|                             |                     | Custom Slot 3    |                                  |
|                             |                     | Custom Slot 4    |                                  |
|                             |                     | Custom Slot 5    |                                  |
|                             |                     | Custom Slot 6    | CROND[12551]                     |
|                             |                     | Custom Slot 7    | nc9048135089                     |
|                             |                     | Custom Slot 8    | 13:01:01                         |
|                             |                     | Custom Slot 9    | 11                               |
|                             |                     | Custom Slot 10   | Mar                              |

## Displaying log file monitoring events

After you configure the OS agent to monitor your application log files, you can create thresholds to raise alarms on the log file conditions that you want to be alerted of.

### Procedure

1. On the Navigation Bar, click  **System Configuration > Threshold Manager**.
2. Select the target OS for **Data Source type**.
3. Click  Add to create a new threshold.
4. Set a severity for the event that exceeds this threshold.
5. Select the data set to create a threshold for. The following data sets are eligible for log file monitoring:
  - Kpp Log File RegEx Statistics
  - Kpp Log File Status
  - Kpp LogfileProfileEvents
6. Click  **Add** to add a condition. In the **Add Condition** box, select an attribute and an operator, and then enter a threshold value.

Repeat this step to add more conditions to your threshold if required.
7. In the Group assignment section, select the resource group that you want to assign your threshold to.
8. Click **Save**.
9. On the Navigation Bar, click  **System Configuration > Advanced Configuration**.
10. In the **UI Integration** category, set the **Enable Subnode Events** value to be True.
11. Click **Save**.

### Results

When the specified condition becomes true, the log file event that triggers the alert is displayed in the Events tab.

## Log file monitoring environment variables

You can set environment variables for log file monitoring in the OS agent environment files.

Set the following environment variables and replace *KPC* with the OS agent code where *PC* is the two character agent code, for example, *klz* is the code for the Linux OS agent.

### **KPC\_FCP\_LOG**

This variable is available in the *install\_dir/config/.pc.environment* file. The default value is *True* and you use it to enable or disable the log monitoring feature.

### **KPC\_FCP\_LOG\_PROCESS\_MAX\_CPU\_PCT**

This setting is the maximum allowable percentage of all system CPU that the agent uses over a 1-minute interval. Valid values are 5 - 100. The default value is 100. This setting is associated with the CPU throttling feature. If you specify a value less than 5, the minimum value of 5 is used.

### **KPC\_FCP\_LOG\_PROCESS\_PRIORITY\_CLASS**

This setting is the operating system scheduler priority for the process. A is lowest, C is the operating system default, and F is the highest priority. The setting is one of the following values: A, B, C, D, E, F. These values are superseded by any values that you specify in the *.conf* file.

### **KPC\_FCP\_LOG\_SEND\_EVENTS**

The default setting is *True* and it is used by the OS agent to send events to the Cloud APM server.

### **KPC\_FCP\_LOG\_SEND{EIF\_EVENTS**

The default setting is *True*. If this option is set to *Yes* the agent sends event data to the Cloud APM server or to any EIF receiver such as the OMNIBus EIF probe. If the option is set to *No*, the agent does not send the event data. The setting of this option is global and applies to all monitoring profiles.

**Note:** The EIF receiver consumes events, otherwise problems might occur when the agent cache fills.

### **KPC\_FCP\_TRUNCATE\_HOSTNAME\_IN\_LONG\_SUBNODE\_MSN**

OS agents with log file event monitoring have a subnode limitation. To manage log file events, the subnode MSN has the following structure: *UX:CTIRAHOSTNAME\_PROFILENAME*. The maximum size limitation for the subnode name is 32 characters. If the built subnode MSN name is too long and it is more than 32 characters, it is truncated to 32 characters. This name corresponds to the substring that is taken from the Profile Name.

In the OS agent configuration file, use the following variables to manage the profile names that are too long:

- UNIX OS agent: *KUX\_FCP\_TRUNCATE\_HOSTNAME\_IN\_LONG\_SUBNODE\_MSN=true*
- Linux OS agent: *KLZ\_FCP\_TRUNCATE\_HOSTNAME\_IN\_LONG\_SUBNODE\_MSN=true*
- Windows OS agent: *KNT\_FCP\_TRUNCATE\_HOSTNAME\_IN\_LONG\_SUBNODE\_MSN=true*

For example, if you have an agent that is called *aixhost\_nc123456789A*, which is 20 characters in length, *CTIRAHOSTNAME=aixhost\_nc123456789A* is 20 characters.

and you have two profiles that are called:

```
ProfileLong12A (14 characters)
ProfileLong12B (14 characters)
```

the following related subnode MSNs are expected:

```
UX:aixhost_nc123456789A_ProfileLong12A (38 characters)
UX:aixhost_nc123456789A_ProfileLong12B (38 characters)
```

However, the subnode MSNs are truncated to the 32 character limitation so the resulting names are the same for both:

```
UX:aixhost_nc123456789A_ProfileL
UX:aixhost_nc123456789A_ProfileL
```

To truncate *CTIRAHOSTNAME* instead of the Profile Name, set the *Kpc\_FCP\_TRUNCATE\_HOSTNAME\_IN\_LONG\_SUBNODE\_MSN=true* variable.

For example, if  $n$  is the length of the Profile Name, such as 14, the substring for the MSN name that relates to *CTIRAHOSTNAME* is truncated to 32- $n$ -3 characters, so the *CTIRAHOSTNAME* variable is: aixhost\_nc1234. Then, the distinguished subnode MSNs are:

```
UX:aixhost_nc1234_ProfileLong12A
UX:aixhost_nc1234_ProfileLong12B
```

## Configuration file

OS agents use a configuration file that is read by the agent when it starts. The file contains configuration options and filters. You must create this configuration file and configure the agent instance to use it.

The configuration file is monitored for changes to its time stamp every 60 seconds thereafter. If the time stamp of the file changes, the agent reinitializes its configuration dynamically, without requiring a restart. For more information, see [“Changing the agent configuration and format files” on page 744](#).

The `.conf` file for the OS agent accepts these options:

### codepage

This parameter is the code page of the monitored file. Use this parameter in the configuration file when the code page of the monitored file is different from the code page of the system. Specify the code page of the monitored file, for example, `ibm-5348_P100-1997`, `UTF-16`, or `UTF-8`.

### ConfigFilesAreUTF8=Y

This parameter specifies that the configuration file and format file are in UTF-8. Use this parameter if the encoding of the configuration files is UTF-8 and the system code page is not. The default is that the agent assumes the system encoding.

### DupDetectionKeyAttributes

A comma-separated list of Cloud APM attributes that is used to determine which events are duplicates. If all the named attributes are the same in two events, then those two events are considered duplicates. This option applies only to events. For more information, see [“Event filtering and summarization” on page 1168](#).

#### Note:

1. The attribute names are case-sensitive, so you must enter the names exactly as described.
2. If you do not provide a list of attributes, the values default to `Class` and `Logname`.

### ENFORCE\_STRICT\_TEC\_COMPATIBILITY

This parameter refers to all white space characters in the log data to ensure that the characters are respected. For example, when you use a format such as `"%s %s"` to extract information from log messages, the OS agent matches not only a literal space but also any other white space characters that are present such as tabs and carriage returns.

When this parameter is not set, the default behavior of the OS agent when it matches a Tivoli Enterprise Console® style format string is to match as much of the input text as it can, while it processes the format from left to right.

For example, for the `%s:%s` format string and the `one:two:three` input string, the OS agent default assigns `one` to the first parameter (corresponding to the first `%s`) and it assigns `three` to the second parameter.

#### Note:

1. This parameter does not apply to format statements that use the regular expression syntax.
2. Setting this parameter has a performance impact. To give greater control over the behavior and performance of matching, avoid setting this parameter and use regular expressions instead.

### EventSummaryInterval

Specifies the number of seconds during which the agent searches for duplicate events to suppress. Set this parameter to a positive integer. This option applies only to events. For more information, see [“Event filtering and summarization” on page 1168](#).

**EventFloodThreshold**

Specifies which events are sent when duplicate events are detected. Set this parameter to `send_none`, `send_all`, `send_first`, or a positive integer. This option applies only to events. For more information, see [“Event filtering and summarization”](#) on page 1168.

**EventMaxSize**

Specifies in bytes, the maximum size of a generated event. If specified, this parameter is used in two places:

1. The parameter can be used by the agent to set the size of a buffer that is used to process events. If not set, this buffer defaults to a size of 16384 bytes. If the buffer is set too small, events are truncated and can be discarded.
2. The parameter can be used by the EIF sender to set the size of a buffer that is used to send events to an EIF receiver, such as the OMNibus EIF probe. If not set, this buffer defaults to a size of 4096 bytes. If the buffer is set too small, events are discarded.

**FileComparisonMode**

Specifies which log files are monitored when more than one file matches a wildcard pattern. The following values are available:

**CompareByAllMatches**

This value is the default behavior. All files that match the wildcard pattern that is specified in `LogSources` are monitored.

**CompareByLastUpdate**

Of the files that match the wildcard pattern that is specified in `LogSources`, the file with the most recently updated time stamp is monitored.

**CompareBySize**

Of the two or more files that match the file name pattern criteria, the larger file is selected for monitoring. Do not use `CompareBySize` with multiple matching files that are being updated at the same time and increasing their file sizes. If the largest file is subject to frequent change, monitoring might continually restart at the beginning of the newly selected file. Instead, use `CompareBySize` for a set of matching files where only one is active and being updated at any specific time.

**CompareByCreationTime**

Of the files that match the wildcard pattern that is specified in `LogSources`, the file with the most recently created time stamp is monitored. This value has the following restrictions:

- The value is applicable only to Windows operating systems because UNIX and Linux operating systems do not store a true creation time for files.
- The value is not supported for remote files that you monitor by using the Secure Shell (SSH) File Transfer Protocol.

**Tip:** The `CompareByLastUpdate`, `CompareBySize`, and `CompareByCreationTime` values can all be used for rolling log files. `CompareByLastUpdate` is typically used for these files.

**FQDomain**

Specifies how and if the agent sets a domain name:

- If set to `yes`, the agent determines the system domain name.
- If set to `no`, the agent does not set a domain name. The `fqhostname` attribute is assigned a blank string.
- If set so that it does not contain a `yes` or `no` value, the domain name is accepted as the value and it is appended to the host name.

For more information, see [“Format file”](#) on page 740.

**IncludeEIFEventAttr**

The agent includes a large attribute that is called *EIFEvent*, which is a representation of the event that is sent through the Event Integration Facility if that feature is enabled. The information that is

contained in the *EIFEvent* attribute can also be found in other attributes. Its large size made it problematic, thus it was disabled by default. Setting this value to *y*, reenables the *EIFEvent* attribute.

**Note:** Using this attribute might cause thresholds to fail if you have large events. A large event in this context is an event where the total number of bytes that is required to contain all values for all attributes and their names results in a string longer than 3600 bytes.

### LognameIsBaseName

When set to *y*, the value of the *Logname* attribute is the base name of the log file in which the event was found. This option applies only to Performance Management events. The path is removed. For example, */data/logs/mylog.log* becomes *mylog.log*. If this value is set to *n*, then you get the full path. However, because the attribute is limited to 64 characters, setting it to *n* means that the name is truncated if it is longer. For this reason, the default value is *y*. To see the full path name in a longer attribute, you can specify it in the mappings section of a format in the *.fmt* file, for example, *filename FILENAME CustomSlot1*. The mapping completes the slot that is named *filename* with the full path of the file in which the event was found and maps it into *CustomSlot1*, which is 256 characters.

### LogSources

Specifies the text log files to poll for messages. The complete path to each file must be specified, and file names must be separated by commas. Within each file name, you can also use an asterisk (\*) to represent any sequence of characters, or a question mark (?) to represent any single character. For example, *mylog\** results in polling all log files whose names begin with *mylog*, whereas *mylog???* results in polling all log files whose names consist of *mylog* followed by exactly 3 characters. These wildcard characters are supported only within the file name; the path must be explicitly specified.

If you want to use regular expressions or pattern matching in the path, see the [RegexLogSources](#) description.

A log file source is not required to exist when the agent is started; the log file is polled when it is created.

### NewFilePollInterval

Specifies the frequency, in seconds, that the agent checks for new files to monitor. For example, if a file name specified by the *LogSources* or *RegexLogSources* configuration file settings does not yet exist when the agent starts, it checks again for the existence of the files after this interval.

### NumEventsToCatchUp

Specifies the event in the log that the agent starts with. This option provides some flexibility if the source that is being monitored is new or the agent is stopped for an extended time. The following values are valid:

**Note:** For text files, values *0* and *-1* apply. For Windows Event Log, values *0*, *-1*, and *n* apply.

**0**

Start with the next event in the logs. This value is the default.

**-1**

When set to *-1*, the agent saves its place in the file that is being monitored. It saves its place so that when the agent is stopped and later restarted, it can process any events that are written to the log while it was stopped. The agent otherwise ignores events that arrived while it was stopped and restarts from the end of the file. This setting does not apply to pipes, or syslog monitoring on UNIX and Linux systems.

**n**

Set to a positive integer. Starts with the *n*th event from the most current event in the logs; that is, start *n* events back from the most current event in the logs. If *n* is greater than the number of events that are available, all the events that are available are processed.

**Note:** You can use the *n* value only for Windows Event Log. The *n* value is ignored when *UseNewEventLogAPI* is set to *y*.

### PollInterval

Specifies the frequency, in seconds, to poll each log file that is listed in the *LogSources* option for new messages. The default value is 5 seconds.

If you upgraded a Windows Event Log adapter from a previous release and you have a value that is set for `PollingInterval` in the Windows registry, you must specify the `PollInterval` option in the agent configuration file with the same value that is used in the Windows registry. This rule applies only if you are replacing a Tivoli Enterprise Console OS agent that had values in the registry.

### **ProcessPriorityClass**

Specifies the process priority for the agent. You can adjust this value to improve system performance if the agent processes large volumes of events and is using too many processor resources. The possible values are:

- A - Very low priority
- B - Low priority
- C - Typical priority
- D - Above typical priority
- E - High priority
- F - Very high priority
- `USE_CONF_FILE_VALUE` - Use the value that is specified in the configuration file. This value is the default.

### **RegexLogSources**

Specifies the text log files to poll for messages. It differs from the `LogSources` option in that regular expression meta characters can be used in the base name portion of the file name and in one subdirectory of the file name. This difference provides greater flexibility than the `LogSources` option in describing multiple files to monitor in multiple directories.

For example, specifying `/var/log/mylog*` for the `LogSources` statement is identical to using the dot (`.`) meta character followed by an asterisk (`*`) meta character to form `/var/log/mylog.*` in the `RegexLogSources` statement. This type of qualifier results in polling all log files in the `/var/log` directory whose base names begin with `mylog` and are followed by zero or more characters. A `/var/log/mylog.+` qualifier results in polling all log files in the `/var/log` directory whose names begin with `mylog` and are followed by one or more characters.

Similar to `LogSources`, the complete path to each file must be specified and the file names must be separated by commas. However, the comma is also a valid character inside a regular expression. To distinguish between a comma that is used as part of a regular expression and one that is used to separate file names, commas that are used as part of a regular expression must be escaped with the backslash (`\`) character.

For example, if you want to search for logs that match either of the following regular expressions, `/logs/*.log` and `/other/logs/[a-z]{0,3}.log`, you must escape the comma in the `{0,3}` clause of the second expression so the agent does not mistake it for the beginning of a new expression: `RegexLogSources=/logs/*.log,/other/logs/[a-z]{0\,3}.log`

If meta characters are used in the path name, the meta characters can be used in only one subdirectory of the path. For example, you can specify `/var/log/[0-9\.]*/mylog.*` to have meta characters in one subdirectory. The `[0-9\.]*` results in matching any subdirectory of `/var/log` that consists solely of numbers and dots (`.`). The `mylog.*` results in matching any file names in those `/var/log` subdirectories that begin with `mylog` and are followed by zero or more characters.

Because some operating systems use the backslash (`\`) as a directory separator it can be confused with a regular expression escape meta character. Because of this confusion, forward slashes must always be used to indicate directories. For example, Windows files that are specified as `C:\temp\mylog.*` might mean the `\t` is a shorthand tab character. Therefore, always use forward slashes (`/`) for all operating systems directory separators. For example, `C:/temp/mylog.*` represents all files in the `C:/temp` directory that start with `mylog`.

If more than one subdirectory contains meta characters, a trace message is also issued. For example, `c:[0-9\.]*/temp.files/mylog.*` has two subdirectories with meta characters. `[0-9\.]*` is the first subdirectory with meta characters and `temp.files` is the second subdirectory that used a

dot ( . ) meta character. In this case, the agent assumes that the first subdirectory with the meta character is used and the subsequent directories with meta characters are ignored.

**SubnodeName**

A string value that can be used to override the default name that is assigned to a monitoring profile subnode. By default the subnode name that is assigned to a monitoring profile corresponds to the base name of the configuration file that is used for that profile. By using this setting, a different subnode name can be assigned.

**SubnodeDescription**

A string value that can be used to assign a value to the *Subnode Description* attribute of *LFAProfiles*.

**UnmatchLog**

Specifies a file to log discarded events that cannot be parsed into an event class by the agent. The discarded events can then be analyzed to determine whether modifications to the agent format file are required. Events that match a pattern that uses *\*DISCARD\** do not appear in the unmatched log because they did match a pattern.

This option is used in a test environment to validate the filters in the format file. This option fills up your file system if you leave it on for extended periods.

**Options for remote log file monitoring by using SSH**

Other than **SshHostList**, which is a list, all options can have only one value, which is applied to all remote hosts that are specified in **SshHostList**.

Only text log files are supported. AIX error report, syslog, and Windows Event Log are not supported.

**Tip:** You can set up syslog to write its output to a text log file and then remotely monitor that text file with the OS agent.

**SshAuthType**

Must be set to either *PASSWORD* or *PUBLICKEY*. If set to *PASSWORD*, the value of **SshPassword** is treated as the password to be used for SSH authentication with all remote systems. If set to *PUBLICKEY*, the value of **SshPassword** is treated as the pass phrase that controls access to the private key file. If set to *PUBLICKEY*, **SshPrivKeyfile** and **SshPubKeyfile** must also be specified.

**SshHostList**

A comma-separated list of remote hosts to monitor. All log files that are specified in the **LogSources** or **RegexLogSources** statements are monitored on each host that is listed here. If *localhost* is one of the specified host names, the agent monitors the same set of files directly on the local system. When you specify *localhost*, SSH is not used to access the files on the local system; the log files are read directly.

**SshPassword**

When the value of **SshAuthType** is *PASSWORD*, this value is the account password of the user that is specified in **SshUserid**. You can supply the account password in clear text, or you can supply a password that is encrypted with the IBM Tivoli Monitoring CLI **itmpwdsnmp** command. For more information about how to encrypt a password by using the **itmpwdsnmp** command, see [“Remote log file monitoring: Encrypting a password or pass phrase” on page 749](#).

When the value of **SshAuthType** is *PUBLICKEY*, this value is the pass phrase that decrypts the private key that is specified by the **SshPrivKeyfile** parameter. You can supply the pass phrase in clear text, or you can supply a pass phrase that is encrypted with the IBM Tivoli Monitoring CLI **itmpwdsnmp** command. For more information about how to encrypt a password by using the **itmpwdsnmp** command, see [“Remote log file monitoring: Encrypting a password or pass phrase” on page 749](#).

**Note:** If the value of **SshAuthType** is *PUBLICKEY*, and you configured SSH not to require a pass phrase, **SshPassword** must be set to null. To set **SshPassword** to null, the entry in the configuration file is:

```
SshPassword=
```

### SshPort

A TCP port to connect to for SSH. If not set, defaults to 22.

### SshPrivKeyfile

If **SshAuthType** is set to *PUBLICKEY*, this value must be the full path to the file that contains the private key of the user that is specified in **SshUserid**, and **SshPubKeyfile** must also be set. If **SshAuthType** is not set to *PUBLICKEY*, this value is not required and is ignored.

### SshPubKeyfile

If **SshAuthType** is set to *PUBLICKEY*, this value must be the full path to the file that contains the public key of the user that is specified in **SshUserid**, and **SshPrivKeyfile** must also be set. If **SshAuthType** is not set to *PUBLICKEY*, this value is not required and is ignored.

### SshUserid

The user name on the remote systems, which the agent uses for SSH authentication.

## Option that is supported on UNIX and Linux systems only

Linux | UNIX

### AutoInitSyslog

If this option is set to Yes, the agent automatically configures the syslog facility to write a standard set of events to a pipe that the agent monitors. By enabling this setting, you can monitor syslog events without maintaining and rolling over log files. If this option is not set in the configuration file, it is the same as being set to No.

**Restriction:** This option is not supported for remote log file monitoring.

## Options that are supported on Windows systems only

Windows

### NTEventLogMaxReadBytes

If you are using the older NT Event Log interface (*UseNewEventLogAPI* is not set to y) to read event log data on a Windows system, the agent reads up to this number of bytes each time it checks the event log for new data. Setting the value to 0 causes the agent to attempt to read all new data, as it did in earlier releases. This activity can occupy the agent for a considerable amount of time on a system with many events. The default value is 655360. When set, the agent might not stop at exactly the value that is specified, but rather at the nearest multiple of an internal buffer size to this value.

### PreFilter

Specifies how events in a Windows Event Log are filtered before agent processing. *PreFilter* statements are used by *PreFilterMode* when the filters determine which events are sent from an event log to the agent. An event matches a *PreFilter* statement when each *attribute=value* specification in the *PreFilter* statement matches an event in the event log. A *PreFilter* statement must contain at least the log specification and can contain up to three more specifications, which are all optional: event ID, event type, and event source. The order of the attributes in the statement does not matter.

The *PreFilter* statement has the following basic format:

```
PreFilter:Log=log_name;EventId=value; EventType=value;Source=value;
```

You can specify multiple values for each attribute by separating each value with a comma.

Each *PreFilter* statement must be on a single line.

*PreFilter* is not mandatory. All Windows log events are sent to the agent if prefilters are not specified and *PreFilterMode*=OUT.

### PreFilterMode

This option applies only to Windows Event Log. The option specifies whether Windows systems log events that match a *PreFilter* statement are sent (*PreFilterMode*=IN) or ignored (*PreFilterMode*=OUT). Valid values are IN, in, OUT, or out. The default value is OUT.

PreFilterMode is optional; if PreFilterMode is not specified, only events that do not match any PreFilter statements are sent to the agent.

**Note:** If you set PreFilterMode=IN, you must also define the PreFilter statements.

### SpaceReplacement

Set to TRUE by default for Windows Event Log (Windows Server 2008 only) but not for previous versions of Event Log. When SpaceReplacement is TRUE, any spaces in the security ID, subsource, Level, and keywords fields of the event log messages are replaced with underscores (\_). When SpaceReplacement is FALSE, any spaces in the security ID, subsource, Level, and keywords fields of the event log messages remain unchanged. For more information about this option, see [“Windows Event Log” on page 1170](#).

### UseNewEventLogAPI

When set to y on Windows systems, uses the new Windows Event Log interface for event logs. The option is supported only on Windows 2008 and later. The option is needed to access many of the new event logs that debuted in Windows 2008 and the applications that run on it. The option is ignored on earlier versions of Windows and on UNIX and Linux. For more information about this option, see [“Windows Event Log” on page 1170](#).

### WINEVENTLOGS

Controls which Windows event logs are monitored.

The WINEVENTLOGS statement is a comma-delimited list with no spaces. For more information, see [“Windows Event Log” on page 1170](#).

**Note:** Any carriage returns, tabs, or new lines in Windows events are replaced by spaces.

## Option that is supported on AIX systems only

AIX

### AIXErrptCmd

An **errpt** (error report) command string that the agent runs can be supplied here. The command output is fed into the stream of log data that is being monitored.

For example, the following command causes the agent to search for the *mmddhhmm* string and replace it with the actual date and time on startup. Only the first occurrence of the string is replaced.

```
AIXErrptCmd=errpt -c -smddhhmm
```

Although you can supply your own **errpt** command, you must use the **-c** (concurrent mode) option so that the command runs continuously. You cannot use the **-t** option or the following options that result in detailed output: **-a**, **-A**, or **-g**.

The data stream is the standard output from the **errpt** command, so regular expressions in the **.fmt** file must be written to match. For example, the data output might be:

| IDENTIFIER | TIMESTAMP  | T | C | RESOURCE_NAME | DESCRIPTION                             |
|------------|------------|---|---|---------------|---|
| F7FA22C9   | 0723182911 | I | O | SYSJ2         | UNABLE TO ALLOCATE SPACE IN FILE SYSTEM |
| 2B4F5CAB   | 1006152710 | U | U | ffdc          | UNDETERMINED ERROR                      |
| 2B4F5CAB   | 1006152610 | U | U | ffdc          | UNDETERMINED ERROR                      |

A sample format that picks up the data rows, but not the header, is:

```
REGEX GenericErrpt
^([A-F0-9]{8}) +([0-9]{10}) ([A-Z]) ([A-Z]) (\S+) +(.*)$
Identifier $1 CustomSlot1
Timestamp $2 CustomSlot2
T $3 CustomSlot3
C $4 CustomSlot4
Resource $5 CustomSlot5
msg $6
END
```

For more information, see *Monitoring an AIX Binary Log* in the [IBM Agent Builder User's Guide](#).

## Options that apply only when events are being forwarded to EIF

**Important:** These options apply to EIF events sent directly to Operations Analytics - Log Analysis, OMNIbus, or any other generic EIF receiver. The options are not intended for use with the Cloud APM server.

### BufferEvents

Specifies how event buffering is enabled. The possible values are:

- **YES** - Stores events in the file that is specified by the *BufEvtPath* option (This value is the default).
- **MEMORY\_ONLY** - Buffers events in memory.
- **NO** - Does not store or buffer events.

### BufEvtPath

Specifies the full path name of the agent cache file. If this path is not rectified the default is:

- **AIX** /etc/Tivoli/tec/cache
- **Windows** \etc\Tivoli\tec\cache

**Note:** If events are being forwarded to more than one server, a *BufEvtPath* value must be specified for each forwarding channel. An index number is appended to the *BufEvtPath* name for each additional entry. For example, use *BufEvtPath1* to indicate the path name of the agent cache file for forwarding to the first extra server. The value that is set in each *BufEvtPath* must be unique.

### BufEvtMaxSize

Specifies the maximum size, in KB, of the agent cache file. The default value is 64. The cache file stores events on disk when the *BufferEvents* option is set to Yes. The minimum size for the file is 8 KB. File sizes specified less than this level are ignored, and 8 KB is used. The value that you specify for the maximum file size does not have an upper limit.

**Note:** If the cache file exists, you must delete the file for option changes to take effect.

### NO\_UTF8\_CONVERSION

Specifies whether the Event Integration Facility encodes event data in UTF-8. When this option is set to YES, the EIF does not encode event data in UTF-8. The data is assumed to already be in UTF-8 encoding when passed to the EIF. However, a prefix is added to the flag to indicate that the data is in UTF-8 encoding (if the flag does not exist at the beginning of the event data). The default value is NO.

### MaxEventQueueDepth

This value indicates the maximum number of events that can be queued for forwarding. When the limit is reached, each new event that is placed in the queue bumps the oldest event from the queue. If not specified, the default value is 1000. This setting applies to all forwarding channels if *NumAdditionalServers* is used.

### NumAdditionalServers

This entry is required if you want to forward events to more than one Netcool/OMNIbus ObjectServer. Its value is used to indicate the number of servers that events are forwarded to. Valid values are 1 - 8.

### ServerLocation

Specifies the name of the host on which the event server is installed. Specify host name or IP address. Use the dotted format for IP address. You can specify failover values such as *ServerLocation1=2.3.4.5,2.3.4.6*. for the server locations if you want to. If you specify failover values for *ServerLocation*, you must also specify an extra *ServerPort* value for each *ServerLocation*.

**Note:** If events are being forwarded to more than one server, a *ServerLocation* value must be specified for each server. An index number is appended to the *ServerLocation* name for each additional entry. For example, use *ServerLocation1* to specify the name of the host on which the first extra server is installed.

### ServerPort

Specifies the port number on which the EIF receiver listens for events. The *ServerPort* option can contain up to eight values, which are separated by commas. If failover values are specified for

*ServerLocation*, you must set an equivalent *ServerPort* value. The *ServerPort* is not used when the *TransportList* option is specified.

**Note:** If events are being forwarded to more than one server, a *ServerPort* value must be specified for each server. An index number is appended to the *ServerPort* name for each additional entry. For example, use *ServerPort1* to specify the port number on which the EIF receiver listens for events for the first extra server.

### **TransportList**

Specifies the user-supplied names of the transport mechanisms, which are separated by commas. When a transport mechanism fails for sender applications, the API uses the following transport mechanisms in the order that is specified in the list. For receiving applications, the API creates and uses all the transport mechanisms. The transport type and channel for each *type\_name* must be specified by using the *Type* and *Channels* keywords:

#### ***type\_name*Type**

Specifies the transport type for the transport mechanism that is specified by the *TransportList* option. SOCKET is the only supported transport type.

The server and port for each *channel\_name* are specified by the *ServerLocation* and *ServerPort* options.

#### ***type\_name*Channels**

##### ***channel\_name*Port**

Specifies the port number on which the transport mechanisms server listens for the specified channel (set by the *Channel* option). When this keyword is set to zero, the portmapper is used. This keyword is required.

##### ***channel\_name*PortMapper**

Enables the portmapper for the specified channel.

##### ***channel\_name*PortMapperName**

Specifies the name of the portmapper if the portmapper is enabled.

##### ***channel\_name*PortMapperNumber**

Specifies the ID that is registered by the remote procedure call.

##### ***channel\_name*PortMapperVersion**

Specifies the version of the portmapper if the portmapper is enabled.

##### ***channel\_name*ServerLocation**

Specifies the name of the event server and the region where the server for transport mechanisms is located for the specified channel. The channel is set by the *Channel* option. This keyword is required.

The configuration file accepts generic EIF options when used directly with OMNIBus. These options operate only over an EIF connection to OMNIBus. They do not affect events that are sent to the Cloud APM server. For more information about these EIF options, see [EIF keywords](#).

## **Format file**

OS agents extract information from system log messages and then match different log messages to event classes. A format file serves as a lookup file for matching log messages to event classes, which tells the event class what to read, what to match, and how to format the data.

When the format file is used as a lookup file, all format specifications in the file are compared from the beginning to the end of the file. When two classes match or when a message has multiple matching classes, the first expression from the end that matches is used. If no match is found, the event is discarded. A discarded event is written to the unmatched log if it is defined in the `.conf` file.

The regular expression syntax that you use to create patterns to match log messages and events is described. Regular expression-filtering support is provided by using the International Components for Unicode (ICU) libraries to check whether an attribute value that is examined matches the specified pattern.

For more information about using regular expressions, see [Regular Expressions](#) in the *ICU User Guide*.

### **Format file specifications**

The format file describes the patterns that the agent looks for to match events in the monitored logs. The format file consists of one or more format specifications.

You can change the format file while an agent instance is running. The file is read by the agent when it starts, and is monitored for changes to its time stamp every 60 seconds thereafter. If the time stamp of the file changes, the agent reinitializes its configuration dynamically, without requiring a restart. For more information, see [“Changing the agent configuration and format files”](#) on page 744.

To create new patterns to match an event, use the new regular expression syntax that consists of the following parts:

- Format header
- Regular expression
- Slot mappings
- End statement

The format header contains the **REGEX** keyword, which informs the agent that you are using a regular expression to match the pattern in the monitored log.

You assign this regular expression to an event class as shown in the following example:

```
REGEX REExample
```

If you use the special predefined event class **\*DISCARD\*** as your event class, any log records matching the associated pattern are discarded, and no events are generated for them. For example:

```
REGEX *DISCARD*
```

When a pattern is matched, nothing is written to the unmatched log. The log file status records that are matched include these discarded events.

**Note:** You can assign multiple event definitions to either the same event class or to different event classes. The class name is arbitrary and you can use it to indicate the type of event or to group events in various ways.

After the format header, the format content consists of a regular expression on the first line, followed by mappings. Each mapping is shown on a separate line and these mappings are described in the following example.

All lines that match the regular expressions are selected and sent to the monitoring server as events. The regular expression contains subexpressions. You can use the subexpressions to match specific parts of these lines that are the same to a variable called a *slot* in the Event Integration Facility.

The following monitoring log contains three lines that you might want to monitor:

```
Error: disk failure
Error: out of memory
WARNING: incorrect login
```

For example, you generate an event for a specific error, such as the lines that begin with **Error** and ignore the line that begins with **Warning**. The regular expression must match the lines that begin with **Error** and also include a subexpression. The subexpression is denoted by parentheses and it must match only the input text that you want to assign to the *msg* slot. The following format definition is a simple regular expression with only one subexpression:

```
REGEX REExample
Error: (.* )
msg $1
END
```

Based on this format specification, and the preceding set of log data, the agent generates two events. Both events are assigned the REEXample event class. In the first event, the disk failure value is assigned to the *msg* slot. Also, in the second event, the out of memory value is assigned to the *msg* slot. Because the Warning line did not match the regular expression, it is ignored and no event is generated.

When you assign the value of \$1 to the *msg* slot, you assign it the value of the first subexpression.

If you have log text that contains the following errors, you might want to assign these error messages to their own event class so that you are informed immediately of a disk failure:

```
Error: disk failure on device /dev/sd0: bad sector
Error: disk failure on device /dev/sd1: temperature out of range
```

You can include a description of the disk on which the error occurred, and more specifically the disk error in the event.

The following regular expression contains two subexpressions that identify this information:

```
REGEX DiskFailure
Error: disk failure on device (/dev/sd[0-9]):(.*)
device $1 CustomSlot1
msg $2
END
```

You assign these two subexpressions to event slots. The two events that are generated contain the following values:

```
"device=/dev/sd0" and "msg=bad sector"
"device=/dev/sd1" and "msg=temperature out of range"
```

If you use EIF to generate the first event, it displays as shown in the following example:

```
DiskError;device='/dev/sd0';msg='bad sector';END
```

If the event is sent to the Cloud APM server, the slot that is named *msg* is assigned to the Performance Management agent attribute with the same name. But the *device* slot has no predefined attribute.

If you need to see the value that is assigned to *device* directly on the Cloud APM console, or write thresholds against it, you must assign it to a Performance Management attribute.

The OS agent includes the following 13 predefined attributes:

- Ten string type attributes that range from *CustomSlot1* to *CustomSlot10*
- Three integer type attributes that range from *CustomInteger1* to *CustomInteger3*

Using these attribute names in the format file populates Performance Management attributes with the same name. Using these attributes does not affect the content of the EIF event sent directly to OMNIbus.

**Note:** The CustomSlot and CustomInteger attribute names are case-sensitive, so you must enter the names exactly as shown.

You assign a slot from the event definition to one of these custom Performance Management attributes in the format file.

You assign the *device* slot to the Performance Management string type attribute called *CustomSlot1* as shown in the following example:

```
REGEX DiskFailure
Error: disk failure on device (/dev/sd[0-9]):(.*)
device $1 CustomSlot1
msg $2
END
```

When the event is displayed in the Application Performance Dashboard, the value that is assigned to the *device* slot is assigned to the Performance Management CustomSlot1 attribute. You view this value in the Cloud APM console or use it to define thresholds. You can assign any slot in the event definition to any

of the 10 custom agent attributes in the same manner, by using "CustomSlot*n*", where *n* is a number from 1 - 10, next to the slot definition.

In this example, the first subexpression is defined specifically as `(/dev/sd[0-9])`, but the second subexpression is defined generally as `(.*)`. In defining the regular expression as specifically as possible, you improve performance. Therefore, if you enter a search for an error on a device that does not match the specific error message that is defined here, the search procedure stops immediately when the error is not found. Time is not wasted looking for a match.

The *END* keyword completes the format specification. The format header, regular expression, and the *END* keyword must each begin on a new line, as shown in the following example:

```
REGEX REExample
Error:
msg $1
END <EOL>
<EOF>
```

**Note:** For the last format in the file, you must insert a new line after the *END* keyword as shown in the example. Otherwise, you get a parsing error.

*CustomInteger1* to *CustomInteger3* are 64-bit custom integer attributes. You can use them in the same manner as the string type *CustomSlot* attributes. You can use these attributes to map individual slots, or subexpressions, from the log file to individual Cloud APM attributes. Because these attributes are numeric, you can use arithmetic comparisons on them, such as `<` and `>`, which is not possible with the string attributes.

**Note:** Although these values are evaluated as integers by the Cloud APM server, for EIF purposes and within the format file, they are still treated as strings. For example, to use an integer slot in a *PRINTF* statement, you still identify it with `"%s"`, not `"%d"`.

The following example illustrates the use of a custom integer attribute. Suppose that a periodic UNIX syslog message is received that reports the percentage of a file system that is free, such as the following hypothetical log record:

```
Oct 24 11:05:10 jimmy fschecker[2165]: Filesystem /usr is 97% full.
```

You can use the following statement in the format file to check for the percentage of the file system that is free:

```
REGEX FileSystemUsage
^([A-Z][a-z]{2}) ([0-9][0-9]) ([0-9]{2}:[0-9]{2}:[0-9]{2}) (.*) (.?):
Filesystem (.*) is ([0-9]+)% full\.$
Month $1 CustomSlot1
Date $2 CustomSlot2
Time $3 CustomSlot3
Host $4 CustomSlot4
Service $5 CustomSlot5
Filesystem $6 CustomSlot6
PctFull $7 CustomInteger1
msg PRINTF("%s: %s% full", Filesystem, PctFull)
END
```

**Note:** In the preceding statement, everything between the `^` and `$` symbols on the second and third lines must be on a single line.

Because you might have other events that put values in *CustomInteger1*, you can avoid confusing the different event types by using the value of the *Class* attribute to limit its effect to the correct type of events. For example, the following threshold formula causes the threshold to fire only when an event of the *FileSystemUsage* event class has a value greater than or equal to 95 in *CustomInteger1*:

```
( Class == 'FileSystemUsage' AND CustomInteger1 >= 95)
```

A different event can then use *CustomInteger1* for a different purpose and not trigger this threshold accidentally.

In summary, you can now write a threshold in Performance Management that uses arithmetic operators on the CustomInteger attributes, which is not possible with the CustomSlots attributes.

**Note:** If you map non-integer data to the CustomInteger attributes, the resulting value might be zero or some unexpected value.

### ***Changing the agent configuration and format files***

The OS agent reads its configuration (.conf) and format (.fmt) files when it starts, and monitors their time stamp every 60 seconds thereafter.

If the time stamp of the configuration or format file changes, the agent reinitializes its configuration dynamically, without requiring a restart. During reinitialization, monitoring is interrupted momentarily. When monitoring resumes, the agent must determine the position in the monitored logs from which to restart. As a result, the agent behaves in the same way as a full stop and restart.

**Note:** Agent reinitialization after a configuration or format file change resets information in the Log File RegEx Statistics, Log File Status, and Log File Event attribute groups.

By default, the agent starts monitoring from the end of the file, when the reinitialization completes. This starting position can cause events that occurred during the interruption of monitoring to be missed. To ensure that such events are picked up when monitoring resumes, use the NumEventsToCatchUp=-1 setting.

Setting NumEventsToCatchUp=-1 causes a position file to be maintained. The position file is updated each time that the agent reads the log file. The update saves the position of the agent in the log file, in case of an agent restart. Maintaining the position file has a small performance impact, so maintain this file only if required. For more information about NumEventsToCatchUp, see [“Configuration file” on page 732](#).

**Note:** Some configuration values are not present in the configuration file and are set during initial configuration. If you change these values, you must restart the agent.

### ***Inheritance***

A format file uses inheritance to derive slot definitions from a previously defined format specification.

Use the FOLLOWS relationship to build specific format specifications from generic format specifications by using inheritance.

First, you define a base class and call it DiskFailure, for example, as shown here:

```
REGEX DiskFailure
Disk Failure on device (.* )
device $1 CustomSlot1
END
```

This regular expression matches the Disk Failure on device/dev/sd0 errors in the monitoring log so that the /dev/sd0 value is assigned to the device slot.

However, you can also see an extended version of this error message reported in the monitoring log.

For example, you might see a Disk Failure on device /dev/sd0, error code: 13 error message.

This error message is matched to a slot as shown in the following example:

```
REGEX DiskFailureError FOLLOWS DiskFailure
Disk Failure on device (.* ), error code: ([0-9]*)
errcode $2 CustomSlot2
END
```

Now, the event includes the device slot and the errcode slot. Because the DiskFailure event class defined a slot for the device name already, you allow the subclass to inherit that slot, and this inheritance saves you from declaring it a second time. The slot is defined as \$1 so the first subexpression in the regular expression is assigned to that slot.

However, the `DiskFailureError` class also defines a second subexpression. You can assign this subexpression to a new slot called `errcode` and define it as `$2` to refer to the second subexpression in the regular expression. This type of assignment is shown in the previous example that displays the log text.

The event now contains the device slot that is assigned the `/dev/sd0` value and the `errcode` slot that is assigned a value of 13. `CustomSlot1` is assigned the device, and `CustomSlot2` is assigned the error code.

Performance Management custom attribute mappings are also inherited. For more information about Performance Management custom attribute mappings, see [“Format file specifications” on page 741](#).

## Multi-line

Use the multi-line syntax to match records that span more than one line to patterns in the log that you are monitoring.

Specify the `\n` new line character as part of the regular expression to indicate where the line breaks occur in the monitoring log. See this type of syntax in the following example:

```
REGEX REMultiLine
Line1:(.*)\nLine2(.*)
msg $1
second_msg $2
END
```

**Note:** Windows Specify a `\r\n` carriage return and new line combination.

If the following error messages are reported in the log text, the `REMultiLine` event is created:

```
Line1: An error occurred
Line2: The error was "disk error"
```

The `msg` slot is assigned the value of `An error occurred` and the `second_msg` slot is assigned the value of `The error was "disk error"`.

## Mappings

The OS agent uses mappings to determine the event class for a system log message. The agent determines the event class by matching the message to a pattern in the format file.

The agent converts log messages to event class instances that contain `attribute name=value` pairs. The event is then sent to the event server.

The agent determines the event class for a system log message at the source. The agent determines the event class by matching a system log message to a pattern in the format file. After you use this matching procedure to determine a class, you must assign values to the attributes.

Attribute values come from various sources, such as:

- Default values that are provided by the agent
- Log text that matches specific subexpressions in regular expressions

A map statement is included in the format file and consists of the following syntax:

```
name      value CustomSlotn
```

Here, you specify any identifier to describe the name of a slot (also known as a variable, attribute, or value identifier). Then, you specify a value to assign to this slot by applying any of the values that are described in [“Value specifiers” on page 746](#).

Use custom slots to view data in the Performance Management console and to define thresholds. When you create thresholds, all custom slot values are strings. Custom slots are also required for duplicate detection to work because you must identify the slots that are used to determine duplicates. For more information about filtering events, see [“Event filtering and summarization” on page 1168](#). `msg` is a special slot name, with its own attribute in the event table. You do not need to use a custom slot for the `msg`.

You can limit the scope of a slot so that it exists only within the format definition. When you define the slot, you precede the slot name with a dash, for example:

```
-name    value
```

Any slot that you define in this way is not included in the final event. However, you can reference the slot elsewhere in the format definition, specifically within a PRINTF statement. In the `REGenericSyslog` example that follows, the `service` slot is not included if you generate but you can reference it in the PRINTF statement. It retains the same value that was applied to the original slot when it was defined without the dash. By using this procedure, you can use temporary variables from the format definition that are not included in the final event. For example, you can define an event class, `REGenericSyslog`, to match generic UNIX syslog events in the following way:

```
REGEX REGenericSyslog
^([A-Z][a-z]{2}) ([ 0-9][0-9]) ([0-9]{2}:[0-9]{2}:[0-9]{2}) (.*) (.?): (.*)$
month $1
date $2
time $3
host $4
-service $5
msg $6
syslog_msg PRINTF("service %s reports %s", service, msg)
END
```

### *Value specifiers*

The mappings in a format specification assign values to attributes.

The mapping part of a format specification consists of the following types of value specifiers:

- `$i`
- String constant
- PRINTF statement

### **\$i**

The `i` indicates the position of a subexpression in a format string. Each subexpression is numbered from 1 to the maximum number of subexpressions in the format string.

The value of a `$i` value specifier (also known as a variable, slot, or attribute) is the portion of the system log message that is matched by the corresponding subexpression.

In the following example, the log agent translates any log message from the UNIX syslog facility into a syslog event with values assigned to it:

```
REGEX REGenericSyslog
^([A-Z][a-z]{2}) ([ 0-9][0-9]) ([0-9]{2}:[0-9]{2}:[0-9]{2})
(.*) (.?): (.*)$
month $1
date $2
time $3
host $4
service $5
msg $6
END
```

Each subexpression numbered from `$1` to `$6` matches an item in parentheses in the regular expression.

Therefore, the following syslog event:

```
Apr  6 10:03:20 jimmy syslogd 1.4.1: restart.
```

is assigned the following values:

```
month=Apr
date=6
time=10:03:20
host=jimmy
```

```
service=syslogd 1.4.1
msg=restart.
```

For example, in the syslog event, the 10:03:20 value matches the third item in parentheses in the regular expression, so the value is assigned to the \$3 time value. Similarly, the jimmy value matches the fourth item in parentheses in the regular expression, so the value is assigned to the \$4 host value.

### string constant

The string constant declares that the value of the attribute is the specified string. If the attribute value is a single constant without any spaces, you specify it without surrounding double quotation marks (") as shown in the following example:

```
severity WARNING
```

Otherwise, if there are spaces in the attribute value, double quotation marks must be used as shown in the following example:

```
component "Web Server"
```

### PRINTF statement

The PRINTF statement creates more complex attribute values from other attribute values. The PRINTF statement consists of the keyword PRINTF followed by a printf() C-style format string and one or more attribute names.

The format string supports only the %s component specifier. The values of the attributes that are used in the PRINTF statement must be derived from either a \$i value specification or a constant string value specification (you cannot derive them from another PRINTF statement).

Use the value of the argument attributes to compose a new constant string according to the format string. This new constant string becomes the value of the attribute.

Based on the previous example where you defined the REGenericSyslog base class, and the service and msg slots, you can define an attribute called syslog\_msg by using the PRINTF keyword.

```
syslog_msg PRINTF("service %s reports %s", service, msg)
```

If the following log message is reported:

```
Apr  6 10:03:20 jimmy syslogd 1.4.1: restart.
```

a new constant string is composed that contains the attribute values from the format string:

```
syslog_msg="service syslogd 1.4.1 reports restart."
```

### Keywords

In the format file, use keywords to assign values that expand at run time.

The following keywords expand at run time:

- DEFAULT
- FILENAME
- LABEL
- REGEX

### DEFAULT

Use the DEFAULT keyword to assign a DEFAULT value to a specific slot or attribute. The OS agent assigns an internal default value to slots that are described in the following table:

| Table 217. Slots and the DEFAULT value |  |
|--|--|
| Slots                                  | Description  |
| <i>hostname</i>                        | <i>hostname</i> is the short host name of the system where the agent is running. It does not include the domain name of the system.  |
| <i>origin</i>                          | <i>origin</i> is the IP address of the system where the agent is running.  |
| <i>fqhostname</i>                      | <i>fqhostname</i> is the fully qualified host name of the system where the agent is running. It includes the domain name of the system.  |
| <i>RemoteHost</i>                      | When an event originates on the local system, this attribute is empty. If an event originates on a remote system, <i>RemoteHost</i> contains a string of the form <i>user@host:port</i> , which indicates the remote host name on which the event occurred, and the user and port on that host that are used to connect. |

The value that is assigned to *fqhostname* is influenced by the following FQDomain (optional) settings in the `.conf` file:

- If you set FQDomain to yes, the agent determines the system domain name itself.
- If you do not set a value for FQDomain or if you set the value to no, the agent does not set a domain name, and the *fqhostname* attribute is assigned a blank string.
- If you set FQDomain so that it does not contain a yes or no value, the domain name is accepted as the value and it is appended to the host name.

In the following example, the format definition contains three attributes or slots:

- *hostname* DEFAULT
- *origin* DEFAULT
- *fqhostname* DEFAULT

If you set the FQDomain to yes in the `.conf` file and you run it on a computer with the following properties:

- *hostname*: myhost
- *IP address*: 192.168.1.100
- *domainname*: mycompany.com

an event is created and the three slots are assigned the following values:

```
"hostname=myhost", "origin=192.168.1.100", "fqhostname=myhost.mycompany.com"
```

## FILENAME

The FILENAME keyword indicates the fully qualified file name (including the path) of the log file that contains the message. If you use a single agent to monitor multiple log files and you need to identify the source of the event, use this keyword to populate an event attribute with the file name. If the message comes from the system log, mapping is set to EventLog for Windows OS agents and SysLogD for UNIX OS agents.

**Note:** The path includes an attribute for this keyword.

## LABEL

The LABEL keyword specifies the host name of the system where the agent is running.

## REGEX

The REGEX keyword expands to the regular expression that matched the message and caused the event.

### *Maximum message length*

This value is the maximum message length that the OS agent can receive without truncating the message.

The maximum message length is different for Performance Management and Tivoli Netcool/OMNIbus.

## Performance Management

For events sent to Performance Management, the msg attribute is limited to 2048 bytes. Messages that are greater in length are truncated.

## Tivoli Netcool/OMNIbus

For events sent through the Probe for Tivoli EIF to Netcool/OMNIbus, the total size of the event, including the class name and all slots and their values cannot exceed 4096 bytes. For example, in the following sample EIF event, ;END does not count against the 4096-byte limit. However, everything else does count against the limit, including the syntactic elements such as the semicolons, quotation marks, and equal signs.

```
Class;attr1=value1;attr2=value2;msg='Hello, world';END
```

## Remote log file monitoring: Encrypting a password or pass phrase

For increased security, you can encrypt passwords and pass phrases that are transmitted to remote systems when you use Remote log file monitoring.

## About this task

The encrypted password and pass phrases are stored in the configuration (.conf) file. For more information about the configuration file, see [“Configuration file” on page 732](#).

## Procedure

- Run the **itmpwdsnmp** command and supply the password or pass phrase that is to be encrypted:
  - Linux** **UNIX** The command is run from the Cloud APM installation directory. The default installation path is `opt/ibm/apm/agent` and `install_dir` is where you installed the agent.
  - Windows** The default installation path is `C:\IBM\APM`.

**Linux** Example of the command when it is run on a Linux system:

```
$ export install_dir=/opt/ibm/apm/agent/bin
$ /opt/ibm/apm/agent/bin

Enter string to be encrypted:
mypassword

Confirm string:
mypassword

{AES256:keyfile:a}Z7BS23aupYqw1Xb1Gh+weg==
$
```

In the example, the entire output from the `{AES256:keyfile:a}Z7BS23aupYqw1Xb1Gh+weg==` command is used to set **SshPassword** in the agent configuration file. The `{AES256:keyfile:a}` prefix tells the agent that the password is encrypted.

To encrypt a pass phrase for a private key file, follow the same procedure.

## Configuring OS agent custom scripting

The Monitoring Agent for Linux OS, Monitoring Agent for UNIX OS, and Monitoring Agent for Windows OS agents are configured automatically. This feature allows users to define scripts to run at OS agents at a defined frequency.

The custom scripting feature is enabled by default. The administrator can enable/disable it by setting a new environment variable `KXX_FCP_SCRIPT=true/false` (the default is true) in the agent configuration file, where XX can be:

- LZ for Monitoring Agent for Linux OS
- UX for Monitoring Agent for UNIX OS
- NT for Monitoring Agent for Windows OS

The details are provided in the following sections.

### Custom scripting Quick Start

Add custom scripting for the OS agents to define scripts to run at OS agents at a defined frequency.

The feature is enabled with default values as soon as the OS agent is started. The only action to start the scripting feature is:

Create a property file under default directory (on Linux™ or UNIX™ it is `install_dir/localconfig/product_code/scripts_definitions`, on Windows™ it is `install_dir\localconfig\nt\scripts_definitions` by using as an example the provided template `script_property.txt`.

Only two properties are required:

#### **ATTRIBUTE\_NAME**

Any name used to uniquely identify the script definition inside the property file.

#### **SCRIPT\_PATH\_WITH\_PARMS**

The fully qualified path of the script with arguments.

Not only shell scripts but also perl and other types of scripts can be used. Specify the full command to run in the `SCRIPT_PATH_WITH_PARMS` property.

For example, `perl C:\IBM\scripts\Custom_Scripts\date.pl`. In this example, make sure that the location of `perl` can be resolved by the agent through the `PATH` variable in its environment. Specify the full path where `perl` is installed otherwise.

### Parameters in OS agent environment files

You can set the parameters for custom scripting in the OS agent environment files.

It is possible to customize the scripting feature by setting parameters in the OS agent environment files:

#### ***install\_dir/config/lz.environment***

The environment file for the Monitoring Agent for Linux OS.

#### ***install\_dir/config/ux.environment***

The environment file for the Monitoring Agent for UNIX OS.

#### ***install\_dir\TMAITM6\_x64\KNTENV***

The environment file for the 64 bit Monitoring Agent for Windows OS.

#### ***install\_dir\TMAITM6\KNTENV***

The environment file for the 32 bit Monitoring Agent for Windows OS.

#### **KXX\_FCP\_SCRIPT**

The scripting feature is enabled by default. To disable it set: `KXX_FCP_SCRIPT=false`

**Other parameters can be defined inside the agent environment files based on specific needs:**

#### **KXX\_FCP\_SCRIPT\_DEFINITIONS**

The location where property files are stored.

The default location on Linux™ or UNIX™ is *install\_dir/localconfig/PC/scripts\_definitions*, on Windows™ it is *install\_dir\localconfig\nt\scripts\_definitions*

### **KXX\_FCP\_SCRIPT\_INTERVAL**

OS agent uses the value of this variable as loop interval in seconds to check execution of running scripts and it sends events if the filter condition is satisfied. The minimum value is 30 seconds and the maximum value is 300 seconds. Invalid values are reset to the default. The default value is 60 seconds.

**Note:** This parameter is ignored if KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS is set to USE\_SCRIPT (see definition for KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS).

### **KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS**

If the agent looping interval defined by KXX\_FCP\_SCRIPT\_INTERVAL is larger than the script execution frequency, it can happen that data produced by some of the script execution loops is lost. In order to avoid this behavior, the script execution frequency can be synchronized with the agent looping interval by setting the KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS to:

- USE\_AGENT - The value of each script execution frequency is forced to be the maximum between KXX\_FCP\_SCRIPT\_INTERVAL and EXECUTION\_FREQUENCY defined in its property file.
- USE\_SCRIPT - The agent looping interval is dynamically set to the minimum frequency value (EXECUTION\_FREQUENCY in property file) between all of the defined scripts. The value set by KXX\_FCP\_SCRIPT\_INTERVAL is ignored. The frequency of the scripts remains as defined in the property files. When you set USE\_SCRIPT, the agent looping interval can change every time a script definition is added, changed, or removed. In any case, it cannot be lower than the value set by KXX\_FCP\_OVERRIDE\_MIN\_FREQUENCY\_LIMIT or bigger than 300 seconds.
- NO - No synchronization is done and some execution results might be lost.

### **KXX\_FCP\_SCRIPT\_DEFINITIONS\_CHECK\_INTERVAL**

At startup and at every interval that is defined by this variable, the OS agent checks for any changes in scripts or property files. Note if KXX\_FCP\_SCRIPT\_DEFINITIONS\_CHECK\_INTERVAL is less than the agent looping interval it is reset to the agent looping interval. The maximum allowed value is the default, 300 seconds.

### **KXX\_FCP\_USER**

This parameter is valid only on Linux™ or UNIX™ OS agents. It defines the user used to create the fcp\_daemon process if different from OS agent process user; all the scripts are run by this user. Be advised the owner of the OS agent must have correct permission to create the fcp\_daemon process. On Windows™, a different user must be defined as login of the service Monitoring Agent for Windows OS "FCProvider". The user must have "Full Control" permission to agent installation directory and scripts repository directories. For more information, see:

[https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/install/install\\_linuxaix\\_agent\\_nonroot.html](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/install/install_linuxaix_agent_nonroot.html)

### **KXX\_FCP\_MAX\_CDP\_DP\_THREAD\_POOL\_SIZE**

It defines the maximum concurrent number of scripts to be run. Maximum value is 32.

### **KXX\_FCP\_MAX\_DAEMON\_RESTARTS**

The OS agent watches the fcp\_daemon: If an abnormal exit of process occurs, the OS agent restarts it. The default value is 4. The restart is done for the KXX\_FCP\_MAX\_DAEMON\_RESTARTS (times at a day). The value 0 must be used to avoid the restart; if -1 is set, the OS agent retries to restart fcp\_daemon forever. The restart counter is reset at OS agent restart.

### **KXX\_FCP\_SEND\_SCRIPT\_RUNTIME\_EVENTS**

The default value is true. If set to false, the OS agent stops sending events for each row of script standard output. In this case script outputs are visible on console workspaces but no situations are displayed and no historical data is collected.

## **KXX\_FCP\_OVERRIDE\_MIN\_FREQUENCY\_LIMIT**

It is used when KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS is set to USE\_SCRIPT. In this condition, it sets the minimum value of the OS agent looping interval.

Using low values for the OS agent looping interval (less than 5 seconds) is highly invasive and can impact OS agent performances. If frequent data collection is needed (for example, every second), it is suggested to customize a script. The script caches data at the needed frequency and returns the collected data to the OS agent at a higher interval (for example, every 60 seconds).

**The following Agent Builder (CDP) variables can also be used to control the behavior of the fcp\_daemon:**

### **CDP\_DP\_REFRESH\_INTERVAL**

(default 60 sec) Global script scheduled start time. Used if the frequency is not passed in the script property file.

### **CDP\_DP\_SCRIPT\_TIMEOUT**

(default 30 sec) Global script execution maximum time. When the execution time of a script exceeds this limit, its Status\_Code is set to TIMEOUT

### **CDP\_DP\_KILL\_ORPHAN\_SCRIPTS**

(Y|N - default N) Global behavior used by fcp\_daemon process for timing out scripts. When set to 'Y', the scripts are ended, otherwise they are abandoned. This value is ignored for a specific script if the KILL\_AFTER\_TIMEOUT key is set in the script property file

### **CDP\_MAXIMUM\_ROW\_COUNT\_FOR\_CPCI\_DATA\_RESPONSES**

(default 1000) Global value is added for performance reasons to limit the maximum number of output rows returned by the scripts. Extra rows after this limit are ignored. Allowed values are positive integer. Invalid values are changed to no limit.

The fcp\_daemon also supports the other environment variables that are used to control Agent Builder agents. For a complete list, see the *IBM Agent Builder User's Guide* here: [Chapter 2, "PDF documentation," on page 49.](#)

## **Parameters in property files**

You can set the parameters for custom scripting in the property files.

The KXX\_FCP\_SCRIPT\_DEFINITIONS directory contains a list of \*.properties files. Each property file contains a list of scripts to run with respective properties in the form of key=value. The properties that can be defined (case-insensitive) are:

### **ATTRIBUTE\_NAME**

Required - string max 256 characters. A name of your choice that defines a specific script and its attributes. The characters that can be used for the ATTRIBUTE\_NAME name can be alphanumeric and only the underscore can be used as a special character. If other special characters (a space or blank) are used, they are converted to underscore (\_). When multiple scripts are listed inside the same property file, more, different ATTRIBUTE\_NAME must be defined (one for each script). It must be the first value that is specified for each defined script and delimits the start of the properties set for the specific script until the next ATTRIBUTE\_NAME.

### **SCRIPT\_PATH\_WITH\_PARMs**

Required - string max 512 characters. This parameter defines the full path to the script with parameters, which are separated by a blank. No special characters can be used in the script path name. Values containing blanks must be enclosed in single (') or double quotation marks ("). Environment variables can be passed, but only enclosed in \${...} for all the operating systems. Environment variables must be available in the OS agent process context.

### **EXECUTION\_FREQUENCY**

Optional - default value is 60 seconds. This parameter defines the script execution frequency.

### **CUSTOM\_NAME**

Optional - string max 256 characters. This parameter can be used for a description of the script.

**IS\_ACTIVE**

Optional - true|false The default value is true. It activates the script. If false, the script is not run.

**DISABLE\_USE\_AGENT\_SYNC**

Optional - true|false The default value is false. If true, the EXECUTION\_FREQUENCY of the script is respected also if the global variable KXX\_FCP\_SCRIPT\_SYNC\_INTERVALS is set to USE\_AGENT.

**KILL\_AFTER\_TIMEOUT**

Optional - true|false The default value is defined by the CDP\_DP\_KILL\_ORPHAN\_SCRIPTS variable. When true, the script is ended after timeout. A timeout occurs when script execution is greater than the value specified by CDP\_DP\_SCRIPT\_TIMEOUT parameter in OS agent configuration file. Otherwise, it is ignored. In both cases, no data is collected. Note when KILL\_AFTER\_TIMEOUT is set, only the script that is defined in property file is ended and not child processes (if any) created by the script. This feature is not supported by Solaris™ and Windows™ 32-bit OS agents and any timing out scripts are abandoned.

**Output rows that are returned by a script are parsed.**

The script returns a standard output (called as first token). When the script returns more values in the output row, they are added as more tokens. A maximum of five strings, five integers and five floats following a predefined syntax.

**OUTPUT\_TYPE**

STRING|INTEGER|FLOAT - Optional - default value is string. It defines the type of the first token that is returned by each row of the script; OUTPUT\_TYPE can be:

- STRING (default) - strings up to 2048 characters. When used, the "Standard\_Output\_String" attribute of KXX\_Custom\_Scripts\_Rtm\_Smp is completed by the first token.
- INTEGER - allows getting numeric values between -9223372036854775806 and 9223372036854775806. When used, the "Standard\_Output\_Integer" attribute of KXX\_Custom\_Scripts\_Rtm\_Smp is completed by the first token.
- FLOAT - allows getting numeric values between -92233720368547758.06 and 92233720368547758.06, with two decimal precisions. When used, the "Standard\_Output\_Float" attribute of KXX\_Custom\_Scripts\_Rtm\_Smp is completed by the first token.

**TOKEN\_TYPES**

STRING|INTEGER|FLOAT - Optional - It defines the output type of more tokens after the first one. The user can define a maximum of five strings, five integers and 5 floats. It is a list of types that are separated by commas: <token\_type>,<token\_type>,... token\_type can be empty or one from (case-insensitive):

- - STRING or S
- - INTEGER or I
- - FLOAT or F
- If TOKEN\_TYPES is empty, the corresponding token is skipped.

Examples of the same valid layouts:

- - TOKEN\_TYPES=S,I,S,,,F,,F,F
- - TOKEN\_TYPES=String,integer,S,,,Float,,f,FLOAT

**TOKEN\_LABELS**

STRING - Optional - Maximum 16 characters each label. It defines the labels of the tokens that are defined in TOKEN\_TYPES. This value is a list of token labels that are separated by commas, and must correspond to the tokens defined by TOKEN\_TYPES. For example:

- TOKEN\_TYPES=S,I,S,,,F,,F,F
- TOKEN\_LABELS=Cpu Name,Cpu number,Description,,,value 1,,value 2,value 3
- TOKEN\_LABELS is ignored if TOKEN\_TYPES is not set.

## TOKEN\_SEPARATOR

Optional - default semicolon ";" It sets the string to be used as separator to split the output row in tokens. It is ignored if TOKEN\_TYPES is not set. Empty value (blank) is accepted as separator and multiple consecutive blanks in output rows are considered as a single one.

**The following two parameters allow filtering the rows output of a script. They are applied by the OS agent only to the first token and they must be used together:**

## FILTER\_VALUE

Optional. The value used for comparison. It is required if FILTER\_OPERATOR is defined. If the OUTPUT\_TYPE is a string, the filter value must reflect exactly the string value that is returned by the script that is intended to be filtered, without any additional quotation marks (no wildcards allowed).

## FILTER\_OPERATOR

Optional. The operator used for the comparison. It is required if FILTER\_VALUE is defined. Accepted FILTER\_OPERATOR values include:

- = (equal to)
- != (not equal to)
- > (larger than) only for numeric type
- >= (not lower than) only for numeric type
- < (less than) only for numeric type
- <= (not bigger than) only for numeric type

## Examples of property file

Examples of setting parameters in the property files.

