process data in the console input buffer or program stack. Such processing, if performed, may prevent REXEC commands from being processed. Additionally, the PROFILE EXEC must not require user intervention.

Notes and Restrictions

- 1. Due to the manner in which command output is obtained from agent machines, secondary consoles must not be defined for them. If a secondary console is defined, REXECD will not be able to send command results back to the REXEC
- 2. When the REXECD server autologs a virtual machine, it passes several parameters. In doing so, the # (pound) symbol is always used as the LINEND character. If a different LINEND character is in effect for the agent machine(s), REXEC commands will not be processed successfully. In such cases, the agent machine's PROFILE EXEC will need to be modified to set the LINEND character to #, with the CP TERMINAL command. For example, when the foreign host is a VM system you would enter:
 - CP TERMinal LINEND #
- 3. Because the REXEC protocol doesn't allow for user interaction, commands to be executed remotely must complete without the need for user intervention. When a VM system is the foreign host involved, commands such as FILELIST should not be executed via REXEC.
- 4. The combined length of all REXEC operands, including spaces, is limited to 255 bytes. Therefore, the number and length of the operands that precede the command operand (such as -d or -l userid) will further restrict the length of a command that can be sent to a foreign host.
 - Commands submitted to remote VM hosts are further limited, because of REXECD processing constraints. Commands that are processed anonymously by an RXAGENT maachine are limited to 227 bytes; those processed by a CMS user's own virtual machine are limited to 189 bytes.

Using RSH commands with REXECD

TCP/IP provides limited support for rsh, remsh, and similar commands. When such commands are issued against a VM host, a command to be executed on the remote VM host must be supplied. There is no support for the processing of interactive commands.

When an rsh command is received, it is processed by the VM REXECD server in essentially the same manner as an REXEC command. The same user ID and password verification mechanisms used for REXEC commands are used for rsh-supplied commands as well. An attempt is made to log on to the VM user ID that is identical to the local login id used to issue the rsh command; the value used is usually that which is maintained in the LOGNAME variable on Unix-based systems. The only exception to this is when a special password value of *guest has been provided.

Because VM requires a password to be supplied when logging on to a user, a password must be available. The rsh and remsh commands however have no inherent provision for doing so. Moreover, there is no rhosts (or similar) file maintained by the VM host for remote user authentication purposes. To bypass these limitations, the -/ flag of the rsh command is used to provide the VM logon password as part of the rsh command. For example, when the following rsh command is issued from an AIX system by the user wellsjr:

rsh qd3vm0 -1 blues2me q cmslevel

the VM user ID WELLSJR will be logged on using the password BLUES2ME. The QUERY CMSLEVEL command is then executed on the host GD3VM0.

On other platforms, the rsh command may need to be specified using different flags. For example, from an OS/2 client, the above rsh command needs to be specified with both the -l and the -u flags:

rsh gd3vm0 -u welljr -l blues2me q cmslevel

If a user has no user ID on a remote VM system, rsh commands can still be issued, though in an anonymous manner. In this case, the supplied command will be processed by an REXEC agent virtual machine. To have an rsh command processed in this way, you need to specify a special value of *guest via the -/ flag as shown below:

rsh gd3vm0 -1 *guest q cmslevel

Using REXEC

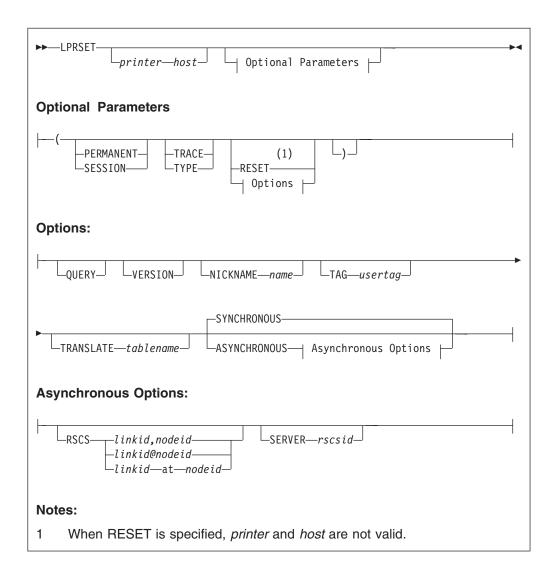

Chapter 10. Using Remote Printing

TCP/IP provides client and server support for remote printing. The remote printing application allows you to spool files remotely to a line printer daemon (LPD). The line printer client (LPR) sends the spooled file to a specified print server host and to a specified printer.

The following commands are described in this chapter:

- LPRSET
- LPR
- LPQ
- LPRM

LPRSET Command

Purpose

Use the LPRSET command to define default printer and host values for the LPQ, LPR, and LPRM remote printing commands, or to set additional defaults for the LPR command.

© Copyright IBM Corp. 1987, 2011 307

Note: You can use the shortest available unique character sequence as a minimum abbreviation for an LPRSET parameter.

Operands

printer

Specifies the name of the printer to be used for the LPQ, LPR, and LPRM remote printing commands; printer is restricted to 255 characters.

host

Specifies the name or internet address (in dotted-decimal form) of the printer host to be used for the LPQ, LPR, and LPRM remote printing commands; host is restricted to 255 characters.

ASYNCHRONOUS

This option will send LPR requests to another server (RSCS) for later printing. As a result, this causes LPR operations to be deferred. When this option is in effect, subsequent LPR commands cause data to be queued to an intermediate print service machine (an RSCS server). As a result, interaction with a remote print daemon is handled by this service machine and ensures your file will be processed with no further action required by you. Messages and status information associated with a deferred transaction are returned to your console.

NICKNAME name

Specifies a nickname (defined in your CMS NAMES file) that identifies the printer and host to which files are directed for printing. Printer-specific options can also be defined using such an entry. See LPR Usage Note 3 on page 319 and "Usage Notes" on page 318 for more information about specifying values through nickname definitions and how nicknames and values can be used.

PERMANENT

Causes values to be maintained on a permanent basis (across separate LOGONs). By default, values are maintained only for the duration of the current initialization (IPL) of CMS. All values are affected when this option is used.

OUERY

Displays the current settings.

RESET

Causes all values to be re-initialized to null values. When this option is used in conjunction with the PERMANENT option, all values are reinitialized; when used with the SESSION option, only session-related values are reinitialized. If neither PERMANENT or SESSION is specified only current, in-storage values are affected.

For information about how to reset individual values, see Usage Note 2.

RSCS linkid, nodeid

RSCS linkid@nodeid

RSCS linkid AT nodeid

Identifies the RSCS link that provides a connection to a target print daemon or device, where:

- linkid is the one- to eight-character link identifier of the RSCS link that provides the connection to the chosen print daemon or device.
- nodeid is the one- to eight-character node name of the remote VM system that provides the connection to a target print daemon or device.

When specific link and node values are not defined, "LPR" is used as the default link identifier (*linkid*) for non-PostScript files, while "LPRP" is used for PostScript files; the local node (as returned by the CMS IDENTIFY command) is used for *nodeid*.

Note: This option applies only to asynchronous LPR processing.

SERVER rscsid

Identifies an RSCS service virtual machine to which print data is to be spooled. By default, the RSCS server reported by the CMS IDENTIFY command is used.

Note: This option applies only to asynchronous LPR processing.

SESSION

Causes values to be defined for a session (generally, from LOGON to LOGOFF). By default, values are maintained only for the duration of the current initialization (IPL) of CMS. All values are affected when this option is used.

SYNCHRONOUS

Causes LPR operations to be processed immediately; this is the default. When this option is in effect, subsequent LPR commands are processed as immediate operations through the TCP/IP server and the chosen print daemon. Delays in command execution (caused by network congestion, for example) may be apparent, because synchronous processing is dependent upon the interaction between the TCP/IP service machine and the specified print daemon.

TAG usertag

Identifies a specific NAMES file tag from which printer and host destination information is to be retrieved. If such a tag is not identified, an attempt is made to retrieve printer and host values from a set of default tag definitions. For more information about how destination information is retrieved for a nickname entry, see LPR Usage Note 4 on page 319.

TRACE

Displays detailed command progress information.

TRANSLATE tablename

Identifies the file name of a translation table to be used for EBCDIC to ASCII data translation. See *TCP/IP Planning and Customization* for more information on creating and loading translation tables, as well as the "Using Translation Tables" chapter in this publication.

TYPE

Displays abbreviated command progress information.

VERSION

Displays program version information.

Usage Notes

 Parameters established using the LPRSET command are maintained using CMS global variables. This allows these values to be shared by the various TCP/IP remote printing commands and allows values to be retained (either temporarily or permanently) for subsequent use. For more information about CMS global variables, see the z/VM: CMS Commands and Utilities Reference.

Note: The *printer* and *host* values are recognized by all of the line printer commands; values set using options (such as NICKNAME and TAG) are recognized only by the LPR command.

- 2. For operands other than *printer* and *host*, values can be reinitialized on an individual basis. For such operands, a value specified as a single period (.) will cause the current value to be nullified. For the RSCS and SERVER options, this will cause an appropriate system default to be reinstated.
- 3. Parameters established with the LPRSET command can be overridden by using appropriate operands when LPQ, LPR and LPRM commands are issued.
- 4. Printer names may be case-sensitive, though this depends upon the host to which remote printing commands are directed. In many cases, the printer name you provide must match the printer definition used by the remote host. For example, on UNIX-like systems, prt1 and PRT1 can refer to different printers.
- 5. In most environments, the system defaults for asynchronous processing (that is, the default SERVER and RSCS linkid and nodeid values) should provide satisfactory results. Before setting non-default values for asynchronous processing, consult your RSCS operations support staff.

Examples

To set the default printer and host as printer LPT01 on host prtsrv, enter the following command:

```
lprset LPTQ1 prtsrv
```

The default values established with this LPRSET command will be lost if CMS is reinitialized (that is, re-IPL'd). To make this selection permanent, use the following command:

```
lprset LPTQ1 prtsrv (perm
```

• To display the version of LPRSET currently in use, enter this command:

 To establish a nickname default so that values defined for the NAMES file entry SIMPLPRT will be used when LPR commands are processed, issue the following command:

```
lprset (nick simplprt
```

· To set a nickname default so that values defined in your CMS NAMES file by the CMPLXPRT nickname will be used when LPR commands are processed, issue the following command:

```
lprset (nick cmplxprt
```

To ensure specific printer and host values defined by the :TSTPRINT tag entry (associated with the CMPLXPRT nickname) are used for LPR commands, use the TAG option in addition to NICKNAME option, as follows:

```
lprset (nick cmplxprt tag tstprint
```

 To reset in-storage nickname and tag values so they will not be used for subsequent LPR commands, but still maintain current values for other parameters, use the following command:

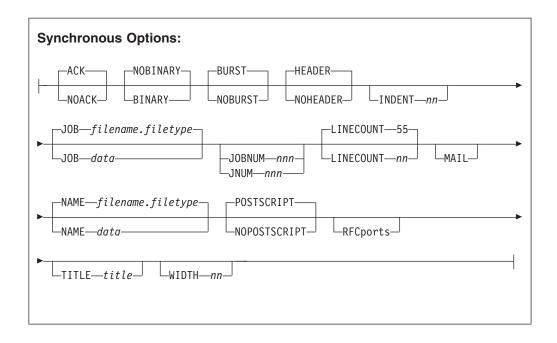

```
lprset (nick . tag .
```

 To establish the default translation table name as MYXLATBL, enter the following command:

```
lprset (translate myxlatbl
```

LPR Command

Purpose

Use the LPR command to print files on remote printers.

Note: With some exceptions, you can use the shortest available unique character sequence as a minimum abbreviation for an LPR parameter. The exceptions are:

- P and PR are presumed to mean PRINTER
- H is presumed to mean HOST

Operands- Synchronous and Asynchronous

```
filename
    Specifies the name of the file to print.
    Specifies the type of the file to print.
```

filemode Specifies the mode of the file to print. If filemode is specified as an asterisk (*), the first file found in the CMS search order is used. If filemode is omitted, a file mode of "A" is assumed. If a CMS file mode number is not specified, the default

Synchronous operations cannot be used to process files that have a file mode number of 3 or 4. For asynchronous operations, this restriction applies to only file mode number 3 files. See the *z/VM: CMS User's Guide* for information about file mode numbers and how they are used by CMS.

ASYNCHRONOUS

This option will send LPR requests to another server (RSCS) for later printing. As a result, this causes LPR operations to be deferred. When this option is in effect, subsequent LPR commands cause data to be queued to an intermediate print service machine (an RSCS server). As a result, interaction with a remote print daemon is handled by this service machine and ensures your file will be processed with no further action required by you. Messages and status information associated with a deferred transaction are returned to your console.

CC Causes the remote system to interpret the first character of each data line as ASA carriage control; this is the default for files with a file type of either LISTING or LIST3800.

NOCC

Prevents the remote system from interpreting the first character of each data line as ASA carriage control; this is the default for all files *except* those with a file type of either LISTING or LIST3800.

COPIES nn

Specifies the number of copies to be printed; the default is 1. Note that some remote servers may not recognize or honor requests to produce multiple copies of a file. For asynchronous operations, a maximum of 255 can be specified.

CLASS data

Specifies the print job classification to be used by the remote system when the print file is processed. By default, the host name (combined with the domain name, if available) defined in the TCPIP DATA file is supplied as *data* for synchronous operations; "A" is the asynchronous default.

For synchronous operations, *data* is restricted to 31 characters. For print requests directed to a UNIX-like lpd, *data* will be printed on the burst (or, banner) page. For requests directed to a VM LPD server, *data* may be used as a spool file class.

For asynchronous operations, *data* specifies a spool file class. For such operations, *data* must be a single alphanumeric value (A-Z or 0-9) or an asterisk (*).

FILTER code

Specifies the type of processing to be performed against print file data by the remote system. The filter *code* value must be a single letter. Both uppercase and lowercase letters are accepted, but uppercase letters are converted to lowercase since only lowercase filter values are recognized by remote print daemons.

Filter codes provide carriage control. When a filter code is specified, LPR changes several of its conventions. When a filter code of \mathbf{f} , \mathbf{l} , or \mathbf{r} , is specified, LPR does not paginate the processed file. Instead, it sends the data within the file as "plain" lines. The list that follows provides a description of available filter codes:

Code	Description
f	Print data as a sequence of lines
1	Print, passing through all control characters

p	Print with	pagination
D	I IIIIL VVILII	paqiilatiori

r Print, and interpret the first column as FORTRAN (ASA) carriage control. The following characters are interpreted as indicated:

Character	Printing Action
Space	Start a new line of output
+	Overprint this line on the previously printed line
-	Produce two blank lines, then begin a new line of output
0	Produce one blank line, then begin a new line of output
1	Start new page, and begin printing at first line

For filter codes c, d, g, n, t, or v, LPR transmits the data as a byte stream (as though the BINARY option has been specified).

HOST host

AT host

0 host

Specifies the name or internet address (in dotted-decimal form) of the printer host where the file is to be printed; host is restricted to 255 characters. H is accepted as the minimum abbreviation for the HOST keyword.

LANDSCAPE

For synchronous operations, this option causes PostScript information to be added to the print file so that it will be printed by the remote system in landscape (rotated) format — provided the remote printer can process PostScript.

For asynchronous operations, this option causes a form name of "LA" to be used when the file is processed. When used in this context, this option will override any FORM value specified as part of a CMS NAMES file entry.

NICKNAME name

Specifies a nickname (defined in your CMS NAMES file) that identifies the printer and host to which files are directed for printing. Printer-specific options can also be defined using such an entry. See Usage Note 3 on page 319 and "Usage Notes" on page 318 for more information about specifying values through nickname definitions and how nicknames and values can be used.

PRINTER printer

Specifies the name of the printer on which the file is to be printed; printer is restricted to 255 characters. P is accepted as the minimum abbreviation for this option.

SYNCHRONOUS

Causes LPR operations to be processed immediately; this is the default. When this option is in effect, subsequent LPR commands are processed as immediate operations through the TCP/IP server and the chosen print daemon. Delays in command execution (caused by network congestion, for example) may be apparent, because synchronous processing is dependent upon the interaction between the TCP/IP service machine and the specified print daemon.

TAG usertag

Identifies a specific NAMES file tag from which printer and host destination information is to be retrieved. If such a tag is not identified, an attempt is made

to retrieve printer and host values from a set of default tag definitions. For more information about how destination information is retrieved for a nickname entry, see Usage Note 4.

TRACE

Displays detailed command progress information. For synchronous operations, information about the interaction with the remote printer is also displayed.

TRANSLATE tablename

Identifies the file name of a translation table file to be used for EBCDIC to ASCII data translation; the file type for this file must be TCPXLBIN. The first tablename TCPXLBIN file found in the CMS search order is used. If this parameter is not specified, a default translation table is used (if one exists), which is defined by either a CMS NAMES file nickname entry or a CMS global variable; if neither exist, data translation is then performed as follows:

- For synchronous processing, LPR searches for and uses the LPR TCPXLBIN file first, and then the STANDARD TCPXLBIN file. If neither is found, an internal translation table is used.
- For asynchronous processing, default data translation processing is performed by the RSCS server to which files are directed, based on the configuration of that server.

For more information about creating and loading translation tables, see *z/VM: TCP/IP Planning and Customization*, SC24-6238.

If your use of LPR requires specific translations to be performed, see Chapter 14, "Using Translation Tables," on page 409.

TYPE

Displays abbreviated command progress information.

VERSION

Displays program version information.

Operands - Synchronous

ACK

Requests the remote printer host to send an acknowledgment to the LPR command when the connection to that host is closed; this is the default.

NOACK

Requests the remote printer host to not return a receipt acknowledgment to the LPR command. This option was previously required if the receiving system was AIX; however, its use is no longer necessary.

BINARY

Causes print data to be sent without translation and without any indication of record boundaries. For example, use this option if the file is already in ASCII. At times a filter may also be required to achieve appropriate results; see the description of the FILTER operand on page 313 for more information about filter use. The BINARY option implies that the file to be printed is not PostScript.

NOBINARY

Causes print data to be converted from EBCDIC to ASCII when it is sent to the remote system; this is the default.

BURST

Causes a burst page to be printed on the remote printer; this is the default. This option controls whether burst (or, banner) page information is sent to the server.

If a VM LPD server does not receive burst page information, it provides the best information available to a spool device, as CMS does not have an option to omit the burst page for print files.

NOBURST

Prevents a burst page from being printed on the remote printer.

Causes a page header to be inserted by the LPR client at the beginning of every printed page — if the NOCC and NOBINARY options are in effect. HEADER is the default. To instead cause the remote printer to insert page headers, use the FILTER **p** and NOHEADER options.

NOHEADER

Prevents the LPR client from inserting page headers.

INDENT nn

Specifies the number of columns the remote printer indents output when the FILTER **f** or FILTER **l** options are in effect.

JOB data

Specifies a print job description, name, or other job information to be used by the remote system; a maximum of 99 characters can be specified. By default, the string "filename.filetype" is used for data.

For a UNIX-like lpd, this option causes job information to be printed on the banner page; for a VM LPD server, it can be used to pass additional job information for use by that LPD server.

JOBNUM nnn

JNUM nnn

Specifies the job number used to construct the file names of protocol-specific files sent to the remote print server. The provided value must be a three-digit, numeric string. If a specific string is not specified using this option, a three-digit random number is used.

This option can be used to reduce the likelihood of problems caused by duplicate file names when many LPR jobs are initiated. To be effective toward this end, the files to be printed must be processed by a single VM user ID; as LPR commands are issued for each file, sequential job numbers should be specified using the JOBNUM option. However, collisions with jobs run by other virtual machines are still possible; a collision occurs when one of the print jobs fails.

LINECOUNT nn

Specifies the number of lines to be printed before a new heading is printed; the default is 55. This parameter has meaning only for files for which the CC option is not in effect (either explicitly or implicitly). A value of zero (0) can be used to prevent page ejects and page headers from being inserted in the print file.

MAIL

Causes mail to be sent to you when the printing operation ends that informs you about the success or failure of the print job. This option may not recognized by all remote printing servers.

NAME data

Specifies job name information to be provided by the remote system in response to a remote printer query (that is, an LPQ command). The supplied data is restricted to 131 characters. By default, the string "filename.filetype" is used for data. This option is not recognized by all remote printing servers.

POSTSCRIPT

Causes header information to be added to the print file so that it will be recognized as PostScript by the remote printer.

NOPOSTSCRIPT

Prevents a file from being recognized as PostScript.

Enforces the use of RFC-compliant printer source ports when print requests are processed. Some printer host machines require the source port to be within either the 721-731 port range, or the alternative range of all "well-known" ports (1-1023).

Note: By default, TCP/IP for z/VM restricts general use of well-known ports. To use the RFCPORTS operand, you may need to contact your local TCP/IP administrator to obtain authorization to use such ports.

TITLE title

Specifies the title assigned to a file printed with the FILTER **p** option. A maximum of 79 characters can be specified for title.

WIDTH nn

Specifies the line width to be used for a file printed with the FILTER f or FILTER I option. The value you provide may be decreased by the remote printer host.

Operands - Asynchronous

FORM formname

Specifies a spool file form name (used by RSCS) to control how data is printed at the destination printer. For PostScript data, formname can be specified as a character string of the form OrFnFsLs, to specify a default orientation, font name, font size, and additional leading size to be used by the destination printer. For *OrFnFsLs* the following can be specified:

-		_	
Or	File O	File Orientation	
	РО	Portrait (default)	
	LA	Landscape	
Fn	Font		
	СВ	Courier Bold	
	CI	Courier Oblique	
	CP	Courier (default)	
	CX	Courier BoldOblique	
	НВ	Helvetica Bold	
	HP	Helvetica	
	HI	Helvetica Oblique	
	НХ	Helvetica BoldOblique	
	SP	Symbol	
	TB	Times Bold	
	TI	Times Italic	
	TP	Times Roman	
	TX	Times BoldItalic	

- Fs Font sizes, 04-99. The default is 11 for portrait (PO) and 10 for landscape (LA).
- Ls Additional leading size, 0.0-9.9 added to font size to give leading, specified as 00 thru 99. The portrait (PO) default is 09; that for landscape (LA) is 12.

Notes:

- 1. The font specified via *OrFnFsLs* must be installed and used by the destination printer for correct results to be achieved.
- 2. For ASCII PostScript files, the default form name used is "P+ASCII"; for EBCDIC PostScript files, the default is "P+SCRIPT". There is no default for non-PostScript files.
- 3. FORM cannot be used with the LANDSCAPE option.
- 4. The spool file form name (formname) is translated to uppercase prior to use.

PREFIX data

Specifies a data string to be passed to the remote printer device by the RSCS server; up to 500 characters can be specified. Prefix data is translated to uppercase and is inserted at the beginning of the data file by RSCS, and might be used to affect printer settings; for example, to select a paper tray.

RSCS linkid.nodeid

RSCS linkid@nodeid

RSCS linkid AT nodeid

Identifies the RSCS link that provides a connection to a target print daemon or device, where:

- linkid is the one- to eight-character link identifier of the RSCS link that provides the connection to the chosen print daemon or device.
- nodeid is the one- to eight-character node name of the remote VM system that provides the connection to a target chosen print daemon or device.

When specific link and node values are not defined, "LPR" is used as the default link identifier (linkid) for non-PostScript files, while "LPRP" is used for PostScript files; the local node (as returned by the CMS IDENTIFY command) is used for nodeid.

SERVER rscsid

Identifies an RSCS service virtual machine to which print data is to be spooled. By default, the RSCS server reported by the CMS IDENTIFY command is used.

SUFFIX data

Specifies a data string to be passed to the remote printer device by the RSCS server; up to 500 characters can be specified. Suffix data is translated to uppercase and is inserted at the end of the data file by RSCS. A suffix data string might be used to affect printer settings; for example, to reset the printer state.

Usage Notes

- When LPR commands are issued and certain operands are omitted, LPR will attempt to use values defined by CMS global variables for the TCPIP group. Operands to which this applies are:
 - printer and host
 - RSCS linkid and nodeid
 - Mode of operation (SYNCHRONOUS or ASYNCHRONOUS)
 - NICKNAME name and TAG usertag

TRANSLATE tablename

Values for these operands can be established and changed using the LPRSET command.

- 2. LPR command operands are selected, in order, from the following sources:
 - a. the LPR command itself
 - b. CMS NAMES file entries
 - c. CMS global variables

Values from different sources may be combined and used for a single LPR command.

3. CMS NAMES file tags recognized by the LPR command and the options to which they correspond follow:

Tag	Corresponding Option(s)
:CSADDR	PRINTER and HOST
:FILTER	FILTER
:LPRADDR	PRINTER and HOST
:NODE	HOST
:TCPADDR	PRINTER and HOST
:USERID	PRINTER
:TRANSLATE	TRANSLATE

:LINKID RSCS
:NODEID RSCS
:PREFIX PREFIX
:SERVER SERVER
:SUFFIX SUFFIX
:FORM FORM

Tags listed in the first group are supported for both synchronous and asynchronous operations; those listed in the second group are applicable only to asynchronous use. For all tags, values should be specified in the same manner as for their corresponding options.

- 4. Print destination information (that is, the combination of a printer and host name) is obtained for NAMES file entries, in order, from the following tags:
 - a. a user-specified tag, as identified by the TAG option
 - b. an "address" tag, if the TAG option is not specified. Address tags are checked, when present, in this order:
 - 1) :LPRADDR
 - 2) :TCPADDR
 - 3) :CSADDR
 - c. the :USERID and :NODE tags, if no information is defined by any of the previously listed tags. In the context of using TCP/IP remote printing commands, these tags are presumed to provide printer and host names, respectively, instead of conventional user ID and node ID information.

Printer and host values for user-specific tags and the address tags previously listed can be specified using one of these formats:

- · linkid nodeid
- linkid,nodeid
- linkid@nodeid
- linkid AT nodeid
- 5. Printer names may be case-sensitive, though this depends upon the host to which remote printing commands are directed. In many cases, the printer

- name you provide must match the printer definition used by the remote host. For example, on UNIX-like systems, prt1 and PRT1 can refer to different printers.
- For certain operands, values can be specified as quoted strings, so that the content between the string delimiters — either single (') or double (") quotation marks — is preserved. Operands for which quoted values are accepted are: PRINTER, HOST, CLASS, JOB, NAME, and TITLE.
- 7. The LPR command can be used to print PostScript documents. When a file is processed by LPR, the file is checked to determine whether it is a PostScript file. If it is, additional checks are performed (for synchronous operations only) to verify that compatible options have been provided. If you want to override these checks when you print a PostScript file, use the NOPOSTSCRIPT option.
 - Remote hosts usually examine the first few characters of a file to determine if that file is PostScript; this is usually indicated by the presence of the character string "%!" in the first line of the file. For synchronous operations, the POSTSCRIPT option can be used to ensure a file is recognized as PostScript.
- 8. Carriage control is interpreted line by line. A file can mix ASA and machine carriage control. Interpretation is done by converting the controls to the appropriate ASCII sequences before the file is sent to the remote system. Lines that have invalid carriage control are not printed.
 - When a file is printed without carriage control, LPR adds a heading line to each page of output that shows the name of the printed file, the name of the system on which the LPR command originated, and a page number. You can specify the number of lines per page (not counting the three heading lines) with the LINECOUNT option.
- 9. The logical record length (LRECL) of files that can be processed is restricted for both synchronous and asynchronous operations.
 - For synchronous operations, LPR processes files using OS file routines. Thus for fixed-format files, the maximum LRECL is 32760; for variable-format files, the maximum LRECL is 32756.
 - For asynchronous operations, files are processed using RSCS services. For non-PostScript (or, "flat") files, only those with an LRECL of 1280 or less can be processed in this manner; there is no restriction for PostScript files.
- 10. Some LPDs require the FILTER I option in addition to the BINARY option to ensure the data file is not changed during BINARY transfers. With such implementations, the receiving LPD converts the incoming line-end character of X'0A' to two characters, X'0D0A', if the FILTER I option is omitted. (This situation has been observed when files are processed by an LPD on some DOS and OS/2 based systems; however, this behavior may not occur in all such environments.)
- 11. Remote printer hosts determine whether sufficient space is available to receive a given file before it is processed. If sufficient space is not available, the file is discarded and the connection is terminated with a message that identifies this
- 12. In most environments, the system defaults for asynchronous processing (that is, the default SERVER and RSCS linkid and nodeid values) should provide satisfactory results. Before setting non-default values for asynchronous processing, consult your RSCS operations support staff.
- 13. For most operations, LPR issues messages only if errors are encountered. To monitor the progress of an LPR command or to obtain information for diagnostic purposes, use the TYPE or TRACE options.

Examples

Examples for General Printing

 To print the file TEST LISTING on printer LPTQ1 on the host prtsrv, enter the following command:

```
lpr test listing (printer LPTQ1 host prtsrv
```

Because the file type is LISTING, the first character of each line is interpreted as carriage control. To prevent this, use the NOCC option as shown in the following command:

```
lpr test listing (printer LPTQ1 at prtsrv nocc
```

 If an LPRSET command was previously issued to set the printer and host defaults to LPTQ1 and prtsrv (for example, LPRSET LPTQ1 prtsrv), the following command has the same effect as the second command shown in the previous LPR example:

```
lpr test listing (nocc
```

Because the lines in a listing file may be wider than a page, you may want to print the listing in "landscape" mode. The next example includes the LANDSCAPE option to print the TEST LISTING file in this mode:

```
lpr test listing (landscape
```

• To print a source program (CSPROG1 FORTRAN) so that 57 lines are printed per page, enter the following command:

```
1pr csprog1 fortran (linecount 57
```

 To print a file and have it processed by an RSCS server named RSCSTST, enter the following command:

```
lpr demotest schedule (async server rscstst printer prt01@prtsys1 In the above example, the file DEMOTEST SCHEDULE is processed by the RSCSTST server, and sent to the printer prt01 defined for the local host PRTSYS1.
```

• To print a file and have data translation performed based on the translation table named MYXLATBL, enter the following command:

```
1pr trantest datafile (printer LPTQ1 host prtsrv translate myxlatbl In the above example, file TRANTEST DATAFILE is sent to the printer LPTQ1 defined for the host prtsrv; the MYXLATBL TCPXLBIN table file is used to perform data translation.
```

Examples for Prnting Using Nicknames

The examples that follow illustrate some typical NAMES file entries that might be constructed for use with the LPRSET or LPR commands. For detailed information about defining and using nicknames, see Usage Notes 2, 3 and 4.

 The following example shows a simple NAMES file entry that defines only a printer and host name.

```
:nick.SIMPLPRT :userid.lpt1 :node.oddjob.endicott.ibm.com
The command:
lpr profile exec (nick simplprt
```

will print file PROFILE EXEC on the oddjob.endicott.ibm.com host printer lpt1.

 In the next example, additional tag entries are included as part of a nickname entry.

```
:nick.ADVPRT1 :userid.nullprt :node.nowhere.endicott.ibm.com
    :myprint.prt1@paradox.endicott.ibm.com
    :lpraddr.LPT2@monolith.endicott.ibm.com
```

With the above entry, two different destinations can be used for printing, based on the options provided with an LPR command.

When following command is issued:

```
1pr deptg79 report (nick advprt1
```

the printer and host name defined by the :LPRADDR tag are used (LPT2 and monolith.endicott.ibm.com). The :LPRADDR tag definition overrides the printer and host information defined by the :USERID and :NODE tags. This would also occur if LPT2 and monolith.endicott.ibm.com were defined using either a :TCPADDR or :CSADDR tag. For more information about how printer and host information is obtained for nickname entries, see Usage Note 4.

If instead, the following command is used:

```
1pr deptg79 report (nick advprt1 tag myprint
```

the printer and host name defined by the :MYPRINT tag are used (prt1 and paradox.endicott.ibm.com). Again, any printer and host information defined by the :USERID and :NODE tags is ignored because the TAG option is specified.

For asynchronous processing of the DEPTG79 REPORT file, the following command could be used:

```
lpr deptg79 report (asynch nick advprt1
```

For this command, the DEPTG79 REPORT file would first be passed to the RSCS server of the local node (the default), and then would be sent to the prt1 printer of the paradox.endicott.ibm.com host. Because no RSCS link identifier was provided, a default link of either LPR or LPRP would be used.

· This last example illustrates how various tags might be defined and then used for synchronous and asynchronous remote printing requests.

```
:nick.CMPLXPRT
    :tstprint.lpt0@rocketman.endicott.ibm.com
    :tcpaddr.PRTQ1@monolith.endicott.ibm.com
    :server.rscstst
    :linkid.lprtst
    :nodeid.GDLVME
* Prefix string to turn duplexing OFF; the PostScript command
* string is: %!PS-AdobeCRLF statusdict begin false setduplexmode
* This string should be one contiguous line; it spans multiple
* lines here only to meet formatting requirements.
    :prefix.252150532D41646F62650D0A73746174757364696374206265676
            96E2066616C7365207365746475706C65786D6F646520656E640D0A
 * Suffix string to turn duplexing (back) ON; the PostScript command
 * string is: %!PS-AdobeCRLF statusdict begin true setduplexmode
 * This string should be one contiguous line; it spans multiple
 * lines here only to meet formatting requirements.
    :suffix.252150532D41646F62650D0A737461747573646963742062
            6567696E20074727565207365746475706C65786D6F646520656E640D0A
    :translate.MYXLATBL
```

If the nickname CMPLXPRT is specified in conjunction with the SYNCHRONOUS option on an LPR command, only values defined by the following tags will be used:

- :TSTPRINT is used if TAG TSTPRINT is specified
- :TCPADDR is used if the TAG option is not specified.
- TRANSLATE is used if the TRANSLATE option is not specified.

If this same nickname is specified, but with the ASYNCHRONOUS option:

- :TSTPRINT is used if TAG TSTPRINT is specified
- :TCPADDR is used if the TAG option is not specified
- :TRANSLATE is used if the TRANSLATE option is not specified.

In addition, the values defined by all of the remaining tags shown will be used for processing — assuming no options are used that override them. For example, if the following command is issued:

lpr weather report (asynch nick cmplxprt tag tstprint

the WEATHER REPORT file would first be passed to the RSCSTST RSCS server, which then sends it to the RSCS node GDLVME. From GDLVME it is printed on printer 1pt0 at host rocketman.endicott.ibm.com, using the RSCS link LPRTST.

Because the :PREFIX and :SUFFIX tags define values, this data will also be passed to the RSCSTST server. Also, since the TRANSLATE option was not specified, data translation will be performed using the translation table named MYXLATBL, as defined by the :TRANSLATE tag.

If the TAG tstprint option were omitted in the above command, the destination printer and host would instead be PRTQ1 and monolith.endicott.ibm.com.

Controlling LPSERVE from other Systems

When you use the LPR command to communicate with LPSERVE, you can provide additional information for LOCAL and RSCS services. This can be done by passing the desired information with the client LPR command options.

For example, the VM LPR CLASS option or the UNIX lpr -C option is used by lpd in UNIX to specify a classification that is printed on the burst page. The VM CLASS or UNIX -C option, when sent to a VM LPD server, is used to alter the VM spooled file's class.

The VM LPR JOB option or the UNIX lpr -J option is used by lpd in UNIX to specify what is printed in this field of the burst page. The VM JOB or UNIX -J option, when used with a VM LPD server, specifies additional information to the VM server such as the distribution code, priority, password, or an alternative user ID or destination. Within the JOB or -J option, additional options can be used to specify these additional job parameters.

The additional JOB options are:

- · For LOCAL services: FOR, PASS, DEST, and DIST
- For RSCS services: FOR, PASS, DEST, IDENTIFIER, PRIORITY, and OTHERS

If you use more than one option, separate each by a comma with no intervening spaces between options. If the OTHERS option is used, it must be the last option. You can enter keywords on the LPR command line in any combination of upper and lower case.

For both LOCAL and RSCS services, you can use either of the following JOB options.

Option	Description
FOR=user_id	Specifies a user ID other than the sending user ID for which the job
	is to be spooled. The default is the sender's user ID.

PASS=password

Specifies the password for *user_id*. The default is no password. This option is required only if the RACF option has been specified for the designated service.

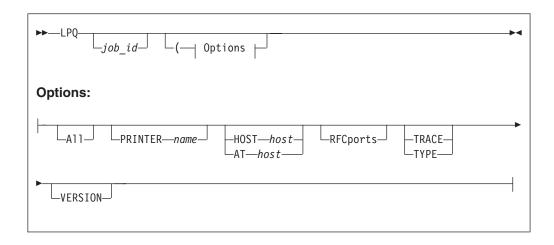

For LOCAL services, you can use the following additional JOB options.

Option	Description
DEST=name	Specifies the destination printer name or destination punch name for the job. The default is DEST=OFF.
DIST=code	Specifies the output distribution code. The default is DIST=OFF.

For RSCS services, you can also give any of the following: the destination node ID, user ID, and priority. These options can also be given in any order (except the OTHERS keyword, which must be last) and must be separated by commas.

Option	Description
DEST=destination	Specifies a RSCS destination node. The default is the node on which LPSERVE is running.
IDENTIFIER=operand	Specifies the second TAG operand, which can be SYSTEM, JOB, a virtual machine user ID, or a workstation node ID. The default is SYSTEM.
OTHERS=option_name	Specifies additional options for the destination RSCS. This option applies only if the specified service has the TAG option specified and is used to supply additional TAG information. This can, for example, be used to designate forms (for an MVS Network Job Entry (NJE) system) or controls for an IBM 3800 printer. The rest of the job data is used to tag the spooled file. The default is no additional options.
PRIORITY=nn	Specifies the transmission priority. The default is 50.

LPQ Command

Purpose

Use the LPQ command to list the printer queue on a remote printer.

Note: You can use the shortest unique sequence as the minimum abbreviation for an LPQ parameter.

Operands

job id

Specifies either a user ID (must not start with a number), or a job number on the remote printer queue. If you do not specify *job_id* with the LPQ command, all jobs in the remote printer queue are listed.

A11

Displays for all printers a report that shows print job information.

PRINTER name

Specifies the name of the printer for which printer queue information is to be obtained.

HOST host

AT host

Specifies the name or internet address of the printer host. AT is accepted as a synonym for HOST.

RFCports

Enforces the use of RFC-compliant printer source ports when printer queues are queried. Some printer host machines require the source port to be within either the 721-731 port range, or the alternative range of all "well-known" ports (1-1023).

Note: By default, TCP/IP for z/VM restricts general use of well-known ports. To use the RFCPORTS operand, you may need to contact your local TCP/IP administrator to obtain authorization to use such ports.

TRACE

Displays detailed information about the interaction with the remote printer.

TYPE

Displays the progress of the command.

VERSION

Displays the version of the program.

Usage Notes

- 1. The LPQ command allows you to query the printer queues on remote systems that support this activity. The VM remote printing server implementation (LPD) does not support such client queries because, typically, the server does not hold print files in its internal queue. Instead, they are almost always spooled immediately to the operating system or, another virtual machine (such as RSCS) for printing. Thus, a window of time for which jobs can be queried while they are in the VM LPD print queue is almost nonexistent.
- 2. If a printer or host name is not provided on the LPQ command, LPQ will use the GLOBALV variables PRINTER and PRTHOST, respectively, from the TCPIP group. These variables can be set by a program or by the LPRSET command in order to provide defaults for these values.

- 3. Printer names can be case sensitive. The printer you provide must match the remote host's definition for that printer. For example, on UNIX systems, psnt and PSNT can refer to different printers.
- 4. A user name, when provided as a job_id, can be case sensitive. For example, smith and SMITH may refer to different users on the same host.
- 5. Some systems will not respond with job information, if you use a job number for a job that was not produced by the querying system.

Examples

 To query the printer psnt on host system test1, enter the following command: LPQ (PRINTER psnt HOST test1

This command displays a short listing of the jobs that are queued for the psnt printer.

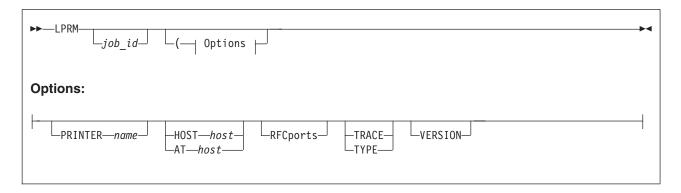

• If the LPRSET command was previously issued, (LPRSET psnt test1), the following LPQ command has the same effect as issuing the command in the first LPQ example:

 To get a long listing, enter the following command: LPO (PRINTER psnt HOST test1 ALL

This command prints a long listing of the jobs queued, including the name of the host that created the jobs.

- To list the jobs for a user named smith, enter the following command: LPQ smith (PRINTER psnt HOST test1
- If you want only the information about job 123, enter the following command: LPQ 123 (PRINTER psnt HOST test1

LPRM Command

Purpose

Use the LPRM command to remove a job from the printer queue on a remote host.

Note: You can use the shortest unique sequence as the minimum abbreviation for an LPRM parameter.

Operands

job id

Specifies either a user ID (must not start with a digit, or a job number in the remote printer queue. If you do not specify *job_id* with the LPRM command, your currently active job is removed.

PRINTER name

Specifies the name of the printer with which the job is associated.

HOST host

AT host

Specifies the name or internet address of the printer's host. AT is accepted as a synonym for HOST.

RFCports

Enforces the use of RFC-compliant printer source ports when a job is removed from a printer queue. Some printer host machines require the source port to be within either the 721-731 port range, or the alternative range of all "well-known" ports (1-1023).

Note: By default, TCP/IP for z/VM restricts general use of well-known ports. To use the RFCPORTS operand, you may need to contact your local TCP/IP administrator to obtain authorization to use such ports.

TRACE

Turns on the trace details for the interaction with the remote printer.

TYPE

Displays the progress of the command.

VERSION

Displays the version of the program.

Usage Notes

- 1. The LPRM command allows you to remove jobs from printer queues on remote systems that support this capability. The VM remote printing implementation (LPD) does not support such client requests because the server does not hold print files in its internal queue. Instead, jobs are usually spooled immediately to the operating system or to another virtual machine (such as RSCS) for printing. Thus, a window of time for which jobs can be removed while they are in the VM LPD print queue is almost nonexistent.
- If a printer or host name is not provided on the LPRM command, LPRM will use the GLOBALV variables PRINTER and PRTHOST, respectively, from the TCPIP group. These variables can be set by a program or by the LPRSET command in order to provide defaults for these values.
- 3. Removing the currently active job can be sensitive to timing. If you have two jobs printing, and you use the LPRM command without the *job_id* parameter, the first job may finish, and you may inadvertently remove the second job.

Examples

• To cancel job number 123 on the printer psnt on the local system test1, enter the following command:

```
LPRM 123 (PRINTER psnt HOST test1
```

If you printed the job, it is removed. If the job is currently active, it is stopped.

• If the LPRSET command LPRSET psnt test1 was previously issued, entering the following LPRM command has the same effect as issuing the command in the first LPRM example:

LPRM 123

• To cancel the currently active job, enter the following command: LPRM (PRINTER psnt HOST test1

Chapter 11. Using GDDMXD/VM with the X Window System

TCP/IP provides the GDDMXD/VM interface for the IBM Graphical Data Display Manager/VM (GDDM*), which allows graphics to be displayed on workstations that support the X Window System.

This chapter describes GDDMXD/VM and the GDDMXD command. This chapter also describes how to use GDDMXD/VM user-specified options and keyboard functions. Problem determination information associated with GDDMXD/VM is also described in this chapter.

Overview of GDDMXD/VM

When GDDMXD/VM is installed and activated, the data stream created by GDDM is translated to the X Window System protocol and transmitted by TCP/IP to the X Window System server for the display. If GDDMXD/VM is installed and not activated, or has been made inactive, GDDM transmits data to its supported display device as if GDDMXD/VM was not present.

GDDM Application Limitations

GDDMXD/VM does not support the following types of applications:

- Multiple instances of GDDM/VM
- · Opening multiple display devices at one time
- · Operator windows

GDDM Display Limitations

GDDMXD/VM appears as an IBM 3179G Color Graphics Display Station device model to GDDM. When the HostRast option is active, the device model is an IBM 3279. The IBM 3179G model is used regardless of the display device nickname presented by the application.

The GDDMXD/VM IBM 3179G device model contains the following features:

Feature	Description
Blink Attribute	Ignores the blinking character attribute.
Detectable Fields	Ignores the selector pen detectable fields.
Character Display	Displays characters with an EBCDIC value of less than X'40' as blanks.
Graphics Cursor	The X Window System pointer device cursor for the GDDMXD window is a crosshair pattern and moves as the pointer device is moved.
Alphanumeric Cursor	The alphanumeric pointer device is an open arrow when the keyboard is unlocked, or an "X" when the keyboard is locked. The cursor can be repositioned by moving the pointer to the desired character location and pressing a pointing device button.
Pixel Spacing	When the HostRast option is not active, the vertical and horizontal pixel spacing of the actual display device that is obtained from the X Window System is supplied to GDDM. When the HostRast option is

© Copyright IBM Corp. 1987, 2011 329

Using GDDMXD/VM

Appearance

active, the pixel spacing of an IBM 3279 Color Display Station is supplied to GDDM.

For all programmed symbol and image data that is received from GDDM, each GDDM pixel is mapped to one X Window System display pixel, which causes a different appearance from the same data stream displayed on an IBM 3179G Color Graphics Display Station. This mapping can also cause display differences in the placement of alphanumeric field data over the graphics display and in the appearance of the filled areas of the graphic display. When the HostRast option is not active, aspect ratio distortion of the displayed graphics appears, unless the aspect ratio of the X Window System display is the same as the IBM 3279.

Color Mixing

GDDMXD/VM supports only the overpaint foreground color mix mode. The initial color of the image area is black, and mixing with the actual background colors is not performed.

An exception is made for data passed by an image data order. In this case, a combined foreground color mix mode is supported, if the series of begin image orders have exactly the same parameter values.

When the HostRast option is active, color mixing is performed by GDDM, not the X Window Display System, so the preceding exception does not apply.

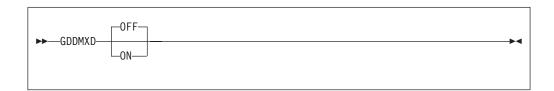

z/VM Considerations

Before you can use GDDM applications with GDDMXD/VM on z/VM, issue the following command to ensure that GETMAIN requests by GDDMXD/VM are processed correctly by CMS.

SET STORECLR ENDCMD

The SET STORECLR ENDCMD command has no parameters.

GDDMXD Command

Purpose

Use the GDDMXD command to activate GDDMXD/VM so you can send GDDM data to an X Window System display.

Operands

ON Enables GDDMXD/VM. GDDM output is sent to the X Window System display. The system responds with GDDMXD/VM active.

0FF

Disables GDDMXD/VM. The system erases the file that was created when GDDMXD/VM was activated and responds with GDDMXD/VM inactive. This is the default.

Usage Notes

 If you do not want to run GDDM applications through the X Window System, do not enable GDDMXD/VM.

Configuring the GDDMXD/VM Environment

You must set several CMS global variables before running GDDM programs through GDDMXD. To create the proper environment, issue the following commands.

GLOBAL LOADLIB SCEERUN

GLOBAL TXTLIB GDDMXD ADMNLIB ADMPLIB ADMGLIB ADMHLIB X11LIB COMMTXT SCEELKED

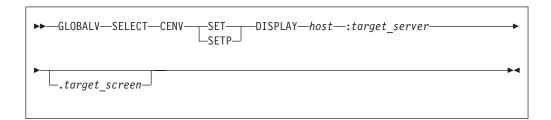

Note: If GDDM/VM Version 2 is in use, omit ADMHLIB from the above GLOBAL TXTLIB command.

These statements force GDDM applications to recognize GDDMXD's presence and allow GDDM output to be directed to the specified X Window System.

Identifying the Target Display

The X Window System uses the C environment variable **DISPLAY** to identify the internet address of the target display.

GLOBALV Command

Purpose

Use the The CMS GLOBALV command to set the required environment variable.

Operands

SELECT CENV

The GLOBALV group that contains C environment variables.

SET

Defines the variable for the current IPL only.

SETP

Defines the variable permanently.

Using GDDMXD/VM

DISPLAY

The C environment variable to be defined.

The name or IP address of the host machine running the X Window System server.

target server

Specifies the number of the display server on the host machine.

target screen

Specifies the screen to be used on the same *target_server*.

Examples

The following is an example of a Geometry option.

GLOBALV SELECT CENV SET DISPLAY charm.cambridg.ibm.com:0.0

GLOBALV SELECT CENV SET DISPLAY 129.42.3.109:0.0

Use the workstation xhost command to allow GDDMXD access to the workstation you have selected. To send GDDM output to your selected X Server, enter the following:

xhost vm host name

User-Specified Commands

The user-specified options for GDDMXD/VM are entries in a file called X DEFAULTS. The X DEFAULTS file is searched during initialization of GDDMXD/VM.

Note: The values in the X DEFAULTS file are case sensitive and must be entered as shown.

The following GDDM commands are supported by GDDMXD/VM:

- Geometry
- GColornn
- GMCPnn
- ZWL
- XSync
- CMap
- HostRast
- XClConn
- Compr
- PDTrace
- ANFontn
- Enter
- NewLine

Resizing the GDDMXD Graphics Window

GDDMXD supports four graphics window sizes. The initial window size is determined by the window width specified in the Geometry option of the X DEFAULTS file. Subsequently, the window size used by GDDMXD is determined by the width of the window resulting from any resizing that you may have done. The relationship of graphics window size (GDDMXD Graphics Presentation Space) to the actual window width is shown in Table 24 on page 333.

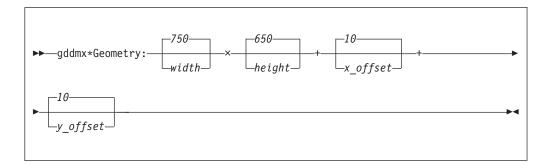

Table 24. Window Width and Window Size

Window Width (pixels)	GDDMXD Graphics Presentation Space (pixels)
< 650	480 horizontal by 352 vertical
>=650 to < 850	720 horizontal by 512 vertical
>= 850 to <= 1024	960 horizontal by 682 vertical
> 1024	1200 horizontal by 864 vertical

For sizes other than the default graphics presentation space size of 720 pixels by 512 pixels, bitmapped data such as symbol sets and images are expanded or contracted to meet the scaling requirements of the specified window size.

Expansion is accomplished by duplicating rows and columns of the data and can result in a slightly different appearance than when viewed at the default size. Contraction is implemented for single-plane data by combining certain rows and columns of the data with a logical OR function. Because this may not yield acceptable results when a black on white image is viewed, a user option, Compr, is provided to specify that a logical AND function be used to contract the data. Contraction of multiplane bitmapped data is accomplished by eliminating certain rows and columns. Data compression results in a different visual appearance than when viewed at the default size. For more information about using this option, see "gddmx*Compr: Command" on page 338.

gddmx*Geometry: Command

Purpose

Use the gddmx*Geometry command to specify the size and location of the initial GDDM graphics window.

Operands

width

Specifies the width of the X-Window in pixels. The default width is 750 pixels.

height

Specifies the height of the X-Window in pixels. The default height is 650 pixels.

x offset

Specifies the location of the upper left corner of the window where *x_offset* is the horizontal offset from the upper left corner of the display. The default horizontal offset is +10 pixels.

Using GDDMXD/VM

y offset

Specifies the location of the upper left corner of the window where y offset is the vertical offset from the upper left corner of the display. The default vertical offset is +10 pixels.

Examples

The following is an example of a Geometry option.

gddmx*Geometry: 600x400+20+20

In the above example, the Geometry entry in the X DEFAULTS file specifies the size of the initial GDDM graphics window.

gddmx*GColornn: Command

Purpose

Use the gddmx*GColornn command to provide a default mapping of GDDM colors (GColors) to X Window System colors.

Operands

nn Specifies the GDDM color entry that is mapped.

Specifies the X Window System color that is used as the GDDM color.

Examples

The following is an example of a GColornn option.

gddmx*GColor3: Pink

In this example, specifying the GColor3 entry in the X DEFAULTS file maps the GDDM color, Magenta, to the X Window System color, Pink.

GDDMXD/VM provides a default mapping of GDDM colors (GColors) to X Window System colors. If you want to override a default color name or if a default color name is not available by your X Window System server, add a GColornn entry in the X DEFAULTS file. Table 25 lists the GDDM colors that GDDMXD/VM maps to the X Window System.

Table 25. GColors

GColornn	GDDM Color	X Window System Color
GColor1	Blue	Blue
GColor2	Red	Red
GColor3	Magenta	Magenta
GColor4	Green	Green
GColor5	Turquoise	Turquoise
GColor6	Yellow	Yellow
GColor7	White	White
GColor8	Black	Black
GColor9	Dark Blue	Dark Slate Blue

Table 25. GColors (continued)

GColornn	GDDM Color	X Window System Color
GColor10	Orange	Orange
GColor11	Purple	Plum
GColor12	Dark Green	Dark Green
GColor13	Dark Turquoise	Dark Turquoise
GColor14	Mustard	Wheat
GColor15	Gray	Gray
GColor16	Brown	Brown

gddmx*GMCPnn: Command

Purpose

Use the gddmx*GMCPnn command to override GDDM multicolor patterns (GMCP) with workstation color names.

Operands

nn Specifies the GDDM multicolor pattern.

Specifies the X Window System color that is used as the GDDM color.

Examples

The following is an example of a GMCPnn option.

gddmx*GMCP126: MediumBlue

In the preceding example, the color MediumBlue is used when multicolor pattern 126 is specified by the GDDM application.

gddmx*ZWL: Command

Purpose

Use the gddmx*ZWL command to specify the line widths of the X Window System.

The X Window System supports a range of line widths. Because some X Window System servers draw wide lines at a slow rate, you can use the Zero Width Lines (ZWL) option to increase the speed at which GDDMXD/VM draws lines.

ZWL directs GDDMXD/VM to draw all lines using zero width lines. The X Window System server uses the fastest drawing algorithm to draw the lines even though the resulting line may not be exactly the same as if it had been drawn as a wide line.

Operands

- Directs GDDMXD/VM to use zero width lines for all drawing.
- Directs GDDMXD/VM to use normal width lines for all drawing. This is the default.

gddmx*XSync: Command

Purpose

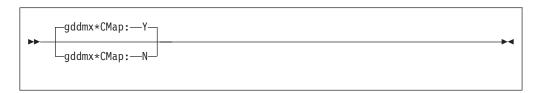

Use the gddmx*XSync command to requests that the X Window System process one request at a time.

The X Window System operates asynchronously. By the time an error has been detected, the application may have issued more requests.

Operands

- Directs GDDMXD/VM to request the X Window System to operate synchronously.
- Allows the X Window System to operate asynchronously. This is the default.

gddmx*CMap: Command

Purpose

Use the gddmx*CMap command to specify whether or not the XInstallColormap is loaded.

During initialization, GDDMXD/VM issues the X Window System call, XInstallColormap, to load the default color map (CMap). If the CMap option is specified as N, the XInstallColormap call is not made. This option accommodates the X Window System servers that load their own color maps and do not want the clients to load different color maps.

Operands

- Directs GDDMXD/VM to load the default colormap. This is the default.
- Directs GDDMXD/VM to bypass loading the default colormap.

gddmx*HostRast: Command

Purpose

Use the gddmx*HostRast command to enable you to perform the raster image processing at the VM host.

The default device model for GDDMXD/VM is an IBM 3179G Color Graphic Display Station with a mouse and raster image processing is performed at the workstation.

When the HostRast option Y is specified, GDDM performs the raster image processing and transmits the picture as a series of characters whose pixel definitions have been transmitted to Programmed Symbol Sets. The picture is mapped exactly as an IBM 3279 Color Display Station.

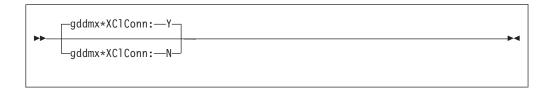

Operands

- Directs GDDMXD/VM to use the IBM 3279 as a device model and perform raster image processing on the VM host.
- Directs GDDMXD/VM to use the IBM 3179G as a device model and perform raster image processing on the workstation. This is the default.

Usage Notes

• The APL2 character set is not supported when the HostRast option is active.

gddmx*XClConn: Command

Purpose

Use the gddmx*XClConn command to instruct GDDMXD/VM not to close the connection to the X Window System when the GDDM device is closed.

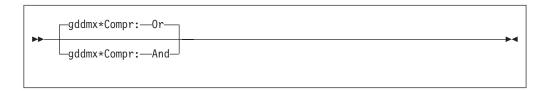

The default operation of GDDMXD/VM creates the GDDMXD/VM window when the GDDM application opens the display device, destroys the window, and breaks the connection to the X Window System display when the application closes the display device.

Some applications can repeatedly close and reopen the display device, which can cause a delay of several seconds to reestablish the connection to the X Window System display. It is no longer necessary to use this option since GDDM will only close the X Window environment after a GDDM FSTERM call has been issued. All GDDM applications should issue the FSTERM call to close the environment. The option remains for the sake of compatibility with existing and older applications.

Operands

- Instructs GDDMXD to close the connection to the X Window System when the display device is closed by the GDDM application. This is the default.
- Instructs GDDMXD to leave the connection to the X Window System active when the display device is closed by the GDDM application. With this parameter, GDDMXD cannot destroy the window and close the connection to the workstation when the application is finished with the device. The last GDDM graphics window created by the application is displayed until a GDDM application is started on the same VM host for the same workstation, or until you explicitly destroy the window using the workstation window manager facilities.

gddmx*Compr: Command

Purpose

Use the gddmx*Compr command to control the technique used to compress (Compr) bitmapped data when a graphices window size of 480 by 352 pixels is in use.

Operands

Or 'O' or 'o' specifies that an OR function should be used. This is the default value.

And

'A' or 'a' specifies that an AND function should be used when compressing bitmapped data.

qddmx*PDTrace: Command

Purpose

Use the gddmx*PDTrace command in your X DEFAULTS file is used to generate a GDDM problem determination trace (PDTrace).

Operands

- Generates GDDMXD trace information.
- Does not generate the GDDMXD trace information. This is the default.

gddmx*ANFontn Command

Purpose

Use the gddmx*ANFont command to specify the X Window System font that GDDMXD should use for displaying characters in the alphanumeric presentation space of the GDDMXD window.

Graphics mode 1 and 2 characters in the graphics presentation space are not affected by this option. The value of n ranges from 1 to 4 and defines the X Window System font for each of the four sizes of presentation space supported by GDDMXD. The ANFontn option can be specified for any, all, or none of the four values of *n*.

Operands

Specifies the size of the presentation space.

fontname

Specifies the name of the X Window System font.

Examples

The X Window System fonts specified should be fixed-spaced fonts whose characters fit into the character box size required by each of the four presentation space sizes shown in Table 26.

Table 26. X Window System Fonts

n	Presentation Space	Character Box	Example Font
1	480 x 352	6 x 11	Rom8
2	720 x 512	9 x 16	Rom11
3	960 x 682	12 x 21	Rom14
4	1200 x 864	15 x 27	Rom17

Selecting a font whose characters are larger than the character box size can result in characters overlapping when displayed.

Remapping the Enter and Newline Keys

GDDMXD/VM provides the following commands to allow remapping of the "Enter" and "Newline" keys by the GDDMXD/VM user.

gddmx*Enter: Command

Purpose

Use the gddmx*Enter command in the X DEFAULTS file to identify which X Window System Keysym is to be mapped to the Enter function

The use of this option overrides the default mapping of the Keysym XK_Execute to the Enter function.

Operands

XXX

Specifies the X Window System Keysym representing the physical key. For standard Keysyms, the XK prefix is not included in specifying the option.

Examples

The following is an example of the Enter Option:

gddmx*Enter: Return

In the preceding example, the X Window System Keysym, XK Return is mapped to the Enter function.

gddmx*NewLine: Command

Purpose

Use the gddmx*NewLine command in the X DEFAULTS file to identify which X Window System Keysym is to be mapped to the NewLine function

The use of this option overrides the default mapping of the Keysym XK_Return to the Newline function.

Operands

XXX

Specifies the X Window System Keysym representing the physical key. For standard Keysyms, the XK prefix is not included in specifying the option.

Examples

The following is an example of the NewLine command:

gddmx*NewLine: KP Enter

In the preceding example, the X Window System Keysym, KP_Enter is mapped to the NewLine function.

GDDMXD/VM Keyboard Functions

When you enter input to GDDM by GDDMXD/VM, use the following keyboard functions.

- · All alphanumeric keys
- F1-F24

If F13—F24 are not available, use Shift + F1 to Shift + F12

Tab or Shift + Tab

- · Directional arrows
- · End key to erase to the end of the field
- Insert key and Delete key
- PA1, PA2, and PA3
- Enter key
- · Newline key

Note: The Backspace key is treated as a cursor left key.

If you cannot locate these keys on your workstation, see your workstation X Window System documentation to determine the mapping of the X Window System key symbol definitions to the physical keys.

GDDMXD/VM to X Window System Keyboard Functions

The following are the GDDMXD/VM keyboard functions that translate to X Window System key symbol definitions. Key functions not listed are not supported.

G	DI)IV	IX	DΛ	/M

Keyboard Function	X Window System Key Symbol
F1—F12	XK_F1—XK_F12
Tab	XK_Tab
Up	XK_Up
Down	XK_Down
Left	XK_Left
Right	XK_Right
End	XK_End
Insert	XK_Insert
Delete	XK_Delete
PA1	XK_Prior
PA2	XK_Next
PA3	XK_Home
Clear	XK_Pause
Enter	XK_Execute
APL2 char set toggle	XK_Backspace with state Mod1Mask
Newline	XK_Return

APL2 Character Set Keyboard

The APL2 character set is activated by simultaneously pressing the X Window System XK_Backspace key (usually the Backspace key) and the State Mod1Mask key (usually the Alt key). For example, if you use the IBM 101 Enhanced Keyboard, the APL2 character set is toggled on and off by pressing and holding Alt, and then pressing Backspace.

When the APL2 character set is active, the characters APL are displayed in the title bar of the GDDMXD/VM window.

Using GDDMXD/VM

In the X Window System, a keycode is assigned to each key on the keyboard. GDDMXD/VM uses keycodes in combination with modifier keys. For example, the Shift and Alt keys determine the data that should be passed back from GDDMXD/VM to the X Window System application to identify the user's keystroke data.

A default mapping for the APL2 character set is provided in GDDMXD/VM, which corresponds to the IBM 101 Key Enhanced Keyboard. You can override this default mapping by creating a file called GDXAPLCS MAP to define the mapping for your workstation. When GDDMXD/VM is initialized, the system searches for a file called GDXAPLCS MAP. If the GDXAPLCS MAP file exists, the data in the GDXAPLCS MAP file replaces the default mapping for all keys.

For additional information about the mapping values defined in the GDXAPLCS MAP file, see Appendix C, "Mapping Values for the APL2 Character Set," on page 427.

Setting Up GDXAPLCS MAP

The following steps describe how to set up the GDXAPLCS MAP file.