#First script definition: script ex\_script1.sh is started every 150 seconds. It returns float values and only the output rows equal to 0.5 are considered by the agent.

```
ATTRIBUTE_NAME=sample1
SCRIPT_PATH_WITH_PARAMS=/opt/ibm/apm/agent/localconfig/lz/scripts_definitions/ex_script1.sh
EXECUTION_FREQUENCY=150
OUTPUT_TYPE=FLOAT
FILTER_VALUE=0.5
FILTER_OPERATOR==
```

#Second script definition: script ex\_script2 is started every 60 seconds. It returns integer values and only the rows different from 0 are considered by the agent.

```
ATTRIBUTE_NAME=ex_script2
SCRIPT_PATH_WITH_PARAMS=${CANDLE_HOME}/tmp/check_out.sh
EXECUTION_FREQUENCY=60
OUTPUT_TYPE=INTEGER
FILTER_VALUE=0
FILTER_OPERATOR!=
```

#Third script definition: script ex\_script3.sh is started every 120 seconds with three input parameters (the first input parameter is an integer, the second and third are string). It is ended if it hangs or if the execution time is greater than the timeout value.

```
ATTRIBUTE_NAME=ex_script3
SCRIPT_PATH_WITH_PARAMS=/opt/scripts/ex_script3.sh 1 "second input parameter" "third input parameter"
EXECUTION_FREQUENCY=120
OUTPUT_TYPE=STRING
KILL_AFTER_TIMEOUT=TRUE
```

#Fourth script definition: script cpu\_mem\_percentage.sh is started every 50 seconds and returns the cpuid as standard output string and two float values for Idle and Used CPU percentage and two integers for Memory and Virtual Memory usage. The pipe is used as separator to parse the output. An example of row that must be returned by the script is:

cpu2|35,5|65,5|3443|123800

```
ATTRIBUTE_NAME=cpu and mem Usage
SCRIPT_PATH_WITH_PARMS=${SCRIPT_HOME}/cpu_mem_percentage.sh
OUTPUT_TYPE=STRING
TOKEN_TYPES=F,F,I,I
TOKEN_LABELS= Idle CPU %, Used CPU %, Virt MEM used MB, MEM used MB
TOKEN_SEPARATOR=|
EXECUTION_FREQUENCY=50
```

## Known problems and limitations

Known problems and limitations

- The Scripting Feature is not supported on Windows™ 2003 64-bit systems.
- Kill after timeout does not work on Solaris™ and Windows™ 32-bit OS agents.
- The fcp\_daemon can stop running scripts in Windows™ 32 bit if some scripts do not complete within the timeout period and the user enabled intensive tracing. If fcp\_daemon stops running scripts, the data reported on the console reflects the last time that the script was run. It is also possible that the OS agent stops returning data. Stopping the fcp\_daemon process allows the agent to resume proper operation.
- SCRIPT\_NONZERO\_RETURN is returned instead of SCRIPT\_NOT\_FOUND or SCRIPT\_LAUNCH\_ERROR on Solaris™.
- The scripting feature does not provide full globalization; some issues can be found by using Nationalized characters in property files or script outputs.
- On Windows™ OS agent, there is no possibility of running scripts residing on a mapped network drive.
- When the Windows™ OS agent is upgraded, the scripting feature is not enabled by default. Edit the KNTENV and change `KNT\_FCP\_SCRIPT=FALSE` to `KNT\_FCP\_SCRIPT=TRUE`

## Troubleshooting custom scripting

Troubleshooting custom scripting

Standard *KBB\_RAS1* variable applies to the OS agent and to the fcp\_daemon processes. To apply a specific trace setting to fcp\_daemon only, use the *KXX\_FCP\_KBB\_RAS1* variable; when *KXX\_FCP\_KBB\_RAS1* is set, the value that is specified by *KBB\_RAS1* is ignored by fcp\_daemon.

To trace the operations logged by the OS agent core threads of the feature:

```
KBB_RAS1=ERROR (UNIT:factory ALL)
```

To trace scripting queries from the APM server and events sent to the server, add the entries:

On the Monitoring Agent for Linux OS

```
(UNIT:klz34 ALL) (UNIT:klz36 ALL)
```

On the Monitoring Agent for UNIX OS

```
(UNIT:kux48 ALL) (UNIT:kux50 ALL)
```

On the Monitoring Agent for Windows OS

```
(UNIT:knt84 ALL) (UNIT:knt86 ALL)
```

To view TEMA traces to verify private situation execution, add the entries:

```
(UNIT:kraavp all) (UNIT:kraapv all)
```

To see the execution of the scripts and how the data from the scripts is being parsed set:

```
KXX_FCP_KBB_RAS1=Error (UNIT:command ALL)
```

To troubleshoot problems in the communication between the os agent and fcp\_daemon, add this trace level to both *KBB\_RAS1* and *KXX\_FCP\_KBB\_RAS1*:

```
(UNIT:cps_socket FLOW) (UNIT:cpci FLOW)
```

To see the interaction between the OS agent process and the fcp\_daemon in detail add to both *KBB\_RAS1* and *KXX\_FCP\_KBB\_RAS1*:

```
(UNIT:cps_socket ALL) (UNIT:cpci ALL)
```

## Quick Start Scenario

This section describes the minimum steps that are needed to configure custom scripting for an example scenario.

The following section describes the minimum steps that are needed to configure a Monitoring Agent for Linux OS to run two custom scripts.

Custom Scripts descriptions

In this example, the user has two scripts under a directory */scripts\_repo*:

*checkDIRsize.sh* – This script checks the size of a specified directory that is passed as input parameter. The output is an integer like: 4594740

*cpu\_mem\_usage.sh* – This script checks the used CPU percentages and used Swap Memory megabytes. The output is returned in the form: *cpu1 | 96, 5 | 23800*

Where the first token is the CPU ID, the second token is the used CPU percentage, the third token is the used swap memory in megabytes.

The customization needed to have the Monitoring Agent for Linux OS run these scripts.

The feature is enabled with default values as soon as the OS agent is started:

You create property files *AnyName.properties* under the default directory *install\_dir/localconfig/lz/scripts\_definitions*. In this example, create two property files, one for each script named *checkDIRsize.properties* and *cpu\_mem\_usage.properties*:

```
#CheckDIRsize.properties
ATTRIBUTE_NAME=OPT_DIR_SIZE
SCRIPT_PATH_WITH_PARMS=/scripts_repo/checkDIRsize.sh /opt
EXECUTION_FREQUENCY=20
OUTPUT_TYPE=INTEGER
```

```
#cpu_mem_usage.properties
ATTRIBUTE_NAME=cpu_mem_usage
SCRIPT_PATH_WITH_PARMS=/scripts_repo/cpu_mem_percentage.sh
OUTPUT_TYPE=string
TOKEN_TYPES=F,I
TOKEN_LABELS= Used CPU %, Swap MEM used MB
TOKEN_SEPARATOR=|
EXECUTION_FREQUENCY=10
```

There is no need to restart the OS agent after you add (or change) the two property files. The OS agent checks script definition directory with a specified time interval (default value 300 seconds). Open the console and under the "Custom Scripts" workspace the scripts details and results are shown.

## Configuring local environment variables

You can configure the local environment to change behavior of the Monitoring Agent for Linux OS.

### About this task

Complete these steps to configure the Monitoring Agent for Linux OS.

### Procedure

1. Create the `install_dir/config/lz.environment` file if the file doesn't exist.
2. Edit the `install_dir/config/lz.environment` file and enter values for the environment variables. For more information about the environment variables that you can configure, see Local Environment Variables following step 3.
3. Restart the Monitoring Agent for Linux OS.

**Note:** Do not modify the `.lz.environment` file since it contains the default settings that are provided by IBM and changes to this file are not preserved when the agent is updated.

#### Local Environment Variables:

##### KBB\_SHOW\_MTAB\_FS

This variable controls the Monitoring Agent for Linux OS data collection for file system. When `KBB_SHOW_MTAB_FS=false`, the agent monitors only the file systems that are listed in `/etc/fstab`. When `KBB_SHOW_MTAB_FS=true`, the agent monitors file systems that are listed in both `/etc/fstab` and `/etc/mtab`.

Starting with APM 8.1.4.013 (LZ agent version 06.35.14.17), the default value is `true`.

##### KBB\_SHOW\_CIFS

Specifies whether CIFS monitoring is enabled. The default value is `false`. Possible values are `'true'` and `'false'`.

##### KBB\_SHOW\_NFS

Specifies whether NFS monitoring is enabled. The default value is `false`. Possible values are `'true'` and `'false'`.

**Note:** Even if the value is set to `'true'`, the UI is configured to not display NFS file system information.

##### KLZ\_EXCLUDE\_DOCKER\_FS\_STR

Exclude Docker mounts that contain the string defined. This variable is a comma-separated list of substring part of a mount point to exclude. The default value is set as follows:

`KLZ_EXCLUDE_DOCKER_FS_STR=/docker/,/var/lib/kubelet/,/var/lib/docker/,/pods/`

**Note:** This variable works together with `KBB_SHOW_MTAB_FS=true`.

##### KLZ\_EXCLUDE\_FSTYPE

Exclude file system to monitor defined mount point. This variable is a comma-separated list of file system type. The names must match those names that are shown by the command `"mount -l"`.

Example: `KLZ_EXCLUDE_FSTYPE=mvfs,ext3`

**Note:** In a conflict with `KBB_SHOW_NFS` or `KBB_SHOW_CIFS` settings, `KLZ_EXCLUDE_FSTYPE` takes priority.

## Configuring Monitoring Agent for Windows OS file monitoring threshold

For any threshold created against the File Change or File Trend data sets, the following guidelines must be followed.

### File Change attributes

Use File Change attributes to monitor changes to your file system and to request notification when resources change. File Change is a multiple-instance data set. You cannot mix these attributes with any other multiple-instance data set.

**Note:** When you define a threshold, the function REGEX is not supported in any attributes that contain the name or the path of the files.

When you create thresholds that use the File Change data set, you must supply values for the following attributes to restrict the monitoring for the threshold:

- Watch Directory (Unicode)
- Watch File (Unicode) optional

The use of this data set requires that you set one or more filter conditions. The following attributes can be used and the values for these filters are single characters, **y** or **n**, where y=yes, and n=no:

- Change File Name
- Change Directory Name
- Change Attributes
- Change Size
- Change Last Write
- Change Last Access
- Change Create
- Change Security
- Monitor all Conditions (activates all of the above)

Any query and threshold must contain only one row of filter data in the threshold formula. If more than one row is provided the results are undefined.

**Note:** The product provided File Change query does not produce data unless a threshold is defined against this data set.

### File Trend attributes

Use File Trend attributes to monitor the growth rate in file space usage, by both change and absolute size change, over various monitoring periods. File Trend is a multiple-instance data set. You cannot mix these attributes with those of any other multiple-instance data set.

**Note:** When you define a threshold, the function REGEX is not supported in any attributes that contain the name or the path of the files.

The File Trend attributes monitor the discrete files only and not subdirectories.

When you create a threshold that uses the File Trend data set, you must supply values for the following attributes to restrict the monitoring for the threshold:

- Watch Directory (Unicode)
- Watch File (Unicode) optional

Thresholds must contain only one row of filter data in the threshold formula. If more than one row is provided the results are undefined.

**Note:** The product provided File Trend query does not produce data unless a threshold is defined against this data set.

## Configuring PHP monitoring

You must configure the Monitoring Agent for PHP so that the agent can collect data from the PHP application that is being monitored.

### Before you begin

1. Ensure that you install the php-process package. If you use the `yum install` command to install PHP, run the `yum install php-process` command to install the php-process package.
2. Ensure that the Apache HTTPD server is started before you configure the agent.

Open the Apache HTTP Server `httpd.conf` configuration file and ensure that both the `mod_status` and `ExtendedStatus On` options are enabled. For example:

```
ExtendedStatus On
<Location /server-status>
    SetHandler server-status
    Order deny,allow
    Allow from all
    Allow from 127.0.0.1
</Location>
```

In the given example, `http://127.0.0.1/server-status` must work fine for the agent to work properly.

**Note:** You must have Lynx or Links installed on Linux for the agent to get monitoring data.

Make sure that the command `apachectl status` works fine in the monitored Apache server with no code changes to the `apachectl` command. Lynx must be installed for the command `apachectl status` to work properly.

### About this task

To avoid permission issues when you configure the agent, be sure to use the same root user or non-root user ID that was used for installing the agent. If you installed your agent as a selected user and want to configure the agent as a different user, see [“Configuring agents as a non-root user”](#) on page 243. If you installed and configured your agent as a selected user and want to start the agent as a different user, see [“Starting agents as a non-root user”](#) on page 1159.

The PHP agent is a multiple instance agent; you must create the first instance and start the agent manually. The Managed System Name includes the instance name that you specify, for example, `instance_name:host_name:pc`, where `pc` is your two character product code. The Managed System Name is limited to 32 characters. The instance name that you specify is limited to 28 characters, minus the length of your host name. For example, if you specify `PHP2` as your instance name, your managed system name is `PHP2:hostname:PJ`.

**Important:** If you specify a long instance name, the Managed System name is truncated and the agent code does not display correctly.

### Procedure

- If your environment is the same as the default settings, you can use the default execution binary path, default `php.ini` file path, and default port to configure the agent:
  - a) Enter:

```
install_dir/bin/php-agent.sh config instance_name install_dir/samples/
php_silent_config.txt
```

Where `instance_name` is the name you want to give to the instance, and `install_dir` is the PHP agent installation directory. The default installation directory is `/opt/ibm/apm/agent`.
  - b) To start the agent, enter:

```
install_dir/bin/php-agent.sh start instance_name
```

- To configure the agent by editing the silent response file and running the script with no interaction, complete the following steps:
  - a) Open `install_dir/samples/php_silent_config.txt` in a text editor.
  - b) For **Location of PHP execution binary**, you can specify the directory where the PHP execution is located. The default location is `/usr/local/bin`.
  - c) For **Location of PHP INI file**, you can specify the directory where the `php.ini` file is located. The default location is `/etc`.
  - d) For **Web server port**, you can specify the port number of the web server that is running WordPress. The default is 80.
  - e) For **Application DocumentRoot**, you can specify the DocumentRoot of the PHP WordPress application. Use a colon to separate multiple records. To allow the agent to find all the records for you, use the default value of ALL.
  - f) Save and close the `php_silent_config.txt` file, then enter:  
`install_dir/bin/php-agent.sh config instance_name install_dir/samples/php_silent_config.txt`  
 Where `instance_name` is the name that you want to give to the instance, and `install_dir` is the PHP agent installation directory. The default installation directory is `/opt/ibm/apm/agent`.
  - g) To start the agent, enter:  
`install_dir/bin/php-agent.sh start instance_name`
- To configure the agent by running the script and responding to prompts, complete the following steps:
  - a) Enter:  
`install_dir/bin/php-agent.sh config instance_name`  
 Where `instance_name` is the name you want to give to the instance, and `install_dir` is the PHP agent installation directory.
  - b) When prompted to Edit Monitoring Agent for PHP settings, enter 1 to continue.
  - c) When prompted for Location of PHP execution binary, press Enter to accept the default location or specify your own location.
  - d) When prompted for Location of PHP INI file, press Enter to accept the default location or specify your own location.
  - e) When prompted for Web server port, press Enter to accept the default port or specify a different port number.
  - f) When prompted for Application DocumentRoot, press Enter to accept the default or specify the DocumentRoot of the PHP WordPress application. You can use a colon to separate multiple records.
  - g) To start the agent, enter:  
`install_dir/bin/php-agent.sh start instance_name`

## Results

The agent evaluates only the performance of PHP requests in WordPress applications. CSS and JS loading are not evaluated. The agent does not use URL arguments to identify URLs.

## What to do next

You can verify the PHP agent data is displayed in the Cloud APM console.

You must ensure that the WordPress plugin-in for the agent is activated. To ensure activation, complete the following steps:

1. In a web browser, enter the following URL `http://hostname:port/wp-admin/`.
2. Access the administrative page by navigating to **Plugins > Installed Plugins**.
3. Ensure that the PHP agent plug-in is activated. The PHP agent plug-in is listed as **WordPress Agent**. Typically, the plug-in is already activated. If it is not already activated, click on **Activate**.

## Configuring PostgreSQL monitoring

You must configure the Monitoring Agent for PostgreSQL so that the agent can collect data from the PostgreSQL database that is being monitored.

### Before you begin

You must install the PostgreSQL JDBC driver before you install this agent. The path to this driver is required at the time of agent configuration.

JDBC type 4 driver is the new version and hence preferable. User can install the subtype of JDBC 4 version according to the JDK version the agent uses. For mapping of JDBC version to JDK version get more information at <https://jdbc.postgresql.org/download.html>.

The `pg_hba.conf` file is the PostgreSQL database file that contains authentication settings. When the `auth-method` parameter value is set to `ident` in the `pg_hba.conf` file, the PostgreSQL agent cannot connect to the PostgreSQL database. Ensure that the authentication settings for the `auth-method` parameter are correct. For example, you can set these values for `auth-method` parameter: `md5`, `trust`, or `password`.

For remote monitoring, `pg_hba.conf` file should be updated according to SSL configuration done in `postgresql.conf` file.

If SSL is off then **host** entry should be added:

| Table 218. |           |             |                       |               |
|------------|-----------|-------------|-----------------------|---------------|
| host       | <DB name> | <user name> | <Agent machine IP>/32 | <auth-method> |

If SSL is on then **hostssl** entry should be added

| Table 219. |           |             |              |      |
|------------|-----------|-------------|--------------|------|
| hostssl    | <DB name> | <user name> | <TEMA IP>/32 | cert |

Here, DB name is specific database name or you can enter all, user name is default user name `postgres` or you can enter all, `auth-method` can be `md5` or `password` or `trust`.

**Note:** **host** or **hostssl** entry is not required for PostgreSQL server local monitoring.

A few of the attributes collected by the agent rely on the `pg_stat_statements` extension. To add `pg_stat_statements` first install the package `postgresql-contrib`. You must modify the `postgresql.conf` configuration file in order for the PostgreSQL server to load the `pg_stat_statements` extension.

1. Open the `postgresql.conf` file in a text editor and update the `shared_preload_libraries` line:

```
shared_preload_libraries = 'pg_stat_statements'
pg_stat_statements.track_utility = false
```

These changes are required to monitor SQL statements, except utility commands.

**Note:** The status of `pg_stat_statements.track_utility` is set or modified by a superuser only.

2. Update the `connection settings` section in `postgresql.conf` file `listen_addresses = <Agent machine IP>` here, mention specific agent IP or `*` to listen all IP addresses.

**Note:** This setting is required for remote monitoring.

3. Restart the PostgreSQL server after you update and save the `postgresql.conf`.
4. Run the following SQL command by using `psql`, that should be connected to the same database that would be provided later in the agent configuration for JDBC connectivity:

```
create extension pg_stat_statements;  
select pg_stat_statements_reset();
```

**Note:** The command `create extension` and function `pg_stat_statements_reset()` are run by a superuser only.

The view `pg_stat_statements` needs to be enabled for specific database, for more details refer <https://www.postgresql.org/docs/9.6/static/pgstatstatements.html>.

Review hardware and software prerequisites. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\) for the PostgreSQL agent](#).

## About this task

The PostgreSQL agent is a multiple instance agent; you must create the first instance and start the agent manually. The managed system name includes the instance name that you specify, for example, `instance_name:host_name:pc`, where `pc` is your two character product code. The managed system name is limited to 32 characters. The instance name that you specify is limited to 28 characters, minus the length of your host name. For example, if you specify `PostgreSQL2` as your instance name, your managed system name is `PostgreSQL2:hostname:PN`.

**Important:** If you specify a long instance name, the managed system name is truncated and the agent code is not displayed completely.

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

## What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console”](#) on page 1109.

## Configuring the agent on Windows systems

You can use the IBM Cloud Application Performance Management window to configure the agent on Windows systems.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Monitoring Agent for PostgreSQL**, and then click **Configure agent**.
3. In the **Enter a unique instance name** field, type the agent instance name and click **OK**.
4. In the **Monitoring Agent for PostgreSQL** window, complete these steps:
  - a. In the **IP Address** field, enter the IP address of a PostgreSQL server that you want to monitor remotely. If the agent is installed on the server to be monitored, retain the default value.
  - b. In the **JDBC database name** field, enter a database name to change the default database name of `postgres`.
  - c. In the **JDBC user name** field, enter a user name to change the default name of `postgres`.
  - d. In the **JDBC password** field, enter the JDBC user password.
  - e. In the **Confirm JDBC password** field, re-enter the password.
  - f. In the **JDBC port number** field, enter a port number to change the default port number of 5432.
  - g. In the **JDBC JAR file** field, enter the path for the PostgreSQL connector for the Java JAR file and click **Next**.

- h. In the **Java trace level** field, enter the trace level according to the IBM support instructions. The default trace level is **Error**.
  - i. Click **OK**. The agent instance is displayed in the IBM Performance Management window.
5. Right-click the **Monitoring Agent for PostgreSQL** instance, and click **Start**.

### What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent on Linux systems

To configure the agent on Linux operating systems, you must run the script and respond to prompts.

### Procedure

1. On the command line, enter the following command:  
`install_dir/bin/postgresql-agent.sh config instance_name`
  2. When you are prompted to edit the agent for PostgreSQL settings, enter 1 to continue.
  3. When you are prompted to enter a value for the following parameters, press Enter to accept the default value or specify a different value and press Enter:
    - **PostgreSQL Server IP Address:** Enter the IP address of a PostgreSQL server that you want to monitor remotely. If the agent is installed on the server to be monitored, retain the default value.
    - **JDBC database name:** Enter a database name to change the default database name of postgres.
    - **JDBC user name:** Enter a user name to change the default name of postgres.
    - **Enter JDBC password:** Enter the JDBC user password.
    - **Re-type JDBC password:** re-enter the password.
    - **JDBC port number:** Enter a port number to change the default port number of 5432.
    - **JDBC JAR file:** Enter the path for the PostgreSQL connector for the Java JAR file.
- Important:** The version of the JDBC JAR file must be compatible with the version of the PostgreSQL database that is being monitored.
4. When you are prompted to enter a value for the `Java trace level` parameter, enter 2 to accept the default value or specify the trace level according to the IBM support instructions.
  5. Run the following command to start the agent:

```
install_dir/bin/postgresql-agent.sh start instance_name
```

### What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

You can use the silent response file to configure the PostgreSQL agent on Linux and Windows systems. After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

- To configure the agent by editing the silent response file and running the script without responding to prompts, complete the following steps:
  1. In a text editor, open the silent response file that is available in this path: *install\_dir*/samples/postgresql\_silent\_config.txt where *install\_dir* is the installation directory of PostgreSQL agent. The default installation directory is /opt/ibm/apm/agent.
  2. To edit the silent configuration file, complete the following steps:
    - a. For the **PostgreSQL Server IP Address** parameter, specify the IP address of a PostgreSQL server that you want to monitor remotely. If the agent is installed on the server to be monitored, retain the default value.
    - b. For the **JDBC database name** parameter, specify a database name to change the default database name of postgres.
    - c. For the **JDBC user name** parameter, specify a user name to change the default name of postgres.
    - d. For the **JDBC password** parameter, enter the JDBC user password.
    - e. For the **JDBC port number** parameter, specify a port number to change the default port number of 5432.
    - f. For the **JDBC JAR file** parameter, specify the path for the PostgreSQL connector for the Java JAR file

**Important:** The version of the JDBC JAR file must be compatible with the version of the PostgreSQL database that is being monitored.

  - g. For the **Java trace level** parameter, specify the trace level according to the IBM support instructions. The default trace level is Error.
- 3. Save and close the silent response file, and run the following command:

```
install_dir/bin/postgresql-agent.sh config  
instance_name  
install_dir/samples/postgresql_silent_config.txt
```

Where *instance\_name* is the name that you want to give to the instance.

4. To start the agent, enter the following command:

```
install_dir/bin/postgresql-agent.sh start instance_name
```

### What to do next

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring Python monitoring

---

Both on-premises and IBM Cloud Python applications can be monitored. Complete the corresponding configuration steps based on your application type.

### About this task

Configure the Python data collector to monitor your on-premises and IBM Cloud Python applications.

### Procedure

- Configure the data collector to monitor IBM Cloud applications.
  - a) Configure the Python data collector to collect and send data for IBM Cloud applications. For instructions, see [“Configuring the Python data collector for IBM Cloud applications” on page 765](#).
  - b) Optional: Customize the monitoring capabilities of the Python data collector. For more information, see [“Customizing the Python data collector for IBM Cloud applications” on page 766](#).
- Configure the data collector to monitor on-premises applications.
  - a) Configure the data collector to collect and send data to the Cloud APM server. For instructions, see [“Configuring the Python data collector for on-premises applications” on page 770](#).
  - b) Optional: Customize the monitoring capabilities of the Python data collector. For more information, see [“Customizing the Python data collector for on-premises applications” on page 771](#).

## Configuring the Python data collector for IBM Cloud applications

To collect information about Python applications on IBM Cloud, you must configure the Python data collector.

### Before you begin

1. Make sure the Python applications that you want to monitor have unique names. The Python data collector handles two different applications with the same name as one application, which might cause data display issues in the Cloud APM console.
2. Download the data collector package from IBM Passport Advantage website. For detailed instructions, see [“Download instructions” on page 131](#).
3. Configure the data collector package with the `make_configuration_packages.sh` and `configure_agent_images.sh` scripts on the system where the Cloud APM server is installed. For detailed instructions, see [“Configuring the downloaded images” on page 182](#).

### About this task

To configure the data collector, you first deploy a pypi package server, and then install the data collector to a Python Django application.

### Procedure

1. Extract files from the data collector package. The `python_datacollector_8.1.4.0.tgz` package is included in the extracted directory.
2. Extract the `python_datacollector_8.1.4.0.tgz` package, for example, by running the following command:

```
tar -zxvf python_datacollector_8.1.4.0.tgz
```

3. Find the `manifest.yml` file of the package server in the extracted directory and define the domain, host, and name in this file as is shown in the following example:

```
domain: mybluemix.net
name: pythondc
host: pythondc
```

**Remember:** The *host* and *name* values must be the same and unique.

4. From the `python_dc` directory, push the `pythondc` application to IBM Cloud by running the following command:

```
cf push
```

5. In the `requirements.txt` file of your Python application, add the following lines:

```
cryptography==1.9.0
--extra-index-url https://<your_host_name_and_domain>/python-dc-repos/simple/
ibm_python_dc
```

6. In the `settings.py` file of your Python application, add `ibm_python_dc.kpg_plugin.ResourceMiddleware` to the beginning of the `MIDDLEWARE_CLASSES` section, for example:

```
MIDDLEWARE_CLASSES = (
    "ibm_python_dc.kpg_plugin.ResourceMiddleware",
    "mezzanine.core.middleware.UpdateCacheMiddleware",
    'django.contrib.sessions.middleware.SessionMiddleware',
    'django.middleware.common.CommonMiddleware',
```

7. From the directory that contains the `manifest.yml` file of your Python application, run the following command:

```
cf push
```

**Tip:** For a sample `manifest.yml` file, see [“Sample manifest.yml file” on page 262](#).

## Results

The data collector is configured and is connected to the Cloud APM server.

## What to do next

You can verify the monitoring data for your IBM Cloud application is displayed in the Cloud APM console. For instructions on how to start the Cloud APM console, see [Starting the Cloud APM console](#). For information about using the Applications editor, see [Managing applications](#).

## Customizing the Python data collector for IBM Cloud applications

You can add environment variables in the IBM Cloud user interface (UI) to customize the monitoring for your IBM Cloud application. Use the following information to add the variables according to your needs.

### User-defined environment variables for the Python data collector

You can use the information in the following table to customize Python monitoring on IBM Cloud.

| Table 220. Supported user-defined environment variables for Python monitoring on IBM Cloud |            |   |  |
|--|------------|---|--|
| Variable name  | Importance | Value   | Description                                |
| APM_BM_GATEWAY_URL   | Optional   | <ul style="list-style-type: none"><li>https://&lt;server ip or hostname&gt;:443</li><li>http://&lt;server ip or hostname&gt;:80</li></ul> | The target on-premises server gateway URL. |

| Table 220. Supported user-defined environment variables for Python monitoring on IBM Cloud (continued) |            |   |  |
|--|------------|---|--|
| Variable name  | Importance | Value   | Description  |
| APM_KEYFILE_PSWD   | Optional   | Encrypted password of the key file                                      | <p>The encrypted key file password that is paired with the key file. If you are a Linux user, you can use the <code>echo -n &lt;keyfile password&gt;   base64</code> command to encrypt your password.</p> <p><b>Note:</b> Set this variable only when you configured the Gateway to use HTTPS.</p>  |
| APM_KEYFILE_URL  | Optional   | <code>http://&lt;hosted http server&gt;:&lt;port&gt;/keyfile.p12</code> | <p>The URL to download the key file.</p> <p><b>Note:</b> Set this variable only when you configured the Gateway to use HTTPS.</p>  |
| KPG_ENABLE_DEEPDIVE  | Optional   | <ul style="list-style-type: none"> <li>False</li> <li>True</li> </ul>   | <p>Enables or disables the collection of diagnostics data.</p> <ul style="list-style-type: none"> <li>True: The default value. If you set this variable to <code>True</code>, diagnostics data are collected.</li> <li>False: If you set this variable to <code>False</code>, diagnostics data are not collected.</li> </ul> <p>If you do not set this variable, diagnostics data are collected.</p>             |
| KPG_DD_CONFIG_FILE   | Optional   | File name of the diagnostics monitoring configuration file.             | <p>File name of the diagnostics monitoring configuration file. The default file name is <code>kpg_dd_config.xml</code>.</p> <p><b>Note:</b> After you customize the settings in this file, you must put it in the application root directory.</p> <p>If you do not set this variable, the default configuration file <code>kpg_dd_config.xml</code> in the data collector package is used.</p>                   |
| KPG_DD_APP_PATH  | Optional   | Path to the Python application.   | <p>The path to the Python application or the module for which the data collector collects diagnostics data. Separate the paths of different Python applications and modules that you want to monitor with a semi-colon ;.</p> <p>If you do not set this variable, the data collector collects data for requests and the modules that your application use. Data of requests in Python lib are not collected.</p> |

Table 220. Supported user-defined environment variables for Python monitoring on IBM Cloud (continued)

| Variable name          | Importance | Value  | Description  |
|------------------------|------------|--|--|
| KPG_DD_SECURITY_FILTER | Optional   | <ul style="list-style-type: none"> <li>• True</li> <li>• False</li> </ul>                  | <ul style="list-style-type: none"> <li>• True: The default value. If you set this variable to <code>True</code>, values (such as the passwords) are masked in SQL statements and parameters are not displayed in group widget <b>Request Context</b>.</li> <li>• False: If you set this variable to <code>False</code>, values in SQL statements are not masked and parameters are displayed in group widget <b>Request Context</b>.</li> </ul> <p>If you do not set this variable, values (such as the passwords) are masked in SQL statements and parameters are not displayed in group widget <b>Request Context</b>.</p> |
| KPG_GC_STATS           | Optional   | True   | <p>All statistical functions of python garbage collection are enabled. When you set this value to <code>True</code>, it equals running the following command:</p> <pre>gc.set_debug(gc.DEBUG_STATS   gc.DEBUG_COLLECTABLE   gc.DEBUG_UNCOLLECTABLE   gc.DEBUG_INSTANCES   gc.DEBUG_OBJECTS )</pre> <p>To disable KPG_GC_STATS, delete this environment variable. Do not set it to <code>False</code>.</p> <p><b>Note:</b> Never set <code>KPG_SAVE_ALL=True</code> in your formal production environment. It is only for the debug mode. Make sure that enough memory is assigned to the application.</p>                    |
| KPG_LOG_LEVEL          | Optional   | <ul style="list-style-type: none"> <li>• DEBUG</li> <li>• ERROR</li> <li>• INFO</li> </ul> | <ul style="list-style-type: none"> <li>• DEBUG: Only useful debug information is printed in the log, for example, collected data, data that are sent to server, and server response.</li> <li>• ERROR: Only information about exceptions and unexpected situations is printed in the log.</li> <li>• INFO: The summary information about the data collector for the user to know what it is doing is printed in the log.</li> </ul>  |

| Table 220. Supported user-defined environment variables for Python monitoring on IBM Cloud (continued) |            |  |  |
|--|------------|--|--|
| Variable name  | Importance | Value  | Description  |
| KPG_LOG_TOCONSOLE  | Optional   | <ul style="list-style-type: none"> <li>• y</li> <li>• True</li> <li>• Any other value that is not False</li> </ul> | The log is printed to console and you can see the log by running the command <b>cf logs &lt;appname&gt;</b> .  |
| KPG_SAVE_ALL   | Optional   | True   | <p>All unreferenced objects are saved into <code>gc.garbage</code>, and you need to clear <code>gc.garbage</code> every minute (the data collector clears it for you). When the value is set to <code>True</code>, it equals running the following command:</p> <pre>gc.set_debug(gc.SAVE_ALL)</pre> <p>To disable <code>KPG_SAVE_ALL</code>, delete this environment variable. Do not set it to <code>False</code>.</p> <p><b>Note:</b> Never set <code>KPG_SAVE_ALL=True</code> in your formal production environment. It is only for the debug mode. Make sure that enough memory is assigned to the application.</p> |

## Unconfiguring the Python data collector for IBM Cloud applications

If you do not need to monitor your Python environment or if you want to upgrade the Python data collector, you must first unconfigure previous settings for the Python data collector.

### Procedure

1. Go to the home directory of your Python application.
2. Remove the following lines from the `requirements.txt` file for the application:

```
--extra-index-url https://<your_host_name_and_domain>/python_dc/static/python-dc-repos/
simple/
ibm-python-dc
```

3. In the `settings.py` file, remove the following line from the `MIDDLEWARE_CLASSES` section:

```
ibm_python_dc.kpg_plugin.ResourceMiddleware
```

4. Run the following command to re-push the application for the changes to take effect:

```
cf push
```

### Results

You have successfully unconfigured the Python data collector.

### What to do next

After you unconfigure the data collector, the Cloud APM console continues to display the data collector in any applications that you added the data collector to. The Cloud APM console will show that no data is available for the application and will not indicate that the data collector is offline. For information about

how to remove the data collector from applications and from resource groups, see [“Removing data collectors from Cloud APM console” on page 262](#).

## Configuring the Python data collector for on-premises applications

To collect information about Python applications that run in your local environment, you must configure the Python data collector.

### Before you begin

1. Make sure the Python applications that you want to monitor have unique names. The Python data collector handles two different applications with the same name as one application, which might cause data display issues in the Cloud APM console.
2. Download the data collector package from IBM Passport Advantage website. For detailed instructions, see [“Download instructions” on page 131](#).
3. Configure the data collector package with the `make_configuration_packages.sh` and `configure_agent_images.sh` scripts on the system where the Cloud APM server is installed. For detailed instructions, see [“Configuring the downloaded images” on page 182](#).

### About this task

The following procedure configures the data collector within your Python application with default settings. To customize data collector configuration, use the environment variables in the data collector configuration files. For more information, see [“Customizing the Python data collector for on-premises applications” on page 771](#).

### Procedure

1. Extract files from the data collector package. The `python_datacollector_8.1.4.0.tgz` package is included in the extracted directory.
2. Extract files from the data collector package, for example, by running the following command:

```
tar -zxvf python_datacollector_8.1.4.0.tgz
```

3. From the `python_dc` directory, run the following command:

```
python server.py
```

4. Run the following command:

```
pip install ibm_python_dc --extra-index-url http://host name or ip:8000/  
python-dc-repos/simple/ --trusted-host host name or ip
```

where *host name or ip* is the name or IP address of the host to run your Python data collector repository.

**Important:** Use either the name or the IP address to specify the host for both the URL and the trusted host in this command. For example, if you specify the host by using the IP address and the IP address is 9.42.36.180, the command is as follows:

```
pip install ibm_python_dc --extra-index-url http://9.42.36.180:8000/  
python-dc-repos/simple/ --trusted-host 9.42.36.180
```

5. In the `settings.py` file of your Python application, add `ibm_python_dc.kpg_plugin.ResourceMiddleware` to the `MIDDLEWARE_CLASSES` section to the format of the following example:

```
MIDDLEWARE_CLASSES = (  
    "ibm_python_dc.kpg_plugin.ResourceMiddleware",  
    "mezzanine.core.middleware.UpdateCacheMiddleware",  
)
```

```
'django.contrib.sessions.middleware.SessionMiddleware',  
'django.middleware.common.CommonMiddleware',
```

## Results

The data collector is configured with default settings and connected to the Cloud APM server.

## What to do next

You can now log in to the Cloud APM server to view the monitoring data.

**Remember:** After you add your Python application to the Cloud APM console, you can view its monitoring data in the component named Python Runtime application.

For instructions on how to start the Cloud APM server, see [Starting the Cloud APM console](#). For information about using the Applications editor, see [Managing applications](#).

## Customizing the Python data collector for on-premises applications

By modifying files in the data collector package, you can set the environment variables to customize the monitoring for your Python application.

Two files are provided to customize data collector settings, `global.environment` and `config.properties`. After you change the settings in these files, restart the Python application for the change to take effect.

By modifying the `global.environment` file, you can customize the connection between the data collector and the Cloud APM server. If you want to use another Cloud APM server instead of the default one, or the key file or its password is changed, modify the Cloud APM server to reconnect the data collector to the Cloud APM server.

By modifying the `config.properties` file, you can customize data collector behaviors according to your needs, such as enabling or disabling method trace.

## The `global.environment` configuration file

Table 221 on page 771 shows the environment variables that you can set in the `global.environment` configuration file and the correlated descriptions. You can find the `global.environment` file in the `etc` folder where your Python data collector is installed, for example, `/root/.pyenv/versions/3.5.2/lib/python3.5/site-packages/ibm_python_dc/etc` directory.

| Table 221. Supported environment variables in the <code>global.environment</code> file |            |   |  |
|--|------------|---|--|
| Variable name  | Importance | Value   | Description  |
| APM_BM_GATEWAY_URL   | Optional   | <ul style="list-style-type: none"><li>https://&lt;server ip or hostname&gt;:443</li><li>http://&lt;server ip or hostname&gt;:80</li></ul> | The target on-premises server gateway URL.   |
| APM_KEYFILE_PSWD   | Optional   | Password of the key file  | The key file password that is paired with the key file.<br><b>Note:</b> Set this variable only when you configured the Gateway to use HTTPS. |
| APM_KEYFILE_URL  | Optional   | http://<hosted http server>:<port>/keyfile.p12  | The URL to download the key file.<br><b>Note:</b> Set this variable only when you configured the Gateway to use HTTPS.                       |

## The config.properties file

Table 222 on page 772 shows the environment variables you can set in the config.properties configuration files and the correlated description. You can find the config.properties file in the installation directory of your Python data collector, for example, /root/.pyenv/versions/3.5.2/lib/python3.5/site-packages/ibm\_python\_dc directory.

| Table 222. Supported environment variables in the config.properties file |            |  |  |
|--|------------|--|--|
| Variable name  | Importance | Value  | Description  |
| KPG_ENABLE_DEEPDIVE  | Optional   | <ul style="list-style-type: none"><li>False</li><li>True</li></ul> | <ul style="list-style-type: none"><li>False: The default value. If you set this variable to False, diagnostics data will not be collected.</li><li>True: If you set this variable to True, diagnostics data will be collected.</li></ul> <p>The default level is True.</p> <p>If you do not set this variable, diagnostics data will not be collected.</p>   |
| KPG_DD_CONFIG_FILE   | Optional   | File name of the diagnostics monitoring configuration file.        | <p>File name of the diagnostics monitoring configuration file. The default file name is kpg_dd_config.xml.</p> <p><b>Note:</b> After you customize the settings in this file, you must put it in the application root directory.</p> <p>If you do not set this variable, the default configuration file kpg_dd_config.xml in the data collector package will be used.</p>  |
| KPG_DD_APP_PATH  | Optional   | Path to the Python application.                                    | <p>The path to the Python application or the module for which the data collector collects diagnostics data. Separate the paths of different Python applications and modules that you want to monitor with a semi-colon ;.</p> <p>If you do not set this variable, the data collector will collect diagnostics data for requests and the modules that your application use. Data of requests in Python lib will not be collected.</p> |

Table 222. Supported environment variables in the `config.properties` file (continued)

| Variable name          | Importance | Value  | Description  |
|------------------------|------------|--|--|
| KPG_DD_SECURITY_FILTER | Optional   | <ul style="list-style-type: none"> <li>• True</li> <li>• False</li> </ul>                  | <ul style="list-style-type: none"> <li>• True: The default value. If you set this variable to <code>True</code>, values (such as the passwords) will be masked in SQL statements and parameters will not be displayed in group widget <b>Request Context</b>.</li> <li>• False: If you set this variable to <code>False</code>, values in SQL statements will not be masked and parameters will be displayed in group widget <b>Request Context</b>.</li> </ul> <p>If you do not set this variable, values (such as the passwords) will be masked in SQL statements and parameters will not be displayed in group widget <b>Request Context</b>.</p> |
| KPG_GC_STATS           | Optional   | True   | <p>All statistical functions of python garbage collection are enabled. When you set this value to <code>True</code>, it equals running the following command:</p> <pre>gc.set_debug(gc.DEBUG_STATS   gc.DEBUG_COLLECTABLE   gc.DEBUG_UNCOLLECTABLE   gc.DEBUG_INSTANCES   gc.DEBUG_OBJECTS )</pre> <p>To disable KPG_GC_STATS, delete this environment variable. Do not set it to <code>False</code>.</p> <p>The default value is <code>True</code>.</p> <p><b>Note:</b> Never set KPG_GC_STATS=<code>True</code> in your formal product environment. It is only for the debug mode. And make sure enough memory is assigned to the application.</p> |
| KPG_LOG_LEVEL          | Optional   | <ul style="list-style-type: none"> <li>• DEBUG</li> <li>• ERROR</li> <li>• INFO</li> </ul> | <ul style="list-style-type: none"> <li>• DEBUG: Only useful debug information will be printed in the log, for example, collected data, data that is sent to server, and server response.</li> <li>• ERROR: Only information about exceptions and very unexpected situations will be printed in the log.</li> <li>• INFO: The summary information about the data collector for the user to know what it is doing will be printed in the log.</li> </ul> <p>The default value is <code>ERROR</code>.</p>   |

| Table 222. Supported environment variables in the <code>config.properties</code> file (continued) |            |  |   |
|---|------------|--|---|
| Variable name   | Importance | Value  | Description   |
| KPG_LOG_TOCONSOLE   | Optional   | <ul style="list-style-type: none"> <li>Y</li> <li>True</li> <li>Any other value that is not False</li> </ul> | <p>The log will be printed to console and you can see the log by running the command <b>cf logs &lt;appname&gt;</b>.</p> <p>The default value is True.</p>  |
| KPG_SAVE_ALL  | Optional   | True   | <p>All unreferenced objects will be saved into <code>gc.garbage</code>, and you need to clear <code>gc.garbage</code> every minute (the data collector does this for you). When the value is set to True, it equals running the following command:</p> <pre>gc.set_debug(gc.SAVE_ALL)</pre> <p>To disable KPG_SAVE_ALL, delete this environment variable. Do not set it to False.</p> <p>The default value is True.</p> <p><b>Note:</b></p> <p>Never set KPG_SAVE_ALL=True in your formal product environment. It is only for the Debug mode. And make sure enough memory is assigned to the application.</p> |
| APM_GW_PROXY_CONNECTION   | Optional   | <code>http://&lt;server ip or hostname&gt;:port</code>   | The HTTP or HTTPS proxy that the Python data collector uses to send monitoring data.  |

## Unconfiguring the Python data collector for on-premises applications

If you do not need to monitor your Python environment or if you want to upgrade the Python data collector, you must first unconfigure previous settings for the Python data collector.

### Procedure

1. Go to the home directory of your Python application.
2. Remove the following lines from the `requirements.txt` file for the application:

```
--extra-index-url https://<your_host_name_and_domain>/python_dc/static/python-dc-repos/
simple/
ibm-python-dc
```

3. In the `settings.py` file, remove the following line from the `MIDDLEWARE_CLASSES` section:

```
ibm_python_dc.kpg_plugin.ResourceMiddleware
```

4. Run the `pip uninstall ibm_python_dc` command to uninstall the Python data collector from the Python run time.

### Results

You have successfully unconfigured the Python data collector.

## What to do next

After you unconfigure the data collector, the Cloud APM console continues to display the data collector in any applications that you added the data collector to. The Cloud APM console will show that no data is available for the application and will not indicate that the data collector is offline. For information about how to remove the data collector from applications and from resource groups, see [“Removing data collectors from Cloud APM console”](#) on page 262.

## Configuring RabbitMQ monitoring

---

The Monitoring Agent for RabbitMQ monitors the health and performance of the RabbitMQ cluster resources, such as the nodes, queues, and channels of the cluster. You must configure the RabbitMQ agent so that the agent can collect the RabbitMQ data.

### Before you begin

- Review the hardware and software prerequisites.
- Ensure that the RabbitMQ user, who connects to the node, has read permission and either the monitoring, administrator, or management tag is enabled for this user.
- If the agent is configured to use HTTPS protocol for monitoring, ensure following prerequisites are met:
  - Ensure that the RabbitMQ management plug-in is enabled on all nodes of the cluster, because if one node of the cluster fails, the RabbitMQ agent connects to a peer node that is available in the cluster.
  - Ensure that user has a CA certificate issued by a trusted vendor and a server certificate signed using this CA.
  - Ensure that user has truststore, in jks format, containing the CA certificate. Path to this truststore must be provided during agent configuration.
  - Ensure that the management plug-in is configured to use SSL. To configure, provide a port that is configured to use SSL, an accessible path, preferably local, to the CA certificate, a server certificate and a private key for the server certificate.

Review hardware and software prerequisites. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\)](#) for the RabbitMQ agent.

### About this task

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

The RabbitMQ agent is a multiple instance agent. You must create the first instance, and start the agent manually.

- To configure the agent on Windows systems, you can use the IBM Cloud Application Performance Management window or the silent response file.
- To configure the agent on Linux systems, you can run the script and respond to prompts, or use the silent response file.

## Configuring the agent on Windows systems

You can use the IBM Cloud Application Performance Management window to configure the agent on Windows systems.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.

2. In the **IBM Performance Management** window, right-click **Monitoring Agent for RabbitMQ**, and then click **Configure agent**.

**Remember:** After you configure the agent for the first time, the **Configure agent** option is disabled. To configure the agent again, click **Reconfigure**.

3. In the **Enter a unique instance name** field, type the agent instance name and click **OK**.
4. In the **Monitoring Agent for RabbitMQ** window, specify values for the configuration parameters, and then click **Next**.

For information about the configuration parameters, see the following topic: [“Configuration parameters for the agent” on page 777](#)

5. Right-click the **Monitoring Agent for RabbitMQ** instance, and click **Start**.

## What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent on Linux systems

To configure the agent on Linux operating systems, you must run the script and respond to prompts.

### Procedure

1. On the command line, enter the following command: `install_dir/bin/rabbitmq.sh config instance_name` where `instance_name` is the name that you want to give to the instance:
2. When you are prompted to provide a value for the following parameters, press Enter to accept the default value, or specify a value and then press Enter:
  - IP Address
  - User Name
  - Password
  - Port Number
  - Java home
  - Java trace level

For information about the configuration parameters, see the following topic: [“Configuration parameters for the agent” on page 777](#)

3. Run the following command to start the agent:

```
install_dir/bin/rabbitmq.sh start instance_name
```

## What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

You can use the silent response file to configure the RabbitMQ agent on Linux and Windows systems. After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

1. Open the silent response file that is available at this path:  
`install_dir\samples\rabbitmq_silent_config.txt`
2. In the `rabbitmq_silent_config.txt` file, specify values for all mandatory parameters. You can also modify the default values of other parameters.

For information about the configuration parameters, see the following topic: [“Configuration parameters for the agent” on page 777](#)

3. Save the response file, and run the following command:

```
Linux | UNIX | install_dir/bin/rabbitmq-agent.sh config install_dir/samples/rabbitmq_silent_config.txt
Windows | install_dir/bin/rabbitmq-agent.bat config install_dir/samples/rabbitmq_silent_config.txt
```

4. Start the agent:

```
Linux | UNIX | Run the following command: install_dir\bin\rabbitmq-agent.sh start
Windows | Right-click Monitoring Agent for RabbitMQ and then click Start.
```

### What to do next

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuration parameters for the agent

When you configure the RabbitMQ agent, you can change the default values of the parameters, such as the instance name and the SSL validation certificates.

The following table contains detailed descriptions of the configuration parameters for the RabbitMQ agent.

| Table 223. Names and descriptions of the configuration parameters for the RabbitMQ agent |   |                 |
|--|---|-----------------|
| Parameter name   | Description   | Mandatory field |
| IP Address   | The IP address of the node where the RabbitMQ application is installed. | Yes             |
| Username   | The user name of the RabbitMQ user.                                     | Yes             |
| Password   | The password to connect to the RabbitMQ management user interface.      | Yes             |
| Confirm Password   | The same password that you entered in the <b>Password</b> field.        | Yes             |

Table 223. Names and descriptions of the configuration parameters for the RabbitMQ agent (continued)

| Parameter name     | Description   | Mandatory field |
|--------------------|---|-----------------|
| Port Number        | The port number where the RabbitMQ management plugin is enabled. Use the default port number 15672, or specify another port number.   | No              |
| Java home          | The path where the java plugin is installed. Use the default path C:\Program Files\IBM\Java50, or the directory path where java plugin is installed.  | No              |
| Java trace level   | The trace level of the Java provider. The valid trace level values are as follows: <ul style="list-style-type: none"> <li>• OFF</li> <li>• ERROR</li> <li>• WARN</li> <li>• INFO</li> <li>• DEBUG_MAX</li> <li>• ALL</li> </ul> | No              |
| Path to Truststore | The path to the truststore that is in the jks format and that contains the trusted CA certificate.  | No              |
| Protocol           | The protocol that is used to create the connection.   | No              |

## Configuring Response Time Monitoring

The Response Time Monitoring agent monitors HTTP and HTTPS transactions on your HTTP server. Real browser-based user transactions (browser timings) are also monitored.

The Response Time Monitoring agent can be used to view the following levels of monitoring information:

### HTTP and HTTPS Transaction Monitoring

HTTP transaction monitoring is automatically available when you install the Response Time Monitoring agent.

Depending on the type of HTTP server you are monitoring, HTTPS transaction monitoring might be automatically available or it might need to be manually configured. For more information, see [“Response Time Monitoring Components” on page 779](#).

The Response Time Monitoring also monitors data relating to user counts, session counts, and devices.

Data is presented in the End User Transactions dashboard in the local time of the user and also used in the Requests and Response Time widget.

### Real End user Transaction Monitoring (Browser timings)

Depending on the type of HTTP server you are monitoring, browser based timings might be automatically available or might need to be configured. For more information, see [“Response Time Monitoring Components” on page 779](#).

Browser based timings are made possible with JavaScript Injection.

With JavaScript Injection, you can see further widgets and detail within the End User Transaction dashboards. JavaScript Injection ensures that the real end-user response time is collected from within the browser. It monitors the performance of HTTP pages and embedded objects for web pages that are served by the HTTP Server. The following additional real end-user transaction details are available:

- Client Total Time in the Transaction Requests and Response Time widget

- Response Time for Client Time transactions in the Transactions - Top 10 widget
- Render Time Breakdown

For information on how to configure JavaScript injection, see [“JavaScript Injection” on page 782](#)

## Viewing transaction dashboards

View transaction data in the Application Performance Dashboard.

A number of widgets are available in the Application Performance Dashboard that give contextual detail about transactions.

*Good requests* have a response time less than 10 seconds. *Slow requests* have a response time greater than 10 seconds. The 10 second value used to determine good vs slow response time is not configurable. The following widgets are available:

- Worst by User - Top 5 group widget
- Worst by Device - Top 5 group widget
- Requests and Response Time group widget
- Transactions - Top 10 group widget
- Transaction Requests and Response Time group widget
- Runs On group widget
- Subtransactions group widget
- Transaction Instances group widget
- Users by Location group widget
- Users at Selected Location group widget
- User Sessions at Selected Location - Top 10 group widget
- User Request and Response Time group widget
- User Sessions - Top 10 group widget
- Device Request and Response Time group widget
- Session group widget
- Session Requests group widget
- Session Instances group widget
- Transaction Instances group widget
- Middleware Transactions Summary dashboard
- Middleware Transactions Details dashboard

**Note:** This dashboard only shows instance details from the last 4 hours by default. If you want to see middleware transaction instance details from more than 4 hours ago and then you must configure the Cloud APM server to retain middleware transaction data for more than 4 hours. For more information, see [“Retaining middleware transactions” on page 1220](#).

- Event thresholds for Transaction Monitoring
- Interaction Aggregate Data
- Transactions Aggregate Data
- WRT Transaction Status

## Response Time Monitoring Components

The base functionality of the Response Time Monitoring agent is:

- HTTP transaction monitoring

- HTTPS transaction monitoring
- Browser-based timings (by using JavaScript Injection) monitoring

To see more detailed descriptions of this functionality, see [“Configuring Response Time Monitoring” on page 778](#).

Depending on the type of HTTP Server you are monitoring, the base functionality of the Response Time Monitoring agent is provided by using one of the following components:

#### **IBM HTTP Server Response Time module**

The IBM HTTP Server Response Time module can monitor only http content type of: text/html, application/xml or application/json. (without Javascript Injection)

The IBM HTTP Server Response Time module can currently not monitor javascript instrument compressed requests.

The IBM HTTP Server Response Time module Javascript Injection can currently monitor only http content type of text/html.

#### **Packet Analyzer**

The Packet Analyzer can only monitor content type of text/html. The Packet Analyzer can monitor gzip compressed requests.

If you are monitoring an IBM HTTP Server or Apache HTTP Server on AIX or Linux, use the IBM HTTP Server Response Time module. It is possible but not recommended to use the Packet Analyzer. IBM HTTP Server Response Time module is not supported on Windows. Use Packet Analyzer in a Windows environment.

If you are monitoring any other HTTP server, use Packet Analyzer. The Packet Analyzer is supported on Window, Linux, and AIX.

## **Planning the installation**

Plan your Response Time Monitoring agent installation based on your operating system and type of HTTP server.

The base functionality of the Response Time Monitoring can be provided by using one of the following components:

- Packet Analyzer
- IBM HTTP Server Response Time module

You determine which component to use based on:

- The type of HTTP server you are installing the Response Time Monitoring agent on.
- Which operating system the HTTP server is installed on.

The considerations for installing the Response Time Monitoring agent with Packet Analyzer are:

- Packet Analyzer is supported on all operating systems (Windows, Linux, and AIX).
- Packet Analyzer monitors HTTP transactions on port 80 for all operating systems.
- HTTPS transaction monitoring is not automatic, and must be configured manually. The Response Time Monitoring agent requires access to the SSL Certificates so that it can decrypt SSL traffic from HTTP servers. For more information, see [“Monitoring HTTPS transactions” on page 799](#).
- Packet Analyzer is supported on all HTTP servers but it is only recommend for Sun Java System Web Server and Microsoft Internet Information Services.
-    To install the Response Time Monitoring agent to work with Packet Analyzer on IBM HTTP Server or Apache HTTP Server, the HTTP server must be stopped. When you install the Response Time Monitoring agent and the HTTP server is stopped Packet Analyzer is automatically enabled.
-    Although Packet Analyzer can be configured for IBM HTTP Server or Apache HTTP Server, it is not recommended; IBM HTTP Server Response Time module is recommended.

- **Windows** WinPcap 4.1.3 is required before you install the Response Time Monitoring agent.
- **Windows** **AIX** **Linux** If you install the Response Time Monitoring agent on Sun Java System Web Server or Microsoft Internet Information Services, Packet Analyzer is automatically configured.

The considerations for installing the Response Time Monitoring agent with IBM HTTP Server Response Time module are:

- The IBM HTTP Server Response Time module is a component of the HTTP Server agent. You must install the HTTP Server agent either before the Response Time Monitoring agent or else install at the same time. For more information, see [“IBM HTTP Server Response Time module” on page 788](#).
- IBM HTTP Server Response Time module is supported on all operating systems (Windows, Linux, and AIX). IBM HTTP Server Response Time module supports IBM HTTP Server version 7, 8, and 9.
- Install the Response Time Monitoring agent and the HTTP Server agent on the same machine.
- IBM HTTP Server Response Time module monitors all ports for HTTP and HTTPS request on AIX, Linux, and Windows.
- IBM HTTP Server Response Time module is only supported for IBM HTTP Server or Apache HTTP Server.
- Both agents are automatically started but you must restart the HTTP server.

The following table describes the different combinations for automatically configuring the Response Time Monitoring agent.

| <i>Table 224. Scenarios for automatically configuring the Response Time Monitoring agent</i> |                                      |  |
|--|--------------------------------------|--|
| <b>HTTP server and OS combinations</b>   | <b>Packet Analyzer</b>               | <b>IBM HTTP Server Response Time module</b>        |
| Sun Java System Web Server or Microsoft Internet Information Services on AIX or Linux        | Automatic                            | Not supported                                      |
| Sun Java System Web Server or Microsoft Internet Information Services on Windows             | Automatic                            | Not supported                                      |
| IBM HTTP Server or Apache HTTP Server on AIX, Linux, or Windows                              | Automatic if HTTP server is stopped. | Automatic if HTTP server is present and configured |

## Planning the configuration

HTTP Monitoring is automatically enabled when you install the Response Time Monitoring agent. Depending on your environment, HTTPS and JavaScript Injection might need to be manually configured.

### HTTP Monitoring

HTTP transaction monitoring is configured automatically for Packet Analyzer and IBM HTTP Server Response Time module, if you follow the installation guidelines. See [“Planning the installation ” on page 780](#).

### HTTPS Monitoring

HTTPS transaction monitoring is configured automatically for IBM HTTP Server Response Time module if you follow the installation guidelines. See [“Planning the installation ” on page 780](#).

HTTPS transaction monitoring needs to be manually configured for Packet Analyzer. For more information, see [“ Packet Analyzer roadmap” on page 797](#).

### Browser-based timings (using JavaScript Injection)

Browser-based timings (using JavaScript Injection) are configured automatically for IBM HTTP Server Response Time module.

Browser-based timings (using JavaScript Injection) needs to be manually configured for Packet Analyzer. For more information, see [“Packet Analyzer roadmap” on page 797](#).

The following table describes how the base functionality is configured for each component:

| <i>Table 225. Base functionality configuration</i>                                      |  |   |
|---|--|---|
|   | <b>Packet Analyzer on Sun Java System Web Server or Microsoft Internet Information Services (Windows, Linux, or AIX)</b> | <b>IBM HTTP Server Response Time module on IBM HTTP Server or Apache HTTP Server (Windows, Linux, or AIX)</b> |
| HTTP transaction monitoring   | Enabled automatically.   | Enabled automatically   |
| HTTPS transaction monitoring  | Must be manually configured.   | Enabled automatically   |
| Real end user transaction monitoring (Browser Timings) using JavaScript Instrumentation | Must be manually configured.   | Enabled automatically   |

## JavaScript Injection

You can customize the data that is collected by the Response Time Monitoring agent for display in the End User Transactions dashboards.

To ensure a good user experience for a web-based application, you must monitor the performance that is perceived by the actual users. This means monitoring at the browser level.

To be able to monitor at the browser level, you need to inject JavaScript Monitoring Code into the pages that you want to monitor. This code then collects data for particular browser timings.

This is done using JavaScript Injection in the web pages and objects that you want to monitor. Depending on the type of HTTP server that you installed your Response Time Monitoring agent on, there are two methods you can use to collect real end-user transaction response time information.

- If you are using an IBM HTTP Server or an Apache HTTP server, use IBM HTTP Server Response Time module. The IBM HTTP Server Response Time module automatically does JavaScript Injection. The IBM HTTP Server Response Time module is a component of the HTTP Server agent. It is installed and configured as part of the HTTP Server agent. For more information, see [“IBM HTTP Server Response Time module” on page 788](#).
- If you are using any other supported HTTP server, use Packet Analyzer. With Packet Analyzer, you must manually instrument your web pages to collect browser timings. For more information, see [“Adding the JavaScript monitoring component to your application” on page 797](#).

The following table shows the features that are available in the Application Performance Dashboard if you configure your environment for Packet Analyzer or IBM HTTP Server Response Time module:

|                       | <b>Packet Analyzer</b> | <b>IBM HTTP Server Response Time module</b> |
|-----------------------|------------------------|---|
| Transactions Top 10   | ✓                      | ✓   |
| Server Time           | ✓                      | ✓   |
| Render Time Breakdown | —                      | ✓   |
| AJAX Subtransactions  | ✓                      | ✓   |

|   | Packet Analyzer | IBM HTTP Server Response Time module |
|---|-----------------|--------------------------------------|
| Resource Timing data in Subtransactions table     | —               | ✓                                    |
| Transaction Instances (Top 10)                    | ✓               | ✓                                    |
| Transaction Instance Topology                     | ✓               | ✓                                    |
| Application Topology                              | ✓               | ✓                                    |
| Automatic instrumentation of JavaScript Injection | N/A             | ✓                                    |

## Reconfiguring the Response Time Monitoring on Windows

Use the `rt-agent` interactive configuration command or IBM Cloud Application Performance Management utility to configure or reconfigure the agent.

### Before you begin

If you are enabling HTTPS transaction monitoring, make sure that the Monitoring Agent for HTTP Server is not installed on the same machine. Otherwise the Response Time Monitoring configuration does not change the HTTPS setting for Packet Analyzer.

### About this task

The Response Time Monitoring agent is configured automatically following installation. Follow the installation guidelines: [“Planning the installation” on page 780](#). You might need to reconfigure, for example, if you want to monitor a different port or monitor HTTPS transactions.

The installation directory is referred to as *install\_dir*. The default installation directory is: C:\IBM\APM\

As an alternative to using the `rt-agent` interactive configuration command, you can configure the agent in the IBM Cloud Application Performance Management utility. For more information, see [“Using the IBM Cloud Application Performance Management window on Windows systems” on page 242](#).

### Procedure

To customize your data settings, complete the following steps:

1. On the computer where the Response Time Monitoring agent is installed, stop the agent:  
`install_dir\BIN\rt-agent.bat stop`
2. Use silent configuration to configure the agent:

```
install_dir\BIN\rt-agent.bat config install_dir\samples\rt_silent_config.txt
```

If you want to enable HTTPS transaction monitoring, uncomment the following lines in the silent configuration file. The sample of `rt_silent_config.txt` to configure the Response Time Monitoring agent to monitor HTTPS on Windows should look like this:

```
# Monitor HTTPS transactions
KT5MONITORHTTPSAPP=YES

# HTTPS keystore (e.g. - /tmp/keys.kdb)
KT5KEYSTORE=C:\keys\key.kdb

# HTTPS server certificate map (eg - certAlias,9.48.152.1,443;...)
KT5SERVERMAP=certalias,9.48.152.1,443

# Monitor network traffic for the NIC hosts this IP address
#KT5MONITORIP=9.48.152.1
```

3. Restart the Response Time Monitoring agent for the changes to take effect:

```
install_dir\BIN\rt-agent.bat start
```

## Results

Data from the new source is displayed in the dashboards that are associated with Response Time Monitoring.

## Reconfiguring the Response Time Monitoring on AIX and Linux

Use the `rt-agent` configuration command to configure or reconfigure the Response Time Monitoring agent.

### About this task

The Response Time Monitoring agent is configured automatically following installation. Follow the installation guidelines: [“Planning the installation” on page 780](#). You might need to reconfigure, for example, if you want to monitor a different port.

The installation directory is referred to as *install\_dir*. The default installation directory is: `/opt/ibm/apm/agent`.

Use the same root user that you used to install the agent to start, stop, and configure the agent.

### Procedure

To reconfigure, complete the following steps:

1. On the computer on which the Response Time Monitoring agent is installed, stop the agent:

```
install_dir/bin/rt-agent.sh stop
```

2. Use either interactive or silent configuration:

- a) Interactive configuration:

```
install_dir/bin/rt-agent.sh config
```

- b) Silent configuration:

```
install_dir/bin/rt-agent.sh config install_dir/samples/rt_silent_config.txt
```

If you want to enable HTTPS transaction monitoring, uncomment the following lines in the silent configuration file. The sample of `rt_silent_config.txt` to configure the Response Time Monitoring agent to monitor HTTPS on AIX and Linux should look like this:

```
# Monitor HTTPS transactions
KT5MONITORHTTPSAPP=YES

# HTTPS keystore (e.g. - /tmp/keys.kdb)
KT5KEYSTORE=/tmp/keys.kdb

# HTTPS server certificate map (eg - certAlias,9.48.152.1,443;...)
KT5SERVERMAP=certalias,9.48.152.1,443

# Monitor network traffic for the NIC hosts this IP address
#KT5MONITORIP=9.48.152.1
```

3. Restart the Response Time Monitoring agent for the changes to take effect:

```
install_dir/bin/rt-agent.sh start
```

## Results

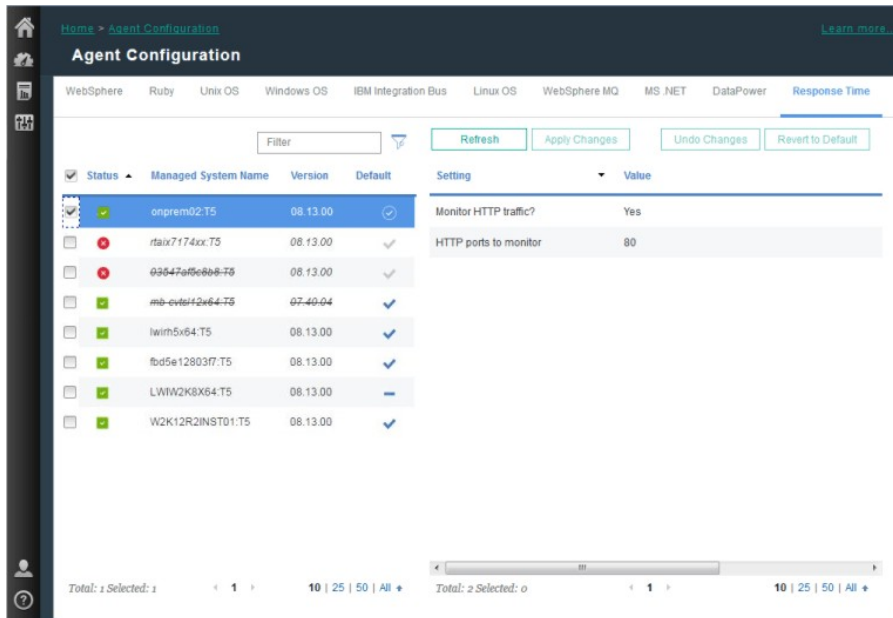

Data from the new source is displayed in the dashboards that are associated with Response Time Monitoring.