- 1. Use the sample program, KEYCODE module, to determine the keycodes for the physical keyboard keys.
 - When the KEYCODE program is executed from your workstation session to the host system, the keycode is displayed for each key depressed at the workstation. Therefore, you can establish the association between a physical key and the character you want to generate.
 - For more information about the mapping values that are defined in the GDXAPLCS MAP file, see Appendix C, "Mapping Values for the APL2 Character Set," on page 427.
- 2. Copy GDXAPLCS SAMPMAP to GDXAPLCS MAP.
- 3. Edit GDXAPLCS MAP to establish the association between the keycodes in KEYCODE and the character set and code values in Appendix C, "Mapping Values for the APL2 Character Set."

Collecting Problem Determination Information

If you are reporting a problem to the IBM Service Representative, you should provide the following information:

- Environment description
- GDDM trace
- GDDMXD problem determination trace
- · Spooled console output

Note: The GDDM and GDDMXD problem determination traces must be in machine-readable form. To minimize the size of these traces, find the shortest sequence of actions that reproduce the problem before obtaining traces. Running with these traces activated reduces system performance.

GDDMXD/VM — X Window System Server Environment

You should include the following information in the environment description:

- Host system software name and level
- X Window System server workstation hardware and software names and levels

Obtaining the GDDM Trace

To generate the GDDM trace on the virtual printer, the following lines should be included in the PROFILE ADMDEFS file.

```
*ADMMDFT TRCESTR='FLOW'
*ADMMDFT TRCESTR='PARMSF'
*ADMMDFT TRCESTR='FULLTCA'
*ADMMDFT CMSTRCE=(,)
```

To activate the trace, you should change the asterisk (*) in column 1 of each line to a blank. You should include the FULLTCA line to provide all the information about GDDMXD/VM. You should provide the GDDM trace in machine readable format to your IBM Service Representative.

Obtaining the GDDMXD Problem Determination Trace

To activate the GDDMXD problem determination trace, add the following entry to your X DEFAULTS file.

```
gddmx*PDTrace: Y
```

By default, a file called GDDMX TRACE is written on your A disk. By issuing a CMS FILEDEF command for the data definition name (ddname) GDXDPDT, you can direct the GDDMX TRACE to another device, including the virtual printer.

If the problem you are experiencing results in an X Window System error message, activate the GDDMXD XSync option by including the following entry in your X DEFAULTS file.

gddmx*XSync: Y

GDDMXD/VM Problem Determination Examples

This section describes the process used to determine the cause of the problems that can occur when you run a GDDM application with GDDMXD/VM.

Problem: Messages from the X Window System or from GDDMXD/VM indicating the connection could not be established.

Explanation: There are problems establishing the connection to the X Window Server.

User response:

- If you received an X Window System message indicating that the server was not authorized to connect to the host, issue an XHOST command at the server specifying the desired host. If the problem persists, seek assistance to verify that the host system and the work station have been set up correctly.
- Is the global variable defining the target X Window System server set up correctly? Issue the following command: GLOBALV SELECT CENV LIST DISPLAY. Is the response correct? If there is more than one display at the server, is the global variable pointing to the correct display? Try using the PING command to check the path to the server. Try an X Windows System application that does not use GDDMXD/VM, for example, XCALC. Try running the GXDEMOn

sample GDDMXD programs. Correct any difficulties before trying other GDDM applications.

Problem: Any other problem such as program check or ABEND.

Explanation: There are problems establishing the connection to the X Window Server.

User response: Collect problem determination information.

Problem: An X Window System message indicating an error or any unexpected ABEND.

Explanation: The connection is established, but the GDDMXD window is not displayed.

User response:

- Try running with a different server.
- Try running without a window manager at the server.
- If the X Window System error message is: XIO: fatal IO error nn (broken pipe) and the message persists, the problem is most likely in the X Window System

Using GDDMXD/VM

and not in GDDMXD/VM. If the error persists, collect problem determination information.

Problem: GDDMXD window is created, but picture drawn is incorrect or user interaction with application produces unexpected results.

User response:

- · Is the server at the correct level?
- · Is the ZWL option being used? If so, try turning it off.
- Is a supported version of GDDM being used?
- · Is the application using GDDM functions that are not supported?
- · If the error persists, collect problem determination information.

Demonstration Programs

The demonstration programs display examples of the GDDM functions. Each program displays a series of frames. To move to the next frame, press Enter.

GXDEMO1

The following describes the GXDEMO1 frames.

Frame	Description
1	GDDM line types and widths
2	GDDM System Markers
3	Simple picture
4	Circular Arcs
5	Elliptic Arcs
6	2-Part Polyfillet
7	5-Part Polyfillet

GXDEMO2

The following describes the GXDEMO2 frames.

Frame	Description
1	Solid area fill
2	Overlapped polygon fill
3	2-Part graphic area fill
4	GDDM System Shading Patterns
5	Output from GSIMG statement
6	Output from GSIMGS statement

GXDEMO3

The following describes the GXDEMO3 frames.

Frame	Description
1	Three GDDM Text Modes
2	Proportional Spacing
3	GDDM Character Angle
4	GDDM Character Direction
5	GDDM Character Shear

GXDEMO4

The GXDEMO4 frames display the 22 standard GDDM fonts.

GXDEMO4A

The GXDEMO4A frames display a subset of the standard GDDM fonts.

GXDEMO5

The following describes the GXDEMO5 frames.

Frame	Description
1	The Four Segment Transformations
2	Example transformation (Part 1)
3	Example transformation (Part 2)
4	Examples of Called Segments

GXDEMO6

The following describes the GXDEMO6 frames.

Frame	Description
1	PGF Line Chart
2	PGF Surface Chart
3	PGF Histogram
4	PGF Bar Chart
5	PGF Tower Chart
6	PGF Polar Chart
7	PGF Composite Bar Versus Multiple Pie Charts
8	PGF Pie Charts
9	PGF Venn Diagram

Using GDDMXD/VM

Chapter 12. Managing TCP/IP Network Resources with SNMP

Simple Network Management Protocol (SNMP) is used to monitor your TCP/IP network resources.

SNMP defines an architecture that consists of network management stations (SNMP clients), network elements (hosts and gateways), and network management agents and subagents, which perform the information management functions.

SNMP allows clients and agents to communicate network management information through network elements, which act as servers.

An SNMP client is a network workstation that executes management applications that are used to monitor and control network elements. When you use SNMP with TCP/IP, you require NetView[®] to provide end-user interface to the SNMP client. A NetView operator can use the SNMP command to communicate with SNMP agents. NetView acts as an SNMP client.

Notes:

- VM SNMP supports Management Information Base (MIB) variables and MIB-II variables. For more information about MIB-II variables, see RFC 1158 and Appendix E, "Management Information Base Objects," on page 439.
- 2. The VM SNMP agent does not support the SET operation. If you use the SET command with the variables listed in Appendix E, "Management Information Base Objects" for a VM Agent, you receive a read-only error.

Sample Command Lists

Two sets of sample NetView command lists with a filetype of NCCFLST are supplied on the Samples tape. One set is written in CLIST (SNMPRUN), and the other set is written in REXX (SNMPMGMT).

You should use CLISTs if your host system does not support REXX. The REXX programs supply the same functionality as the CLISTs. These command lists enable you, through revision and modification, to develop a set of NetView/SNMP client/user interface pannels that are customized to your needs.

You can issue SNMP requests with the two sets of sample command lists that are shipped with the TCP/IP product, with command lists that you write, or directly from the command line. The SNMPRUN and the SNMPMGMT commands invoke the main panel from which a NetView operator can execute most of the SNMP requests in full-screen mode. The SNMPRUN command uses a set of command lists written in NetView Command List language; the SNMPMGMT command uses a set of REXX command lists.

For more information about these sample command lists, see the SNMPCLST README and SNMPREXX README files on the client common disk (TCPMAINT 592).

SNMP/NetView Overview

Figure 65 illustrates how the interface between the NetView and TCP/IP virtual machines is set up. An additional virtual machine running a special server called the Query Engine(SNMPQE) actually implements the communication function.

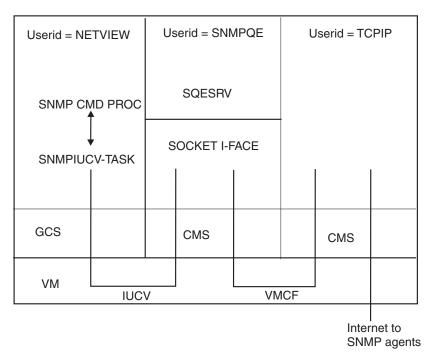

Figure 65. Overview of NetView SNMP Support

The Query Engine communicates with an optional subtask, called SNMPIUCV, running under NetView. It also communicates with TCP/IP. This is done through socket interfaces that are based on the IUCV cross-memory facility.

The SNMP Query Engine uses three types of sockets:

- Datagram sockets through which the SNMP requests and responses flow and traps are received, because the management protocol is based on UDP
- A raw socket into ICMP for the implementation of the PING facility, which is an ICMP echo application
- A stream socket for communication with NetView

To use the interface, a NetView operator or command list issues the SNMP command with the appropriate parameters. This invokes the SNMP command processor, which validates the syntax of the input and, if no errors are found, it queues the request to the SNMPIUCV task. Then, the task passes the request to the SNMP Query Engine, which validates the request, encodes it in ASN.1 format, and builds the protocol data unit (PDU) that is sent to the SNMP agent.

When the Query Engine receives a response from the agent, it decodes the PDU and passes it to the SNMPIUCV NetView task. The task converts the response into a multiline message. The messages are prefixed with SNM, so that they can be assigned to specific NetView operators or autotasks.

SNMP Commands

To issue an SNMP request, use the SNMP command. The following is a list of the SNMP commands you can use on NetView.

Note: The SNMP commands can be abbreviated; the shortest acceptable form appears in uppercase.

The SNMP Query Engine issues SNMP requests to the agents and processes SNMP responses returned by the agents. The agents can also forward unsolicited messages, known as traps, to NetView and other clients.

NetView can use the following SNMP commands.

- SNMP Get
- SNMP GETNext
- SNMP Set
- SNMP TRAPson
- SNMP TRAPSOFf
- SNMP MIBvname
- SNMP PING

The following sections describe these commands.

SNMP Commands Overview

The following provides information about SNMP commands.

- When the SNMP command is issued from the NetView Command Facility command line, all input is translated to uppercase (standard NetView) before it is sent to the SNMP Query Engine.
- When the SNMP command is issued from a CLIST, input is passed in whatever case it was passed from the CLIST (for example, mixed case).
- · The short names for the variables passed to the query engine are compared against the entries in the MIB DESC DATA file in a case insensitive way. For more information about this file, see *z/VM: TCP/IP Planning and Customization*.
- · The community name is passed to the SNMP agent in the same case as it was received by the query engine.
- If multiple variables are specified with the GET, GETNEXT, or SET commands, they are all packaged in one SNMP PDU to be sent to the agent.
- For PING, you can specify only one host_name.
- The responses may not be received in the same order they are issued.
- The SNMP agent can receive SNMP requests over any interface.

Return Codes

The following is a list of the return codes generated by SNMP.

Code	Description
1	Error from DSIGET, cannot continue
2	Invalid function specified
3	Missing SNMP function
4	Not enough parameters
5	Missing variable name

Using SNMP

6	Missing variable value
7	Missing or invalid host name
8	Missing community name
9	SNMPIUCV not active
10	Error from DSIMQS
11	Invalid net_mask/desired network
12	Missing/Invalid trap filter_id
1001+	All return codes above 1001 indicate that the command was successful

The return code represents the sequence number (or filter_id) passed to SNMP Query engine. The asynchronous response is identified by this sequence number. For a TRAPSON request, this is the filter_id to be used for a subsequent TRAPSOFF request.

SNMP GET Command

Purpose

Use the SNMP GET command to obtain one or more variables from an SNMP agent.

Operands

host

Specifies the name of the destination host where the SNMP request is sent. The host can be specified with its name or with its IP address in dotted-decimal notation.

Note: The SNMP Query Engine treats numbers with leading zeros as octal numbers. Therefore, do not use leading zeros.

Specifies the community name to use when querying the SNMP agent on the destination host.

Note: This parameter is case sensitive.

var name

Specifies one or more MIB variable names to be obtained. You can specify the names in short form or in ASN.1 notation (for example, sysDescr.0 or 1.3.6.1.2.1.1.1.0). Currently, a maximum of 10 variables for each request is implemented in the SNMP Query Engine.

Note: This parameter is not case sensitive.

Usage Notes

- 1. You must specify the host name or IP address of the host where the agent is running, as well as the community name to be used when making the query.
- 2. You must specify the variable name of each variable to be obtained. All standard MIB and MIB-II variable names (defined in RFC 1156 and RFC 1158) are supported by the VM SNMP client. In addition, you can specify enterprise-specific variables that are defined by the implementer of a particular SNMP agent. See z/VM: TCP/IP Planning and Customization for information about how to add the enterprise-specific variables to the MIB_DESC DATA file.
- 3. All lines do not need to be present, but the first line is always message SNM040I, and the last line is always message SNM049I.
- 4. If an error was detected, messages SNM042–SNM044 may not be present. You can get (in addition to other messages) error messages in the following form (all as part of multiline message SNM040I).

```
SNM045I Major error code: n
SNM046I Minor error code: y
SNM047I Error index: z
SNM048I Error text: message text
```

See "Major and Minor Error Codes and SNMP Value Types" on page 364 for information about value types and minor and major error codes.

- 5. If you issue a GET for multiple variables, messages SNM042 through SNM044 are displayed for each variable.
- 6. If a variable value is too long, message SNM044 may not fit on an 80-character line. If this happens, the value is split and multiple SNM044 messages are displayed.
- 7. The SNMP response always displays the variable name in ASN.1 notation. You can use SNMP MIBVNAME to obtain the short name for the variable. For more information, see "SNMP MIBVNAME Command" on page 359.
- 8. According to RFC 1157, a message exchanged between SNMP entities (including version identification and community name) can be as small as 484 octets. If you specify up to 10 variables in a GET/GETNEXT command, the names may be short enough to send the GET command to the SNMP agent, but the response may be too long to fit in the message. As a result, you receive a tooBig error.
- 9. When you issue a GET for multiple variables, they are returned in the same sequence as requested. In the example on page 352, GET was issued for sysDescr.0 sysObjectID.0 sysUpTime.0.. The same three variables are returned in the response. If one (or more) of the variables requested results in an error, all variables listed after the first variable in error are ignored, and data is not returned for them.
- 10. For more information about value types, minor, and major error codes, see "Major and Minor Error Codes and SNMP Value Types" on page 364.
- 11. For a description of all variables and the meaning of their values, see RFC 1156 and RFC 1158.

Examples

If you know:

```
hostname - anyhost
IP address - 129.34.222.72
community name - public
variable name - sysDescr.0
```

Using SNMP

```
asn.1 variable name - 1.3.6.1.2.1.1.1.0
asn.1 variable name - 1.3.6.1.2.1.1.2.0
asn.1 variable name - 1.3.6.1.2.1.1.3.0
```

You can issue the following SNMP GET commands:

```
snmp get 129.34.222.72 public 1.3.6.1.2.1.1.1.0
snmp get 129.34.222.72 public sysDescr.0
snmp get anyhost public 1.3.6.1.2.1.1.0
snmp get anyhost public sysDescr.0
snmp get anyhost public sysObjectID.0
\verb|snmp| get anyhost public sysUpTime.0|\\
snmp get anyhost public sysDescr.0 sysObjectID.0 sysUpTime.0
```

After the SNMP command is completed, you get a message similiar to the following:

```
SNM050I SNMP Request 1001 from NETOP accepted, sent to Query Engine
```

When the response arrives in NetView (asynchronously), NetView displays it as a multiline message in the following form.

```
SNM040I SNMP Request 1001 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.1.0
SNM043I Variable value type: 9
SNM044I Variable value: AIX 2.2.1 SNMP Agent Version 1.0
SNM042I Variable name: 1.3.6.1.2.1.1.2.0
SNM043I Variable value type: 3
SNM044I Variable value: 1.3.6.1.4.1.2.1.1
SNM042I Variable name: 1.3.6.1.2.1.1.3.0
SNM043I Variable value type: 8
SNM044I Variable value: 98800
SNM049I SNMP Request 1001 end of response
```

For a list of variables supported by the VM Agent, see Appendix E, "Management Information Base Objects."

SNMP GETNEXT Command

Purpose

Use the SNMP GETNEXT command in the following format to obtain the next variable in the MIB tree from an SNMP agent.

Operands

host

Specifies the name of the destination host where the SNMP request is sent. The host can be specified with its name or with its IP address in dotted-decimal notation.

Note: The SNMP Query Engine treats numbers with leading zeros as octal numbers. Therefore, do not use leading zeros.

com name

Specifies the community name to use when querying the SNMP agent on the destination host.

Note: This parameter is case sensitive.

var name

Specifies one or more MIB variable names to be obtained. You can specify the names in short form or in ASN.1 notation (for example, sysDescr.0 or 1.3.6.1.2.1.1.1.0). Currently, a maximum of 10 variables for each request is implemented in the SNMP Query Engine.

Note: This parameter is not case sensitive.

Usage Notes

- You must specify the host name or IP address of the host where the agent is running, as well as the community name to be used when making the query. You must specify the name of the variable preceding the desired variable. In addition to the standard MIBs, there may be enterprise-specific variables as defined by the implementer of a particular SNMP agent.
- 2. The GETNEXT command is used to interrogate a table (for example, the interface table) or an array. You can issue a GETNEXT command at the start of a table (use instance 0.0). The first element in the table is returned. The process continues in a loop, performing GETNEXT requests on the previously obtained variable name, until the name of the variable returned no longer has the same prefix as the one at the start of the table. This condition occurs when the GETNEXT request returns a variable that is in the next group.

Examples

If you know:

```
hostname - anyhost
IP address - 129.34.222.72
community name - public
variable name - ifAdminStatus (in ifTable)
asn.1 variable name - 1.3.6.1.2.1.2.2.1.7
```

You can issue an SNMP GETNEXT command in one of the following ways:

```
snmp getnext 129.34.222.72 public 1.3.6.1.2.1.2.2.1.7.0
snmp getnext 129.34.222.72 public ifAdminStatus.0
snmp getnext anyhost public 1.3.6.1.2.1.2.2.1.7.0
snmp getnext anyhost public ifAdminStatus.0
```

 The GETNEXT command is completed in the same manner as the GET command, and you receive an asynchronous response similiar to the following example.

The first instance of the variable has a status of 1 or greater (ends in 7.1) in this example:

```
SNM040I SNMP Request 1001 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.2.2.1.7.1
SNM043I Variable value type: 1
SNM044I Variable value: 1
SNM049I SNMP Request 1001 end of response
```

You can then issue another GETNEXT command in one of the following ways:

```
snmp getnext 129.34.222.72 public 1.3.6.1.2.1.2.2.1.7.1
snmp getnext 129.34.222.72 public ifAdminStatus.1
snmp getnext anyhost public 1.3.6.1.2.1.2.2.1.7.1
snmp getnext anyhost public ifAdminStatus.1
```

Using SNMP

 The GETNEXT command is completed in the same manner as the GET command, and you receive an asynchronous response similiar to the following example.

The second instance of the variable has a status of 1 or greater (ends in 7.2) in this example:

```
SNMO40I SNMP Request 1002 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.2.2.1.7.2
SNM043I Variable value type: 1
SNM044I Variable value: 1
SNM049I SNMP Request 1002 end of response
```

You can then issue another GETNEXT command in one of the following ways:

```
snmp getnext 129.34.222.72 public 1.3.6.1.2.1.2.2.1.7.2
snmp getnext 129.34.222.72 public ifAdminStatus.2
snmp getnext anyhost public 1.3.6.1.2.1.2.2.1.7.2
snmp getnext anyhost public ifAdminStatus.2
```

 The GETNEXT command is completed in the same manner as the GET command, and you receive an asynchronous response similiar to the following:

```
SNMO40I SNMP Request 1003 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.2.2.1.8.1
SNM043I Variable value type: 1
SNM044I Variable value: 1
SNM049I SNMP Request 1003 end of response
```

The returned variable is the first entry in the next instance, which has a value of 1 or greater (ends in 8.1 rather than 7.x). The returned variable indicates that the end of the table for the ifAdminStatus variable has been reached.

SNMP SET Command

```
▶►—SNMP Set—host—com name—var name—var value
```

Purpose

Use the SNMP SET command to set or change the value of one or more variables in an SNMP agent.

Operands

host

Specifies the name of the destination host where the SNMP request is sent. The host can be specified with its name or with its IP address in dotted-decimal notation.

Note: The SNMP Query Engine treats numbers with leading zeros as octal numbers. Therefore, do not use leading zeros.

com name

Specifies the community name to use when querying the SNMP agent on the destination host.

Note: This parameter is case sensitive.

var name

Specifies one or more MIB variable names to be obtained. You can specify the names in short form or in ASN.1 notation (for example, sysDescr.0 or 1.3.6.1.2.1.1.1.0). Currently, a maximum of 10 variables for each request is implemented in the SNMP Query Engine.

Note: This parameter is not case sensitive.

var value

Specifies the value(s) to be stored in the variable(s).

Usage Notes

 You must specify the host name or IP address of the host where the agent is running, as well as the community name to be used. The community name used for a SET request is frequently different than the community name for a GET request. You must specify the names and values of each variable to be set. RFC 1156 and RFC 1158 define the variables that you can set with read-write access. In addition, there may be enterprise-specific variables as defined by the implementer of a particular SNMP agent.

Examples

• If you know:

```
hostname - anyhost
IP address - 129.34.222.72
community name - publicw
variable name - ifAdminStatus
asn.1 variable name - 1.3.6.1.2.1.2.2.1.7.1
(instance 1)
```

You can then issue an SNMP SET command in one of the following forms to set the administrative status of the first interface in the ifTable (first instance) to test.

```
snmp set 129.34.222.72 publicw 1.3.6.1.2.1.2.2.1.7.1 3
snmp set 129.34.222.72 publicw IfAdminStatus.1 3
snmp set anyhost publicw 1.3.6.1.2.1.2.2.1.7.1 3
snmp set anyhost publicw ifAdminStatus.1 3
```

 When the response arrives in NetView (asynchronously), NetView displays it as a multiline message in the following form.

```
SNM040I SNMP Request 1001 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.2.7.1
SNM043I Variable value type: 1
SNM044I Variable value: 3
SNM049I SNMP Request 1001 end of response
```

SNMP TRAPSON Command

```
►►—SNMP TRAPson—net_mask—net_desired—
```

Purpose

Use the SNMP TRAPSON command to request that the SNMP Query Engine forward SNMP traps to NetView.

Using SNMP

The SNMP Query Engine can forward only those traps that it receives. Each agent has a trap destination table, which lists all the hosts that should receive that agent's traps. The host name of your system should be in the trap destination table of all agents from which you want to receive traps.

Operands

net mask

Specifies, in dotted-decimal notation, the network mask to be evaluated with the IP address of incoming traps. The dotted decimal IP address is ANDed with this

net desired

Specifies the network from which you want to receive traps. When you request traps using the SNMP TRAPSON command, it returns a request number of filter_id, which the SNMP Query Engine associates with the TRAPSON request. To stop receiving traps, specify this *filter_id* in the TRAPSOFF request.

var name

Specifies one or more MIB variable names to be obtained. You can specify the names in short form or in ASN.1 notation (for example, sysDescr.0 or 1.3.6.1.2.1.1.1.0). Currently, a maximum of 10 variables for each request is implemented in the SNMP Query Engine.

Note: This parameter is not case sensitive.

This command permits the specification of a filtering condition, which enables the Query Engine to perform filtering.

The SNMP TRAPSON command assigns a unique request number to each filter (also called a *filter id*) and returns this number in a message and in the return code. This filter id is the argument to an SNMP TRAPSOFF command, which is used to stop receiving traps that pass this filter.

Usage Notes

- 1. In the response to the SNMP TRAPSON request, not all lines need to be present; but the first line is always message SNM040I, and the last line is always message SNM049I.
- For the multiline trap message, not all lines need to be present; but the first line is always message SNM030I, and the last line is always message SNM0391.
- Additional messages (SNM036I-SNM038I) may be present if the trap has additional data.
- 4. If a variable value is too long, message SNM038 may not fit on an 80-character line. If this happens, the value is split and multiple SNM038 messages are displayed.
- 5. The SNMP trap data always displays the variable name in ASN.1 notation. You can use SNMP MIBVNAME to obtain the short name for the variable.
- 6. A trap always shows the agent address in the form of an IP address in dotted-decimal notation.
- 7. See "Major and Minor Error Codes and SNMP Value Types" on page 364 for information about value types, minor, and major error codes.
- 8. See Appendix F, "SNMP Generic TRAP Types," on page 467 for a description of the traps and the meanings of the generic trap types.

- 9. You can issue multiple TRAPSON requests, either with the same or with a different filter. If a trap passes multiple filters, the trap is sent to NetView multiple times. However, in NetView, the header and trailer lines (messages SNM030I and SNM039I) of the duplicate trap are different, because they contain the filter_id (request number) by which the trap was forwarded. Different types of traps from different hosts can have the same filter_id, if these traps pass the same trap filter. If an SNMP request is issued with the wrong community name, it receives three AUTHENTICATION FAILURE traps with the same filter_id but different time stamps from the same host. This is because the SNMP Query Engine tries to send the same request three times if a response is not received from the host, and each attempt causes the host to generate an AUTHENTICATION FAILURE trap.
- 10. Once the TRAPSON command has been issued, traps can start to arrive asynchronously. They can even arrive after the operator who issued the TRAPSON command logs off. Often, a TRAPSON command is issued by a CLIST, and the received trap data triggers another CLIST to handle the trap data. Therefore, the messages in the range SNM030 through SNM039 are sent to the *authorized receiver*. For a NetView operator to see the traps, the operator must have the following statement in the profile.

```
AUTH MSGRECVR=YES
```

However, only one operator receives the message. The messages also go to the log file, so you can always browse the log file to see trap data. And as a last resort, you can assign trap messages to go to a specific operator using the NetView ASSIGN operator command.

Examples

• If you know:

```
IP address - 129.34.222.72
net mask - 255.255.255.255
```

You can issue the following SNMP TRAPSON commands:

```
snmp trapson
snmp trapson 255.255.255.255 129.34.222.72
```

The first command receives all traps (the default is a mask of 0 and a desired network of 0). The second command only receives traps from a specific host named anyhost.

After the command is completed, you receive a message similiar to the following: SNM050I SNMP Request 1001 from NETOP accepted, sent to Query Engine

When the response arrives in NetView (asynchronously), NetView displays it as a
multiline message in the following form to indicate that the TRAPSON request
was accepted.

```
SNM040I SNMP Request 1001 from NETOP Returned the following response:
SNM045I Major error code: 0
SNM046I Minor error code: 0
SNM047I Error index: 0
SNM048I Error text: no error
SNM049I SNMP Request 1001 end of response
```

When traps arrive, NetView displays each trap with a multiline message in the following form. This multiline message is sent to the authorized receiver (AUTH MSGRECVR=YES); it may not show up on the console of the operator who issues the TRAPSON command.

```
SNM030I SNMP request 1001 received following trap:
SNM031I Agent Address: 129.34.222.34
SNM032I Generic trap type: 4
SNM033I Specific trap type: 0
SNM034I Time stamp: 472600
SNM035I Enterprise Object ID: 1.3.6.1.4.1.2.1.1
SNM039I SNMP request 1001 End of trap data
```

SNMP TRAPSOFF Command

```
►►—SNMP TRAPSOFf—filter id-
```

Purpose

When you have asked the SNMP Query Engine to forward traps to NetView, it keeps doing so until the IUCV connection breaks or until you issue an SNMP TRAPSOFF command.

Operands

```
filter_id
    Specifies the trap filter ID.
```

When you request traps using the SNMP TRAPSON command, it returns a request number or filter id, which the SNMP Query Engine associates with the TRAPSON request. To stop receiving traps, specify this filter_id in the TRAPSOFF request.

The SNMP TRAPSON command assigns a unique request number to each filter (also called a *filter id*) and returns it in a message as the return code. This *filter id* can later be used as the argument to an SNMP TRAPSOFF command if you want to stop receiving traps that pass this filter. Only one filter id for each SNMP TRAPSOFF command can be passed. Extraneous arguments are ignored.

Examples

 If you know the filter_id is 1001, you can issue the following SNMP TRAPSOFF command to tell the SNMP Query Engine to quit sending traps that would pass filter 1001.

```
snmp trapsoff 1001
```

The command completes with a message similiar to the following:

SNM050I SNMP Request 1001 from NETOP accepted, sent to Query Engine

 When the response arrives in NetView (asynchronously), NetView displays it as a multiline message in the following form to indicate that the TRAPSOFF request was accepted.

```
SNMO40I SNMP Request 1002 from NETOP Returned the following response:
SNM045I Major error code: 0
SNM046I Minor error code: 0
SNM047I Error index: 0
SNM048I Error text: no error
SNM049I SNMP Request 1002 end of response
```

SNMP MIBVNAME Command

Purpose

When you get an ASN.1 variable name as part of a trap, use the SNMP MIBVNAME command to find the short name of the variable.

Operands

asn.1 name

Specifies the ASN.1 notation of one MIB variable. You can specify only one variable, so additional arguments are ignored.

Usage Notes

- 1. All lines do not need to be present, but the first line is always message SNM040I, and the last line is always message SNM049I. If an error occurs, an error message explains what is wrong.
- 2. If an error is detected, messages SNM042 through SNM044 may not be displayed. You receive error messages (in addition to other messages) in the following form (all as part of multiline message SNM040I).

```
SNM045I Major error code: n
SNM046I Minor error code: y
SNM047I Error index: z
SNM048I Error text: message text
```

See "Major and Minor Error Codes and SNMP Value Types" on page 364 for information about value types and minor and major error codes.

3. One ASN.1 variable name only can be passed for each SNMP MIBVNAME command. Additional parameters are ignored.

Examples

If you have a trap that tells you:

```
SNM030I SNMP request 1001 received following trap:
SNM031I Agent Address: 129.34.222.34
SNM032I Generic trap type: 2
SNM033I Specific trap type: 0
SNM034I Time stamp: 472600
SNM035I Enterprise Object ID: 1.3.6.1.4.1.2.1.1
SNM036I Variable name: 1.3.6.1.2.1.2.2.1.1
SNM037I Variable value type: 1
SNM038I Variable value: 2
SNM039I SNMP request 1001 End of trap data
```

You can issue the following SNMP MIBVNAME command to find the short MIB variable name.

```
snmp mibvname 1.3.6.1.2.1.2.2.1.1
```

The command completes with a message similar to the following:

SNM050I SNMP Request 1002 from NETOP accepted, sent to Query Engine

Using SNMP

When the response arrives in NetView (asynchronously), NetView displays it as a multiline message in the following form.

```
SNM040I SNMP Request 1002 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.2.1.2.2.1.1
SNM043I Variable value type: 9
SNM044I Variable value: ifIndex
SNM049I SNMP Request 1002 end of response
```

SNMP PING Command

Purpose

Use the SNMP PING command to obtain the minimum round trip response time from the Query Engine to a specific node.

Operands

host.

Specifies the name of the destination host where the SNMP request is sent. The host can be specified with its name or with its IP address in dotted-decimal notation.

Note: The SNMP Query Engine treats numbers with leading zeros as octal numbers. Therefore, do not use leading zeros.