## Configuring using the Agent Configuration Page

You can use the **Agent Configuration** page in the Cloud APM console to see what agents are installed. Where applicable, you can disable or enable HTTP transaction monitoring and set the ports that are monitored by Response Time Monitoring agents.

### Agent Configuration

To access the Response Time Monitoring **Agent Configuration** page, in the Cloud APM console, select **System Configuration > Agent Configuration**, then select the **Response Time** tab.

The **Agent Configuration** page lists the systems in your environment on which Response Time Monitoring is installed.

For each system with a Response Time Monitoring agent installed, the **Agent Configuration** page shows:

- Whether the system is online (check mark with green background) or offline (cross with red background).
- The version of the Response Time Monitoring agent that is installed.
- If central configuration cannot determine the type of the agent (that is, whether the Packet Analyzer or IBM HTTP Server Response Time module is being used to monitor HTTP transactions), only the agent is struck through. Generally, the type of agent can't be determined where the agent is not sending agent details through ASF activity.
- Whether the system uses the default configuration values or has some custom values set.
- The ports that are monitored if the Response Time Monitoring agent is using the Packet Analyzer to monitor HTTP transactions.

| Setting               | Value |
|-----------------------|-------|
| Monitor HTTP traffic? | Yes   |
| HTTP ports to monitor | 80    |

- Whether IBM HTTP Server Response Time module, together with HTTP Server agent, is being used to monitor HTTP transactions.

| Setting  | Value |
|--|-------|
| Is IBM HTTP Server Response Time module enabled? | Yes   |

**Tip:** IBM HTTP Server Response Time module monitors HTTP and HTTPS transactions automatically. No further configuration of the Response Time Monitoring agent is required.

Select an agent to display its configuration settings. To find a particular agent, enter part or all of the name of the system on which it is installed in the **Filter** field.

Customizations that are made on the **Agent Configuration** page take precedence over any other customization and over default values.

If you change your mind about the settings you changed, click **Undo Changes** to revert to the last settings that were saved, or click **Revert to Default** to revert to the default values.

The new configuration values are sent to Central Configuration Services and online agents are then automatically reconfigured without having to be restarted. If the agent is offline, it downloads the new configuration settings when it comes online. Data from the new ports is displayed in the dashboards that are associated with Response Time Monitoring when the data is refreshed.

## Adding Applications

After you install the Response Time Monitoring agent, you might need to add the applications that you want to monitor to the Application Performance Dashboard.

### Procedure

To add applications to the Application Performance Dashboard:

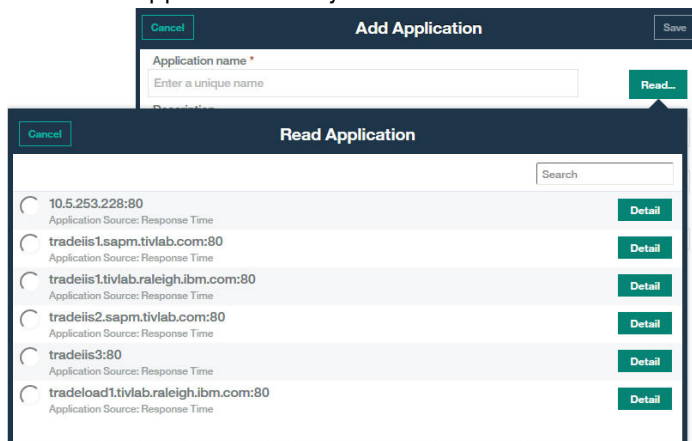

1. In the Application Performance Dashboard, click **Add Application**.

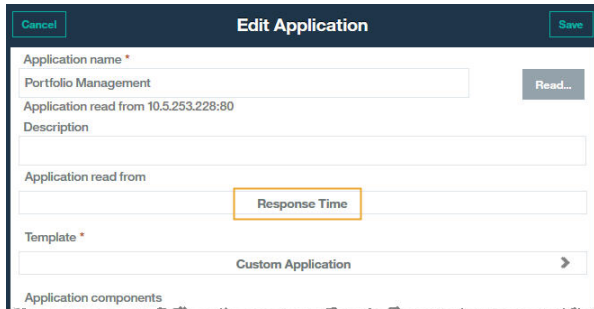

2. Select **Read** to open a list of discovered applications.

3. Select the application that you want to monitor.

**Response Time** is displayed as the source repository in the **Application read from** field, and any components are listed in **Application components**.

4. No further configuration is needed to display applications that are monitored by the Response Time Monitoring agent in the Application Performance Dashboard. Click **Save** in the **Add Application** window.

## Results

Applications that are detected by the Response Time Monitoring agent are listed in **All My Applications** in the Application Performance Dashboard.

## Configuring the IBM HTTP Server Response Time module

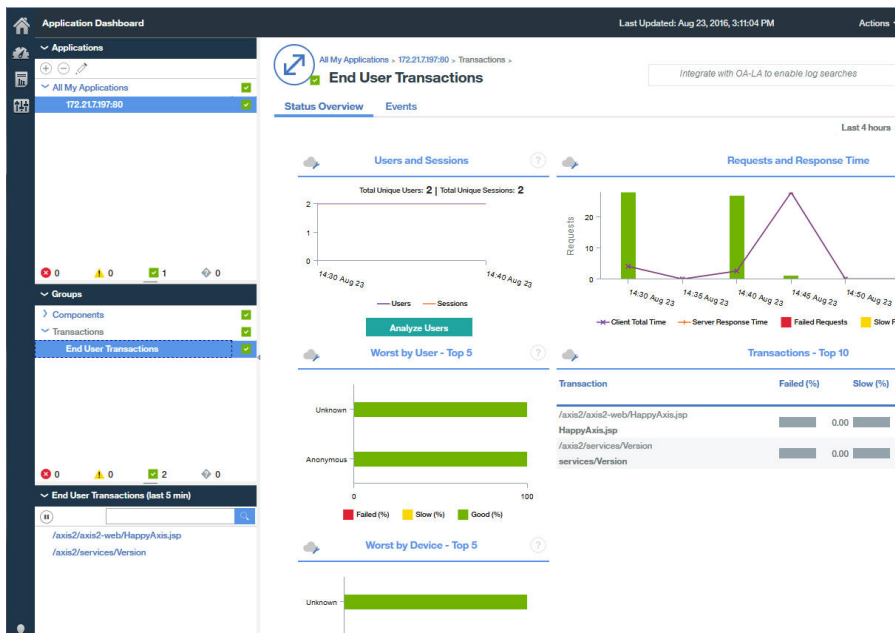

For IBM HTTP Server and Apache HTTP Server, use the IBM HTTP Server Response Time module to view real-end user response time monitoring metrics for HTTP pages.

The IBM HTTP Server Response Time module is installed and configured as part of the HTTP Server agent. The IBM HTTP Server Response Time module only works in conjunction with IBM HTTP Server and Apache HTTP Server on AIX, Linux, and Windows. The IBM HTTP Server Response Time module monitors all ports for HTTP and HTTPS requests.

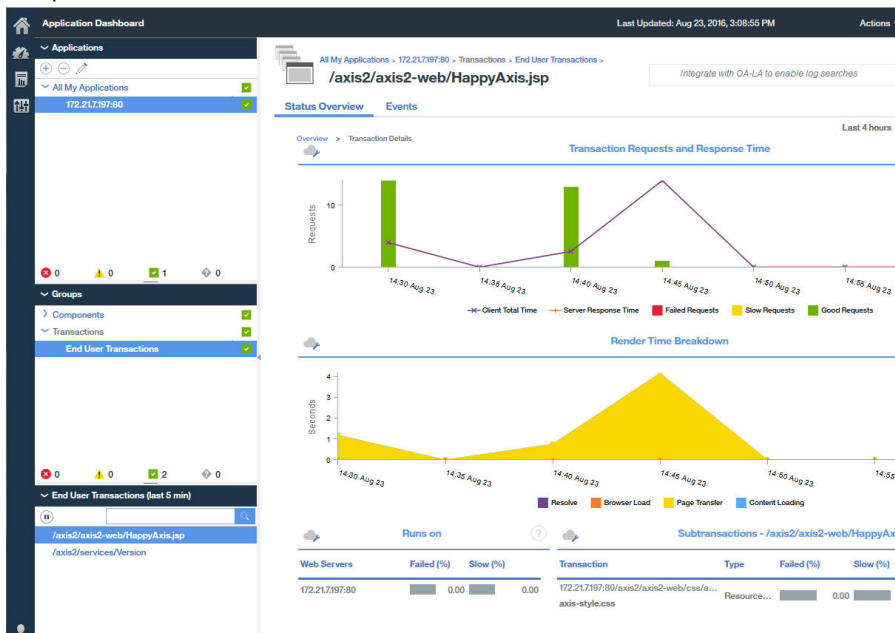

Using JavaScript, IBM HTTP Server Response Time module inserts a header into web pages that are served by an IBM HTTP Server so that the Response Time Monitoring agent can monitor those pages. Embedded objects that are loaded by the page are tracked by using cookies. Transaction information from web pages that are served by IBM HTTP Server or Apache is then included in the End User Transactions dashboards.

For example:

End User Transactions workspace that shows data that is collected from the IBM HTTP Server Response Time module in the Transactions - Top 10:

End User Transactions workspace that shows data that is collected from the IBM HTTP Server Response Time module in the **Subtransactions** table

## IBM HTTP Server Response Time module

The IBM HTTP Server Response Time module is a part of the HTTP Server agent. But it works in conjunction with the Response Time Monitoring agent to monitor application transactions on supported HTTP servers.

When you install the Response Time Monitoring agent to work with IBM HTTP Server Response Time module, it monitors all ports for HTTP and HTTPS requests.

The IBM HTTP Server Response Time module is a part of the HTTP Server agent. You must install the HTTP Server agent either before the Response Time Monitoring agent or else install at the same time.

The HTTP Server agent, is composed of two plug-ins:

1. `khu_module` - this is the HTTP Server agent. This plug-in is responsible for all the dashboards associated with the HTTP Server agent. For more information, see the [HTTP Server agent Reference](#).

2. `wrt_module` - this is the IBM HTTP Server Response Time module.

These two plug-ins are indicated in the HTTP Server agent configuration file. The HTTP Server agent configuration file is as follows for Apache HTTP Server:

```
khu.usr.local.apache24.conf.httpd.conf
```

The file is as follows for IBM HTTP Server:

```
khu.opt.IBM.HTTPServer.conf.httpd.conf
```

The naming rule of this file is: `khu.(full path of the http server conf file, change the / to .).conf`

```
LoadModule khu_module
```

```
LoadModule wrt_module
```

For the IBM HTTP Server Response Time module to work, the HTTP server configuration file must have an include statement referencing the HTTP Server agent configuration file. For example:

```
include /opt/ibm/apm/agent/tmp/khu/khu.opt.IBM.HTTPServer.conf.httpd.conf
```

This include statement, enables both plugins at the same time. For more information, see [“Configuring HTTP Server monitoring”](#) on page 344.

## Installing and configuring the IBM HTTP Server Response Time module

Configuration is automatic on the Response Time Monitoring agent side. The IBM HTTP Server Response Time module needs to be installed and configured as part of the HTTP Server agent. The Response Time Monitoring agent automatically detects the IBM HTTP Server Response Time module and enables it.

### About this task

#### Procedure

1. Install HTTP Server agent which automatically installs the IBM HTTP Server Response Time module.
2. Configure the HTTP Server agent. This enables the IBM HTTP Server Response Time module. For more information, see [“Configuring HTTP Server monitoring”](#) on page 344.
3. Install Response Time Monitoring agent as `root` or `Administrator`, depending on your operating system. For detailed instructions, see Chapter 7, “Installing your agents,” on page 181.
4. Restart IBM HTTP Server. When the Response Time Monitoring installer detects the HTTP Server agent, the Response Time Monitoring agent enables the IBM HTTP Server Response Time module automatically.

## Enabling IBM HTTP Server Response Time module manually

You can enable IBM HTTP Server Response Time module manually to monitor the performance of HTTP pages and embedded objects for web pages that are served by IBM HTTP Server.

### About this task

The IBM HTTP Server Response Time module is enabled automatically when the HTTP Server agent is installed and configured. However, you might want to manually enable the IBM HTTP Server Response Time module.

## Procedure

To enable IBM HTTP Server Response Time module manually on Linux, AIX, or Windows, complete the following steps:

### 1. Linux | UNIX

To enable the IBM HTTP Server Response Time module manually on Linux or AIX, complete the following steps:

- a) Stop the Response Time Monitoring agent.

Run

```
$AGENT_HOME/bin/rt-agent.sh stop
```

where `$AGENT_HOME` might be `/opt/ibm/apm/agent` on a Linux system, or `/opt/ibm/ccm/agent` on an AIX system.

- b) Run a configuration command and use `$AGENT_HOME/samples/rt_silent_config_ihs.txt` to add the load modules to the web server configuration file and set the configuration parameters for the IBM HTTP Server Response Time module.
- c) Restart the Response Time Monitoring agent.

### 2. Windows

To enable IBM HTTP Server Response Time module manually on Windows, complete the following steps:

- a) Stop the Response Time Monitoring agent.

Run

```
AGENT_HOME/bin/rt-agent.bat stop
```

where `AGENT_HOME` might be `C:\IBM\APM` on a Windows system.

- b) Run a configuration command and use `AGENT_HOME\samples\rt_silent_config_ihs.txt` to add the load modules to the web server configuration file and set the configuration parameters for the IBM HTTP Server Response Time module.

For example,

```
AGENT_HOME\bin\rt_agent.bat config AGENT_HOME\samples\rt_silent_config_ihs.txt
```

- c) Restart the Response Time Monitoring agent.

## Disabling the IBM HTTP Server Response Time module manually

To disable the IBM HTTP Server Response Time module and use the Packet Analyzer again, reconfigure the agent and turn off monitoring by the IBM HTTP Server Response Time module.

## About this task

Use the following procedures to disable the IBM HTTP Server Response Time module.

## Procedure

To reconfigure the agent interactively on Linux, AIX, or Windows, complete the following steps:

### 1. Linux | UNIX

To reconfigure the agent interactively on Linux and AIX, complete the following steps:

- a) Run `install_dir/bin/rt-agent.sh config`

Where `install_dir` is `/opt/ibm/apm/agent` on Linux and AIX.

- b) Restart the Response Time Monitoring agent.

Alternatively, to set the parameters manually:

- a) Open *install\_dir/config/hostname\_t5.cfg* in a text editor.  
where *install\_dir* is */opt/ibm/apm/agent* on Linux and AIX.
- b) Set the following parameters:

```
KT5DISABLEANALYZER=NO
KT5ENABLEWEBPLUGIN=NO
```

- c) Restart the Response Time Monitoring agent.

## 2. **Windows**

To reconfigure the agent interactively on Windows, complete the following steps:

- a) Set the related parameters manually, open the *install\_dir\TMAITM6\_x64\hostname\_t5.cfg* in a text editor.  
where *install\_dir* is *C:\IBM\APM* on Windows.
- b) Set the following parameters:

```
KT5DISABLEANALYZER=NO
KT5ENABLEWEBPLUGIN=NO
```

- c) Restart the Response Time Monitoring agent.

## Advanced Configuration of IBM HTTP Server Response Time module

There are a number of advanced configuration options for the IBM HTTP Server Response Time module.

The IBM HTTP Server Response Time module is configured automatically, but there are a number of advanced configuration tasks you can perform to fine tune the performance and features.

### **Disabling resource timing monitoring**

Resource timing monitoring is enabled for all IBM HTTP Server Response Time module instances installed by HTTP Server agent.

### **About this task**

If you want to reduce the number of resources that are monitored by IBM HTTP Server Response Time module, or disable resource timing monitoring to reduce the processing load that is required for monitoring a particular IBM HTTP Server, complete the following steps:

### **Procedure**

To edit the generated HTTP Server agent configuration file, complete the following steps:

1. At the end of the HTTP server configuration file (*httpd.conf*), append

```
WrtMaxPostResourcesSize
```

2. Set one of the following values:

- *WrtMaxPostResourcesSize -1*, to monitor all resources
- *WrtMaxPostResourcesSize 0*, to turn off resource monitoring
- *WrtMaxPostResourcesSize n*, to monitor a particular number of resources, 10 by default. For example, set *WrtMaxPostResourcesSize 2* to set a maximum of two resources to post to the server.

3. Restart the HTTP server.

## Disabling ARM Correlator generation

By default, ARM Correlator generation is enabled which allows the IBM HTTP Server Response Time module to link to any back-end servers in the topology. You can disable ARM Correlator generation if required.

### About this task

**Restriction:** If you disable ARM Correlator generation, IBM HTTP Server Response Time module cannot link to back-end servers such as WebSphere Application Server. Disable ARM Correlator generation only under advice from IBM Software Support.

### Procedure

To disable ARM Correlator generation, complete the following steps:

1. At the end of the HTTP server configuration file (`httpd.conf`), append

```
WrtDisableArmCorr
```

2. Restart the HTTP server

## Disabling Response Time Monitoring with Client Time (JavaScript Instrumentation)

In IBM Application Performance Management, Response Time Monitoring with Client Time (JavaScript Instrumentation) is enabled for all IBM HTTP Server installations running on all computers.

### About this task

### Procedure

To disable JavaScript Injection manually, complete the following steps:

1. Open the HTTP server configuration file located here: `HTTP_Server_root/conf/httpd.conf`
2. Navigate to the line added for HTTP Server agent, and append the following line after it:

```
WrtDisableJSI
```

For example,

```
include /opt/ibm/apm/agent/tmp/khu/khu.opt.IBM.HTTPServer.conf.httpd.conf
WrtDisableJSI
```

3. Save `httpd.conf` file, and recycle the HTTP server.

## Bypassing the WRTCorrelator cookie

When JavaScript injection is enabled for the Response Time Monitoring agent on the WebSphere Portal, cookies such as the WRTCorrelator cookie might cause issues while you are using the WebSphere Portal. To prevent these issues, you can set the WRTCorrelator cookie to ignore.

### Procedure

1. If necessary, start the `WebSphere_Portal` server.
2. Log in to the WebSphere® Integrated Solutions Console.
3. Go to **Resources > Resource Environment > Resource Environment Providers**.
4. Select **WP ConfigService**.
5. Under Additional Properties, select **Custom Properties**.
6. Click **New**.
7. Specify the name of the property, the WRTCorrelator cookie in this case, and set the value of the property to ignore.

To set the WRTCorrelator cookie to ignore, enter the following:

```
cookie.ignore.regex =  
digest\.\ignore.*|LTPAToken|LTPAToken2|JSESSIONID|WASReqURL|WRTCorrelator  
|PD_STATEFUL.*
```

8. Click **Apply** and save your changes.
9. Log out of the WebSphere® Integrated Solutions Console.

## Results

The WRTCorrelator cookie is set to ignore and issues such as looping are prevented.

### ***Excluding pages from client time reporting***

You might want to exclude particular pages from client time reporting from the browser.

## About this task

You can add a parameter to the configuration file to stop the IBM HTTP Server Response Time module from injecting JavaScript into any file that matches the patterns you specify. This in turn stops client time reporting from the browser for those pages.

## Procedure

To exclude particular pages from client time reporting from the browser, complete the following steps:

1. Open the following file in a text editor:

```
Linux      UNIX      install_dir/config/hostname_t5.cfg where install_dir  
is /opt/ibm/apm/agent  
Windows   install_dir\TMAITM6_x64\hostname_t5.cfg where install_dir is C:\IBM\APM
```

2. In the **advconfig** section, add

```
{KT5WEBPLUGIN_JSI_EXCLUDE_URI_WITH_PATTERNS=URL_path_pattern to_exclude}
```

For example,

```
{KT5WEBPLUGIN_JSI_EXCLUDE_URI_WITH_PATTERNS=*/DoNotJSIme.jsp,/absolutePath/index.jsp,/skipThisDir/*}
```

The URL path is limited to 256 characters.

**Tip:** Use an asterisk (\*) as a prefix or suffix to match patterns. Add multiple values separated by a comma to the parameter if required.

3. Save and close *hostname\_t5.cfg*.
4. Restart the Response Time Monitoring agent:

```
rt-agent.sh stop  
rt-agent.sh start
```

### ***Using the IBM HTTP Server Response Time module as a non-root user***

With some careful setup, you can use the IBM HTTP Server Response Time module with a user ID other than root. Remember that if you are using the Network Packet Analyzer, you must use the root user.

To use a user ID other than root, follow these guidelines.

## For the Response Time Monitoring agent

Install the Response Time Monitoring agent by using the user ID you are going to run it with, to a directory that has write access.

- For this procedure, the Response Time Monitoring agent user ID is *agentuser*. The directory to which the agent is installed is *\$AGENT\_HOME*.

- If you install the Response Time Monitoring agent as root, and then run the agent as a different user, you will not be able to create files.

## For the IBM HTTP Server Response Time module

`ServerRoot` must be owned by the same user ID that is used to run `apache start|stop`.

- During `apache start`, a `wrt` tracking directory is created under `ServerRoot`. Therefore, the user needs sufficient permissions to create files and directories under `ServerRoot`.
- If the IBM HTTP Server Response Time module user, *ihuser* is different from *agentuser*, it requires write access to `$AGENT_HOME/tmp`.

`$AGENT_HOME/tmp` is created during the installation of agents. The *ihuser* needs permission to create a `kt5` directory in `$AGENT_HOME/tmp`.

- There can be multiple versions of `ServerRoot`, each administered by different users.

## For both the Response Time Monitoring agent and IBM HTTP Server Response Time module

Both *agentuser* and *ihuser* need read/write access to the following directories:

- `$AGENT_HOME/tmp/kt5`
- `ServerRoot/wrt`

Normally the IBM HTTP Server Response Time module is started first and the `wrt` directories are created automatically by the Response Time Monitoring when it first starts up, with read/write access for all.

`ServerRoot/wrt` is also used by `camconfig` to push configuration. The *ihuser* creates shared queue ID files that are picked up by the *agentuser*; the *agentuser* reads the queue ID from the directory and pushes configuration.

If root is used to run `apache start` initially and *ihuser* is not root, complete the following steps:

1. Stop the Response Time Monitoring agent.
2. Using root, run `apachectl stop`.
3. Delete the following directories:
  - `$AGENT_HOME/tmp/kt5`
  - `ServerRoot/wrt`
4. Using *ihuser*, run `apachectl start` to re-create the directories with the correct permissions.

## For resetting the IBM HTTP Server Response Time module permission to the wrt directory

You can reset the permission of the IBM HTTP Server Response Time module `wrt` directory for more security. The update involves adding a parameter in the configuration file to limit permission to the `wrt` directory that was created by the non-root user during IBM HTTP Server installation.

Complete this procedure on the system where the IBM HTTP Server Response Time module is installed to change the permission of the `wrt` directory for the non-root user from 777 to 700:

1. Open `$IHS_HOME/conf/httpd.conf` file in a text editor.
2. Add property **WrtDisableDirPermNonRoot** to the end of the file:
  - When the property is enabled, only the user ID that started the `httpd` and matches the user ID that created the directory is used to create the `wrt` directory with permission 700. All other users are denied access to work with this directory.
  - When the property is not enabled, the `wrt` directory is created with the default permission 777.

### 3. Restart the Response Time Monitoring agent:

```
rt-agent.sh stop  
rt-agent.sh start
```

The Response Time Monitoring configuration data and some persistent files are stored in the `wrt` directory, which is used during the communication process, and each connection process creates a `wrt` configuration file in the directory. After you add **WrtDisableDirPermNonRoot** to the `httpd.conf` file, only the limited certain user can communicate with Response Time Monitoring monitoring agent successfully.

### **Using load balancers**

If you are using load balancers in your environment, some additional customization is required.

### **Procedure**

If you are using a load balancer, follow these guidelines:

1. Turn off URL Rewrite on the load balancer.
2. Install a Response Time Monitoring agent on each web server that you want to monitor.  
Do not install Response Time Monitoring on the load balancer.

### **What to do next**

If you are running the Response Time Monitoring agent behind a load balancer, you can configure the load balancer to forward the IP address of the client to optimize monitoring performance. Use the following steps as an example:

1. In the HTTP header, set the IP address of the client in the **X-Forwarded-For** field.
2. In the `$AGENT_HOME/config/hostname_t5.cfg` file, add `{KT5WEBPLUGIN_OVERRIDE_SOURCE_ADDR_HEADERS=X-Forwarded-For}` to the `SECTION=advconfig` section.

**Tip:** Add multiple values to the parameter if required. For example, `{KT5WEBPLUGIN_OVERRIDE_SOURCE_ADDR_HEADERS=x-forwarded-for, iv-remote-address}`

3. Restart the Response Time Monitoring agent. Run the following commands:

```
rt-agent.sh stop  
rt-agent.sh start
```

### **Limiting the CPU used to monitor IBM HTTP Server**

In saturated environments, you might want to limit the percentage of CPU used by IBM HTTP Server instrumentation.

### **About this task**

Specify the percentage of CPU that the IBM HTTP Server Response Time module can use. The percentage of CPU used is not limited by default. Configure the CPU percentage on the server where the agent is installed.

### **Procedure**

To configure the percentage of CPU used, complete the following steps:

1. Reconfigure the agent interactively or manually:
  - Run the agent script for configuring interactively:

Linux | UNIX

```
$AGENT_HOME/bin/rt-agent.sh config
```

Windows

```
install_dir\BIN\rt-agent.bat config
```

- Open the following file in a text editor:

Linux | UNIX

```
/opt/ibm/apm/agent/config/hostname_t5.cfg
```

Windows

```
C:\IBM\APM\TMAITM6_x64\hostname_T5.cfg
```

2. In the **advconfig** section, add the following parameter and set a value from 0 to 100:

```
KT5WEBPLUGIN_TARGET_CPU_PERCENTAGE=10
```

where the value you specify is the percentage limit of CPU use. The default value of 0 means that the CPU use is not limited.

3. You can also set the following parameters:

| Option                                      | Description   |
|---|---|
| <b>KT5WEBPLUGINCONFIGPOSTURL</b>            | List of URLs corresponding to an IBM HTTP Server installation.<br><br>Default: <code>http://localhost/WrtUpdateConfig.dat</code>  |
| <b>KT5WEBPLUGIN_MAX_REQUESTS_PER_SECOND</b> | Number of requests per second monitored by each IBM HTTP Server installation. If the number of requests exceeds this number, the subsequent requests are not monitored. If the limit is reached, JavaScript insertion stops, and no data is sent back to the Response Time Monitoring agent.<br><br>Default: 0 (no maximum) |
| <b>KT5WEBPLUGIN_CPUMAN_PERIOD_IN_SEC</b>    | The period, in seconds, at which CPU use is checked to determine whether the target has been exceeded.<br><br>Default: 60 seconds   |
| <b>KT5WEBPLUGIN_CATCHUP_PERIOD_COUNT</b>    | Number of periods that are allowed at the same state before the CPU is scaled back. For example, by using the default, if the CPU use is high and 4 cycles later, it remains high, CPU use is scaled back.<br><br>Default: 3  |

## Results

The percentage CPU available to the IBM HTTP Server Response Time module is set at a fixed percentage.

## Packet Analyzer roadmap

Use the Packet Analyzer to monitor HTTP transactions. You need to manually configure HTTPS monitoring. You need to manually instrument your web pages to collect browser timings.

To determine the environments in which you can use Packet Analyzer, see [“Response Time Monitoring Components”](#) on page 779 and [“Planning the installation ”](#) on page 780.

Packet Analyzer is automatically enabled when you install the Response Time Monitoring agent, but there are a number of further steps and customizations that you might need to perform.

1. You can customize Packet Analyzer settings, for example, port number in the Agent Configuration window. For more information, see [“Configuring Packet Analyzer using Agent Configuration window”](#) on page 797.
2. To monitor HTTPS transactions, manually instrument your web pages to collect browser timings. For more information, see [“Monitoring HTTPS transactions”](#) on page 799.
3. To enable browser timings, add the JavaScript Injection component to your application and associate the JavaScript monitoring component with your application, for more information, see [“Adding the JavaScript monitoring component to your application”](#) on page 797.
4. If you are operating a high transaction load environment, there are some advanced tuning steps that you might need perform. For more information, see [“Advanced Configuration of the Packet Analyzer”](#) on page 803

## Configuring Packet Analyzer using Agent Configuration window

You can use the Agent Configuration window to configure Packet Analyzer.

To monitor HTTP traffic for a particular system by using the Packet Analyzer, complete the following steps:

1. To access the Agent Configuration page, in the APM UI select **System Configuration > Agent Configuration**, then select the **Response Time** tab.
2. Select the system or systems that you want to update. Select multiple systems if you want to use the same HTTP settings for each of those systems.  
  
If the systems you select have different HTTP values set, **Multiple Values** or **Multiple Lists** is displayed instead of individual values. You cannot update systems with different values at the same time.
3. In the **Monitor HTTP traffic?** field, double-click the value and select **Yes** from the list.
4. In the **HTTP Ports to monitor** field, double-click the value and enter any additional ports that you want to monitor, other than the default port 80 and any other ports already listed.  
  
To stop monitoring a port, select the port that you no longer want to monitor and click **Remove**.
5. Click **Apply Changes**.

## Adding the JavaScript monitoring component to your application

To help you understand the performance of your web pages in a browser and any errors, the Response Time Monitoring agent needs to be able to collect timing data from the browser. To enable this feature, you must configure the application that you want to monitor.

### About this task

Before you can monitor interactions within your web pages, you need to add the JavaScript monitoring component to each web page for your application. The JavaScript monitoring component captures the state of each web page and associated JavaScript interactions. Add the JavaScript monitoring component to the application that you want to monitor. The relevant content and actions are automatically captured and sent to the Cloud APM server for analysis and correlation.

## Procedure

Complete the following steps to enable collection of real user monitoring data from the browser. These steps need to be completed only once, unless the application configuration changes.

1. Add the JavaScript monitoring component to the application. The procedure that you use depends on the application type:
  - a) For Java EE applications, extract *install\_dir/clienttime/ClientTime.war* from the installation package to a directory accessible to the HTTP Server.
  - b) For non-Java EE applications, such as Ruby, .NET, Python, and Node.js, save *install\_dir/clienttime/wrtInstrumentation.js* from the installation package to a directory accessible to the HTTP Server.

Extract the *install\_dir/clienttime/ClientTime.war* file to a temporary path. You must copy the extracted *wrtTimingTarget.dat* file to the document root. Document root is a setting on the HTTP Server (Apache, IIS, and so on). It is a directory to store your documents. By default, all requests are taken from this directory but symbolic links and aliases might be used to point to other locations. For example, the document root for Apache is */opt/IBM/HTTPServer/htdocs*.

The *wrtInstrumentation.js* file can be placed in any directory. Ensure you update the path location to the *wrtInstrumentation.js* file in the HTML header.

2. Associate the JavaScript monitoring component with the application.

This association can normally be done by modifying an application header script. Typically, only one header script needs to be modified for each component or application that is to be monitored.

For both Java EE applications and non-Java EE applications, add the following JavaScript to the application header before any other JavaScript:

```
<script language="JavaScript" src="path/wrtInstrumentation.js"
type="text/JavaScript"></script>
```

where *path* is the relative path to the JavaScript monitoring component

For example:

```
<script language="JavaScript" src="/ClientTime/wrtInstrumentation.js"
type="text/JavaScript"></script>
```

## Results

Pages that are instrumented with the JavaScript monitoring component are monitored, and data from the pages is analyzed and displayed in End User Transactions dashboards.

### **Enabling browser timing**

By enabling resource timing monitoring, the Response Time Monitoring agent processes the W3C Resource Timing data by using the Packet Analyzer. With this function enabled, you can view detailed performance information on front-end elements.

## About this task

Before you can monitor resource timing data, you must add the resource timing monitoring component to your application and associate the resource timing monitoring component with the application. The resource timing monitoring component automatically captures the state and interactions of the front-end elements, and sends the data to the Cloud APM server for analysis. The results of this analysis are displayed in the **Subtransactions** dashboard.

## Procedure

Complete the following steps to enable the resource timing monitoring function. Complete these steps only once, unless the application configuration changes.

1. Add the resource timing monitoring component to the application.
  - a) Extract `install_dir/clienttime/wrtInstrumentation.js` file from the installation package.
  - b) Add the `wrtInstrumentation.js` file to the JavaScript directory of your application.
2. Append the following line to the application header:

```
<script> var wrt_enableResourceTiming=true; </script>
```

For example,

```
<script language="JavaScript" src="path/wrtInstrumentation.js"
type="text/JavaScript"></script>
<script> var wrt_enableResourceTiming=true; </script>
```

## Results

The pages are instrumented with the resource timing monitoring component. This component is enabled by default. The resource timing data on pages that are instrumented with the resource timing monitoring component is analyzed and displayed in the **Subtransactions** dashboards.

## What to do next

If you want to disable the resource timing monitoring component, set the `wrt_enableResourceTiming` parameter to `false`.

## Monitoring HTTPS transactions

Response Time Monitoring monitors HTTP transactions by default. To monitor HTTPS transactions, Response Time Monitoring requires access to the SSL Certificates so that it can decrypt SSL traffic from your local web servers.

## Before you begin

Identify the HTTPS web servers that you want to monitor, including their IP addresses and configured ports. For example, 192.168.1.23, port 443. For each HTTPS web server, check that Response Time Monitoring can read its ciphers. Response Time Monitoring supports the ciphers supported by IBM Java, including the following ciphers.

- RSA\_WITH\_RC4\_40\_MD5
- RSA\_WITH\_RC4\_128\_MD5
- RSA\_WITH\_RC4\_128\_SHA
- RSA\_WITH\_RC4\_40\_SHA
- RSA\_WITH\_DES40\_CBC\_SHA
- RSA\_WITH\_DES\_CBC\_SHA
- RSA\_WITH\_3DES\_EDE\_CBC\_SHA
- RSA\_WITH\_AES\_128\_CBC\_SHA
- RSA\_WITH\_AES\_256\_CBC\_SHA
- RSA\_EXPORT1024\_WITH\_RC4\_56\_MD5
- RSA\_EXPORT1024\_WITH\_RC2\_CBC\_56\_MD5
- RSA\_EXPORT1024\_WITH\_DES\_CBC\_SHA
- RSA\_EXPORT1024\_WITH\_RC4\_56\_SHA
- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256

**Restriction:** Response Time Monitoring cannot decrypt traffic that uses Diffie-Hellman key exchange.

## Procedure

To enable HTTPS transaction monitoring, complete the following steps:

1. Set up the keystore. For more information, see [“Setting up the keystore”](#) on page 800.
2. Configure the Response Time Monitoring agent by running one of the following commands and providing values when prompted:

For example:

```
Configuring Response Time Monitoring Agent
Edit 'Response Time Monitoring Agent' settings? [1=Yes,2=No](default is: 1): 1

Basic Configuration : Specify basic monitoring configuration. Note: HTTP is
now configured centrally using the Response Time tab under Agent Configuration.

Specifies if HTTPS transactions should be monitored
Monitor HTTPS transactions [ 1=Yes, 2=No ] (default is:2): 1

This keystore contains the certificates of the HTTPS websites being monitored
HTTPS keystore (e.g. - /tmp/keys.kdb) (default is: ): /tmp/keys.kdb

This table maps HTTPS servers to the appropriate certificates (e.g. cert1,
server ip,server port; cert2,server2 ip,server2 port);...
HTTPS server certificate map (eg - certAlias,9.48.152.1,443;...)(default is: ):
label11,10.0.0.1,9443;label11,9.185.150.71,443

Advanced Configuration :
Specify advanced monitoring configuration

The NIC card which has the selected IP address will be monitored.
IP address of the NIC to be monitored (default is: ): 10.0.0.1

Data Collection and Analysis Configuration :
Specify Configuration Information on how Data is Analyzed.

Configuration completed successfully.
Agent restart required to apply configuration changes.
```

where:

- HTTPS keystore is the keystore configured in step 1
  - HTTPS server certificate map, specify:
    - `label 1` - the key label configured in step 1
    - `server ip` - the IP address of the server, which must match the Source/Destination attribute in the IPV4 header of the packets
    - `server port` - server port number, which must match the Source/Destination port attribute in the TCP header of the packets
- Add multiple entries for multiple possibilities of the server IP of the same key label.
- IP address of the NIC to be monitored, the interface that can see the packets and is mapped to `eth0`, `en0`, and so on. The name does not need to match any attributes of IPV4 or the TCP headers of the packets. If `10.0.0.1` corresponds to `eth0`, use `tcpdump -s0 -i eth0 ...` to see all the packets that need to be analyzed by the Packet Analyzer.

3. Restart the Response Time Monitoring agent.

## Setting up the keystore

To monitor HTTPS transactions, import keys into the KT5Keystore for all web servers that you want to monitor.

## About this task

You can either export the SSL certificates from the web servers that you are monitoring and import them into the HTTPS Keystore by using IBM Key Management (iKeyman), or specify the web server's keystore

stash file (.kdb) in the HTTPS Keystore. When you install or configure Response Time Monitoring, you are prompted for the location of the keys.kdb file.

If you do not have keystore stash files (.kdb and .sth), check that the CMS Provider is enabled in your Java version so that you can use iKeyman to set up the key database:

1. Go to the `install_dir/ibm-jre/jre/lib/security` directory. For example:

- **Linux** `/opt/ibm/apm/agent/JRE/1x8266/lib/security`
- **Windows** `C:\Program Files\IBM\APM\ibm-jre\jre\lib\security`

2. In the `java.security` file, add the following statement to the list of security providers as shown, where *number* is the last sequence number in the list.

```
security.provider.number=com.ibm.security.cmskeystore.CMSProvider
```

The list of providers looks like the following example:

```
## List of providers and their preference orders #
security.provider.1=com.ibm.jsse.IBMJSSEProvider
security.provider.2=com.ibm.crypto.provider.IBMJCE
security.provider.3=com.ibm.security.jgss.IBMJGSSProvider
security.provider.4=com.ibm.security.cert.IBMCertPath
security.provider.5=com.ibm.security.cmskeystore.CMSProvider
...
#
```

3. Save and close the file.

**Restriction:** Response Time Monitoring cannot decrypt traffic by using Diffie-Hellman key exchange.

## Procedure

To enable HTTPS transaction monitoring, collect the SSL certificates from the web servers that you want to monitor and import the certificates and keystore stash files into the HTTPS Keystore by using iKeyman. The following example uses iKeyman to export the certificates from an IBM HTTP Server, and import them to HTTPS Keystore:

1. Install a Response Time Monitoring agent on each HTTPS web server that you want to monitor.
2. Run **IBM Key Management** (iKeyman) from within the IBM Java bin directory by running one of the following commands, depending on your operating system.

- **AIX** **Linux** `/opt/ibm/apm/agent/JRE/1x8266/bin/ikeyman`

**Note:** You must have X-Window on the environment for iKeyman to work properly.

- **Windows** `c:\IBM\APM\java\java80_x64\jre\bin\ikeyman`

3. Create a new Keystore database. In the **New** dialog box, complete the following steps:

a) From the **Key database type** list, select **CMS**.

If CMS is not available in the list, the CMS Provider might not be enabled. Enable the CMS Provider in the Java security file.

b) In the **File Name** field, enter the name of the HTTPS Keystore file and click **OK**.  
For example, keys.kdb.

4. In the **Password Prompt** dialog box, complete the following steps:

a) In the **Password** and **Confirm Password** fields, enter and confirm the password to access keys.kdb.

Do not set an expiration time unless you want to re-create the keystore database and restart the Response Time Monitoring agent periodically.

b) Select **Stash the password to a file?** to store the password for keys.kdb in an encrypted form in a stash file, keys.sth.

**Note:** The Response Time agent supports stashed password version 1 only. After APM 8.1.4, run following command to store the password for keys.kdb in an encrypted stash file, keys.sth.

On Linux:

```
cp keyfile.sth keyfile.sth.new-format
```

```
cd /opt/IBM/ccm/agent/lx8266/gs/bin
```

```
#export LD_LIBRARY_PATH=/opt/ibm/apm/agent/lx8266/gs/lib64:$LD_LIBRARY_PATH
```

```
./gsk8capicmd_64 -keydb -stashpw  
-db /opt/IBM/ccm/agent/keyfiles/keyfile.kdb -v1stash
```

On Windows:

```
copy server.sth server.sth.backup
```

```
set PATH=c:\IBM\APM\GSK8_x64\lib64;%PATH%
```

```
C:\IBM\APM\GSK8_x64\bin\gsk8capicmd_64 -keydb  
-stashpw -db .\server.kdb -pw passw0rd -v1stash
```

5. In the **Key database content** section of the iKeyman window, complete the following steps:

- a) Select **Personal Certificates**.
- b) Click **Import**.
- c) In the **Import Key** dialog box, from the **Keyfile type** list, select **CMS**.
- d) Browse to the keystore file and click **Open**, and then click **OK**.
- e) In the **Password Prompt** dialog box, enter the keystore password.
- f) Select the key from the list and click **OK**.
- g) In the **Change Labels** dialog box, select the key label name. In the **Enter a new label** field, specify the host name of the server and click **Apply**.

**Note:** You will need this value when you configure Response Time Monitoring, so make a note of it.

- h) Click **OK**.

6. Save the HTTPS Keystore.

### Importing keys from Internet Information Services

To extract keys from Internet Information Services and import them into the KT5Keystore, complete the following steps:

1. Install a Response Time Monitoring agent on each HTTPS web server that you want to monitor.
2. Export a .pfx file from Internet Information Services:
  - a. From the Windows **Start** menu, select **Administrative Tools > Internet Information Services (IIS) Manager**.
  - b. Select the web server and site whose private key you want to export, then right-click and select **Properties** from the context menu.
  - c. Select the **Directory Security** tab, then select **Server Certificate** in the **Secure communications** section.
  - d. In the **IIS Certificate Wizard**, click **Next**.
  - e. Select **Export the current certificate to a .pfx file** and click **Next**.
  - f. Enter the path and file name and click **Next**.
  - g. Enter an export password for the key and click **Next**.
  - h. Click **Next** on all subsequent pages, then click **Finish**.
3. Extract Personal and Signer Certificates from the .pfx file:

- a. Run **IBM Key Management** (iKeyman) from within the IBM Java bin directory using the command `c:\IBM\APM\java\java80_x64\jre\bin\ikeyman`. Ensure that the environment variable `JAVA_HOME` is set.
  - b. In the Keystore database, select **File > Open**.
  - c. From the **Key database type** list, select **PKCS12**.
  - d. Enter the name and path for the .pfx file you created above, then click **OK**. When prompted, enter the password, then click **OK**.
  - e. Select **Key Database Content > Personal Certificates**, then click **Export/Import**.
  - f. Select an Action Type of **Export Key** and a Key File Type of **PKCS12**. Enter a file name and location for the exported key and click **OK**. When prompted, enter an export password, then click **OK** again.
  - g. If the Personal Certificate was signed by a Certificate Authority, select **Key Database Content > Signer Certificates** and click **Extract**. Select the default file type, and enter a file name and location for the exported certificate, then click **OK**.
4. Extract Signer .cer files (if needed):
- a. If a Signer Certificates file was extracted from the .pfx file, navigate to the directory where it was saved, and make a new copy with the extension .cer. Double-click the new copy to open it using the Windows Certificate viewer.
  - b. On the **Certification Path** tab, you can view the signer certificate chain. The lowest item in the chain should be the Personal Certificate. For all certificates above it, do the following:
    - i) Select a certificate and click **View Certificate**.
    - ii) Select **Details** and click **Copy to File**.
    - iii) Accept all defaults in the Certificate Export Wizard and enter a filename with the .cer extension.
5. Create a new Keystore database. In the **New** dialog box, complete the following steps:
- a. From the **Key database type** list, select **CMS**, and enter a filename and location. When prompted, enter a password for the new keystore.  
**Note:** Ensure you select **Stash the password to a file**.
  - b. If Signer Certificates were extracted from the .pfx file, do the following:
    - i) Select **Key Database Content > Signer Certificates**.
    - ii) For each signer certificate, click **Add** and add the .cer file.
  - c. Select **Key Database Content > Personal Certificates** and click **Import**.
  - d. Select the key file type **PKCS12**, and the name and location of the .p12 file. When prompted, enter the password.
  - e. Save the keystore and exit the key management utility.
  - f. Copy the .kdb and .sth files to the KT5Keystore on the Response Time Monitoring appliance machine.
  - g. Place the IBM Key Management database files (.kdb) and stash (.sth) in a safe directory, and ensure that they are only readable by Administrator or root (or the user ID that was used to install the Response Time Monitoring agent).

## Advanced Configuration of the Packet Analyzer

There are a number of advanced configuration options for the Packet Analyzer.

After you have configured the Packet Analyzer, there are a number of advanced configuration tasks you can perform to fine tune the performance and features.

## Using load balancers

If you are using load balancers in your environment, some additional customization is required.

### Procedure

If you are using a load balancer, follow these guidelines:

1. Turn off URL Rewrite on the load balancer.
2. Install a Response Time Monitoring agent on each web server that you want to monitor.  
Do not install Response Time Monitoring on the load balancer.
3. Add the JavaScript monitoring component to your application. For more information, see [“Adding the JavaScript monitoring component to your application”](#) on page 797.

### What to do next

If you are running the Response Time Monitoring agent behind a load balancer, you can configure the load balancer to forward the IP address of the client to optimize monitoring performance. Use the following steps as an example:

1. In the HTTP header, set the IP address of the client in the **X-Forwarded-For** field.
2. Configure the Response Time Monitoring agent to use the IP address header of the client. Set the IP address header of the client in the **KFC\_OVERRIDE\_SOURCE\_ADDR\_HEADER** field in one of the following files, depending on your operating system:

- **AIX** **Linux** /opt/ibm/apm/agent/tmaitm6/wrm/kfcmenv
- **Windows** C:\IBM\ITM\TMAITM6\_x64\wrm\Analyzer\kfcmenv

For example:

```
KFC_OVERRIDE_SOURCE_ADDR_HEADER=x-forwarded-for
```

or if you are using WebSEAL:

```
KFC_OVERRIDE_SOURCE_ADDR_HEADER=iv-remote-address
```

## Configuring CPU overhead limit

If you are operating a high transaction load environment, you can limit the monitoring resources used by the Response Time Monitoring agent.

### About this task

This function limits the CPU usage of the Response Time Monitoring agent by monitoring and reporting only a portion of the web traffic by using sampling. The `CPU overhead limit` is not configured by default. You must configure the `CPU overhead limit` on the server where the agent is installed.

### Procedure

To configure `CPU overhead limit`, complete the following steps:

1. Open the following file in a text editor:

```
Linux UNIX /opt/ibm/apm/agent/tmaitm6/wrm/kfcmenv  
Windows C:\IBM\ITM\TMAITM6_x64\wrm\Analyzer\kfcmenv
```

2. Configure the values for the following parameters:

#### **KFC\_MAX\_PROTOCOL\_PACKETRATE**

The initial maximum packet rate. For example, if you set the parameter as

**KFC\_MAX\_PROTOCOL\_PACKETRATE=2000**, the maximum packet rate is 2000 packets per second.

This rate varies dynamically based on the value for **KFC\_CPUTHROTTLE\_TARGET** and the current CPU usage.

### KFC\_CPUTHROTTLE\_TARGET

The percentage of the overall CPU resource that can be used by the `kfcmsvr` process. For example, if you set the parameter as **KFC\_CPUTHROTTLE\_TARGET=10.0**, the `kfcmsvr` process can use up to 10% of the overall CPU resource.

**Note:** The value for parameter **KFC\_CPUTHROTTLE\_TARGET** is the percentage of the overall CPU resource that is available for the `kfcmsvr` process. For example, if you have 4 CPU cores and **KFC\_CPUTHROTTLE\_TARGET** is set to 10, the Resource Monitor in Windows measures CPU resource as 400%. As a result, the `kfcmsvr` process can use up to 40% of the total 400% CPU resources available.

## Results

The `CPU overhead limit` is configured for the Response Time Monitoring agent.

## Reconfiguring from IBM HTTP Server Response Time module to Packet Analyzer

You might want to change your monitoring environment from IBM HTTP Server Response Time module to Packet Analyzer.

### Procedure

1. Uninstall the HTTP Server agent
  - a) Edit `/etc/httpd/conf/httpd.conf` by commenting the Response Time plugin line. For example

```
#include /opt/ibm/apm/agent/tmp/khu/khu.etc.httpd.conf.httpd.conf
```

- b) Uninstall the HTTP Server agent. For example

```
/opt/ibm/apm/agent/bin/http_server-agent.sh uninstall
```

- c) Open a new command prompt window to clean the system variate before reconfiguring the Response Time agent in the next step.

2. Open the following file

```
Linux | UNIX | install_dir/config/hostname_t5.cfg
Where install_dir is /opt/ibm/apm/agent
Windows | install_dir\TMAITM6_x64\hostname_t5.cfg
where install_dir is C:\IBM\APM
```

3. Set the parameters as follows:

```
{ KT5DISABLEANALYZER=NO } { KT5ENABLEWEBPLUGIN=NO }
```

4. Reconfigure the agent as follows:

```
re-agent.bat config install_dir\samples\rt_silent_config.txt
```

## Customizing End User Transaction location values

You can customize the locations applied to specific IP addresses or address ranges in the End User Transaction dashboards for your particular environment.

### Before you begin

Use the **Geolocation** tab in the **Agent Configuration** to customize location values.

Use this feature to set the location of IP addresses that are displayed in the dashboard as **Unknown**. These addresses might be internal addresses, for example `192.168.x.x` or `10.x.x.x`, or external IP

addresses that are not resolved. You can also use this feature to override incorrect locations for IP addresses. For example, if you know that the IP address 9.1.1.1 is in Los Angeles, but it is shown as San Francisco, override the location, and set 9.1.1.1 to Los Angeles.

## About this task

Customize location values in the End User Transaction dashboards by uploading a CSV file containing the values you require. You can find a sample CSV file on the **Geolocation** tab.

The CSV file must have the following values as a header. The values can be in any order, and the entries must match that order.

```
IP_ADDRESS, COUNTRY, REGION, CITY
```

For example,

```
IP_ADDRESS, COUNTRY, REGION, CITY
10.0.5.0/24, Australia, WA, Perth
10.1.0.6, Australia, VIC, Melbourne
```

You can specify a single IPv4 address, or a range. If you specify a range, ensure that you use a valid value in the range 1-32.

## Procedure

To customize the location values displayed in the End User Transaction dashboards, complete the following steps in the Application Performance Dashboard.

1. Set up your CSV file or files, with IP addresses matched to locations.
2. Upload the CSV file.
  - a) Go to **Agent Configuration > Geolocation**.
  - b) Click **Upload CSV**, select the files you want to upload, and click **Open**.
    - Ensure that your CSV file lists general IP address ranges first, before more specific IP addresses.
    - Upload multiple files if required.
    - If the values in one file overlap those in another, the values in the newer file override the values in the first.
3. Expand **Upload Results** to check for errors. Check for the following problems:
  - Overrides
  - Invalid IP addresses
  - Invalid rows
  - Values longer than 250 characters

## Results

Wait a few minutes and view your customized values in the End User Transaction dashboards.

## What to do next

You can remove customized values if required. Complete one of the following steps:

- To remove some of your customized values, select the IP addresses that you want to remove, click **Clear Selected Entries**, and click **OK** to confirm the removal
- To remove all customized values, click **Clear All Entries**, and click **OK** to confirm the removal

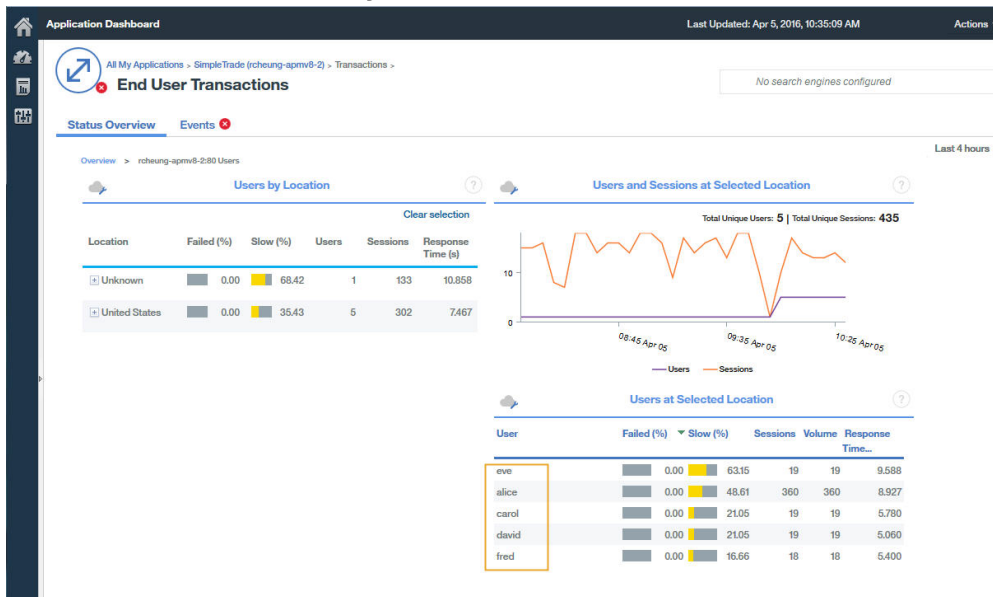

## Tracking additional web applications

To track web applications in addition to those tracked by default, you must identify and configure user and session tracking methods.

### Before you begin

If your application is not supported by the defaults, the dashboards do not contain user and session details, the username is displayed as anonymous or unknown, and no session information is available.

If user tracking methods are configured correctly, the user ID is extracted and is listed in the **End User Transactions > User Summary > Users at Selected Locations** dashboard.

Note: The user tracking is based on session tracking. You need to set the correct session tracking methods variable first, in the Response Time agent configuration settings, for user and session tracking methods.

### About this task

In IBM Application Performance Management V8.1.4 and later, you can use the **Agent Configuration > Response Time** page to add applications to track by either the Packet Analyzer or IBM HTTP Server Response Time module. Values defined on this page take precedence over the values in the WRT\_Defaults.xml file.

To track additional applications, you must first identify the user ID and session ID methods and values for the application you want to monitor. For example:

1. Open the developer tool for your browser, so that you can see the requests for the application you want to monitor.
2. Select the last request in the browser network log, so that you can identify your test request easily.
3. Create a test request with parameters you will recognize. For example, log in to your website with `testuser`.
4. Select the test request and look at the Headers.
5. Identify the session ID from the request log. Session ID is typically specified in cookie, POST, request/response header, or query string. If the cookie is already defined in the default profile, you won't need to add it in step 2.
6. Identify the user ID from the request log. User ID can be specified in cookie, request header, POST, or query string content. For example, search for `testuser` which will give you the value for user ID.

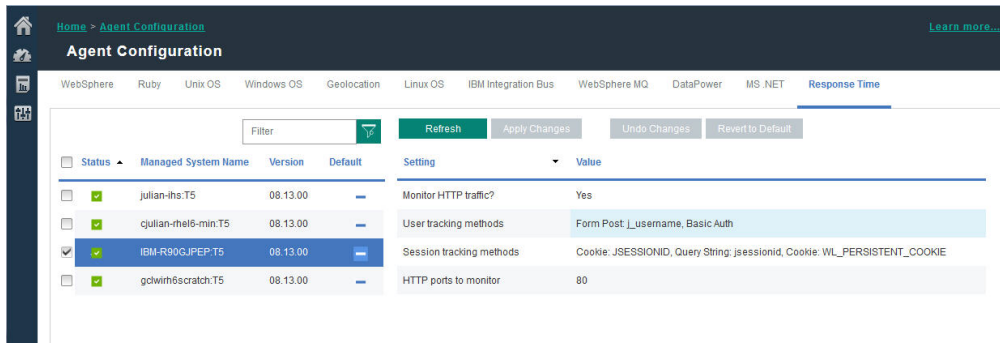

7. Both **User tracking methods** and **Session tracking methods** must be updated with the correct value name of session and user in use in the customer's application code. How to identify the value name of Session and Username depends on the code of application. The following is the default value of User/Session setting in 8.1.4.

```
Session tracking methods=cookie\:JSESSIONID,querystring\:jsessionid,cookie\
:WL_PERSISTENT_COOKIE
User tracking methods=formpost\:j_username,formpost\:uid,formpost\
:ctl00%24MainContent%24uid,basicauth\:Authorization\: Basic
```

## Procedure

After you have identified the user and session tracking methods and values used in your application, complete the following steps:

1. Go to the **Agent Configuration > Response Time** configuration page.

2. Select the managed system that you want to update.
3. If required, update the session tracking methods:
  - a) Click the value in the **Session tracking methods** field.

**Specify Methods to Track Sessions**

If your application is not supported by the defaults, no session information is available in the workspaces. Add the methods by which you would like sessions to be tracked.

| <input type="checkbox"/> Tracking Type | Tracking Value       |
|--|----------------------|
| <input type="checkbox"/> Cookie        | JSESSIONID           |
| <input type="checkbox"/> Query String  | jsessionid           |
| <input type="checkbox"/> Cookie        | WL_PERSISTENT_COOKIE |

- b) In the **Specify Methods to Track Sessions** window, click **Add**.
  - c) From the **Tracking Type** list, select the tracking type. For example, Cookie.
  - d) In the **Tracking Value** field, specify a value. For example, WL\_PERSISTENT\_COOKIE.
  - e) Click **Finished**.
4. If required, update the user tracking methods:
    - a) Click the value in the **User tracking methods** field.

**Specify Methods to Track Users**

If your application is not supported by the defaults, no user details are displayed in the workspaces and the usernames are missing. Add the methods by which you would like users to be tracked.

Delete
Add

| <input type="checkbox"/> Tracking Type | Tracking Value                          |
|--|---|
| <input type="checkbox"/> Form Post     | <input type="text" value="i_username"/> |
| <input type="checkbox"/> Basic Auth    |   |

Finished

- b) In the **Specify Methods to Track Users** window, click **Add**.
  - c) From the **Tracking Type** list, select the tracking type. For example, Header.
  - d) In the **Tracking Value** field, specify a value. For example, username.
  - e) Click **Finished**.
5. In the agent configuration page, click **Apply Changes**.

## Results

Applications using the newly specified tracking methods are displayed in the Application Dashboard.

## What to do next

Test that the user IDs and session information from your application are displayed in the Application Dashboard.

## Specifying unique managed system name for the Response Time Monitoring agent

The Response Time Monitoring agent instance name displayed on the Cloud APM console is also known as the managed system name(MSN). You can use the agent configuration parameter to specify unique MSN for each agent instance.

### About this task

The managed system name for the Response Time Monitoring agent is in the following format:

```
instancename:hostname:T5
```

T5 is the product code for the Response Time Monitoring agent.

### Procedure

1. Stop all existing agent instances. If you do not have any existing agent instances, proceed to the next step. For more information about stopping agent instances, see [“Using agent commands” on page 236](#).
2. Linux UNIX Change **CTIRA\_SUBSYSTEM\_ID** in the runagent file. Normally all agent instances on a machine use the same hostname value.
  - a) Make a backup copy of the file:

```
Linux | UNIX install_dir/platform/t5/bin/runagent
```

b) Edit the file. Add *newinstancename* on Linux or AIX systems.

```
Linux | UNIX CTIRA_SUBSYSTEM_ID=newsubsystemid
```

3. Start existing instances of the agent.

4. Start the Cloud APM console. Modify your applications by removing the agent instances under the old MSNs and adding the new agent instances.

## Configuring Ruby monitoring

You can monitor both on-premises and IBM Cloud Ruby applications. To monitor on-premises Ruby applications, configure the Ruby agent. To monitor IBM Cloud Ruby applications, configure the Ruby data collector.

### About this task

The following procedure is a roadmap for configuring the Ruby agent and the Ruby data collector, which includes both required and optional steps. Complete the configuration steps according to your needs.

### Procedure

- To monitor on-premises Ruby applications, complete the following steps to configure the Ruby agent:
  - a) Configure agent instances to monitor Ruby applications. See [Configuring the Ruby agent to monitor Ruby applications](#).
  - b) Install the data collector for monitoring data to display in Cloud APM console. See [Installing the data collector](#).
  - c) Optional: If you are a Cloud APM, Advanced user, you can complete the following tasks according to your needs:
    - To configure the data collector to collect diagnostics data, see [Configuring the diagnostics data collector](#).
    - To enable method trace for requests and adjust the length for the file path parameter that is displayed in the Request Stack Trace widget, see [Enabling method trace and adjusting the path display](#).
    - To increase the JVM heap size to avoid the out of memory error, see [Increasing the JVM heap size](#).
    - To disable diagnostics, see [Disabling or enabling diagnostics data for Ruby applications](#).
- To monitor IBM Cloud Ruby applications, complete the following tasks to configure the Ruby data collector:
  - a) Configure the Ruby data collector for IBM Cloud applications. For instructions, see [“Configuring the Ruby data collector for IBM Cloud applications”](#) on page 817.
  - b) Optional: To change the behavior of the Ruby data collector, see [“Customizing the Ruby data collector for IBM Cloud applications”](#) on page 818.

## Configuring the Ruby agent

To have the Ruby agent monitor your applications, specify the Ruby run time. As a result, you use the run time to gather data from the Ruby applications and to configure the agent.

### Before you begin

Determine the server that you use to start Ruby applications, and the qualified bin directory for the Ruby or Rake executable that the agent uses:

1. To determine the application server that you are using, run the following command:

```
ps -ef | grep ruby
```

You see the name of the server that is used to start your application. The possible server names are listed as follows:

- Passenger
- Unicorn
- Puma
- Thin

If the command output does not indicate the server names that are shown in the preceding list, the server that you use to start the application might be WEBrick.

**Important:** If you use multiple web servers to start your Ruby applications, you must create one agent instance for each application web server, for example, one instance for PUMA and one for Unicorn.

2. To determine the qualified bin directory for the Ruby or Rake executable that the Ruby agent uses, run the following command:

```
which ruby
```

## About this task

You can repeat this task to configure multiple agent instances according to your needs.

## Procedure

1. To configure the agent, run the following command:

```
install_dir/bin/ruby-agent.sh config instance_name
```

where *instance\_name* is the name you want to give to the instance, and *install\_dir* is the installation directory of the Ruby agent. The default installation directory is `/opt/ibm/apm/agent`.

**Important:** Do not specify a long instance name. The total length of your host name and the agent instance name must not exceed 28 characters. If the length exceeds the limit, the Managed System Name is truncated, and the product code for the Ruby agent does not display correctly.

The Managed System Name includes the instance name that you specify, for example, *instance\_name: host\_name: pc*, where *pc* is your two character product code for the agent. For example, if you specify Ruby2 as your instance name, your managed system name is Ruby2: hostname: KM, where *KM* is the two character product code for the Ruby agent.

2. When you are prompted with Edit 'Monitoring Agent for Ruby' settings, enter 1 to continue.
3. When you are prompted with Fully Qualified Rubies Bin Directory, specify the binary directory. for example, if you use Ruby Version Manager (RVM), enter `/usr/local/rvm/rubies/ruby-2.0.0-p247/bin`.
4. When prompted with Auto Detect Ruby Applications Flag, enter Y to continue. The agent receives the data that the agent data collector sends.
5. When you are prompted with Application Server Process name, press Enter to accept the default of ruby, or specify the value for the server that you use according to the following list:
  - For WEBrick servers, accept the default or specify `ruby`; if Rails is installed by Ruby Stack, specify `.ruby.bin`.
  - For Passenger servers, specify `passenger`.
  - For Unicorn servers, specify `unicorn`.
  - For Puma servers, specify `puma`.

- For Thin servers, if the applications are started by running the command `thin start`, accept the default to use `ruby`; if the applications are started by running the command `thin start -d`, specify `thin`; if Rails is installed by Ruby Stack and the applications are started by running the command `thin start`, specify `.ruby.bin`.
6. When you are prompted with `Socket Data Source`, press Enter to accept the default of 0 to use the ephemeral port.
  7. When you are prompted with `Edit 'Application' settings`, enter 5 to exit the setting.
  8. To start the agent, run the following command:  
`install_dir/bin/ruby-agent.sh start instance_name`

## What to do next

Install the data collector for the Ruby agent to work properly and for the data to display in Cloud APM UI. For instructions, see [Installing the data collector](#)

## Installing the data collector

You must install the data collector for the agent to work properly. After you install the data collector, monitoring data is displayed on the Application Performance Dashboard.

### Before you begin

If you installed your Ruby on Rails application on a Linux system by using a non-root account, and you plan to collect diagnostics data, the non-root user must have access to the diagnostics data collector home directory. Verify that the non-root user has read and write access in the `install_dir/install-images/kkm` directory, where `install_dir` is the installation directory of the Ruby agent. The default installation directory is `/opt/ibm/apm/agent`. If required, provide read and write permissions by using the `chmod 777` command.

## Procedure

1. Stop your Ruby on Rails application.
2. Optional: If you are upgrading the Ruby data collector to a new version, you must first uninstall the old version data collector by running the following command:

```
gem uninstall stacktracer
```

3. Install the diagnostics data collector. Enter `gem install --local install_dir/1x8266/km/bin/stacktracer-version.gem`, where `version` is the version number, and `install_dir` is the installation directory of the Ruby agent. The version number in the name of the `stacktracer-version.gem` file in the agent installation directory indicates the version number that you need to enter here. The default installation directory is `/opt/ibm/apm/agent`.

**Important:** Install the data collector as the same user when you install and run the Ruby on Rails application.

4. Navigate to the home directory of your application, open its `Gemfile`, and add the following line to the end of the file: `gem 'stacktracer', 'version'` where `version` is the version number of the data collector. The version number is indicated in the name of the `stacktracer-version.gem` file that is in the `install_dir` of the Ruby agent. For example, if you install the Ruby data collector Version 1.0 Fix Pack 8, you can find a `stacktracer-01.00.08.00.gem` file in the installation directory of you agent. And then you add the `gem 'stacktracer', '01.00.08.00'` line to your application to install the data collector.

**Note:** If there is only one version of `stacktracer` in the environment, add the `gem 'stacktracer'` line to the end of the file. Do not specify the version number in the line.

5. In the home directory of your application, enter `bundle install`.
6. Restart your Ruby on Rails application.

## Results

The data collector is installed and configured and your Ruby on Rails application is started.

## What to do next

- If you are not logged in, follow the instructions in [“Starting the Cloud APM console”](#) on page 1109. Select  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard, and drill down to the Ruby App resource monitoring dashboards and diagnostic dashboards to observe your Ruby on Rails applications from the status summary overview down to individual request instances.
- To see and modify the settings for the diagnostics data collector, continue to the next topic, [“Configuring the diagnostics data collector”](#) on page 813.
- To display method trace data for requests in Cloud APM UI, see [Enabling method trace and adjusting the path display](#).
- When method trace is enabled or the data requests are large, you might receive out of memory errors. You can increase JVM heap size to avoid these errors. See [Increasing the JVM heap size](#).
- You can disable and enable diagnostics data collection for one or more managed Ruby on Rails applications at any time through the Cloud APM console. See [“Disabling or enabling diagnostics data for Ruby applications”](#) on page 817. This function is not available for resource monitoring.

## Configuring the diagnostics data collector

If you are a user of Cloud APM, Advanced, you can continue to configure the data collector for diagnostics data. Diagnostics data collection is disabled by default in the data collector configuration file.

### Before you begin

You must have installed the diagnostics data collector and configured support for the collection of diagnostics data, as described in [“Installing the data collector”](#) on page 812.

### About this task

The `instrumenter_settings.rb` configuration file appears after the agent registers a Ruby on Rails application's existence by properly configuring the Gemfile. This configuration file can be modified while the Ruby agent is running, and the changes are picked up automatically. Alternatively, you can apply the changes to all Ruby on Rails applications that are being monitored, which requires the applications to be stopped while you edit the configuration file.

## Procedure

- To modify the data collector settings of a specific application that is running:
  1. Navigate to the `install_dir/install-images/kkm/dchome/appClassName/config` directory, where `appClassName` is the Ruby application class name, and `install_dir` is the installation directory of Ruby agent. The default installation directory is `/opt/ibm/apm/agent`.
  2. Open `instrumenter_settings.rb` in a text editor.
  3. Modify the data collector settings:

**:instrumentation\_enabled**  
To enable support for the collection of diagnostics data, set `:instrumentation_enabled => true`.  
To disable support for the collection of diagnostics data, set `:instrumentation_enabled => false`.

**:sample\_frequency**  
To modify the sampling frequency of requests, enter the number of requests between samplings.

The data collector collects diagnostic data only for sampled requests. If you set `:sample_frequency => 10`, for example, data is collected for 1 in every 10 requests.

#### **:max\_methods\_to\_instrument**

To disable method trace collection or to enable method trace collection and limit the number of methods that are traced, set the value to zero, or enter the maximum number of methods to trace.

To disable the collection of method traces, set `:max_methods_to_instrument => 0`.

To enable the collection of method traces, set `:max_methods_to_instrument => 10000`. The value can be higher, but a much higher value might cause performance issues. When method data is collected, calls to methods are included in the Request Traces dashboard's Method Trace widget, which shows all the request instances and their nested requests.

#### **:min\_wallclock\_to\_include\_in\_trace**

To modify the threshold that determines whether the request or method should be traced, set the minimum response time. If you set `:min_wallclock_to_include_in_trace => 0.001`, for example, only the requests and methods whose response times are longer than 1 millisecond are traced.

**Remember:** From the **Request Trace** diagnostic dashboard, you can drill down to a specific request instance from the Request Stack Trace group widget. The response times totals for the instance might be incorrect due to the filters set for `:min_wallclock_to_include_in_trace` and `:min_wallclock_to_include_stacks`, which can exclude some data.

#### **:min\_wallclock\_to\_include\_stacks**

To modify the threshold that determines whether the stacktrace information should be collected for a request or a method, set the minimum response time.

If you set `:min_wallclock_to_include_stacks => 0.1`, for example, the stacktrace information is collected for all the requests and methods whose response time is longer than 100 milliseconds.

#### **:include\_subclasses\_of\_these\_modules**

The Request Traces diagnostics dashboard helps you to identify the sequence of calls to nested requests and methods for a request instance. The data collector preemptively filters out methods from classes that are not included in the filter list. If operations that you want to trace are not included in the method stack traces, you can add them here.

To specify the methods to trace, add their class names.

Consider, for example, that you want to trace the Moped APIs in the following kind of Ruby code:

```
session = Moped::Session.new(['ip:27017'])
session.use(:HR)
session[:profiles].insert({...})
session[:profiles].find {...}.remove
```

Add the module names of these Moped APIs to the property:

```
:include_subclasses_of_these_modules => {
  ActionController => true,
  "ERB" => true,
  "erb" => true,
  "Arel" => true,
  "Mongoid" => true,
  "Moped" => true
},
```

**Restriction:** The method traces do not include class methods and private methods (methods defined in a class that have implicit or explicit "private" access specifiers).

#### **:include\_sql\_text**

To collect context data for methods, set this property to `true`.

### **:num\_samples\_per\_file**

To modify the maximum number of traced requests to store in each file, enter a value such as `:num_samples_per_file => 1000`. After the limit set here is reached, a new file is created.

Consider setting `:num_samples_per_file` to a lesser value if you adjust the configuration in a way that causes more data to be collected. For example, setting `:include_subclasses_of_these_modules` to trace more classes and methods can increase data collection. Setting any of the following properties to a lower value can also increase data collection: `:sample_frequency`, `:min_wallclock_to_include_in_trace`, and `:min_wallclock_to_include_stacks`.

### **:verbose\_request\_instrumentation**

### **:verbose\_class\_instrumentation**

### **:verbose\_method\_instrumentation**

To increase the logging level of the diagnostics data collector, set these properties to `true`.

**Tip:** If operations that you specifically want to trace are not included in the method stacktraces, set `:verbose_class_instrumentation => true` and check the log to find out whether the class that you want to trace is instrumented. If it is not instrumented, add the class name of the module name of the class to the `:include_subclasses_of_these_modules` property.

4. If you edited any of the following properties, restart the corresponding Ruby on Rails application to have your changes take effect:

```
:include_subclasses_of_these_modules
:max_methods_to_instrument
```

The restart is necessary because these properties are used only when an application is launched to determine which class or method is to be instrumented by the Ruby data collector.

- To modify the data collector settings of all Ruby on Rails applications, complete these steps:
  1. Stop any Ruby on Rails applications that are currently running.
  2. Remove the `instrumenter_settings.rb` from the `install_dir/install-images/kkm/dchome/application_name/config` directory.
  3. Modify the data collector settings in `Gem_dir/gems/stacktracer-version/config/instrumenter_settings_template.rb` where `version` is the version number, such as `01.00.05.00`, and `Gem_dir` is the installation directory of `stacktracer-version.gem`, such as `/usr/local/rvm/gems/ruby-2.1.4/`. For more information, see step “3” on page 813 in the procedure for modifying the data collector settings of a specific application.
  4. Restart any Ruby on Rails applications that are currently running.

## **Results**

The configuration of the diagnostics data collector has changed for the running application that you specified or for all applications.

## **Enabling method trace and adjusting the path display**

IBM Cloud Application Performance Management, Advanced Private with diagnostic data enables users to have a **Request Traces** dashboard. If method data is collected, calls to methods are shown. The **Method Trace** widget displays request instances and their nested requests. You can enable method trace to include calls to methods in the nested requests. You can also adjust the configuration of the **Request Stack Trace** widget to show more than the default 50 characters of each file path.

## **About this task**

Method trace is disabled by default. Complete the first procedure to enable method trace for display in the **Request Traces** dashboard. You can enable method trace by changing a setting in the configuration file.

Complete the second procedure to adjust the number of characters shown for the file path in the **Request Stack Trace** widget.

## Procedure

- To enable method trace, edit the `instrumenter_settings.rb` settings:
  - a) Locate the `instrumenter_settings.rb` file in the Ruby agent installation, for example, `install_dir/install-images/kkm/dchome/appClassName/config` where `appClassName` is the Ruby application class name, and `install_dir` is the installation directory of Ruby agent. The default installation directory is `/opt/ibm/apm/agent`.
  - b) Open `instrumenter_settings.rb` in a text editor.
  - c) Set the following property to 10000.

```
max_method_to_instrument
```

The value can be higher, but a much higher value might cause performance issues. (See also [“Increasing the JVM heap size”](#) on page 816.)

- d) Restart the Ruby on Rails applications to begin method data collection.
- For more information about all the `instrumenter_settings.rb` properties, see [“Configuring the diagnostics data collector”](#) on page 813.
- To adjust the file path display size in the **Request Stack Trace** widget, edit the `dfe.properties` file:
    - a) Locate the `dfe.properties` file in the Ruby agent installation, for example, `install_dir/1x8266/km/bin/dfe.properties` where `install_dir` is the installation directory of Ruby agent. The default installation directory is `/opt/ibm/apm/agent`.
    - b) Open `dfe.properties` in a text editor.
    - c) Change the maximum size of the file path to display in each stack trace element by adjusting the value of the following property:

```
dfe.stacktrace.filepath.maxsize
```

- d) Restart the Ruby agent.

## Increasing the JVM heap size

When method trace is enabled for the Ruby Diagnostics **Request Traces** dashboard or data requests are very large, you can increase the JVM heap size to avoid out of memory errors.

## About this task

The Ruby agent is an agent based on Java, and the default JVM heap size is 384 MB. Take these steps to increase the heap size and thus reduce the likelihood of the out of memory condition. The out of memory condition can occur from frequent large data requests and when you have method trace turned on.

## Procedure

1. Find the JVM heap size setting in the Ruby agent installation directory, for example, `install_dir/1x8266/km/bin/runDeepDiveClient.sh`  
Where `install_dir` is the installation directory of Ruby agent. The default installation directory is `/opt/ibm/apm/agent`.  
The default value is `-Xmx384m`.
2. Increase the value, for example, to 1024 MB, shown as `-Xmx1024m`:  
`export JAVA_OPT="-Djlog.common.dir=$CANDLEHOME/logs -DCONFIG_DIR=$DC_RUNTIME_DIR -Dkqe.cache.interval=60 -Xmx1024m -Dkqe.timespan=900 -Djlog.propertyFileDir.CYN=$CANDLEHOME/$ITM_BINARCH/$PRODUCT_CODE/bin"`

3. Restart the Ruby agent.

## Disabling or enabling diagnostics data for Ruby applications

If you have IBM Cloud Application Performance Management, Advanced Private, you can use the **Agent Configuration** page in the Cloud APM console to disable or enable diagnostics data collection at any time for one or more managed systems.

### Before you begin

- You must have Cloud APM, Advanced Private in your environment.

**Note:** This function is not available for IBM Monitoring.

- You must install and configure the Monitoring Agent for Ruby on a virtual machine, as described in [“Installing agents” on page 189](#) on AIX systems or [“Installing agents” on page 199](#) on Linux systems and in [“Configuring Ruby monitoring” on page 810](#).
- You must install the diagnostics data collector and configure support for the collection of diagnostics, as described in [“Installing the data collector” on page 812](#).

### About this task

After you configure support for diagnostics data in the data collector configuration, the collection of diagnostics data is disabled by default for each managed system. To display data in the diagnostics dashboards, you must enable the collection of diagnostics data for each managed system you are monitoring.

Take these steps to enable and disable the collection of diagnostics data for each managed system:

### Procedure

1. From the navigation bar, select  **System Configuration->Agent Configuration**.  
The **Agent Configuration** page is displayed.
2. Click the **Ruby** tab.
3. Select the check boxes of the managed systems on which you want to disable or enable diagnostics data collection.
4. From the **Actions** list, select one of the following options to disable or enable diagnostics data collection for the selected managed systems:
  - Select **Disable Data Collection**. The status in the Data Collector Enabled column is updated to No for each of the selected managed systems.
  - Select **Enable Data Collection**. The status in the Data Collector Enabled column is updated to Yes for each of the selected managed systems.

### Results

You configured the collection of diagnostics data for each of the selected managed systems.

## Configuring the Ruby data collector for IBM Cloud applications

To collect information about Ruby applications on IBM Cloud, you must configure the Ruby data collector.

### Before you begin

1. Download the data collector package from IBM Passport Advantage website. For detailed instructions, see [“Download instructions” on page 131](#).
2. Configure the data collector package by running the `make_configuration_packages.sh` and `configure_agent_images.sh` scripts on the system where the Cloud APM server is installed. For detailed instructions, see [“Configuring the downloaded images” on page 182](#).

## Procedure

1. Extract files from the data collector package. The `ruby_datacollector_8.1.4.0.tgz` package is included in the extracted directory.
2. Extract the files in `ruby_datacollector_8.1.4.0.tgz` by running the following command:

```
tar -zxvf ruby_datacollector_8.1.4.0.tgz
```

You get an `ibm_ruby_dc` folder.

3. Copy the entire `etc` folder in `ibm_ruby_dc` to the root folder of your Ruby application by running the following command:

```
cp -r directory to the etc folder home directory of your Ruby application
```

The following command extract the data collector to the `/opt/ibm/ccm/ibm_ruby_dc/etc` directory and the home directory of your Ruby application is `/root/ruby_app/`:

```
cp -r /opt/ibm/ccm/ibm_ruby_dc/etc /root/ruby_app/
```

4. Add the following section to the `Gemfile` in the home folder of your Ruby application:

```
gem 'logger', '>= 1.2.8'
source 'https://maagemserver.ng.bluemix.net/' do
  gem 'ibm_resource_monitor'
  gem 'stacktracer'
end
```

5. Run the `bundle lock` command to regenerate the `Gemfile.lock` file.
6. From the directory that contains the `manifest.yml` file of your Ruby application, run the following command:

```
cf push
```

**Tip:** For a sample `manifest.yml` file, see [“Sample manifest.yml file” on page 262](#).

## Results

The data collector is configured and is connected to the Cloud APM server.

## What to do next

You can verify the monitoring data for your IBM Cloud application is displayed in the Cloud APM console. For instructions on how to start the Cloud APM console, see [Starting the Cloud APM console](#). For information about using the Applications editor, see [Managing applications](#).

## Customizing the Ruby data collector for IBM Cloud applications

You can add environment variables in the IBM Cloud user interface (UI) to customize the monitoring for your IBM Cloud application. Use the following information to add the variables according to your needs.

## User-defined environment variables for the Ruby data collector

You can use the information in the following table to customize Ruby monitoring on IBM Cloud.

Table 226. Supported user-defined environment variables for Ruby monitoring on IBM Cloud

| Variable name                 | Importance | Value  | Description  |
|-------------------------------|------------|--|--|
| APM_BM_GATEWAY_URL            | Optional   | <ul style="list-style-type: none"> <li>https://&lt;server ip or hostname&gt;:443</li> <li>http://&lt;server ip or hostname&gt;:80</li> </ul> | The target on-premises server gateway URL.   |
| APM_KEYFILE_PSWD              | Optional   | Encrypted password of the key file   | <p>The encrypted key file password that is paired with the key file. If you are a Linux user, you can use the <code>echo -n &lt;keyfile password&gt;   base64</code> command to encrypt your password.</p> <p><b>Note:</b> Set this variable only when you configured the Gateway to use HTTPS.</p>  |
| APM_KEYFILE_URL               | Optional   | http://<hosted http server>:<port>/keyfile.p12   | <p>The URL to download the key file.</p> <p><b>Note:</b> Set this variable only when you configure the Gateway to use HTTPS.</p>   |
| kkm_instrumentation_enabled   | Optional   | <ul style="list-style-type: none"> <li>true</li> <li>false</li> </ul>  | <p>Enables or disables the collection of diagnostics data.</p> <p>true: If you set the value to true, diagnostics data are collected.</p> <p>false: If you set the value to false, diagnostics data are not collected.</p> <p>The default value is true.</p>   |
| kkm_max_methods_to_instrument | Optional   | Maximum number of methods that are traced  | <p>The maximum number of methods that are traced.</p> <p>You can disable method trace by setting the value to 0.</p> <p>By default, the value is 10000 and method trace is enabled.</p> <p><b>Note:</b> It is recommended that you do not set the value higher than 10000. A value much higher than 10000 might decrease application execution efficiency.</p> |

| Table 226. Supported user-defined environment variables for Ruby monitoring on IBM Cloud (continued) |            |   |  |
|--|------------|---|--|
| Variable name  | Importance | Value   | Description  |
| kkm_sample_frequency   | Optional   | Sampling frequency of requests                                  | The number of requests from which a sample request is taken, for example, if you set the value to 10, monitoring data is collected for one in every 10 requests.<br><br>The default value is 10.   |
| kkm_min_wallclock_to_include_in_trace  | Optional   | Response time threshold for collecting method trace, in seconds | If the response time of a request instance exceeds the value of this variable, the data collector collects its method trace. If you set it to 0.001, for example, requests and methods whose response time is longer than 1 millisecond are traced.<br><br>The default value is 0, which means method trace is enabled for all requests and methods. |
| kkm_min_wallclock_to_include_stack   | Optional   | Response time threshold for collecting stack trace, in seconds  | If the response time of a request instance exceeds the value of this variable, the data collector collects its stack trace. If you set it to 0.001, for example, requests and methods whose response time is longer than 1 millisecond are traced.<br><br>The default value is 0, which means stack trace is enabled for all requests and methods.   |

## Unconfiguring the Ruby data collector for IBM Cloud applications

If you do not need to monitor your Ruby environment or if you want to upgrade the Ruby data collector, you must first unconfigure previous settings for the Ruby data collector.

### Procedure

1. Go to the application root folder.
2. Remove the following lines from the Gemfile in the home folder of your Ruby application:

```
gem 'logger', '>= 1.2.8'
source 'https://maagemserver.ng.bluemix.net/' do
  gem 'ibm_resource_monitor'
  gem 'stacktracer'
end
```

3. Run the `bundle lock` command.
4. From the application home directory, run the following command to re-push the application to IBM Cloud for the changes to take effect.

```
cf push
```

## Results

You have successfully unconfigured the Ruby data collector.

## What to do next

After you unconfigure the data collector, the Cloud APM console continues to display the data collector in any applications that you added the data collector to. The Cloud APM console will show that no data is available for the application and will not indicate that the data collector is offline. For information about how to remove the data collector from applications and from resource groups, see [“Removing data collectors from Cloud APM console” on page 262](#).

## Configuring SAP monitoring

---

To monitor a SAP system, the Monitoring Agent for SAP Applications must connect to an application server in the system to be monitored so that the agent can access the Advanced Business Application Programming (ABAP) code that is provided with the product.

### Before you begin

- Review the hardware and software prerequisites, see [Software Product Compatibility Reports for SAP agent](#)
- The SAP agent does not support non-unicode SAP systems.
- To monitor SAP S/4 HANA 2020 with SAP Basis version 755, implement SAP Note 2767860 on the SAP system.

### About this task

The SAP agent is a multiple instance agent; you must create the first instance and start the agent manually.

- To configure the agent on Windows systems, you can use the **IBM Performance Management** window or the silent response file.
  - [“Configuring the agent on Windows systems” on page 822](#)
  - [“Configuring the agent by using the silent response file” on page 824](#)
- To configure the agent on Linux or AIX systems, you can run the script and respond to prompts, or use the silent response file.
  - [“Configuring the agent on Linux or AIX systems” on page 823](#)
  - [“Configuring the agent by using the silent response file” on page 824](#)

After you install the SAP agent, you can import the Advanced Business Application Programming (ABAP) transport on the SAP system to support data collection in the SAP system. For more information, see [“Importing the ABAP transport on the SAP system” on page 830](#).

After you configure the SAP agent, you must verify the agent configuration. For more information, see [“Verifying agent configuration” on page 837](#).

After you configure the SAP agent, you can add Database Communication Port number that is required for OSLC (Open Source Lifecycle Collaboration) compliance. For more information, see [“Adding Database Communication Port number” on page 841](#).

To delete the ABAP transport from the SAP system, you must import delete transport to the SAP system. For more information, see [“Deleting the ABAP transport from the SAP system” on page 836](#).

The new CCMS design is enabled by default. Entry is present in the database table/IBMMON/ITM\_CNGF for isnewccmsdesign parameter whose value is set to YES.

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see

Agent version command. For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

## Configuring the agent on Windows systems

You can configure the SAP agent on Windows systems by using the **IBM Performance Management** window so that the agent can collect data of the SAP Applications Server that is being monitored.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Template** under the **Task/SubSystem** column, and click **Configure Using Defaults**.

The **Monitoring Agent for SAP Applications** window opens.

3. In the **Enter a unique instance name** field, type an agent instance name and click **OK**.

**Important:** The agent instance name must match the 3-digit system identifier (SID) of the managed SAP Applications Server. For example, if the SID of the managed SAP Applications Server is PS1, enter PS1 as the instance name.

4. Configure the SAP agent in the Application Server mode or the Logon Group mode.

- Complete the following steps to configure the SAP agent in the Application Server mode:
  - a. In the **Connection Mode** field, select **Application Server Mode** and click **Next**.
  - b. In the **Specify Application Server Information** area, specify values for the configuration parameters and click **Next**.
  - c. In the **Specify Logon Information to the SAP System** area, specify values for the configuration parameters and click **OK**.

For information about the configuration parameters, see [“Configuration parameters of the agent”](#) on page 824

- Complete the following steps to configure the SAP agent in the Logon Group mode:
  - a. In the **Connection Mode** field, select **Logon Group Mode** and click **Next**.
  - b. In the **Specify Logon Group Information** area, specify values for the configuration parameters and click **Next**.
  - c. In the **Specify Logon Information to the SAP System** area, specify values for the configuration parameters and click **OK**.

For information about the configuration parameters, see [“Configuration parameters of the agent”](#) on page 824

**Important:** For the Application Server mode, it is mandatory to configure the Dialog Instance having dispatcher on the SAP system where the message server or ASCS is configured. For the Logon Group mode, it is not mandatory to configure the Dialog Instance having dispatcher on the SAP system where the message server or ASCS is configured.

5. In the **IBM Performance Management** window, right-click the agent instance that you created and click **Start**.

**Important:** If you want to create another instance of the SAP agent, repeat Steps 1 to 6. Use a unique system identifier for each SAP agent instance that you want to create.

### What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console”](#) on page 1109.
- You must edit the predefined R3\_Alert\_Crit situation and R3\_Alert\_Warn situation to set the condition of Alert Status attribute as `Alert Status != DONE` so that these situations do not get triggered for closed CCMS alerts.

## Configuring the agent on Linux or AIX systems

You can configure the SAP agent on Linux or AIX systems so that the agent can collect data of the SAP Applications Server that is being monitored.

### Procedure

1. On the command line, change the path to the agent installation directory.  
Example: `/opt/ibm/apm/agent/bin`
2. Run the following command where `instance_name` is the name that you want to give to the instance:  
`./sap-agent.sh config instance_name`  
**Important:** The agent instance name must match the 3-digit system identifier (SID) of the managed SAP Applications Server. For example, if the SID of the managed SAP Applications Server is PS1, enter PS1 as the instance name.
3. When the command line displays the following message, type 1 and press Enter: Edit 'Monitoring Agent for SAP Applications' setting? [1=Yes, 2=No]
4. Configure the SAP agent by using the Application Server mode or the Logon Group mode.
  - Complete the following steps to configure the SAP agent in the Application Server mode:
    - a. When the command line displays the following message, type 1 and press Enter: Connection Mode [ 1=Application Server Mode, 2=Logon Group Mode ]
    - b. Specify values for the configuration parameters.  
For information about the configuration parameters, see ["Configuration parameters of the agent" on page 824](#)
  - Complete the following steps to configure the SAP agent in the Logon Group mode:
    - a. When the command line displays the following message, type 2 and press Enter: Connection Mode [ 1=Application Server Mode, 2=Logon Group Mode ]
    - b. Specify values for the configuration parameters.  
For information about the configuration parameters, see ["Configuration parameters of the agent" on page 824](#)
5. Run the following command to start the SAP agent:  
`./sap-agent.sh start instance_name`  
**Important:** If you want to create another instance of the SAP agent, repeat Steps 1 to 5. Use a unique System Identifier for each SAP agent instance that you create.

### What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see ["Starting the Cloud APM console" on page 1109](#).
- You must edit the predefined R3\_Alert\_Crit situation and R3\_Alert\_Warn situation to set the condition of Alert Status attribute as `Alert Status != DONE` so that these situations do not get triggered for closed CCMS alerts.

## Configuring the agent by using the silent response file

You can configure the SAP agent on Windows, Linux, or AIX systems by using the silent response file.

### Procedure

1. In a text editor, open the `sap_silent_config.txt` file that is available at the `install_dir\samples` path, and specify values for all the configuration parameters.

**Windows** `C:\IBM\APM\samples`

**Linux** **UNIX** `/opt/ibm/apm/agent/samples`

For information about the configuration parameters, see [“Configuration parameters of the agent” on page 824](#)

2. On the command line, change the path to the bin directory:

**Windows** `install_dir\BIN`

**Linux** **UNIX** `install_dir\bin`

3. Run the following command:

**Windows** `sap-agent.bat config instance_name install_dir\samples\sap_silent_config.txt`

**Linux** **UNIX** `sap-agent.sh config instance_name install_dir\samples\sap_silent_config.txt`

**Important:** The agent instance name must match the 3-digit system identifier (SID) of the managed SAP Applications Server. For example, if the SID of the managed SAP Applications Server is PS1, enter PS1 as the instance name.

4. Start the agent.

**Windows** In the **IBM Performance Management** window, right-click the agent instance that you created, and click **Start**.

**Linux** **UNIX** Run the following command: `./sap-agent.sh start instance_name`

**Important:** If you want to create another instance of the SAP agent, repeat Steps 1 to 4. Use a unique System Identifier for each SAP agent instance that you create.

### What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).
- You must edit the predefined R3\_Alert\_Crit situation and R3\_Alert\_Warn situation to set the condition of Alert Status attribute as `Alert Status != DONE` so that these situations do not get triggered for closed CCMS alerts.

## Configuration parameters of the agent

When you configure the SAP agent, you can change the default value of the parameters, such as the SAP hostname and the SAP system number.

The following table contains detailed descriptions of configuration parameters of the SAP agent.

Table 227. Names and descriptions of configuration parameters of the SAP agent

| Parameter name                  | Description   | Mandatory field | Examples           |
|---------------------------------|---|-----------------|--------------------|
| SAP Hostname (Primary)          | The host name of the SAP application server to which the agent connects. If your SAP servers communicate over a private LAN, the computers that host the servers have two or more network cards. For the host name, enter a name by which the application server can be reached from external systems, such as the SAPGUI logon. Do not use the private LAN host name. The default value is the host name where the agent is installed. | Yes             | saphost.domain.com |
| SAP System Number (Primary)     | The two-digit SAP system or instance number that is used for connecting to a SAP host server. The default value is 00.  | Yes             |                    |
| SAP Hostname (Alternate 1)      | The second choice for the host name if the primary host is unavailable.   | No              |                    |
| SAP System Number (Alternate 1) | The system number for the host name of the first alternate.   | No              |                    |
| SAP Hostname (Alternate 2)      | The third choice for the host name if both the SAP Hostname (Primary) and SAP Hostname (Alternate 1) hosts are unavailable.   | No              |                    |
| SAP System Number (Alternate 2) | The system number for the host name of the second alternate.  | No              |                    |
| SAP Client Number               | The SAP client number for the RFC logon to SAP. The default value is 000. If the IBMMON_AGENT user that is generated by ABAP is used, enter the client number that was specified in the transport import. This number is the same as the nnn client number under the profile.   | Yes             |                    |
| SAP User Id                     | The SAP user ID for the RFC logon to SAP. The default value is IBMMON_AGENT, which is the predefined user ID that is created during the import.   | Yes             |                    |
| SAP User Password               | Use the default password or specify a different password.   | Yes             |                    |
| Confirm SAP User Password       | The password that is specified in the <b>SAP User Password</b> field.   | Yes             |                    |

Table 227. Names and descriptions of configuration parameters of the SAP agent (continued)

| Parameter name          | Description   | Mandatory field | Examples |
|-------------------------|---|-----------------|----------|
| SAP Language Code       | <p>The language code that indicates the language that the agent uses when it connects to the SAP system. The specified language determines the language in which you see SAP information, such as alert messages, syslog messages, and job log messages.</p> <p>All SAP systems are delivered in English and German. If you require a different language, confirm with your SAP administrator that the language is installed on the SAP system. If you specify a language that is not supported, the agent cannot connect to the SAP system.</p> <p>The following languages and codes are supported:</p> <ul style="list-style-type: none"> <li>• CS - Czech</li> <li>• EN - English</li> <li>• FR - French</li> <li>• DE - German</li> <li>• HU - Hungarian</li> <li>• IT - Italian</li> <li>• ES - Spanish</li> <li>• JA - Japanese</li> <li>• KO - Korean</li> <li>• PL - Polish</li> <li>• PT - Portuguese</li> <li>• RU - Russian</li> <li>• ZH - Chinese</li> <li>• ZF - Traditional Chinese</li> </ul> | Yes             |          |
| RFC Trace               | The Remote Function Call (RFC) trace setting for the <code>SAPTRACE</code> variable. When you select this check box, you activate the RFC tracing and the default value is no RFC tracing. For the command line, 2 = No trace and 1 = Do trace. Because the RFC tracing generates extensive diagnostic information, use it carefully. For more information about the RFC tracing, contact IBM support.  | No              |          |
| SAP Logon Group         | The name of the SAP Server Logon group.   | Yes             |          |
| SAP Message Server Name | The host name of the SAP message server.  | Yes             |          |

| Table 227. Names and descriptions of configuration parameters of the SAP agent (continued) |   |                 |   |
|--|---|-----------------|---|
| Parameter name   | Description   | Mandatory field | Examples  |
| SAP Message Service  | <p>The name of the service where the SAP message server is located.</p> <p>You must include service names in the following operating system services files:</p> <ul style="list-style-type: none"> <li>• /etc/services</li> <li>• \windows\system32\drivers\etc\services</li> </ul> | Yes             | You might use the message service name sapmsTV1, or the full message service port number 3601.  |
| SAP Route String   | Specify the SAP router string if you want access to the SAP server with a SAP router.   | No              | The router string /H/host/H/ must be in the following format: /H/beagle/H/brittany/H/ or /H/amsaix11.tivlab.raleigh.ibm.com/W/tivoli/H/amsaix25 |
| SNC  | Specify whether you want to enable or disable Secure Network Communications (SNC). Default value is disabled.   | Yes             | <b>sap_conn.sap_snc_mode</b><br>=true or false  |
| SNC Security Level   | The security level of SNC.  | Yes             | <b>sap_snc_mode1.sap_snc_qop</b> =QOP value.<br>Default value is 8.   |
| Client or Agent SNC Name   | The SNC name of the client or agent.  | Yes             | <b>sap_snc_mode1.sap_snc_client</b> =<br>Client SNC Name  |
| Partner or SAP Server SNC Name   | The SNC name of the partner or SAP Server.  | Yes             | <b>sap_snc_mode1.sap_snc_server</b> =<br>Server SNC Name  |
| SAP Cryptolibrary Path   | The path of SAP Cryptolibrary.  | Yes             | <b>sap_snc_mode1.sap_snc_library</b> =<br>Crypto library path   |

## Configuring local environment variables

You can configure local environment variables to change the behavior of the SAP agent.

### Procedure

1. On Windows systems, click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, from the **Actions** menu, click **Advanced > Edit ENV File**.

3. On Linux or UNIX systems, go to the command line and edit the `.sa.environment` file from the `<andle_home>/config` directory. Where, `andle_home` is the agent installation directory.

**Note:** The `.sa.environment` file is a hidden file.

4. In the environment variable file, enter values for the environment variables.

For information about the environment variables that you can configure, see [“Local environment variables”](#) on page 828.

## Local environment variables

You can change the behavior of the SAP agent by configuring the local environment variables.

### Variables for limiting the alerts to be cached by SAP Agent

To limit the alerts to be cached by SAP agent, use the following environment variables:

- **MAX\_CCMS\_ALERT\_THRESHOLD:** To set the number of ccms alerts that the SAP agent will cache, use the `MAX_CCMS_ALERT_THRESHOLD` variable. The default value is 1000.
- **MAX\_MAI\_ALERT\_THRESHOLD:** To set the number of mai alerts of each type that the SAP agent will cache, use the `MAX_MAI_ALERT_THRESHOLD` variable. The default value is 500.

### Variable to set the threshold for long running jobs

To set the threshold for long running jobs, use the following environment variables:

- **LONG\_RUNNING\_JOB\_THRESHOLD:** To set the threshold for duration (in hours) of long running jobs, use `LONG_RUNNING_JOB_THRESHOLD` variable. It is used for calculating the count of long running jobs greater than the threshold. Minimum value that can be set is 4 and maximum is 24. Default value of this parameter is 5.

### Variables to delete idx file at SAP Agent restart and SAP system restart

To delete IDX file at SAP Agent restart and SAP system restart, use the following environment variables:

- **DELETE\_IDXFILE\_AT\_AGENT\_RESTART:** This parameter enables the feature of IDX file deletion when SAP Agent is restarted. IDX file stores the timestamp. It is recommended to set the parameter value to N. When set to N, it collects all alerts from the timestamp stored in IDX file. If you want to collect all alerts after the SAP agent restart, set the value to Y.
- **DELETE\_IDXFILE\_AT\_SAP\_RESTART:** This parameter enables the feature of IDX file deletion when SAP System is restarted. It is recommended to set the parameter value to N. When set to N, it collects all alerts from the timestamp stored in IDX file. If you want to collect all alerts after the SAP system restart, set the value to Y.

### Variable to replace invalid characters with blank characters

To replace the invalid characters with blank characters, use the following environment variables:

- **SAP\_BLANK\_INVALID\_CHARACTERS:** This parameter enables the feature of replacing any invalid characters with blank characters. If it is set to Y, then SAP agent will replace invalid characters with blank characters. If its set to N, then SAP agent will not replace invalid characters with blank characters. Default value of this parameter is N. It is recommended to set as Y for UTF languages.

## SAP hostname is trimmed according to Managed System Name length limit

The Managed System Name of any resources that is published on APM console is limited to 32 characters. The SAP agent supports the trimming of domain name to form the Managed System Name within the limit.

### Scenario 1

The Managed System Name for sub-node of **Sys** type has the following format:

*SID-DBHOST:Sys*

Where:

- The *SID* is the SAP system ID.
- The *DBHOST* is the SAP system hostname.

Example:

Given the *SID* is **P27** and the *DBHOST* is **VPT02F90.mycorporation.co.in**, the fully qualified domain name (FQDN) of the Managed System Name that is formed would be **P27-VPT02F90.mycorporation.co.in:Sys**.

When the Managed System Name has more than 32 characters, SAP agent trims the domain name to form the Managed System Name **P27-VPT02F90:Sys**. The trimmed Managed System Name of the sub-node will be published on the APM console.

**Note:** If the Managed System Name length that includes the domain name is less than or equal to 32 characters, the FQDN of the Managed System Name will not be trimmed. The FQDN of the Managed System Name is published on the APM console accordingly.

The trimming of the domain name, when necessary to meet the Managed System Name length limit is applicable to all sub-node types published by SAP agent.

### Scenario 2

The Managed System Name for the agent instance sub-node **mySAP** has the following format:

*\$SAPSYSTEMNAME-\$dbhost:\$CTIRA\_HOSTNAME:mySAP*

Where:

- The *\$SAPSYSTEMNAME* is the agent instance name provided during configuration.
- The *\$dbhost* is the SAP system hostname.
- The *\$CTIRA\_HOSTNAME* is the agent machine hostname.

Example:

Given the *\$SAPSYSTEMNAME* is **SA2**, *\$dbhost* is **VPT02F90.mycorporation.co**, and the *\$CTIRA\_HOSTNAME* is **mysap1-v27.mycorp.co**, the fully qualified domain name (FQDN) of the Managed System Name that is formed would be **SA2-VPT02F90.mycorporation.co.in:mysap1-v27:mySAP**.

**Note:** The default domain name of the agent machine hostname is trimmed and it will be **mysap1-v27**.

The Managed System Name has more than 32 characters. Firstly, the SAP agent trims the domain name of the SAP system hostname to form **SA2-VPT02F90:mysap1-v27:mySAP**.

If the resultant Managed System Name remains exceeding 32 characters, the SAP agent will trim the trailing character(s) of the agent machine hostname to form the Managed System Name within 32 characters limit. Then, the Managed System Name of the sub-node is published on the APM console.

## SAP agent node name format under custom applications

From APM release 8.1.4.0.14, node name of SAP agent under custom applications will be displayed as given in this topic.

### Node Name format

| Table 228.              |   |  |  |
|-------------------------|---|--|--|
| Node Type               | Node Name and example   | Example of Old Node Name displayed under Overview Page | Example of New Node Name displayed under Overview Page |
| SAP System              | <SID> - <SAP Hostname>:Sys P35-ibm1089:Sys                                | ibm1089-SAP System                                     | P35-ibm1089-SAP System                                 |
| SAP Instance            | <SID> - <SAP Hostname>_<SID>_<Instance Number>:Ins P35-ibm1089_P35_02:Ins | ibm1089_P35_02-SAP Instance                            | P35-ibm1089_P35_02-SAP Instance                        |
| SAP Process Integration | <SID> - <SAP Hostname>:PI P35-ibm1089:PI                                  | ibm1089- SAP Process Integration                       | P35-ibm1089- SAP Process Integration                   |
| SAP Solution Manager    | <SID> - <SAP Hostname>:Slm P35-ibm1089:Slm                                | ibm1089- SAP Solution Manager                          | P35-ibm1089- SAP Solution Manager                      |

## Importing the ABAP transport on the SAP system

You can install one SAP agent for each SAP system where you import the Advanced Business Application Programming (ABAP) transport request to support data collection in the SAP system.

### Before you begin

Before you import ABAP transport on the SAP system, ensure that the following prerequisites are met:

- To import the product transport request, R3trans Version 01.07.04, or later is required because the Dynpro and Export and Import tables are incompatible. The basic operation of the agent is not affected by the Dynpro or Export and Import incompatibility issues; only the SAP configuration windows are affected.
- You must ensure that you import the SAP agent V7.1.1 transport on the client where the MAI configuration is available to monitor the Solution Manager System. To view features of the PI system, import the SAP agent V7.1.1 transport on the PI system on a client where PI configuration is available.
- To view data in the group widgets that are under SLM subnode, you must complete the MAI configurations for PI and Solution Manager. You must also configure business process monitoring so that you can view data in the BPM Alerts group widget. To view data for the Latest Critical and High Priority Alerts group widget, make the following configurations:
  - In Solution Manager 7.1, run SOLMAN\_SETUP transaction and select **System Monitoring**, activate or enable the third-party component, and add **Implementation: BADI Definition for Alert Reactions** and third-party connector.
  - Set the scope filter to **All Alerts and Metrics**.
  - Ensure that the Implementation state is **Active**.

For more information, see the following Online Service System (OSS) Notes, which include a list of required SAP service pack levels:

- OSS Note 454321
- OSS Note 330267
- OSS Note 743155
- To monitor the SAP systems, the SAP agent needs the SAP statistics data. On SAP 7.0 systems, you must set the SAP system time zone to match the time zone for the operating system so that SAP statistics are collected with the correct time stamps. Similarly, update the SAP system time zone for the SAP agent so that the agent can collect data. For more information about this issue, see SAP Note 926290.

## About this task

For information about importing the SAP transport, see [“Importing the SAP transport”](#) on page 832.

## MAI Alert related prerequisites for importing the ABAP transport

You must verify the MAI Alert related prerequisites before you import the ABAP transport.

### Configuration settings in the `transport.prop` file

When you use the new MAI Alert fetching mechanism that includes fetching MAI Alerts without configuring email notification settings and without BAdi implementation, then you must modify the following configuration setting in the `transport.prop` file.

Add the `SPLEVEL=X` line, where X is the support pack (SP) level of the Solution Manager system.

For example, if the System ID is S10 and the support pack level is 13, then add `SPLEVEL=13`.

**Important:** For the SAP system with SP level 10, or later, the value of the Technical Name (MEA) attribute is not populated on the Latest MAI Alerts with Rating 'Red' group widget in the SAP Solution Manager Dashboard when the MAI Alerts are fetched without configuring email notification in the SAP Solution Manager and without BAdi implementation. The value of the Technical Name (MEA) attribute is populated on the Latest MAI Alerts with Rating 'Red' group widget in the SAP Solution Manager Dashboard when the MAI Alerts are fetched by configuring email notification in the SAP Solution Manager and BAdi implementation.

## Determination of old and new mechanism for fetching MAI Alerts based on the Solution Manager Support Pack (SP) Level

### Old MAI Alert fetching mechanism

This mechanism is based on configuring email notification settings and the `/IBMMON/ITM_IMPL_ALRTINBX` BAdi implementation with the `IF_ALERT_DYN_COFIGURATION` interface to collect MAI Alerts and send them to the SAP agent.

### New MAI Alert fetching mechanism

This mechanism is based on fetching MAI Alerts without configuring email notification settings and without the `/IBMMON/ITM_IMPL_ALRTINBX` BAdi implementation with the `IF_ALERT_DYN_COFIGURATION` interface.

You can use the following table to understand the usage of the `transport.prop` file and its dependency on the configuration of email notification settings.

Table 229. Usage of transport.prop file and its dependencies

| SAP system SP Level | transport.prop settings   |                           | Configuration of email notification settings | MAI Alert mechanism to be used   |
|---------------------|---------------------------|---------------------------|--|--|
|                     | MAI_CONFIGURED            | Solution Manager SP level |  |  |
| Any                 | No or file does not exist | Not Applicable            | Configured or not configured                 | The SLM subnode does not appear instead the SOL subnode appears.                                   |
| SP 6 through 9      | Yes                       | Mentioned                 | Configured                                   | Old mechanism  |
| SP 6 through 9      | Yes                       | Not mentioned             | Configured                                   | Old mechanism  |
| SP 6 through 9      | Yes                       | Not mentioned             | Not configured                               | Old mechanism does not work because the configuration of email notification settings is mandatory. |
| SP 6 through 9      | Yes                       | Mentioned                 | Not configured                               | Old mechanism does not work because the configuration of email notification settings is mandatory. |
| SP 10, or later     | Yes                       | Mentioned                 | Configured                                   | New mechanism  |
| SP 10, or later     | Yes                       | Mentioned                 | Not configured                               | New mechanism  |
| SP 10, or later     | Yes                       | Not mentioned             | Configured                                   | Old mechanism  |
| SP 10, or later     | Yes                       | Not mentioned             | Not configured                               | Old mechanism does not work because the configuration of email notification settings is mandatory. |

## Importing the SAP transport

The SAP agent provides a set of Advanced Business Application Programming (ABAP) routines to support data collection in the SAP system. This ABAP code is delivered as an SAP transport that must be installed on each SAP system that is to be monitored. Your SAP administrator installs the transport.

### About this task

The **ZITM\_610AUTH** authorization profile and **ZITM\_610AUT** authorization role are valid until the 6.1 release only. From release 6.2 or later, the **/IBMMON/AUTH** authorization profile is used. To protect against unauthorized use, the ABAP code that is installed in the SAP system is not visible from within the SAP system. In addition, this code cannot be modified or generated. You must obtain the support for this code from the IBM software support website.

In addition to installing ABAP code, the transport also installs translated language text elements to provide multicultural support for SAP transport text elements.

**Important:** Before you import the transport into the SAP system, you must not start the SAP agent instance that is configured to monitor the SAP system.

When you import the SAP transport, users get implicitly defined in the SAP system.

Use this procedure to import the SAP transport into the SAP system.

## Procedure

1. Copy the IBM Tivoli Monitoring transport file from the following paths on the computer where the agent is installed.
  - For Windows: `install_dir\TMAITM6_x64\ABAP`
  - For Non-Windows: `install_dir/intrp/sa/ABAP`, where `intrp` must be **1x8266** or **aix526**.
2. Copy the following transport files from the paths that are mentioned in step 1 into the SAP environment:
  - K711\_00xxxU.ITM and R711\_00xxxU.ITM  
These files are Unicode versions of the transport. They contain the SAP agent ABAP code and Unicode support for text strings for Latin code pages and double-byte code pages.
  - K711\_00xxx\_DELETE.ITM and R711\_00xxx\_DELETE.ITM  
These files remove the ABAP code. The DELETE transport does not need to be imported, unless you stop the use of product entirely and want to remove the transports from the SAP systems. See [“Deleting the ABAP transport from the SAP system” on page 836](#)
3. Copy your transport files to the SAP Transport System data directory as follows, and do not change the transport file name:  
Unicode transport
  - a. Copy the K711\_00xxxU.ITM file to the `cofiles` directory
  - b. Copy the R711\_00xxxU.ITM file to the `data` directory.
4. To install the single IBM Tivoli Monitoring transport file on the SAP system, select one of the following file import options:
  - For the SAP system that is a Solution Manager 7.1 Service Pack 6 level, or later and has MAI configured, you must create the `transport.prop` file in the `usr/sap/SID/DVEBMGSinstancenumber/work` work directory of the SAP system. If the SAP system is a distributed system with ABAP SAP Central Services (ASCS), create the `transport.prop` file in the Central Instance (CI) `usr/sap/SID` directory. Then, add `MAI_CONFIGURED = YES` entry in that file. This entry creates a `MAI_CONFIGURED = YES` entry in the `/IBMMON/ITM_CNFG` table. You can now import the single IBM Tivoli Monitoring transport file on the SAP system.  
**Note:** Before you import the single IBM Tivoli Monitoring transport file, you must create the `transport.prop` file in the `usr/sap/SID/DVEBMGSinstancenumber/work` work directory of the SAP system and add `MAI_CONFIGURED = YES` entry in that file. You must not edit the entry in the `/IBMMON/ITM_CNFG` table.
  - For all other SAP systems with basis version equal to 7.0, or later and Solution Manager V7.1 without MAI configuration, you must directly import the single IBM Tivoli Monitoring transport file.
5. Run the following command to import SAP transport:

```
tp addtobuffer ITMK711_00xxxU SID  
pf=\usr\sap\trans\bin\PROFILE_NAME
```

Where:

### SID

Target SAP system ID.

## PROFILE\_NAME

Name of the tp profile file. Make sure that the current tp parameter file is specified when you import the agent transport files from the command line. The tp parameter file is typically named TP\_DOMAIN\_SID.PFL. This file name is case sensitive on UNIX systems.

## nnn

Number for the target client where the agent runs and for which the user ID, IBMMON\_AGENT, authorization profile, and /IBMMON/AUTH, are defined.

Alternately, you can use the SAP STMS transaction to import the ITMK711\_00xxxU.ITM transport requests. Ensure that the following options are selected in the **Import Options** tab of the **Import Transport Request** window.

- **Leave Transport Request in Queue for Later Import**
- **Import Transport Request Again**
- **Overwrite Originals**
- **Overwrite Objects in Unconfirmed Repairs**

For the SAP Basis version, if the **Ignore Invalid Component Version** option is enabled, ensure that it is selected.

## Results

Depending on your SAP release level, when you run the **tp import** command, you might receive return code 4, which does not indicate a problem. Receiving return code 4 is an expected result from the **import** command.

## Users and authorizations required by the SAP agent

To safeguard against unauthorized access to the SAP system, you can assign authorizations to a user who logs in to the SAP system. These authorizations define the access levels for a user in the SAP system.

After you import the ABAP transport, the SAP agent creates the default user ID as IBMMON\_AGENT in the SAP system with the default password as ITMMYSAP. This user is a system user and the /IBMMON/AUTH authorization profile is associated with the user. The /IBMMON/AUTH profile and the IBMMON\_AGENT user are created after ABAP transport is imported. With the /IBMMON/AUTH profile, the IBMMON\_AGENT user can access transactions that are required to read performance data from the SAP system. Some examples of transactions that are used are as follows:

- CCMS alerts and administration
- Authorization for PI/XI message monitoring
- Solution Manager authorizations

You can create any other system type user for the agent. The user must be assigned the /IBMMON/AUTH profile.

To view and access data of SAP components, ensure that the user that is created for the agent has all the authorizations that are specified in the following table:

Table 230. The list of authorizations

| Components  | Authorization objects    | Authorization description   |
|---|--------------------------|---|
| General system authorizations that include the following components: <ul style="list-style-type: none"> <li>• SAP Instance</li> <li>• SAP System</li> </ul> | S_ADMI_FCD               | To access the SAP system  |
|   | S_BDS_DS -BC-SRV-KPR-BDS | To access the document set  |
|   | S_BTCH_JOB               | To run operations on the background jobs  |
|   | S_CCM_RECV               | To transfer the central system repository data  |
|   | S_C_FUNCT                | To make C kernel function calls in the ABAP programs  |
|   | S_DATASET                | To access files   |
|   | S_RFC                    | To check RFC access. The S_RFC authorization object contains the following two sub-authorizations: <ul style="list-style-type: none"> <li>• RFC1: To provide the authorizations for the RFC1 function group.</li> <li>• SDIFRUNTIME: To provide the authorizations for the SDIFRUNTIME function group.</li> </ul> |
|   | S_RFCACL                 | To check authorization for RFC users  |
|   | S_RZL_ADM                | To access Computing Center Management System (CCMS) for R/3 System administration   |
|   | S_TCODE                  | To check authorizations for starting the transactions that are defined for an application   |
|   | S_TOOLS_EX               | To display external statistics records in monitoring tools  |
| Authorizations for PI that include the SAP Process Integration  | S_XMB_MONI               | To access XI message monitoring   |

Table 230. The list of authorizations (continued)

| Components   | Authorization objects | Authorization description  |
|--|-----------------------|--|
| Authorizations for MAI that include the SAP Solution Manager | AI_DIAGE2E            | To restrict E2E Diagnostics functions  |
|  | AI_LMDB_OB            | To access Landscape Management Database (LMDB) objects                                     |
|  | SM_MOAL_TC            | To control the access to the alerting and monitoring functionality in SAP Solution Manager |
|  | SM_WC_VIEW            | To restrict access to specific UI elements in work centers of the Solution Manager         |
|  | S_RFC_ADM             | To control rights for administering RFC destinations                                       |
|  | S_RS_AUTH             | To specify analysis authorizations within a role   |
|  | SM_APPTYPE            | To access Solution Manager app type  |
|  | SM_APP_ID             | To access applications provided in work centers  |

## Deleting the ABAP transport from the SAP system

If you choose to remove the SAP agent from your system, you must import delete transport to the SAP system. Delete transport deletes the SAP agent dictionary objects and function modules.

### Before you begin

Before you delete the transport from the SAP system, you must stop the SAP agent instance that is configured to monitor the SAP system.

If the SAP system is version 7.20 or later, before you import the delete transport, in your transport profile, you must add the following transport profile parameter: **tadirdeletions=true**. This transport profile parameter is available in tp version 375.57.68 and also in the R3trans version 6.14 release 700 or higher. For more information about removing transport requests from the SAP system, see [Deleting transport requests](#).

### Procedure

- Go to the following path:
  - For Windows: `install_dir\TMAITM6_x64\ABAP`
  - For Non-Windows: `install_dir/intrp/sa/ABAP`, where `intrp` must be **1x8266** or **aix526**.
- Copy the transport files into the SAP environment.
- Copy the K711\_00xxx\_DELETE and R711\_00xxx\_DELETE files to the SAP Transport System data directory as follows:
  - Copy the K711\_00xxx\_DELETE file to the `cofiles` directory.
  - Copy the R711\_00xxx\_DELETE file to the `data` directory.
- Run the following commands to import the delete transport:

- a) **tp addtobuffer ITMK711\_00xxx\_DELETE SID pf=\usr\sap\trans\bin\PROFILE\_NAME**  
b) **tp import ITMK711\_00xxx\_DELETE SID client=nnn U16 pf=\usr\sap\trans\bin\PROFILE\_NAME** where:

**SID**

Target SAP system ID.

**PROFILE\_NAME**

Name of the tp profile file.

**nnn**

Number for the target client where the agent is to run.

## Verifying agent configuration

After you install the SAP agent, you must verify the agent configuration by downloading, copying, and verifying the NetWeaver RFC SDK V7.20 library. You must also verify the configuration of Solution Manager V7.1 with MAI\_Monitoring, verify MAI Alerts, and verify the configuration setting specific to third-party component.

Verify the agent configuration by completing the following procedures:

- [“Downloading the NetWeaver RFC SDK V7.20 library” on page 837](#)
- [“Copying the NetWeaver RFC SDK V7.20 library in SAP agent setup” on page 838](#)
- [“Verifying the NetWeaver RFC SDK V7.20 library” on page 838](#)
- [“Verifying the configuration of Solution Manager V7.1 with MAI-Monitoring” on page 839](#)
- [“Verifying MAI Alerts” on page 840](#)
- [“Verifying configuration settings specific to third-party component” on page 840](#)

## Downloading the NetWeaver RFC SDK V7.20 library

Download the NetWeaver RFC SDK V7.20 library after you finish installing the SAP agent. All the files that are related to the NetWeaver RFC SDK V7.20 library are available for download from the SAP website.

### Procedure

1. Log in to SAP Marketplace by using the following URL:  
<http://service.sap.com>
2. Click **SAP Support Portal**.
3. Enter your Service Marketplace user name and password.
4. Click **Software Downloads** and expand the **Support Packages and Patches** link.
5. Click **Browse our Download Catalog**, and then click **Additional Components**.
6. Click **SAP NetWeaver RFC SDK**, and then click **SAP NetWeaver RFC SDK 7.20**.
7. Select the operating system where you have the SAP agent.
8. Download the \*.SAR file on your computer.
9. To extract the SAP Netweaver RFC SDK \*.SAR file by using the SAPCAR utility that is provided by SAP, run the following command:  
`sapcar -xvf SAP NetWeaver RFC SDK File Name.SAR`

**Note:** You can download the SAPCAR utility from the SAP website.

10. Navigate to the lib folder inside the extracted folder.

### What to do next

Copy the NetWeaver RFC SDK V7.20 library in to the SAP agent setup.

## Copying the NetWeaver RFC SDK V7.20 library in SAP agent setup

The NetWeaver RFC SDK V7.20 library contains files that you must manually copy in the SAP agent setup location.

### Procedure

1. Navigate to the directory where you downloaded the NetWeaver RFC SDK V7.20 library.
2. Copy the files to the SAP agent setup location.

- For Windows 64-bit operating systems you must copy the following files:

- icuin34.dll
- libicudcnumber.dll
- libsapucum.dll
- icudt34.dll
- icuuc34.dll
- sapnwrfc.dll

You must copy the files to `install_dir\TMAITM6_x64` location.

- For operating systems other than Windows, you must copy the files to the `install_dir/intrp/sa/lib` location, where *intrp* is the operating system code (aix526, li6263, sol606). You must copy the following files:

- libsapnwrfc.so
- libicudcnumber.so
- ibicuuc34.a
- libicui18n34.a
- libicudata34.a
- libsapucum.so

### What to do next

Verify the version of the NetWeaver RFC SDK V7.20 library that is downloaded.

## Verifying the NetWeaver RFC SDK V7.20 library

You must verify the version of the file after you copy the extracted file.

### Procedure

- **Windows** To verify the version of the file, complete the following steps:
  - a) Right-click `sapnwrfc.dll` and click **Properties**.
  - b) Click the **Version** tab.
  - c) In the **Product Version** section, ensure that you have the following version: 720, patch 514, changelist 1448293, or later.
- **Linux** **UNIX** To verify the version of the file, complete the following steps:
  - a) Go to the `lib` folder in the extracted \*.SAR file.
  - b) Run the following command: **`strings libsapnwrfc.so | grep SAPFileVersion`**
  - c) You must see the following message: `[root@IBMSAP2V6 lib]# strings libsapnwrfc.so | grep SAPFileVersion GetSAPFileVersion #[%]SAPFileVersion: 7200, 514, 22, 6206 .GetSAPFileVersion`

**Note:** The message shows that this library has the version 720 patch 514, or later.

## Verifying the configuration of Solution Manager V7.1 with MAI-Monitoring

To receive data for MAI Alerts, you must verify whether the Solution Manager V7.1 is configured correctly.

### About this task

You can use Solution Manager V7.1 with MAI-Monitoring and Alerting Infrastructure to monitor the Managed Systems. Solution Manager V7.1 monitors itself and the satellite systems. Each satellite system has a plug-in and diagnostics agents. Diagnostics agents fetch the data for Host or Operating System level. Each host can have multiple diagnostics agents for different Solution Managers monitoring the host. Following are the keywords that are used in Solution Manager MAI Monitoring:

- Metrics: Data from the satellite systems.
- Alerts: Notifications that are based on some crossovers of threshold values that can be configured.
- Incident: Alerts that are converted into tickets and assigned to any user.

To verify the configuration of Solution Manager V7.1 with MAI monitoring, you must verify the basic settings, global level settings, and template level settings.

### Procedure

1. To verify the basic settings, enter the Transaction Code: SOLMAN\_SETUP and click **Enter**.

Ensure that all the LEDs are green in the following tabs:

- Overview
- Basic Configuration
- Managed System Configuration

**Note:** There are different categories of Managed Systems such as Technical Systems, Technical Scenarios, Host, Database, Instance, PI Domain, Technical Component, and Connection. You must configure these Managed Systems according to business requirements. The MAI Alerts are based on the Managed Systems that you configured.

2. Enter the Transaction code: SE38 and click **Enter**.

3. Provide the program name as RTCCTOOL and run the report.

Ensure that all the LEDs are green in the output.

4. To verify the global level settings, enter the Transaction code: SOLMAN\_WORKCENTER and click **Enter**.

Ensure that all the LEDs are green in the following tabs:

- Overview
- Configure Infrastructure
- Pre-requisites
- Configure

5. Verify whether the **Global Settings** for **Notification** status is **Active**.

6. To verify the template level settings, enter the Transaction Code: SOLMAN\_SETUP and click **Enter**.

In **Technical Settings**, in the **Auto-Notifications** list, ensure **Active** is selected.

**Note:** For initial troubleshooting, ensure that email notifications are active.

7. For MAI system monitoring, verify the configuration of End-User Experience Monitoring (EEM) by using the following steps:

a) Enter the Transaction code: SE37 and press **Enter**.

b) Enter **AI\_EEM\_LIST\_ALL\_SCENARIOS** in the **Function Module name** field and press F8.

There must be an entry for End-User Experience Monitoring (EEM).

## Verifying MAI Alerts

To ensure that Solution Manager MAI is configured correctly for monitoring the MAI Alert Inbox in Technical Monitoring, you must verify that you receive MAI Alerts as output.

### Procedure

1. Enter the Transaction code SOLMAN\_WORKCENTER and click **Enter**. Check whether you can view MAI Alerts in the Solution Manager MAI Alert Inbox under Technical Monitoring.
2. Check for BAdi implementation by using the following steps:
  - a) Enter the Transaction code: SE19 and click **Enter**
  - b) Enter /IBMMON/ITM\_IMPL\_ALRTINBX in the **Enhancement Implementation** field.
  - c) Click **Display** and check if BAdi implementation is active in **Runtime Behavior** section.
3. Check whether the database /IBMMON/ITM\_ALIX contains MAI Alerts by using the following steps:
  - a) Enter the Transaction code: SE16 and press **Enter**.
  - b) In the **Table Name** field, enter /IBMMON/ITM\_ALIX and run it. Ensure that you are receiving MAI Alerts in the table.
4. Enter the Transaction code: SE37 and click **Enter**.
5. In the **Function Module Name** field, enter /IBMMON/ITM\_MAIALRT\_INX and press F8.  
You must see MAI Alerts as output.

### What to do next

If you are not able to view MAI Alerts in the /IBMMON/ITM\_ALIX database, you must verify the settings in the Third-Party Component.

## Verifying configuration settings specific to third-party component

If you are not able to view MAI Alerts, then you must verify the settings in the third-party component.

### Procedure

1. Verify that Third-Party Component is active.
2. Verify that in **OS Adapter**, under **BAdi Implementation**, **Alert Reaction** is available. If **Alert Reaction** is not available, remove the default settings, and select the **BAdi implementation - Alert Reaction**.
3. Check the template settings by using the following steps:
  - a) Verify the settings that are used to transfer specific alerts to the Third-Party System such as SAP ABAP 7.0.0.
  - b) Select **Expert Mode**, select **Alerts**, and then click **Third Party Component**.  
Ensure that you are able to view the Alert Reaction BAdi name.  
**Note:** Ensure that the latest SAP notes are implemented. For Solution Manager V7.1 Service Pack 8, check if the following notes are implemented:
    - <https://service.sap.com/sap/support/notes/1959978>
    - <https://service.sap.com/sap/support/notes/1820727>
4. If you are not able to view MAI Alerts in the /IBMMON/ITM\_MAIALRT\_INX database, you must run the following Solution Manager MAI configurations steps for Third-Party Component:
  - a) Enter the Transaction code: SOLMAN\_SETUP and click **Enter**.
  - b) In **Technical Monitoring**, select **System Monitoring**.
  - c) Click **Configure Infrastructure** tab and then click **Default Settings** tab.
  - d) Click **Third Party Components** tab and then click **Edit**.
  - e) Select **Active** from the list.

- f) Ensure that scope filter is set as **All alerts, Events and Metrics (with Internal Events)** for the selected connector.

**Note:** OS Command Adapter is also one of the methods to push data to the third-party connector. To configure the OS Command Adapter, read the configuration detail settings in the How-to guide for OS Command Adapter.

## Adding Database Communication Port number

A Database Communication Port number is essential to uniquely identify the database entity in the integrated scenarios. To achieve inter-component collaboration, the components of SCM AI included OSLC (Open Source Lifecycle Collaboration). In OSLC compliance, it is essential to identify the collaborating components uniquely. Therefore, the Database Communication Port number is important.

### About this task

When you import the relevant IBM Tivoli Monitoring transport into the SAP System, the `/IBMMON/ITM_PORT` database table is created automatically. The table contains the following database fields:

- System ID
- System Hostname
- DB (Database) Communication Port #

### Procedure

To add SAP Database Communication Port number for the SAP agent that is required for OSLC compliance, do the following steps:

1. Go to the SE16 Transaction Code, and press Enter.
2. In the **Database table name** field, enter `/IBMMON/ITM_PORT`, and press F7.
3. When the selection screen of the **/IBMMON/ITM\_PORT** database table appears, press F8.

The **/IBMMON/ITM\_PORT** database table contains the following three database fields:

- System ID
- System Hostname
- DB Communication Port #

**Note:** The SAP systems that appear in the `/IBMMON/ITM_PORT` database table are for both the Java and ABAP architectures.

4. In the **DB Communication Port #** field, enter the relevant SAP Database Communication Port number for the respective SAP System ID and SAP System Hostname, and save the changes.

**Note:** If you do not enter any value in the **DB Communication Port #** field in the `/IBMMON/ITM_PORT` database table, then, by default the DB Communication Port number is 0.

## Advanced installation and configuration of the SAP agent

These are advance installation and configurations which are SAP agent specific.

The following installation and configuration topics are described:

- [“SAP function module” on page 842](#)
- [“SAP user IDs” on page 842](#)
- Utilities for the SAP agent
- [“SAP RFC connections” on page 842](#)
- [“Test Connection feature” on page 853](#)
- [“Optional advanced configuration in SAP” on page 845](#)
- [“CEN CCMS reporting” on page 851](#)

- [“Uninstalling the Advanced Business Application Programming \(ABAP\) transport from the SAP system” on page 852](#)

**Note:** The advance installation and configuration of the SAP agent contains references to IBM Tivoli Monitoring so as to make the documentation compatible with ABAP transport custom transaction code UI.

## SAP function module

When the data volume is high on the SAP server, you might experience problems with certain widgets causing a slow response time from the server. If the widgets are not critical, you can disable the associated SAP function module.

By default, the SAP agent function modules are enabled. However, the following function modules are disabled by default:

- HTTP services under the SYS subnode (/IBMMON/ITM\_HTTP\_SRVS)
- XML messages under the PI/XI subnode (/IBMMON/ITM\_SXMB\_MONI\_NEW)
- Sync/Async communication under the PI/XI subnode (/IBMMON/ITM\_SYN\_ASYNC\_COMM)
- qRFC inbound queue details under the Sys subnode (/IBMMON/ITM\_QIN\_QDETAILS)

After disabling the SAP function module, if you select a widget, data isn't displayed on the IBM Application Performance Management dashboard. Therefore, you avoid any performance-related problems.