The Query Engine issues one PING (an ICMP echo on a raw socket) and returns the value in milliseconds in an IBM-defined SNMP variable minRTT. For more information about the SNMP PING command, see z/VM: TCP/IP Planning and Customization. Because only one PING is issued, this is also the average and the maximum response time. If the PING does not respond, the Query Engine retries twice, once after 1 second and again after 2 seconds (Query Engine default retry mechanism). If a response is not received after all retries have been exhausted, a variable value of -1 is returned to indicate that a reply was not received.

Usage Notes

- All lines do not need to be present, but the first line is always message SNM040I, and the last line is always message SNM049I. If an error occurs, an error message explains what is wrong.
- 2. If an error is detected, messages SNM042 through SNM044 may not be displayed. You receive error messages (in addition to other messages) in the following form (all as part of multiline message SNM040I).

```
SNM045I Major error code: n
SNM046I Minor error code: y
SNM047I Error index: z
SNM048I Error text: message text
```

See "Major and Minor Error Codes and SNMP Value Types" on page 364 for information about value types and minor and major error codes.

3. One ASN.1 variable name only can be passed for each SNMP MIBVNAME command. Additional parameters are ignored.

Examples

If you know:

nodename - anynode IP address - 129.34.222.72

You can issue the following SNMP PING commands:

SNMP PING ANYNODE SNMP PING 129.34.222.72

The command completes with a message similiar to the following:

SNM050I SNMP Request 1001 from NETOP accepted, sent to Query Engine

When the response arrives in NetView (asynchronously), NetView displays it as a multiline message in the following form:

```
SNM040I SNMP Request 1001 from NETOP Returned the following response:
SNM042I Variable name: 1.3.6.1.4.1.2.2.1.3.2.129.34.222.72
SNM043I Variable value type: 1
SNM044I Variable value: 26
SNM049I SNMP Request 1001 end of response
```

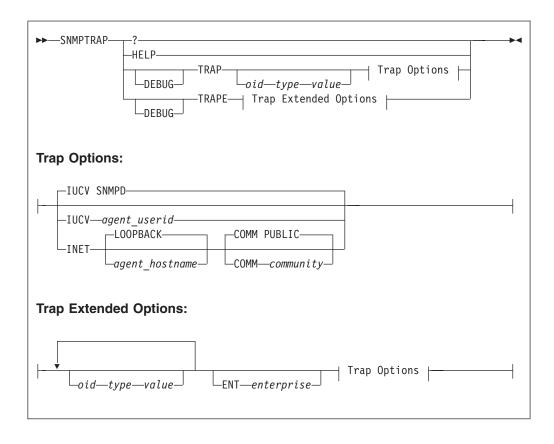

SNMP Native Commands

Traps are unsolicited data messages sent by an SNMP agent to its SNMP managing system. These messages are usually used to inform the managing station about a special condition that has occurred either in an agent system or in the network.

SNMPTRAP is a command line utility for generating SNMP version 1 enterprise-specific traps to report events to the SNMP manager. The SNMPTRAP utility allows you to generate:

- enterprise specific traps
- · extended enterprise specific traps

SNMPTRAP Command

Purpose

Use the SNMPTRAP command to generate a notification (trap) to report an event to the SNMP manager.

Operands

HELP or ?

Invokes output with an explanation about how the SNMPTRAP command is used. You cannot place the HELP or ? operand on the SNMPTRAP command line with any other operands.

DEBUG

Specifies that extra messages are to be printed. DEBUG must be the first operand.

TRAP

Generates an enterprise specific trap (generic trap type is 6 for EnterpriseSpecific) with the following options:

oid

The SNMP OID associated with the specific data for the trap generated.

type

The value of type can be one of the following (which correspond to the types defined in the include file "snmp_dpi.h")

NUMBER integer

STRING hex value of string (each byte is an EBCDIC value)

OID object identifier EMPTY any value (ignored)
IPADDR internet address
COUNTER non-negative integer
GAUGE non-negative integer

TICKS time in 1/100th of seconds since agent initialized TEXT display string (each byte is an ASCII value)

value

Passes data as an additional value for the variable type specified. For STRING and TEXT data with imbedded blanks, see 1. For type EMPTY, a value must be specified on the command line, but it is ignored when the request is created.

TRAPE

Generates an extended enterprise specific trap with the following options:

oid

The SNMP OID associated with the specific data for the trap generated.

type

Same data types as defined for trap above.

value

Passes data values for additional variable bindings. Consists of name-value pairs that further describe the trap notification. For each name-value pair, specify an OID, a value type, and a value. Maximum number of variable bindings is 10.

ENT enterprise

Specifies the object identifier, in dot notation, of this trap. This is valid only with TRAPE. If enterprise is not specified, the SNMP agent will place the value of sysObjectID in the enterprise field of the SNMP Trap-PDU.

IUCV

Specifies that an AF_IUCV socket is to be used to connect to the SNMP agent. The IUCV operand is the default.

agent userid

Specifies the user ID where the SNMP agent (SNMPD) is running. The default is SNMPD.

INET

Specifies that an AF_INET socket is to be used to connect to the SNMP agent.

agent hostname

Hostname or internet address of the SNMP agent generating the trap.

The default is the local host, or loopback address (127.0.0.1).

COMM community

Specifies the community name to get the dpiPort. The default is PUBLIC.

The COMM community option is only valid with INET. The query_DPI_port function is used to obtain the port number on which the DPI capable SNMP agent at the specified host is listening for connections (TCP).

Usage Notes

 Use double quotation marks (") to enclose STRING and TEXT data which contain imbedded blanks. If STRING and TEXT data with imbedded blanks is entered from the CMS command line and your virtual machine's TERMINAL ESCAPE symbol is set to ", you will need to enclose the string data in two

- double quotation marks ("") or change your virtual machine's logical escape symbol using the CP TERMINAL ESCAPE command.
- The target network manager host(s) to which the trap message will be sent is determined by the contents of the SNMPTRAP DEST file. See "Configuring the SNMP Servers" in z/VM: TCP/IP Planning and Customization

Return Code	Description
0	Command Successful
4	Resolver Error
8	Syntax Error
12	Packet Allocation Error
16	Socket Error
100	Command line is too long

Examples

Example 1:

```
snmptrap trap 1.3.6.1.2.1.1.4.1 counter 132 IUCV SNMPD03
```

The example above will send a trap using an AF_IUCV socket to the SNMP agent SNMPD03 that looks like this:

```
version
             = SNMPv1
community
             = public
generic type = 6 (enterpriseSpecific
          = 1.3.6.1.2.1.1.4.1
specific type = 6 (COUNTER)
value
            = 132
```

Example 2:

```
snmptrap trape 1.3 TICKS 12 1.3.7 text "Error 2pm" ent 1.6.7 inet 9.60.2.1 comm test
```

This example will send an extended trap using an AF_INET socket to the SNMP Agent on host 9.60.2.1 that looks like this:

```
version
             = SNMPv1
community
            = TEst
enterprise = 1.6.7
generic type = 6 (enterpriseSpecific)
            = 1.3
specific type = 8 (TICKS)
value = 12
            = 1.3.7
oid
specific type = 9 (TEXT)
           = Error 2pm
value
```

Major and Minor Error Codes and SNMP Value Types

The following are the possible major and minor error codes and variable value types that can be returned in an SNMP response or trap.

The major error code can have one of the following values.

Value **Major Error Code** 0 No error detected 1 SNMP agent reported error Internally detected error

The minor error code can have one of the following values when the major error code indicates that an SNMP agent detected an error.

```
Value
      SNMP Agent Detected Minor Error Code
      No error
```

- 1 Too big
- 2 No such name
- 3 Bad value
- 4 Read only
- 5 General error
- The minor error code can have one of the following values when the major error code indicates that an internal error was detected.

Value Internal Minor Error Code 0 No error 1 Protocol error 2 Out of memory 3 No response—all retries failed

- 4 Some I/O error occurred
- 5 Illegal request
- 6 Unknown host specified
- 7 Unknown MIB variable
- 8 No such filter
- 9 Too many variables specified
- · If the major error code indicates that an SNMP agent detected the error, the error index indicates the position of the first variable in error.
- The variable value type is one of the following (as specified in RFC 1155 and RFC 1156).

Value	Value Type
0	Text representation
1	Number (integer, signed)
2	Binary data string
3	Object identifier
4	Empty (no value)
5	Internet address
6	Counter (unsigned)
7	Gauge (unsigned)
8	Time ticks (1/100ths seconds)
9	Display string

Note: The binary data string is displayed in NetView as a contiguous string of hexadecimal characters (for example, X'0123' is displayed as 0123).

qethostbyname()

When a host name is specified with an SNMP request, the SNMP Query Engine looks up the IP address of that host. It uses the standard gethostbyname() function to perform that function. The IP address is then saved in an in-memory cache for future references. For more information about gethostbyname(), see z/VM: TCP/IP Programmer's Reference.

The cache cannot be refreshed, and if for some reason the mapping between host names and IP addresses changes, the SNMP Query Engine (the SQESERV module) has to be restarted to rebuild its cache. This is also true for a host name that was found to be nonexistent at the time of the first SNMP request, but which has been added to the name server database.

This gives a performance boost to subsequent requests for the same host.

Chapter 13. Using the Domain Name System

This chapter describes the domain name system (DNS), resolvers, and resource records. This chapter also provides descriptions of the NSLOOKUP and DIG programs used to query name servers.

Overview of the Domain Name System

The TCP/IP for z/VM DNS is comprised of only resolver application programs. For more information about these services, see "Resolvers" on page 369. Configuring these services is described in *z/VM: TCP/IP Planning and Customization*. "Domain Name Servers" on page 368 provides general information about the servers that are part of a Domain Name System.

TCP/IP applications map domain names to an internet address to identify network nodes. Mapping must be consistent across the network to ensure interoperability. The DNS provides this mapping, through network nodes called domain name servers. The DNS can provide additional information about nodes and networks, including the TCP/IP services available at a node and the location of name servers in a network.

The DNS defines a special domain called in-addr.arpa to translate internet addresses to domain names. An in-addr.arpa name is composed of the reverse octet order of an IP address concatenated with the in-addr.arpa string. For example, a host named Host1 has 9.67.43.100 as an internet address. The in-addr.arpa domain translates the host1 internet address 9.67.43.100 to 100.43.67.9.in-addr.arpa.

For a complete description of the DNS, see RFC 1033, RFC 1034, and RFC 1035, which define the internet standard.

Domain Names

The DNS uses a hierarchical naming convention for naming hosts. Each host name is composed of domain labels separated by periods. Local network administrators have the authority to name local domains within an internet. Each label represents an increasingly higher domain level within an internet. The fully qualified domain name of a host connected to one of the larger internets generally has one or more subdomains.

For example:

host.subdomain.subdomain.rootdomain or host.subdomain.rootdomain

Domain names often reflect the hierarchy level used by network administrators to assign domain names. For example, the domain name eng.mit.edu. is the fully qualified domain name where eng is the host, mit is the subdomain, and edu is the highest level domain (root domain).

Figure 66 on page 368 is an example of the DNS used in the hierarchy naming structure across an internet.

© Copyright IBM Corp. 1987, 2011 367

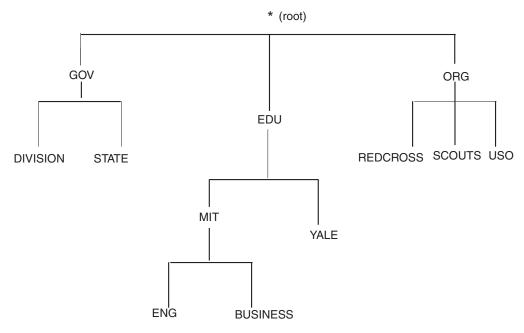

Figure 66. Hierarchical Tree

You can refer to hosts in your domain by host name only; however, a name server requires a fully qualified domain name. The local resolver appends the domain name before sending the query to the domain name server for address resolution.

Domain Name Servers

Domain name servers are designated network nodes that maintain a database of information about all nodes in a zone. The complete database is not kept by any one name server on a network. A name server has a zone of authority that is a subnetwork, or a group of subnetworks, for which the name server maintains a database. A name server is authoritative only within its zone of authority.

To minimize dependency on a particular node, the name server's database for a zone is replicated at several nodes. At least one of the nodes is designated as the primary name server. The others are secondary name servers. The zone data updates and maintenance are reflected in the primary name server. The secondary name servers update their database by contacting the primary name server at regular intervals. Both primary and secondary name servers are authoritative for a zone.

The zones of authority are arranged in a hierarchy based on the domain origin components. A special zone known as the root exists at the top of the domain name hierarchy in a network. The root zone contains a list of all the root servers. For example, in the internet, the root name servers store information about nodes in the root domain, and information about the delegated domains, such as com (commercial), edu (education), and mil (military). The root name servers store the names of name servers for each of these domains, which in turn store the names of name servers for their delegated subdomains.

TCP/IP applications contact a name server whenever it is necessary to translate a domain name into an internet address, or when information is required about a domain. The name server performs the translation if it has the necessary information. If it does not have the necessary information, the name server can contact other name servers, which in turn can contact other name servers. This

process is called a recursive query. Alternatively, a name server can simply return the address of another name server that might hold the requested information. This is called a referral response to a query. Name server implementations must support referrals, but are not required to perform recursive queries. For more information about query responses, see "Resolvers."

Some name server implementations maintain a cache of query responses sent out to other name servers on behalf of clients. This improves the processing speed for queries about domain names outside the server's zone of authority. However, responses derived from cached information are considered nonauthoritative and are flagged as such in the response.

The Network Information Center (NIC) is responsible for network and user registration, including network number, top-level domain name assignment, and in-addr.arpa zone assignment. For more information contact:

```

```

Resolvers

TCP/IP provides three programs for interactively querying a name server:

- NSLOOKUP
- DIG
- A CMS command interface (CMSRESOL)

For more information about these programs, see "NSLOOKUP—Querying Name Servers" on page 373, "DIG—Querying Name Servers" on page 393, and "CMSRESOL—Resolver and Name Server" on page 405.

Programs that query a name server are called resolvers. Because many TCP/IP applications need to query the name server, a set of routines is usually provided for application programmers to perform queries. Under z/VM, these routines are available in the TCP/IP application programming interface (API) for each supported language.

Resolvers operate by sending query packets to a name server, either over the network or to the local name server.

A query packet contains the following fields:

- · a domain name
- · a query type
- a query class

"Resource Records" on page 370 lists valid query class (network class) and query type (data type) records. The name server attempts to match the three fields of the query packet to its database.

The name server can return the following query responses:

Response	Description
Authoritative	Returned from a primary or secondary name server. The name server contains all the domain data used to define the zone for the specified query.

Nonauthoritative

Returned from a cache kept by a name server. The cache does not contain the domain data used to define the zone for the specified

query.

Referral Contains the addresses of other name servers that can answer the

query. A referral response is returned when a recursive query is not

supported, not requested, or cannot be answered because of

network connectivity.

Negative Indicates that no records of the requested type were found for the

domain name specified, if returned from an authoritative name

server.

Name Error Indicates that no resource records of any type (including wildcards)

exist for the domain name specified.

Format Error Indicates that the name server found an error in the query packet

sent by the resolver.

Not-implemented

Indicates that the name server does not support the type of query

requested.

Refused Indicates that the name server refuses to perform the specified

operation. For example, some root name servers limit zone

transfers to a set number of IP addresses.

Data from a name server is stored and distributed in a format known as a resource record. Resource record fields are described in detail in "Resource Records." Each response from a name server can contain several resource records that can contain a variety of information. The format of a response is defined in RFC 1035, and includes the following sections:

- A question section, echoing the query for which the response is returned.
- An answer section, containing resource records matching the query.
- An additional section, containing resource records that do not match the query, but might provide useful information for the client. For example, the response to a guery for the host name of a name server for a specific zone includes the internet address of that name server in the additional section.
- · An authority section, containing information specific to the type of response made to the query. If a referral is returned, this section contains the domain names of name servers that could provide an authoritative answer. If a negative response is returned indicating the name does not exist, this section contains a Start Of Authority (SOA) record defining the zone of authority of the responding name server.

Resource Records

Resource records are name server database records. These records contain the following fields, in order:

Field	Description
Domain name	Specifies the domain name identifying a network object. A network object can be a network, a specific node, a mailbox (for a network user's mail), or other objects addressable by the DNS.
TTL	Indicates the number of seconds that a record is valid in a cache.
Network class	Specifies the network class. The allowable values are:

CHAOS CHAOS system (obsolete)

HESIOD Hesiod class

IN The internet (most Domain Name Systems support

only the internet (IN) class)

The wildcard value ANY is defined to match any of these classes.

Data type

Indicates the type of data record. The following is a list of valid record types:

SOA Start of authority record

> The SOA record is unique to a zone. This record contains the administrative details of the zone. including:

- · The domain name of the name server responsible for the zone
- The mail address of the user responsible for the
- · The serial number of the zone database, which identifies the current revision of the data
- The refresh interval, which indicates the length of time, in seconds, you must allow between the refreshing of a database from a remote name server
- The retry interval, which indicates the length of time, in seconds, you must allow before retrying a failed refresh
- The expiration TTL, which indicates the maximum time, in seconds, for records to be valid in the zone database
- · The minimum TTL, which indicates the minimum time, in seconds, for records to be valid in the zone database

NS Name server record

> The name server record contains the domain name of a name server for the current zone.

Address record Α

> The address record contains the dotted-decimal notation internet address for the domain name identifying the record.

CNAME Canonical name record

> The canonical name record is used to provide alias or alternative name information for a domain name. The domain name specified in the first field of the record is an alternative to the canonical or real domain name specified in the data field.

HINFO Host Information Record

> This record type contains a text string specifying the CPU (central processing unit) type and operating system of a node.

MB The mailbox record (experimental)

> The mailbox record contains the domain name of a host machine to receive mail for the user specified

in the domain name field.

Mail group member record (experimental) MG

> The mail group member record specifies the mail address of a person belonging to the mail group

specified in the domain name field.

MINFO Mailbox information record (experimental)

> The mailbox information record specifies the mail addresses of the persons responsible for the mail

group specified in the domain name field.

MR Mail rename name record (experimental)

> The mail rename name record specifies a mailbox that is a rename of the mailbox specified in the

domain name field.

MX Mail exchanger record

> The mail exchanger record identifies a host able to act as a mail exchange for the domain specified in the domain name field. A mail exchange runs a mail agent that delivers or forwards mail for the domain

name specified in the first field.

NULL Null resource record (experimental)

> The null resource record contains any information, providing it is less than 65 535 octets in length.

PTR Domain name pointer record

> The domain name pointer record is mainly used to store data for the in-addr.arpa domain, and contains the domain name referenced by an

internet address.

TXT Text string record

The text string record contains descriptive text.

Well-known services record **WKS**

> The well-known services record stores the protocol numbers of multiple services in a single record. Each of the defined TCP/IP services has a unique protocol number. For more detailed information, see

RFC 1060.

For flexibility, the following wildcard query data are defined:

ANY Any record type for the domain name

AXFR The guery type used by secondary name servers to

transfer all records in the zone (the query class is

set to IN when using the AXFR query type)

MAILB Any mailbox records for the domain name.

Data Contains information appropriate for the data type indicated in the

data type field, in the format defined for that specific data type.

NSLOOKUP—Querying Name Servers

NSLOOKUP is a program for querying name servers. The NSLOOKUP program allows you to:

- · Locate information about network nodes
- Examine the contents of a name server database
- · Establish the accessibility of name servers

Note: Currently, NSLOOKUP supports IPv4 only.

NSLOOKUP Internal State Information

The internal state information of NSLOOKUP determines the operation and results of your name server queries. The following list shows (in order) the places where the code checks for state information:

- 1. TCP/IP client program configuration file, TCPIP DATA
- 2. NSLOOKUP startup file, NSLOOKUP ENV
- 3. NSLOOKUP subcommands in command line mode
- 4. NSLOOKUP subcommands in interactive session mode

NSLOOKUP retains the last value set by any one of the items in the list. This means you can configure the internal state information of NSLOOKUP according to the last value set by any one of the items.

For more information about the TCPIP DATA file, see z/VM: TCP/IP Planning and Customization.

After parsing the command line, NSLOOKUP attempts to read the startup file, NSLOOKUP ENV. This file contains NSLOOKUP set subcommands only, which define the NSLOOKUP defaults. Enter each **set** subcommand on a separate line: blank lines are not accepted. For more information about set subcommands available in NSLOOKUP, see "NSLOOKUP set Subcommands" on page 381.

The following is an example of the contents of the NSLOOKUP ENV file:

set domain=powers.oz querytype=HINFO set norecurse ٧C

Note: Specifying set before the NSLOOKUP subcommands in the NSLOOKUP ENV file is optional.

NSLOOKUP Command

Using the NSLOOKUP command line mode: (2) -NSLOOKUP domain_address (1) -domain name--server address -server name set subcommand Starting an NSLOOKUP interactive session: (2) -NSLOOKUP (1) -server address set subcommand--server name Using the NSLOOKUP interactive session mode: Enter (2) -interactive subcommand -set—set subcommand-Notes: Space is not allowed between the dash (-) and the set subcommand. 1

2 NSLOOKUP operands and subcommands are case sensitive and must be entered in lowercase. Operand and subcommand values and domain names are not case sensitive.

Purpose

Use the NSLOOKUP command to issue a single name server query in command line mode or multiple name server queries in interactive session mode.

Operands

set subcommand

Specifies an NSLOOKUP set subcommand. For available set subcommands, see "NSLOOKUP set Subcommands" on page 381.

interactive subcommand

Specifies an NSLOOKUP interactive session subcommand. For available interactive session subcommands, see "NSLOOKUP Interactive Session Subcommands" on page 376.

domain address

Reverses the components of the address, and generates a pointer type (PTR) query to the name server for the in-addr.arpa domain mapping of the address to a domain name.

domain name

Queries the name server for information about domain name using the current query type. The default query type is A (address query).

server address

Specifies the internet address of the name server to be queried other than the default name server. A query for the address in the in-addr.arpa domain is initially made to the default name server to map the internet address to a domain name for the server.

server name

Directs the default name server to map server name to an internet address and then uses the name server at that internet address.

Usage Notes

- 1. You must specify the host name or internet address of the host where the agent is running, as well as the community name to be used. The community name used for a SET request is frequently different than the community name for a GET request. You must specify the names and values of each variable to be set. RFC 1156 and RFC 1158 define the variables that you can set with read-write access. In addition, there may be enterprise-specific variables as defined by the implementer of a particular SNMP agent.
- 2. If the NSLOOKUP ENV file exists, the set subcommands are read from the file and executed before any queries are made. For more information about configuring NSLOOKUP internal state information using the NSLOOKUP ENV file, see "NSLOOKUP Internal State Information" on page 373.
- 3. NSLOOKUP interprets typing or syntax errors as queries. This results in a query being sent and the name server response displayed. The response is usually Non-existent Domain, which indicates that the server could not find a match for the query.
- 4. A timeout occurs if the name server is not running or is unreachable.
- 5. A Non-existent Domain error occurs if any resource record type for the specified domain name is not available from the name server.
- 6. A Server Failed error occurs when the local name server cannot communicate with the remote name server.
- 7. NSLOOKUP performs a query for the domain specified. The query requests all information about the domain using the current class and query (resource record) type. You can specify a server other than the current server to perform the domain name resolution.
- 8. In interactive session mode, an initial query is made to the selected name server to verify that the server is accessible. All subsequent interactive queries are sent to that server, unless you specify another server using the set server or set Iserver subcommands.
- 9. You can make a guery by entering the domain name of the node or subnetwork for which information is required and define the data type of information to be retrieved using the **set querytype** subcommand. You can define only one type of resource record for a domain name in a single query, unless the wildcard query type of any has been set.
- 10. Queries processed by NSLOOKUP that specify an address can give unexpected results. If the current query type is address (A) or domain name pointer (PTR), NSLOOKUP generates a PTR type guery for the specified address in the in-addr.arpa domain. This returns PTR records, which define the host name for the specified address. If the current query type is neither of these two types, a query is performed using the current query type, with the domain name specified as the address given.

NSLOOKUP Command

- 11. NSLOOKUP does not issue a guery for a domain name if the name is unqualified and is the same as one of the defined options.
- 12. A name server often requires a fully qualified domain name for queries. However, NSLOOKUP allows the specification of a default subnetwork domain using the set domain subcommand, with the initial default obtained from the TCPIP DATA file. When **defname** is enabled, using the **set defname** subcommand, the default domain name specified by set domain is appended to all unqualified domain names. For example, if the default domain name is fourex.oz and defname is enabled, a query for the name toolah automatically generates a query packet containing the domain name toolah.fourex.oz.
- 13. The domain name or address for a query can be followed by the domain name or internet address of a name server to contact for the query. If this is not specified, the current name server is used. For example, toolah wurrup.fourex.oz queries the name server on wurrup.fourex.oz for information about the node toolah.
- 14. When specifying domain names that include periods, the trailing period (indicating a fully qualified domain name) is optional. NSLOOKUP strips the trailing period if it is present. If you are specifying a root domain, the domain name must have two trailing periods. For example, specify mynode.. when the node mynode is in the root domain.

Examples

When you specify NSLOOKUP set subcommands in command line mode, do not use **set** preceding the subcommand. For example, to specify a name server (NS) type record lookup for the domain name fourex.oz, enter the following on the command line:

nslookup -querytype=ns fourex.oz

The option -querytype=ns is a set subcommand, but set is omitted from the command. For more information about using set subcommands, see "NSLOOKUP set Subcommands" on page 381.

NSLOOKUP Interactive Session Subcommands

The NSLOOKUP subcommands explained in this topic can be used during an NSLOOKUP interactive session. For more information on starting and using an NSLOOKUP interactive session, see "NSLOOKUP Command" on page 374.

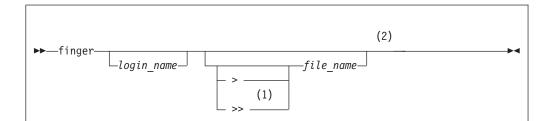

exit

NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the exit interactive session subcommand to exit from interactive session mode.

finger

Notes:

- 1 There must be at least one space before and after the > and >> operands.
- 2 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **finger** interactive session subcommand to extract information from the finger server of the host found in the last address query.

Operands:

login name

The login name of the user for which to return information about. The login name is case sensitive and must be specified in the same case (upper or lower) as that used by the host.

- Specifies that the output will overwrite the contents of the file specified by file_name.
- >> Specifies that the output will be appended to the contents of the file specified by file_name.

file name

The file name of the file where output will be written for later viewing.

Usage Notes:

- 1. By default, a list of users logged in on the host last queried is returned. Specify a user's login name to return information about a specific user.
- 2. The **finger** subcommand expects that the finger server is operating on the host found in the last address query. An error message is displayed if the finger server is not operating or if the host cannot be reached.
- 3. If a current host is not defined, querying the name server defines that name server to be the current host for a subsequent finger operation.
- 4. An error message is displayed if the preceding subcommand was not a successful address query or finger operation.

help / ?

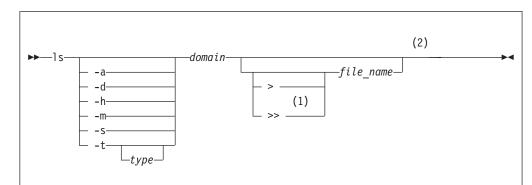

Notes:

NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the help or ? interactive session subcommand to display a brief summary of subcommands.

Is

Notes:

- There must be at least one space before and after the > and >> operands. 1
- 2 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **Is** interactive session subcommand to list the information available for the specified domain.

Operands:

- -a Retrieves the CNAME resource record.
- -d Retrieves the ALL resource record.
- -h Retrieves the HINFO resource record.
- -m Retrieves the MX resource record.
- -s Retrieves the WKS resource record.
- -t

type

Retrieves the resource record type specified by type. If no record type is specified, the current default type is used. For more information on valid resource record field types, see "Data type" on page 371.

doma i.n

The domain name zone to be queried.

- > Specifies that the output will overwrite the contents of the file specified by *file_name*.
- >> Specifies that the output will be appended to the contents of the file specified by file_name.

file name

The file name of the file where output will be written for later viewing.

Usage Notes:

 The Is subcommand works correctly only if the name server is configured using the one-answer zone transfer format. If the name server sends multiple answer records, the DIG command can be used to correctly process the zone transfer. Use the DIG command AXFR query type option to perform the zone transfer. For example:

DIG @nameserver domain AXFR

where *nameserver* is the host name or internet address of your name server and *domain* is the domain name.

- The **Is** subcommand creates a virtual circuit (TCP/IP connection) with the current name server to service the request. An error message is displayed if the virtual circuit cannot be established.
- 3. An error message is displayed and no information is listed if the domain name specified by *domain* refers to a host.
- 4. If the output is being written to a file, a number sign (#) is displayed as every 50 lines of output are written to the file to indicate the command is still processing.

Iserver

Notes:

1 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **Iserver** interactive session subcommand to change the current name server.

Operands:

address

name

The new name server internet address (address) or host name (name).

Usage Notes:

NSLOOKUP Command

- 1. If a host name is specified, the internet address is resolved using the initial name server defined at command invocation. An error will occur when the host name cannot be mapped to an internet address.
- 2. The Iserver subcommand does not verify that you can contact the name server at the specified address; it simply changes a local variable storing the address of the default name server.

root

Notes:

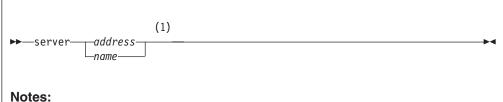

NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the root interactive session subcommand to change the current name server to the root name server.

Usage Notes:

- 1. The default root name server is ns.nic.ddn.mil. To change the default root name server, use the set root subcommand (which is equivalent to Iserver name). For more information on using the set root subcommand, see "NSLOOKUP set Subcommands" on page 381.
- 2. An error will occur if the root name server internet address cannot be resolved.
- 3. The **root** subcommand does not verify that you can contact the name server at the defined address; it simply changes a local variable storing the address of the default root name server.

server

NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the server interactive session subcommand to change the current name server.

Operands:

address name

The new name server internet address (address) or host name (name).

Usage Notes:

- 1. If a host name is specified, the internet address is resolved using the current name server. An error will occur when the host name cannot be mapped to an internet address.
- The server subcommand does not verify that you can contact the name server at the specified address; it simply changes a local variable storing the address of the default name server.

view

Notes:

1 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **view** interactive session subcommand to sort and list the contents of a file one screen at a time.

Operands:

file name

The file name of the file of which the contents will be sorted and listed. An error occurs if the file does not exists.

NSLOOKUP set Subcommands

Internal state information affects the operation and results of your queries. You can change the internal state information maintained by NSLOOKUP using the NSLOOKUP set subcommands. Some internal state information is initially retrieved from the TCPIP DATA file. For more information about the TCPIP DATA file, see *z/VM: TCP/IP Planning and Customization*. For more information about configuring NSLOOKUP internal state information, see "NSLOOKUP Internal State Information" on page 373.

The NSLOOKUP **set** subcommands explained in this topic can be used on the command line, during an NSLOOKUP interactive session, or in the NSLOOKUP ENV file. When NSLOOKUP **set** subcommands are specified in a command line query, you must omit "set"; preceding the subcommand. If the NSLOOKUP **set** subcommands are specified in an interactive session query, "set" is required. In the NSLOOKUP ENV file, specifying "set" is optional.

For more information on using an NSLOOKUP command line session or starting and using an NSLOOKUP interactive session, see "NSLOOKUP Command" on page 374.

set all

Notes:

- Omit set when using the NSLOOKUP command line mode.
- 2 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set all subcommand to display the current values of the internal state variables.