## SAP user IDs

This section provides information about SAP user IDs and permissions required by the SAP agent.

User IDs support the following purposes:

- [“SAP RFC connections” on page 842](#)
- [“Basic agent monitoring” on page 842](#)

### ***SAP RFC connections***

The SAP agent uses Remote Function Calls (RFC) connections for internal Centralized Computing Center Management (CCMS) polling and CCMS alert data collection. This behavior is specific to the SAP RFC architecture.

The SAP agent opens one dedicated RFC connection to the SAP system that is monitored by the agent. The SAP system then opens one internal connection per application server for data collection through function modules and programs. If CCMS alerts are collected by the agent, the SAP system opens one additional (system internal) RFC connection to each application server for this collection thread. When data collection starts, one RFC connection for the agent is opened. Then, up to twice the number of SAP application servers for additional internal system RFC connections are opened.

You must ensure that the instance that is monitoring can accommodate the additional RFC sessions, especially in large systems with 10 or more instances. When the anticipated RFC load for monitoring might adversely affect system performance and tolerances, adjust the SAP profile parameter. Contact your SAP Administrator and see the following SAP Notes:

- Terminal Sessions (default setting: 200) 22099
- Communication/Gateway/Conversation Settings 887909 316877 384971

### ***Basic agent monitoring***

The SAP agent creates an IBMMON\_AGENT in the SAP system when the agent transport is imported.

This user ID is IBMMON\_AGENT with the default password ITMMYSAP. It is preconfigured to be Communication Type user-only and to use the /IBMMON/AUTH authorization profile. This profile, which is created at transport import time, contains the minimal set of permissions to run the agent Advanced

Business Application Programming (ABAP) code. Also, this profile accepts a set of limited actions on your SAP system.

If this user ID name is unacceptable, for example, if it violates your installation naming conventions, you can create a different user ID. The user ID can be any allowable SAP user ID, but it requires the complete set of permissions in the /IBMMON/AUTH profile. The user ID requires Communication Type user-only access.

The default user ID provides sufficient authority only for the following purposes:

- Monitoring and data collection
- Closing Computing Center Management System (CCMS) alerts
- Enabling, disabling, and resetting gateway statistics
- Resetting Oracle database statistics

If you choose to limit the action capabilities of the agent, you can remove some of the action permissions such as closing CCMS alerts.

To access data on the IBM Application Performance Management UI Portal for specific components, ensure that you have appropriate authorizations. Following table lists the authorizations that are required to access the data from different sub nodes:

| <i>Table 231. The list of authorizations</i>   |                              |   |
|--|------------------------------|---|
| <b>Sub nodes</b>   | <b>Authorization objects</b> | <b>Authorization description</b>  |
| General system authorizations that include the following sub nodes: <ul style="list-style-type: none"> <li>• Ins</li> <li>• Sys</li> </ul> | S_ADMI_FCD                   | To access the System  |
|  | S_BDS_DS -BC-SRV-KPR-BDS     | To access the Document Set  |
|  | S_BTCH_JOB                   | To run operations on the background jobs  |
|  | S_CCM_RECV                   | For transferring the Central System Repository data   |
|  | S_C_FUNCT                    | To make C calls in the ABAP programs  |
|  | S_DATASET                    | To access files   |
|  | S_RFC                        | To check RFC access. The S_RFC authorization object contains the following two sub-authorizations: <ul style="list-style-type: none"> <li>• RFC1: To provide the authorizations for the RFC1 function group.</li> <li>• SDIFRUNTIME: To provide the authorizations for the SDIFRUNTIME function group.</li> </ul> |
|  | S_RFCACL                     | For RFC User  |
|  | S_RZL_ADM                    | To access Computing Center Management System (CCMS): System Administration  |
|  | S_TCODE                      | To check Transaction Code at Transaction Start  |
|  | S_TOOLS_EX                   | To access Tools Performance Monitor   |

Table 231. The list of authorizations (continued)

| Sub nodes  | Authorization objects | Authorization description                                |
|--|-----------------------|--|
| Authorizations for Solution manager that include the following sub nodes: <ul style="list-style-type: none"> <li>• Lds</li> <li>• Sol</li> </ul> | D_MD_DATA -DMD        | To view Data Contents of Master Data                     |
|  | D_SOLMANBU            | To access a Session Type of the Solution Manager         |
|  | D_SOLM_ACT            | To access a Solution in the Solution Manager             |
|  | D_SOL_VSBL            | To view a Solution in the Solution Manager               |
|  | S_CTS_SADM            | To view System-Specific Administration (Transport)       |
|  | S_TABU_RFC            | To view Client Comparison and Copy: Data Export with RFC |
| Authorizations for PI that includes the PI sub node  | S_XMB_MONI            | To access XI Message Monitoring                          |
| Authorizations for MAI that includes the SIm sub node  | AI_DIAGE2E            | To access Solution Diagnostics end-to-end analysis       |
|  | AI_LMDB_OB            | To access Landscape Management Database (LMDB) Objects   |
|  | SM_MOAL_TC            | To access Monitoring and Alerting                        |
|  | SM_WC_VIEW            | To access Work Center User Interface Elements            |
|  | S_RFC_ADM             | To access Administration options for RFC Destination     |
|  | S_RS_AUTH             | To access BI Analysis in Role                            |
|  | SM_APPTYPE            | To access Solution Manager App Type                      |
|  | SM_APP_ID             | To access applications provided in Work center           |

## Using Central User Administration (CUA)

The Central User Administration (CUA) is used to monitor a SAP system.

### Procedure

To use the predefined user ID and authorization role to monitor a SAP system set up with Central User Administration, complete one of the following steps:

- Install the transport into the Central User Administration parent logical system client.
- Manually create the user ID or role in the client where you want to install the transport. The user ID or role is in the client where the transport is installed (imported).
- Manually create the user ID or role in the Central User Administration parent logical system client. Then, distribute the user ID or role to the client where the agent runs.

- Manually create the user ID or role in the Central User Administration parent logical system client and run the agent in this client.

## Optional advanced configuration in SAP

You can configure the SAP agent by using standard SAP or agent-provided SAP functions.

Use agent-provided transactions in SAP to customize a number of agent behaviors. After you run the /n/IBMMON/ITM\_CONFIG transaction to access the main configuration menu in SAP, select one of the following configuration options:

- [“Copy, back up, restore feature and transactions” on page 845](#)
- [“Copy, back up, and restore data by using transactions” on page 846](#)
- [“Command-line utility tool” on page 847](#)
- [“Running the command-line utility on a Windows environment” on page 847](#)
- [“Running the command-line utility on a Non-Windows environment” on page 848](#)
- [“Alerts maintenance” on page 848](#)
- [“Select monitor sets and monitors transaction” on page 849](#)
- [“Configure Dialog Step Response Threshold in the SAP system” on page 849](#)

**Note:** You must preface all /IBMMON/ITM\* transactions with /n.

Configuration changes made in these transactions are used immediately by the SAP agent except for those changes made to maintain managed groups. When the managed group configuration changes, the changes are discovered by the SAP agent at the next heartbeat.

Use SAP standard functions to complete the following configuration: [“Configure Dialog Step Response Threshold in the SAP system” on page 849](#)

### ***Copy, back up, restore feature and transactions***

The copy, back up, and restore features are available to you after you log on to the SAP server and run the following transaction: /n/IBMMON/ITM\_CONFIG.

Copy, backup, and restore operations allow you to copy, backup, and restore the IBM Tivoli Monitoring configuration data.

Use this feature to select from the following functions and to save the IBM Tivoli Monitoring configuration data:

#### • **Copy**

Use this feature to copy the IBM Tivoli Monitoring configuration settings from one SAP server to another SAP server. For example, you might want to copy the IBM Tivoli Monitoring configuration settings from agent **a1** to SAP server instance SAP2. This agent runs on system **m1** and is configured for SAP server instance SAP 1. All the IBM Tivoli Monitoring configuration settings, except the SAP server instance monitoring settings are copied to the target SAP system. You implement the copy feature by using either the command line utility or the SAP GUI.

#### • **Backup**

You can store agent-specific configurations that you completed on the SAP server by taking a backup of the system. Use this feature to save IBM Tivoli Monitoring specific configuration settings on the SAP system. You use the /IBMMON/ITM\_CONFIG transaction to enter the settings. The backup file is stored in the work directory on the SAP server to the following path: /usr/sap//DVEBMGS/work.

#### • **Restore**

Use this feature to restore IBM Tivoli Monitoring configuration data on the SAP server from the work directory. You can restore the IBM Tivoli Monitoring configuration data on the same SAP server where you completed the backup procedure of this configuration data or another SAP server. You can restore IBM Tivoli Monitoring configuration data to specific SAP and IBM Tivoli Monitoring tables. Configuration

files are stored with a date and time stamp so you can select the point to which you want to restore your files.

Agent-specific configurations include configuration settings in the /IBMMON/ITM\_CONFIG transaction in SAP. You can complete the following configuration procedures:

- Sample the frequency for alerts.
- Enable specific alerts.
- Store log file names.
- Manage group definitions.
- Select monitor sets and monitors.
- Select SAP instances for monitoring purposes.

### ***Copy, back up, and restore data by using transactions***

On the SAP user interface, you copy, back up, and restore data by using the /n/IBMMON/ITM\_CONFIG transaction.

### **Before you begin**

Use the copy, backup, and restore procedures to copy the IBM Tivoli Monitoring configuration settings from one SAP server to another SAP server. All the IBM Tivoli Monitoring configuration settings, except the SAP server instance monitoring settings are copied to the target SAP system.

### **Procedure**

Complete the following procedures to copy, back up, and restore your data on SAP:

#### **• Copy**

- a. Enter the target SAP system ID and the existing file name as source system id\_\_<filename>date\_time.

The /IBMMON/ITM\_COPY transaction creates an IBM Tivoli Monitoring configuration file in the work directory with the filename as SAP target SAP system id\_\_<filename>\_date\_time.

- b. Click **Execute** to copy the IBM Tivoli Monitoring configuration data to the file.
- c. Click **Back** or **Cancel** for returning to the previous IBM Tivoli Monitoring configuration screen.

Input parameters expected are **Target System id** and **filename** that are to be copied.

#### **• Backup**

- a. Log on to the SAP server and start the /IBMMON/ITM\_CONFIG transaction.
- b. Select **Backup**.
- c. Enter the backup filename.

The file name is stored as sys\_id\_<filename>\_date\_time.

- d. Click **Execute** to run the backup and to store the file on the Application Server.

**Note:** The backup file is stored in the work directory of the application server.

- e. Click **Back** or **Cancel** for returning to the previous IBM Tivoli Monitoring configuration screen.

#### **• Restore**

- a. Log on to the SAP server and start the /IBMMON/ITM\_CONFIG transaction.
- b. Select **Restore**.
- c. Enter the filename to restore as sys\_id\_<filename>\_date\_time.
- d. Click **Execute** to restore IBM Tivoli Monitoring configuration data.
- e. Click **Back** or **Cancel** for returning to the previous IBM Tivoli Monitoring configuration screen.

## Command-line utility tool

You can use the command-line utility tool to copy, backup, and restore IBM Tivoli Monitoring configuration data on the SAP server.

You can run the command-line utility tool on Windows and Non-Windows environment. See [“Running the command-line utility on a Windows environment” on page 847](#) and [“Running the command-line utility on a Non-Windows environment” on page 848](#).

### • Copy

Run the **backup** command to copy the IBM Tivoli Monitoring configuration file from the agent directory SAP server instance sap1 to sap2. Enter the file name and sap1 as the source system from the sap1 agent directory. Then, the ABAP function is called that copies the IBM Tivoli Monitoring settings from this file to the IBM Tivoli Monitoring configuration file for Sap2. Now select **Copy** from the sap1 agent directory utility tool and enter a file name and sap2 as the target SAP system.

### • Backup

After running the command-line utility tool, select the **Backup** option. Then, you need to enter the file name and the SAP system ID. The tool calls the /IBMMON/ITM\_BACKUP SAP function module. The function module reads the specific IBM Tivoli Monitoring configuration settings that are stored in tables and stores them with a row and column separator. Then, the command-line utility tool reads the string and writes the data into a file. The file name that is generated has the following format: ID>\_<filename>-<date&time>. This file is stored in the directory where the utility program is stored.

### • Restore

After you run the command-line utility tool, enter the file name to restore and the target SAP system where you want to restore the file. The command-line utility tool reads the file from the agent directory and calls the /IBMMON/ITM\_RESTORE SAP function module. Then, the tool passes the IBM Tivoli Monitoring configurations as a string. The SAP function module updates the specific IBM Tivoli Monitoring tables and restores the specific IBM Tivoli Monitoring configurations.

## Running the command-line utility on a Windows environment

You can run the command-line utility on a Windows environment to complete copy, backup, and restore procedures.

## Procedure

1. Depending on your operating system, complete one of the following procedures:
  - For a 64-bit operating system, set the CANDLEHOME path using command **set CANDLE\_HOME = C:\IBM\APM** and run the **ksacopybackuprestore.bat** command from the following path: %candle\_home%\ TMAITM6x64.
2. To create a backup file, complete the following steps:
  - a) Select **Backup** and enter the file name and source SAP system name.
  - b) The backup file is created with the following format: SYS ID>\_<filename>-<date&time>.
3. To restore the file, complete the following steps:
  - a) Select **Restore** and enter the target SAP system name.
  - b) Enter the filename.
4. To copy the file, complete the following steps:
  - a) From the source agent, select **Backup** and create a backup file.
  - b) Copy the backup file from the source agent directory to the target agent directory.
  - c) From the source directory, run the command-line utility tool and select **Copy**.
  - d) Enter the file name and the target SAP system.

## ***Running the command-line utility on a Non-Windows environment***

You can run the command-line utility on a Non-Windows environment to complete copy, backup, and restore procedures.

### **Procedure**

1. Run the **ksacopybackuprestore.sh** command from the following path: /candle\_home/<arch>/sa/shell.
2. To create a backup file, complete the following steps:
  - a) Select **Backup** and enter the file name and source SAP system name.
  - b) The backup file is created with the following format: SYS ID>\_<filename>\_<date&time>. The backup file is saved to this location: %candlehome% / arch /sa/bin.
3. To restore the file, complete the following steps:
  - a) Select **Restore** and enter the target SAP system name.
  - b) Enter the file name.
4. To copy the file, complete the following steps:
  - a) From the source agent, select **Backup** and create a backup file.
  - b) Copy the backup file from the source agent directory to the target agent directory.
  - c) From the source directory, run the command-line utility tool and select **Copy**.
  - d) Enter the file name and the target SAP system.

### ***Alerts maintenance***

You can modify alerts that are generated by Tivoli Monitoring by changing their status and thresholds.

This transaction is used to enable or disable alerts generated by Tivoli Monitoring and to set warning and critical thresholds. All alerts generated by Tivoli Monitoring are shown with their current status and threshold values.

When you modify alert status and thresholds, the modified values are used at the next sample time.

### **Default sample period maintenance**

The default sample period provides information about real-time reporting for certain attribute groups.

Some attribute groups have an implicit date and time for each record in the group. For example, the R/3\_Abap\_Dumps attribute group reports the create time for the dump and the R/3\_System\_Log attribute group reports the create time for the log entry. These records have a date and time field. You can obtain a report for a short history of the table instead of just the most recent information. This time interval is the time span for data collection and is used as the real-time interval when collecting data. The /IBMMON/ITM\_PERIOD transaction defines a default sample period (time span for real-time reporting) for each of these attribute groups. The sample period identifies the length of the data sample period that starts from the current time and works back in time.

### **Log file name maintenance**

Specific log files that are matched only to instances are included in IBM Tivoli Monitoring reports with log file information.

This transaction is used to identify which log files to consider for inclusion in IBM Tivoli Monitoring reports that contain log file information. All log files with a name that matches the specified name patterns on the specified instances are included in the report at the next data collection interval.

### **Managed group maintenance**

The Managed Group names transaction monitors and processes specific transactions in the SAP system.

Use this transaction to maintain IBM Tivoli Monitoring Managed Group definitions. All Managed Group names are passed to the IBM Application Performance Management UI Portal and shown in the Managed System Selection Lists. At the time of data collection, only data that matches the Attribute selection conditions are sent to the SAP agent. This data is shown in reports or used for evaluation in situations and policies.

You use Managed Groups to monitor subsets of information in the SAP system. You focus only on the parts of the SAP system in which you are interested and you ignore other parts that do not concern you. For example, if you are only interested in the response time of transactions that are part of the Financial Application, you create a Managed Group named Financials. Then, you include only Financial transaction codes in it. Whenever the Financials Managed Group is processed by the Tivoli Enterprise Portal only information that contains the specified transaction codes is considered when showing a report, evaluating a situation, or evaluating a policy.

### **Select monitor sets and monitors transaction**

Use the select monitor sets and monitors transaction to edit the Centralized Computing Central Management (CCMS) alerts configuration. For example, you can turn off CCMS alert collection completely.

This transaction is used to select the CCMS monitors from which IBM Tivoli Monitoring retrieves alerts. By default, the Entire System monitor is selected the first time this window is shown. You can change the monitor set, the monitor, or both the monitor set and monitor, and then save the configuration. You can select a maximum of three monitors for which to collect CCMS alerts.

To turn off CCMS alert collection completely, clear the check boxes for all of the monitors and save this configuration.

The agent that is already running reads this configuration and collects the CCMS alerts for the monitors that you selected. However, any CCMS alerts that were already collected by the agent before changing the CCMS alerts configuration remain with the agent and IBM Tivoli Monitoring.

In addition to selecting monitors and monitors sets, this transaction specifies the number of occurrences of an alert type to retrieve. Also, it helps you to decide whether to automatically close the older occurrences of the alerts that are not retrieved.

### **Configure Dialog Step Response Threshold in the SAP system**

You can configure a Dialog Step Response Threshold for any transaction by running the SE16 transaction.

#### **Procedure**

1. In the **Table Name** field, type /IBMMON/ITM\_TRSH, and then select **Table Contents (F7)** to access the table.
2. To view the current threshold settings, select **Execute (F8)**. The transaction names are shown under **WORKLOAD** column; the threshold values are shown under the **THRESHOLD** column.
3. To add a new threshold setting, select **Create (F5)**. Type the transaction name in the **WORKLOAD** field. The following wildcards are accepted for the **WORKLOAD** value:
  - \* matches multiple characters
  - + matches any single character
4. Type the threshold value, in milliseconds, in the **THRESHOLD** field. Select **Save** to save this setting. New and changed threshold values do not take effect immediately, but take effect under either of the following conditions:
  - The agent is restarted.
  - The agent reopens its RFC connection to the SAP system. This procedure occurs every 12 heartbeats, which, by default, is about every 2 hours and 10 minutes.

#### **Results**

The value entered for the **Threshold** column is returned in the Dialog Step Response Threshold attribute of the R/3\_Transaction\_Performance attribute group.

## Batch Job Operations

You can fetch all Batch Jobs within a specified time interval.

### Procedure

Follow the steps after [“Importing the ABAP transport on the SAP system”](#) on page 830.

**Remember:** Critical Constant is set for all the batch jobs.

1. To fetch all Active and Canceled Batch Jobs within a specified time interval.

Add the following entry in /IBMMON/ITM\_CNFG table.

| Table 232. /IBMMON/ITM_CNFG |            |
|-----------------------------|------------|
| PARAM_NAME                  | VALUE_CHAR |
| BATCH_JOBS_PERF             | YES        |

2. To fetch all Canceled jobs within a specified time interval and all Active jobs irrespective of time interval.

Add the following entry in /IBMMON/ITM\_CNFG table.

| Table 233. /IBMMON/ITM_CNFG |              |
|-----------------------------|--------------|
| PARAM_NAME                  | VALUE_CHAR   |
| BATCH_JOBS_PERF             | YES_LONG_RUN |

3. To fetch all Batch Jobs within a specified time interval and all Active Batch Jobs irrespective of time interval.

Add the following entry in /IBMMON/ITM\_CNFG table.

| Table 234. /IBMMON/ITM_CNFG |            |
|-----------------------------|------------|
| PARAM_NAME                  | VALUE_CHAR |
| BATCH_JOBS_PERF             | YES_ALL    |

**Note:**

- If the configuration parameter is not added, it fetches all Batch Jobs within a specified time interval without Critical Constant set.
- Number of rows that are fetched is always equal to value of Critical Constant set in Transaction Code /n/IBMMON/ITM\_CONFIG.

## Improving /IBMMON/ITM\_MAIALRT\_INX Function Module's performance

You can enhance the /IBMMON/ITM\_MAIALRT\_INX Function Module's performance for SAP agent.

### Procedure

Follow the steps to improve the /IBMMON/ITM\_MAIALRT\_INX function module's performance.

1. Log on toSAP agent GUI.
2. Run SE16 transaction code and enter the table name as /IBMMON/ITM\_CNFG and press F7.
3. Press F5 or click **Create Entries** and add the following entry in the IBMMON/ITM\_CNFG table.

| Table 235. /IBMMON/ITM_CNFG |            |
|-----------------------------|------------|
| PARAM_NAME                  | VALUE_CHAR |
| MAI_ALERTS_PERF             | YES        |

**Note:**

- If the Critical Constant is not set in the Transaction Code - /N/IBMMON/ITM\_CONFIG, then default value is 2500.
  - This process is only applicable for fetching the MAI Alerts from the SAP system where the PERIOD\_START and PERIOD\_END is initial.
- Remember:** Now the Function Module /IBMMON/ITM\_MAIALRT\_INX fetches the number of MAI Alerts equivalent to the Critical Constant set in the Transaction Code - /N/IBMMON/ITM\_CONFIG.
- If this entry in the /IBMMON/ITM\_CNFG is not created by default, then the 2500 latest MAI alerts are fetched.
  - The number of rows that are fetched is always equal to value of Critical Constant set in Transaction Code /n/IBMMON/ITM\_CONFIG.

## CEN CCMS reporting

Centralized (CEN) Computing Center Management System (CCMS) is a SAP monitoring capability.

Use this capability to report CCMS alerts for multiple SAP systems to a central monitoring hub. You monitor the SAP environment from one CCMS console. Centralized CCMS reporting is best used in the following environments:

- Primarily a CCMS operation where CCMS alerts are the only monitoring data needed.
- Centralized CCMS is part of the SAP environment.
- Large SAP environments with many SAP systems such as ISV and ISP.
- IBM Tivoli Monitoring V5.x integration with SAP agent CCMS adapters.
- Collect alerts from non-ABAP SAP components and application servers.

The SAP agent supports Centralized CCMS for reporting alerts only. Then, you place one SAP agent on a Centralized SAP system and view CCMS alerts for the entire SAP environment. This support is provided in the following ways:

- When reporting CCMS alerts, the agent checks if the alerts are associated with the SAP system that is directly monitored by the agent. If the agent determines that an alert belongs to a different SAP system, it assumes Centralized CCMS and automatically creates additional R3\_Group managed systems.
- The <local\_SID>-All\_CCMS\_alerts:Grp managed system is used to report the complete set of alerts from all remote SAP systems. The value of <local\_SID> is the system identifier for the SAP system that is directly monitored. For example, if the local SAP system is QA1, this group name would be QA1-All\_CCMS\_alerts:Grp.
- The <local\_SID>-<remote\_SID>\_CCMS\_alerts:Grp managed system is used to report all alerts for one remote SAP system. The value of <local\_SID> is the system identifier for the SAP system that is directly monitored. The value of <remote\_SID> is the system identifier for the remote SAP system. For example, if the local SAP system is QA1 and the remote SAP system is QA2, this group name would be QA1-QA2\_CCMS\_alerts:Grp.
- Each of these managed systems in the Navigator tree has the complete set of widgets under it, but only the Alerts widgets has meaningful data.

The SAP agent maintains its definitions of Centralized CCMS groups in the Advanced Business Application Programming (ABAP) code in the directly managed SAP system. You might need to modify these definitions if a SAP system for which you are receiving centralized alerts is also being monitored directly by another instance of the SAP agent. You do not want alerts reported under both systems. You can limit the centralized alert reporting as follows:

- Use the /IBMMON/ITM\_CONFIG transaction to Maintain Managed Groups. Change the All CCMS alerts group. Remove the remote system from this list by editing the group definition to EXCLUDE the remote system identifier.
- Use the /IBMMON/ITM\_CONFIG transaction to Maintain Managed Groups. Delete the <remote\_SID> CCMS alerts group. For example, if the remote SAP system is QA2, this group name would be QA2 CCMS alerts.

Alternatively, you can use Centralized CCMS to report alerts from all SAP systems, but prevent alert reporting from each locally installed agent. Use the following steps to set up this configuration:

- Configure an instance of the SAP agent to monitor the Centralized CCMS system. Allow the agent to detect and report all alerts from all remote SAP systems.
- Configure an instance of the SAP agent to monitor each remote SAP system. Disable alert collection and reporting for these agent instances by using the /IBMMON/ITM\_CONFIG transaction to Select Monitor Sets and Monitors. Within this function, clear the check boxes for all monitors and save this configuration.

The SAP agent support for Centralized CCMS is used in a pure CCMS monitoring environment to view all alerts on a common console. Also, it can be used with its complete set of functions to provide situations, policies, and Take Action commands for the remote SAP systems.

## Uninstalling the Advanced Business Application Programming (ABAP) transport from the SAP system

If you choose to remove the SAP agent from your system, you must import Delete transport to the SAP system. Delete transport deletes the SAP agent dictionary objects and function modules.

### Before you begin

If the SAP system is version 7.20 or later, before you import the delete transport, in your transport profile, you must add the following transport profile parameter: **tadirdeletions=true**. This transport profile parameter is available in tp version 375.57.68 and also in the R3trans version 6.14 release 700 or higher. For more information about removing transport requests from the SAP system, see [Deleting transport requests](#).

### Procedure

1. Go to the /ABAP directory on the product CD.
2. Copy the transport files into the SAP environment.
3. Copy the K711\_00xxx\_DELETE and R711\_00xxx\_DELETE files to the SAP Transport System data directory as follows:
  - a) Copy the K711\_00xxx\_DELETE file to the cfiles directory.
  - b) Copy the R711\_00xxx\_DELETE file to the data directory.
4. Run the following commands:
  - a) **tp addtobuffer ITMK711\_00xxx\_DELETE SID pf=\usr\sap\trans\bin\PROFILE\_NAME**
  - b) **tp import ITMK711\_00xxx\_DELETE SID client=nnn U16 pf=\usr\sap\trans\bin\PROFILE\_NAME**

Where:

#### **SID**

Target SAP system ID

#### **PROFILE\_NAME**

Name of the tp profile file

#### **nnn**

Number for the target client where the agent is to run

## SAP instance customization

By default, all the instances of the SAP system are monitored and shown on the IBM Application Performance Management UI Portal.

As an administrator, you choose which SAP instance you want to monitor. Also, as an administrator, you can turn off an SAP instance that you don't want to monitor.

The /IBMMON/ITM\_INSTANCE custom transaction links to the /IBMMON/ITM\_CONFIG transaction.

You select the **SAP Instances** option to view the available instances of the SAP server. Then, you select the instance that you want to monitor. These instances are displayed on the IBM Application Performance Management UI Portal. Any inactive or cleared instances aren't shown on the IBM Application Performance Management UI Portal.

## Test Connection feature

The Test Connection feature allows you to verify that you can connect your agent to the SAP system that is monitored.

You enter parameters on the GUI to complete the test connection procedure. If you connect to the SAP system successfully, a success message is displayed. Alternatively, if the connection fails, a failure message is displayed.

The **Test Connection** button is available only in the IBM Application Performance Management window.

## Modifying the threshold value of an alert

You can modify the **max ccms alert** threshold value that is associated with an alert. By default, the value is 1000, which means that you can view 1000 alerts in the IBM Application Performance Management. Older alerts are removed from the cache

## Procedure

1. Complete one of the following steps:
  - On Windows operating system, open the `<cancel home>\tmaitm6\KSAENV` file.
  - On a Non-Windows operating system open the `<cancel home>/config/sa.ini` file.
2. Add the `MAX_CCMS_ALERT_THRESHOLD=< Value>` to the end of the file.

**Note:** The value must be greater than 100.

## Master Control Panel

Master Control Panel provides central console with a user-friendly GUI for all types of configuration settings like Logging of Function Modules, Performance Improvement, Enable/Disable Function Modules, and other configurations like CCMS Old/New Design setting, MAI Configuration, Roll Key Format and Statistical File. Master control panel has some unique features that make it more efficient:

- No special authorizations are required for accessing the Master Control Panel
- Configuration settings set by user are clearly distinguishable with the help of Traffic light signal indicators
- In case of PMR investigation, there is an inbuilt functionality in Master Control Panel in which user can collect diagnostic information containing all Configuration Settings, System Information, Transport Information, Transaction Tracking details, Authorization Objects etc.

To launch Master Control Panel:

1. Go to Transaction code - `/n/ibmmon/itm_mcp` and press **Enter**
2. Master Control Panel will be launched

## Set Configurable Parameters

This topic provides detailed information about Set Configurable Parameters operation available under Master Control Panel

This section allows you to set all types of configuration settings provided under **Select Configurations** such as:

- Enable / Disable Logging for Function Modules
- Performance Improvement for Function Modules

- Other Configuration settings that include setting of CCMS design, Roll Key Format, MAI configuration, Statistical File

Click on **Set Configurable Parameters** or  icon in the **Master Control Panel Main Screen** to launch for Set Configurable Parameters.

## Logging of Function Modules

Click on **Logging of Function Modules** or  icon in the **Set Configurable Parameters** to launch **Logging of Function Modules**.

Features of logging function modules are:

- Master Control Panel enables Logging of any Function Modules without navigating to database table - / IBMMON/ITM\_CNFG
- The Application logs generated by applying the settings for the required Function Modules can be accessed using Transaction Code SLG1
- Function Modules/Attribute groups are populated only if logging mechanism is implemented
- Logging of function modules displays information in a tabular format that contains
  - Function Module Name
  - Attribute Group Name
  - Logging Status with Traffic light signal – Red  or Green 
  - Logging status – Logging Enabled/Logging Disabled
- The Function Modules are displayed according to their nodes with the respective tabs. Nodes are fetched dynamically according to SAP system configurations. For example, SLM node Function Modules are fetched only on systems where MAI is configured, PI node Function Modules are fetched only on systems where Process Integration is configured

Logging of Function Modules enable few operations such as:

- Enable Logging
  - Click on **Enable Logging** to enable logging for required Function Modules and click on **Enable Logging** button
  - The traffic light signal corresponding to the selected Function module turns green  if Logging is enabled successfully
  - A success message Logging Enabled will appear on screen indicating that the Logging has been enabled
  - The function modules not having logging as enabled shows a red traffic signal light 
- Disable Logging
  - To Disable Logging, select the required Function Modules and click on **Disable Logging** button
  - The traffic light signal corresponding to the selected Function module turns to red traffic light signal  if Logging is disabled successfully
  - A success message Logging Disabled appears on screen indicating that the Logging has been disabled.
  - The function modules for which logging is enabled shows a green traffic light signal .

**Note:** Logging can not be disabled for Function Modules with data collection is disabled.

- Select All

- A **Select All** button is available at the bottom of the table
- This operation selects all the entries in the table

**Note:** This option does not select the Function module for which data collection is disabled.

- Deselect All

- A **Deselect All** button is available at the bottom of the table
- This operation lets you deselect all the entries in the table

**Note:** This option does not select the Function module for which data collection is disabled.

## Performance Improvement

Click on **Performance Improvement** or  icon in the **Set Configurable Parameters** to launch **Performance Improvement** window.

Features of Performance Improvement are:

- Performance Improvement is used when there is large number of data or data fetching is taking long time
- It populates only those Function Modules/Attribute groups for which Performance Improvement is implemented
- Data is populated according to nodes and system configurations. For example, SLM node Function Module is populated on systems that do not have MAI configuration and vice versa
- Performance Improvement displays information in a tabular format that contains:
  - Function Module Name
  - Attribute Group Name
  - Performance Improvement Status with Traffic light signal – Red  or Green 
  - Buttons for Enable/Disable
  - Value of parameter set in the database table - /IBMMON/ITM\_CNFG
- A single button **Enable/Disable** is used to enable or disable the functionality.
- Performance improvement is provided to two Function Modules/Attribute Groups given in the section **Data Fetching can be controlled for below attributes**

Data fetching can be controlled for attributes such as:

- Function Module /IBMMON/ITM\_JOBS
  - To enable the parameters for this Function module, click on **Enable/Disable** button.
  - A default time period gets set in the SAP system for fetching Batch Jobs
  - Four configuration options are available under this feature:
    1. Fetch all Canceled and Active Jobs present within time interval set in the system
      - This configuration setting fetches all Canceled jobs and Active jobs present in the system within the predefined interval set
      - To enable this configuration, click on the radio button for this corresponding configuration and click on **Set Configuration** button
      - The traffic light signal corresponding to the configuration option turns to green  if configuration parameter is set successfully
      - The total number of rows returned for the Function module are equivalent to the critical constant value set
      - All other Batch Job configuration settings are removed

2. Fetch all Active Jobs in the system and all Canceled jobs present within the time interval set in the system
  - This configuration setting fetches all Canceled jobs present in the system within the predefined interval set and all Active jobs irrespective of the time interval set
  - To enable this configuration, click on the radio button for this corresponding configuration and click on **Set Configuration** button
  - The traffic light signal corresponding to the configuration option turns to green  if configuration parameter is set successfully
  - The total number of rows returned for the Function module are equivalent to the critical constant value set
  - All other Batch Job configuration settings are removed
3. Fetch all Active Jobs in the system and all Canceled, Scheduled, Finished, Released, Ready jobs present within the time interval set in the system
  - This configuration setting fetches all Canceled, Scheduled, Finished, Released, Ready jobs present in the system within the predefined interval set and all Active jobs irrespective of the time interval set
  - To enable this configuration, click on the radio button for this corresponding configuration and click on **Set Configuration** button
  - The traffic light signal corresponding to the configuration option turns to green  if configuration parameter is set successfully.
  - The total number of rows returned for the Function module are equivalent to the critical constant value set
  - All other Batch Job configuration settings are removed
4. Remove Batch Job configurations
  - This configuration setting fetches all Active, Canceled, Scheduled, Finished, Released, Ready jobs present in the system within the predefined interval set
  - To enable this configuration, click on the radio button for this corresponding configuration and click on **Set Configuration** button
  - The traffic light signal corresponding to all the configuration options turns red  if configuration parameter is removed successfully

After setting the configurations, click on **Confirm** . The Parameter Value Set column shows the selected configuration value. Only one configuration can be set at a time.

**Note:** Enable/Disable Performance parameter is not permitted if the data collection for Function Module is disabled

- Function Module - /IBMMON/ITM\_MAIALRT\_INX
  - To enable the parameters for this Function module, click on **Enable/Disable** button.
  - The traffic light signal corresponding to the Function module turns green  if performance parameter is enabled successfully
  - The Parameter Value Set column shows the selected configuration value
  - The same **Enable/Disable** button must be clicked to disable the performance parameter
  - The traffic light signal corresponding to the Function module turns red  if performance parameter is disabled successfully. The Parameter Value Set column will be blank

**Note:** Enable/Disable Performance parameter is not permitted if the data collection for function module is disabled.

Critical Constant:

- Critical constant value is a limit on total number of entries returned by Function Module. Click on **Set Critical Constant** tab to set a valid critical constant value.
- Default value gets populated in the text box. You can change it if required.

## Other Configurations

Click on **Other Configurations** or  icon in the **Set Configurable Parameters** window to launch **Other Configurations**.

Other configurations enables operations such as:

- CCMS design
  - This operation enables setting of Old CCMS Design or New CCMS Design according to the requirement
  - To enable New CCMS Design, select the **New CCMS Design** radio button and click on **Set CCMS Design** button.
  - The traffic light signal corresponding to the configuration option turns green  if New CCMS Design is enabled successfully
  - The text corresponding to the configuration is shown as New CCMS Design is Enabled
  - To enable Old CCMS Design, select the **Old CCMS Design** radio button and click on **Set CCMS Design** button.
  - The traffic light signal corresponding to the configuration option turns yellow  if Old CCMS Design is enabled successfully
  - The text corresponding to the configuration is shown as Old CCMS Design is Enabled
- MAI Configuration
  - This is a predefined setting. If MAI configuration is enabled, the traffic light signal is shown as green  with a message MAI Configuration is Enabled
  - If MAI configuration is not enabled, the traffic light signal is shown as red  with a message MAI Configuration is not Enabled.
- Roll Key Format
  - This operation enables you to set or remove Roll Key Format according to the requirement
  - To set the Roll Key Format, select the **Yes** radio button and click on **Set Roll Key Format** button
  - The traffic light signal corresponding to the configuration option turns green  if Roll Key Format is set successfully
  - The text corresponding to the configuration is shown as Roll Key Format is Set
  - To remove the Roll Key Format, select the **No** radio button and click on **Set Roll Key Format** button
  - The traffic light signal corresponding to the configuration option turns red  if Roll Key Format is removed successfully
  - The text corresponding to the configuration will be shown as Roll Key Format is not Set
- Statistical File
  - This setting is applicable for systems that have statistical records
  - At times, few dumps can occur due to statistical records. To avoid these dumps, Statistical file dumps are set to No in the database table
  - This operation allows you to set or remove Statistical File settings according to the requirement

- To set the Statistical file dumps to No, select the **Enable** radio button and click on **Set Statistical File Setting** button
- The traffic light signal corresponding to the configuration option turns green  if the Statistical file dumps are set to No successfully
- The text corresponding to the configuration is shown as Statistical File Settings Enabled (Statfile Dumps are set to “NO”).
- To remove the Statistical file settings, select the **Disable** radio button and click on **Set Statistical File Setting** button
- The traffic light signal corresponding to the configuration option turns to red  if the Statistical file settings are removed successfully
- The text corresponding to the configuration will be shown as Statistical File Settings Disabled

### ***ITM Maintenance Transactions***

This topic provides detailed information about ITM Maintenance Transaction and how to launch it.

ITM Maintenance Transaction is an old functionality already present with the Transaction code /n/ibmmon/itm\_config. It is merged in Master Control Panel.

To launch the ITM Maintenance Transactions through Master Control Panel refer the given step:

1. Click on **ITM Maintenance Transactions** or  icon in the **Master Control Panel** main screen to launch **ITM Maintenance Transactions**

### ***Enable/Disable Function Modules***

This topic provides detailed information on Enable/Disable Function Modules of Master Control Panel.

Click on **Enable/Disable Function Modules** or  icon in the **Master Control Panel** to launch **Enable/Disable Function Modules**.

Features of Enable/Disable Function Modules are:

- Master Control Panel enables to Enable or Disable Data collection of any Function Modules without navigating to database table - / IBMMON/ITM\_CNFG
- This section populates only those Function Modules or Attribute groups that are applicable to enable or disable data collection
- This operation provides information in a tabular format that contains:
  - Function Module Name
  - Attribute Group Name
  - Data collection Status with Traffic light signal – Red  or Green 
  - Data collection status- Data Collection Enabled or Data Collection Disabled
- The Function Modules are displayed according to their nodes. Nodes are fetched dynamically according to SAP system configurations. For example, SLM node Function Modules are fetched only on systems where MAI is configured, PI node Function Modules are fetched only on systems where Process Integration is configured.

Enable/Disable Function modules enables operations such as:

- Enable Data Collection
  - To enable Data Collection, select the required Function Modules and click on **Enable Data Collection** button
  - The traffic light signal corresponding to the selected Function module turns green  if Data Collection is enabled successfully

- A message **Data Collection Enabled** appears on screen indicating that the Data Collection has been enabled
- **Disable Data Collection**
  - To disable Data Collection, select the required Function Modules and click on **Disable Data Collection** button
  - The traffic light signal corresponding to the selected Function module turns red  if Data Collection is disabled successfully
  - A message **Data Collection Disabled** appears on screen indicating that the Data Collection has been disabled
  - The function modules for which logging is enabled is shown with a green traffic light signal 
- **Select All**
  - A **Select All** button is provided in the bottom of table
  - It lets you select all the entries in the table
- **Deselect All**
  - A **Deselect All** button is provided in the bottom of table
  - It lets you deselect all the entries in the table

### ***Collect Diagnostic Information***

This topic provides detailed information about Collect Diagnostic Information operation available under Master Control Panel

Click on **Collect Diagnostic Information** or  icon in the **Master Control Panel** to launch **Collect Diagnostic Information**.

Diagnostic Information collected through this operation:

- List of Enable/Disable Function Modules
- Function Module sub-nodes
- Logging for Function Module
- Other Configuration Settings
- Product Information
- SAP Transaction Tracking
- Statistical file
- System Information
- Transport Information
- Authorization Objects

**Note:** The report of diagnostic information is downloaded by clicking on the control tab . The report collects most of the data that is present in the database table - /IBMMON/ITM\_CNFG. If there is no data in the table, the report is not populated.

## Configuring SAP HANA Database monitoring

---

You must configure the SAP HANA Database agent so that the agent can collect data of the SAP HANA database server that is being monitored.

### Before you begin

Review the hardware and software prerequisites, see [Software Product Compatibility Reports for SAP HANA Database agent](#)

Following are the prerequisites before you configure the SAP HANA Database agent

1. Ensure to create users in all the databases (system and tenant) of the SAP HANA system with the following privileges:

- Role: Monitoring
- System privileges: Monitor Admin

The user name and password for the system and tenant databases must be the same.

2. When the switching between master to standby connectivity takes place on the SAP HANA Database agent system the agent uses the hostname of Standby Server which needs to be resolved on the agent system. To resolve the hostname to an IP address you need to add a mapping entry in host file of the machine on which the agent is installed.

**Note:** If you configure the agent using Master Host, then enter the fully qualified host name or IP address of Master Host. If user is configuring agent using Stand by Host, then enter the fully qualified host name or IP address of Stand Host. When you configure the agent through Stand by node the Master node must be down along with the host machine.

### About this task

The SAP HANA Database agent is a multiple instance agent. You must create the first instance and start the agent manually.

### Procedure

- **Windows** To configure the agent on Windows systems, complete the following steps:
  - a) Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
  - b) In the **IBM Performance Management** window, right-click **Template** under the **Task/SubSystem** column, and click **Configure Using Defaults**.

The **Monitoring Agent for SAP HANA Database** window opens.
  - c) In the **Enter a unique instance name** field, type an agent instance name and click **OK**.

**Important:** The agent instance name must match the 3-digit HANA database system identifier (SID). For example, if the SID of the managed SAP HANA database is H01, enter H01 as the instance name.
  - d) In the **Monitoring Agent for SAP HANA Database** window, specify values for the following fields:
    - Instance Name**

The default value for this field is identical to the value that you specified in the **Enter a unique instance name** field.
    - Server Name**

The fully qualified host name or IP address of the SAP HANA server where the system database is installed.
    - Database Name**

The name of the SAP HANA database.

**Port Number**

The SQL port number of the index server service on the system database of the SAP HANA database server.

**HANA DB Administrator**

The user name for accessing the SAP HANA database server.

**HANA DB Administrator Password**

The password for accessing the SAP HANA database server.

**Confirm HANA DB Administrator Password**

The password that is specified in the **HANA DB Administrator Password** field.

- e) Click **OK**.
- f) In the **IBM Performance Management** window, right-click the agent instance that you created and click **Start**.
- **Linux** **UNIX** To configure the agent on Linux or AIX systems, complete the following steps:
  - a) On the command line, change the path to the agent installation directory.  
Example: `/opt/ibm/apm/agent/bin`
  - b) Run the following command where `instance_name` is the name that you want to give to the instance:  
`./sap_hana_database-agent.sh config instance_name`  
**Important:** The instance name must match the 3-digit HANA database system identifier (SID). If the SID of the managed SAP HANA database is H01, enter H01 as the instance name.
  - c) When the command line displays the following message, type 1 and press Enter: Edit 'Monitoring Agent for SAP HANA Database' setting? [1=Yes, 2=No]
  - d) Specify values for the following agent parameters:

**Server Name**

The fully qualified host name or IP address of the SAP HANA server where the system database is installed.

**Database Name**

The name of the SAP HANA database.

**Port Number**

The SQL port number of the index server service on the system database of the SAP HANA database server.

**HANA DB Administrator**

The user name for accessing the SAP HANA database server.

**HANA DB Administrator Password**

The password for accessing the SAP HANA database server.

**Confirm HANA DB Administrator Password**

The password that is specified **HANA DB Administrator Password** field.

- e) Run the following command to start the SAP HANA Database agent:  
`./sap_hana_database-agent.sh start instance_name`
- To configure the agent by using the silent response file, complete the following steps:
  - a) In a text editor, open the `sap_hana_silent_config.txt` file that is available at the `install_dir\samples` path, and specify values for all the parameters.

**Windows** `C:\IBM\APM\samples`

**Linux** **UNIX** `/opt/ibm/apm/agent/samples`

- b) On the command line, change the path to `install_dir\bin`
- c) Run the following command:

```
Windows sap_hana_database-agent.bat config instance_name install_dir  
\\samples\\sap_hana_silent_config.txt
```

```
Linux | UNIX sap_hana_database-agent.sh config instance_name  
install_dir\\samples\\sap_hana_silent_config.txt
```

d) Start the agent.

**Windows** In the **IBM Performance Management** window, right-click the agent instance that you created, and click **Start**.

**Linux** | **UNIX** Run the following command: `./sap_hana_database-agent.sh start instance_name`

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

## What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console”](#) on page 1109.

## Configuring SAP NetWeaver Java Stack monitoring

You must configure the SAP NetWeaver Java Stack agent so that the agent can collect resource monitoring data of the SAP NetWeaver Application Server that is being monitored. To monitor transaction tracking and diagnostics data, you must complete some configuration tasks.

### Before you begin

Review the hardware and software prerequisites, see [Software Product Compatibility Reports for SAP NetWeaver Java Stack agent](#)

Ensure to complete the following prerequisites tasks before you configure the agent:

- Copy the following JAR files to the bin directory:
  - `sapj2eeclient.jar` (the SAP J2EE Engine client API that includes the JMX Adapter)
  - `logging.jar` (the logging library)
  - `com_sap_pj_jmx.jar` (the SAP-JMX library)
  - `exception.jar` (the SAP exception framework)

The bin directory is at the following path:

**Windows** `candle_home\TMAITM6_x64`

**Linux** `candle_home/interp/sv/bin`

**Important:** The JAR files are the same for all the supported operating systems. These files are available in the Diagnostics Agent patch or Software Update Manager (SUM).

- In Environment Variables, add `<candleHome>|svdchome|<build number>|toolkit|lib|win64|ttapi` to path variable.
- To enable Transaction tracking and Diagnostic Data feature, install and configure agent along with Data Collector on SAP NetWeaver Java Server. If the SAP NetWeaver Java Server is Multi Host – Multi Instance then agent needs to be installed and configured along with Data Collector on each host for which Transaction Tracking and Diagnostic Data needs to be enabled.
- Assign the NWA\_READONLY role to the *Guest* user for collecting the transaction tracking and diagnostics data.

## About this task

The SAP NetWeaver Java Stack agent is a multiple instance agent. You must create the first instance and start the agent manually.

- To configure the agent on Windows systems, you can use the GUI or the silent response file.
- To configure the agent on Linux or AIX systems, you can use the command line or the silent response file.

To configure the collection of transaction tracking and diagnostics data, complete the following tasks:

1. Configure the data collector. For details, see [“Configuring the data collector”](#) on page 865.
2. Enable the collection of transaction tracking and diagnostics data. For details, see [“Enabling the collection of transaction tracking and diagnostics data”](#) on page 866.

The directions that are mentioned in this topic are for the most current release of the agent, except as indicated. For information about how to check the version of an agent in your environment, see [Agent version](#).

## Configuring the agent on Windows systems

You can configure the agent on Windows operating systems by using the **IBM Performance Management** window.

### Before you begin

Ensure that the files, which are listed in the "Before you begin" section of the [“Configuring SAP NetWeaver Java Stack monitoring”](#) on page 862 topic, are available in the bin directory.

## About this task

The SAP NetWeaver Java Stack agent provides default values for some parameters. You can specify different values for these parameters.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Template** under the **Task/SubSystem** column, and click **Configure agent**.  
The **Monitoring Agent for SAP NetWeaver Java Stack** window opens.
3. In the **Enter a unique instance name** field, type an agent instance name and click **OK**.  
**Important:** The agent instance name must match the 3-digit SAP NetWeaver Java Stack system identifier (SID). For example, if the SID of the managed SAP NetWeaver Java Stack is P14, enter P14 as the instance name.
4. In the **Monitoring Agent for SAP NetWeaver Java Stack** window, specify values for the configuration parameters and click **OK**.  
For information about the configuration parameters, see [“Configuration parameters of the agent”](#) on page 869.
5. In the **IBM Performance Management** window, right-click the agent instance that you created and click **Start**.

### What to do next

- Log in to the Cloud APM console to view the resource monitoring data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [Starting the Performance Management console](#).
- To collect transaction tracking and diagnostics data, configure the data collector and enable data collection for transaction tracking and diagnostics.

## Configuring the agent on Linux or AIX systems

To configure the agent on Linux or AIX systems, you must run the script and respond to prompts.

### Before you begin

Ensure that the files, which are listed in the "Before you begin" section of the [“Configuring SAP NetWeaver Java Stack monitoring” on page 862](#) topic, are available in the `bin` directory.

### Procedure

1. On the command line, change the path to the agent installation directory.

```
Linux /opt/ibm/apm/agent/bin
```

```
Linux | UNIX /opt/ibm/apm/agent/bin
```

2. Run the following command:

```
./sap_netweaver_java_stack-agent.sh config instance_name
```

where *instance\_name* is the name that you want to give to the instance.

**Important:** The agent instance name must match the 3-digit SAP NetWeaver Java Stack system identifier (SID). For example, if the SID of the managed SAP NetWeaver Java Stack is P14, enter P14 as the instance name.

3. When the command line displays the following message, type 1 and press Enter:

```
Edit 'Monitoring Agent for SAP NetWeaver Java Stack' setting? [1=Yes, 2=No]
```

4. When you are prompted, specify values for the configuration parameters.

For information about the configuration parameters, see [“Configuration parameters of the agent” on page 869](#)

5. Run the following command to start the agent:

```
./sap_netweaver_java_stack-agent.sh start instance_name
```

### What to do next

- Log in to the Cloud APM console to view the resource monitoring data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [Starting the Performance Management console](#).
- To collect transaction tracking and diagnostics data, configure the data collector and enable data collection for transaction tracking and diagnostics.

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### Before you begin

Ensure that the files, which are listed in the "Before you begin" section of the [“Configuring SAP NetWeaver Java Stack monitoring” on page 862](#) topic, are available in the `bin` directory.

### About this task

The silent response file contains the agent configuration parameters with default values defined for some parameters. You can edit the silent response file to specify different values for the configuration parameters.

After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

## Procedure

1. In a text editor, open the `sap_netweaver_java_stack_silent_config.txt` file that is available at the following path, and specify values for the configuration parameters.

**Windows** `C:\IBM\APM\samples`

**Linux** | **UNIX** `/opt/ibm/apm/agent/samples`

For information about the configuration parameters, see [“Configuration parameters of the agent” on page 869](#)

2. On the command line, change the path to `install_dir\bin`
3. Run the following command:

**Windows** `sap_netweaver_java_stack-agent.bat config instance_name  
install_dir\samples\sap_netweaver_java_stack_silent_config.txt`

**Linux** | **UNIX** `./sap_netweaver_java_stack-agent.sh config instance_name  
install_dir\samples\sap_netweaver_java_stack_silent_config.txt`

4. Start the agent.

**Windows** In the IBM Cloud Application Performance Management window, right-click the agent instance that you created, and click **Start**. Alternatively, you can also run the following command:  
`sap_netweaver_java_stack-agent.bat start instance_name`

**Linux** | **UNIX** Run the following command: `./sap_netweaver_java_stack-agent.sh  
start instance_name`

## What to do next

- Log in to the Cloud APM console to view the resource monitoring data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [Starting the Performance Management console](#).
- To collect transaction tracking and diagnostics data, configure the data collector and enable data collection for transaction tracking and diagnostics.

## Configuring the data collector

You can use configure the data collector for each application server instance that you want to monitor.

### Before you begin

Ensure that the files, which are listed in the "Before you begin" section of the [“Configuring SAP NetWeaver Java Stack monitoring” on page 862](#) topic, are available in the `bin` directory.

## Procedure

To configure the data collector by responding to prompts, complete the following steps:

1. On command line, change the path to **Windows** `install_dir\svdchome\build no\bin  
\configNW` or **Linux** | **UNIX** `install_dir/svdchome/build no/bin/configNW` directory and run the following script:

**Windows** `config.bat`

**Linux** | **UNIX** `config.sh`

2. Select the SAP NetWeaver Application Server version by typing the number that corresponds to product for which you want to configure the data collector and press Enter.

3. When you are prompted for user name, enter the user name that is configured on the SAP NetWeaver Application Server with Java Stack, and press Enter.
4. When you are prompted for password, enter the password, and press Enter.
5. When you are prompted to reenter password, enter the password again, and press Enter.
6. When you are prompted for a P4 port number, enter the P4 port number of the SAP NetWeaver Application Server instance available on the local computer, and press Enter.

**Important:** Use this formula for calculating the P4 port number:  $50000 + (\text{instance number} * 100) + 4$

7. When you are prompted to select the SAP NetWeaver Application Server instance number, enter the number that corresponds to the instance that you want to configure, and press Enter.

**Remember:** For each instance, you need to configure the data collector separately.

8. If you are prompted to enter path to Java home, then use JAVA\_HOME from SAP instance. For example, E:\usr\sap\J01\J04\exe\sapjvm\_6.
9. When you are prompted, enter 1 if you want to enable the collection of transaction tracking data. Otherwise, enter 2, and press Enter.
10. When you are prompted, enter 1 if you want to enable the collection of diagnostic data. Otherwise, enter 2 and press Enter.

## Results

The path is generated for loading class files.

## What to do next

1. Add the path that is generated to the appropriate environment variable.

**Windows** *PATH*  
**Linux** *LD\_LIBRARY\_PATH* and *LIBPATH*  
**AIX** *LD LIBRARY PATH* and *LIB PATH*

### Remember:

**Windows** Add the generated path to *PATH* environment variable.

**Linux** Add the generated path to *LD\_LIBRARY\_PATH* and *LIBPATH* in the `/home/sidadm/.cshrc` file in the following format.

```
setenv LD_LIBRARY_PATH /path
setenv LIBPATH /path
```

**AIX** Add the generated path to *LD LIBRARY PATH* and *LIB PATH* in the `/etc/environment` file in following format.

```
LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/path
LIBPATH=$LIBPATH:/path
```

2. Restart the application server instances.
3. Enable data collection for transaction tracking and diagnostics. For details, see [“Enabling the collection of transaction tracking and diagnostics data”](#) on page 866.

## Enabling the collection of transaction tracking and diagnostics data

On the **Agent Configuration** page, you can enable or disable the data collection for transaction tracking or diagnostics.

### Before you begin

Ensure that the data collector is configured. For details, see [“Configuring the data collector”](#) on page 865.

## About this task

When you enable the collection of transaction tracking data, the agent collects data of the following components:

- Servlet JSP
- RemoteEJB
- JMS

## Procedure

Complete the following steps to configure the data collection for each SAP NetWeaver Application Server instance.

1. Log in to the Cloud APM console.
2. From the navigation bar, click  **System Configuration > Agent Configuration**.  
The **Agent Configuration** page is displayed.
3. Click the **NetWeaver** tab.
4. Select the check boxes of the SAP NetWeaver Application Server instances for which you want to configure the data collection and complete any of the following actions from the **Actions** list.
  - To enable transaction tracking, click **Set Transaction Tracking > Enabled**. The status in the **Transaction Tracking** column is updated to Enabled for each selected SAP NetWeaver Application Server instance.
  - To enable the diagnostic data collection, select **Set Diagnostic Mode > Enabled Diagnostic Mode Only**. The status in the Diagnostic Mode column is updated to Enabled for each selected SAP NetWeaver Application Server instance.
  - To enable the diagnostic data collection and method trace, select **Set Diagnostic Mode > Enabled Diagnostic Mode and Method Trace**. The status in the Diagnostic Mode and Method Trace columns is updated to Enabled for each selected SAP NetWeaver Application Server instance.
  - To disable transaction tracking, click **Set Transaction Tracking > Disabled**. The status in the **Transaction Tracking** column is updated to Disabled for each selected SAP NetWeaver Application Server instance.
  - To disable diagnostic data collection, click **Set Diagnostic Mode > Disabled Diagnostic Mode and Method Trace**. The status in the **Diagnostic Mode and Method Trace** columns is updated to Disabled for each selected SAP NetWeaver Application Server instance.

## Results

The data collection is configured for each SAP NetWeaver Application Server instance.

## What to do next

Log in to the Cloud APM console to view the transaction tracking and diagnostics data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

## Removing the data collector configuration

You can roll back the changes that were done when the data collector was configured for a SAP Netweaver Application Server with Java Stack instance.

## Procedure

To remove the data collector configuration by responding to prompts, complete the following steps:

1. On command line, change the path to  `install_dir\svdchome\build no\bin\configNW` or  `install_dir/svdchome/build no/bin/configNW` directory, and run the following script:

**Windows** unconfig.bat

**Linux** **UNIX** unconfig.sh

All the instances for which data collector is configured are listed.

2. Enter the number that corresponds to the instance for which you want to remove the data collector configuration and press Enter.

**Tip:** To remove the data collector configuration of multiple instances, enter the number that corresponds to the instances separated by commas. To remove the data collector configuration of all instances, you can run the following scripts:

**Windows** config.bat -a

**Linux** **UNIX** config.sh -a

## What to do next

Restart the SAP NetWeaver AS with Java Stack instances.

## Restoring the SAP NetWeaver Application Server instance

You can use the restore utility to restore JVM parameters if the SAP NetWeaver Application Server instance does not start after SAP NetWeaver Data Collector configuration or to restore SAP NetWeaver Application Server instance.

### Procedure

To restore the SAP NetWeaver Application Server instance by responding to prompts, complete the following steps:

1. On command line, change the path to **Windows** install\_dir\svdchome\build no\bin\configNW or **Linux** **UNIX** install\_dir/svdchome/build no/bin/configNW directory and run the following script:

**Windows** restoreNW.bat

**Linux** **UNIX** restoreNW.sh

2. Select the SAP NetWeaver Application Server version by typing the number that corresponds to product for which you want to restore the JVM parameters and press Enter.
3. When you are prompted for user name, enter the user name for the SAP NetWeaver Application Server instance, and press Enter.
4. When you are prompted for user password, enter the user password for the SAP NetWeaver Application Server instance, and press Enter.
5. When you are prompted for a P4 port number, enter the P4 port number of the SAP NetWeaver Application Server instance available on the local computer, and press Enter.

If instance information is not found by using the entered P4 port, then the Could not connect to SAP NetWeaver Server message is displayed and you are prompted to provide path to the SAP NetWeaver Application Server instance home.

Example, usr\sap\System\_Name\Instance\_Number

6. When you are prompted to select the SAP NetWeaver Application Server instance number, enter the number that corresponds to the instance that you want to restore, and press Enter.

### Results

The following message is displayed:

Restore successful. Please restart the instance.

## Configuration parameters of the agent

When you configure the SAP NetWeaver Java Stack agent, you can change the default value of the parameters, such as `SAP_NETWEAVER_P4_HOSTNAME` and `SAP_NETWEAVER_P4_PORT`.

The following table contains detailed descriptions of configuration parameters of the SAP NetWeaver Java Stack agent. You must specify a value for all the fields because these fields are mandatory.

| Table 236. Names and descriptions of configuration parameters |   |
|---|---|
| Parameter name  | Description   |
| Instance Name   | The name of the instance. The default value for this field is identical to the value that you specified in the <b>Enter a unique instance name</b> field. |
| <code>SAP_NETWEAVER_P4_HOSTNAME</code>                        | The host name or IP address of the SAP NetWeaver Application Server.  |
| <code>SAP_NETWEAVER_P4_PORT</code>                            | The P4 port number of the SAP NetWeaver Application Server.   |
| <code>SAP_NETWEAVER_P4_USERNAME</code>                        | The user name of the administrator for accessing the SAP NetWeaver Application Server.  |
| <code>SAP_NETWEAVER_P4_PASSWORD</code>                        | The password of the administrator for accessing the SAP NetWeaver Application Server.   |
| Confirm <code>SAP_NETWEAVER_P4_PASSWORD</code>                | The password that is specified for the <b><code>SAP_NETWEAVER_P4_PASSWORD</code></b> parameter.   |

## Configuring Siebel monitoring

The Siebel agent provides a central point of monitoring for your Siebel resources, including Siebel statistics, user sessions, components, tasks, application server, Siebel Gateway Name Server, process CPU and memory usage, and log event monitoring.

### Before you begin

- Read the entire “[Configuring Siebel monitoring](#)” on [page 869](#) topic to determine what is needed to complete the configuration.
- The product version and the agent version often differ. The directions here are for the most current release of this agent. To access the documentation for earlier agent releases, see [Table 237 on page 869](#).

| Table 237. Agent versions          |                                 |
|------------------------------------|---------------------------------|
| Agent version                      | Documentation                   |
| 1.0.0, 1.0.0.1, 1.0.0.2, 1.0.0.2.1 | <a href="#">Cloud APM 8.1.4</a> |

- The directions here are for the most current release of the agent, except as indicated.
- Make sure that the system requirements for the Siebel agent are met in your environment. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\) for the Siebel agent](#).
- Before you configure the Siebel agent, you must [verify the Siebel user account](#) that is used by the Siebel agent.

Per Component Statistics Monitoring is disabled by default. You can [enable Per Component Statistics Monitoring](#).

## About this task

The Siebel agent is a multiple-instance agent. You must create the first instance, and start the agent manually.

## Procedure

1. To configure the agent on Windows systems, you can use the IBM Performance Management window or the silent response file.
  - [“Configuring the agent on Windows systems” on page 872.](#)
  - [“Configuring the agent by using the silent response file” on page 877.](#)
2. To configure the agent on Linux and UNIX systems, you can run the script and respond to prompts, or use the silent response file.
  - [“Configuring the agent by responding to prompts” on page 876.](#)
  - [“Configuring the agent by using the silent response file” on page 877.](#)

## What to do next

In the Cloud APM console, go to your Application Performance Dashboard pages to view the data that was collected. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109.](#)

If you are unable to view the data in the agent dashboards, first check the server connection logs and then the data provider logs. The default paths to these logs are as follows:

- **Linux** **UNIX** /opt/ibm/apm/agent/logs
- **Windows** C:\IBM\APM\TMAITM6\_x64\logs

For help with troubleshooting, see the [Cloud Application Performance Management Forum.](#)

## Verify Siebel user account

You must verify the user account that is used to run the Siebel agent before you configure the agent.

## About this task

The user account that is used to run the Siebel agent must have permissions to run the Siebel **srvmgr** command line utility. To verify that the user account has the required permissions, perform these steps:

## Procedure

1. Log on to the computer with the user account that is used to run the Siebel agent.
2. Change directory to the location where the Siebel server is installed.
3. Source the Siebel environment file:

**source siebenv.sh**

4. Run the following command:

```
srvmgr /s Siebel_server /g Siebel_gateway /e Siebel_enterprise  
/u useraccount /p password  
/c "list servers"
```

where

**Siebel\_server**

Name of the Siebel Application Server.

**Siebel\_gateway**

Name of the currently active Gateway Name Server.

**Siebel\_enterprise**

Name of the Siebel Enterprise.

**useraccount**

User account that you use to log on to the computer.

**password**

Password that is associated with the user account.

If the user account has the required permissions, you see output that is similar to the following example where the fields returned are limited to three:

```
Connected to 1 server(s) out of a total of 1 server(s) in the enterprise
srvrmgr:s82win8> list servers show SBLSRVR_NAME, HOST_NAME, SBLSRVR_STATUS
SBLSRVR_NAME  HOST_NAME  SBLSRVR_STATUS
-----
s82win8       s82win8    16.0.0.0 [23057] LANG_INDEPENDENT
1 row returned.
```

If the **srvrmgr** command does not run correctly, consult with the Siebel administrator of the server. Ensure that you set the required Siebel environment variables for the user account and the user account has the appropriate permissions to run the **srvrmgr** command.

## Enabling Per Component Statistics Monitoring

Per Component Statistics Monitoring is disabled by default. You can enable Per Component Statistics Monitoring by using the KUY\_ENABLE\_COMP\_STATS environment variable.

### Before you begin

Because of a known issue with servers of Siebel V8.1 and later, gathering Siebel Component Statistics might have a negative effect on the memory usage of Siebel Gateway Server. This issue is addressed in the Oracle published technote that is named "Gateway Service on Siebel 8.1 or 8.2 Might Consume High Memory Consumption: Recovery (Doc ID 1269177.1)". A fix for the issue is provided in that article. The fix is implemented on the Siebel server.

If Per Component Statistic Monitoring is required in the environment, apply the Oracle fix to the Gateway Servers of Siebel V8.1 and later before you enable Per Component Statistics Monitoring.