Usage Notes:

The set all subcommand does not alter the internal state of NSLOOKUP.

set class

Notes:

- Omit set when using the NSLOOKUP command line mode.
- 2 Space is not allowed between the equal sign (=) and class.
- 3 The minimum abbreviation for this subcommand is cl.
- NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set class subcommand to change the class of information returned by a query.

Operands:

class

The class mnemonic for the class of information to be returned by a query. For more information about classes recognized by NSLOOKUP, see the resource record field, "Network class" on page 370.

set d2 / set nod2

Notes:

- Omit set when using the NSLOOKUP command line mode. 1
- 2 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set d2 subcommand to enable extra debugging mode.

Use the **set nod2** subcommand to disable extra debugging mode.

Usage Notes:

- Extra debugging mode is disabled by default.
- Debug mode is also enabled when using the set d2 subcommand.

set debug / set nodebug

Notes:

- 1 Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for these subcommands are **deb** and **nodeb**.
- NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **set debug** subcommand to enabled debugging mode.

Use the **set nodebug** subcommand to disable debugging mode.

Usage Notes:

- 1. Debug mode is disabled by default.
- 2. Extra debugging mode is also disabled when using the set nodebug subcommand.

set defname / set nodefname

Notes:

- 1 Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for these subcommands are **def** and **nodef**.
- 3 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set defname subcommand to enable appending the default domain name to an unqualified domain name in a guery.

Use the **set nodefname** subcommand to disable appending the default domain name to an unqualified domain name in a query. That is, the specified domain name is passed to the name server without modification.

Usage Notes:

- 1. The default domain name is initially obtained from the TCPIP DATA file, but can be changed using the set domain subcommand. For more information on using the set domain subcommand, see "set domain."
- 2. Appending the default domain name to an unqualified domain name is enabled by default.

set domain

Notes:

- 1 Omit **set** when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for this subcommand is **do**.
- 3 Space is not allowed between the equal sign (=) and name.
- 1 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set domain subcommand to change the default domain name. In addition, the search list is updated to contain only the domain name specified.

Operands:

name

The domain name to be used as the default domain name. The value specified is not verified. The default domain name is initially obtained from the TCPIP DATA file.

set ignoretc / set noignoretc

Notes:

- 1 Omit **set** when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for these subcommands are **ig** and **noig**.
- 3 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the **set ignoretc** subcommand to direct NSLOOKUP to ignore the truncation indicator when it is set in a name server response.

Use the **set noignoretc** subcommand to direct NSLOOKUP to automatically try the query again, using a TCP connection, when a response is sent with the truncation indicator set.

The truncation indicator, in the response header, is set by the name server when a complete query response did not fit into a single UDP packet and has been truncated.

Usage Notes:

- NSLOOKUP does not handle responses greater than 512 characters in length.
 Responses greater than 512 characters are truncated and the internal truncation
 flag is set. This condition is revealed only when debugging mode is enabled.
 For more information on enabling debugging mode, see "set debug / set
 nodebug" on page 383.
- 2. The truncation indicator is ignored by default.

set port

Notes:

- Omit set when using the NSLOOKUP command line mode. 1
- 2 The minimum abbreviation for this subcommand is **po**.
- 3 Space is not allowed between the equal sign (=) and port.
- NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

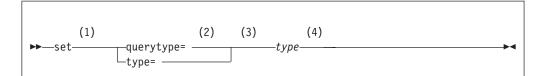

Purpose: Use the set port subcommand to change the default port used to contact a name server.

Operands:

port

The port number to be used as the default port for contacting a name server. The default port used by NSLOOKUP for contacting a name server is port 53.

set querytype / set type

Notes:

- 1 Omit **set** when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for this subcommand is q.
- 3 Space is not allowed between the equal sign (=) and type.
- 4 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set querytype or set type subcommand to change the type of information to be returned by a name server query.

Operands:

type

The query type to be used when querying a name server. The default query type is "A" (address information). For more information about query types recognized by NSLOOKUP, see the resource record field, "Data type" on page 371.

Usage Notes:

- 1. Only one query type can be specified.
- 2. NSLOOKUP cannot generate type NULL queries. In this case, NSLOOKUP displays the number of bytes returned in the NULL record.
- 3. Global queries that return all resource records for a specific domain name are specified by the wildcard value ANY.

set recurse / set norecurse

Notes:

- 1 Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for these subcommands are **rec** and **norec**.
- 3 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set recurse subcommand to request a recursive guery when querying a name server.

Use the **set norecurse** subcommand to request a non-recursive query when querying a name server.

Usage Notes:

1. Recursive queries are returned by default.

set retry

Notes:

- 1 Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for this subcommand is **ret**.
- 3 Space is not allowed between the equal sign (=) and *limit*.
- 4 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set retry subcommand to change the number of times a request is resent.

Operands:

limit

The number of repeat attempts to send a request to a name server. That is, when a request is sent and the timeout period expires, the request is resent until the specified limit has been exceeded. The default limit is initially obtained from the TCPIP DATA file.

Usage Notes:

- 1. Setting the limit to zero disables NSLOOKUP from contacting the name server. The result is the following message: no response from server.
- 2. The NSLOOKUP retry algorithm uses both a limit and a timeout period. The timeout period for each resent request is twice the timeout period of the previous request.

set root

Notes:

- 1 Omit **set** when using the NSLOOKUP command line mode.
- 2 Space is not allowed between the equal sign (=) and name.
- 3 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set root subcommand to change the domain name of the root server.

Operands:

name

The domain name of the new root server. The default root server is ns.nic.ddn.mil.

set search / set nosearch

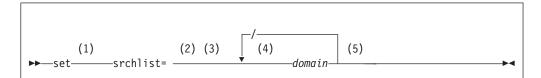

Notes:

- 1 Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for these subcommands are sea and nosea.
- NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set search subcommand to enable the use of a search list.

Use the set nosearch subcommand to disable the use of a search list.

set srchlist

Notes:

- Omit set when using the NSLOOKUP command line mode.
- 2 The minimum abbreviation for this subcommand is **srchl**.
- 3 Space is not allowed between the equal sign (=) and domain.
- 4 A maximum of three domains can be specified. Each domain is separated by a forward slash (/).
- 5 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set srchlist subcommand to specify up to three domain names to be appended to unqualified host names when attempting to resolve the host name.

Operands:

Specifies the domain name to be appended to unqualified host names. Each domain name specified is tried, in turn, until a match is found.

Usage Notes:

1. This subcommand changes the default domain to be the first domain name specified in the search list.

set timeout

Notes:

- Omit set when using the NSLOOKUP command line mode. 1
- 2 The minimum abbreviation for this subcommand is t.
- 3 Space is not allowed between the equal sign (=) and interval.
- NSLOOKUP subcommands are case sensitive and must be entered in 4 lowercase. Subcommand values and domain names are not case sensitive.

NSLOOKUP Command

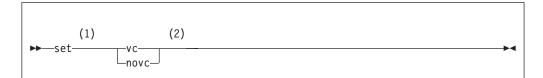

Purpose: Use the set timeout subcommand to change the number of seconds to wait before a request times out.

Operands:

interval

Number of seconds to wait before a request times out. The default interval is initially obtained from the TCPIP DATA file.

set vc / set novc

Notes:

- Omit set when using the NSLOOKUP command line mode.
- 2 NSLOOKUP subcommands are case sensitive and must be entered in lowercase. Subcommand values and domain names are not case sensitive.

Purpose: Use the set vc subcommand to enable the use of a virtual circuit (TCP connection) to transport queries to the name server.

Use the set novc subcommand to disable the use of a virtual circuit (TCP connection) to transport queries to the name server and instead use datagrams (UDP).

Usage Notes:

1. The default setting is retrieved from the TCPIP DATA file. If no entry is found, the default is to use datagrams (UDP).

NSLOOKUP Examples

This section contains examples of NSLOOKUP command line mode queries, and interactive session mode queries using the various options available for NSLOOKUP commands.

In Figure 67 on page 391, the router, wurrup, has two internet addresses and there are two name servers, wurrup being the primary name server. This network is described by a single zone in the domain naming hierarchy stored in the name servers. The domain name is fourex.oz.

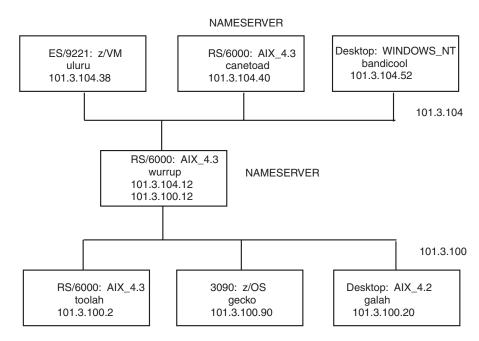

Figure 67. A TCP/IP Network

The following are examples of how to use NSLOOKUP to extract information from a name server. The queries are executed from the z/VM host uluru at IP address 101.3.104.38 on the network described in Figure 67.

The following examples are command line mode gueries.

1. To make a simple address query:

```
User: nslookup toolah.fourex.oz wurrup.fourex.oz
System: Server: wurrup
Address: 101.3.104.12

Name: toolah.fourex.oz
Address: 101.3.100.2
```

2. To specify a name server (NS) type record lookup:

```
User: nslookup -query=ns fourex.oz
System: Server: canetoad
Address: 101.3.104.40

fourex.oz nameserver = wurrup.fourex.oz
fourex.oz nameserver = canetoad.fourex.oz
wurrup.fourex.oz internet address = 101.3.100.12
wurrup.fourex.oz internet address = 101.3.104.12
canetoad.fourex.oz internet address = 101.3.104.40
```

The following command places NSLOOKUP in interactive session mode with wurrup as the default server.

```
User: nslookup - wurrup
System: Default Server: wurrup
Address: 101.3.104.12
```

The following examples are all in the interactive session mode initiated in the preceding example.

1. Show the default flag settings:

```
User: set all
System: >; Default Server: wurrup
Address: 101.3.104.12
```

```
Set options:
              nodebug
                             defname
                                             nosearch
                                                             recurse
              nod2
                             novc
                                                             port=53
                                             noignoretc
              querytype=A
                             class=IN
                                             timeout=60
                                                             retry=1
              root=ns.nic.ddn.mil
              domain=FOUREX.OZ
              srchlist=FOUREX.OZ
2. Perform a simple address query:
      User:
              toolah
              >; Server: wurrup
    System:
              101.3.104.12
   Address:
                      toolah.FOUREX.OZ
              Name:
              Address: 101.3.100.2
3. Set the query record type to HINFO, and perform another query:
              set q=HINFO
      User:
              toolah
    System:
              >; >; Server: wurrup
   Address:
             101.3.104.12
              toolah.FOUREX.OZ CPU = RS6000
                                                 OS = AIX3.2
4. Find out the name servers available for a domain:
      User:
              set q=NS
              fourex.oz
    System:
              >; >; Server: wurrup
   Address:
              101.3.104.12
              fourex.oz nameserver = wurrup.fourex.oz
              fourex.oz nameserver = canetoad.fourex.oz
              wurrup.fourex.oz internet address = 101.3.100.12
              wurrup.fourex.oz internet address = 101.3.104.12
              canetoad.fourex.oz internet address = 101.3.104.40
5. Change the current server from wurrup to canetoad and make more queries:
      User:
              server canetoad
              >; Default Server: canetoad.fourex.oz
    System:
            101.3.104.40
   Address:
      User:
              set q=A
              gecko
    System:
              >; Server: canetoad.fourex.oz
   Address:
              101.3.104.40
                      gecko.fourex.oz
              Name:
              Address: 101.3.100.90
6. Enable debugging and execute a simple query to see the result, and then
   disable debugging:
      User:
              set deb
              wurrun
    System:
              >; >; Server: canetoad.FOUREX.OZ
   Address:
              101.3.104.40
              res mkquery(0, wurrup.FOUREX.OZ, 1, 1)
              Got answer:
                 HEADER:
                    opcode = QUERY, id = 7, rcode = NOERROR
                    header flags: response, auth. answer, want recursion,
                    recursion avail
                    questions = 1, answers = 2, authority records = 0,
                    additional = 0
```

```
QUESTIONS:
    wurrup.FOUREX.OZ, type = A, class = IN

ANSWERS:
    ->; wurrup.FOUREX.OZ
    internet address = 101.3.104.12
    ttl = 9999999 (115 days 17 hours 46 mins 39 secs)
    ->; wurrup.FOUREX.OZ
    internet address = 101.3.100.12
    ttl = 9999999 (115 days 17 hours 46 mins 39 secs)

Name: wurrup.FOUREX.OZ
    Addresses: 101.3.104.12, 101.3.100.12

User: set nodeb
```

7. Find all addresses in the fourex.oz domain using the **Is** subcommand:

```
1s fourex.oz
          >; canetoad.FOUREX.OZ
System:
          fourex.oz
                                        server = wurrup.fourex.oz
                                        101.3.100.12
          wurrup
                                        101.3.104.12
          wurrup
          fourex.oz
                                        server = canetoad.fourex.oz
          canetoad
                                        101.3.104.40
          gecko
                                        101.3.100.90
                                         101.3.100.12
          wurrup
          wurrup
                                         101.3.104.12
                                         101.3.100.20
          galah
          bandicoot
                                         101.3.104.52
                                         101.3.100.2
          toolah
                                         101.3.104.40
          canetoad
          1oopback
                                         127.0.0.1
          uluru
                                         101.3.104.38
```

8. Find all aliases in the fourex.oz domain, then exit from NSLOOKUP interactive session mode:

```
User: ls -a fourex.oz
System: >; canetoad.FOUREX.OZ
```

localhost loopback.fourex.oz infoserver wurrup.fourex.oz pabxserver wurrup.fourex.oz

DIG—Querying Name Servers

DIG is a program for querying domain name servers. The DIG program allows you to:

Exercise name servers

User:

- Gather large volumes of domain name information
- · Execute simple domain name queries

Note: Currently, DIG supports IPv4 only.

DIG Internal State Information

The internal state information of DIG determines the operation and results of your name server queries. You can configure the internal state information of DIG using the following methods, listed in order of precedence:

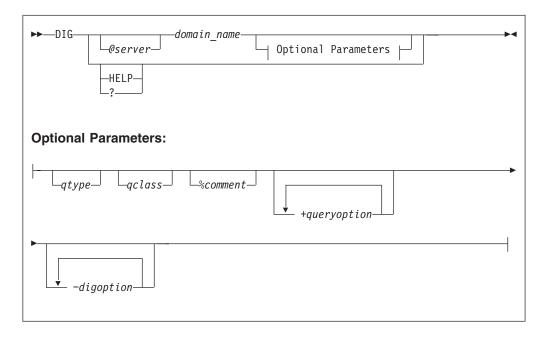

- TCP/IP client program configuration file, TCPIP DATA
- DIG startup file, DIG ENV
- · Query options on the command line or in a batch file

The DIG ENV file contains a list of query option defaults. This list is initialized from the DIG ENV file when DIG is invoked. The default values in DIG ENV are used for

all queries unless overridden by query flags on the command line. The defaults can be reset during a batch run by using the -envset flag on a batch file line. For more information about the query options available for DIG, see "Query Options" on page 395.

The DIG ENV file is created and updated using the -envsav option, which writes the current defaults out to the file after parsing the query options on the command line. The -envsav option specified on the command line and the existing default values are saved in the DIG ENV file as the default environment for future invocations of DIG. The DIG ENV file is not reread when the environment is updated during batch queries and the -envsav flag has no effect on subsequent queries in a batch file. The DIG ENV file is written in nontext format and cannot be viewed or edited.

DIG Command

Note: The queryoption and digoption parameters are case sensitive and must be entered in lowercase. Domain names, query types, query classes, and the values associated with queryoption and digoption parameters are not case sensitive.

Purpose

Use the DIG command to query a domain name server in command line mode or batch mode.

Operands

server

Specifies the domain name or internet address of the name server to contact for the query. The default is the name server specified in the TCPIP DATA file.

If a domain name is specified, DIG uses the resolver library routines provided in the TCP/IP for VM programming interface to map the name to an internet address.

HELP

Provides help information about the DIG command. You cannot place the HELP operand on the DIG command line with other operands; they will be ignored.

domain name

Specifies the name of the domain for which information is requested. If the domain name does not exist in the default domain specified in the TCPIP DATA file, a fully qualified domain name must be specified.

qtype

Specifies the type of query to be performed. DIG does not support MAILA, MD, MF, and NULL query types. The wildcard query types are ANY, MAILB, and AXFR.

For more information about valid query types, see the resource record field "Data type" on page 371.

If the *qtype* option is omitted, the default query type is A (an address query).

qclass

Specifies which network class to request in the query. DIG recognizes only the IN, CHAOS, HESIOD, and ANY network classes.

For descriptions of these classes, see the resource record field "Network class" on page 370.

comment

Enables you to include comments in a DIG command. Any characters following the percent (%) character up to the next space character (space or end-of-record) are ignored by DIG. This option is useful in batch files for annotating a command.

For example, using a dotted-decimal notation internet address rather than a domain name removes any overhead associated with address mapping; however, this makes the command less readable. Therefore, in a batch file you can include the domain name as a comment for readability.

queryoption

Interprets the string following the plus sign (+) character as a query option. Query options have the format:

parameter[=value]

and are a superset of the set subcommand options for NSLOOKUP. See "Query Options" for the available query options.

digoption

Interprets the string following the minus sign (–) as a DIG option. The DIG options are either a parameter or a single character followed by a parameter. See "DiG Options" on page 398 for the available DIG options.

Query Options

[no]aaonly

Specifies whether to accept only authoritative responses or all responses to queries. The default is noaaonly (accept all responses).

[no]addit

Specifies whether to print the additional section of the response. The additional section contains resource records that have not been explicitly requested, but could be useful. For more information about this option, see RFC 1035. The default is addit (print the additional section).

[no]answer

Specifies whether to print the answer section of the response. The answer

section contains the set of all resource records from the name server database that satisfy the guery. The default is answer (print the answer section).

[no]cl

Specifies whether to print network class information for each of the resource records returned. The default is nocl (do not print network class information).

Specifies whether to echo the parsed options. The default is cmd (echo parsed options).

[no]d2

Specifies whether to print the details of each guery sent out to the network. including send time-stamp and time-out time-stamp. When a server does not respond within the time-out period, DIG either sends the query to another server, or resends the query to the original server. The details of the query are visible when d2 is set. The default is nod2 (do not print query details).

[no] debug

Directs DIG to print additional error messages. The default is debug (print additional error messages).

[no]defname

Specifies whether to append the default domain name to all unqualified domain names in a query. The default domain name is set by specifying the +domain=name option. If the nodefname option is set, the domain name specified is passed to the server without modification. The default is defname (append the default domain name).

domain=name

Sets the default domain name to *name*. Initially, the default domain name is obtained from the TCPIP DATA file. The validity of name is not verified. If the defname option is set, the domain name specified in name is appended to all unqualified domain names before the queries are sent to the name server.

[no]Header

Specifies whether to print the header line containing the operation code, returned status, and query identifier of each response. This option is distinct from the header option. The default is Header (print the header).

[no]header

Specifies whether to print the query flags of each response. The query flags are defined in RFC 1035. The default is header (print the guery flags).

[no]ignore

Specifies whether to report truncation errors. Truncation errors occur when a response is too long for a single datagram. Specifying ignore directs DIG to ignore truncation errors. The default is no ignore (report any truncation errors).

[no]ko

Specifies whether to keep the virtual circuit open for gueries in batch mode only. This option has no effect when used on the command line or when datagrams are used to transport queries (see the novc option). The default is noko (create a new virtual circuit for each batch query).

pfand=number

Performs a bitwise AND of the current print flags with the value specified in number. The number can be octal, decimal, or hexadecimal.

pfdef

Sets the print flags to their default values.

pfmin

Sets the print flags to the minimum default values. This option specifies that minimal information should be printed for each response.

pfor=number

Performs a bitwise OR of the current print flags with the value specified in number. The number can be octal, decimal, or hexadecimal.

pfset=number

Sets the print flags to the value specified in *number*. The number can be octal, decimal, or hexadecimal.

[no]gr

Specifies whether to print the outgoing query. The outgoing query consists of a header, question section and empty answer, additional, and authoritative sections. See RFC 1035 for more information about outgoing queries. The default is nogr (do not print the outgoing query).

[no] ques

Specifies whether to print the question section of a response. The question section contains the original query. The default is ques (print the question section).

[no]recurse

Specifies whether to request a recursive query when querying a name server. The norecurse option specifies that a recursive guery is not requested. The default is recurse.

[no]reply

Specifies whether to print the response from the name server. When this option is disabled, other print flags that affect printing of the name server response are ignored and no sections of the response are printed. The default is reply (print the response).

retry=limit

Specifies the number of times a request is resent. When a request is sent and the time-out period expires for a response, the request is resent until the value specified in limit has been exceeded. The value specified in limit determines the number of attempts made to contact the name server. The default value for *limit* is retrieved from the TCPIP DATA file.

Setting limit to zero disables DIG from contacting the name server. The result is an error message no response from server.

The retry algorithm for DIG uses both the *limit* value and the time-out period. Each time a request is resent, the time-out period for the request is twice the time-out period used for the last attempt.

[no]sort

Specifies whether to sort resource records before printing. When performing the wildcard query type AXFR, the sort option is ignored if the name server being contacted sends DNS packets containing multiple answer records. The default is nosort (do not sort resource records).

[no]stats

Specifies whether to print the query statistics including round trip time, time and date of query, size of query and response packets, and name of server used. The default is stats (print the guery statistics).

timeout=time out value

Specifies the number of seconds to wait before timing out of a request. The default time out value is retrieved from the TCPIP DATA file.

[no]ttlid

Specifies whether to print the TTL (time to live) for each resource record in a response. The default is ttlid (print time to live).

[no]vc

Specifies whether to use a virtual circuit (TCP connection) to transport queries to the name server or datagrams (UDP). The default is retrieved from the TCPIP DATA file. If no entry is found, the default is novc (use datagrams)

DiG Options

c query class

Specifies that the command line query or batch query retrieves resource records having the given network class. The *qclass* parameter, described on page 395, can also be used to specify the query class. In addition to the mnemonics, this option also accepts the equivalent numeric value that defines the class.

envsav

Directs DIG to save the environment specified on the current command line in the DIG ENV file. This DIG ENV file initializes the default environment each time DIG is invoked.

The DIG environment is described in "DIG Internal State Information" on page 393.

envset

Directs DIG to set the default environment, specified on the current line in the batch file. This default environment remains in effect for all subsequent queries in the batch file, or until the next line in the batch file containing the -envset option is reached. This option is valid for batch mode only.

The DIG environment is described in "DIG Internal State Information" on page 393.

Specifies a file for DIG batch mode queries. The batch file contains a list of queries that are to be executed in order. The keyword DIG is not used when specifying queries in a batch file. Lines beginning with a number sign (#) or semicolon (;) in the first column are comment lines, and blank lines are ignored. Options that are specified on the original command line are in effect for all queries in the batch file unless explicitly overwritten. The following is an example of a batch file.

```
# A comment
; more comments
wurrup any in +noH =noqu -c IN
toolah +pfmin
```

Directs DIG to execute a ping command for response time comparison after receiving a query response. The last three lines of output from the following command are printed after the guery returns:

```
PING -s server name 56 3
```

p port

Use the port number given when contacting the name server. The Domain Name System is a TCP/IP well-known service and has been allocated port 53. DIG uses 53 by default, but this option allows you to override the port assignment.

[no]stick

Restores the default environment, before processing each line of a batch file.

This flag is valid for batch mode only. If you set the stick option, queries in the batch file are not affected by the options specified for preceding queries in the file.

The DIG environment is described in "DIG Internal State Information" on page 393.

If you set the nostick option, the query option specified on the current line in the batch file remains in effect until the option is overridden by a subsequent query. The result of each query in the batch file depends on the preceding queries. The default is nostick.

T seconds

Specifies the wait time between successive queries when operating in batch mode. The default wait time is 0 (do not wait).

t query type

Specifies that the query retrieves resource records having the given resource record type. The *qtype* parameter on page 395 can also be used to specify the query type. In addition to the mnemonics, this parameter also accepts the equivalent numeric value that defines the type.

x dotted decimal notation address

Simplifies the specification of a query for the in-addr.arpa domain. Normally these queries are made by specifying a query type of PTR for nn.nn.nn.in-addr.arpa, where the four nn components are replaced by the dotted-decimal notation internet address components in reverse order. This option allows you to make this query by simply specifying the dotted-decimal notation internet address.

For example, the domain name corresponding to internet address 101.3.100.2 is found by a query for the domain name 2.100.3.101.in-addr.arpa. You can use DIG -x 101.3.100.2 instead of reversing the address and appending in-addr.arpa.

Usage Notes

- You can use DIG in command line mode, where all options are specified on the invoking command line, or in batch mode, where a group of queries are placed in a file and executed by a single invocation of DIG. DIG provides a large number of options for controlling queries and screen output, including most of the functions of NSLOOKUP.
- 2. You can create a file for batch mode queries using the -f file option. The file contains complete queries, one for each line, that are executed in a single invocation of DIG. The keyword DIG is not used when specifying queries in a batch file. Blank lines are ignored, and lines beginning with a number sign (#) or a semicolon (;) in the first column are comment lines.
- 3. Options specified on the initial command line are in effect for all queries in the batch file unless explicitly overridden. Several options are provided exclusively for use within batch files, giving greater control over the operation of DIG.
- 4. Some internal state information is retrieved from the TCPIP DATA file. See *z/VM: TCP/IP Planning and Customization* for more information about the TCPIP DATA file.

DIG Examples

The following section provides examples of how to use DIG to extract information from a name server. In Figure 67 on page 391, the router wurrup has two internet addresses, and there are two name servers, wurrup being the primary name server.

This network is described by a single zone in the domain naming hierarchy stored in the name servers. In the examples, all queries are issued from the z/VM uluru system.

1. Create a default environment (default options) that gives minimal output from subsequent DIG commands:

```
System:
         Ready
  User:
         dig wurrup +noqu +noH +nohe +nost +noad +noau +nost +nocl
         +nottl -envsav
          ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
System:
          ;; ANSWERS:
         wurrup.FOUREX.OZ. A
                                     101.3.104.12
         wurrup.FOUREX.OZ. A
                                     101.3.100.12
```

The following queries show which part of the response output is controlled by each of the output control options. Each example enables or disables query options for tailoring output. The wurrup.fourex.oz domain name is used for the following queries.

1. Set the query type to ns, the query class to in, and print the additional section of the output:

```
System:
         Ready
 User:
         dig fourex.oz ns in +ad
         ; Ques: 1, Ans: 2, Auth: 0, Addit: 3
System:
         ;; ANSWERS:
                           wurrup.fourex.oz
         fourex.oz NS
         fourex.oz NS
                           canetoad.fourex.oz
         ;; ADDITIONAL RECORDS:
                                   101.3.100.12
         wurrup.fourex.oz A
         wurrup.fourex.oz A
                                   101.3.104.12
         canetoad.fourex.oz
                                   Α
                                           101.3.104.40
```

2. Set the query type to ns, the query class to in, print the additional section of the output, but do not print the answer section:

```
System:
         Ready
 User:
         dig fourex.oz ns in +addit +noanswer
         ; Ques: 1, Ans: 2, Auth: 0, Addit: 3
         ;; ADDITIONAL RECORDS:
         wurrup.fourex.oz A
                                  101.3.100.12
         wurrup.fourex.oz A
                                  101.3.104.12
         canetoad.fourex.oz
                                          101.3.104.40
```

3. Query a nonexistent domain and print the authoritative section of the output:

```
System:
         Ready
          dig noname +author
  User:
System:
          ;; ->>HEADER<<- opcode: QUERY , status: NXDOMAIN, id: 3
          ; Ques: 1, Ans: 0, Auth: 1, Addit: 0
          ;; AUTHORITY RECORDS:
          fourex.oz SOA
                            wurrup.fourex.oz adb.wurrup.fourex.oz (
                                 10003 ;serial
                                 3600
                                         ;refresh
                                 300
                                         ;retry
                                 3600000 ;expire
                                 86400 ) ; minim
```

4. Use the default query options:

```
System:
          Ready
         dig wurrup
 User:
System:
         ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
          ;; ANSWERS:
          wurrup.FOUREX.OZ. A
                                     101.3.104.12
         wurrup.FOUREX.OZ. A
                                     101.3.100.12
```

Print the network class information:

```
System:
                Readv
       User:
                dig wurrup +cl
     System:
                ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
                ;; ANSWERS:
                wurrup.FOUREX.OZ. IN A 101.3.104.12
                wurrup.FOUREX.OZ. IN A 101.3.100.12
 6. Echo the input query:
     System:
                Ready
       User:
                dig wurrup +cmd
                ; <>>> DiG 2.0 <>>> wurrup +cmd
     System:
                ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
                ;; ANSWERS:
                wurrup.FOUREX.OZ. A
                                           101.3.104.12
                wurrup.FOUREX.OZ. A
                                           101.3.100.12
 7. Print the question section of the output:
     System:
                Ready
       User:
                dig wurrup +qu
     System:
                ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
                ;; QUESTIONS:

         ; Ques: 1, Ans: 2, Auth: 0, Addit: 3
          ;; ANSWERS:
          fourex.oz 9999999 NS
                                    wurrup.fourex.oz
          fourex.oz 9999999 NS
                                    canetoad.fourex.oz
```

13. Enable extra debugging mode:

```
System:
         Ready
 User:
         dig wurrup +d2
System:
         ;; res mkquery(0, wurrup, 1, 1)
          ;; Querying server (# 1) address = 101.3.104.40
         ;; id = 3 - sending now: 4044656426 msec
          ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
          ;; ANSWERS:
          wurrup.FOUREX.OZ. A
          wurrup.FOUREX.OZ. A
                                   101.3.100.12
```

The following examples show how options control the use and value of the default

1. Do not append the default domain name to unqualified domain names and print the question section of the response:

```
System:
         Ready
         dig wurrup +nodefname +qu
 User:
         ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
System:
         ;; QUESTIONS:
                  wurrup, type = A, class = IN
         ;; ANSWERS:
         wurrup.fourex.oz A
                                    101.3.104.12
         wurrup.fourex.oz A
                                    101.3.100.12
```

2. Set the default domain name to fourexpd and print the question section of the response:

```
System:
          Ready
          dig wurrup +do=fourexpd +qu
 User:
          ;; ->>HEADER<<- opcode: QUERY , status: SERVFAIL, id: 3
System:
          ; Ques: 1, Ans: 0, Auth: 0, Addit: 0
          ;; QUESTIONS:
                  wurrup.fourexpd, type = A, class = IN
```

3. Set the query type to ns, the query class to in, and sort the output:

```
System:
          Ready
          dig fourex.oz ns in +sort
  User:
System:
          ; Ques: 1, Ans: 2, Auth: 0, Addit: 3
          ;; ANSWERS:
                            canetoad.fourex.oz
          fourex.oz NS
          fourex.oz NS
                            wurrup.fourex.oz
```

4. Query the domain at the address 101.3.100.20 and print the question section of the response:

```
Ready
System:
         dig -x 101.3.100.20 +qu
 User:
System:
         ; Ques: 1, Ans: 1, Auth: 0, Addit: 0
         ;; QUESTIONS:
               20.200.9.192.in-addr.arpa, type = ANY, class = IN
         ;;
          ;; ANSWERS:
         20.200.9.192.in-addr.arpa.
                                       PTR
                                                 galah.
```

5. Retrieve resource records with a network class of ANY and print the question section of the response:

```
System: Ready
User: dig wurrup -c any +qu
System: ; Ques: 1, Ans: 2, Auth: 0, Addit: 0
;; QUESTIONS:
;; wurrup.FOUREX.OZ, type = A, class = ANY

;; ANSWERS:
wurrup.FOUREX.OZ. A 101.3.104.12
wurrup.FOUREX.OZ. A 101.3.100.12
```

6. Retrieve resource records with a query type of ANY and print the question section of the response:

The batch file, test.digbat used for this example is shown below. The default environment has been removed by discarding the DIG ENV file. The DiG command is omitted for all entries in the file.

Note the effect of the -envset and -stick options on the output.

```
wurrup any in +noH +nohe +noqu +noad +noau -envset -stick
wurrup any in
toolah a in +d2
toolah a in
toolah a in +d2 -nostick
toolah a in
toolah a in
toolah a in
toolah a in
```

1. Specify the batch file test.digbat:

```
System:
            Ready
  User:
            dig -f test.digbat
            ; <<>> DiG 2.0 <<>> dig wurrup any in +noH +nohe +noqu +noad
System:
            +noau -envset -st k
            ; Ques: 1, Ans: 3, Auth: 0, Addit: 0

CMSRESOL—Resolver and Name Server

The resolver is a program or subroutine that obtains information from a name server or site tables to convert host names into internet addresses.

The name server is used for cross-referencing a name to its corresponding internet address. The name server uses an internal database or other name servers as its source of information.

Note: Currently, CMSRESOL supports IPv4 only.

RESOLV Command—Interface to the CMSRESOL MODULE

Purpose

ı

The RESOLV EXEC provides a sample EXEC interface to the CMSRESOL MODULE to perform standard Name Server queries. The sample provided has limited capability, but can be modified as needed using a VMSES/E local modification.

Operands

quest name

Specifies the name of the resource that is the target of the query. This is a required parameter.

quest type

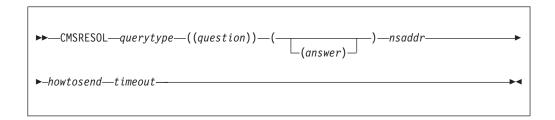

Specifies the query question type (Qtype). If omitted, the Qtype defaults to A (host address query type).

The valid values for this parameter are listed in the header file CMOLVER.H. They are also listed in RFC 883.

nsaddr

Specifies the internet address of the name server from which you want a response. If omitted, the first NSINTERADDR value defined in the TCPIP DATA file is used; if no such value is found, the VM TCP/IP loopback address (127.0.0.1) is used.

CMSRESOL Command—Interface to the Resolver

Purpose

The CMSRESOL program can send queries to the name server using TCP or UDP. The CMSRESOL program sends the query and receives the results by the communication method defined on the CMSRESOL command. The results are placed on the program stack.

Operands

I

querytype

Specifies QUERY or IQUERY.

Specifies the standard query QUERY **IQUERY** Specifies the inverse query

question

Specifies the form of Qname, Qtype, and Qclass.

Specifies the form of Name, Type, Class, TTL, and Data.

nsaddr

Specifies the internet address of the name server. For example: 101.3.104.40.

howtosend

Indicates the form of the query. The form can be: DATAGRAM Specifies the use of UDP datagrams CONN Specifies the use of TCP streams

timeout

Indicates the number of seconds to wait when attempting to open a connection to the name server.

The question, answer, and authority sections are returned as separate lines in the program stack (system data queue). They can be extracted from the queue with the REXX PULL instruction. The CMSRESOL command results in one of the following return codes:

Return Code	Description
0	No error condition
1	Format error
2	Name server failure
3	Domain name does not exist
4	Not implemented
5	Refused by name server
20	Parameter error
21	Error in communicating with name server
22	Software error
100	Command line is too long

Notes:

- 1. The name server uses an internal buffer of 4096 bytes to transfer data. If this limit is exceeded, a name server failure-error condition is returned.
- 2. Each line in the program stack can hold as many as 255 characters. Data in excess of this limit is wrapped into additional lines in the program stack.
- 3. You must allow at least one space between adjacent sets of parentheses for these queries to work.

Types of Queries

This section contains examples of standard, inverse, in-addr.arpa domain, and database queries, as well as examples of queries outside your domain.

Note: The figure of 86 400, which appears in the program stack, is a typical TTL value of 24 hours, expressed in seconds.

The Standard Query

A standard query provides the *question*, and the *answer* is returned. An example of a standard query is:

```
CMSRESOL QUERY ( ( RALPH.YKT.IBM.COM A IN ) ) ( ) ( ) 9.0.0.1 DATAGRAM 60
```

The results of the query are placed on the program stack. An example of the format of the data on the stack resulting from this standard query is:

```
( ( RALPH.YKT.IBM.COM A IN ) )
( ( RALPH.YKT.IBM.COM A IN 86400 192.5.5.5 ) )
( )
( )
```

The Inverse Query

An inverse query provides the *answer*, and the *question* is returned. An example of an inverse query using a TCP virtual circuit and the resulting stack contents is:

```
CMSRESOL IQUERY ( ) ( ( X.YKT.IBM.COM A IN 0 192.5.5.5 ) ) ( ) 9.0.0.1 CONN 60
```

The stack contents are:

```
( ( RALPH.YKT.IBM.COM A IN ) )
( ( RALPH.YKT.IBM.COM A IN 86400 192.5.5.5 ) )
( )
( )
```

Querying the in-addr.arpa Domain

Only local, authoritative data is returned from a name server in response to an inverse query. Recursion is not available, because an inverse query does not supply the domain origin in the data field. To resolve an internet address to a domain name, a special domain exists called in-addr.arpa. The in-addr.arpa domain contains the internet address of the name field in reverse order, suffixed with in-addr.arpa. To resolve the internet address to a domain name, do a standard query supplying the internet address, in reverse order, suffixed with in-addr.arpa in the name field.

An example of this type of query is:

```
CMSRESOL QUERY ( ( 126.43.67.9.IN-ADDR.ARPA PTR IN ) ) ( ) ( ) 9.0.0.1 DATAGRAM 45
```

The results of the query are placed on the program stack. An example of the format of the data on the stack resulting from this query is:

```
( ( 126.43.67.9.IN-ADDR.ARPA PTR IN ) )
( ( 126.43.67.9.IN-ADDR.ARPA PTR IN 86400 VMX.RALEIGH.IBM.COM ) )
( )
```

Querying Outside Your Domain

The following is a sample of a query outside your domain:

```
CMSRESOL QUERY ( ( ALPHA.UNKNOWN.COM A IN ) ) ( ) ( )
              9.0.0.1 DATAGRAM 30
```

The results of the query are placed on the program stack. An example of the format of the data on the stack resulting from this query is:

```
( ALPHA.UNKNOWN.COM A IN ) )
 ( UNKNOWN.COM NS IN 86400 NAMESERVER.UNKNOWN.COM ) )
( ( NAMESERVER.UNKNOWN.COM A IN 86400 128.1.2.3 ) )
```

Chapter 14. Using Translation Tables

TCP/IP uses translation tables to convert transmitted data between EBCDIC and ASCII. Because the meanings of the terms "EBCDIC" and "ASCII" depend on the particular operating system and the national language (English, French, etc.) being used on a particular system, TCP/IP provides many different translation tables to meet the diverse needs of z/VM users.

In addition to the more than 200 translations provided by IBM, you can create custom tables to meet your specific requirements.

The following sections provide the information you need to understand what translation tables are, how they are used by TCP/IP applications, and how you can create your own custom translations.

Character Sets and Code Pages

When you display or print a document, you see a collection of characters or symbols. A group of characters or symbols taken together and treated as a single entity is called a **character set**. A character set may contain hundreds or even thousands of characters.

In a Single-Byte Character Set (SBCS), one 8-bit byte is used to represent a single character. This means there are only 256 possible bit patterns or **code points** available to represent a character. All Western languages can be represented by an SBCS character set.

A Double-Byte Character Set (DBCS) uses *two* bytes to represent a single character, providing a theoretical maximum of 65536 characters. In practice, DBCS character sets contain far fewer than 65536 characters. Eastern languages such as Japanese Kanji, Korean Hangeul, and traditional Chinese require a DBCS character set.

A collection of all of 256 (for SBCS) or 65536 (for DBCS) code points and their corresponding individual character assignments are called a **code page**.

While it is true that always using a universal DBCS character set such as Unicode would eliminate the need to perform EBCDIC-ASCII translation, most of the operating systems and standard TCP/IP application protocols in use today were developed before the advent of DBCS. As a consequence, every country or common geographic region developed its own country-specific SBCS code page, particularly in the EBCDIC environment. Characters were deleted, added, and their order changed.

Consequently, it is necessary to understand and manage the use of code pages. To assist in that effort, IBM has assigned a unique number to many of the EBCDIC and ASCII code pages you will use. The specific code page translations provided with TCP/IP are listed in Table 29 on page 412. Facilities are provided so that you may supplement the translations provided by IBM with your own.

The TCP/IP translation tables convert data from one code page to another, so the table you choose depends on the code pages being used by the systems involved and your knowledge of how a file was created.

© Copyright IBM Corp. 1987, 2011 409

Using Translation Tables

It is important to recognize that changing the default translation table for servers such as FTP and NFS can corrupt data in a file if that file is uploaded and downloaded using different translation tables. (This does not apply to binary transfers, of course.)

TCP/IP Translation Table Files

TCP/IP translation tables are machine-readable binary files that are usually kept on the TCP/IP user disk, TCPMAINT 592.

Most of these files are provided by IBM, and others may be created by compiling SBCS or DBCS translation table source files using the CONVXLAT command, described in "Converting Translation Tables to Binary" on page 419.

Table 27. Translation Table Files

Character Set	Language	Source File Type	Table File Type
SBCS	Any	TCPXLATE	TCPXLBIN
DBCS	Japanese Kanji	TCPKJLAT	TCPKJBIN
DBCS	Korean Hangeul	TCPHGLAT	TCPHGBIN
DBCS	Traditional Chinese	TCPCHLAT	TCPCHBIN

Note that the file types for the different languages are different. There can be up to four translation table that have the same file name – one for all SBCS languages, and one for each of the three DBCS languages.

SBCS tables contain translations for one pair of code pages. DBCS tables may contain multiple translations.

To modify an IBM-provided translation table:

- 1. Modify the source file as required
- 2. Run the CONVXLAT program, specifying the modified source as input
- 3. Copy the resulting TCPxxBIN file to the TCP/IP user disk, TCPMAINT 592. Translation tables made available to servers should also be made available to clients.

To create a new translation table, first copy an existing source file and then follow the procedure outlined above.

SBCS translation tables may be read by CMS applications using the DTCXLATE CSL routine. For more information on DTCXLATE, see the z/VM: CMS Callable Services Reference.

Translation Table Search Order

Most TCP/IP client and server programs provide a way for the you to change the translation table that is used. This is done using either client command line options, server initialization parameters, or configuration file statements. For example, the CMS FTP client provides a TRANSLATE option that you can use to provide the name of a translation table.

If no such option or configuration statement is provided, the clients and servers will use a preferred translation table that is specific to a particular client or server. If the preferred table cannot be found, the common standard translation will be used. The standard translation is loaded from STANDARD TCPxxBIN, if it is available, or from an equivalent that is compiled into the program.

Table 28 shows the option or configuration statement that may be used to provide the name of a translation table to be used by each client or server. Any program not listed can be assumed to use STANDARD.

Table 28. Preferred Translation Tables

Program	Option	Preferred Translation Table
SMTP Server	None ¹	SMTP
SMTP Client (SENDFILE)	TRANSLATE table_name ² , ³	STANDARD
FTP Server	SITE TRANSLATE table_name ² ,4	SRVRFTP
FTP Client	TRANSLATE table_name ²	FTP
UFT Client (SENDFILE)	TRANSLATE table_name ²	STANDARD
UFT Server	TRANSLATE table_name ²	STANDARD
LPR Client	TRANSLATE table_name ²	LPR
LPD Server	TRANSLATETABLE table_name ²	LPD
NFS Server	XLATE=table_name ²	VMNFS
REXECD Server	None	REXECD
TELNET Client	TRANSLATE table_name ²	TELNET
TELNET Server (line mode)	None	STLINMOD

Note¹: For SMTP, an additional translation table may be specified for 8-bit MIME support. The *z/VM: TCP/IP Planning and Customization* contains more information in the "8BITMIME Statement" section.

Note²: *table_name* is the file name of a TCP/IP translation table.

Note3: This applies only when the MIME option is specified on the SENDFILE command.

Note⁴: SITE TRANSLATE is a command, issued by the FTP client, that tells the FTP server which translation table to use for the current session. For more information, see "SITE" on page 87.

If a table is explicitly referenced by a program option or configuration statement, the program will display an error message and stop if the translation table file cannot be found or loaded.

The file type of the translation table depends on whether any DBCS features are used. If Kanji translation is requested, the file type is TCPKJBIN. If Korean translation is requested, the file type is TCPHGBIN. For traditional Chinese, the file type is TCPCHBIN.

The *z/VM: TCP/IP User's Guide* contains information on the TRANSLATE option for the TCP/IP clients, and the *z/VM: TCP/IP Planning and Customization* contains information for the servers. See the *z/VM: CMS Commands and Utilities Reference* for information about the SENDFILE command.

Special Telnet Requirements

Telnet Client

The Telnet client requires a translation table that is different from the default table. STANDARD. The preferred translation table is provided by IBM as TELNET TCPXLBIN. If this file is not found, however, the default table will be used.

Country-specific translation tables for the Telnet application are provided. These tables have the file type TELXLATE. You must rename the selected file to TELNET TCPXLATE before it is converted to binary using the CONVXLAT command. The resulting TELNET TCPXLBIN should then be copied to TCPMAINT 592, replacing the IBM version.

Note: You cannot use the Telnet translation tables to change the LineFeed (X'0A')

Telnet Server

For line mode Telnet sessions, translation is performed by the Telnet server using the STANDARD translation table. If this table does not meet your needs, you can create an STLINMOD TCPXLATE table, convert it to binary using CONVXLAT, and copy the resulting STLINMOD TCPXLBIN file to the TCP/IP customization disk, TCPMAINT 198.

IBM-Supplied Translation Tables

In order to meet the translation needs of users and installations worldwide, more than 200 translation tables are provided with TCP/IP for your use. Some tables already exist in binary form; others require conversion using the CONVXLAT command, as described in "Converting Translation Tables to Binary" on page 419.

In order to make an IBM-supplied translation table the default translation table for a particular client or server program, store a copy of that translation table (in binary form) under the preferred translation table name for that program, as specified in Table 28 on page 411.

Table 29. IBM Translation Tables

Note: In this table hhhh and rrrr represent four-digit host and remote code page numbers, respectively.

Notes:

- STANDARD TCPXLBIN is a 7-bit non-reversible translation table. For inbound data, all ASCII characters with values in the range X'80'-X'FF' will have the same translation as values X'00'-X'7F'. The high-order bit of each ASCII byte is ignored and is assumed to be zero. For example, ASCII X'B1' and X'31' will both be converted to EBCDIC X'F1'. For outbound data, EBCDIC control characters that do not have ASCII equivalents are converted to ASCII X'1A'. STANDARD should be used in situations where a client or server is known to treat the high-order bit in each byte as a parity bit.
- 2. All other SBCS translation tables provide a unique, one-to-one mapping of all 256 code points.
- 3. All tables translate ASCII LineFeed (LF, X'0A') to and from EBCDIC LF (X'25'), except for POSIX and 1047rrrr, which use EBCDIC NewLine (NL, X'15') instead.
- 4. Host code pages 924 and 1140-1149 include translations for the euro currency symbol.

Customizing SBCS Translation Tables

All SBCS translation table files contain two tables. The first table is used to translate from ASCII to EBCDIC. The second table is used to translate from EBCDIC to ASCII.

To read the translation tables, find the row for the first hex digit (1) and the column for the second hex digit (2). The point where the row and column intersect is the translation value.

For example, to find the EBCDIC translation for the ASCII character X'A7', find row A0 (3) and column 07 (4) in the following example. The point where row A0 and column 07 intersect shows a value of X'7D', so the ASCII character X'A7' will be

translated to a X'7D' in EBCDIC. To customize the translation table, alter the translate value where the row and column intersect to the new value.

Syntax Rules for SBCS Translation Tables

- · Blanks are used only as delimiters for readability purposes.
- Comments may be included, either on a separate line or at the end of a line. Comments must start with a semicolon (;).

Customizing DBCS Translation Tables

Each DBCS translation table file contains more than one translation table. TCPHGLAT and TCPHGBIN, for example, contain EBCDIC to ASCII and ASCII to EBCDIC translation tables for both the KSC 5601 and Hangeul PC code pages.

The standard DBCS binary tables are used by the FTP server, SMTP server, and FTP client programs.

The figures on the following pages show examples of the standard source for the Kanji, Hangeul, and Traditional Chinese DBCS translation tables.

Using Translation Tables

These source files contain two column pairs for each code page. The first column pair specifies double-byte EBCDIC to ASCII code point mappings for the indicated code page. The second column pair specifies double-byte ASCII to EBCDIC code point mappings for the indicated code page.

Existing code point mappings may be changed by simply overwriting the existing hexadecimal code. New code point mappings may be specified by adding a new column pair with two double-byte hexadecimal codes. Code point mappings that are not specified, and are within the valid range for the code page, default to the "undefined" character, X'FFFF'.

The source file format allows EBCDIC to ASCII and ASCII to EBCDIC mappings to be specified separately. When adding or changing a code point mapping, care should be taken to modify both mappings for the code point. If, for example, a new mapping is added for EBCDIC to ASCII only, the ASCII to EBCDIC mapping for that code point will be the "undefined" character.

Any new code point mappings added outside the valid range for the corresponding code page will not be used by the programs that load the binary table.

DBCS Translation Table

The DBCS translation tables also contain SBCS code point mappings. These are used for mixed-mode DBCS strings, containing both SBCS and DBCS characters. Shift-out (X'0E') and shift-in (X'0F') characters are used on the EBCDIC host to denote the beginning and end of DBCS characters within a mixed-mode string.

The DBCS source files must contain exactly 256 SBCS code point mappings, situated at the end of the table. These may be modified to contain the required hexadecimal value.

Syntax Rules for DBCS Translation Tables

- Comments may be included, either on a separate line or at the end of a line. Comments must start with a semicolon (;).
- Code point mappings in the file are position dependent. The first non-comment line for the DBCS and SBCS tables in the file will be used to establish the column position of the code point mappings, and must contain a conversion pair for each code page. Any conversion pairs on following lines must use the same column positions.
- It is permissible to leave blanks for code point mappings after the first line in the DBCS and SBCS areas. For example, if a line contains only one conversion pair, the column position will be used to determine which code page it refers to.
- The first column of each code page column pair, the "code index", must be in ascending numerical order. Any gaps in the ascending order will be marked as "undefined" in the binary table created by CONVXLAT.

Sample DBCS Translation Tables

The following examples are from the STANDARD DBCS translation table source files. Because these files are very large, only excerpts from the tables are shown. Ellipses (...) are used to indicate that information has been deleted.

Converting Translation Tables to Binary

The CONVXLAT command converts a translation table source file to a binary file that usable by TCP/IP client and server programs. CONVXLAT may be used to convert both SBCS and DBCS source file.

CONVXLAT Command

Purpose

Used to convert a translation table source file to a binary file that is usable by TCP/IP client and server programs. May be used to convert both SBCS and DBCS source file.

Operands

input filename

Specifies the file name of the source file to be converted. The source file must have a file type of TCPXLATE for SBCS tables, or a file type of TCPKJLAT, TCPHGLAT, or TCPCHLAT for DBCS tables. The first file with the required file name and file type in the standard minidisk search order is used.

output_filename

Specifies the destination file name created by the conversion. If this parameter is not specified, it defaults to the name STANDARD. The destination file type will be TCPXLBIN for SBCS tables, or TCPKJBIN, TCPHGBIN, or TCPCHBIN for DBCS tables. The destination file mode is A, which must be accessed in write mode.

KANJI

Specifies that the table being converted is the Kanji DBCS/SBCS translation table. The file type of the source file must be TCPKJLAT. The file type of the destination file will be TCPKJBIN.

HANGEUL

Specifies that the table being converted is the Hangeul DBCS/SBCS translation table. The file type of the source file must be TCPHGLAT. The file type of the destination file will be TCPHGBIN.

TCHINESE

Specifies that the table being converted is the Traditional Chinese DBCS/SBCS translation table. The file type of the source file must be TCPCHLAT. The file type of the destination file will be TCPCHBIN.

If no optional parameters are specified, then <code>input_filename</code> is assumed to contain an SBCS translation table.

Appendix A. Specifying Files and Data Sets

This appendix describes the file naming formats for the AIX, OS/390, DOS, OS/2 and Windows operating systems, as well as for the AS/400[®] operating system. Examples of each format are provided to show how the files appear to a TCP/IP user who is logged on to the different operating systems.

AIX Files

For the Advanced Interactive Executive (AIX) operating system, data is stored in files. Related files are stored in a directory.

The following is the format of an AIX file name.

Parameter Description

directory_name

Specifies a directory name. Directories contain the names of files,

other directories, or both.

file_name Specifies a file name. It can be up to 14 characters long.

The complete name of an AIX file contains the directory name and the file name. The following is an example of an AIX file.

/mailfiles/cooks

Where:

mailfiles Is the directory name. cooks Is the file name.

In AIX, you specify the first slash (/) only when you begin at the root directory. If you are specifying a file in the current directory, enter only the file name. For example, if you are in the current directory *mailfiles* and you want to access the *cooks* file, specify:

cooks

The directory name and file name can each be up to 14 characters. The AIX operating system distinguishes between uppercase and lowercase letters in file names.

A directory name and file name should not include characters, such as backslash (\), ampersand (&), and period (.), which have a special meaning to the AIX operating system shell.

For more information about AIX files, see AIX System User's Guide.

OS/390 Data Sets

The two most common data set types used for storing user files on an OS/390 operating system are sequential data sets and partitioned data sets.

Sequential Data Sets

A sequential data set is a single file that can be allocated with any record length specified. The naming requirements for a sequential data set on an OS/390 host are minimal, and most of the requirements apply to any data set name under OS/390.

The naming requirements for a sequential data set are:

- No part of the name can start with a numeric.
- No part of the name can be more than eight characters in length.
- · Each part of the name is separated by a period.
- If single quotation marks are not used when specifying the data set name, the OS/390 system appends the logon user ID as the first part of the name.

A sequential data set name can have a minimum of two and a maximum of 44 characters.

The following examples show the naming conventions for sequential data sets on an OS/390 host.

To access the sequential data set KC00852.NAMES, the user KC00852 enters one of the following:

```
'KC00852.NAMES'
     or
NAMES
```

Either of these formats is acceptable to access a sequential data set.

Partitioned Data Sets

A partitioned data set (PDS) is a group of files contained in a library. The individual files that make up a PDS are called members. You can access an entire PDS or any individual member of a PDS.

The following restrictions apply to the naming conventions that are used with a partitioned data set:

- No part of the name can start with a numeric.
- No part of the name can be more than eight characters in length.
- Each part of the name is separated by a period.
- If single quotation marks are not used when specifying the PDS name, the OS/390 system appends the logon user ID as the first part of the name.

The difference between a sequential and partitioned data set specification is that the partitioned data set user accesses the directory of members in the PDS, and the sequential data set user accesses an individual file.

The following examples show the naming conventions for partitioned data sets on an OS/390 host.

To access the partitioned data set KC00852.PDS.NAMES, the user KC00852 enters one of the following:

```
'KC00852.PDS.NAMES'
     or
PDS.NAMES
```

Specifying Files and Data Sets

Either of these formats is acceptable to access a partitioned data set.

To access an individual file in a PDS, the member name is entered in parentheses.

To access the member PROPER in the PDS KC00852.PDS.NAMES, the user KC00852 enters one of the following:

```
'KC00852.NAMES(PROPER)'
     or
NAMES (PROPER)
```

Either of these formats is acceptable to access members in a partitioned data set.

DOS, OS/2, and Windows 98 Files

DOS, OS/2, and Windows 98 files are stored on high-capacity storage device, usually fixed disks or to a lesser extent, a diskette. Files, the smallest unit of organization on a hard drive are organized in directories and branching subdirectories. A storage device is identified by a drive letter.

The complete name of a DOS, OS/2, or Windows 98 file contains the storage device identifier, directory name, file name, and extension. The following is an example of a complete name for a DOS, OS/2, or Windows file:

```
C:\WP\MAIL.LST
```

In this example, the storage device identifier is C: and the directory name is WP, which could be a group of word processing files. The file name is MAIL, and the file extension is .LST.

In DOS, OS/2, and Windows 98, the device identifier is a drive letter that is assigned by the file system, followed by a colon. The drive letter, such as A, B, or C, can represent either a physical device or a logical device. If a device identifier is not specified, the default is the device from which the system was booted or the current drive.

You assign the directory name, preceded by a backslash. A directory name is optional. If a directory name is not specified, the system searches the current directory.

Normally, you would also assign a file name. In DOS, file names can be eight characters long and have a three character extension. The file extension is a character string that consists of one to three characters, preceded by a period. A file extension is optional.

With OS/2, you will generally use one of two file systems: File Allocation Table or FAT, or else the High Performance File System, known as HPFS. You can have both these file systems active at the same time. For example, you can have the FAT file system on one hard disk, and the HPFS active on another.

The FAT format uses the familiar but limited naming convention, where a file or directory name can have up to eight letters, followed by a period and then the three-letter extension. HPFS provides support for long file names, up to 254 characters, including path information. including path information.

Windows 98 supports 256-character filenames as well as upper and lowercase characters.

Specifying Files and Data Sets

If you use an invalid file name, the system gives you an error message.

The following are examples of different DOS OS/2, and Windows 98 file names that are valid.

TEMP START.BAT A:COMMAND.COM C:SPF\SPFPC.HLP C:REPORTS\ThisISALongFilename.TXT (Windows 98)

AS/400 Operating System

For the AS/400 operating system, data is stored in files.

The following is the format of an AS/400 file.

Parameter	Description
library	Is a library name. Libraries contain the names of programs, files, and commands.
file.member	Is the file name.

In AS/400, files can have one or more members. Each file can consist of data records, source programs, or database definitions.

The FTP subcommand PUT is used to copy a local file member into a file at the remote host. The following is an example:

PUT TCPLIBA/FILEA.MBRA TCPLIBB/FILEA.MBRA

In this example, the PUT subcommand copies the file member MBRA in file FILEA into library TCPLIBA at the local host to MBRA in FILEA in library TCPLIBB at the remote host. If the member already exists at the remote host, it is overwritten.

Appendix B. Using the NETRC DATA File

This appendix describes the NETRC DATA File and how it is used by:

- FTP Client
- REXEC
- OPENVM MOUNT CMS Command

NETRC-capable commands use fully-qualified host domain names when attempting to match a *command* specified host name with those in the NETRC DATA file. Thus, you may specify fully-qualified host domain names on the command in the NETRC DATA file. Otherwise, the command will construct a fully-qualified host domain name for you, by concatenating the host name you have provided with the domain origin specified on the DOMAINORIGIN statement of the TCPIP DATA configuration file.

You maintain the NETRC DATA file on your own minidisk or directory. The first NETRC DATA file found in the CMS search order will be used when the command is invoked. Since the NETRC DATA file contains logon passwords, ensure you restrict access to this file using security measures appropriate for your environment. Do not keep this file on a disk or directory to which other persons have access. A file mode number of 0 will not adequately protect this file.

The format for entries in the NETRC DATA file follows:

```
machine foreign host login user id password password
```

The IPv6 addresses are currently available for FTP service only.

Several sample NETRC DATA file entries follow:

```
machine oddjob login anonymou password anonymou machine 123.45.67.89 login guest password guest machine 123:5678::9abc login guest password guest machine oddjob.specific.domain.com login cibulama password onion1 machine filmore.east.com login bluespwr password albertk machine rocketman login gordon password flash
```

If the password contains leading or trailing blanks, or beings with a single quotation mark, it must be surrounded by single quotation marks and any imbedded single quotation mark must be doubled. For example:

```
machine bronzedragon login alan password ride'em cowboy machine bluedragon login karen password ' and they''re off ' machine cisko login ben password watch the wormhole
```

Using The NETRC DATA File with FTP

I

The NETRC DATA file provides an alternative to responding to FTP prompts for logon information when you connect to a foreign host. When a user name and password for a specific host are defined in this file, FTP will use those values instead of prompting for this information.

When the FTP command, or its OPEN subcommand is issued, FTP searches the NETRC DATA file for the first valid match on the specified host. If found, that host's user name and password are used when a connection to that host is attempted. If no match is found for the host in question, you are prompted for a user name and password, unless the NOPROMPT option has been specified.

© Copyright IBM Corp. 1987, 2011 425

Using The NETRC DATA File with REXEC

The NETRC DATA file provides an alternative for specifying the REXEC user_id and password parameters. If these parameters are defined within this file for a specific host, they can be omitted when you issue a REXEC command against that host.

REXEC searches the NETRC DATA file for the first valid match on the specified host. If found, that host's user name and password are used when a connection to that host is attempted. If no match is found for the host in question, you are prompted for a user name and password, unless the -k option has been specified.

The following example shows a REXEC command for which the required login userid and password values have been supplied by a NETRC DATA file entry. In this example the DIR C: command has been issued against the OS/2 host FILMORE:

```
rexec filmore dir c:
The volume label in drive C is OS2.
The Volume Serial Number is A6B0 11-30-93
                                                      <DIR>
                                                                      0.

Using the NETRC DATA File with the OPEN MOUNT CMS Command

The NETRC DATA file provides an alternative for specifying the username and password parameters on the OPENVM MOUNT command. OPENVM MOUNT is a CMS commnd, documented in the z/VM: OpenExtensions Commands Reference that provides NFS client support for z/VM. This allows you to NFS-mount remote file systems in your Byte File System (BFS) hierarchy.

If the username and password are defined within the NETRC DATA file for a specific foreign host, you can omit them from an OPENVM MOUNT command issued for that host.

Appendix C. Mapping Values for the APL2 Character Set

GDDMXD/VM has default mapping values for the APL2 character set. However, if the GDXAPLCS MAP file exists, the default mapping values are overridden.

Each entry in the GDXAPLCS MAP file (alternative character set) contains the mapping for a particular physical key that corresponds to three characters. The characters correspond to the physical key by:

- · Pressing the key alone
- · Pressing the key and the Shift key simultaneously
- Pressing the key and the Alt key simultaneously

GDXAPLCS MAP file entries must contain the following seven single byte hexadecimal values entered as EBCDIC characters.

- Value 1 is the hexadecimal keycode for the physical key.
- Values 2, 4, and 6 identify whether the character is in the primary or alternative character set for the emulated 3179G. If the character is in the primary set, the value is 0; if the character is in the alternative set, the value is 8.
- Values 3, 5, and 7 specify the EBCDIC code of the character in the character set.

The combination of values 2 and 3 define the bytes that describe the character when the key corresponding to the keycode is pressed alone.

The combination of values 4 and 5 define the bytes that describe the character when the key corresponding to the keycode and the Shift key are pressed simultaneously.

The combination of values 6 and 7 define the bytes that describe the character when the key corresponding to the keycode and the Alt key are pressed simultaneously.

Table 30 lists the mapping values for the APL2 character set.

Appendix D. Using DBCS with FTP and Mail

This appendix describes how to use the DBCS facilities provided by FTP and SMTP.

Using DBCS with FTP

This section describes how to use FTP with DBCS support to exchange DBCS files between hosts supporting DBCS file transfer.

DBCS Translation Tables

The VM TCP/IP FTP server and client programs access files containing data that is usually in EBCDIC format. To transfer these files to or from an ASCII based host requires the use of a translation table.