### About this task

After you apply the Oracle fix, complete the following steps to enable Per Component Statistics Monitoring in the Siebel agent:

### Procedure

- Go to the agent installation directory of the Siebel agent:
  - Windows** `install_dir\TMAITM6_x64`
  - Linux** | **UNIX** `install_dir/config`
- Edit the Siebel agent configuration file to set KUY\_ENABLE\_COMP\_STATS to true.
  - Windows** `KUYENV_instance_name`
  - Linux** | **UNIX** `uy.environment`

where *instance\_name* is the instance name of the Siebel agent.
- Restart the agent.

**Important:** To make this setting the default for all new agent instances, set KUY\_ENABLE\_COMP\_STATS to true in the configuration template files:

- **Windows** KUYENV
- **Linux** **UNIX** This setting is already made the default for new agents instances by editing `uy.environment` in [Step 2](#).

## Configuring the agent on Windows systems

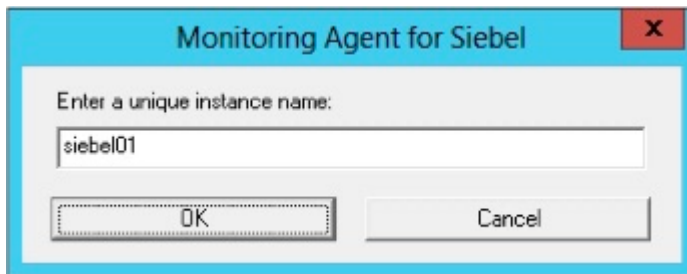

You can configure the Siebel agent on Windows operating systems by using the IBM Cloud Application Performance Management window. After you update the configuration values, you must start the agent to save the updated values.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Cloud Application Performance Management**.
2. In the **IBM Performance Management** window, right-click the **Monitoring Agent for Siebel** template, and then click **Configure agent**.

**Remember:** After you configure an agent instance for the first time, the **Configure agent** option is disabled. To configure the agent instance again, right-click on it and then click **Reconfigure**.

3. Enter a unique instance name then click **OK**. Use only letters, Arabic numerals, the underline character, and the minus character in the instance name. For example: `siebel01`.

*Figure 22. The window to enter a unique instance name.*

4. Select a Server type and enter values for the required fields for that server type, then click **Next**. See [Table 238 on page 878](#) for an explanation of each of the configuration parameters.

**Monitoring Agent for Siebel**

**Siebel Settings**

**Configuration for Siebel Application Server Resource Monitoring**

\* Instance Name: siebel01

\* Server type(s): Both Siebel and Gateway s

Enterprise Name: SCRM

Siebel Server Name: s82win12a

Siebel Gateway Name (and port): s82win12a

Siebel Server Root Directory: s:\siebel\siebsvr

Siebel Admin ID: SADMIN

Siebel Admin Password: .....

Confirm Siebel Admin Password: .....

Back Next OK Cancel

Figure 23. The window for configuration parameters for Siebel server types that are installed on a Siebel host

**Important:** If the Siebel agent is installed on a computer with the Siebel Gateway Name Server but without the Siebel Server, data that is displayed in the Application Dashboard is applicable only to the Siebel Gateway Name Server for this instance. All other Siebel agent views are empty.

5. Optional: Edit the values for Siebel server logging, then click **Next**.

See [Table 239 on page 879](#) for an explanation of each of the configuration parameters.

Figure 24. The window to specify Siebel server logging settings.

6. Optional: Edit the values for Siebel component logging, then click **Next**. By default, logs of components in [Table 242 on page 880](#) are monitored by the Siebel agent. To add up to 10 additional component logs to be monitored, specify the corresponding component alias, for example, SCBroker1. See [Table 240 on page 879](#) for an explanation of each of the configuration parameters.

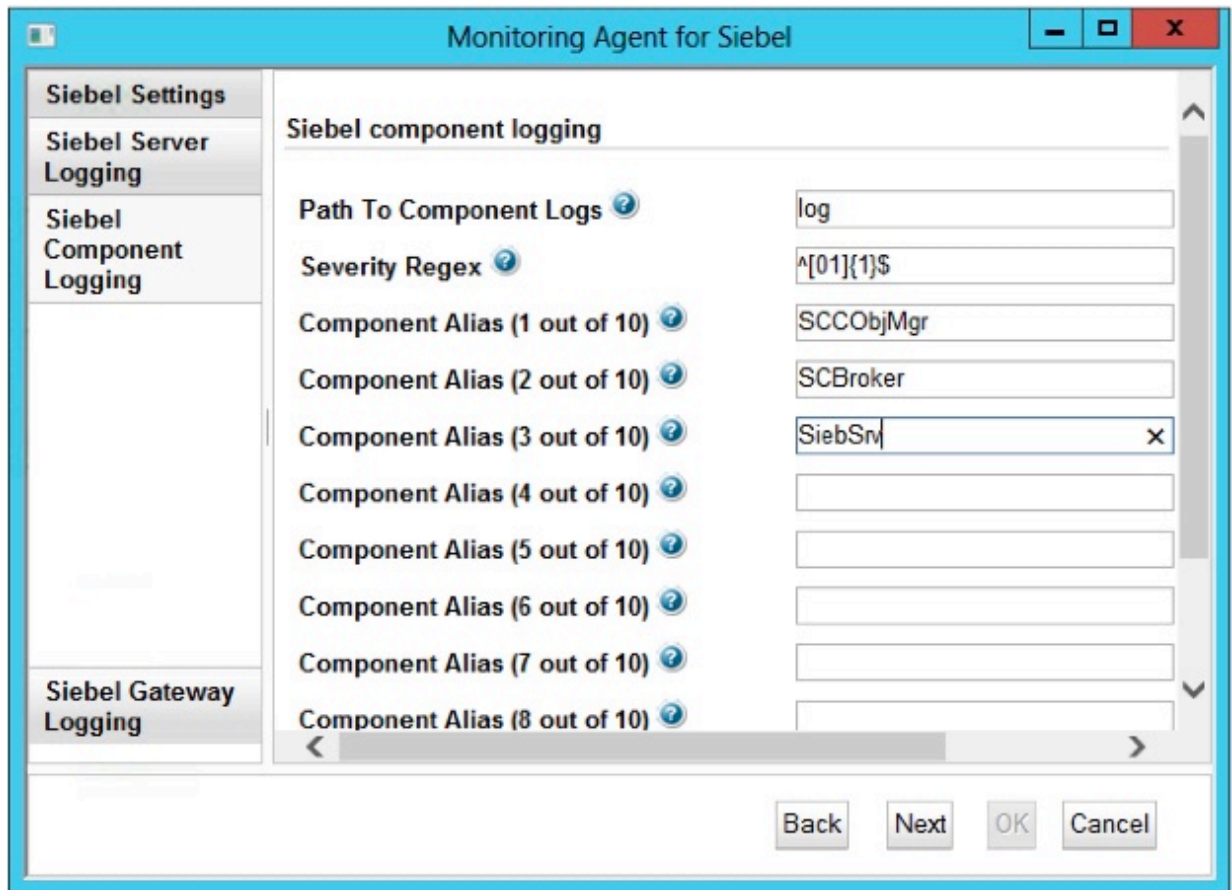

Figure 25. The window to specify extra component logs that you want to monitor.

7. Optional: Edit the values for Siebel gateway logging.

See [Table 241 on page 880](#) for an explanation of each of the configuration parameters.

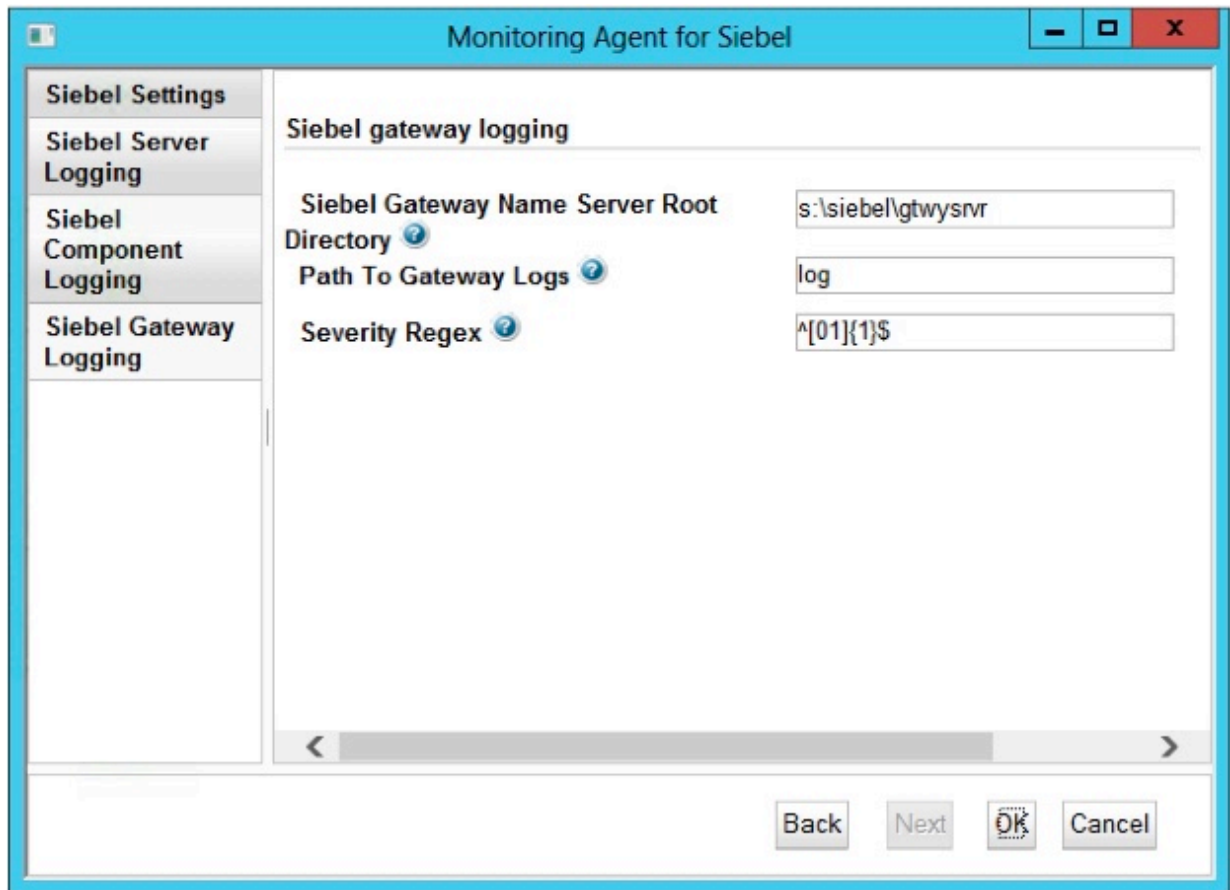

Figure 26. The window to specify Siebel gateway logging settings.

8. Click **OK** to complete the configuration.
9. In the IBM Cloud Application Performance Management window, right-click the instance that you configured, and then click **Start**.

## Configuring the agent by responding to prompts

After installation of the Siebel agent, you must configure it before you start the agent. If the Siebel agent is installed on a local Linux or UNIX computer, you can follow these instructions to configure it interactively through command line prompts.

### About this task

**Remember:** If you are reconfiguring a configured agent instance, the value that is set in the last configuration is displayed for each setting. If you want to clear an existing value, press the space key when the setting is displayed.

### Procedure

- Follow these steps to configure the Siebel agent by running a script and responding to prompts.
  - a) On the command line, run the following command:

```
install_dir/bin/siebel-agent.sh config instance_name
```

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name that you want to give to the agent instance.

Example

```
/opt/ibm/apm/agent/bin/siebel-agent.sh config example-inst01
```

- b) Respond to the prompts to set configuration values for the agent.

See “Configuration parameters for the Siebel agent” on page 878 for an explanation of each of the configuration parameters.

- c) Run the following command to start the agent:

```
install_dir/bin/siebel-agent.sh start instance_name
```

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name of the agent instance.

Example

```
/opt/ibm/apm/agent/bin/siebel-agent.sh start example-inst01
```

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

The silent response file contains the agent configuration parameters with default values that are defined for some parameters. You can edit the silent response file to specify different values for the configuration parameters.

After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

- To configure the Siebel agent in the silent mode, complete the following steps:
  - In a text editor, open the `siebel_silent_config.txt` file that is available at the following path:

- Linux | UNIX `install_dir/samples/siebel_silent_config.txt`
  - Windows `install_dir\samples\siebel_silent_config.txt`

where *install\_dir* is the path where the agent is installed.

Example

- Linux | UNIX `/opt/ibm/apm/agent/samples/siebel_silent_config.txt`
  - Windows `C:\IBM\APM\samples\siebel_silent_config.txt`

- In the `siebel_silent_config.txt` file, specify values for all mandatory parameters. You can also modify the default values of other parameters.

See “Configuration parameters for the Siebel agent” on page 878 for an explanation of each of the configuration parameters.

- Save and close the `siebel_silent_config.txt` file, and run the following command:

- Linux | UNIX `install_dir/bin/siebel-agent.sh config instance_name  
install_dir/samples/siebel_silent_config.txt`
  - Windows `install_dir\bin\siebel-agent.bat config instance_name  
install_dir\samples\siebel_silent_config.txt`

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name of the agent instance.

**Important:** Ensure that you include the absolute path to the silent response file. Otherwise, the agent data is not shown in the dashboards.

Example

- **Linux** **UNIX** /opt/ibm/apm/agent/bin/siebel-agent.sh config example-inst01 /opt/ibm/apm/agent/samples/siebel\_silent\_config.txt
- **Windows** C:\IBM\APM\bin\ siebel-agent.bat config example-inst01 C:\IBM\APM\samples\siebel\_silent\_config.txt

d) Run the following command to start the agent:

- **Linux** **UNIX** install\_dir/bin/siebel-agent.sh start **instance\_name**
- **Windows** install\_dir\bin\siebel-agent.bat start **instance\_name**

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name of the agent instance.

Example

- **Linux** **UNIX** /opt/ibm/apm/agent/bin/siebel-agent.sh start example-inst01
- **Windows** C:\IBM\APM\bin\siebel-agent.bat start example-inst01

## Configuration parameters for the Siebel agent

The configuration parameters for the Siebel agent are displayed in tables which group them according to categories.

1. [Siebel Settings](#) - General Siebel environment settings.
2. [Siebel Server Logging](#) - Settings specific to monitoring Siebel server logs.
3. [Siebel Component Logging](#) - Settings specific to monitoring a custom list of Siebel component logs.
4. [Siebel Gateway Logging](#) - Settings specific to monitoring Siebel gateway logs.

| Table 238. Siebel Settings |  |   |  |
|----------------------------|--|---|--|
| Parameter name             | Description  | Required for server type choice   | Silent configuration file parameter name |
| Server type(s)             | Indicates the server types that are installed on the local computer.   | <ul style="list-style-type: none"><li>• Gateway server only</li><li>• Siebel server only</li><li>• Both Siebel and Gateway server</li></ul> | KUY_SERVER_TYPE                          |
| Enterprise Name            | The name of the Siebel enterprise.   | <ul style="list-style-type: none"><li>• Siebel server only</li><li>• Both Siebel and Gateway server</li></ul>                               | KUY_ENTERPRISE                           |
| Siebel Server Name         | The name of the Siebel Server to monitor.<br><b>Note:</b> This name is not the host name of the server. It is the server name that is used when you run the Siebel <b>srvrmgr</b> command. | <ul style="list-style-type: none"><li>• Siebel server only</li><li>• Both Siebel and Gateway server</li></ul>                               | KUY_SERVER                               |

Table 238. Siebel Settings (continued)

| Parameter name               | Description   | Required for server type choice  | Silent configuration file parameter name |
|------------------------------|---|--|--|
| Siebel Gateway Name          | The Siebel Gateway Name Server to monitor and optionally the port, for example, <code>gtwysrvr</code> or <code>gtwysrvr:1234</code> .                       | <ul style="list-style-type: none"> <li>• <b>Siebel server only</b></li> <li>• <b>Both Siebel and Gateway server</b></li> </ul> | KUY_GATEWAY                              |
| Siebel Server Root Directory | The base installation directory for the Siebel Application Server.  | <ul style="list-style-type: none"> <li>• <b>Siebel server only</b></li> <li>• <b>Both Siebel and Gateway server</b></li> </ul> | KUY_INSTALL_ROOT                         |
| Siebel Admin ID              | The Siebel specific user ID that the agent uses to authenticate to the Siebel enterprise when you run the <code>srvrmgr</code> command. For example: SADMIN | <ul style="list-style-type: none"> <li>• <b>Siebel server only</b></li> <li>• <b>Both Siebel and Gateway server</b></li> </ul> | KUY_ADMIN_ID                             |
| Siebel Admin password        | The password for the Siebel Server administrator.   | <ul style="list-style-type: none"> <li>• <b>Siebel server only</b></li> <li>• <b>Both Siebel and Gateway server</b></li> </ul> | KUY_ADMIN_PASSWORD                       |

Table 239. Siebel Server Logging Settings

| Parameter name      | Description   | Silent configuration file parameter name |
|---------------------|---|--|
| Path To Server Logs | The relative path from "Siebel Server Root Directory" to server logs. To disable capturing of Siebel server logging, enter any invalid path. For example: xyz.                              | KUY_SERVER_LOGGING_PATH                  |
| Severity Regex      | The regular expression that is used to capture Siebel server logs matching a severity level. Using the default of <code>^[01]{1}\$</code> facilitates capturing level 0 and level 1 errors. | KUY_SERVER_LOGGING_SEVERITY_REGEX        |

Table 240. Siebel Component Logging Settings

| Parameter name         | Description  | Silent configuration file parameter name |
|------------------------|--|--|
| Path To Component Logs | The relative path from "Siebel Server Root Directory" to server logs. To disable capturing of Siebel server logging, enter any invalid path. For example: xyz. | KUY_COMPONENT_LOGGING_PATH               |

Table 240. Siebel Component Logging Settings (continued)

| Parameter name                        | Description   | Silent configuration file parameter name                    |
|---------------------------------------|---|---|
| Severity Regex                        | The regular expression that is used to capture Siebel server logs matching a severity level. Using the default of <code>^[01]{1}\$</code> facilitates capturing level 0 and level 1 errors. | <b>KUY_COMPONENT_LOGGING_SEVERITY_REGEX</b>                 |
| Component Alias ( <i>N</i> out of 10) | The Component alias for which to monitor an additional Component's log. Example: SCBroker. Where <i>N</i> is 1 - 10 optional components.  | <b>KUY_CUSTCOMPLOG_00</b> through <b>KUY_CUSTCOMPLOG_09</b> |

Table 241. Siebel Gateway Logging Settings

| Parameter name                            | Description   | Silent configuration file parameter name |
|---|---|--|
| Siebel Gateway Name Server Root Directory | The base installation directory for the Siebel Gateway Name Server.   | <b>KUY_GATEWAY_ROOT</b>                  |
| Path To Gateway Logs                      | The relative path from Siebel Gateway Name Server Root Directory to gateway logs. To disable capturing of Gateway Name Server logging, enter any invalid path. For example: xyz.            | <b>KUY_GW_LOGGING_PATH</b>               |
| Severity Regex                            | The regular expression that is used to capture Siebel server logs matching a severity level. Using the default of <code>^[01]{1}\$</code> facilitates capturing level 0 and level 1 errors. | <b>KUY_GW_LOGGING_SEVERITY_REGEX</b>     |

## Siebel component logs that are always monitored

Component logs are always monitored for 10 Siebel components.

Table 242. Siebel component aliases and names for which component logs are always monitored.

| Component alias | Component name                  |
|-----------------|---------------------------------|
| SCCObjMgr       | Call Center Object Manager      |
| SObjMgr         | Marketing Object Manager        |
| SSEObjMgr       | Sales Object Manager            |
| CommInboundRcvr | Communications Inbound Receiver |
| CommOutboundMgr | Communications Outbound Manager |
| CommSessionMgr  | Communications Session Manager  |
| WorkMon         | Workflow Monitor Agent          |
| WfProcBatchMgr  | Workflow Process Batch Manager  |

Table 242. Siebel component aliases and names for which component logs are always monitored.  
(continued)

| Component alias | Component name           |
|-----------------|--------------------------|
| WfProcMgr       | Workflow Process Manager |
| SiebSrvr        | Siebel Server            |

## Configuring Sterling Connect Direct monitoring

You must configure the Sterling Connect Direct agent so that the agent can collect data from the Connect Direct servers to monitor the statistics of file transfer and health of Connect Direct servers.

### Before you begin

Review the hardware and software prerequisites, see [Software Product Compatibility Reports for Sterling Connect Direct agent](#)

### About this task

- To configure the agent on Windows systems, you can use the IBM Cloud Application Performance Management window or the silent response file.
- To configure the agent on Linux systems, you can run the script and respond to prompts, or use the silent response file.

## Configuring the agent on Windows systems

You can use the IBM Cloud Application Performance Management window to configure the agent on Windows systems.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Template** in the **Task/SubSystem** column, and click **Configure agent**.
3. In the **Enter a unique instance name** field, type an agent instance name and click **OK**.  
**Note:** Limit the length of agent instance name. Preferably in the range 7 - 10 characters.
4. In the **Monitoring Agent for Sterling Connect Direct** window, in the **Connect Direct Server Details** tab specify values for the configuration parameters and click **OK**.

For information about the configuration parameters, see [“Configuration parameters of the agent” on page 883](#).

5. Click **Next**.
6. On Java Parameters tab, keep default values and click **Next**.
7. On Java API Client Configuration tab, click **OK**.
8. In the **IBM Performance Management** window, right-click the agent instance that you created and click **Start** to start the agent.

### What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the console, see [“Starting the Cloud APM console” on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent on Linux systems

To configure the agent on Linux operating systems, you must run the script and respond to prompts.

### Procedure

1. On the command line, change the path to the agent installation directory.  
Example `/opt/ibm/apm/agent/bin`
2. Run command `/sterling_connect_direct-agent.sh config instance_name`.  
**Note:** The *instance\_name* is the name that you want to give to the agent instance.
3. Command line displays the message Edit 'Monitoring Agent for Sterling Connect Direct' setting? [1=Yes, 2=No].
4. Enter 1 to edit the settings.
5. Specify values for the configuration parameters when you are prompted. For information about the configuration parameters, see ["Configuration parameters of the agent" on page 883](#).
6. Run the command to start the agent `./sterling_connect_direct-agent.sh start instance_name`

### What to do next

Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. Get more information on using the Cloud APM console, at ["Starting the Cloud APM console" on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

You can use the silent response file to configure the Monitoring Agent for Sterling Connect Direct on Linux and Windows systems. After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

1. Open silent response file present at *install\_dir*/samples/sterling\_connect\_direct\_silent\_config.txt in a text editor.
2. Enter server name, username, password, installation directory in the file and save the file.
3. In the command prompt, go to *install\_dir*/bin and run the command

```
Linux | UNIX ./sterling_connect_direct-agent.sh config <Instance_name>  
install_dir/samples/sterling_connect_direct_silent_config.txt.
```

```
Windows ./sterling_connect_direct-agent.bat config <Instance_name>  
install_dir/samples/sterling_connect_direct_silent_config.txt.
```

### What to do next

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see ["Starting the Cloud APM console" on page 1109](#).

For help with troubleshooting, see the [Troubleshooting](#) section.

## Configuration parameters of the agent

While configuring the Monitoring Agent for Sterling Connect Direct you can set the values for configuration parameters.

The following table contains detailed descriptions of the configuration parameters of the Monitoring Agent for Sterling Connect Direct.

| Table 243. Names and descriptions of the configuration parameters |   |                 |
|---|---|-----------------|
| Parameter name  | Description   | Mandatory field |
| Instance Name   | The default value for this field is identical to the value that you specify in the <b>Enter a unique instance name</b> field. | Yes             |
| Server name   | The host name or IP of Sterling Connect Direct server.  | Yes             |
| Server port   | The Port of Sterling Connect Direct server. Default value for Sterling Connect Direct is 1363.                                | Yes             |
| Username  | The username to connect to Sterling Connect Direct server.  | Yes             |
| Password  | The password to connect to Sterling Connect Direct server.  | Yes             |
| Java Home   | Path to the folder where Java is installed.   | No              |
| Java trace level  | The trace level used by Java providers. Default value for Sterling Connect Direct is Error                                    | Yes             |
| JVM arguments   | This parameter allows you to specify an optional list of arguments to the java virtual machine.                               | No              |
| Class Path for external jars                                      | The path for jars required by Java API data provider that are not included with the agent.                                    | No              |

## Configuring Sterling File Gateway monitoring

The Monitoring Agent for Sterling File Gateway monitors the IBM Sterling File Gateway application by using the business-to-business (B2B) REST APIs and file gateway database. You must configure the Sterling File Gateway agent so that the agent can collect data from the data sources and monitor the statistics and health of the Sterling File Gateway application. You can configure the agent on Windows and Linux systems.

### Before you begin

- Review the hardware and software prerequisites, see [Software Product Compatibility Reports for Sterling File Gateway agent](#).
- Ensure that the B2B REST APIs are installed on your file gateway node. For more information about the B2B REST API installation, see “Installing the B2B REST API” on page 884.

### About this task

The Sterling File Gateway agent is a multiple instance agent. You must create the first instance and start the agent manually.

- To configure the agent on Windows systems, you can use the **IBM Performance Management** window or the silent response file.
- To configure the agent on Linux systems, you can run the script and respond to prompts, or use the silent response file.

## Installing the B2B REST API

You can install and configure the business-to-business (B2B) REST APIs on your Sterling File Gateway node. The B2B REST APIs are available in the B2B Integrator installer (V5.2.6.2).

### Procedure

1. Navigate to the `<install_dir>/bin` directory.

Where, *install\_dir* is the agent installer directory for the B2B integrator.

2. Run the following command:

- **Linux** `./InstallService.sh/install_dir/bin/b2bAPIs_10000602.jar`

Where, *<install\_dir>* is the location where you extracted the media file content.

- **Windows** `./InstallService.cmd/install_dir/bin/b2bAPIs_10000602.jar`

Where, *<install\_dir>* is the B2B installer folder.

## Configuring the Sterling File Gateway agent on Windows systems

You can configure the Sterling File Gateway agent on Windows operating systems by using the **IBM Cloud Application Performance Management** window. After you update the configuration values, you must start the agent to save the updated values.

### About this task

The Sterling File Gateway agent provides default values for some parameters. You can specify different values for these parameters.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Monitoring Agent for Sterling File Gateway**, and then click **Configure agent**.

**Remember:** After you configure the agent for the first time, the **Configure agent** option is not available. To configure the agent again, click **Reconfigure**.

3. In the Sterling File Gateway agent window, complete the following steps:
  - a) Enter a unique name for the Sterling File Gateway agent instance, and click **OK**.
  - b) On the **B2B API Details** tab, specify values for the configuration parameters, and then click **Next**.
  - c) On the **Database Details** tab, specify values for the configuration parameters, and then click **Next**.
  - d) On the **Java API** tab, specify values for the configuration parameters, and then click **OK**.

For more information about the configuration parameters in each tab of the Sterling File Gateway agent window, see the following topics:

- [“Configuration parameters for the B2B API details” on page 888](#)
- [“Configuration parameters for database details” on page 889](#)
- [“Configuration parameters for the Java API” on page 889](#)

4. In the **IBM Performance Management** window, right-click **Sterling File Gateway agent**, and then click **Start**.

## Configuring the Sterling File Gateway agent on Linux systems

You can run the configuration script and respond to prompts to configure the Sterling File Gateway agent on the Linux operating systems.

### Procedure

1. Go to the command line and run the **<install\_dir>/bin/sterling\_file\_gateway-agent.sh config instance\_name** command.

Where, the *instance\_name* is the name that you want to give to the instance and *install\_dir* is the agent installation directory path.

2. You are prompted to provide values for all the mandatory configuration parameters. You can modify the default values of configuration parameters.

For more information about the configuration parameters, see the following topics:

- [“Configuration parameters for the B2B API details” on page 888](#)
- [“Configuration parameters for database details” on page 889](#)
- [“Configuration parameters for the Java API” on page 889](#)

3. To start the agent, run the **<install\_dir>/bin/sterling\_file\_gateway-agent.sh start instance\_name** command.

## Configuring Sterling File Gateway agent by using the silent response file

You can use the silent response file to configure the Sterling File Gateway agent without responding to prompts when you run the configuration script. You can configure the agent that uses the silent response file on both Windows and Linux systems. The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

The silent response file contains the agent configuration parameters with default values that are defined for some parameters. You can edit the silent response file to specify different values for the configuration parameters.

After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

- To configure the Sterling File Gateway agent in the silent mode, complete the following steps:
  - a) In a text editor, open the `sterling_file_gateway_silent_config.txt` file that is available at the following path:
    - **Linux** `install_dir/samples/sterling_file_gateway_silent_config.txt`  
Example `/opt/ibm/apm/agent/samples/sterling_file_gateway_silent_config.txt`
    - **Windows** `install_dir\samples\sterling_file_gateway_silent_config.txt`  
Example `C:\IBM\APM\samples\sterling_file_gateway_silent_config.txt`
  - b) In the `sterling_file_gateway_silent_config.txt` file, specify values for all the mandatory parameters. You can also modify the default values of other parameters.

For more information about the configuration parameters, see the following topics:

- [“Configuration parameters for the B2B API details” on page 888](#)

- [“Configuration parameters for database details”](#) on page 889
  - [“Configuration parameters for the Java API”](#) on page 889
- c) Save and close the `sterling_file_gateway_silent_config.txt` file, and run the following command:
- **Linux** `install_dir/bin/sterling_file_gateway-agent.sh config`  
`instance_name`  
`install_dir/samples/sterling_file_gateway_silent_config.txt`  
 Example **`/opt/ibm/apm/agent/bin/sterling_file_gateway-agent.sh config`**  
**`instance_name /opt/ibm/apm/agent/samples/sterling_file_gateway_silent_config.txt`**
  - **Windows** `install_dir/bin/sterling_file_gateway-agent.bat config`  
`instance_name`  
`install_dir/samples/sterling_file_gateway_silent_config.txt`  
 Example **`C:\IBM\APM\bin\sterling_file_gateway-agent.bat config`**  
**`instance_name C:\IBM\APM\samples\sterling_file_gateway_silent_config.txt`**
- Where *instance\_name* is the name that you want to give to the instance and *install\_dir* is the path where the agent is installed.

**Important:** Ensure that you include the absolute path to the silent response file. Otherwise, the agent data is not shown in the dashboards.

- d) Run the following command to start the agent:

- **Linux** `install_dir/bin/sterling_file_gateway-agent.sh start`  
`instance_name`  
 Example **`/opt/ibm/apm/agent/bin/sterling_file_gateway-agent.sh start`**  
**`instance_name`**
- **Windows** `install_dir\bin\sterling_file_gateway-agent.bat start`  
`instance_name`  
 Example **`C:\IBM\APM\bin\sterling_file_gateway-agent.bat start`**  
**`instance_name`**

## Configuring agent environment variables for the data provider on Linux

You can configure the Sterling File Gateway agent environment variables for the data provider on Linux operating systems.

### About this task

The Sterling File Gateway agent provides environment variables that you can configure for the data provider.

### Procedure

1. Go to the `<install_dir>/agent/config` directory.
2. Open the `.fg.environment` file in an editor and edit the environment variables.

For more information about the agent environment variables that you can configure, see [“Environment variables for the data provider”](#) on page 887.

## Configuring agent environment variables for the data provider on Windows

You can configure the Sterling File Gateway agent environment variables for the data provider on Windows operating systems by using the **IBM Performance Management** window.

### About this task

The Sterling File Gateway agent provides environment variables that you can configure for the data provider.

### Procedure

1. Click **Start > All Programs > > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click the agent instance and click **Advanced > Edit ENV File** and edit default values for the environment variables.

For more information about the agent environment variables that you can configure, see [“Environment variables for the data provider”](#) on page 887.

## Environment variables for the data provider

After you configure the Sterling File Gateway agent, you can modify some threshold duration values related to the agent data collection. You can specify these values in the agent environment file.

The following table contains detailed description of the environment variables for the data provider.

| Table 244. Name and description of the environment variables for the data provider  |  |
|---|--|
| Parameter name  | Description  |
| Collection duration for files transfer (in hours)<br>( <b>KFG_FILE_ARRIVED_INTERVAL</b> )   | The duration in hours for which the agent collects data for file transfers. The default value is 24 hours.   |
| Collection intervals for files transfer activities that are displayed as a line chart (in hours)<br>( <b>KFG_FILE_ACTIVITY_INTERVAL</b> ) | The duration in hours for which the agent collects data for file transfer activities. The default value is 1 hour.<br><br>For example, the agent collects file transfer activities that occurred in last 1 hour. This data is visible in terms of line charts on the instance page. The default value is 1 hour. |
| Threshold interval for inactive partners (in days)<br>( <b>KFG_INACTIVE_PARTNERS_INTERVAL</b> )   | The threshold duration when the partner is inactive or not received or uploaded any file. The default value is 10 days.<br><br>For example, if any partner that does not receive or transfer a file in last 10 days, displays as "Inactive" on the agent.  |
| Maximum number of data provider log files<br>( <b>KFG_LOG_FILE_MAX_COUNT</b> )  | The maximum number of log files that the data provider creates before it overwrites the previous log files. The default value is 10.   |
| Maximum size in KB of each data provider log<br>( <b>KFG_LOG_FILE_MAX_SIZE</b> )  | The maximum size in KB that a data provider log file must reach before the data provider creates a new log file. The default value is 5190 KB.   |

| <i>Table 244. Name and description of the environment variables for the data provider (continued)</i> |   |
|---|---|
| Parameter name  | Description   |
| Level of detail in data provider log<br>( <b>KFG_LOG_LEVEL</b> )                                      | <p>The level of details that are included in the log file that the data provider creates. The default value is 4 (Info). The following values are valid:</p> <ul style="list-style-type: none"> <li>• 1 (Off): No messages are logged.</li> <li>• 2 (Severe): Only errors are logged.</li> <li>• 3 (Warning): All errors and messages that are logged at the severe level and potential errors that might result in undesirable behavior.</li> <li>• 4 (Info): All errors and messages that are logged at the warning level and high-level informational messages that describe the state of the data provider when it is processed.</li> <li>• 5 (Fine): All errors and messages that are logged at the information level and low-level informative messages that describe the state of the data provider when it is processed.</li> <li>• 6 (Finer): All errors and messages that are logged at the fine level plus detailed informative messages, such as performance profiling information and debug data. Selecting this option can adversely affect the performance of the monitoring agent. This setting is intended only as a tool for problem determination along with the IBM support staff.</li> <li>• 7 (Finest): All errors and messages that are logged at the Fine level and the most detailed informative messages that include low-level programming messages and data. Selecting this option might adversely affect the performance of the monitoring agent. This setting is intended only as a tool for problem determination along with the IBM support staff.</li> <li>• 8 (All): All errors and messages are logged.</li> </ul> |
| Fetching events for all file transfers ( <b>KFG_ALL_FGEVENTS</b> )                                    | <p>The flag for fetching events for all file transfers. The valid values are, Yes or No. The default value is No. If the value is set to No, then agent fetches events for failed file transfers for a user configurable duration. If the value is set to Yes, then the agent fetches events for all file transfers for a user configurable duration.</p>   |

## Configuration parameters for the B2B API details

When you configure the Sterling File Gateway agent, you must specify values of the configuration parameters for the business-to-business (B2B) API details.

The following table contains detailed description of the configuration parameters for the B2B API details.

| <i>Table 245. Name and description of the configuration parameters for the B2B API details</i> |   |
|--|---|
| Parameter name   | Description   |
| Instance Name<br>( <b>KFG_Instance_Name</b> )  | <p>The name of the instance.</p> <p><b>Restriction:</b> The Instance Name field displays the name of the instance that you specify when you configure the agent for the first time. When you configure the agent again, you cannot change the instance name of the agent.</p> |
| Server Name<br>( <b>KFG_API_SERVICES_Node_ADDRESS</b> )  | The host name or IP address of the B2B API service.   |

| Table 245. Name and description of the configuration parameters for the B2B API details (continued) |  |
|---|--|
| Parameter name  | Description  |
| Server Port<br>(KFG_API_SERVICES_PORT)  | The port of the B2B API.   |
| User Name<br>(KFG_API_SERVICES_USERNAME)  | A user name to connect to the B2B API service.                                 |
| Password<br>(KFG_API_SERVICES_PASSWORD)   | The password for the user name that you use to connect to the B2B API service. |

## Configuration parameters for database details

When you configure the Sterling File Gateway agent, you must specify values of the configuration parameters for the database details.

The following table contains detailed description of the configuration parameters for the database details.

| Table 246. Name and description of the configuration parameters for the database details |   |
|--|---|
| Parameter name   | Description   |
| Database Server Name<br>(KFG_DB_Node_ADDRESS)  | The host name or IP address of the Sterling File Gateway database server. |
| Database User (KFG_DB_USERNAME)  | The name of the database user.  |
| Database Password (KFG_DB_PASSWORD)  | The password of the database.   |
| Database Port (KFG_DB_PORT)  | The port of the database.   |
| Database Type (KFG_DB_TYPE)  | The type of the database.   |

## Configuration parameters for the Java API

When you configure the Sterling File Gateway agent, you must specify values of the configuration parameters for the Java API.

The following table contains detailed description of the configuration parameters for the Java API.

| Table 247. Name and description of the configuration parameters for the Java API |   |
|--|---|
| Parameter name   | Description   |
| Class path for the external JAR<br>(KFG_CLASSPATH)                               | The database driver JAR path that you want to specify for the corresponding database. |

## Configuring Sybase Server monitoring

The Sybase agent offers a central point of management for distributed databases. It collects the required information for database and system administrators to examine the performance of the Sybase server system, detect problems early and prevent them. Database and system administrators can set the required threshold levels and flags to trigger alerts when the system reaches these thresholds. You must configure the Monitoring Agent for Sybase Server to monitor Sybase server.

### Before you begin

Review the hardware and software prerequisites. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\) for the Sybase agent](#).

## About this task

The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see [“Change history” on page 58](#).

The Sybase agent is a multiple instance agent, you must configure and start each agent instance manually.

## Procedure

1. Configure the monitoring agent.

- [“Configuring the agent by using the command line interface” on page 891](#)
- [“Configuring the agent by using the silent response file” on page 893](#)

2. Start and stop the monitoring agent by using agent command **sybase-agent**.

For more information about the **sybase-agent**, see *Using agent commands* in [https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/welcome.htm](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/welcome.htm).

3. Connect the monitoring agent to the Performance Management server by using the command **agent2server**.

For more information about the **agent2server**, see *Using agent commands* in [https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/welcome.htm](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/welcome.htm).

## Granting permissions

You must grant permissions to the user ID that is used to monitor the Sybase server.

### Before you begin

Install the Sybase agent.

You must have the database administrator role to grant permissions.

## About this task

The user ID that is used by the monitoring agent must have access to Sybase tables and the installed monitor tables.

You can perform the following tasks:

- Create a user ID for the monitoring agent.
- Grant permission to the new user ID and the installed monitor tables.

If you are not running the Sybase agent as root user, make sure that the user ID belongs to the Sybase group and has read-access to the Sybase log files.

## Procedure

1. Enter the command for the operating system you are using.

- Windows

```
cd install_dir\tmaitm6\SQLLIB
```

- UNIX

```
cd install_dir/misc
```

Where, *install\_dir* is the home directory where the Sybase server is installed.

2. Use the **isql** command to log in to the Sybase server as user sa.

3. Run the following command to configure the ID that is used by the Sybase agent to communicate with Sybase server:

```
1>sp_addlogin user_name, password 2>g
```

Where:

- *user\_name* is the user ID. By default, it is *tivoli*.  
If the user ID is not *tivoli*, edit the *koygrant.sql* file and change the *tivoli* to the correct user ID.
- *password* is the password of the user.

**Note:**

Location of the *koygrant.sql* file:

- Windows \opt\ibm\apm\agent\misc\  
• UNIX /opt/ibm/apm/agent/misc/

4. Run the following command to grant permission to the tables in the database:

```
isql -U sa -P password -S servername -i koygrant_filepathkoygrant.sql
```

Where:

- *password* is the password of user *sa*.
- *servername* is the database server name.
- *koygrant\_filepath* is at the following location:

**Note:**

- Windows \opt\ibm\apm\agent\misc\  
– UNIX /opt/ibm/apm/agent/misc/

5. Run the following command to create proxy tables that are used for the installed monitor tables:

```
isql -U sa -P password -S servername  
-i $SYBASE/ASE-12_5/scripts/installmontables
```

Where:

- *password* is the password of user *sa*.
- *servername* is the database server name.

## What to do next

When the permissions are successfully granted, you can configure the monitoring agent.

## Configuring the agent by using the command line interface

You can configure the Monitoring Agent for Sybase Server by using the command line interface.

### Before you begin

The Sybase agent does not support remote configuration. Hence, you need to ensure that the Sybase server is installed on the same host where the Sybase agent is installed.

The Sybase agent supports Sybase Server version 15.7 and 16.0 only.

The user ID that is used to connect to the database server is created.

## About this task

The Sybase agent is a multiple instance agent, you must configure and start each agent instance manually.

## Procedure

1. Run the following command to configure the agent.

- Windows

```
install_dir\bin\sybase-agent.bat instance_name
```

- UNIX

```
install_dir/bin/sybase-agent.sh instance_name
```

Where:

- *install\_dir* is the agent installation directory.
  - *instance\_name* is the Sybase server instance name.
2. When you are prompted to provide values for the following parameters, press Enter to accept the default value, or specify a value and press Enter.
    - a) For the Home Directory parameter, enter the path of the Sybase server home directory path.
      - Windows  
The example of Home Directory is \opt\sybase.
      - UNIX  
The example of Home Directory is /opt/sybase.
    - b) For the ASE Directory parameter, enter the path of the database server ASE.
      - Windows  
The example of ASE Directory is \opt\sybase\ASE-12\_5.
      - UNIX  
The example of ASE Directory is /opt/sybase/ASE-12\_5.
    - c) For the Open Client Directory parameter, enter the Sybase open client installation location.
      - Windows  
The example of Open Client Directory is \opt\sap\ocs-16\_0.
      - UNIX  
The example of Open Client Directory is /opt/sap/ocs-16\_0.
    - d) For the USER ID parameter, enter the user ID that is used by the monitoring agent to connect to the Sybase server.  
The default USER ID is `tivoli`.
    - e) For the PASSWORD parameter, enter the password of the user ID that is used by the monitoring agent to connect to the Sybase server.
    - f) For the VERSION parameter, enter the Sybase server version.  
The Sybase agent supports Sybase server versions 15.7 and 16.0 only.
    - g) For the ERROR LOG FILE parameter, enter the fully qualified file name of the error log file for the Sybase server.
      - Windows  
The example of the ERROR LOG FILE is \opt\sap\ASE-16\_0\install\servername.log.

- UNIX

The example of the ERROR LOG FILE is `/opt/sap/ASE-16_0/install/servername.log`.

Where *servername* is the Sybase server name.

- h) For the EXTENDED parameter, enter the extended parameter that is used by support to exclude certain cursor execution. Optionally, press Enter without specifying any values to execute all cursors.

The options for the EXTENDED parameter are DBD2, DBD15, KOYSEGD.

- DBD2 will exclude cursor execution for datasets Sybase\_Database\_Detail and Sybase\_Database\_Summary.
- DBD15 will exclude cursor execution for dataset Sybase\_Database\_Detail.
- KOYSEGD will exclude cursor execution for dataset Sybase\_Segment\_Detail.

## What to do next

When the configuration is completed, you can start the monitoring agent and connect the monitoring agent to the Performance Management server.

To start the Sybase agent, use the agent command `sybase-agent` command.

To connect the Sybase agent to the Performance Management server, use the `agent2server` command.

For more information about the `sybase-agent` and `agent2server`, see *Using agent commands* in [https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/welcome.htm](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/welcome.htm).

## Configuring the agent by using the silent response file

You can configure the Monitoring Agent for Sybase Server by using the silent response file.

### Before you begin

The Sybase agent does not support remote configuration. Hence, you need to ensure that the Sybase server is installed on the same host where the Sybase agent is installed.

The Sybase agent supports Sybase server version 15.7 and 16.0 only.

The user ID that is used to connect to the database server is created.

### About this task

The Sybase agent is a multiple instance agent, you must configure and start each agent instance manually.

You must edit the silent response file and run the agent command to configure the monitoring agent.

### Procedure

1. Edit the silent response file.

- Windows

Silent response file is at: `install_dir\samples\sybase_silent_config.txt`.

- UNIX

Silent response file is at: `install_dir/samples/sybase_silent_config.txt`.

Where *install\_dir* is the agent installation directory.

- a) For the Home Directory parameter, specify the path of the Sybase server home directory.

- Windows

The example of Home Directory is \opt\sybase.

- UNIX

The example of Home Directory is /opt/sybase.

b) For the ASE Directory parameter, specify the path of the database server ASE.

- Windows

The example of ASE Directory is \opt\sybase\ASE-12\_5.

- UNIX

The example of ASE Directory is /opt/sybase/ASE-12\_5.

c) For the Open Client Directory parameter, specify the Sybase open client installation location.

- Windows

The example of Open Client Directory is \opt\sap\ocs-16\_0.

- UNIX

The example of Open Client Directory is /opt/sap/ocs-16\_0.

d) For the USER ID parameter, specify the user ID that is used by the monitoring agent to connect to the Sybase server.

The default USER ID is tivoli.

e) For the PASSWORD parameter, specify the password of the user ID that is used by the monitoring agent to connect to the Sybase server.

f) For the VERSION parameter, specify the Sybase server version.

The Sybase agent supports Sybase server versions 15.7 and 16.0 only.

g) For the ERROR LOG FILE parameter, specify the fully qualified file name of the error log file for the Sybase server.

- Windows

The example of the ERROR LOG FILE is \opt\sap\ASE-16\_0\install\servername.log.

- UNIX

The example of the ERROR LOG FILE is /opt/sap/ASE-16\_0/install/servername.log.

Where *servername* is the Sybase server name.

h) For the EXTENDED parameter, specify the extended parameter that is used by support to exclude certain cursor execution. Optionally, leave it blank to execute all cursors.

The options for the EXTENDED are DBD2, DBD15, KOYSEGD.

- DBD2 will exclude cursor execution for datasets Sybase\_Database\_Detail and Sybase\_Database\_Summary.
- DBD15 will exclude cursor execution for dataset Sybase\_Database\_Detail.
- KOYSEGD will exclude cursor execution for dataset Sybase\_Segment\_Detail.

2. Save the silent response file.

3. Run the following agent command to configure the monitoring agent.

- Windows

```
install_dir\bin\sybase-agent.bat config instance_name  
install_dir\samples\sybase_silent_config.txt
```

- UNIX

```
install_dir/bin/sybase-agent.sh config instance_name  
install_dir/samples/sybase_silent_config.txt
```

Where:

- *install\_dir* is the agent installation directory.
- *instance\_name* is the Sybase server name.

## What to do next

When the configuration is completed, you can start the monitoring agent and connect the monitoring agent to the Performance Management server.

To start the Sybase agent, use the **sybase-agent** command.

To connect the Sybase agent to the Performance Management server, use the **agent2server** command.

For more information about the **sybase-agent** and **agent2server**, see *Using agent commands* in [https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/welcome.htm](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/welcome.htm).

## Disabling dirty reads for query

The Sybase agent enables dirty reads for its query execution by default to prevent locking.

The variable `COLL_USE_NOLOCK` is used to enable or disable the query dirty reads.

When dirty reads is enabled, query is executed with isolation level zero to avoid locking.

If you wish to disable the dirty reads for agent query, you can set the variable `COLL_USE_NOLOCK` to zero.

## Before you begin

To disable dirty reads for agent query, ensure that the agent is installed.

## About this task

The Sybase agent enables dirty reads by default. To disable the dirty reads for the agent query, complete the following steps.

## Procedure

1. Stop the agent.
2. Set the variable `COLL_USE_NOLOCK` to zero.
  - UNIX
    - a. Add **`COLL_USE_NOLOCK=0`** in `CANDLEHOME/config/.oy.environment` file.
    - b. Save and close the file.
  - Windows
    - a. Locate the agent instance file `CANDLEHOME\TMAITM6_x64\Koyenv_INSTANCENAME`.
    - b. Add the following line in the file.  
**`COLL_USE_NOLOCK=0`**
    - c. Save and close the file.

The `CANDLEHOME` is the agent installation directory.

The `INSTANCENAME` is the agent instance name.

3. Start the agent.

## Configuring Synthetic Playback monitoring

You must configure the Synthetic Playback agent so that the agent can collect data on the availability and performance of internal web applications. This data is displayed in the Application Performance Dashboard.

### About this task

Configure the Synthetic Playback agent by running a script and by responding to prompts. Then, start the script and verify that the script is running.

### Procedure

- To configure the agent by running the script and responding to prompts, complete the following steps:
  - a) Enter `install_dir/bin/synthetic_playback-agent.sh config` where `install_dir` is the Synthetic Playback agent installation directory.
  - b) When prompted to Edit Monitoring Agent for Synthetic Playback settings, enter 1 to continue.
  - c) When prompted to enter a data center name for your playback point of presence, enter a name that identifies the location of your agent.

**Important:** Choose a descriptive name for your playback point of presence. When you complete the installation of your agent, you can then select that location by name as a playback location for your synthetic transactions and view transaction data from that location in the Application Performance Dashboard.

- d) When prompted for Java parameters, choose a Java trace level. Press Enter to choose the default parameter, or enter a number from 1 - 8 to specify a trace level.
  - e) When prompted for Class path for external jars, press Enter to leave blank, or else specify the location of an external jar.
- To configure the agent by using the silent response file, complete the following steps:
    - a) In a text editor, open the `synthetic_playback_silent_config.txt` file that is available at the `install_dir/samples` path.  
For example

```
Linux /opt/ibm/apm/agent/samples
```

- b) In the `synthetic_playback_silent_config.txt` file, uncomment and assign values to the following properties:
  - For LOCATION, equate this parameter to the name of your data center or a name describing where your agent is installed.
  - For JAVA\_TRACE\_LEVEL, equate this parameter to one of the listed trace levels, such as `JAVA_TRACE_LEVEL=ERROR`.

Save the file.

- c) On the command line, change the path to `install_dir/bin`.
- d) Run the following command to configure the agent in silent mode:

```
synthetic_playback-agent.sh config install_dir/samples/  
synthetic_playback_silent_config.txt
```

- To start the Synthetic Playback agent, enter: `install_dir/bin/synthetic_playback-agent.sh start`.
- To verify that the Synthetic Playback agent is running, enter: `install_dir/bin/synthetic_playback-agent.sh status`. For more information, see [Table 28 on page 238](#).

## What to do next

To view the performance of internal web applications, you must create synthetic transactions in the Synthetic Script Manager. For more information, see [“Managing synthetic transactions and events ” on page 1177.](#)

## Enabling upstream proxy support for the Synthetic Playback agent

Enable upstream proxy support for the Synthetic Playback agent to monitor HTTP requests from internal web applications to external web applications.

### Before you begin

Ensure that you are running Synthetic Playback agent version 01.00.05.08 or later. To check what agent version you are running, enter `install_dir/bin/cinfo -t` in the command line, where `install_dir` is the installation location of the agent. If you are running any other version of the Synthetic Playback agent, you must download and install IBM Cloud Application Performance Management, Private 8.1.4.0 Synthetic Playback agent interim fix 08 from [IBM Fix Central](#) (Enter Synthetic in the **Search** field and the list of Synthetic Playback agent interim fixes are displayed). For installation instructions, see [8.1.4.0-IBM-IPM-SYNTHETIC-PLAYBACK-AGENT-IF0008 Readme.](#)

### About this task

Internal web applications behind an enterprise firewall require an upstream proxy to access external web resources. Configure the proxy setting of the Synthetic Playback agent to allow your agent to support your upstream proxy so that you can monitor HTTP requests from internal web applications to external web applications.

### Procedure

- To configure and enable upstream proxy support for your agent, complete the following steps.
  - a) As the root user, configure the proxy settings by running the following commands in the command line.

```
cd install_dir/agent/lx8266/sn/bin
#./set_proxy.sh
```

When you are prompted, enter the agent installation path, the default path is `/opt/ibm/apm/agent`. Enter the number for the proxy type that you want to configure for your Synthetic Playback agent.

For example:

```
# cd /install_dir/agent/lx8266/sn/bin/
#./set_proxy.sh
please input the agent install path, default is (/opt/ibm/apm/agent)
agent install path is:/opt/ibm/apm/agent
please input the number of proxy type:
1 system proxy
2 manual proxy
3 pac proxy
4 no proxy
```

- b) Enter `install_dir/bin/synthetic_playback-agent.sh start` to restart your agent.
- **Linux** To disable upstream proxy support for your agent, run the `./set_proxy.sh` command again, and select 4 no proxy. Then, restart your agent.

## Configuring Tomcat monitoring

---

You can configure the Monitoring Agent for Tomcat with the default or custom settings to monitor the resources of Tomcat application servers. The agent can be configured on Windows and Linux systems.

### Before you begin

Review the hardware and software prerequisites. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\)](#) for the Tomcat agent.

### About this task

The Tomcat agent is a multiple instance agent; you must create the first instance and start the agent manually. The managed system name includes the instance name that you specify, for example, *instance\_name: host\_name: pc*, where *pc* is your two character product code. The managed system name is limited to 32 characters. The instance name that you specify is limited to 28 characters that excludes the length of your host name. For example, if you specify TOMCAT2 as your instance name, your managed system name is TOMCAT2: hostname: OT. If you specify a long instance name, the managed system name is truncated, and the agent code is not displayed completely.

To avoid permission issues when you configure the agent, be sure to use the same root user or non-root user ID that was used for installing the agent. If you installed your agent as a selected user and want to configure the agent as a different user, see [“Configuring agents as a non-root user”](#) on page 243. If you installed and configured your agent as a selected user and want to start the agent as a different user, see [“Starting agents as a non-root user”](#) on page 1159.

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

## Configuring the Tomcat agent with the default settings

You can use the default settings of the Tomcat agent to monitor the Tomcat server. You do not need to provide more configuration information other than the new instance name.

### Before you begin

Before you configure the agent with the default settings, ensure that the following prerequisites are met:

- The agent is installed in the default directory.
- The JMX service URL uses the 8686 port.
- The Tomcat server is configured without the JMX authorization.

### About this task

**Remember:** When you configure the agent with the default settings, the collection of transaction tracking and deep-dive diagnostics data is not enabled.

### Procedure

1. Run the following command:

```
Linux install_dir/bin/tomcat-agent.sh config instance_name install_dir/samples/tomcat_silent_config.txt
```

```
Windows install_dir/bin/tomcat-agent.bat config instance_name install_dir/samples/tomcat_silent_config.txt
```

Where

**install\_dir**

The installation directory of the Tomcat agent.

### ***instance\_name***

The name that you want to give to the instance.

2. Run the following command to start the agent:

|                |   |
|----------------|---|
| <b>Linux</b>   | <code>install_dir/bin/tomcat-agent.sh start instance_name</code>  |
| <b>Windows</b> | <code>install_dir/bin/tomcat-agent.bat start instance_name</code> |

## **What to do next**

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

## **Configuring the agent on Windows systems**

You can configure the agent on Windows operating systems by using the **IBM Performance Management** window.

### **Before you begin**

Ensure that the following prerequisites are met:

- Java is installed on the Tomcat Server where the agent is installed.
- JDK 1.6 or later version is set on the prompt from where the agent installer is installed.
- JMX Remote is enabled for the Tomcat Server. For details, see [Enabling JMX Remote](#).
- The Tomcat Server is up and running.

### **About this task**

You can configure the agent from the command prompt. For details, follow the steps that are given in the [“Configuring the Tomcat agent on Linux systems” on page 902](#) topic, and run the commands with the .bat extension instead of .sh extension. The following procedure explains configuring the agent by using the agent configuration panel.

### **Procedure**

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.
2. In the **IBM Performance Management** window, right-click **Monitoring Agent for Tomcat**.
3. Click **Configure agent**.

**Attention:** If **Configure agent** is unavailable, click **Reconfigure**.

4. In the **Instance Name** window, specify a unique name for the Tomcat agent instance, and click **OK**.

**Restriction:** The MSN must not exceed 32 characters.

5. In the **SERVER NAME** field, enter a unique name to identify the Tomcat Server that is being monitored.
6. In the **Java Parameter Settings** window, complete one of the following steps:
  - Click **Next** to accept the default location where Java is installed. The default installation path is C:\IBM\APM\java\java80\_x64\jre.
  - In the **Java Home** field, specify the path when IBM Java is installed at a different path.
7. In the **JSR-160-Complaint Server** window, specify the details of the following parameters:
  - a) In the **JMX user ID** field, specify the ID of the user that is used to connect to the Tomcat MBean server when the JMX authorization is enabled in Tomcat.
  - b) In the **JMX password** field, specify the password of the JMX user when the JMX authorization is enabled in Tomcat.
  - c) In the **JMX service URL** field, enter the URL that is used for connecting to the Tomcat MBean server.

The format of the URL is `service:jmx:rmi:///jndi/rmi://host_name:port_number/jmxrmi`. The default URL is valid when the server runs on the local host and uses the 8686 port as a JMX port. You can modify the host name and port number in the URL, keeping the same format.

- d) From the **Data Collector Configuration** list, select Yes if you want to enable collection of transaction tracking and deep dive data.
8. In the **Monitoring Agent for Tomcat** window, right-click the Tomcat agent instance, and click **Start**.
9. Enable the collection of Transaction Tracking and Deep Dive data and restart the Tomcat Server.

## What to do next

If Tomcat agent is running as a service, after configuring the agent on Windows, configure Tomcat Data Collector. For more information, see [“Configuring Tomcat Data Collector”](#) on page 901.

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console”](#) on page 1109.

## Providing Local Security Policy for running Monitoring Agent for Tomcat on Windows by a Non-Admin user

Local security policies are available to run a Monitoring Agent for Tomcat on Windows by a non-admin user.

### About this task

A combination of following two local security policies works to run the Tomcat agent on Windows by a non-admin-user. For a Tomcat agent to start/stop, Configure, and Data verification these two policies work.

1. Debug Programs.
2. Log on as Service.

Follow the procedure that is given to avail the Local Security permissions for a non-administrator user.

### Procedure

1. Go to TEMA and change the Tomcat agent startup with non-admin user.
2. Add non-admin user under Tomcat Agent Installation Folder and Give Full Permissions to it.
3. Add non-admin user under Registry key HKEY\_LOCAL\_MACHINE and click **Full Permissions**.
4. Run the **secpol.msc** command in **startmenu** to open the Local Security policies
5. Then, to add Non-admin user in the policies refer [“Local Security Policy permissions”](#) on page 900
6. Restart the Tomcat Agent.
7. Check Tomcat Agents status and verify the data on APM portal.

## Local Security Policy permissions

### *Granting Debug Programs permission*

#### About this task

To grant the Debug Programs permission, follow the procedure on Tomcat agent as described here:

#### Procedure

1. Click **Start > Administrative Tools > Local Security Policy**. The **Local Security Settings** window opens
2. Expand **Local Policies** and click **User Rights Assignment**. The list of user rights opens.

3. Double-click **Debug Programs** policy. The **Debug Programs Properties** window opens.
4. Click **Add User or Group**. The **Select Users or Groups** window opens.
5. In the Enter the object names to select field, enter the user account name to whom you want to assign permissions, and then click **OK**.
6. Click **OK**.

### ***Granting Log on as Service permission***

#### **About this task**

To grant the Log-on as service permission, follow the procedure on Tomcat agent as described here.

#### **Procedure**

1. Click **Start > Administrative Tools > Local Security Policy**. The **Local Security Settings** window opens
2. Expand **Local Policies** and click **User Rights Assignment**. The list of user rights opens.
3. Double-click **Log-on as service** policy. The **Log-on as service Properties** window opens.
4. Click **Add User or Group**. The **Select Users or Groups** window opens.
5. In the Enter the object names to select field, enter the user account name to whom you want to assign permissions, and then click **OK**.
6. Click **OK**.

### **Configuring Tomcat Data Collector**

If Tomcat agent is running as a service, after configuring the agent on Windows, configure Tomcat Data Collector with the instructions given here.

#### **About this task**

After configuring and starting Tomcat agent instance, it generates or updates `setenv.bat` file in `/CANDLEHOME/setenv_<instance_name>.bat`. This file contains data collector configuration parameters necessary for configuration of Tomcat Data Collector.

#### **Procedure**

1. Open **Apache Tomcat Properties** window, and click **Java**
2. Open `setenv_<instanceName>.bat` from the location `/CANDLEHOME/setenv_<instance_name>.bat`
3. Copy the value of **JAVA\_OPTS** parameter from `setenv_<instance_name>.bat` shown in the block:

```
agentlib:am_ibm_16=C:\IBM\APM\otdchome\7.3.0.13.0\runtime\TOMTKWIN1
-Xbootclasspath/p:C:\IBM\APM\otdchome\7.3.0.13.0\toolkit\lib\bcm-bootstrap.jar
-Djava.security.policy=C:\IBM\APM\otdchome\7.3.0.13.0\itcamdc\etc\datacollector.policy
-Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=
C:\IBM\APM\otdchome\7.3.0.13.0\runtime\TOMTKWIN1\TOM_TK_1_DCManual.txt
-Dcom.ibm.tivoli.itcam.serverHome=C:\TOMCAT_9\apache-tomcat-9.0.5\apache-tomcat-9.0.5
-Dam.home=C:\IBM\APM\otdchome\7.3.0.13.0\itcamdc
-Dcom.ibm.tivoli.itcam.toolkit.runtime.dir=C:\IBM\APM\otdchome\7.3.0.13.0\runtime
```

4. Paste this value into the text box labeled **Java Options** in the **Java** tab of **Apache Tomcat Properties**
5. Click **Apply**
6. Go to **Control Panel**, click **System > Advanced > Environment Variables**
7. In **System variables**, edit the variable `PATH` by appending file path `<OTDC_home>\toolkit\lib\win64;<OTDC_HOME>\ toolkit\lib\win64\ttpi` and click **OK**

**Note:** Replace <OTDC\_home> with the real path of the toolkit installation directory. For instance,  
C:\IBM\APM\otdchome\7.3.0.13.0\toolkit\lib\win64;C:\IBM\APM\otdchome  
\7.3.0.13.0\toolkit\lib\win64\ttapi

8. Click **NEW** to add a variable *RUNTIME\_DIR*.
9. Add **Variable Name** as *RUNTIME\_DIR* and **Variable Path** as C:\IBM\APM\otdchome  
\7.3.0.13.0\runtime. This path is available in setenv\_<instancename>.bat
10. Restart Windows. Make sure that the Tomcat service startup is set to Automatic

## Configuring the Tomcat agent on Linux systems

You run the configuration script and respond to prompts to configure the Tomcat agent on Linux systems.

### Before you begin

- JMX Remote is enabled for the Tomcat Server. For details, see [Enabling JMX Remote](#).
- The Tomcat Server is up and running.

### Procedure

1. Run the following command:  
`install_dir/bin/tomcat-agent.sh config instance_name`  
Where *instance\_name* is the name that you want to give to the instance.
2. When you are prompted to specify a value for SERVER, specify a unique name to identify the Tomcat Server that is being monitored, and press Enter.
3. When you are prompted to specify a value for Java home, press Enter to accept the default location where the Java virtual machine is installed. The default location is /opt/ibm/apm/agent/JRE/1x8266/jre. If the agent is not installed in the default directory, specify *install\_dir/JRE/1x8266/jre*.
4. When you are prompted to specify a value for JMX user ID, specify the ID of the user who connects to the Tomcat MBean server. If the JMX authorization is not enabled, press Enter.
5. When you are prompted to specify a value for JMX password, specify the password of the JMX user and confirm it. If JMX authorization is not enabled, press Enter.
6. When you are prompted to specify a value for JMX service URL, press Enter to accept the default URL or specify another service URL for connecting to the Tomcat MBean server.  
The format of the URL is `service:jmx:rmi:///jndi/rmi://host_name:port_number/jmxrmi`. The default URL is valid when the server runs on the local host and uses the 8686 port as a JMX port. You can modify the host name and the port in the URL, keeping the same format.
7. When you are prompted to specify a value for Data Collector Configuration, specify 1 and press Enter to enable collection of transaction tracking and deep dive data.
8. Run the following command to start the agent:  
`install_dir/bin/tomcat-agent.sh start instance_name`
9. Enable the collection of Transaction Tracking and Deep Dive data, restart the Tomcat Server.

### What to do next

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

## Configuring the Tomcat agent by using the silent response file

You can use the silent response file to configure the Tomcat agent without responding to prompts.