The FTP server and client may be configured to load a number of DBCS translation tables. These are used during file transfers to convert EBCDIC DBCS characters to and from ASCII. The LOADDBCSTABLE statement in FTP DATA is used by both the FTP server and client to determine which DBCS translate table files should be loaded at initialization time.

Control and Data Connection Translation

The transfer of a DBCS file by FTP actually uses three different translation tables; two SBCS and one DBCS. The control connection that is used to transfer FTP commands and replies, uses the SBCS translation table that is normally loaded from the STANDARD TCPXLBIN file. The data connection that is used to transfer the file, uses both an SBCS and DBCS translation table that are normally loaded from either the STANDARD TCPKJBIN, STANDARD TCPHGBIN, or STANDARD TCPCHBIN file.

Both SBCS and DBCS translation tables are required for the transfer of a DBCS file, as the file may contain mixed-mode strings. A mixed mode string contains both SBCS and DBCS data, delimited by shift-out and shift-in characters.

Although DBCS support for FTP does not include direct support for Katakana, it is possible to separately configure the SBCS table used for the control connection (user interface), and the data connection. The SBCS translation table for SJISKANJI, for example, could be altered to a Katakana based code page.

DBCS Subcommands

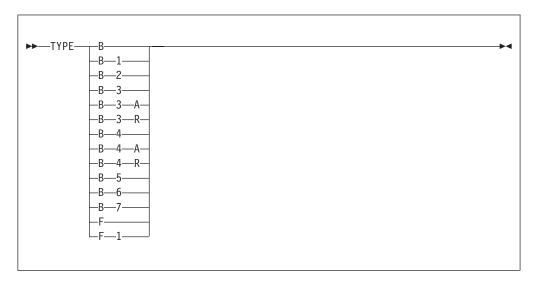

DBCS files are transferred using the standard FTP subcommands "put" and "get". Before the transfer commences, however, the current transfer type for the session must be set to the required DBCS type. To set the transfer type to DBCS for an FTP session, requires the sending of a TYPE command from the client to the server in the correct format. The VM TCP/IP FTP client provides three ways of generating TYPE commands:

- 1. TYPE subcommand
- 2. TYPE subcommand aliases
- 3. QUOTE subcommand

© Copyright IBM Corp. 1987, 2011 433

TYPE Subcommand

The TYPE command sets the transfer type for the client and server at the same time with one command. The following DBCS TYPE subcommands are supported by the VM TCP/IP FTP server and client.

Parameter	Description
TYPE B	Change current transfer type to Shift JIS Kanji
TYPE B 1	Change current transfer type to Shift JIS Kanji
TYPE B 2	Change current transfer type to Extended Unix Code Kanji
TYPE B 3	Change current transfer type to JIS 1983 Kanji using ASCII shift-in escape sequence ESC ($\ensuremath{\mathtt{B}}$
TYPE B 3 A	Change current transfer type to JIS 1983 Kanji using ASCII shift-in escape sequence ESC ($\ensuremath{\mathtt{B}}$
TYPE B 3 R	Change current transfer type to JIS 1983 Kanji using JISROMAN shift-in escape sequence ESC (${\tt J}$
TYPE B 4	Change current transfer type to JIS 1978 Kanji using ASCII shift-in escape sequence ESC ($\ensuremath{\mathtt{B}}$
TYPE B 4 A	Change current transfer type to JIS 1978 Kanji using ASCII shift-in escape sequence ESC ($\ensuremath{\mathtt{B}}$
TYPE B 4 R	Change current transfer type to JIS 1978 Kanji using JISROMAN shift-in escape sequence ESC (J
TYPE B 5	Change current transfer type to Hangeul
TYPE B 6	Change current transfer type to Korean Standard Code KSC-5601, 1989 version
TYPE B 7	Change current transfer type to Traditional Chinese (5550)
TYPE F	Change current transfer type to IBM (EBCDIC) Kanji
TYPE F 1	Change current transfer type to IBM (EBCDIC) Kanji

TYPE Subcommand Aliases

Each DBCS TYPE subcommand may be specified using a single word alias. Each TYPE subcommand alias generates the same TYPE command to the client and

server as the corresponding TYPE subcommand. The TYPE subcommand aliases may be abbreviated using the minimum unambiguous client subcommand abbreviations.

The TYPE subcommand aliases also have an optional parameter (NOTYPE, that specifies that the DBCS type should only be set locally. This is used when connecting to an FTP server that does not support the TYPE command generated by the TYPE subcommand alias. For example, SJISKANJI (NOTYPE causes the FTP client to change its transfer type to Shift JIS Kanji, without changing the transfer type in the FTP server. The server in this example should be set to the ASCII transfer type before the (NOTYPE subcommand is issued. Table 31 indicates the actual server command that would be generated for each client subcommand alias:

Table 31. FTP TYPE commands

Server Command	Description
TYPE B 1	Shift JIS Kanji transfer type
TYPE B 2	Extended Unix Code Kanji transfer type
TYPE B 3	JIS 1983 Kanji using ASCII shift-in transfer type
TYPE B 3 A	JIS 1983 Kanji using ASCII shift-in transfer type
TYPE B 3 R	JIS 1983 Kanji using JISROMAN shift-in transfer type
TYPE B 4	JIS 1978 Kanji using ASCII shift-in transfer type
TYPE B 4 A	JIS 1978 Kanji using ASCII shift-in transfer type
TYPE B 4 R	JIS 1978 Kanji using JISROMAN shift-in transfer type
TYPE B 5	Hangeul transfer type
TYPE B 6	Korean Standard Code KSC-5601 transfer type
TYPE B 7	Traditional Chinese (5550) transfer type
TYPE F 1	IBM (EBCDIC) Kanji transfer type
	TYPE B 1 TYPE B 2 TYPE B 3 TYPE B 3 A TYPE B 3 R TYPE B 4 TYPE B 4 TYPE B 4 A TYPE B 4 R TYPE B 5 TYPE B 6 TYPE B 7

QUOTE Subcommand

The QUOTE subcommand may be used to send an uninterpreted string of data to the server. The QUOTE subcommand may be used to generate any of the DBCS TYPE commands supported by the server. The QUOTE subcommand would be used when the FTP server supports the DBCS TYPE command, but the FTP client does not. For example, QUOTE TYPE B 1 causes the FTP server to change its transfer type to Shift JIS Kanji, without changing the transfer type in the FTP client. The client in this example should be set to the ASCII transfer type before the QUOTE subcommand is issued.

The following examples show the screen display when setting the DBCS transfer type to JIS78KJ, shift-in JISROMAN, using a VM TCP/IP FTP client connected to a VM TCP/IP FTP server. All three methods of setting the DBCS transfer type are demonstrated.

Using DBCS with FTP and Mail

Defining FTP with Kanji Support

The following FTP subcommands can set the appropriate transfer type for the Kanji file transfer. The translation table STANDARD TCPKJBIN converts the transmitted data between Kanji and ASCII. This file is installed in the user visible minidisk from FTPSERVE user ID. The following are the FTP Kanji transfer type subcommands:

Subcommand	Option
SJISKANJI	(notype
EUCKANJI	(notype
JIS83KJ	(notype
JIS78KJ	(notype
IBMKANJI	(notype

The (notype option is used for the standard FTP server that does not have Kanji support. FTP sets the data type for the client and server at the same time with one command. If Kanji support is only in the FTP user, the FTP server cannot accept Kanji data types with the TYPE subcommand. The Kanji subcommands with the (notype option should be used, without the TYPE subcommand.

Using FTP with Kanji Support

The FTP TYPE subcommand supports single byte transfer for ASCII and EBCDIC data transfer (TYPE A or TYPE E). Kanji data types allow you to transfer text files with a Kanji code set. TYPE B defines the data type of the Kanji code based on the ASCII code set. TYPE F defines the data type of the Kanji code based on the EBCDIC code set.

The following are the Kanji code set types, based on ASCII (TYPE B) AND EBCDIC (TYPE F):

Command	Kanji Code Set
TYPE B 1	Shift JIS
TYPE B 2	Extended UNIX Code
TYPE B	JIS 1983 edition
TYPE B 4	JIS 1978 edition
TYPE F 1	IBM Kanji

The number associated with the data type is the argument of the TYPE command. For example, if JIS 1983 edition code is used in the data transfer, issue the command TYPE B 3. If IBM code is used in the data transfer, issue the command TYPE F 1.

If the FTP user does not support the Kanji extension, you should issue the FTP QUOTE subcommand to change the data type in the FTP Kanji server. For

example, QUOTE TYPE B 1 causes the FTP server to change its data type to Shift JIS code without changing the data type in the FTP user. In this example, you must set the ASCII data type before you issue the QUOTE subcommand.

Using DBCS with Mail

This section describes how to use SMTP with DBCS support to exchange DBCS mail and messages between hosts supporting DBCS mail.

SMTP Server DBCS Support

Mail in EBCDIC DBCS Kanji, Hangeul, or Traditional Chinese, may be sent to a remote host via the CMS NOTE and SENDFILE commands, if the local SMTP server or agent is configured with the corresponding DBCS support. For more information on configuring DBCS support for the SMTP server, see z/VM: TCP/IP Planning and Customization.

SMTP Protocol for 8-bit characters

The protocol specification for SMTP describes a transport service that provides an 8-bit byte transmission channel, with each 7-bit character transmitted right-justified in an octet with the high-order bit cleared to zero. JIS Kanji DBCS may be transmitted using this protocol, as its code consists of two bytes with 7-bit ASCII and three bytes of escape sequences. JUNET, which is the Japanese academic and research network connecting various UNIX operating systems, provides network services using JIS Kanji code. Other DBCS types, such as Shift-JIS Kanji, require transmission using 8-bit characters. To allow transmission of these other types, the protocol has been extended in the VM SMTP server to accept 8-bit characters.

To successfully distribute mail with 8-bit DBCS characters, requires that other SMTP servers on the same network support this extension to the SMTP protocol. The AIX SMTP server and the MVS version 3.1 SMTP server also support the transmission of 8-bit characters.

Conversion of DBCS Mail

The transmission of DBCS mail by SMTP actually uses three different translation tables; two SBCS and one DBCS. Mail headers are converted to ASCII using the SBCS translation table that is normally loaded from the STANDARD TCPXLBIN file. The body of the mail is converted using both the SBCS and DBCS translation tables that are normally loaded from either the STANDARD TCPKJBIN, STANDARD TCPHGBIN, or STANDARD TCPCHBIN file.

Both SBCS and DBCS translation tables are required for the transmission of DBCS mail, as the mail may contain mixed-mode strings. A mixed mode string contains both SBCS and DBCS data, delimited by shift-out and shift-in characters.

Although DBCS support for SMTP does not include direct support for Katakana, it is possible to separately configure the SBCS table used for mail headers, and that used for the body of the mail. If the SMTP server was configured with SJISKANJI, for example, then the SBCS translation table for SJISKANJI could be altered to a Katakana based code page.

DBCS conversion is only performed on outgoing and incoming mail to and from other hosts. Mail spooled to SMTP via NOTE or SENDFILE for the local host, is delivered directly, without any DBCS code conversion.

Using DBCS with FTP and Mail

Conversion of DBCS Files

The transmission of DBCS files by UFT uses three different translation tables; two SBCS and on DBCS. UFT protocol statements are converted to ASCII using the SBCS translation table imbedded in the UFT client (which maps to the STANDARD table). The file data is converted using both the SBCS and DBCS translation tables that are normally loaded from the filename specified on the SENDFILE TRANSLATE option with a filetype of either TCPKJBIN, TCPHGBIN or TCPCHBIN.

Appendix E. Management Information Base Objects

This appendix describes the objects defined by the Management Information Base (MIB) and MIB-IIvariables supported by VM.

The following list contains the supported variables.

- System
- Interfaces
- · Address Translation
- Internet Protocol (IP)
- Internet Control Message Protocol (ICMP)
- Transmission Control Protocol (TCP)
- User Datagram Protocol (UDP)
- Bridge (dot1dBridge)

For a complete list of the MIB and MIB-II variables, see RFC 1156 (MIB) and RFC 1158 (MIB-II).

The object types are defined using the following fields:

Object A textual name, called the OBJECT DESCRIPTOR, for the object

type, along with its corresponding OBJECT IDENTIFIER.

Syntax The syntax for the object type, using ASN.1 notation. The syntax

indicates that the following data is to be treated as a collection of objects that can be repeated. For example, the collection of objects can be row entries in a routing table with an unspecified number of rows. Therefore, these descriptors are not really MIB objects that can be manipulated, but only the objects within the sequence.

Definition A description of the object type. Because this MIB is intended for

use in multivendor environments, object types must have consistent

meanings across all machines.

Access One of read-only, read-write, write-only, or not-accessible.

VM Support One of yes, no, or read-only.

Structure and Identification of Management Information (SMI)

Managed objects are accessed through a virtual information store, known as the Management Information Base (MIB). Objects in the MIB are defined using Abstract Syntax Notation One (ASN.1).

Each object type has a name, a syntax, and an encoding description. The name is represented uniquely as an object identifier, which assigned by a systems administrater.

The syntax for an object type defines the abstract data structure corresponding to that object type. For example, the structure of a given object type might be an integer or an octet string. RFC 1155 restricts the ASN.1 constructs that can be used. These restrictions are made solely for the sake of simplicity.

The encoding of an object type describes how instances of that object type are represented using the object's type syntax. RFC 1155 specifies the use of the basic encoding rules of ASN.1.

Names

Names are used to identify managed objects and they are hierarchical in nature. For example, each international standard has an object identifier assigned to it for the purpose of identification. In short, object identifiers are a means for identifying some object, regardless of the semantics associated with it.

The root node itself is unlabeled, but has at least three nodes directly under it: one node is administered by the International Standards Organization (ISO), with label iso(1); another is administered by the International Telegraph and Telephone Consultative Committee (CCITT), with label ccitt(2); and the third is jointly administered by the ISO and the CCITT, joint-iso-ccitt(3).

Under the iso(1) node, the ISO has designated one subtree for use by other (inter)national organizations, org(3). Under this node, one of the subtrees has been allocated to the US Department of Defense (DOD), dod(6), under which only one node has been assigned to the Internet community, and it is administered by the Internet Activities Board (IAB). Therefore, the Internet subtree of object identifiers starts with the prefix 1.3.6.1.

The Management Subtree

Under the IAB node, four subtrees have been defined, namely, directory(1), mgmt(2), experimental(3), and private(4). The administration of the mgmt(2) subtree was delegated by the IAB to the Internet Assigned Numbers Authority for the Internet. This subtree is used to identify objects that are defined in IAB-approved documents. So far, the prefix of the object identifiers is: 1.3.6.1.2.

When RFCs, which define new versions of the Internet-standard MIB, are approved, they are assigned an object identifier for identifying the objects defined by that RFC. The Internet-standard MIB has been assigned management document number one. Therefore, its object identifier is:

```
{ mgmt 1 }
or
   1.3.6.1.2.1
```

The private(4) subtree is used to define enterprise-specific variables in the MIB, which means that you can add your own objects to the MIB. The prefix of these variables is: 1.3.6.1.4.

Figure 68 illustrates the hierarchical ISO tree that has been adopted to identify managed objects.

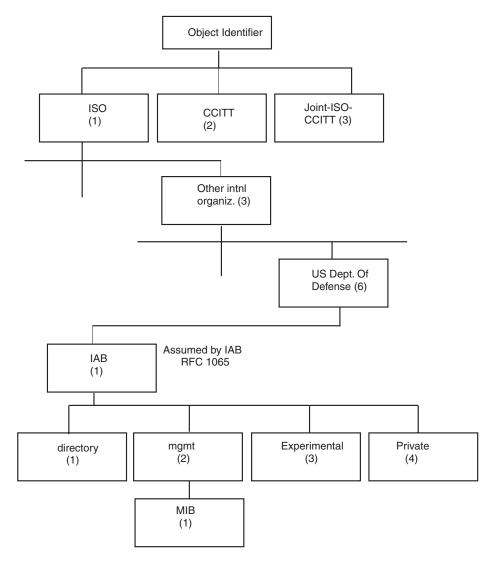

Figure 68. The SMI Hierarchical Tree

The SMI is not supposed to define objects in the MIB, but it does specify a format to be used by the RFCs that define these objects. An object type definition consists of the following fields.

Field Name	Description
Object	Specifies a textual name, termed the object descriptor, for the object type, along with its corresponding object identifier
Syntax	Specifies the abstract syntax for the object type, such as integer, octet string, counter, timeticks, and so on
Definition	Specifies a textual description of the semantics of the object type
Access	Specifies read-only, read-write, write-only or not-accessible
Status	Specifies mandatory, optional, or obsolete

The following is an example of an object type definition:

Object: sysDescr.

MIB Objects

Syntax:

Octet string.

Definition:

A textual description of the entity. This value should include the full name and version identification of the system's hardware type, software operating system, and networking software. It is mandatory that this only contain printable ASCII characters.

Access:

read-only.

Status:

mandatory.

Group Name Description

For more information, see RFC 1155.

MIB/Network Elements

The MIB defines the information that can be obtained from SNMP agents. The MIB defines objects, such as packet counts and routing tables that are relevant to a TCP/IP environment. The objects defined by the MIB are divided into groups, with each group representing a set of management data.

Currently, the following groups have been defined:

Group Hamo	2000 phon
System	Contains information about the entity, such as system hardware, software, and the version number.
Interfaces	Contains all the interfaces through which the nodes can send and receive IP datagrams. It also contains counters for packets sent and received and errors.
Address transla	ation
	Contains information for mapping a network address into a specific subnetwork or physical address. This group is deprecated, meaning that it still exists but will be deleted in the future.
IP	Contains information about the IP layer, such as the number of datagrams sent, received, and forwarded. It includes two tables: the IP address table contains the IP addressing information for the entity; the IP routing table contains one entry for each route presently known to it.
ICMP	Contains the ICMP input and output statistics.
TCP	Contains information about the TCP connections, such as the maximum number of connections the entity can support, the total number of retransmitted segments, the minimum and maximum time-out values, and so on.
UDP	Contains information about the UDP layer, such as counters for datagrams sent and received.
EGP	Contains information about EGP peers, such as the number of messages sent and received, error counters, and so on.
Transmission	Contains media-specific information. This group is not currently implemented.

SNMP	Contains information about the SNMP agent, such as the number of SNMP packets received, the number of SNMP requests with bad community names, and so on.
Bridge	Contains information about bridges and devices used to connect Local Area Network segments below the network layer. The VSWITCH is z/VM's implementation of a virtual bridge.

The system group is the first group in the MIB. Therefore, it is identified as:

```
{ mib 1 }
or
1.3.6.1.2.1.1
```

Each group has its own subtree. For example, the first variable in the system group is the system description (sysDescr), so that it can be represented as:

```
{ system 1 } or 1.3.6.1.2.1.1.1
```

To summarize the explanation, the following describes the composition of the ASN.1 object identifier for sysDescr.

iso org dod internet mgmt mib system sysDescr
1 3 6 1 2 1 1 1

System Group

Table 32 lists the objects in the system group. The system objects identify the type of system with a text description and the vendor-assigned object-ID as an identification to the type of SNMP server.

Table 32. Implementation of the System Group

Object	Syntax	Definition	Access
sysDescr { system 1 }	DisplayString	A description of the entry. This value should include the full name and version identification of the system's hardware type, software operating system, and networking software. This description must only contain printable ASCII characters.	read-only
sysObjectID { system 2 }	OBJECT IDENTIFIER	The vendor's authorization identification of the network management subsystem contained in the entry. This value is allocated within the Structure for Management Information (SMI) enterprise's subtree (1.3.6.1.4.1) and provides an easy and clear means for determining what kind of box is being managed. For example, if vendor Stones, Inc. was assigned the subtree 1.3.6.1.4.1.42, it could assign the identifier 1.3.6.1.4.1.42.1.1 to the router Fred Router.	read-only

^{1.} All accesses of read-write indicate a read-only access for VM.

MIB Objects

Table 32. Implementation of the System Group (continued)

Object	Syntax	Definition	Access
sysUpTime { system 3 }	TimeTicks	The time (in hundredths of a second) since the network management portion the system was last started.	read-only of
sysContact { system 4 }	DisplayString	The textual identification of the contact person for this managed node, together with information about how to contact the person.	
sysName { system 5 }	DisplayString	An administratively-assigned name for t managed node. By convention, this is the node's fully-qualified domain name	
sysLocation { system 6 }	DisplayString	The physical location of this node (for example, telephone closet, 3rd floor)	read-only
sysServices { system 7 }	INTEGER	A value that indicates the set of service that this entity potentially offers. The value is a sum. This sum initially takes the value, then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added the sum. For example, a node that performs only routing functions would have a value of 4 (2^(3-1)). In contrast, node that is a host offering application services would have a value of 72 (2^(4 + 2^ (7-1))). Note that in the context of the internet suite of protocols, values should be calculated accordingly:	ue lue d to a 1)
		Layer Functionality	
		1 Physical (for example, repeate	•
		2 Datalink/subnetwork (for example bridges)	ole,
		Internet (for example, supports the IP)	
		4 End-to-end (for example, supports the TCP)	
		7 Applications (for example, supports the SMTP)	
		For systems including OSI protocols, layers 5 and 6 can also be counted	

layers 5 and 6 can also be counted.

Interfaces Group

Table 33 lists the objects in the interfaces group. The interfaces objects are a set of entries for each network interface below the IP layer that can send and receive

Table 33. Implementation of the Interfaces Group

Object	Syntax	Definition	Access
ifNumber { interfaces 1 }	INTEGER	The number of network interfaces (regardless of their current state) present on this system.	read-only
ifTable { interfaces 2 }	SEQUENCE of IfEntry	A list of interface entries. The number of entries is given by the value of ifNumber.	not applicable

Table 33. Implementation of the Interfaces Group (continued)

Object	Syntax	Definition	Access
fEntry	IfEntry ::= SEQUENCE	An interface entry that contains objects at the subnetwork layer and	read-write
{ ifTable 1 }	ifIndex	below for a particular interface.	
	INTEGER,		
	ifDescr		
	(DISPLAY STRING in MIB-II)		
	ifType		
	INTEGER,		
	ifMtu		
	INTEGER,		
	ifSpeed		
	Gauge,		
	ifPhysAddress		
	OCTET STRING,		
	ifAdminStatus		
	INTEGER,		
	ifOperStatus		
	INTEGER,		
	ifLastChange		
	TimeTicks,

	Counter,		
	ifOutDiscards		
	Counter,		
	ifOutErrors		
	Counter,		
	ifOutQLen		
	Gauge		
	ifSpecific		
	Object ID		
fIndex	INTEGER	A unique value for each interface.	read-only
		Values range between 1 and the	
{ ifEntry 1 }		value of ifNumber. The value for each	
		interface must remain constant for at	
		least one start of the systems	
		network management system to the	
		next start.	

Table 33. Implementation of the Interfaces Group (continued)

Object	Syntax	Definition	Access
fDescr { ifEntry 2 }	DisplayString	A text string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface.	read-only
ifType { ifEntry 3 }	other (1), regular 1822 (2), hdh1822 (3), ethernet-csmacd (6), iso88023-csmacd (7), iso88024-tokenBus (8), iso88025-tokenRing (9), iso88026-kman (10), starLan (11), proteon-10Mbit (12), proteon-80Mbit (13), hyperchannel (14), fddi (15), lapb (16), sdlc (17), tl-carrier (18), cept (19), basicISDN (20), primaryISDN (21), propPointToPointSerial (22), terminalServer-asypcPort (23), softwareLoopback (24), eon (25), ethernet-3Mbit (26), nsip (27), slip (28)	The type of interface, distinguished according to the physical/link/network protocol(s) immediately below IP in the protocol stack.	read-only
ifMtu	INTEGER	The size of the largest datagram that can be sent or received on the interface, specified in octets. For	read-only
{ ifEntry 4 }		interfaces, specified in octets. For interfaces that are used for transmitting IP datagrams, this is the size of the largest IP datagram that can be sent on the interface.	
ifSpeed	Gauge	An estimate of the interface's current bandwidth in bits per second. For	read-only
{ ifEntry 5 }		interfaces that do not vary in bandwidth or for those where no accurate estimate can be made, this object should contain the nominal bandwidth.	
ifPhysAddress	OCTET STRING	The interface's address at the protocol layer immediately <i>below</i> IP in	read-only
{ ifEntry 6 }		the protocol stack. For interfaces that do not have such an address (for example, a serial line), this object should contain an octet string of length 0.	

Table 33. Implementation of the Interfaces Group (continued)

Object	Syntax	Definition	Access
ifAdminStatus { ifEntry 7 }	INTEGER up (1), down (2), testing (3)	The desired state of the interface. The testing (3) state indicates that operational packets cannot be passed.	read-write ¹
ifOperStatus { ifEntry 8 }	INTEGER up (1), down (2), testing (3)	The current operational state of the interface. The testing (3) state indicates that operational packets cannot be passed.	read-only
ifLastChange { ifEntry 9 }	TimeTicks	The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered before the last start-up of the local network management subsystem, then this object contains a value of 0.	read-only
ifInOctets { ifEntry 10 }	Counter	The total number of octets received on the interface, including framing characters.	read-only
ifInUcastPkts { ifEntry 11 }	Counter	The number of subnetwork-unicast packets delivered to a higher-layer protocol.	read-only
IfInNUcastPkts { ifEntry 12 }	Counter	The number of non-unicast (for example, subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol.	read-only
ifInDiscards { ifEntry 13 }	Counter	The number of inbound packets that were chosen to be discarded even though errors had not been detected to prevent their delivery to a higher-layer protocol. One possible reason for discarding such a packet could be to free buffer space.	read-only
ifInErrors { ifEntry 14 }	Counter	The number of inbound packets that contain errors that prevent delivery to a higher-layer protocol.	read-only
ifInUnknownProtos { ifEntry 15 }	Counter	The number of packets received through the interface that were discarded because of an unknown or unsupported protocol.	read-only
ifOutOctets { ifEntry 16 }	Counter	The total number of octets transmitted out of the interface, including framing characters.	read-only
ifOutUcastPkts { ifEntry 17 }	Counter	The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent.	read-only

Table 33. Implementation of the Interfaces Group (continued)

Object	Syntax	Definition	Access
ifOutNUcastPkts { ifEntry 18 }	Counter	The total number of packets that higher-level protocols request to be transmitted to a non-unicast (for example, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent.	read-only
ifOutDiscards { ifEntry 19 }	Counter	The number of outbound packets that were chosen to be discarded even though errors had not been detected to prevent their being transmitted. One reason for discarding such a packet could be to free buffer space.	read-only
ifOutErrors { ifEntry 20 }	Counter	The number of outbound packets that could not be transmitted because of errors.	read-only
ifOutQLen { ifEntry 21 }	Gauge	The length of the output packet queue (in packets).	read-only
ifSpecific { ifEntry 22 }	OBJECT IDENTIFIER	A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If an agent is not configured to have a value for any of these variables, the following object identifier is returned: nullSpecific OBJECT IDENTIFIER ::= { 0 0 } Note that nullSpecific is a syntactically valid object identifier, and any conformant implementation of ASN.1 and BER must be able to generate and recognize this value.	read-only

Address Translation Group

Table 34 lists the objects in the address translation group. The address translation objects are a set of entries for each network interface, below the IP layer, that can send and receive datagrams.

Table 34. Implementation of the Address Translation Group

Object	Syntax	Definition	Access
atTable	SEQUENCE OF AtEntry	The Address Translation tables contain the NetworkAddress to physical address	read-write ¹
{ at 1 }		equivalences. Some interfaces do not use translation tables to determine address equivalences. If all interfaces are of this type, then the Address Translation table is empty; it has 0 entries.	

Table 34. Implementation of the Address Translation Group (continued)

Object	Syntax	Definition	Access
atEntry	AtEntry ::= SEQUENCE	Each entry contains one NetworkAddress to the physical address equivalent.	read-write
{ atTable 1 }	atifindex INTEGER, atPhysAddress OCTET STRING, atNetAddress NetworkAddress		
atlfIndex { atEntry 1 }	INTEGER	The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface that is identified by the same value of ifIndex.	read-write
atPhysAddress	OCTET STRING	The media-dependent physical address.	read-write
{ atEntry 2 }			
atNetAddress	NetworkAddress	The NetworkAddress (for example, the IP address) corresponding to the	read-write
{ atEntry 3 }		media-dependent physical address.	

IP Group

Table 35 lists the objects in the IP group. The IP objects are the statistics and gateway routing tables for the IP layer.

Table 35. Implementation of the IP Group

Object	Syntax	Definition	Access
ipForwarding { ip 1 }	INTEGER gateway (1), — entry forwards datagrams host (2) — entry does NOT forward datagrams	Indicates if this entry is acting as an IP gateway for the forwarding of datagrams received by, but not addressed to, this entry. IP gateways forward datagrams; hosts do not, except those source-routed through the host.	read-only
ipDefaultTTL { ip 2 }	INTEGER	When a TTL value is not supplied by the transport layer protocol, the default value inserts into the time-to-live field of the IP header of datagrams that originate at this entry.	read-write ¹
ipInReceives { ip 3 }	Counter	The number of input datagrams received from interfaces, including those received in error.	read-only
ipInHdrErrors { ip 4 }	Counter	The number of input datagrams discarded because of errors in their IP headers. For example, bad checksums, mismatched version number, format errors, time-to-live exceeded, and processing errors in IP options.	read-only

Table 35. Implementation of the IP Group (continued)

Object	Syntax	Definition	Access
ipInAddrErrors { ip 5 }	Counter	The number of input datagrams discarded because the IP address in their IP header's destination field was not a valid address to be received at this entry. This count includes invalid addresses (for example, 0.0.0.0), addresses of unsupported classes (for example, Class E), and destination addresses that were not local addresses (for example, IP gateways).	read-only
ipForwDatagrams { ip 6 }	Counter	The number of input datagrams for which this entry is not their final IP destination. As a result, an attempt is made to find a route to their final destination. For entries that do not act as IP gateways, this count includes only those packets that are source-routed successfully through this entry.	read-only
ipInUnkownProtos { ip 7 }	Counter	The number of locally-addressed datagrams received successfully, but discarded because of an unknown or unsupported protocol.	read-only
ipInDiscards { ip 8 }	Counter	The number of input IP datagrams that are processed without problems, but are discarded (for example, for lack of buffer space). This count does not include any datagrams discarded while awaiting reassembly.	read-only
ipInDelivers { ip 9 }	Counter	The number of input datagrams successfully delivered to IP user-protocols including ICMP.	read-only
ipOutRequests { ip 10 }	Counter	The number of IP datagrams that are supplied to IP and ICMP in requests for transmission. This count does not include datagrams counted in ipForwDatagrams.	read-only
ipOutDiscards { ip 11 }	Counter	The number of output IP datagrams that transmit without problems, but are discarded (for example, for lack of buffer space). This count includes datagrams in ipForwDatagrams that meet this discard criterion.	read-only
ipOutNoRoutes { ip 12 }	Counter	The number of IP datagrams discarded because no route can transmit them to their destination. This count includes packets in ipForwDatagrams that meet this no-route criterion.	read-only
ipReasmTimeout { ip 13 }	INTEGER	The maximum number of seconds that received fragments are held while awaiting reassembly at this entry.	read-only
ipReasmReqds { ip 14 }	Counter	The number of IP fragments that are received and need to be reassembled at this entry.	read-only

Table 35. Implementation of the IP Group (continued)

Object	Syntax	Definition	Access
ipReasmOKs { ip 15 }	Counter	The number of IP datagrams reassembled without problems.	read-only
ipReasmFails { ip 16 }	Counter	The number of failures detected by the IP reassembly algorithm. This is not a count of discarded IP fragments because some algorithms can lose track of the number of fragments by combining them as they are received.	read-only
ipFragOKs	Counter	The number of IP datagrams that have fragmented at this entry without problems.	read-only
{ ip 17 } ipFragFails { ip 18 }	Counter	The number of IP datagrams that should have been fragmented at this entry, but were not because their <i>Don't Fragment</i> flag was set.	read-only
ipFragCreates { ip 19 }	Counter	The number of IP datagram fragments that have been generated, because of fragmentation at this entry.	read-only
ipAddrTable	SEQUENCE OF IpAddrEntry	A table that contains addressing information relevant to this entry's IP	read-only
{ ip 20 }		addresses.	
ipAddrEntry { ipAddrTable 1 }	IpAddrEntry ::= SEQUENCE ipAdEntAddr	The addressing information for one of this entry's IP addresses.	read-only
<pre>ipAdEntAddr { ipAddrEntry 1 }</pre>	IpAddress	The IP address pertaining to this entry's addressing information.	read-only
ipAdEntIfIndex { ipAddrEntry 2 }	INTEGER	The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface that is identified by the same value of ifIndex.	read-only
ipAdEntNetMask { ipAddrEntry 3 }	IpAddress	The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1 and all the host bits set to 0.	read-only

Table 35. Implementation of the IP Group (continued)

Object	Syntax	Definition	Access
ipAdEntBcastAddr { ipAddrEntry 4 }	INTEGER	The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the internet standard all-ones broadcast address is used, the value is 1.	read-only
pAdEntReasmMaxSize { ipAddrEntry 5 }	INTEGER	The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface.	read-only
pRoutingTable	SEQUENCE OF	This entry's IP routing table.	read-write
[ip 21 }	IpRouteEntry		
ipRouteEntry { ipRoutingTable 1 }	ipRouteEntry ::= SEQUENCE ipRouteDest IpAddress, ipRouteIfIndex INTEGER, ipRouteMetric 1 INTEGER, ipRouteMetric 2 INTEGER, ipRouteMetric 3 INTEGER, ipRouteMetric 4 INTEGER, ipRouteMetric 4 INTEGER, ipRouteNextHop IpAddress, ipRouteType INTEGER, ipRouteType INTEGER, ipRouteProto INTEGER, ipRouteAge INTEGER ipRouteMask INTEGER	A route to a particular destination.	read-write
ipRouteDest { ipRouteEntry 1 }	IpAddress	The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple default routes can appear in the table, but access to these multiple entries is dependent on the table-access mechanisms defined by the network management protocol in use.	read-write
ipRouteIfIndex { ipRouteEntry 2 }	INTEGER	The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface that is identified by the same value of iflndex.	read-write

Table 35. Implementation of the IP Group (continued)

Object	Syntax	Definition	Access
ipRouteMetric1 { ipRouteEntry 3 }	INTEGER	The primary routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to -1.	read-write ¹
ipRouteMetric2 { ipRouteEntry 4 }	INTEGER	An alternative routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to -1.	read-write
ipRouteMetric3 { ipRouteEntry 5 }	INTEGER	An alternative routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to -1.	read-write
ipRouteMetric4 { ipRouteEntry 6 }	INTEGER	An alternative routing metric for this route. The semantics of this metric are determined by the routing protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to -1.	read-write
ipRouteNextHop { ipRouteEntry 7 }	IpAddress	The IP address of the next hop of this route.	read-write
ipRouteType	INTEGER	The type of route.	read-write
{ ipRouteEntry 8 }	other (1), invalid (2), direct (3), remote (4)	,	
ipRouteProto { ipRouteEntry 9 }	other (1), local (2), netmgmt (3), icmp (4), egp (5), ggp (6), hello (7), rip (8), is-is (9), es-is (10), ciscolgrp (11), bbnSpflgp (12), ospf (13)	The routing mechanism by which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols.	read-only
ipRouteAge { ipRouteEntry 10 }	INTEGER	The number of seconds since this route was last updated or otherwise determined to be correct. Note semantics of <i>too old</i> cannot be implied, except through knowledge of the routing protocol by which the route was learned.	read-write

Table 35. Implementation of the IP Group (continued)

Object	Syntax	Definition	Access
ipRouteMask { ipRouteEntry 11 }	ipAddress	Indicate the mask to be logically ANDed with the destination address before being compared to the value in the ipRouteDest field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the ipRouteMask by determining whether the value of the correspondent ipRouteDest field belongs to a class–A, B, or C network. Then use one of the following:	read-write
		mask network 255.0.0.0 class-A 255.255.0.0 class-B 255.255.255.0 class-C If the value of the ipRouteDest is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. All IP routing subsystems implicitly use this mechanism.	

IP Address Translation Table

Table 36 lists the objects in the IP Translation table.

Table 36. IP Address Translation Table

Object	Syntax	Definition	Access
ipNetToMediaTable	SEQUENCE OF IpNetToMediaEntry	The IP Address Translation table used for mapping from IP addresses to physical	read-write ¹
{ ip 22 }		addresses.	
IpNetToMediaEntry	IpNetToMediaEntry ::= SEQUENCE	Each entry contains one IpAddress to physical address equivalence.	read-write
{ ipNetToMediaTable 1 }			
	ipNetToMedialfIndex INTEGER, ipNetToMediaPhysAddress OCTET STRING, ipNetToMediaNetAddress IpAddress, ipNetToMediaType INTEGER		
ipNetToMedialfIndex	INTEGER	The interface on which this entry's equivalence is effective. The interface	read-write
{ ipNetToMediaEntry 1 }		identified by a particular value of this index is the same interface as identified by the same value of ifIndex.	
ipNetToMediaPhysAddress	OCTET STRING	The media-dependent physical address.	read-write
{ ipNetToMediaEntry 2 }			
ipNetToMediaNetAddress	IpAddress	The IpAddress corresponding to the media-dependent physical address.	read-write
{ ipNetToMediaEntry 3 }			

Table 36. IP Address Translation Table (continued)

Object	Syntax	Definition	Access
ipNetToMediaType	INTEGER	The type of mapping.	read-write
{ ipNetToMediaEntry 4 }	other(1), invalid(2), dynamic(3), static(4),	Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the ipNetToMediaTable. That is, it effectively disassociates the interface identified with the entry from the mapping identified with the entry. Whether the agent removes an invalidated entry from the table is an implementation-specific matter. Accordingly, management stations must be prepared to receive tabular information from agents that correspond to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipNetToMediaType object.	

ICMP Group

Table 37 lists the objects in the ICMP group. The ICMP objects are the input and output error and control message statistics for the IP layer.

Table 37. Implementation of the ICMP Group

Object	Syntax	Definition	Access
icmpInMsgs	Counter	The number of ICMP messages that the entry receives. This counter includes all those counted	read-only
{ icmp 1 }		by icmpInErrors.	
icmpInErrors	Counter	The number of ICMP messages that the entry receives and determines ICMP specific errors	read-only
{ icmp 2 }		(bad ICMP checksums, bad length).	
icmpInDestUnreachs	Counter	The number of ICMP destination messages that cannot be reached.	read-only
{ icmp 3 }			
icmpInTimeExcds	Counter	The number of ICMP destination messages that cannot be reached.	read-only
{ icmp 4 }			
icmpInParmProbs	Counter	The number of ICMP Parameter Problem messages received.	read-only
{ icmp 5 }			
icmpInSrcQuenchs	Counter	The number of ICMP Source Quench messages received.	read-only
{ icmp 6 }			
icmpInRedirects	Counter	The number of ICMP Redirect messages received.	read-only
{ icmp 7 }			
icmpInEchos	Counter	The number of ICMP Echo (request) messages received.	read-only
{ icmp 8 }			

Table 37. Implementation of the ICMP Group (continued)

Object	Syntax	Definition	Access
icmpInEchoReps	Counter	The number of ICMP Echo Reply messages received.	read-only
{ icmp 9 }			
icmpInTimestamps	Counter	The number of ICMP Timestamp (request) messages received.	read-only
{ icmp 10 }			
icmpInTimestampReps	Counter	The number of ICMP Timestamp Reply messages received.	read-only
{ icmp 11 }			
icmpInAddrMasks	Counter	The number of ICMP Address Mask Request messages received.	read-only
{ icmp 12 }			
icmpInAddrMaskReps	Counter	The number of ICMP Address Mask Reply messages received.	read-only
{ icmp 13 }			
icmpOutMsgs	Counter	The number of ICMP messages sent. This counter includes icmpOutErrors.	read-only
{ icmp 14 }			
icmpOutErrors { icmp 15 }	Counter	The number of ICMP messages that this entry did not send, because of problems within ICMP (for example, no buffers). This value should not include errors outside the ICMP layer (for example, the inability of IR to result	read-only
		example, the inability of IP to route the resulting datagram). In some implementations, there may not be error types that contribute to the counter's value.	
icmpOutDestUnreachs	Counter	The number of ICMP Destination Unreachable messages sent.	read-only
{ icmp 16 }			
icmpOutTimeExcds	Counter	The number of ICMP Time Exceeded messages sent.	read-only
{ icmp 17 }			
icmpOutParmProbs	Counter	The number of ICMP Parameter Problem messages sent.	read-only
{ icmp 18 }			
icmpOutSrcQuenches	Counter	The number of ICMP Source Quench messages sent.	read-only
{ icmp 19 }	0	The mumber of IOMP Delivery	uaaal culu
icmpOutRedirects { icmp 20 }	Counter	The number of ICMP Redirect messages sent. For a host, this object is always 0, because hosts do not send redirects.	read-only
	Countar		road only
icmpOutEchos	Counter	The number of ICMP Echo (request) messages sent.	read-only
{ icmp 21 }		TI (1010 F) F :	
icmpOutEchoReps	Counter	The number of ICMP Echo Reply messages sent.	read-only
{ icmp 22 }			
icmpOutTimestamps	Counter	The number of ICMP Timestamp (request) messages sent.	read-only
{ icmp 23 }			

Table 37. Implementation of the ICMP Group (continued)

Object	Syntax	Definition	Access
icmpOutTimestampReps	Counter	The number of ICMP TimeStamp Reply messages sent.	read-only
{ icmp 24 }			
icmpOutAddrMasks	Counter	The number of ICMP Address Mask Request messages sent.	read-only
{ icmp 25 }			
icmpOutAddrMasksReps	Counter	The number of ICMP Address Mask Reply messages sent.	read-only
{ icmp 26 }			

TCP Group

Table 38 lists the objects in the TCP group. The TCP objects are the data transmission statistics and connection data for the TCP layer.

Note: Objects that represent information about a particular TCP connection are transient; the objects exist only as long as the specified connection is in use.

Table 38. Implementation of the TCP Group

Object	Syntax	Definition	Access
tcpRtoAlgorithm { tcp 1 }	other (1), none of the following constant (2), a constant rto rsre (3), MIL-STD-1778, Appendix B vanj (4) Van Jacobson's algorithm	The algorithm used to determine the time-out value used for retransmitting unacknowledged octets.	read-only
tcpRtoMin { tcp 2 }	INTEGER	The minimum value allowed by a TCP implementation for the retransmission time-out, measured in milliseconds. Semantics for objects of this type depend upon the algorithm used to determine the retransmission time-out. For example, when the time-out algorithm is rsre (3), an object of this type has the semantics of the LBOUND quantity.	read-only
tcpRtoMax { tcp 3 }	INTEGER	The maximum value allowed by a TCP implementation for the retransmission time-out, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission time-out. For example, when the time-out algorithm is rsre (3), an object of this type has the semantics of the UBOUND quantity.	read-only

Table 38. Implementation of the TCP Group (continued)

Object	Syntax	Definition	Access
tcpMaxConn { tcp 4 }	INTEGER	The limit on the number of TCP connections the entry can support. In entries where the maximum number of connections is dynamic, this object should be -1 .	read-only
tcpActiveOpens { tcp 5 }	Counter	The number of TCP connections that have made a direct transition to the SYN-SENT state from the CLOSED state.	read-only
tcpPassiveOpens { tcp 6 }	Counter	The number of times TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state.	read-only
tcpAttemptFails { tcp 7 }	Counter	The number of TCP connections that have made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state.	read-only
tcpEstabResets { tcp 8 }	Counter	The number of TCP connections that have made a direct transition to the CLOSED state from either the ESTABLISHED or CLOSE-WAIT state.	read-only
tcpCurrEstab { tcp 9 }	Gauge	The number of TCP connections of the current state that are either ESTABLISHED or CLOSE-WAIT.	read-only
tcpInSegs { tcp 10 }	Counter	The number of TCP segments including those received in error. This count includes segments received on established connections.	read-only
tcpOutSegs { tcp 11 }	Counter	The number of TCP segments sent including those on established connections, but excluding those containing only retransmitted octets.	read-only
tcpRetransSegs { tcp 12 }	Counter	The number of TCP segments retransmitted that contain one or more previously transmitted octets.	read-only
tcpConnTable { tcp 13 }	SEQUENCE OF TcpConnEntry	A table that contains TCP connnection-specific information.	read-only
tcpConnEntry	TcpConnEntry ::= SEQUENCE tcpConnState INTEGER, tcpConnLocalAddress IpAddress, tcpConnLocalPort INTEGER (065535), tcpConnRemAddress IpAddress, tcpConnRemPort INTEGER (065535)	Information about a certain current TCP connection. An object of this type is transient. It does not exist when (or soon after) the connection makes the transition to the CLOSED state.	read-only

Table 38. Implementation of the TCP Group (continued)

Object	Syntax	Definition	Access
tcpConnState { tcpConnEntry 1 }	INTEGER closed(1), listen(2), synSent(3), synReceived(4), established(5), finWait1(6), finWait2(7), closeWait(8), lastAck(9), closing(10), timeWait(11)	The TCP connection status.	read-only
tcpConnLocalAddress	IpAddress	The local IP address of this TCP connection.	read-only
{ tcpConnEntry 2 }			
tcpConnLocalPort	INTEGER	The local port number of this TCP connection.	read-only
{ tcpConnEntry 3 }	(065535)		
tcpConnRemAddress	IpAddress	The remote IP address of this TCP connection.	read-only
{ tcpConnEntry 4 }			
tcpConnRemPort	INTEGER	The remote port number of this TCP connection.	read-only
{ tcpConnEntry 5 }	(065535)		
tcpInErrs	Counter	The total number of segments received in error (for example, bad TCP checksums).	read-only
{ tcp 14 }			
tcpOutRsts	Counter	The number of TCP segments sent containing the RST flag.	read-only
{ tcp 15 }			

UDP Group

Table 39 lists the objects in the UDP group. The UDP objects are the datagram statistics of the UDP layer.

Table 39. Implementation of the UDP Group

Object	Syntax	Definition	Access
udpInDatagrams	Counter	The number of UDP datagrams delivered to UDP users.	read-only
{ udp 1 }			
udpNoPorts	Counter	The number of UDP datagrams received where there was no application at the	read-only
{ udp 2 }		destination port.	
udpInErrors	Counter	The number of UDP datagrams received that could not be delivered for reasons	read-only
{ udp 3 }		other than the lack of an application at the destination port.	
udpOutDatagrams	Counter	The number of UDP datagrams sent from this entry.	read-only
{ udp 4 }		•	
udpTable	SEQUENCE of UDPEntry	Information about this ENTITY's UDP end-points on which a local application is	read-only
{ udp 5 }		currently accepting datagrams.	

Table 39. Implementation of the UDP Group (continued)

Object	Syntax	Definition	Access
udpEntry	UdpEntry ::= SEQUENCE	Information about a certain current UDP listener.	read-only
{ udpTable 1 }	udpLocalAddress IpAddress, udpLocalPort INTEGER		
udpLocalAddress { udp Entry 1 }	IpAddress	The local IP address for this UDP listener. 0.0.0.0 is a listener which is willing to accept datagrams for any IP interface associated with the node.	read-only
udpLocalPort	INTEGER	The local port number for this UDP listener.	read-only
{ udpEntry 2 }			

Bridge Group

"Bridge Group" lists the objects in the Bridge group.

Table 40. Implementation of the Bridge Group - dot1dBase

Object	Syntax	Definition	Access
dot1dBase {dot1dBase 1}	OBJECT IDENTIFIER	This mandatory group contains the objects which are applicable to all types of bridges.	read-only
		Note for z/VM: The virtual switch (VSWITCH) is the z/VM implementation of a bridge.	
dot1dBaseBridgeAddress {dot1dBridge 1}	MacAddress	The MAC address used by this bridge when it must be referred to in a unique fashion. It is recommended that this be the numerically smallest MAC address of all ports that belong to this bridge. However, it is only required to be unique. When concatenated with dot1dStpPriority, a unique Bridgeldentifier is formed which is used in the Spanning Tree Protocol.	read-only
		Note for z/VM: This is set using SET VSWITCH MACID command or the MODIFY VSWITCH MACID configuration statement.	
dot1dBaseNumPorts {dot1dBase 2}	INTEGER	The number of ports controlled by this bridging entity.	read-only
		Note for z/VM: This is the number of guest NICs active for the virtual switch plus the number of RDEVs active for the virtual switch.	

Table 40. Implementation of the Bridge Group - dot1dBase (continued)

Object	Syntax	Definition	Access
dot1dBaseType {dot1dBase 3}	unknown(1), transparent-only(2), sourceroute-only(3), srt(4)	Indicates what type of bridging this bridge can perform. If a bridge is actually performing a certain type of bridging, this will be indicated by entries in the port table for the given type.	read-only
		Note for z/VM: Virtual switches have a value of transparent-only (2).	
dot1dBasePortTable {dot1dBase 4}	SEQUENCE OF dot1dBasePortEntry	A table that contains generic information about every port that is associated with this bridge. Transparent, sourceroute, and srt ports are included.	read-only
dot1dBasePortEntry {dot1dBasePortTable 1}	dot1dTpPortEntry := SEQUENCE	A list of information for each port of this transparent bridge.	read-only
	dot1dBasePort INTEGER, dot1dBasePortIfIndex INTEGER, dot1dBasePortCircuit OBJECT IDENTIFER, dot1dBasePortDelayExceeded DiscardsCounter, dot1dBasePortMtuExceeded DiscardsCounter		
dot1dBasePort {dot1dBasePortEntry 1}	INTEGER (165535)	The port number of the port for which this entry contains bridge management information.	read-only
		Note for z/VM: The port number may change if a guest uncouples its NIC from the virtual switch. However, if the interface is stopped and restarted, the port number remains constant.	
dot1dBasePortIfIndex {dot1dBasePortEntry 2}	INTEGER	The value of the instance of the ifIndex object, defined in MIB-II, for the interface corresponding to this port.	read-only
dot1dBasePortCircuit {dot1dBasePortEntry 3}	OBJECT IDENTIFIER	For a port which (potentially) has the same value of dot1dBasePortIfIndex as another port on the same bridge, this object contains the name of an object instance unique to this port.	read-only
		For a port which has a unique value of dot1dBasePortIfIndex, this object can have the value of { 0 0 }.	
		Note for z/VM: This contains { 0 0 }.	
dot1dBasePortDelay- ExceededDiscards {dot1dBasePortEntry 4}	Counter	The number of frames discarded by this port due to excessive transit delay through the bridge. It is incremented by both transparent and source route bridges.	read-only
		Note for z/VM: This contains a value of 0.	

Table 40. Implementation of the Bridge Group - dot1dBase (continued)

Object	Syntax	Definition	Access
dot1dBasePortMtu- ExceededDiscards {dot1dBasePortEntry 5}	Counter	The number of frames discarded by this port due to an excessive size. It is incremented by both transparent and source route bridges.	read-only
		Note for z/VM: This contains a value of 0.	
dot1dTp {dot1dBridge 4}	OBJECT IDENTIFIER		read-only
dot1dTpLearned- EntryDiscards {dot1dTp 1}	Counter	The total number of Forwarding Database entries, which have been or would have been learned, but have been discarded due to a lack of space to store them in the Forwarding Database. If this counter is increasing, it indicates that the Forwarding Database is regularly becoming full (a condition which has unpleasant performance effects on the subnetwork). If this counter has a significant value but is not presently increasing, it indicates that the problem has been occurring but is not persistent.	read-only
		Note for z/VM: This contains a value of 0.	
dot1dTpAgingTime {dot1dTp 2}	INTEGER (101000000)	The timeout period in seconds for aging out dynamically learned forwarding information. 802.1D-1990 recommends a default of 300 seconds.	read-only
		Note for z/VM: This contains a value of 1000000.	
dot1dTpFdbTable {dot1dTp 3}			read-only
dot1dTpFdbEntry {dot1dTpFdbTable 1}	dot1dTpFdbAddress	Information about a specific unicast MAC address for which the bridge has some forwarding and/or filtering information.	read-only
	dot1dTpFdbPort dot1dTpFdbStatus	Note for z/VM: For a virtual switch the IP attribute, only one MAC address is known to the outside world — the MACID associated with the virtual switch network connection. Therefore only one instance of this information is returned for an IP (Layer 3) virtual switch.	
		For an ETHERNET (Layer 2) virtual switch, information is returned for all guest ports and all ports associated with virtual switch RDEV connections to the external network.	
dot1dTpFdbAddress {dot1dTpFdbEntry 1}	MacAddress	A unicast MAC address for which the bridge has forwarding and/or filtering information.	read-only

Table 40. Implementation of the Bridge Group - dot1dBase (continued)

Object	Syntax	Definition	Access
dot1dTpFdbPort {dot1dTpFdbEntry 2}	INTEGER	Either the value 0, or the port number of the port on which a frame having a source address equal to the value of the corresponding instance of dot1dTpFdbAddress has been seen. A value of 0 indicates that the port number has not been learned but that the bridge does have some forwarding/filtering information about this address (for example, in the dot1dStaticTable). Implementors are encouraged to assign the port value of this object whenever it is learned, even for addresses for which the corresponding value of dot1dTpFdbStatus is not learned(3).	read-only
dot1dTpFdbStatus {dot1dTpFdbEntry 3}	other (1), invalid (2), learned (3), self (4), mgmt (5)	The status of this entry. The meanings of the values are: other(1) none of the following. This would include the case where some other MIB object (not the corresponding instance of dot1dTpFdbPort, nor an entry in the dot1dStaticTable) is being used to determine if and how frames addressed to the value of the corresponding instance of dot1dTpFdbAddress are being forwarded. invalid(2) this entry is not longer valid (for example, it was learned but has since aged-out), but has not yet been flushed from the table. learned(3) the value of the corresponding instance of dot1dTpFdbPort was learned, and is being used. self(4) the value of the corresponding instance of dot1dTpFdbAddress represents one of the bridge's addresses. The corresponding instance of dot1dTpFdbPort indicates which of the bridge's ports has this address. mgmt(5) the value of the corresponding instance of dot1dTpFdbAddress is also the value of an existing instance of dot1dStaticAddress. Note for z/VM: This always has the value	read-only
dot1dTnPortTnbla	SECHENCE OF	of learned (3).	road only
dot1dTpPortTable {dot1dTp 4}	SEQUENCE OF dot1dTpPortEntry	A table that contains information about read-only every port that is associated with this transparent bridge.	

Table 40. Implementation of the Bridge Group - dot1dBase (continued)

Object	Syntax	Definition	Access
dot1dTpPortEntry {dot1dTpPortTable 1}	dot1dTpPortEntry := SEQUENCE	A list of information for each port of this transparent bridge.	read-only
	dot1dTpPort INTEGER dot1dTpPortMaxInfo INTEGER dot1dTpPortInFrames Counter dot1dTpPortOutFrames Counter dot1dTpPortInDiscards Counter		
dot1dTpPort {dot1dTpPortEntry 1}	INTEGER (165535)	The port number of the port for which this entry contains transparent bridging management information.	read-only
dot1dTpPortMaxInfo {dot1dTpPortEntry 2}	INTEGER	The maximum size of the INFO (non-MAC) field that this port will receive or transmit.	read-only
dot1dTpPortInFrames {dot1dTpPortEntry 3}	Counter	The number of frames that have been received by this port from its segment. Note that a frame received on the interface corresponding to this port is only counted by this object if and only if it is for a protocol being processed by the local bridging function, including bridge management frames.	read-only
dot1dTpPortOutFrames {dot1dTpPortEntry 4}	Counter	The number of frames that have been transmitted by this port to its segment. Note that a frame transmitted on the interface corresponding to this port is only counted by this object if and only if it is for a protocol being processed by the local bridging function, including bridge management frames.	read-only
dot1dTpPortInDiscards {dot1dTpPortEntry 5}	Counter	Count of valid frames received which were discarded (that is, filtered) by the Forwarding Process.	read-only

Appendix F. SNMP Generic TRAP Types

This appendix lists the generic trap types that can be received by SNMP.

Value	Туре	Description
0	coldStart	A coldStart trap signifies that the sending protocol entity is reinitializing itself so that the agent's configuration or the protocol entity implementation can be altered.
1	warmStart	A warmStart trap signifies that the sending protocol entity is reinitializing itself so that neither the agent configuration nor the protocol entity implementation can be altered.
2	linkDown	A linkDown trap signifies that the sending protocol entity recognizes a failure in one of the communication links represented in the agent's configuration.
		A Trap-PDU of type linkDown contains, as the first element of its variable-bindings, the name and value of the ifIndex instance for the affected interface.
3	linkUp	A linkUp trap signifies that the sending protocol entity recognizes that one of the communication links represented in the agent's configuration has come up.
		A Trap-PDU of type linkUp contains, as the first element of its variable-bindings, the name and value of the ifIndex instance for the affected interface.
4	authenticationFailure	An authenticationFailure trap signifies that the sending protocol entity is the addressee of a protocol message that is not properly authenticated.
5	egpNeighborLoss	An egpNeighborLoss trap signifies that an EGP neighbor for whom the sending protocol entity was an EGP peer has been marked down and the peer relationship no longer exists.
		The Trap-PDU of the egpNeighborLoss contains, as the first element of its variable-bindings, the name and value of the egpNeighAddr instance for the affected neighbor.

SNMP Generic TRAP Types

Value	Туре	Description
6	enterpriseSpecific	An enterpriseSpecific trap signifies that the sending protocol entity recognizes that some enterprise-specific event has occurred. The specific-trap field identifies the particular trap that occurred.

Appendix G. Related Protocol Specifications

IBM is committed to industry standards. The internet protocol suite is still evolving through Requests for Comments (RFC). New protocols are being designed and implemented by researchers, and are brought to the attention of the internet community in the form of RFCs. Some of these are so useful that they become a recommended protocol. That is, all future implementations for TCP/IP are recommended to implement this particular function or protocol. These become the *de facto* standards, on which the TCP/IP protocol suite is built.

Many features of TCP/IP for z/VM are based on the following RFCs:

RFC	Title	Author
768	User Datagram Protocol	J.B. Postel

These documents can be obtained from:

Government Systems, Inc. Attn: Network Information Center 14200 Park Meadow Drive Suite 200 Chantilly, VA 22021

Many RFCs are available online. Hard copies of all RFCs are available from the NIC, either individually or on a subscription basis. Online copies are available using FTP from the NIC at nic.ddn.mil. Use FTP to download the files, using the following format:

RFC:RFC-INDEX.TXT RFC:RFCnnnn.TXT RFC:RFCnnnn.PS

Where:

Is the RFC number. nnnn TXT Is the text format.

PS Is the PostScript format.

You can also request RFCs through electronic mail, from the automated NIC mail server, by sending a message to service@nic.ddn.mil with a subject line of RFC nnnn for text versions or a subject line of RFC nnnn.PS for PostScript versions. To request a copy of the RFC index, send a message with a subject line of RFC INDEX.

For more information, contact nic@nic.ddn.mil. Information is also available at Internet Engineering Task Force (www.ietf.org).

Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing IBM Corporation North Castle Drive Armonk, NY 10504-1785 U.S.A.

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing Legal and Intellectual Property Law IBM Japan Ltd. 1623-14, Shimotsurama, Yamato-shi Kanagawa 242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

Site Counsel IBM Corporation 2455 South Road Poughkeepsie, NY 12601-5400 U.S.A.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurement may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information may contain examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information may contain sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Programming Interface Information

This publication primarily documents information that is NOT intended to be used as Programming Interfaces of z/VM.

This publication also documents intended Programming Interfaces that allow the customer to write programs to obtain the services of z/VM. This information is identified where it occurs, either by an introductory statement to a chapter or section or by the following marking:

<...Programming Interface information...>

Trademarks

IBM, the IBM logo, and ibm.com are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the web at IBM copyright and trademark information - United States (www.ibm.com/legal/us/en/copytrade.shtml).

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Linux is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Java and all Java-based trademarks and logos are trademarks of Oracle and/or its affiliates.

Glossary

For a list of z/VM terms and their definitions, see z/VM: Glossary.

The z/VM glossary is also available through the online z/VM HELP Facility. For example, to display the definition of the term "dedicated device", issue the following HELP command:

help glossary dedicated device

While you are in the glossary help file, you can do additional searches:

 To display the definition of a new term, type a new HELP command on the command line:

help glossary newterm

This command opens a new help file inside the previous help file. You can repeat this process many times. The status area in the lower right corner of the screen shows how many help files you have open. To close the current file, press the Quit key (PF3/F3). To exit from the HELP Facility, press the Return key (PF4/F4).

 To search for a word, phrase, or character string, type it on the command line and press the Clocate key (PF5/F5). To find other occurrences, press the key multiple times.

The Clocate function searches from the current location to the end of the file. It does not wrap. To search the whole file, press the Top key (PF2/F2) to go to the top of the file before using Clocate.

SMTPQUEU 106	internetwork layer 4
SMTPQUEU Command 106	network layer 4
Smurf attack 175	transport layer 4
SNMP	TCP/IP protocols and functions 4
command 349	TELNET 115, 121
command processor 348	TELNET (NETSTAT subcommand) 183, 206
generic TRAP types 467	TELNET command format 115
major and minor error codes 364	TELNET control characters in line mode 120
managing an internet environment 347	TELNET function keys 117
MIB/Network elements 442	TELNET modes
overview 10	line mode 117
Protocol 347	transparent mode 117
Query Engine Host Lookup 365	TELNET parameters
return codes 349	FIREWALL 116
sample command lists 347	LINEMODE 116
value types	RECORD 116
SNMP GET 350, 362	TRANSLATE 116
SNMP GETNEXT 352	TELNET PF key functions 117
SNMP MIBVNAME 359	Telnet Protocol 9
SNMP PING 360	TELNET subcommands
SNMP SET 354	AO 118
SNMP TRAPSOFF 358	AYT 118
SNMP TRAPSON 355	BRK 118
SNMP command processor 348	HELP 119
SNMP generic TRAP types 467	IP 119
SNMP Get command 352	PA1 119
SNMP GET command 350	QUIT 120
SNMP MIBVNAME command 359, 360	SYNCH 120
SNMP Set command 354	TELNET support display stations 117
SNMP TRAPSOFF command 358	trace
SNMP TRAPSON command 355	debug levels 128
SNMP/Netview overview 348	traceroute function (TRACERTE) 208
SNMPIUCV task 348	translation tables
SNMPMGMT command 347	Chinese DBCS 418
SNMPRUN command 347	converting to binary 419
SNMPTRAP command 362	Hangeul DBCS 417
SOCKET (NETSTAT parameter) 183, 205	IBM 412
socket interfaces 12	Japanese Kanji DBCS 416
sockets	search order 410
datagram 348	Transmission Control Protocol (TCP) 8
raw 348	Transmission Control Flotocol (TOF) 0