### Procedure

1. In a text editor, open the `tomcat_silent_config.txt` file that is available at the following path:

`install_dir/samples`

- For the **KOT\_SERVER** parameter, specify a unique name to identify the Tomcat Server that is being monitored.
- For the **Java home** parameter, specify the path where the Java virtual machine is installed. The default location is `/opt/ibm/apm/agent/JRE/1x8266/jre`. If the agent is not installed in the default directory, specify `install_dir/JRE/1x8266/jre`.
- For the **JMX user ID** parameter, specify the ID of the user that is used to connect to the Tomcat MBean server. You must specify a value for this parameter when the JMX authorization is enabled in Tomcat.
- For the **JMX password** parameter, specify the password of the JMX user. You must specify a value for this parameter when the JMX authorization is enabled in Tomcat.
- For the **JMX service URL** parameter, specify the service URL for connecting to the Tomcat MBean server. The format of the URL is `service:jmx:.rmi:///jndi/rmi://host_name:port_number/jmxrmi`. The default URL is valid when the server runs on the local host and uses the 8686 port as a JMX port. You can modify the host name and the port number in the URL, keeping the same format.
- For the **KOT\_DCCONFIGURATION** parameter, specify Yes if you want to enable collection of transaction tracking and deep dive data.
- Save and close the `tomcat_silent_config.txt` file, and run the following command to update the agent configuration settings:  

**Linux** `install_dir/bin/tomcat-agent.sh config instance_name install_dir/samples/tomcat_silent_config.txt`

**Windows** `install_dir/bin/tomcat-agent.bat config instance_name install_dir/samples/tomcat_silent_config.txt`

Where *instance\_name* is the name that you want to give to the instance, and *install\_dir* is the installation directory of the Tomcat agent.
- Run the following command to start the agent:  

**Linux** `install_dir/bin/tomcat-agent.sh start instance_name`

**Windows** `install_dir/bin/tomcat-agent.bat start instance_name`
- If you enable the collection of transaction tracking and deep dive data, restart the Tomcat Server.

## What to do next

Log in to the Cloud APM console to view data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

## Enabling the collection of transaction tracking and diagnostics data

On the **Agent Configuration** page, you can enable or disable the collection of transaction tracking and diagnostics data.

### About this task

When you enable the collection of transaction tracking data, the agent collects data of the following components:

- Servlet JSP
- EJB applications
- JMS

### Procedure

Complete the following steps to configure the data collection for each managed system.

- Log in to the Cloud APM console.
- From the navigation bar, click  **System Configuration** > **Agent Configuration**.

The **Agent Configuration** page is displayed.

3. Click the **Tomcat** tab.
4. Select the check boxes of the managed systems for which you want to configure the data collection and complete any of the following actions from the **Actions** list.
  - To enable transaction tracking, click **Set Transaction Tracking > Enabled**. The status in the **Transaction Tracking** column is updated to Enabled for each selected managed system.
  - To enable the diagnostic data collection, select **Set Diagnostic Mode > Enabled Diagnostic Mode Only**. The status in the Diagnostic Mode column is updated to Enabled for each selected managed system.
  - To enable the diagnostic data collection and method trace, select **Set Diagnostic Mode > Enabled Diagnostic Mode and Method Trace**. The status in the Diagnostic Mode and Method Trace columns is updated to Enabled for each selected managed system.
  - To disable transaction tracking, click **Set Transaction Tracking > Disabled**. The status in the **Transaction Tracking** column is updated to Disabled for each selected managed system.
  - To disable diagnostic data collection, click **Set Diagnostic Mode > Disabled Diagnostic Mode and Method Trace**. The status in the **Diagnostic Mode and Method Trace** columns is updated to Disabled for each selected managed system.

## What to do next

- Log in to the Cloud APM console to view the transaction tracking and diagnostics data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console”](#) on page 1109.
- Review the data that is presented in the Tomcat agent dashboard pages. For more information, see [“Group and Instance - Application Performance Dashboard”](#) on page 1259.
- The **Method traces** widget lists the method names, their stack trace, and their response times. To optimize response time, the number of methods are limited by the threshold value for response time (default is 50 milliseconds) taken by each method call. Thus, you do not see the method traces for the responses that complete within 50 milliseconds. If you prefer to see all method calls in the Method traces widget, you can update the agent configuration:

1. Open the `/<agent_installation>/otdcchome/<toolkit_version>/gdc/etc/appMethods.xml` file in a text editor.

2. Locate the **collectContextData** parameter. These are the default values:

```
<collectContextData>false</collectContextData>
  <collectStackTrace>ifThresholdExceeded</collectStackTrace>
  <perfThreshold>50</perfThreshold>
  <secondaryPerfThreshold>200</secondaryPerfThreshold>
  <dataToCollect>instanceAndSummary</dataToCollect>
  <createDataRow>ifThresholdExceeded</createDataRow>
  <showParentMethodId>true</showParentMethodId>
```

3. Set `<collectStackTrace>` to true.

4. Set `<createDataRow>` to true.

5. Restart the Tomcat server.

The threshold limit affects the behavior of the Method traces widget. Therefore, the total response time might not be the sum of the method trace that is displayed on the dashboard.

**Note:** Diagnostics must be enabled for the `<collectStackTrace>` true setting to take effect. For more information, see [“Configuring collection of detailed diagnostic information”](#) on page 905 and [“Customizing the request thresholds”](#) on page 906.

## Configuring collection of detailed diagnostic information

If you have IBM Cloud Application Performance Management, Advanced Private, you can use the data collector to collect detailed diagnostic information on the monitored application server instance. To configure the behavior of the diagnostic data collection, including the amount of diagnostic information that the data collector stores, customize the `gdc_custom.properties` configuration file.

### About this task

You can find the `gdc_custom.properties` file in the `dc_home/runtime/<server_name>/custom/gdc` directory.

The following examples describe how to use the properties in the `gdc_custom.properties` configuration file to do the following things:

- [Setting limits for the size and number of detailed information files](#)
- [Setting full or partial collection of request and method diagnostic data](#)

You can also set other properties in the `gdc_custom.properties` file to customize collection of diagnostic data. Refer to the comments in the file that describe the properties.

**Remember:** After you complete editing the `gdc_custom.properties` file, you must restart the monitored application server instance for the changes to take effect.

### *Setting limits for the size and number of detailed information files*

#### About this task

The data collector stores diagnostic information in a number of files. By default, it stores 100 files; if 100 files are already stored and a new file is created, the oldest file is deleted. The data collector creates a new file every 15 minutes, or when the size of the current file exceeds 200 megabytes. When the total size of the directory that contains the files exceeds 2 gigabytes, the data collector deletes the oldest file.

#### Procedure

You can change the following settings in the `dc_home/runtime/<server_name>/custom/gdc/gdc_custom.properties` file:

- To set the maximum number of files with diagnostic information, set the `com.ibm.itcam.gdc.dfe.filelimit` property.  
For example:

```
com.ibm.itcam.gdc.dfe.filelimit=100
```

- To set the time, in minutes, after which the data collector creates a new diagnostic data file, set the `com.ibm.itcam.gdc.dfe.frequency` property.  
For example:

```
com.ibm.itcam.gdc.dfe.frequency=15
```

- To set the maximum diagnostic data file size, in megabytes, set the `dfe.file.maxlimit` property.  
For example:

```
dfe.file.maxlimit=200
```

If the current diagnostic data file reaches this size, the data collector creates a new diagnostic data file.

- To set the maximum total size of all data files, in bytes, set the `trace.dir.size.limit` property.  
For example:

```
trace.dir.size.limit=2147483648
```

If the sum of the sizes of all the diagnostic data files exceeds this value, the data collector deletes the oldest data file. The minimum total size is 25 megabytes.

## ***Setting full or partial collection of request and method diagnostic data***

### **About this task**

The data collector has the following default settings:

- The data collector collects diagnostic data only for the selected requests. The selection (sampling) of the requests aims to include all errors and some good requests.
- Method data collection is disabled at server startup.
- When method data collection is enabled, the data collector gathers method data only for some requests (of those for which diagnostic data is collected). This further selection (sampling) again aims to include all errors and some good requests.

**Important:** Changing these settings affects performance of the application server. On production servers, the performance degradation might be critical.

### **Procedure**

You can change these settings by using properties in the `dc_home/runtime/<server_name>/custom/gdc/gdc_custom.properties` file.

- To enable method data collection, set the property as follows:

```
dfe.enable.methoddata=true
```

**Tip:** You can also use the **Agent Configuration** page to dynamically enable or disable the method trace data collection.

- To collect diagnostic data for every request, disable the sampling by setting the property as follows:

```
dc.sampling.enable=false
```

- To enable method data collection for every request for which diagnostic data is collected, set the property as follows:

```
dc.sampling.enable=false  
dc.sampling.methsampler.enabled=false
```

**Remember:** The `dc.sampling.methsampler.enabled` property takes effect only when method data collection is enabled on the Agent Configuration page or by the `dfe.enable.methoddata` property.

## **Customizing the request thresholds**

Some of the requests might not have enough information if the default thresholds are high. You can customize the request thresholds so that more requests or request context data can be captured by the data collector.

### **About this task**

Each request type has two threshold types, which are named **perfThreshold** and **secondaryPerfThreshold**. A request is captured by the data collector only when it takes more time than what is specified for the **perfThreshold** threshold. Context data, such as stack trace and SQL statement, is captured only when the request takes more time than what is specified for the **secondaryPerfThreshold** threshold. You can adjust these threshold values to suit your needs.

## Procedure

1. Go to the etc directory of the Tomcat agent.

- **Linux** `/<dc_home>/gdc/etc`
- **Windows** `\<dc_home>\gdc\etc`

where `<dc_home>` is the installation directory of the Tomcat agent. The default is `C:\IBM\APM\otdchome` on Windows systems and `/opt/ibm/apm/agent/otdchome` on Linux systems.

2. In a text editor, open the XML file for the request type that you want to customize. You can tell which file is for which request type from the XML file name.  
For example, the `servlet.xml` file is for servlet requests, the `custom.xml` file is for custom requests, and the `appMethods.xml` file is for class and methods when method trace is enabled.
3. Set the `<collectContextData>`, `<collectStackTrace>`, and `<createDataRow>` tags to `ifThresholdExceeded`.

```
<collectContextData>ifThresholdExceeded</collectContextData>
<collectStackTrace>ifThresholdExceeded</collectStackTrace>
<createDataRow>ifThresholdExceeded</createDataRow>
```

4. Set the `<perfThreshold>` tags to the threshold value that you desire. The unit of the threshold is millisecond.  
For example, the `servlet.xml` file has the following settings for servlet requests. As a result, only the servlet requests that take more than 2000 milliseconds are captured by the data collector if `createDataRow` is set to `ifThresholdExceeded`.

```
<collectContextData>true</collectContextData>
<collectStackTrace>ifThresholdExceeded</collectStackTrace>
  <perfThreshold>2000</perfThreshold>
<dataToCollect>instanceAndSummary</dataToCollect>
<createDataRow>ifThresholdExceeded</createDataRow>
```

5. You can update the configuration for threshold check and it will force all method calls to be visible on APM dashboard.

Edit the `dc_home/gdc/etc/appMethods.xml` file as given below:

- a. Set `<collectContextData>` to true
- b. Set `<collectStackTrace>` to true
- c. Set `<createDataRow>` to true

Updating these configurations will result in an overall performance impact on web-applications which are deployed on Tomcat server.

6. Save your desired changes and restart the application server.

## Update or Change Tomcat Application Server

To update or change Tomcat application server after Tomcat agent configuration, follow the steps given in this topic. These steps are common for both, Tomcat configured through Windows and Linux.

## Procedure

1. Stop Tomcat agent instance and Tomcat Server
2. Go to `<TOMCAT_SERVER>/bin` and open `setenv.sh` file in editor
3. Remove all the startup parameters for Data Collector from `setenv.sh`. Remove following lines from the file

```
export LD_LIBRARY_PATH="<CANDLE_HOME>/otdchome/7.3.0.13.0/toolkit/lib/1x8266"
export RUNTIME_DIR="<CANDLE_HOME>/otdchome/7.3.0.13.0/runtime"
export JAVA_OPTS="-agentlib:am_ibm_16=<CANDLE_HOME>/otdchome/7.3.0.13.0/runtime/
<Tomcat_Application_
Server> -
Xbootclasspath/p:<CANDLE_HOME>/otdchome/7.3.0.13.0/toolkit/lib/bcm-bootstrap.jar -
```

```
Djava.security.policy=<CANDLE_HOME>/otdchome/7.3.0.13.0/itcamdc/etc/datacollector.policy -
Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=<CANDLE_HOME>/otdchome/7.3.0.13.0/runtime/
<Tomcat_
Application_Server>/<Agent_Instance>_DCManual.txt -
Dcom.ibm.tivoli.itcam.serverHome=<TOMCAT_HOME> -
Dam.home=<CANDLE_HOME>/otdchome/7.3.0.13.0/itcamdc -
Dcom.ibm.tivoli.itcam.toolkit.runtime.dir=<CANDLE_HOME>/otdchome/7.3.0.13.0/runtime"
```

4. Save the changes and start Tomcat Server
5. Reconfigure the Tomcat agent to update or change Tomcat Application Server
6. Update or Change only the Tomcat Application Server and do not change any the other configuration setting
7. Start Tomcat agent instance
8. Check setenv . sh file is updated with new Tomcat Application Server in startup parameters for Data Collector
9. Restart Tomcat Server
10. Verify the changes made to Tomcat Application Server are reflected in Agent Machine and IBM Cloud Application Performance Management dashboard
  - Verify Tomcat Application Server change at <CANDLE\_HOME>/otdchome/7.3.0.13.0/runtime/<Tomcat\_Application\_Server> location on Agent machine
  - Verify Tomcat Application Server change on **Aggregate Transaction Topology** page and *appserver* attribute under *KOT\_Server* Attribute Group on IBM Cloud Application Performance Management dashboard

## Prerequisites for upgrading Tomcat APM agent to latest toolkit build 7.3.0.15.0

To upgrade the Tomcat agent to toolkit build 7.3.0.15.0, you must ensure the prerequisites given in this topic are complete.

### Procedure

1. Before agent upgrade, remove the DC startup parameters from setenv . sh/setenv . bat file. Remove following DC startup parameters from setenv . sh/setenv . bat file.

```
export LD_LIBRARY_PATH="/opt/ibm/apm/agent/otdchome/7.3.0.13.0/toolkit/lib/
1x8266":$LD_LIBRARY_PATH
export RUNTIME_DIR="/opt/ibm/apm/agent/otdchome/7.3.0.13.0/runtime":$RUNTIME_DIR
export JAVA_OPTS="-agentlib:am_ibm_16=<Agent_Install_Dir>/otdchome/7.3.0.13.0/runtime/
<Tomcat_Application_Server>
-Xbootclasspath/p:<Agent_Install_Dir>/otdchome/7.3.0.13.0/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=<Agent_Install_Dir>/otdchome/7.3.0.13.0/itcamdc/etc/
datacollector.policy
-Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=<Agent_Install_Dir>/otdchome/7.3.0.13.0/
runtime/<Tomcat_Application_Server>/<Tomcat_Agent_Instance>_DCManual.txt
-Dcom.ibm.tivoli.itcam.serverHome=<Tomcat_Server>/apache-tomcat-<Version>
-Dam.home=<Agent_Install_Dir>/otdchome/7.3.0.13.0/itcamdc
-Dcom.ibm.tivoli.itcam.toolkit.runtime.dir=<Agent_Install_Dir>/otdchome/7.3.0.13.0/
runtime":$JAVA_OPTS
```

2. Restart the server.
3. Stop the server.
4. Upgrade the agent with new upgraded toolkit build (7.3.0.15.) build
5. Verify the agent version and required /otdchome and otdchome\_backup folders.
6. Start the Tomcat Server
7. Restart the Tomcat agent
8. Verify that the setenv . sh/setenv . bat has the upgraded toolkit 7.3.0.15.0 DC startup parameters.
9. Restart the Tomcat Server. Server should stop properly without any issues
10. Verify the End-To-End agent functionality.

## Configuring VMware VI monitoring

---

After installing the Monitoring Agent for VMware VI, you must create the first instance, and manually start the agent so that the agent can collect data of the VMware Virtual Infrastructure that is being monitored.

### Before you begin

- Review the hardware and software prerequisites.
- Create a user ID in your VMware Virtual Infrastructure. The agent uses this user ID to connect to the VMware vCenter for monitoring the VMware Virtual Infrastructure. Ensure that you have the "System.View" and "System.Read" privileges on all the vCenters and ESX servers that are being monitored. For information about how to create the user ID, see the VMware documentation for managing users, groups, permissions, and roles.
- Determine whether the vCenter is configured for SSL communication. If it is configured, then you must configure the VMware VI agent to use SSL for communicating with the vCenter.
  - To determine whether the vCenter uses SSL for communication, use the `https://vCenterIPAddress` URL to access the vCenter. If you can access the vCenter, then it indicates that the vCenter uses SSL to communicate over the network.
  - To configure the VMware VI agent to use SSL for communicating with the vCenter, complete the steps that are described in [“Enabling SSL communication with VMware VI data sources”](#) on page 910.
- Decide the number of agent instances that you need to monitor your VMware Virtual Infrastructure. For information about sizing the agent instances according to your monitoring environment, see [“Sizing and planning the VMware VI agent deployment”](#) on page 909.

### About this task

The VMware VI agent is a multiple instance agent. Unlike a single instance agent, for which you can configure the agent to monitor and collect data for only one monitored application, the VMware VI agent can have multiple configured instances that connect to multiple vCenter servers and remotely monitor your VMware Virtual Infrastructure.

The configuration parameters define the VMware VI data sources that are monitored and define a connection to either the VMware vCenter, vCenter Server Appliance, or to an individual VMware ESX server. To know the supported versions of these applications, see the [Software Product Compatibility Reports for the VMware VI agent](#).

The product version and the agent version often differ. The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see the [“Change history”](#) on page 58.

You must manually configure the agent to view data for all the agent attributes.

- To configure the agent on Windows operating systems, you can use the **IBM Performance Management** window or the silent response file.
- To configure the agent on Linux operating systems, you can run the script and respond to prompts, or use the silent response file.

## Sizing and planning the VMware VI agent deployment

The number of agent instances that you can configure on a single system depends on the availability and utilization of resources on the system.

The following table categorizes the VMware environment into various sizes with the required Java heap size:

Table 248. VMware environment and Java heap size

| VMware environment size       | Number of ESX servers  | Java heap size               |
|-------------------------------|--|------------------------------|
| <b>Small environment</b>      | A vCenter server that manages up to 125 ESX(i) servers and 300 - 1500 guests.          | <b>-Xmx2048m</b><br>(2 GB)   |
| <b>Medium environment</b>     | A vCenter server that manages between 125 - 250 ESX(i) servers and 1500 - 4000 guests. | <b>-Xmx4096m</b><br>(4 GB)   |
| <b>Large environment</b>      | A vCenter server that manages between 250 - 500 ESX(i) servers and 4000 - 7500 guests. | <b>-Xmx8192m</b><br>(8 GB)   |
| <b>Very large environment</b> | A vCenter server that manages more than 500 ESX(i) servers and more than 7500 guests.  | <b>-Xmx16384m</b><br>(16 GB) |

To increase the heap size for the Java data provider, complete the steps that are described in [“Increasing the Java heap size”](#) on page 916.

For the agent instances to successfully monitor the environment, the server on which you install the agent, must have adequate memory resources to accommodate the data that is collected by these agent instances. A single instance of the VMware VI agent requires approximately 300 - 400 MB to monitor a small environment. See the following guidelines about the number of agent instances to be configured:

- Use a single instance to monitor a single vCenter. Do not use the same instance to monitor multiple vCenters.
- In a non-cluster environment, use a single instance to monitor a maximum of 8 small ESX servers (100 - 200 virtual machines in one ESX server). Do not configure multiple individual ESX servers under the single agent instance.
- Use multiple agent instances of the VMware VI agent to monitor an environment that contains multiple vCenters. Before you configure multiple instances, ensure that you have adequate memory resources on the system where you install the agent.

## Enabling SSL communication with VMware VI data sources

Before you configure the agent to securely communicate with its VMware VI data sources by using SSL, you must add a data source SSL certificate to the certificate truststore of the agent.

### About this task

**Important:** The following information applies only if the agent is configured to validate SSL certificates.

If the SSL certificate validation is turned off, the VMware VI agent connects to VMware data sources even if their SSL certificates are expired, untrusted, or invalid. However, turning off SSL certificate validation is potentially not secure and must be done with care.

If a VMware data source uses an SSL certificate that is signed by a common Certificate Authority (for example, Verisign, Entrust, or Thawte), then it is not necessary to add certificates to the VMware VI agent certificate truststore. However, if the data source uses a certificate that is not signed by a common Certificate Authority, as is the case by default, you must add the certificate to the truststore to allow the agent to successfully connect and collect data.

#### Note:

1. The default VMware certificate file is named `ru1.crt`.
2. For a Virtual Center, the SSL certificate file is located by default in the following path:

C:\Documents and Settings\All Users\Application Data\VMware\VMware  
VirtualCenter\SSL

3. For an ESX server, the SSL certificate file is located by default in the `/etc/vmware/ssl` directory.

## Procedure

1. Copy the certificate file from your data source to the agent computer.
2. On the agent computer, place the certificate file in a directory of your choice. Do not overwrite the certificate files. Use a unique file name and a label for each certificate that you add.
3. Use the `keytool` command to add the data source certificate to the certificate truststore of the agent:

```
keytool -import -noprompt -trustcacerts -alias CertificateAlias -file  
CertificateFile -keystore Truststore -storepass TruststorePassword
```

Where

### ***CertificateAlias***

Unique reference for each certificate added to the certificate truststore of the agent, for example, an appropriate alias for the certificate from *datasource.example.com* is *datasource*.

### ***CertificateFile***

Complete path and file name to the VMware data source certificate to add to the truststore.

### ***Truststore***

Complete path and file name to the VMware VI agent certificate database. Use the following path and file name:

- **Windows** (64 bit): *install\_dir*\tmaitm6\_x64\kvm.truststore
- **Linux** (64 bit): *install\_dir*/lx8266/vm/etc/kvm.truststore

### ***TruststorePassword***

ITMVMWAREVI is the default password for the VMware VI agent truststore. To change this password, consult the Java Runtime documentation for information about the tools to use.

**Important:** To use the `keytool` command, the Java Runtime bin directory must be in your path. Use the following commands:

- **Windows** (64 bit): `set PATH=%PATH%;install_dir\java\java70_x64\jre\bin`
- **Linux** (64 bit): `PATH="$PATH":/opt/ibm/apm/agent/JRE/lx8266/bin`

4. After you add all the data source certificates, start the monitoring agent.

## What to do next

Complete the agent configuration.

## Configuring the agent on Windows systems

You can configure the agent on Windows operating systems by using the **IBM Performance Management** window. After you update the configuration values, you must start the agent to save the updated values.

### About this task

The VMware VI agent provides default values for some parameters. You can specify different values for these parameters.

## Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**.

2. In the **IBM Performance Management** window, right-click **Monitoring Agent for VMware VI**, and then click **Configure agent**.

**Remember:** After you configure the agent for the first time, the **Configure agent** option is disabled. To configure the agent again, click **Reconfigure**.

3. In the Monitoring Agent for VMware VI window, complete the following steps:
  - a) Enter a unique name for the VMware VI agent instance, and click **OK**.
  - b) On the **Data Provider** tab, specify values for the configuration parameters, and then click **Next**.
  - c) On the **Data Source** tab, specify values for the configuration parameters, and then click **Next**.

The VMware VI agent is a multi-data source agent. You can monitor multiple data sources from the same agent.

- If you want to configure a new data source, click **New**.
- If you want to delete an existing data source, click **Delete**.

For information about the configuration parameters in each tab of the Monitoring Agent for VMware VI window, see the following topics:

- [Configuration parameters for the data provider](#)
- [Configuration parameters for the data source](#)

4. In the **IBM Performance Management** window, right-click the instance that you configured, and then click **Start**.

## What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

If you need help with troubleshooting, see the [Troubleshooting](#) section.

- If you are monitoring a large VMware environment with more than 500 ESX hosts, you might need to increase the heap size for the Java data provider. For more information, see [“Increasing the Java heap size” on page 916](#).

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

The silent response file contains the agent configuration parameters with default values that are defined for some parameters. You can edit the silent response file to specify different values for the configuration parameters.

After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

- To configure the VMware VI agent in the silent mode, complete the following steps:
  - a) In a text editor, open the `vmware_vi_silent_config.txt` file that is available at the following path:
    - **Linux** `install_dir/samples/vmware_vi_silent_config.txt`  
Example `/opt/ibm/apm/agent/samples/vmware_vi_silent_config.txt`
    - **Windows** `install_dir\samples\vmware_vi_silent_config.txt`

Example C:\IBM\APM\samples\vmware\_vi\_silent\_config.txt

- b) In the vmware\_vi\_silent\_config.txt file, specify values for all mandatory parameters. You can also modify the default values of other parameters.

For information about the configuration parameters, see the following topics:

- “Configuration parameters for the data provider” on page 915
- “Configuration parameters for the data source” on page 914

- c) Save and close the vmware\_vi\_silent\_config.txt file, and run the following command:

- **Linux** `install_dir/bin/vmware_vi-agent.sh config instance_name install_dir/samples/vmware_vi_silent_config.txt`

Example `/opt/ibm/apm/agent/bin/vmware_vi-agent.sh config instance_name /opt/ibm/apm/agent/samples/vmware_vi_silent_config.txt`

- **Windows** `install_dir\bin\vmware_vi-agent.bat config instance_name install_dir\samples\vmware_vi_silent_config.txt`

Example `C:\IBM\APM\bin\ vmware_vi-agent.bat config instance_name C:\IBM\APM\samples\vmware_vi_silent_config.txt`

Where

**instance\_name**

Name that you want to give to the instance.

**install\_dir**

Path where the agent is installed.

**Important:** Ensure that you include the absolute path to the silent response file. Otherwise, the agent data is not shown in the dashboards.

- d) Run the following command to start the agent:

- **Linux** `install_dir/bin/vmware_vi-agent.sh start instance_name`

Example `/opt/ibm/apm/agent/bin/vmware_vi-agent.sh start instance_name`

- **Windows** `install_dir\bin\vmware_vi-agent.bat start instance_name`

Example `C:\IBM\APM\bin\vmware_vi-agent.bat start instance_name`

## What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see “Starting the Cloud APM console” on page 1109.
- If you need help with troubleshooting, see the [Troubleshooting](#) section.
- If you are monitoring a large VMware environment with more than 500 ESX hosts, you might need to increase the heap size for the Java™ data provider. For more information, see “Increasing the Java heap size” on page 916.

## Configuring the agent by responding to prompts

To configure the agent on Linux operating systems, you must run the script and respond to prompts.

### Procedure

- To configure the agent by running the script and responding to prompts, complete the following steps:
  - a) On the command line, run the following command:

`install_dir/bin/vmware_vi-agent.sh config instance_name`

Example `/opt/ibm/apm/agent/bin/vmware_vi-agent.sh config instance_name`

Where

**instance\_name**

Name that you want to give to the instance.

**install\_dir**

Path where the agent is installed.

b) Respond to the prompts by referring to the following topics:

- [“Configuration parameters for the data provider” on page 915](#)
- [“Configuration parameters for the data source” on page 914](#)

c) Run the following command to start the agent:

```
install_dir/bin/vmware_vi-agent.sh start instance_name
```

Example **/opt/ibm/apm/agent/bin/vmware\_vi-agent.sh start instance\_name**

## What to do next

- Log in to the Cloud APM console to view the data that is collected by the agent in the dashboards. For information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#).

If you need help with troubleshooting, see the [Troubleshooting](#) section.

- If you are monitoring a large VMware environment with more than 500 ESX hosts, you might need to increase the heap size for the Java™ data provider. For more information, see [“Increasing the Java heap size” on page 916](#).

## Configuration parameters for the data source

When you configure the VMware VI agent, you can change the default values of the parameters for the data source, such as the address, user id, and password of the data source.

The following table contains detailed descriptions of the configuration parameters for the data source.

| Table 249. Names and descriptions of the configuration parameters for the data source |  |                 |
|---|--|-----------------|
| Parameter name  | Description  | Mandatory field |
| Data Source ID  | The ID of the data source.   | Yes             |
| Data Source Address   | <p>Address of the data source.</p> <p>If you do not want the agent to validate the SSL certificates, set the value to the host name or IP address of the VMware Virtual Center or ESX server that is being monitored.</p> <p>If you want the agent to validate the SSL certificates when using SSL to communicate over the network, configure the agent by using the Subject Alternative Name that is provided in the certificate.</p> <p>To view the subject alternative name of the data center, complete the following steps:</p> <ol style="list-style-type: none"><li>1. Open the certificate.</li><li>2. In the <b>Certificate</b> window, click the <b>Details</b> tab.</li><li>3. Select <b>Subject Alternative Name</b>, and use the value of DNS Name. For example, if the value of DNS Name is "ibmesx3v3vc.ITMfVS.com", then use the "ibmesx3v3vc.ITMfVS.com" value for the host name.</li></ol> | Yes             |

| <i>Table 249. Names and descriptions of the configuration parameters for the data source (continued)</i> |   |                 |
|--|---|-----------------|
| Parameter name   | Description   | Mandatory field |
| Use SSL Connection to Data Source  | Indicates whether the agent uses an SSL connection to connect to the data sources of the VMware Virtual Infrastructure.<br><br>Specify Yes if the agent uses an SSL connection to connect to the data sources. Otherwise, specify No. The default value is Yes. | Yes             |
| Data Source User ID  | The user ID that has sufficient privileges to collect monitoring data, and is known to the data source.   | Yes             |
| Data Source Password   | The password of the user ID that is configured for accessing the data source.   | Yes             |
| Confirm Data Source Password   | The same password that you specified in the <b>Data Source Password</b> field.  |                 |

## Configuration parameters for the data provider

When you configure the VMware VI agent, you can change the default values of the parameters for the data provider, such as the maximum number of data provider log files, the maximum size of the log file, and the level of detail that is included in the log file.

The following table contains detailed descriptions of the configuration parameters for the data provider.

| <i>Table 250. Names and descriptions of the configuration parameters for the data provider</i> |   |                 |
|--|---|-----------------|
| Parameter name   | Description   | Mandatory field |
| Instance Name  | The name of the instance.<br><br><b>Restriction:</b> The <b>Instance Name</b> field displays the name of the instance that you specify when you configure the agent for the first time. When you configure the agent again, you cannot change the instance name of the agent.   | Yes             |
| Valid SSL Certificates   | Indicates whether the agent validates SSL certificates when the agent uses SSL to communicate over the network.<br><br>Set the value to Yes if you want the agent to validate SSL certificates when the agent uses SSL to communicate over the network. Set the value to No to prevent the agent from validating SSL certificates. The default value is Yes.<br><br>For information about adding a data source SSL certificate to the certificate truststore of the agent, see <a href="#">“Enabling SSL communication with VMware VI data sources” on page 910</a> . | Yes             |
| Maximum number of Data Provider Log Files  | The maximum number of log files that the data provider creates before it overwrites the previous log files. The default value is 10.  | Yes             |
| Maximum Size in KB of Each Data Provider Log   | The maximum size in KB that a data provider log file must reach before the data provider creates a new log file. The default value is 5190 KB.  | Yes             |
| Level of Detail in Data Provider Log   | The level of detail that can be included in the log file that the data provider creates. The default value is INFO. The following values are valid: OFF, SEVERE, WARNING, INFO, FINE, FINER, FINEST, and ALL.   | Yes             |

| Table 250. Names and descriptions of the configuration parameters for the data provider (continued) |  |                 |
|---|--|-----------------|
| Parameter name  | Description  | Mandatory field |
| <b>KEY_STORE_PASSWORD</b>   | <p>The <b>KEY_STORE_PASSWORD</b> allows user to configure the agent with new key-store password set for the agent JRE. Please note that this Java key-store has no relation with the key-store of vCenter.</p> <p>It is not mandatory to enter the password on each configuration. If this field is left blank, the agent assumes that the default Java key-store password should be used while using the agent JRE.</p> | No              |

## Increasing the Java heap size

After you configure the VMware VI agent, if you are monitoring a large VMware Virtual Infrastructure environment, then you might need to increase the heap size for the Java™ data provider.

### About this task

The default maximum heap size for the Java data provider is 256 megabytes. You must set the maximum heap size to an appropriate value that depends on the size of the VMware environment. For information about the heap sizes that are required for the various VMware environments, see [Table 248 on page 910](#).

**Important:** The system, on which you install and configure the VMware VI agent, must have adequate memory space to accommodate the required heap size.

If any of the following problems arise, then you might need to increase the heap size:

- The Java data provider stops because of a javacore problem, and creates a file that is named `javacore.date.time.number.txt` in the `CANDLEHOME\tmaitm6_x64` directory.
- The `javacore.date.time.number.txt` file contains the string `java/lang/OutOfMemoryError`.

### Procedure

#### Windows

Complete the following steps to set a value of 1 GB as the heap size:

1. Open the `%CANDLE_HOME%\TMAITM6_x64\kvm_data_provider.bat` file.
2. Add the following line before the line that starts with `KVM_JVM_ARGS=%KVM_CUSTOM_JVM_ARGS...`:

```
SET KVM_CUSTOM_JVM_ARGS=-Xmx1024m
```

3. Restart the agent.

#### Linux

Complete the following steps to set a value of 1 GB as heap size:

1. Open the `$CANDLEHOME/1x8266/vm/bin/kvm_data_provider.sh` file.
2. Add the following line before the line that starts with `KVM_JVM_ARGS=$KVM_CUSTOM_JVM_ARGS...`:

```
KVM_CUSTOM_JVM_ARGS=-Xmx1024m
```

3. Restart the agent.

## Configuring Environment Variables

You can configure environment variables to change the behavior of the agent.

### About this task

**Note:** For Windows platform, user can edit the environment variable that will change the behavior of the specific agent instance.

For non-Windows platform, environment variable setting will impact all the running agent instances.

### Procedure

1. Stop all the agent instances.
2. Locate the environment variable file.

- Windows:

Locate the `KVMENV_instance_name` file by navigating to the agent folder, where *instance\_name* is the agent instance name.

- Agent of 32-bit system: `%CANDLEHOME%\TMAITM6`
- Agent of 64-bit system: `%CANDLEHOME%\TMAITM6_x64`

- Non-Windows:

Locate the `.vm.environment` file by navigating to the agent folder.

- Agent of 32-bit system: `$CANDLEHOME/config`
- Agent of 64-bit system: `$CANDLEHOME/config`

3. Edit environment variables according to the requirement and save the file.

- **KVM\_DATA\_PROVIDER\_CONNECTION\_RETRY\_COUNT**

Example:

```
KVM_DATA_PROVIDER_CONNECTION_RETRY_COUNT=0
```

**Note:**

In the event of connection failure, if the environment variable **KVM\_DATA\_PROVIDER\_CONNECTION\_RETRY\_COUNT** is not configured or set to 0, the agent will continuously attempt connection to data source every 30 seconds.

In the event of connection failure, user can limit the number of connection attempts by setting the environment variable **KVM\_DATA\_PROVIDER\_CONNECTION\_RETRY\_COUNT** to a valid non-zero value.

- **KVM\_VIRTUAL\_MACHINE\_IP\_TIMEOUT**

Example:

```
KVM_VIRTUAL_MACHINE_IP_TIMEOUT=200
```

**Note:** The environment variable **KVM\_VIRTUAL\_MACHINE\_IP\_TIMEOUT** in attribute group Virtual Machines allows the agent to wait for the configured duration (in milliseconds) before returning the value of FQDN and subsequently all other attributes. If this field is not configured or if this field is set to 0, the timeout functionality is disabled and attribute group collection follows the default behavior.

4. Start the agent instance.

## Configuring WebLogic monitoring

The Monitoring Agent for WebLogic provides you with a central point of monitoring for the health, availability, and performance of your WebLogic server environment. The agent displays a comprehensive

set of metrics to help you make informed decisions about your WebLogic resources, including Java virtual machines (JVMs), Java messaging service (JMS), Java Database Connectivity (JDBC).

## Before you begin

- The product version and the agent version often differ. The directions here are for the most current release of this agent. To access the documentation for earlier agent releases, see the [Table 251 on page 918](#) table.

| Table 251. Agent versions |   |
|---------------------------|---|
| Agent version             | Documentation   |
| 8.1.4, 8.1.4.1            | <a href="#">Cloud APM 8.1.4</a> <sup>2</sup>                  |
| 8.1.3.2                   | <a href="#">IBM Performance Management 8.1.3</a> <sup>1</sup> |

<sup>1</sup> The link opens an on-premises Knowledge Center topic.

<sup>2</sup> April 2018 agent version 8.1.4.1 enabled transaction tracking and deep-dive diagnostics on AIX. Previous agent versions only supported transaction tracking and deep-dive diagnostics on Linux and Windows.

- Make sure that the system requirements for the WebLogic agent are met in your environment. For the up-to-date system requirement information, see the [Software Product Compatibility Reports \(SPCR\)](#) for the WebLogic agent.
- Before you configure the WebLogic agent, the Oracle WebLogic server first must be configured by completing the following tasks:

**Note:** Most of the Oracle WebLogic server configuration is done by using the administrative console, typically at <http://weblogic-server:7001/console>.

1. Set up a monitor user in the Monitors group.
  - a. Select the domain to monitor/edit.
  - b. Select **Security Realms**.
  - c. Select your security realm (or create one if one does not exist).
  - d. Create a user that will be used to communicate with WebLogic over JMX.
  - e. Add this user the Monitors group.
  - f. Save the changes to the domain.
2. Enable the Listen Ports.
  - a. Select the domain to monitor/edit.
  - b. On each server that you want to monitor, click **Environment > Servers > Select a server**.
  - c. Ensure that the **Listen Port** is enabled and note its port number.
  - d. If you want to enable SSL, then ensure that the **SSL Listener Port** is enabled and set a port for SSL as well.
3. Enable the JMX MBean Server Connections.
  - a. Select the domain that you want to monitor/edit.
  - b. Select **Configure > Advanced**.
  - c. Check **Platform Mbean Server Enabled**.
  - d. Save the change.
4. Enable the IIOP Protocol option.
  - a. Select the domain that you want to monitor/edit.
  - b. On each server that you would like to monitor, click **Environment > Servers** then select a server.

- c. Select the **Protocol Tab** > **Select IIOP**.
  - d. Under the **Advanced** section, enter the default IIOP user name and password.
  - e. Save the change.
5. Enable SSL.
- a. Enable HTTP Tunneling.
    - i) Go to **Environment** > **Servers** > **Select a server** > **Protocol** > **General**.
    - ii) Check **Enable HTTP Tunneling**.
  - b. Enable SSL Listen Port.
    - i) Go to **Environment** > **Servers** > **Select a server** > **Configuration** > **General**.
    - ii) Configure a port number.

## About this task

The WebLogic agent is both a multiple instance agent and also a multiple subnode agent. You can create one agent instance with multiple subnodes – one for each WebLogic server, or you can create an agent instance for each WebLogic server with one subnode for that server. Or you can create a combination of each type of configuration. After you configure agent instances, you must start each agent instance manually.

## Procedure

1. To configure the agent on Windows systems, use the **IBM Performance Management** window or the silent response file with the agent configuration batch file.
  - [“Configuring the agent on Windows systems” on page 920.](#)
  - [“Configuring the agent by using the silent response file” on page 925.](#)
2. To configure the agent on Linux and UNIX systems, run the agent configuration script and respond to prompts, or use the silent response file.
  - [“Configuring the agent by responding to prompts” on page 924.](#)
  - [“Configuring the agent by using the silent response file” on page 925.](#)
3. Optional: To configure transaction tracking, configure individual agent instances to provide transaction tracking data and configure your Application Performance Dashboard to display transaction tracking data.
  - a) Follow the procedure for [“Configuring transaction tracking for the WebLogic agent” on page 927.](#)
  - b) Follow the procedure for [“Configuring your Application Performance Dashboard to display transaction tracking data for the WebLogic agent” on page 932.](#)

**Note:** Transaction tracking capability is available for the WebLogic agent in the Cloud APM, Advanced offering. For the WebLogic agent with basic resource monitoring capability, which is in the Cloud APM, Base offering, skip this step.

## What to do next

In the Cloud APM console, go to your Application Performance Dashboard to view the data that was collected. For more information about using the Cloud APM console, see [“Starting the Cloud APM console” on page 1109.](#)

If you are unable to view the data in the agent dashboards, first check the server connection logs and then the data provider logs. The default paths to these logs are as follows:

- **Linux**    **UNIX**    /opt/ibm/apm/agent/logs
- **Windows**    C:\IBM\APM\TMAITM6\_x64\logs

For help with troubleshooting, see the [Cloud Application Performance Management Forum](#).

## Configuring the agent on Windows systems

You can configure the WebLogic agent on Windows operating systems by using the IBM Cloud Application Performance Management window. After you update the configuration values, you must start the agent to save the updated values.

### Procedure

1. Click **Start > All Programs > IBM Monitoring agents > IBM Cloud Application Performance Management**.
2. In the **IBM Performance Management** window, right-click the **Monitoring Agent for WebLogic** template, and then click **Configure agent**.

**Remember:** After you configure an agent instance for the first time, the **Configure agent** option is disabled. To configure the agent instance again, right-click on it and then click **Reconfigure**.

3. Enter a unique instance name then click **OK**. Use only letters, Arabic numerals, the underline character, and the minus character in the instance name. For example: `weblogic01`.

Figure 27. The window to enter a unique instance name

4. Click **Next** on the **Instance Name** agent configuration panel.

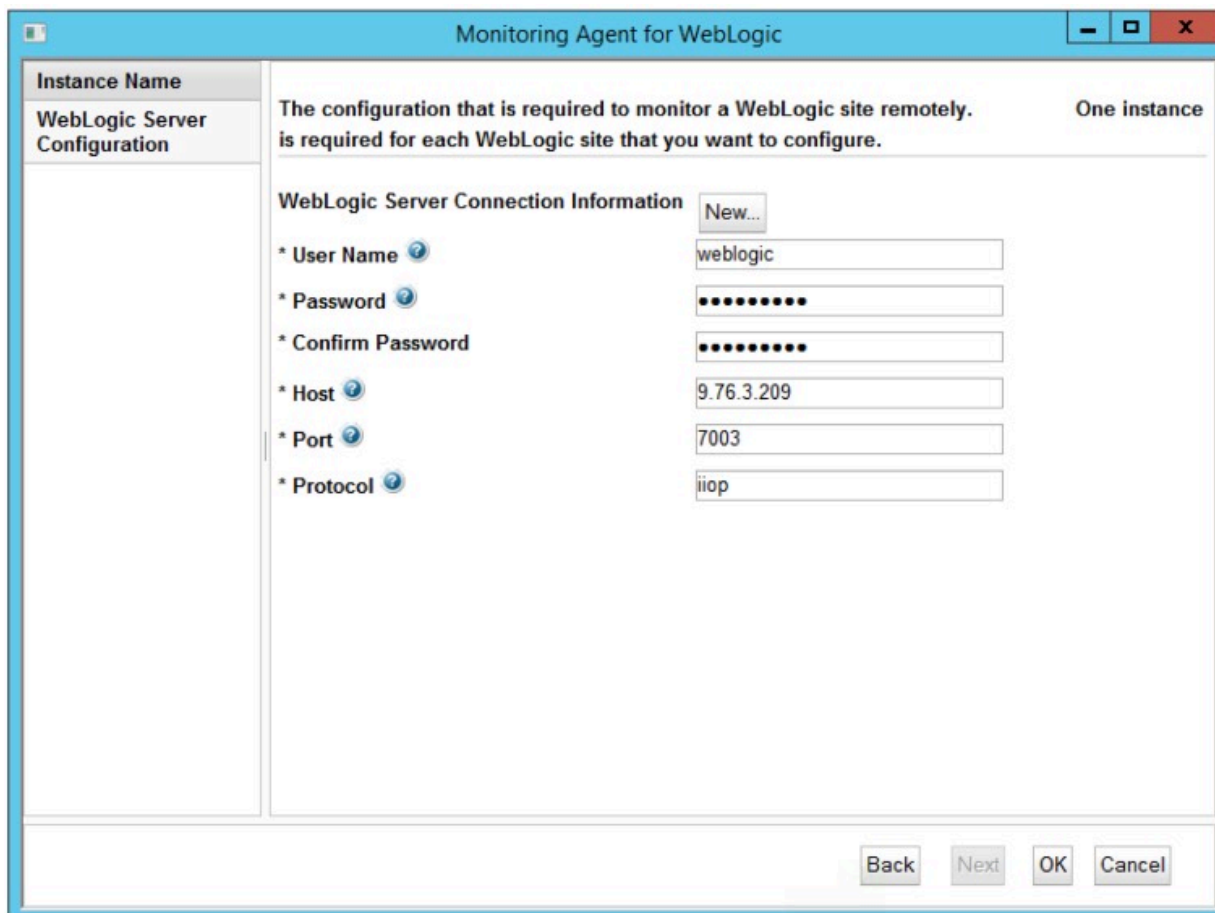

The image shows a window titled "Monitoring Agent for WebLogic". On the left is a tree view with "Instance Name" selected. The main area contains the text "The name of the instance." followed by a label "\* Instance Name" and a text input field containing "weblogic01". At the bottom left of the main area is a button labeled "WebLogic Server Configuration". At the bottom right are four buttons: "Back", "Next", "OK", and "Cancel".

Figure 28. The window displaying the agent instance name

5. Enter the **WebLogic Server Configuration** instance template settings.

**Note:** This section is not the WebLogic server connection instance configuration. It is a template section for setting what is used as the default values when you add the actual WebLogic server connection instance configurations beginning in [step 6](#).

See [Table 252 on page 926](#) for an explanation of each of the configuration parameters.

The image shows a software window titled "Monitoring Agent for WebLogic". On the left is a tree view with "Instance Name" and "WebLogic Server Configuration". The main area contains instructions: "The configuration that is required to monitor a WebLogic site remotely. One instance is required for each WebLogic site that you want to configure." Below this is a section for "WebLogic Server Connection Information" with a "New..." button. It includes fields for:
 

- \* User Name: weblogic
- \* Password: masked with dots
- \* Confirm Password: masked with dots
- \* Host: 9.76.3.209
- \* Port: 7003
- \* Protocol: iiop

 At the bottom right are "Back", "Next", "OK", and "Cancel" buttons.

Figure 29. The window to specify WebLogic server connection instance template settings

6. Press **New** and enter WebLogic server connection instance settings, then click **Next**.  
See [Table 252 on page 926](#) for an explanation of each of the configuration parameters.

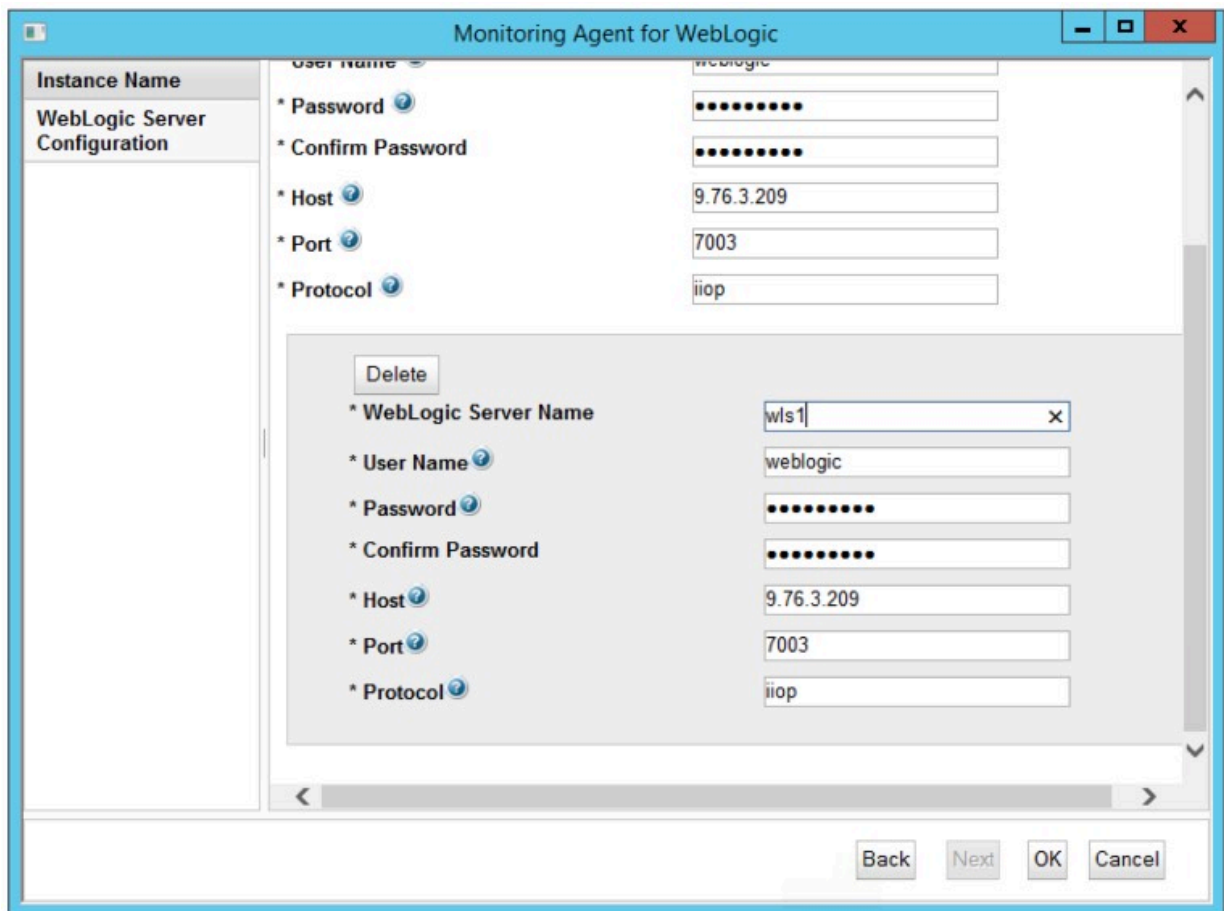

Figure 30. The window to specify WebLogic server connection instance settings

7. Click **OK** to complete the configuration.
8. Copy the WebLogic security files into the WebLogic agent binary directory.
  - a. Locate the `wlclient.jar` and `wljmxclient.jar` files under `ORACLE_HOME`. For example, `C:\Oracle\Middleware\Oracle_Home\wlserver\server\lib`.
  - b. Copy the files from step “8.a” on page 923 to the WebLogic agent binary directory.
    - **Linux** | **UNIX** `install_dir/bin`.
    - **Windows** `install_dir\TMAITM6_x64`

where `install_dir` is the path where the agent is installed. The default `install_dir` paths are listed here:

    - **Linux** | **UNIX** `/opt/ibm/apm/agent`
    - **Windows** `C:\IBM\APM\TMAITM6_x64`
9. In the IBM Cloud Application Performance Management window, right-click the instance that you configured, and then click **Start**.

## Configuring the agent by responding to prompts

After installation of the WebLogic agent, you must configure it before you start the agent. If the WebLogic agent is installed on a local Linux or UNIX computer, you can follow these instructions to configure it interactively through command line prompts.

### About this task

**Remember:** If you are reconfiguring a configured agent instance, the value that is set in the last configuration is displayed for each setting. If you want to clear an existing value, press the space key when the setting is displayed.

### Procedure

Follow these steps to configure the WebLogic agent by running a script and responding to prompts.

1. Run the following command.

```
install_dir/bin/weblogic-agent.sh config instance_name
```

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name that you want to give to the agent instance.

Example

```
/opt/ibm/apm/agent/bin/weblogic-agent.sh config example-inst01
```

2. Respond to the prompts to set configuration values for the agent.

See [“Configuration parameters for the WebLogic agent” on page 926](#) for an explanation of each of the configuration parameters.

3. Copy the WebLogic client library files into the WebLogic agent binary directory.

a) Locate the `wlclient.jar` and `wljmxclient.jar` files under `ORACLE_HOME`.

b) Copy the files from step [“3.a” on page 924](#) to the WebLogic agent binary directory.

```
install_dir/bin
```

where *install\_dir* is the path where the agent is installed.

Example

```
/opt/ibm/apm/agent/bin
```

4. Run the following command to start the agent:

```
install_dir/bin/weblogic-agent.sh start instance_name
```

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name of the agent instance.

Example

```
/opt/ibm/apm/agent/bin/weblogic-agent.sh start example-inst01
```

## Configuring the agent by using the silent response file

The silent response file contains the agent configuration parameters. You can edit the silent response file to modify the values of these parameters, and run the configuration script to create an instance and update the agent configuration values. This mode of configuration is called the silent mode.

### About this task

The silent response file contains the agent configuration parameters with default values defined for some parameters. You can edit the silent response file to specify different values for the configuration parameters.

After you update the configuration values in the silent response file, you must run the configuration script to configure the agent with these updated values.

### Procedure

Configure the WebLogic agent in the silent mode by completing the following steps.

1. In a text editor, open the `weblogic_silent_config.txt` file that is available at the following path:

- **Linux** **UNIX** `install_dir/samples/weblogic_silent_config.txt`
- **Windows** `install_dir\samples\weblogic_silent_config.txt`

where *install\_dir* is the path where the agent is installed.

Example

- **Linux** **UNIX** `/opt/ibm/apm/agent/samples/weblogic_silent_config.txt`
- **Windows** `C:\IBM\APM\samples\weblogic_silent_config.txt`

2. In the `weblogic_silent_config.txt` file, specify values for all mandatory parameters. You can also modify the default values of other parameters.

See [“Configuration parameters for the WebLogic agent” on page 926](#) for an explanation of each of the configuration parameters.

3. Save and close the `weblogic_silent_config.txt` file, and run the following command:

- **Linux** **UNIX** `install_dir/bin/weblogic-agent.sh config instance_name install_dir/samples/weblogic_silent_config.txt`
- **Windows** `install_dir\bin\weblogic-agent.bat config instance_name install_dir\samples\weblogic_silent_config.txt`

where *install\_dir* is the path where the agent is installed and *instance\_name* is the name that you want to give to the agent instance.

The default *install\_dir* paths are listed here:

- **Linux** **UNIX** `/opt/ibm/apm/agent`
- **Windows** `C:\IBM\APM\TMAITM6_x64`

**Important:** Ensure that you include the absolute path to the silent response file. Otherwise, the agent data is not shown in the dashboards.

Example

- **Linux** **UNIX** `/opt/ibm/apm/agent/bin/weblogic-agent.sh config example-inst01 /opt/ibm/apm/agent/samples/weblogic_silent_config.txt`
- **Windows** `C:\IBM\APM\bin\weblogic-agent.bat config example-inst01 C:\IBM\APM\samples\weblogic_silent_config.txt`

4. Copy the WebLogic client libraries into the WebLogic agent binary directory.

- a. Locate the `wlclient.jar` and `wljmxclient.jar` files under `ORACLE_HOME`.
- b. Copy the files from step “5.a” on page 926 to the WebLogic agent binary directory.
  - **Linux** **UNIX** `install_dir/bin`.
  - **Windows** `install_dir\TMAITM6_x64`

where `install_dir` is the path where the agent is installed. The default `install_dir` paths are listed here:

- **Linux** **UNIX** `/opt/ibm/apm/agent`
- **Windows** `C:\IBM\APM\TMAITM6_x64`

5. Run the following command to start the agent:

- **Linux** **UNIX** `install_dir/bin/weblogic-agent.sh start instance_name`
- **Windows** `install_dir\bin\weblogic-agent.bat start instance_name`

where `install_dir` is the path where the agent is installed and `instance_name` is the name of the agent instance.

The default `install_dir` paths are listed here:

- **Linux** **UNIX** `/opt/ibm/apm/agent`
- **Windows** `C:\IBM\APM\TMAITM6_x64`

Example

- **Linux** **UNIX** `/opt/ibm/apm/agent/bin/weblogic-agent.sh start example-inst01`
- **Windows** `C:\IBM\APM\bin\weblogic-agent.bat start example-inst01`

## Configuration parameters for the WebLogic agent

The configuration parameters for the WebLogic agent are displayed in a table.

1. [WebLogic Agent Settings](#) - WebLogic agent environment settings.

| Table 252. WebLogic Agent Settings |  |  |
|------------------------------------|--|--|
| Parameter name                     | Description  | Silent configuration file parameter name   |
| WebLogic Server Name               | Provide a name to identify the WebLogic server agent instance. Example: <code>wls1</code><br><br><b>Note:</b> This alias can be anything you choose to represent the WebLogic server agent instance with the following restrictions. Only letters, Arabic numerals, the underline character, and the minus character can be used in the connection name. The maximum length of a connection name is 25 characters. | Each of the following parameters must have an instance name suffix which will be the same for each parameter of an agent instance. New agent instances must use a unique instance name for its set of parameters. For example, one agent instance can use <code>.wls1</code> and another agent instance can use <code>.wls2</code> in place of <code>.instance_name</code> in the parameter names below. |
| User Name                          | Username that is used to authenticate with the WebLogic server.  | <b>KWB_WLS_USERNAME.instance_name</b>  |
| Password                           | Password that is used to authenticate with the WebLogic server.  | <b>KWB_WLS_PASSWORD.instance_name</b>  |

| Table 252. WebLogic Agent Settings (continued) |   |  |
|--|---|--|
| Parameter name                                 | Description   | Silent configuration file parameter name |
| Host   | Host that is used to authenticate with the WebLogic server. Type either the fully qualified host name or the IP address of the WebLogic server. | <b>KWB_WLS_HOST.instance_name</b>        |
| Port   | Port that is used to authenticate with the WebLogic server.   | <b>KWB_WLS_PORT.instance_name</b>        |
| Protocol                                       | Protocol that is used to authenticate with the WebLogic server. Supported protocols are <i>iiop</i> and <i>https</i> .                          | <b>KWB_WLS_PROTOCOL.instance_name</b>    |

## Configuring transaction tracking for the WebLogic agent

The transaction tracking capability of the WebLogic agent requires changes to the agent instance environment settings file and the WebLogic server startup file. A script is provided to help you make the changes.

### Before you begin

**Linux** | **UNIX** Ensure that the resource limit for open files is greater than 5,000 for the transaction tracking toolkit to work properly.

- Display the current open file limit setting. **ulimit -n**
- Example setting the open file limit to 5,056. **ulimit -n 5056**

Perform “Configuring WebLogic monitoring” on page 917 **Windows** step 1 or **Linux** | **UNIX** step 2 before you follow this procedure.

**Note:** Transaction tracking capability is available for the WebLogic agent in the Cloud APM, Advanced offering. For the WebLogic agent with basic resource monitoring capability, which is in the Cloud APM, Base offering, skip this step.

The WebLogic agent must be installed locally to the WebLogic server that is monitored with the transaction tracking capability.

The user account that runs this script must have write permission to the following directories and files:

1. The *WEBLOGIC\_HOME* directory.
2. The *WEBLOGIC\_HOME/bin* directory and files.
3. The *install\_dir/config* directory.
4. The *install\_dir/config/hostname\_wb\_instance\_name.cfg* file.

where

#### **WEBLOGIC\_HOME**

WebLogic server installation directory.

#### **install\_dir**

Path where the agent is installed. The default paths to these logs are as follows.

- **Linux** | **UNIX** /opt/ibm/apm/agent
- **Windows** C:\IBM\APM\TMAITM6\_x64

#### **hostname**

Name of the host computer where the agent is installed.

### ***instance\_name***

Name of the agent instance that is assigned in the agent configuration method topic:

- Configuring the agent on Windows systems, step “3” on page 920
- Configuring the agent by responding to prompts, step “1” on page 924
- Configuring the agent by using the silent response file, step “2” on page 925

## **Procedure**

Run the **simpleConfig** script.

1. Log in to the WebLogic server with the WebLogic agent installed.
2. Change directory to the agent installation directory.

- **Linux** | **UNIX** `install_dir`
- **Windows** `install_dir\TMAITM6_x64`

where *install\_dir* is the path where the agent is installed.

The default *install\_dir* paths are listed here:

- **Linux** | **UNIX** `/opt/ibm/apm/agent`
- **Windows** `C:\IBM\APM\TMAITM6_x64`

3. Change directory to `wbdchome/8.1.4.0.0/bin`.
4. Run the setup script.

- **Linux** | **UNIX** `./simpleConfig.sh`
- **Windows** `simpleConfig.bat`

5. Follow the prompts to enter parameters for your environment:

- a) Choose the WebLogic agent *instance\_name* and subnode to configure from the list of detected agent instance and subnode combinations where *instance\_name* is the name of the agent instance.
- b) Type the number of the WebLogic server startup method.
- c) Type the WebLogic domain root search path.  
This path is used as the base from which to search for WebLogic domains. If the *WEBLOGIC\_HOME* environment variable is set, its value is offered as the default value.
- d) Type the number of the WebLogic domain for the WebLogic server to configure.
- e) Type the number of the WebLogic server name to configure.

**Linux** Example configuration with a WebLogic startup method of WebLogic startup script.

```
./simpleconfig.sh

The following agents and subnodes are not yet configured for transaction tracking:
1) wlinst1 Server1
2) wlinst1 Server2

Type the number that corresponds to the agent instance and subnode that you want to
configure.

Type your selection here (For example: 1): 1

The following WebLogic startup methods are supported:
1) WebLogic startup script
2) WebLogic Node Manager

Type your selection here (default is 1): 1

The path to begin looking for WebLogic domains.
WebLogic domain search root (default is: ): /home/wlsadmin

The found WebLogic domain paths are:
```

```
1) /home/wlsadmin/oracle/user_projects/domains/ttdd
```

Type the number that corresponds to the WebLogic domain containing the WebLogic server that you want to configure.

Type your selection here (For example: 1): **1**

The following WebLogic servers are available for configuration:

- 1) AdminServer
- 2) Server1

Select a WebLogic server name (default is: 2): **2**

INFO: [2000] Automatic configuration of agent environment file succeeded.

INFO: [3000] Automatic configuration of WebLogic start script succeeded.

INFO: [9000] Restart the WebLogic agent and WebLogic server for configuration to take effect.

6. Follow these steps if WebLogic Node Manager is selected as the **WebLogic server startup method** in step “5.b” on page 928. Otherwise, proceed to step “7” on page 930.

- a) Open the `weblogic_nodemanager_dc_opts` file that is listed in information message number 3011 of the output text from step “5” on page 928.

**Windows** Example configuration output with a WebLogic startup method of WebLogic Node Manager.

```
INFO: [2000] Automatic configuration of agent environment file succeeded.
INFO: [3010] Automatic configuration of WebLogic start script skipped.
INFO: [3011] Please review C:\IBM\APM\TMAITM6_x64\wbdchome\8.1.4.0.0\runtime\ttdd_win
\win_Server1\
staging\weblogic_nodemanager_dc_opts.win for required WebLogic JVM start options.
INFO: [9000] Restart the WebLogic agent and WebLogic server for configuration to take
effect.
```

- b) Log in to the WebLogic console and select **Environment > Servers**.
- c) Select the server to configure.
- d) Select the **Configuration > Server Start** tab.
- e) Copy the server start arguments from the `weblogic_nodemanager_dc_opts` file to the server’s **Start Server Arguments** in the WebLogic console and save the changes.
- The server start arguments are all the lines that follow the comment line `# Add the following lines to the server start arguments in the weblogic_nodemanager_dc_opts file.`
- f) Ensure that the transaction tracking toolkit is in the shared library path at run time.
- Choose a method.

- Update the Node Manager start script.

**Note:** All WebLogic servers started by the Node Manager have this library path set with the transaction tracking toolkit object file libraries included.

- i) Open the `weblogic_nodemanager_dc_opts` file that is listed in information message number 3011 of the output text from step “5” on page 928.
- ii) Set the transaction tracking toolkit path in the Node Manager start script. The command to set the path is the line that follows the comment line `# Make sure that the executable path available to the WebLogic server includes the toolkit lib directory in the weblogic_nodemanager_dc_opts file.`
  - **Linux** Copy the `LD_LIBRARY_PATH` line from the generated `weblogic_nodemanager_dc_opts.linux` file and paste it below the `export JAVA_OPTIONS` line in the Node Manager start script. Example, `WEBLOGIC_HOME/user_projects/domains/domain_name/bin/startNodeManager.sh`.
  - **Windows** Copy the `PATH` from the generated `weblogic_nodemanager_dc_opts.win` file and paste it below the `export JAVA_OPTIONS` line in the Node Manager start script. Example, `WEBLOGIC_HOME\user_projects\domains\domain_name\bin\startNodeManager.bat`.

where *WEBLOGIC\_HOME* is the WebLogic server installation directory and *domain\_name* is the name of the WebLogic domain.

- Update the environment for the user account that starts the Node Manager.

**Note:** All applications started by the user account have this library path set with the Toolkit object file libraries included.

- i) Edit environment settings for the user that starts the Node Manager.

- **Linux** | **UNIX** Edit the shell resource file or shell profile file. For example, in the bash shell, `.bashrc` or `.bash_profile`.
- **Windows** Edit **Control Panel > System and Security > System > Advanced system settings > Environment Variables... > User variables for user\_name > Path** where *user\_name* is the name of the user account that is used to start the WebLogic server.

- ii) Set the transaction tracking toolkit path in the user account environment. The command to set the path is the line that follows the comment line `# Make sure that the executable path available to the WebLogic server includes the toolkit lib directory in the weblogic_nodemanager_dc_opts file.`

- **Linux** | **UNIX** Copy the `export LD_LIBRARY_PATH` line from the generated `weblogic_nodemanager_dc_opts.linux` file. If an `export LD_LIBRARY_PATH` line does not exist, add it. If it does exist, edit it to add only the path from the right of the equals sign to the existing path with the correct path delimiter.
- **Windows** Copy the `set PATH` line from the generated `weblogic_nodemanager_dc_opts.win` file. If a **Path** variable does not exist in the **User variables for user\_name** section where *user\_name* is the name of the user account that is used to start the WebLogic server, add it by entering **Path** as the variable name and the path from the right of the equals sign as the value. If it does exist, edit the value to add only the path from the right of the equals sign to the existing path with the correct path delimiter.

- iii) Reload the environment.

**Warning:** The `startNodeManager` scripts are generated by the WebLogic configuration utility. So you might lose your changes when the WebLogic configuration is run again.

7. If the WebLogic server and the agent are running, restart them.

## Results

WebLogic server files that are changed during transaction tracking configuration:

- The `startManagedWebLogic` script.

- **Linux** | **UNIX** `WEBLOGIC_HOME/bin/startManagedWebLogic.sh`
- **Windows** `WEBLOGIC_HOME\bin\startManagedWebLogic.cmd`

where *WEBLOGIC\_HOME* is the WebLogic server installation directory.

This file is updated with the configuration settings for the transaction tracking capability. Configuration markers are inserted into the file for use when you disable the transaction tracking capability. A backup file is saved in the `WEBLOGIC_HOME/bin/bak/` directory before the script adds or removes the transaction tracking capability changes.

Agent files that are changed during transaction tracking configuration:

- Agent instance configuration file

- **Linux** | **UNIX** `install_dir/config/hostname_wb_instance_name.cfg`
- **Windows** `install_dir\TMAITM6_x64\hostname_WB_instance_name.cfg`

- Agent environment settings file

- **Linux** **UNIX** `install_dir/config/wb_instance_name.environment`
- **Windows** `install_dir\TMAITM6_x64\KWBENV_instance_name`

where

#### **install\_dir**

Path where the agent is installed. The default paths to these logs are as follows.

- **Linux** **UNIX** `/opt/ibm/apm/agent`
- **Windows** `C:\IBM\APM\TMAITM6_x64`

#### **hostname**

Name of the host computer where the agent is installed.

#### **instance\_name**

Name of the agent instance that is assigned in the agent configuration method topic:

- Configuring the agent on Windows systems, step “3” on page 920
- Configuring the agent by responding to prompts, step “1” on page 924
- Configuring the agent by using the silent response file, step “2” on page 925

**Note:** If the WebLogic agent is re-configured after WebLogic agent transaction tracking or diagnostics was configured, the agent environment settings file will be overwritten by the WebLogic agent reconfiguration. You need to re-run the steps in the Procedure section to configure the WebLogic agent transaction tracking or diagnostics data collector. Or else, you might see no transaction tracking data in the Application Performance Dashboard, and the default 5457 port is not listening.

## **Disabling transaction tracking for a WebLogic agent instance**

The transaction tracking capability of the WebLogic agent can be removed. A script is provided to remove the transaction tracking capability for an agent instance.

### **Before you begin**

Ensure that the WebLogic server and the WebLogic agent are shut down.

The user account that runs this script must have write permission to the following directories and files:

1. The `WEBLOGIC_HOME` directory.
2. The `WEBLOGIC_HOME/bin` directory and files.
3. The `install_dir/config` directory.
4. The `install_dir/config/hostname_wb_instance_name.cfg` file.

### **Procedure**

Run the **unconfig** script with the **remove** option.

1. Log in to the WebLogic server with the WebLogic agent installed.
2. Change directory to the agent installation directory.
  - **Linux** **UNIX** `install_dir`
  - **Windows** `install_dir\TMAITM6_x64`
3. Change directory to `wbdchome/8.1.4.0.0/bin`.
4. Run the **unconfig** script with the **remove** option and the agent instance name the subnode name.
  - To disable one subnode for an agent instance, use the `subnode_name` parameter.
  - **Linux** **UNIX** `./unconfig.sh remove instance_name subnode_name`
  - **Windows** `unconfig.bat remove instance_name subnode_name`

- To disable all subnodes for an agent instance, omit the *subnode\_name* parameter.

- **Linux** **UNIX** `./unconfig.sh remove instance_name`
- **Windows** `unconfig.bat remove instance_name`

5. Start the WebLogic server and the agent.

## Uninstalling transaction tracking for the WebLogic agent

The transaction tracking capability of the WebLogic agent can be uninstalled. A script is provided to remove the transaction tracking capability from all agent instances and also to remove the transaction tracking toolkit.

### Before you begin

Ensure that the WebLogic server and all WebLogic agent instances are shut down.

The user account that runs this script must have write permission to the following directories and files:

1. The *WEBLOGIC\_HOME* directory.
2. The *WEBLOGIC\_HOME/bin* directory and files.
3. The *install\_dir/config* directory.
4. The *install\_dir/config/hostname\_wb\_instance\_name.cfg* file.

### Procedure

Run the **unconfig** script with the **uninstall** option.

1. Log in to the WebLogic server with the WebLogic agent installed.
2. Change directory to the agent installation directory.

- **Linux** **UNIX** `install_dir`
- **Windows** `install_dir\TMAITM6_x64`

3. Change directory to `wbdchome/8.1.4.0.0/bin`.
4. Run the **unconfig** script with the **uninstall** option.

- **Linux** **UNIX** `./unconfig.sh uninstall`
- **Windows** `unconfig.bat uninstall`

5. Start the WebLogic server and all agent instances.

## Configuring your Application Performance Dashboard to display transaction tracking data for the WebLogic agent

Viewing data that is gathered by the transaction tracking capability of the WebLogic agent requires configuration changes to your Application Performance Dashboard.

### Before you begin

Perform [“Configuring transaction tracking for the WebLogic agent” on page 927](#) before you follow this procedure.

### Procedure

1. Enable the transaction tracking data in the Application Performance Dashboard if you have the WebLogic agent with transaction tracking capability, which is in the Cloud APM, Advanced offering, and you want to enable the transaction tracking capability.
  - a) From the navigation bar, click  **System Configuration > Agent Configuration**.

The **Agent Configuration** page is displayed.

- b) Select the **WebLogic** tab.
- c) Select the check boxes for the WebLogic server agent instances that you want to monitor and take one of the following actions from the **Actions** list:
  - To enable transaction tracking, click **Set Transaction Tracking > Enabled**. The status in the **Transaction Tracking** column is updated to *Enabled*.
  - To disable transaction tracking, click **Set Transaction Tracking > Disabled**. The status in the **Transaction Tracking** column is updated to *Disabled*.
2. To view the WebLogic agent transaction tracking data dashboards, add the WebLogic agent instance to an application in your Application Performance Dashboard.

For more information about the Applications editor, see [Managing applications](#).
3. Ensure that user accounts are assigned to a role that includes the Diagnostic Dashboard permission to have access to the following WebLogic agent transaction tracking Application Dashboard buttons. Otherwise, these buttons are disabled for that user in the Application Dashboard.
  - a. The **Diagnose** drill-down button on the **Slowest 5 Response Time** widget.
  - b. The **Inflight Requests** button on the **Applications** widget.

## Configuring WebSphere Applications monitoring

Configuring WebSphere Applications monitoring involves configuring a data collector for your application servers. The data collector can be either stand-alone or embedded with the WebSphere Applications agent.

### Embedded data collector

Most of the WebSphere application servers can be monitored by the embedded data collector, except for the Liberty profile on IBM Cloud. The embedded data collector can provide all available monitoring features.

To configure the embedded data collector, you must first install the WebSphere Applications agent on the system where the application server is running. After that, use the provided configuration utilities to configure the data collector interactively or silently.

### Stand-alone data collector

The stand-alone data collector is applicable only for WebSphere Application Server Liberty on Linux for System x and for WebSphere Liberty profile on IBM Cloud.

If you choose to configure a stand-alone data collector, you can skip the agent installation procedure and directly configure the data collector in Liberty.

However, some on-demand diagnostics data will not be collected by the stand-alone data collector, such as heap dump at the current time or in-flight request information. It means you can only enable the data collector to automatically collect heap dump information at specified intervals but you cannot take heap snapshot whenever you want by using the **Take Snapshot** button from the Cloud APM console. All in-flight request related dashboards, which can be provided by the embedded data collector, are not available to the stand-alone data collector.

Use [Table 253 on page 933](#) to determine the appropriate data collector for your application server.

| Table 253. WebSphere applications and applicable data collectors |                           |   |
|--|---------------------------|---|
| Application to be monitored                                      | Applicable data collector | Documentation   |
| WebSphere Application Server traditional                         | Embedded data collector   | <a href="#">“Configuring the data collector for WebSphere Applications agent” on page 934</a> |

Table 253. WebSphere applications and applicable data collectors (continued)

| Application to be monitored                        | Applicable data collector   | Documentation   |
|--|---|---|
| WebSphere Application Server Liberty (on-premises) | <ul style="list-style-type: none"> <li>• Embedded data collector</li> <li>• Stand-alone data collector (Linux for System x only)</li> </ul> | <ul style="list-style-type: none"> <li>• For Liberty 19, 20 and future versions, you can configure the Liberty data collector to monitor Liberty: <ul style="list-style-type: none"> <li>– <a href="#">Configuring the Liberty data collector in on-premises environments</a></li> </ul> </li> <li>• For Liberty 18 and older versions, you can choose to configure the WebSphere Applications agent or the Liberty data collector to monitor Liberty: <ul style="list-style-type: none"> <li>– Option 1: <a href="#">“Configuring the data collector for WebSphere Applications agent” on page 934</a></li> <li>– Option 2: <a href="#">“Configuring the Liberty data collector in on-premises environments (Liberty V18.* and older versions)” on page 558</a></li> <li>– Option 3: <a href="#">Configuring the Liberty data collector in on-premises environments</a></li> </ul> </li> </ul> |
| WebSphere Liberty profile on IBM Cloud             | Stand-alone data collector  | <a href="#">“Configuring the Liberty data collector in IBM Cloud environment (Liberty V18.* and older versions)” on page 562</a>  |
| WebSphere Liberty profile in Docker container      | Embedded data collector   | <a href="#">“Monitoring WebSphere Application Server Liberty inside a Docker container” on page 966</a>   |

## Configuring the data collector for WebSphere Applications agent

The WebSphere Applications agent does not need any configuration after agent installation, unless you want to change the default port. However, you must configure the data collector, which is a component of the agent, to set up monitoring for your WebSphere environment.

### About this task

The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see [“Change history” on page 58](#).

### Procedure

- (Fast track) If you only use the WebSphere Applications agent without the legacy product ITCAM Agent for WebSphere Applications in your environment, to quickly set up the environment for monitoring, see [“Fast track: Configuring the data collector for WebSphere Applications agent” on page 935](#) for a simplified configuration flow.
- (Simple configuration) For a complete configuration flow for a pure IBM Cloud Application Performance Management environment, see [“Configuring the data collector with the simple configuration utility” on page 938](#).
- (Full configuration) To configure the data collector with more customization options, use the full configuration utilities. For instructions, see [“Configuring or reconfiguring the data collector with full configuration utilities” on page 940](#).

- (Silent configuration) To deploy the same monitoring for many application server instances, configure the data collector in silent mode. For instructions, see [“Configuring the data collector in silent mode”](#) on page 949.
- (WebSphere Portal Server) To monitor WebSphere Portal Server instances, use the advanced configuration procedure. For instructions, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940.
- (Manual configuration) If you cannot use the provided configuration utilities to configure the data collector for WebSphere Applications agent, manually configure the data collector in the WebSphere Administrative Console. For instructions, see [“Manually configure the data collector if the configuration utilities fail”](#) on page 955.
- (Agent coexistence) If you want to configure the data collector to work in an agent coexistence environment where both WebSphere Applications agent and ITCAM Agent for WebSphere Applications are installed, see [“\(Agent coexistence\) Configuring the WebSphere Applications agent and the data collector”](#) on page 959.
- (Docker monitoring) To monitor WebSphere Application Server Liberty running inside a Docker container, see [“Monitoring WebSphere Application Server Liberty inside a Docker container”](#) on page 966.

## Fast track: Configuring the data collector for WebSphere Applications agent

The WebSphere Applications agent does not need any configuration after agent installation. However, you must configure the data collector, which is a component of the agent, to set up monitoring for your WebSphere environment.

### Before you begin

1. Install the WebSphere Applications agent on the system where the application server to be monitored is installed and running.
2. Check the user access requirements.
  - **Windows** Use the administrator ID that is used to install the application server to configure the data collector. Make sure that this user ID has full write permission the data collector home directory, `install_dir\dchome\7.3.0.14.08`.
  - **Linux** **UNIX** Use the user ID that is used to install the application server to configure the data collector. Make sure that this user ID has read and write permissions to the following subdirectories within `install_dir/yndchome/7.3.0.14.08`:
    - bin
    - data
    - runtime

### About this task

A simple configuration utility, `simpleconfig`, is used in this procedure to provide the basic configuration of data collector.

The `simpleconfig` utility configures the data collector with default settings. To configure the data collector with more customization options, use the full configuration utility, `config`, in the same directory. For instructions, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940.

In most cases, the `simpleconfig` utility is sufficient. For more complex environment, you can use the `config` configuration utility to configure the data collector. If the `simpleconfig` utility fails, use the `config` utility instead.

## Procedure

1. Log in to the system with the user ID that is used to install the application server.
2. Change to the bin directory within the data collector home directory.

- **Windows** `install_dir\dchome\7.3.0.14.08\bin`
- **Linux** | **UNIX** `install_dir/yndchome/7.3.0.14.08/bin`

3. Run the following simple configuration utility:

- **Windows** `simpleconfig.bat`
- **Linux** | **UNIX** `./simpleconfig.sh`

4. Follow the prompts to continue with the data collector configuration.

You are required to do some or all of the following things, depending on the application server settings:

- For traditional WebSphere Application Server:
  - Select the auto-discovered WebSphere installation directory or manually specify the installation directory.
  - Select the WebSphere Application Server profile to monitor.
  - Select the security properties profile to use or provide the user name and password of the WebSphere administrative console (if security is enabled for the application server).
- For WebSphere Application Server Liberty:
  - Specify the full path of the Liberty home directory that contains bin and servers directories. For example, /opt/ibm/wlp.
  - Specify the home directory of the JRE that is used by Liberty.

5. After the data collector configuration completes, restart the application server.

- a) Go to the bin directory under the home directory for the application server profile. For example, opt/IBM/WebSphere/AppServer/profiles/profile\_name/bin.

- b) Stop the application server by entering the **stopServer** command in the command console.

- **Linux** | **UNIX** `./stopServer.sh server_name`
- **Windows** `stopServer.bat server_name`

- c) When prompted, enter the user ID and password of WebSphere administrative console administrator.

- d) Start the application server again by entering the **startServer** command in the command console.

- **Linux** | **UNIX** `./startServer.sh server_name`
- **Windows** `startServer.bat server_name`

6. Log in to the Cloud APM console to view data in the dashboards.

- a) Open a browser window and enter the following URL where *server\_host* is the IP address of the server:

`https://server_host:9443`

- b) When prompted for a logon ID, enter the following credentials for the default user or enter the credentials that were assigned by your Cloud APM console administrator:

- User name: *apmadmin*
- Password: *apmpass*

The initial user credentials after Cloud APM server installation are apmadmin with password apmpass.

- c) Use the Applications editor to add the monitored application server to the Application Performance Dashboard. You can add it as a new component to your existing application or create an application to contain this component.

For more information about the Applications editor, see [“Managing applications” on page 1269](#).

## Results

The data collector is configured to monitor the application server instance. Remember that data collection can increase the application server overhead. You can control the data collection with more advanced configuration options for tuning.

## Checking user access requirements

The WebSphere Applications agent has some user access requirements for the user ID that is to configure the data collector.

## About this task

Use the ID that is used to install the application server to configure the data collector after you grant appropriate permissions for the application server installation ID.

## Procedure

- **Windows** Use the administrator ID that is used to install the application server to configure the data collector. Make sure that this user ID has full write permission the data collector home directory, `install_dir\dchome\7.3.0.14.08`.
- **Linux** **UNIX** Use the user ID that is used to install the application server to configure the data collector. Make sure that this user ID has read and write permissions to the following subdirectories within `install_dir/yndchome/7.3.0.14.08`:
  - bin
  - data
  - logs
  - runtime

**Remember:** If you use different user IDs to install application servers, you might need to use different user IDs to configure the data collector. After you configure the data collector for the first time, grant the write permission to the following files every time you use a different user ID to configure the data collector, where *profile\_name* is the application server profile name:

- `install_dir/yndchome/7.3.0.14.08/data/findservers.inputlist`
- `install_dir/yndchome/7.3.0.14.08/data/profile_name.findservers.progress`
- `install_dir/yndchome/7.3.0.14.08/data/config_inputlist`
- `install_dir/yndchome/7.3.0.14.08/runtime/custom/connections.properties`

## Handling other existing data collector in the application server

If a data collector already exists in the application server, you must decide what to do with the existing data collector, so that it does not conflict with the WebSphere Applications agent data collector.

## About this task

The following types of data collector might already exist in the application server that is to be monitored:

- The data collector of WebSphere Applications agent, which is installed in a previous version of IBM Cloud Application Performance Management

- The data collector of ITCAM Agent for WebSphere Applications, which is installed in the old IBM® Tivoli® Monitoring infrastructure
- Any other data collector that is not provided by IBM

## Procedure

Take appropriate actions to avoid the data collector conflicts.

- For a previous version of the WebSphere Applications agent data collector, which is installed in a previous version of IBM Cloud Application Performance Management, you have the following options:
  - Migrate the data collector with the migration utility from the latest data collector home directory. For instructions, see [“WebSphere Applications agent: Migrating the data collector”](#) on page 1349.
  - Unconfigure the previous version of the data collector and then configure the data collector again with the configuration utility from latest data collector home directory. For information about unconfiguring the data collector, see [“WebSphere Applications agent: Unconfiguring the data collector”](#) on page 213.
- For the data collector of ITCAM Agent for WebSphere Applications, complete the following steps if you want to deploy monitoring in an agent coexistence environment:
  - a) Uninstall the data collector of ITCAM Agent for WebSphere Applications.
  - b) Configure only one data collector to send data to both WebSphere Applications agent and ITCAM Agent for WebSphere Applications. For instructions, see [“\(Agent coexistence\) Configuring the WebSphere Applications agent and the data collector”](#) on page 959.
- For other data collectors that are not provided by IBM, evaluate whether it is necessary to remove these data collectors. The WebSphere Applications agent data collector uses the Java Byte Code manipulation to collect data. Other data collectors that use the same way to collect data might conflict with the WebSphere Applications agent data collector.

## Configuring the data collector with the simple configuration utility

The WebSphere Applications agent starts automatically after installation, but you must manually configure the data collector, which is a component of the agent, to monitor application server instances.

### Before you begin

- Make sure that the user access requirements are met in your environment. For instructions, see [“Checking user access requirements”](#) on page 937.
- If other data collector exists in the application server that is to be monitored, take appropriate actions to avoid data collector conflicts. For instructions, see [“Handling other existing data collector in the application server”](#) on page 937.

### About this task

#### Important:

- If you want to configure the data collector only for resource monitoring or to set extra options, use the full configuration procedure. For instructions, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940.
- If you want to change the name of the server in the monitoring user interface, reconfigure the data collector and specify a server alias. For instructions, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940.

For the WebSphere Applications agent, the `dc_home` variables refer to the home directory of the data collector. The location of the `dc_home` variable on each operating system is as follows:

- **Windows** `install_dir\dchome\7.3.0.14.08`
- **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08`

## Procedure

1. Log in to the system with the user ID that is used to install the application server.
2. Change to the bin directory within the data collector home directory.

- **Windows** `install_dir\dchome\7.3.0.14.08\bin`
- **Linux** | **UNIX** `install_dir/yndchome/7.3.0.14.08/bin`

3. Run the following simple configuration utility:

- **Windows** `simpleconfig.bat`
- **Linux** | **UNIX** `./simpleconfig.sh`

The **simpleconfig** utility automatically discovers the home directories of the application servers.

4. Follow the prompts to continue with the data collector configuration.

You are required to do the following things, depending on the application server settings:

- For traditional WebSphere Application Server:
    - Select the auto-discovered WebSphere installation directory or manually specify the installation directory.
    - Select the WebSphere Application Server profile to monitor.
    - Select the security properties profile to use or provide the user name and password of the WebSphere administrative console (if security is enabled for the application server).
  - For WebSphere Application Server Liberty:
    - Specify the full path of the Liberty home directory that contains the `bin` and `servers` directories (for example, `/opt/ibm/wlp`).
    - Specify the home directory of the JRE that is used by Liberty.
5. If possible, restart the application server instance after the data collector configuration completes.
    - a) Go to the `bin` directory under the home directory for the application server profile. For example, `opt/IBM/WebSphere/AppServer/profiles/profile_name/bin`.
    - b) Stop the application server by entering the **stopServer** command in the command console.
      - **Linux** | **UNIX** `./stopServer.sh server_name`
      - **Windows** `stopServer.bat server_name`
    - c) When prompted, enter the user ID and password of WebSphere administrative console administrator.
    - d) Start the application server again by entering the **startServer** command in the command console.
      - **Linux** | **UNIX** `./startServer.sh server_name`
      - **Windows** `startServer.bat server_name`

## Results

- The data collector is configured to monitor all instances in a profile, or, for WebSphere Application Server Liberty, a single instance or multiple instances in the same directory. To monitor more profiles or instances, repeat the configuration.
- The data collector is configured within the server instances, providing maximum monitoring.
- For Cloud APM, Base Private, resource monitoring is enabled.
- For Cloud APM, Advanced Private, resource monitoring, transaction tracking, and diagnostic data is enabled.

**Known limitation:** When monitoring WebSphere Application Server Liberty, the data collector cannot generate Java Naming and Directory Interface (JNDI) events.

## What to do next

- Log in to the Cloud APM console and use the Applications editor to add the monitored application server to the Application Performance Dashboard. For instructions on how to start the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#). For information about using the Applications editor, see [“Managing applications” on page 1269](#).

**Remember:** If the WebSphere Applications agent is configured to monitor WebSphere Portal Server, the agent is related to the WebSphere Portal Server application component on the Application Performance Dashboard, not WebSphere Application Server.

- If the monitoring user interface on the Application Performance Dashboard shows no information for the application server instance, restart the monitoring agent component of the WebSphere Applications agent by completing the following steps:

### – Windows

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

### – Linux | UNIX

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

## Configuring or reconfiguring the data collector with full configuration utilities

To set additional configuration options, you can use the full configuration utilities (interactive or silent) to configure the data collector instead of the simple configuration utility. You can also use full configuration utilities to reconfigure the data collector when it is already configured. Also, you need to use the full configuration utility to configure monitoring for WebSphere Portal Server instances.

## Before you begin

- Make sure that the user access requirements are met in your environment. For instructions, see [“Checking user access requirements” on page 937](#).
- If other data collector exists in the application server that is to be monitored, take appropriate actions to avoid data collector conflicts. For instructions, see [“Handling other existing data collector in the application server” on page 937](#).

## About this task

The configuration and reconfiguration utilities can be found in the following directories:

- **Windows** `install_dir\dchome\7.3.0.14.08\bin`
- **Linux | UNIX** `install_dir/yndchome/7.3.0.14.08/bin`

## Procedure

- The configuration utility is named **config**. You might need to configure the data collector with the full configuration utility in the following cases:
  - The **simpleconfig** configuration utility fails.
  - You want to configure monitoring for WebSphere Portal Server instances.

- You want to specify a server alias that is displayed in the monitoring user interface during the data collector configuration.
- You want to have more control of what data to be collected. For example, you want to use resource monitoring only and disable diagnostics data and transaction tracking.
- You do not want to configure all application servers within the same profile at one time.
- The data collector is not configured within the application server and you want to reconfigure it.

For information about the interactive full configuration utility, see [“Configuring the data collector interactively” on page 941](#).

- The reconfiguration utility is named **reconfig**. You might need to reconfigure the data collector in the following cases:
  - You want to reconfigure the data collector after it is configured either interactively or silently.

For information about interactive reconfiguration utility, see [“Reconfiguring the data collector interactively” on page 945](#).

- For silent configuration, see [“Configuring the data collector in silent mode” on page 949](#).

### **Configuring the data collector interactively**

Use the interactive configuration utility (`config.sh` or `config.bat`) to configure the data collector when the `simpleconfig` utility fails. You can use the `config.sh` or `config.bat` utility to configure the data collector for each application server instance that you want to monitor.

### **Before you begin**

If you will configure the data collector to monitor WebSphere Application Server Liberty, set the **JAVA\_HOME** system environment variable to the same JVM as the one used for the application server. For example, on a Windows system, set **JAVA\_HOME** value to `C:\Program Files\IBM\java`. Or on a Linux system, run `export JAVA_HOME=/opt/IBM/java`.

### **About this task**

Use the following full configuration utility to configure the data collector:

- **Windows** `install_dir\dchome\7.3.0.14.08\bin\config.bat`
- **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08/bin/config.sh`

### **Procedure**

To configure the data collector by responding to prompts, complete these steps:

1. Log in to the system with the user ID that is used to install the application server.
2. Go to the `bin` directory within the `dc_home` data collector home directory.
3. Start the configuration utility by issuing the following command:

- **Windows** `config.bat`
- **Linux** **UNIX** `./config.sh`

The configuration utility displays the IP addresses and host names of all network cards that are found on the local computer system.

4. Enter the number that corresponds to the IP address and host name. If the IP address and host name that you want to use are not on the list, enter the IP address or host name.
5. Specify the home directory of the application server that is to be monitored.
  - For traditional WebSphere Application Server, enter the number that corresponds to an auto-discovered application server home directory or specify a full path to an application server home directory.

- For WebSphere Application Server Liberty, enter the full path to the WebSphere Application Server Liberty home directory that contains the bin and servers directories, for example /opt/ibm/wlp.
6. If you are configuring the data collector for WebSphere Application Server Liberty, you are prompted for the Java home directory. Specify the Java home directory that is used for the application server. For example, /opt/IBM/java.
  7. When the configuration utility lists all profiles under the specified application server home directory, enter the number that corresponds to the application server profile that you want to configure.
    - For traditional WebSphere Application Server, the configuration utility then indicates whether WebSphere Global Security is enabled for the WebSphere Application Server profile that you specified. If global security is not enabled, proceed to the Step “9” on page 942.
    - For WebSphere Application Server Liberty, proceed to Step “10” on page 942.
  8. If global security is enabled for the WebSphere Application Server profile, specify whether to retrieve security settings from a client properties file. Enter 1 to allow the configuration utility to retrieve the user name and password from the appropriate client properties file. Otherwise, enter 2 to enter the user name and password.

The data collector communicates with the WebSphere Administrative Services by using the Remote Method Invocation (RMI) or the SOAP protocol. If global security is enabled for a profile, you must specify the user ID and password of a user who is authorized to log in to the WebSphere Application Server administrative console for the application server profile. Alternatively, you can encrypt the user name and password and store them in client properties files before you configure the data collector. You must use the `sas.client.props` file for an RMI connection, or the `soap.client.props` file for an SOAP connection.

9. When you are prompted for the host name of WebSphere administrative console, press Enter to accept the default or specify the host name or IP address of the WebSphere administrative console. The default value is localhost.
- Remember:** For a Network Deployment environment, enter the host name or IP address of the Deployment Manager.
10. When the configuration utility lists all the server instances that are not configured yet for data collection, select one or more application server instances from the list. Enter the number that corresponds to the application server instance to configure for data collection or enter an asterisk (\*) to configure all application server instances for data collection. To specify a subset of servers, enter the numbers that represent the servers, separated by commas. For example, 1, 2, 3.

**Remember:**

- For a stand-alone environment, application server instances must be running during the configuration. (A WebSphere Application Server Liberty instance does not need to be running).
  - For a Network Deployment environment, the Deployment Manager must be running.
  - Ensure that the application server instances that you select are the actual servers that host the applications or services that you want to monitor.
11. In the **Integration with Agent for WebSphere Applications** section, specify that you want to integrate the data collector with the WebSphere Applications agent. You must enter 1 to select this integration option, and then press Enter.  
The selected server will be registered for PMI resource monitoring.
  12. If you are configuring the data collector for traditional WebSphere Application Server, specify whether you want to configure the data collector within the application server instance.
    - Enter 1 to configure the data collector within the application server. With this option, the data collector is integrated with the application server, which is required for the full range of operational monitoring and diagnostics data collection. However, configuring the data collector within the application server requires restarting the application server. Also, the data collector might affect server performance.

- Enter 2 to not to configure the data collector within the application server and proceed to Step “14” on page 943. With this option, the data collector runs as a stand-alone process and only resource monitoring can be enabled.
13. When prompted, specify whether to enable the data collector for diagnostics data. Enter 1 to enable diagnostics data collection. The default is 2.
  14. When you are prompted for the host name of the V8 monitoring agent, enter the host name or IP address of the WebSphere Applications agent or press Enter to accept the default. The default value corresponds to your choice in Step 3.  
  
The V8 monitoring agent refers to the WebSphere Applications agent, which is installed with IBM Cloud Application Performance Management.
  15. When you are prompted for the port number of the V8 monitoring agent, enter the port number of the WebSphere Applications agent or press Enter to accept the default. The default is 63335.
  16. When you are asked whether to configure V6 monitoring agent for WebSphere Applications, press Enter to accept the default for No.  
  
The V6 monitoring agent refers to the ITCAM Agent for WebSphere Applications, which is installed in the old IBM® Tivoli® Monitoring infrastructure. Configuring V6 monitoring agent is required only for agent coexistence environment.
  17. When you are prompted for the server alias, press Enter to accept the default or enter another alias. If you are configuring several application server instances, the configuration utility prompts you for an alias for every instance.  
  
**Important:** The alias can contain only the following characters: A-Z, a-z, underbar (\_), dash (-), and period (.). Do not use other characters in the alias.  
  
The server alias is the first qualifier of the agent instance name (also known as MSN) that is displayed on the Cloud APM console. The default is the node name combined with the server name. For example, the **node1server1** alias indicates the server named **server1** in the node named **node1**.
  18. When you are prompted for a port number for PMI resource monitoring, press Enter to accept the default or enter a new number. The default port is 63355.  
  
This port is used for internal communication between components that are running on the same host. If the default is in use, you can set a different number.
  19. In the **Support for transaction tracking** section, specify whether to enable transaction tracking. Enter 1 to enable support for transaction tracking. Otherwise, enter 2 and skip to Step “22” on page 943.
  20. When you are prompted for host name or IP address of the Transaction Framework Extension, press Enter to accept the default or enter another host name or IP address.  
  
Transaction Framework Extension is an internal component of the WebSphere Applications agent that gathers metrics from the data collector.
  21. When you are prompted for the port number that the data collector uses to connect to the Transaction Framework Extension, press Enter to accept the default or enter another port number. The default is 5457.
  22. Specify whether to integrate the data collector with Application Performance Diagnostics Lite. Press Enter to accept the default for no.
  23. In the **Advanced settings** section, specify whether to change the garbage collection log path. Enter 1 to select a garbage collection log path. Otherwise, enter 2 and skip to Step “25” on page 944. To use the log path that is already specified in the JVM argument of the application server, enter 2.
  24. Specify the garbage collection log path. Enter a file name with its full path. For WebSphere Application Server Liberty, do not use variables in the path. The data collector automatically modifies the log file name, adding the server instance information to it.

For example, if you specify `gc.log` as the file name, the actual name is set to `profile_name.cell_name.node_name.server_name.gc.log` for every configured application server instance.

**Important:** In the garbage collection log path, you can use WebSphere variables such as `{SERVER_LOG_ROOT}`. However, do not use templates, such as `%pid`.

25. Review the summary of the data collector configuration that is to be applied to the specified application server instances. If necessary, reconfigure parts of the data collector configuration before you apply the changes.

26. Enter `a` to accept your changes.

27. When prompted, specify whether you want to create a backup of your current configuration. Enter `1` to create a backup of the current configuration. Otherwise, enter `2`.

The configuration utility applies the changes and presents a status message to indicate that the configuration of the data collector for the profile is completed.

28. If you are configuring the data collector for traditional WebSphere Application Server, restart the application server instances or restart the agent, depending on your choice in Step “12” on page 942.

- If you have enabled the data collector within the application server, restart the application server instances as indicated by the configuration utility.
- If you have enabled PMI resource monitoring without enabling the data collector within the application server, restart the WebSphere Applications agent by running the following commands:

– **Windows**

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

– **Linux** | **UNIX**

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

The data collector configuration takes effect after the application server or agent restart.

29. Log in to the Cloud APM console to view data in the dashboards.

- a) Open a browser window and enter the following URL where *server\_host* is the IP address of the server:

`https://server_host:9443`

- b) When prompted for a logon ID, enter the following credentials for the default user or enter the credentials that were assigned by your Cloud APM console administrator:

- User name: *apmadmin*
- Password: *apmpass*

The initial user credentials after Cloud APM server installation are *apmadmin* with password *apmpass*.

- c) Use the Applications editor to add the monitored application server to the Application Performance Dashboard. You can add it as a new component to your existing application or create an application to contain this component.

For more information about the Applications editor, see “Managing applications” on page 1269.

## What to do next

- If the current user ID that is used to configure the data collector is not the same ID of the user running the application server, verify that the user ID for configuring the data collector has read and write permissions to the `runtime` and `logs` directories within the data collector home directory. These two subdirectories are created by the ID of the user running the application server when the server is restarted.

- Log in to the Cloud APM console to view the monitoring data in the dashboards. If monitoring data are not available immediately, restart the WebSphere Applications agent by running the following commands:

– **Windows**

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

– **Linux** | **UNIX**

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

- Changing the server alias changes the agent instance name that is registered with the Cloud APM console. If this is not the first time that you configure the data collector and you changed the server alias, you must clear some cache files by completing the following steps:

1. Stop the monitoring agent if it is running.
2. Open the *hostname\_yn.xml* file in the following directory with a text editor, where *hostname* is the name of the host where the WebSphere Applications agent is installed.

– **Windows** *install\_dir\TMAITM6\_x64* (Default is C:\IBM\APM\TMAITM6\_x64)

– **Linux** | **UNIX** *install\_dir/config* (Default is /opt/ibm/apm/agent/config)

3. Locate the line that starts with the following string and contains the previous server name. For example, was85.win4net01Cell02.win4net01Node02.AppSrv01.server1, where *server1* is previous name of the application server.

```
<!ENTITY was_product_code.cellname.nodename.profilename.servername
```

where *was\_product\_code* is the product code of WebSphere Application Server; *cellname* is the name of the cell; *nodename* is the node name; *profilename* is the name of the application server profile; *servername* is the previous name of the application server.

4. Locate the .XML file that is indicated in the line within the current directory and delete the file.
5. Remove the line that you located in Step 3 from the *hostname\_yn.xml* file.
6. At the end of the *hostname\_yn.xml* file, remove the line that contains the previous server names.
7. Save and close the file.
8. Restart the monitoring agent.

## Reconfiguring the data collector interactively

If you configured the data collector to monitor one or more application server instances, you can reconfigure the data collector by using the reconfiguration utility (*reconfig.sh* or *reconfig.bat*).

## Before you begin

If you will configure the data collector to monitor WebSphere Application Server Liberty, set the **JAVA\_HOME** system environment variable to the same JVM as the one used for the application server. For example, on a Windows system, set **JAVA\_HOME** value to C:\Program Files\IBM\java. Or on a Linux system, run `export JAVA_HOME=/opt/IBM/java`.

## About this task

Use the following full reconfiguration utility to configure the data collector:

- **Windows** *install\_dir\dchome\7.3.0.14.08\bin\reconfig.bat*
- **Linux** | **UNIX** *install\_dir/yndchome/7.3.0.14.08/bin/reconfig.sh*

**Remember:** The **reconfig** utility is not applicable in the following cases. Use the **config** configuration utility instead. Although the **config** utility warns that the server is already configured, but it still can make any required changes.

- The data collector is already configured for resource monitoring only and you want to reconfigure the data collector.
- You want to reconfigure the data collector for WebSphere Portal Server.

**Tip:** In the prompts asking for agent configuration settings, the reconfiguration utility offers the currently configured values as defaults.

## Procedure

To reconfigure the data collector by responding to prompts, complete these steps:

1. Log in to the system with the user ID that is used to install the application server.
2. Go to the `bin` directory within the `dc_home` data collector home directory.
3. Start the reconfiguration utility by issuing the following command:

- **Windows** `reconfig.bat`
- **Linux** **UNIX** `./reconfig.sh`

**Tip:** Running this reconfiguration utility has the same effect as running the `config.bat` script with the `-reconfig` argument on Windows systems or the `config.sh` script with the `-reconfig` argument on Linux or AIX systems.

The reconfiguration utility displays the IP addresses of all network cards that are found on the local computer system.

4. Enter the number that corresponds to the IP address to use.  
The reconfiguration utility displays all application server instances for which the data collector is configured on this host, and prompts you to select one or more application server instances from the list.
5. Select one or more application server instances from the list. Enter the number that corresponds to the application server instance to reconfigure for data collection or enter an asterisk (\*) to reconfigure all application server instances for data collection. To specify a subset of servers, enter the numbers, separated by commas, that represent the servers. For example: 1,2,3.

### Remember:

- For a stand-alone environment, application server instances must be running during the configuration. (A WebSphere Application Server Liberty instance does not need to be running).
  - For a Network Deployment environment, the Deployment Manager must be running.
  - Ensure that the application server instances that you select are the actual servers that host the applications or services that you want to monitor.
6. In the **Integration with Agent for WebSphere Applications** section, specify that you want to integrate the data collector with the WebSphere Applications agent. You must enter 1 to select this integration option, and then press Enter.
  7. If you are configuring the data collector for traditional WebSphere Application Server, specify whether you want to configure the data collector within the application server instance.
    - Enter 1 to configure the data collector within the application server. With this option, the data collector is integrated with the application server, which is required for the full range of operational monitoring and diagnostics data collection. However, configuring the data collector within the application server requires restarting the application server. Also, the data collector might affect server performance.
    - Enter 2 to not to configure the data collector within the application server and process to Step “9” [on page 947](#). With this option, the data collector runs as a stand-alone process and only PMI resource monitoring can be enabled.

8. When prompted, specify whether to enable diagnostics data collection for the data collector. Enter 1 for yes, or enter 2 for no.
9. When you are prompted for the host name, enter the host name or IP address of the WebSphere Applications agent or press Enter to accept the default. The default value corresponds to your choice in Step “4” on page 946.
10. When you are prompted for the port number, enter the port number of the monitoring agent or press Enter to accept the default. The default is 63335.
11. When you are asked whether to configure V6 monitoring agent for WebSphere Applications, press Enter to accept the default for No.

The V6 monitoring agent refers to the ITCAM Agent for WebSphere Applications, which is installed in the old IBM® Tivoli® Monitoring infrastructure. Configuring V6 monitoring agent is required only for agent coexistence environment.

12. When you are prompted for the server alias, press Enter to accept the default or enter another alias. If you are configuring several application server instances, the configuration utility prompts you for an alias for every instance.

**Important:** The alias can contain only the following characters: A-Z, a-z, underbar (\_), dash (-), and period (.). Do not use other characters in the alias.

The server alias is the first qualifier of the agent instance name (also known as MSN) that is displayed on the Cloud APM console. The default is the node name combined with the server name. For example, the **node1server1** alias indicates the server named **server1** in the node named **node1**.

13. When you are prompted for a port number for PMI resource monitoring, press Enter to accept the default or enter a new number. The default port is 63355.

This port is used for internal communication between components that are running on the same host. If the default is in use, you can set a different number.

14. In the **Support for transaction tracking** section, specify whether to enable transaction tracking. Enter 1 to enable support for transaction tracking. Otherwise, enter 2 and skip to Step “17” on page 947.
15. When you are prompted for host name or IP address of the Transaction Framework Extension, press Enter to accept the default or enter another host name or IP address.

Transaction Framework Extension is an internal component of the WebSphere Applications agent that gathers metrics from the data collector.

16. When you are prompted for the port number that the data collector uses to connect to the Transaction Framework Extension, press Enter to accept the default or enter another port number. The default is 5457.
17. Specify whether to integrate the data collector with Application Performance Diagnostics Lite. Press Enter to accept the default for No.
18. In the **Advanced settings** section, specify whether to change the garbage collection log path. Enter 1 to select a garbage collection log path. Otherwise, enter 2 and skip to Step “20” on page 947. To use the log path that is already specified in the JVM argument of the application server, enter 2.
19. Specify the garbage collection log path. Enter a file name with its full path. For WebSphere Application Server Liberty, do not use variables in the path. The data collector automatically modifies the log file name, adding the server instance information to it.

For example, if you specify `gc.log` as the file name, the actual name is set to `profile_name.cell_name.node_name.server_name.gc.log` for every configured application server instance.

**Important:** In the garbage collection log path, you can use WebSphere variables such as `{SERVER_LOG_ROOT}`. However, do not use templates, such as `%pid`.

20. Review the summary of the data collector configuration that is to be applied to the specified application server instances. Reconfigure parts of the data collector configuration before you apply the changes, if required.

21. Enter a to accept your changes.
22. When prompted, specify whether you want to create a backup of your current configuration. Enter 1 to create a backup of the current configuration. Otherwise, enter 2.  
The configuration utility applies the changes and presents a status message to indicate that the configuration of the data collector for the profile is completed.
23. If you are configuring the data collector for traditional WebSphere Application Server, restart the application server instances or restart the agent, depending on your choice in Step “7” on page 946.
  - If you have enabled the data collector within the application server, restart the application server instances as indicated by the configuration utility.
  - If you have enabled PMI resource monitoring without enabling the data collector within the application server, restart the WebSphere Applications agent by running the following commands:

– **Windows**

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

– **Linux**

**UNIX**

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

The data collector configuration takes effect after the application server or agent restart.

## What to do next

- Changing the server alias changes the agent instance name that is registered with the Cloud APM console. If you changed the server alias during the reconfiguration procedure, you must clear some cache files by completing the following steps:

1. Stop the monitoring agent if it is running.
2. Open the *hostname\_yn.xml* file in the following directory with a text editor, where *hostname* is the name of the host where the WebSphere Applications agent is installed.

– **Windows**

*install\_dir*\TMAITM6\_x64 (Default is C:\IBM\APM\TMAITM6\_x64)

– **Linux**

**UNIX**

*install\_dir*/config (Default is /opt/ibm/apm/agent/config)

3. Locate the line that starts with the following string and contains the previous server name. For example, was85.win4net01Cell02.win4net01Node02.AppSrv01.server1, where server1 is previous name of the application server.

```
<!ENTITY was_product_code.cellname.nodename.profilename.servername
```

where *was\_product\_code* is the product code of WebSphere Application Server; *cellname* is the name of the cell; *nodename* is the node name; *profilename* is the name of the application server profile; *servername* is the previous name of the application server.

4. Locate the .XML file that is indicated in the line within the current directory and delete the file.
5. Remove the line that you located in Step 3 from the *hostname\_yn.xml* file.
6. At the end of the *hostname\_yn.xml* file, remove the line that contains the previous server names.
7. Save and close the file.
8. Restart the monitoring agent.

## Configuring the data collector in silent mode

If you want to configure many application server instances, it might be more convenient to configure the data collector in silent mode.

### About this task

When you configure the data collector in silent mode, you first specify configuration options in a properties file. A sample properties file, `sample_silent_config.txt`, is packaged with the configuration utility. The file is available in the following directories, where `dc_home` is the directory where the data collector is installed. For the full path of the `dc_home` directory, see the introduction in [Configuring the data collector for WebSphere Applications agent](#).

- **Windows** `dc_home\bin`
- **Linux** | **UNIX** `dc_home/bin`

For detailed information about each available configuration property in this file, see [“Properties file for silent configuration of data collector”](#) on page 950.

### Procedure

Complete the following steps to perform a silent configuration:

1. Specify configuration options in the properties file. You can copy the sample properties file and change the required options.
2. Set the location of the Java home directory before you run the utility.  
For example:

- **Windows**

```
set JAVA_HOME=C:\Program Files\IBM\WebSphere\AppServer80\java
```

- **Linux** | **UNIX**

```
export JAVA_HOME=/opt/IBM/AppServer80/java
```

**Important:** If you are configuring monitoring for WebSphere Application Server Liberty, you must use same JVM version as the one used for the application server. Otherwise, the monitoring might fail.

3. Go to the following directory:

- **Windows** `dc_home\bin`
- **Linux** | **UNIX** `dc_home/bin`

4. Run the command to configure the data collector in silent mode.

- **Windows** Run the following command as the administrator who installed the WebSphere Application Server.

```
config.bat -silent [dir_path]\silent file
```

- **Linux** | **UNIX** Run the following command with root user privileges.

```
config.sh -silent [dir_path]/silent file
```

**Tip:** If the `wsadmin` user was used to install the application server, run the `config` utility either as the `wsadmin` user or with root user privileges.

5. After configuring the data collector to monitor application server instances, if you have enabled the data collector within the application server, you must restart the instances. The data collector configuration takes effect when the application server instances are restarted.
6. If you have enabled PMI resource monitoring without enabling the data collector within the application server, you might need to restart the WebSphere Applications agent to start the monitoring. If

monitoring data is not available immediately, restart the monitoring agent by running the following commands:

- **Windows**

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

- **Linux** | **UNIX**

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

## What to do next

After silent configuration, to reconfigure the data collector, you have two options:

- Reconfigure it interactively by using the **reconfig** reconfiguration utility. For instructions, see [“Reconfiguring the data collector interactively” on page 945](#).
- Unconfigure it silently and then use the same procedure to configure it silently again. For instructions, see [“Unconfiguring the data collector in silent mode” on page 215](#).

## Related reference

[“Properties file for silent configuration of data collector” on page 950](#)

To silently configure the data collector, you first specify configuration options in a properties file and then run the configuration utility.

## Properties file for silent configuration of data collector

To silently configure the data collector, you first specify configuration options in a properties file and then run the configuration utility.

When you create your properties file, keep in mind the following considerations:

- A line in the file that starts with a number sign (#) is treated as a comment, and is not processed. If the number sign is used elsewhere in the line, it is not considered to be the start of a comment.
- Each property is described on a separate line, in the following format: *property = value*.

### **property**

Name of property. The list of valid properties that you can configure is shown in [Table 254 on page 950](#).

### **value**

Value of the property. Default values for some properties are already provided. You can delete default values to leave property values blank or empty. An empty value is treated as if the property is not specified, as opposed to using the default value. If you want to use default values, you can comment out the property in the file.

- Passwords are in plain text.
- Properties and their values are case-sensitive.

[Table 254 on page 950](#) describes the properties that are available when configuring the data collector in silent mode.

**Important:** If you are configuring the data collector for a WebSphere Application Server Liberty instance, some of the properties are not used.

| Table 254. Available properties for running the configuration utility in silent mode |  |
|--|--|
| Property   | Comment  |
| default.hostip   | If the computer system uses multiple IP addresses, specify the IP address for the data collector to use. |

| Table 254. Available properties for running the configuration utility in silent mode (continued)   |   |
|--|---|
| Property   | Comment   |
| <b>Integration of the data collector with the ITCAM for Application Diagnostics Managing Server</b><br><b>Important:</b> The Managing Server is only available if you have ITCAM for Application Diagnostics.<br>For a WebSphere Application Server Liberty instance or in a Cloud APM environment, these properties are not used. |   |
| ms.connect   | Specifies whether the data collector is configured to connect to the managing server in an ITCAM for Application Diagnostics environment. Valid values are True and False.  |
| ms.kernel.host   | Specifies the fully qualified host name of the managing server.   |
| ms.kernel.codebase.port  | Specifies the codebase port on which the managing server is listening.  |
| ms.am.home   | Specifies the managing server home directory.   |
| ms.am.socket.bindip  | Specifies the IP address or host name to be used by the data collector to communicate with the managing server. If more than one network interface or IP address is configured on data collector computer system, choose one of them.   |
| ms.probe.controller.rmi.port   | If the data collector is behind a firewall or you have special requirements to change the Controller RMI port of data collector, set this port number range. Configure this port number as permitted by the firewall for the data collector host. For example:<br>ms.probe.controller.rmi.port=8300-8399 or<br>ms.probe.controller.rmi.port=8300. |
| ms.probe.rmi.port  | If the data collector is behind a firewall, or you have special requirements to change the RMI port of data collector, set this port number range. Configure this port number as permitted by the firewall for the data collector host. For example: ms.probe.rmi.port=8200-8299 or<br>ms.probe.rmi.port=8200.                                    |
| <b>Support for transaction tracking</b><br>To view transaction tracking information, you must have topology views available in the Cloud APM console and enable transaction tracking in the Agent Configuration window.  |   |
| ttapi.enable   | Specifies whether the data collector supports transaction tracking. Valid values are True and False.  |
| ttapi.host   | Specifies the host of the Transaction Framework Extension, which is the component of the Monitoring Agent for WebSphere Applications that gathers metrics from the data collector. use the local host value, 127.0.0.1.   |
| ttapi.port   | Specifies the port of the Transaction Framework Extension. Use 5457.  |
| <b>Integration of the data collector with ITCAM for SOA</b><br><b>Important:</b> For a WebSphere Application Server Liberty instance or in a Cloud APM environment, this property is not used.   |   |
| soa.enable   | Specifies whether to integrate the data collector with ITCAM for SOA. The ITCAM for SOA agent must be installed to complete the configuration.  |

| Table 254. Available properties for running the configuration utility in silent mode (continued)   |   |
|--|---|
| Property   | Comment   |
| <b>Integration of the data collector with the Tivoli Performance Monitoring</b><br><b>Important:</b> For a WebSphere Application Server Liberty instance or in a Cloud APM environment, this property is not used.   |   |
| tpv.enable   | Specifies whether to integrate the data collector with the Tivoli Performance Monitoring when the data collector is included as part of ITCAM for WebSphere Application Server version 8.5. Tivoli Performance Monitoring is accessed with the WebSphere Application Server administrative console. Valid values are <i>True</i> and <i>False</i> .   |
| <b>Integration of the data collector with Application Performance Diagnostics Lite</b><br><b>Important:</b> For a WebSphere Application Server Liberty instance, this property is not used.  |   |
| de.enable  | <p>Specifies whether to collect diagnostics data, required for Application Performance Diagnostics and Application Performance Diagnostics Lite. Valid values are <i>True</i> and <i>False</i>.</p> <p>Enable this integration if you have Application Diagnostics or might have it in the future. In this case, collection of diagnostic data is enabled at server startup. Otherwise, it is disabled at startup; you can enable it using the Agent Configuration page in the user interface, but if the server is restarted, collection of diagnostic data is disabled again.</p> <p>This setting also enables integration with Application Performance Diagnostics Lite, which is a tool for diagnostic investigation of applications running on WebSphere Application Server and WebSphere Portal Server. Using this tool, you can analyze data in real time or you can save diagnostic information to a file for later analysis.</p> |
| <b>PMI resource and data collector monitoring</b><br>The selected server is always configured for resource (PMI) monitoring, without any changes to the application server. This monitoring option provides limited metrics and works only with WebSphere Applications agent, but does not require restarting the application server and can not affect performance. |   |
| tema.appserver   | <p>Specifies whether you want to configure the data collector within the application server instance. The data collector within the application server instance is required for the full range of metrics in WebSphere Applications agent and for integration with any other products. However, configuring the data collector requires restarting the application server. Also, the data collector might affect server performance. Valid values are <i>True</i> and <i>False</i>.</p> <p>If this parameter is set to <i>False</i>, data collector configuration parameters for integrating with products other than WebSphere Applications agent are disregarded. When this parameter is set to <i>False</i>, diagnostics and transaction tracking features are not available, and only resource monitoring data is collected.</p>  |
| tema.jmxport   | TCP/IP port number for resource monitoring. The port is used for internal communication between components running on the same host. The default port is 63355; if this port is in use, you can set a different number.   |
| <b>Integration of the data collector with the monitoring agent component of WebSphere Applications agent and with Application Performance Diagnostics Lite</b>   |   |

| Table 254. Available properties for running the configuration utility in silent mode (continued)   |  |
|--|--|
| Property   | Comment  |
| temaconnect  | Specifies whether the data collector connects to the monitoring agent component of WebSphere Applications agent. Valid values are True and False.<br><br><b>Important:</b> You must use the True value to use the WebSphere Applications agent.  |
| tema.appserver   | Specifies whether you want to configure the data collector within the application server instance. The data collector within the application server instance is required for the full range of metrics in the WebSphere Applications agent and for integration with any other products. However, it requires restarting the application server. Also, the data collector might affect server performance. Valid values are True and False.<br><br>If this parameter is set to False, the configuration parameters for integrating data collector with products other than WebSphere Applications agent are disregarded, as well as the following tema.host and tema.port parameters. When this parameter is set to False, diagnostics and transaction tracking features are not available, and only resource monitoring data is collected. |
| tema.host  | Specifies the fully qualified host name or IP address of the monitoring agent component of WebSphere Applications agent. Use the local host address (127.0.0.1).   |
| tema.port  | Specifies the port number of the monitoring agent component of WebSphere Applications agent. Do not change the default value of 63335.   |
| tema.jmxport   | TCP/IP port number for resource monitoring. The port is used for internal communication between components running on the same host. The default port is 63355; if this port is in use, you can set a different number.  |
| <b>Integration of the data collector with ITCAM Agent for WebSphere Applications version 6</b><br>Use the following properties to configure one data collector to collect data for both WebSphere Applications agent and ITCAM Agent for WebSphere Applications version 6. |  |
| config.tema.v6   | Specifies whether to integrate the data collector with the monitoring agent component of ITCAM Agent for WebSphere Applications version 6. Valid values are True and False. The default is False.  |
| tema.host.v6   | Specifies whether to integrate the data collector with the monitoring agent component of ITCAM Agent for WebSphere Applications version 6. Valid values are True and False. The default is False.  |
| tema.port.v6   | Specifies the port number of the monitoring agent component of ITCAM Agent for WebSphere Applications version 6. Do not change the default value 63336.  |
| <b>WebSphere Application Server backup</b>   |  |
| was.backup.configuration   | Specifies whether to back up the current configuration of the WebSphere Application Server configuration before applying the new configuration. Valid values are True and False.   |
| was.backup.configuration.dir   | Specifies the location of the backup directory.  |
| <b>Advanced configuration settings</b>   |  |

| Table 254. Available properties for running the configuration utility in silent mode (continued) |   |
|--|---|
| Property   | Comment   |
| was.gc.custom.path   | Specifies whether to set a custom path for the Garbage Collection log.  |
| was.gc.file  | <p>Specifies the path to the custom Garbage Collection log. Set this value to a file name with its full path. The data collector automatically modifies the log file name, adding the server instance information to it. For example, if you specify <code>gc.log</code> as the file name, the actual name is set to <code>profile_name.cell_name.node_name.server_name.gc.log</code> for every configured application server instance.</p> <p><b>Important:</b> In the Garbage Collection log path, you can use WebSphere variables, such as <code>\${SERVER_LOG_ROOT}</code>. However, do not use templates, such as <code>%pid</code>.</p> |
| WebSphere Administrative Services connection settings  |   |
| was.wsadmin.connection.host  | <p>Specifies the name of the host to which the wsadmin tool is connecting. In a Network Deployment environment, specify the wsadmin connection to the Deployment Manger. In a stand-alone environment, specify the wsadmin connection to the server.</p> <p><b>Remember:</b> If the WebSphere Administrative console is on the same system, the value of <code>localhost</code> will be used for connection. However, in some cases, <code>localhost</code> is not allowed for communication due to system network or security settings. In that case, you must specify this parameter in the silent response file.</p>                       |
| was.wsadmin.connection.type  | Specifies the port that the wsadmin tool must use to connect to the WebSphere Application Server.   |
| was.wsadmin.connection.port  | Specifies the port that the wsadmin tool must use to connect to the WebSphere Application Server.   |
| WebSphere Application Server global security settings  |   |
| was.wsadmin.username   | Specifies the user ID of a user who is authorized to log in to the IBM WebSphere Application Server administrative console. This user must have the agent role on the application server.   |
| was.wsadmin.password   | Specifies the password that corresponds to the user specified in the <code>was.wsadmin.username</code> property.  |
| was.client.props   | Specifies whether to retrieve security settings from a client properties file. Possible values are <code>True</code> and <code>False</code> .   |
| WebSphere Application Server settings  |   |
| was.appserver.profile.name   | Specifies the name of the application server profile that you want to configure. Not used for WebSphere Application Server Liberty.   |
| was.appserver.home   | Specifies the WebSphere Application Server home directory.  |
| was.appserver.cell.name  | Specifies the WebSphere Application Server cell name. Not used for WebSphere Application Server Liberty.  |
| was.appserver.node.name  | Specifies the WebSphere Application Server node name. Not used for WebSphere Application Server Liberty.  |
| WebSphere Application Server runtime instance settings   |   |

Table 254. Available properties for running the configuration utility in silent mode (continued)

| Property                  | Comment  |
|---------------------------|--|
| was.appserver.server.name | <p>Specifies the application server instance within the application server profile to configure.</p> <p><b>Tip:</b></p> <ul style="list-style-type: none"> <li>• The silent response file can have multiple instances of this property</li> <li>• When adding a second server, uncomment the second server (this is, #[SERVER]) and add the server name.</li> </ul>  |
| tema.serveralias          | <p>Specifies the name of the node in monitoring user interface that contains the monitoring information for this application server instance. The default is the node name combined with the server name.</p> <p><b>Important:</b> The alias can contain only the following characters: A-Z, a-z, underbar (_), dash (-), and period (.). Do not use other characters in the alias.</p> <p><b>Tip:</b> The silent response file can have multiple instances of this property.</p> <p><b>Remember:</b> Changing the server alias changes the agent instance name that is registered with the Cloud APM console. If this is not the first time that you configure the data collector and you changed the server alias, you must clear some cache files. For detailed instructions, see <a href="#">Clearing the cache files with the old server names</a>.</p> |

## Manually configure the data collector if the configuration utilities fail

If you cannot use the provided configuration utility to configure the data collector for WebSphere Applications agent, you can manually configure the data collector in the WebSphere Administrative Console.

### Before you begin

- Install the WebSphere Applications agent.
- Get to know the data collector home directory, which is required by the data collector configuration. The default is /opt/ibm/apm/agent/yndchome/7.3.0.14.08 on Linux and UNIX systems or C:\IBM\APM\dchome\7.3.0.14.08 on Windows systems.
- If you want to configure the data collector for a Liberty server, get to know the Liberty server home directory. For example, /opt/ibm/was/liberty/usr/servers/defaultServer.
- Make sure that a file named itcam\_wsBundleMetaData.xml exists in the dc\_home/runtime/wsBundleMetaData folder and it contains the following content. If the folder or the file does not exist, manually create it.

**Remember:** The `plugins_dir_within_dc_home` value must be set to the absolute path of the plugins folder within the data collector home directory. The default is /opt/ibm/apm/agent/yndchome/7.3.0.14.08/plugins on Linux and UNIX systems or C:\IBM\APM\dchome\7.3.0.14.08\plugins on Windows systems.

```
<bundles>
  <directory path="plugins_dir_within_dc_home">
    <bundle>com.ibm.tivoli.itcam.bundlemanager_7.2.0.jar</bundle>
  </directory>
  <directory path="plugins_dir_within_dc_home">
    <bundle>com.ibm.tivoli.itcam.classicsca_7.2.0.jar</bundle>
  </directory>
  <directory path="plugins_dir_within_dc_home">
    <bundle>com.ibm.tivoli.itcam.toolkitsca.classicsca_7.2.0.jar</bundle>
  </directory>
</bundles>
```

```
</directory>  
</bundles>
```

## About this task

### Important:

- You must make manual changes to the WebSphere Application Server configuration for data collectors as the WebSphere administrative user.
- You must be an experienced WebSphere administrator to make manual changes to the WebSphere Application Server for data collection. Any error in the manual configuration change can result in the application server not starting.
- After you manually configure the data collector to monitor application server instances, you cannot use the unconfiguration utility to unconfigure the data collector. You must manually unconfigure the data collector instead.

## Procedure

- To manually configure the data collector for the WebSphere application server, see [“Manually configuring data collector for WebSphere Application Server traditional”](#) on page 956.
- To manually configure the data collector for the Liberty server, see [“Manually configuring the data collector for WebSphere Application Server Liberty”](#) on page 958.

### *Manually configuring data collector for WebSphere Application Server traditional*

## Procedure

1. Log in to the WebSphere Administrative Console as the administrator.
2. In the navigation pane, click **Servers**, expand **Server Types** and click **WebSphere application servers**.
3. Under the **Server Infrastructure** section in the Configuration tab, expand **Java and Process Management** and click **Process Definition**.
4. Under the **Additional Properties** section, click **Java Virtual Machine**.
5. In the **Generic JVM arguments** field, add the following entries.

```
-agentlib:am_ibm_16=${WAS_SERVER_NAME} -Xbootclasspath/p:${ITCAMDCHOME}/  
toolkit/lib/bcm-bootstrap.jar -Djava.security.policy=${ITCAMDCHOME}/itcamdc/  
etc/datacollector.policy -verbosegc
```

When you add the entries, take note of the following:

- All entries must be on a single line.
  - Separate different arguments by spaces before the minus sign (-), and do not use spaces anywhere else.
6. Click **Apply** and then save the changes to the master configuration.
    - If you are not under a Network Deployment environment, click **Save**.
    - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected in the **Console preferences** options and then click **Save**.
  7. In the navigation pane, click **Servers**, expand **Server Types**, click **WebSphere application servers** and then click the server name.
  8. In the Configuration tab, go to **Server Infrastructure > Java and Process Management > Process Definition > Environment Entries**.
  9. Depending on the operating system, the hardware platform, and the application server JVM, set the following environment entry.

| Table 255. Environment entry                 |                        |   |
|--|------------------------|---|
| Platform                                     | Environment entry name | Environment entry value                     |
| AIX R6.1 (64-bit JVM)                        | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix536 |
| AIX R7.1 (64-bit JVM)                        | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix536 |
| Solaris 10 (64-bit JVM)                      | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/sol296 |
| Solaris 11 (64-bit JVM)                      | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/sol296 |
| Linux Intel R2.6 (32-bit JVM)                | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/li6263 |
| Linux x86_64 R2.6 (64-bit JVM)               | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lx8266 |
| Linux on Power Little Endian<br>(64-bit JVM) | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lpl266 |
| Linux on System z (32-bit JVM)               | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/ls3263 |
| Linux on System z (64-bit JVM)               | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/ls3266 |
| Windows (32-bit JVM)                         | PATH                   | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/win32  |
| Windows (64-bit JVM)                         | PATH                   | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/win64  |

10. Click **Apply** and then save the changes to the master configuration.
  - If you are not under a Network Deployment environment, click **Save**.
  - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected in the **Console preferences** options and then click **Save**.
11. In the navigation pane, click **Environment > WebSphere Variables**.
12. Specify the scope to appropriate server level and add the *ITCAMDCHOME* variable. Set the *ITCAMDCHOME* variable value to the data collector home directory. For example, /opt/ibm/apm/agent/yndchome/7.3.0.14.08.
13. Click **Apply** and then save the changes to the master configuration.
  - If you are not under a Network Deployment environment, click **Save**.
  - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected in the **Console preferences** options and then click **Save**.
14. Restart the application server.

## Results

Now you can check the WebSphere Applications agent data in the Cloud APM console after you add this application component to your applications. For instructions on how to start the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#). For instructions on how to add or edit an application, see [“Managing applications” on page 1269](#).

## What to do next

After you manually configure the data collector, you cannot use the provided `unconfig` utility to unconfigure the data collector. Manually unconfigure the data collector instead. For instructions, see [“Manually unconfigure the data collector” on page 219](#).

## Manually configuring the data collector for WebSphere Application Server Liberty

### Procedure

1. Navigate to the Liberty server home directory. For example, `/opt/ibm/wlp/usr/servers/defaultServer`.
2. Edit the `jvm.options` file by adding the following parameters, where `dc_home` is the data collector home directory and `server_name` is the Liberty server name. If the `jvm.options` file does not exist, create it with a text editor.

```
-agentlib:am_ibm_16=server_name
-Xbootclasspath/p:dc_home/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=dc_home/itcamdc/etc/datacollector.policy
-verbosegc
```

When you add the entries, take note of the following things:

- Each entry must be on a single line.
  - Replace `server_name` with the actual Liberty server name. For example, `defaultServer`.
  - Replace `dc_home` with the actual data collector home directory. For example, `/opt/ibm/apm/agent/yndchome/7.3.0.14.08`.
3. Open the `server.env` file in the same directory and add the following path to the environment entry according to the operating system, where `dc_home` is the data collector home directory. If the `server.env` file does not exist, create it with a text editor.

| Table 256. Environment entry   |                        |                                     |
|--------------------------------|------------------------|-------------------------------------|
| Platform                       | Environment entry name | Environment entry value             |
| AIX R6.1 (64-bit JVM)          | LIBPATH                | /lib:dc_home/<br>toolkit/lib/aix536 |
| AIX R7.1 (64 bit JVM)          | LIBPATH                | /lib:dc_home/<br>toolkit/lib/aix536 |
| Solaris 10 (64-bit JVM)        | LIBPATH                | /lib:dc_home/<br>toolkit/lib/sol296 |
| Solaris 11 (64-bit JVM)        | LIBPATH                | /lib:dc_home/<br>toolkit/lib/sol296 |
| Linux x86_64 R2.6 (64-bit JVM) | LD_LIBRARY_PATH        | /lib:dc_home/<br>toolkit/lib/lx8266 |
| Linux Intel R2.6 (32-bit JVM)  | LD_LIBRARY_PATH        | /lib:dc_home/<br>toolkit/lib/li6263 |
| Windows (32-bit JVM)           | PATH                   | /lib;dc_home/<br>toolkit/lib/win32  |
| Windows (64-bit JVM)           | PATH                   | /lib;dc_home/<br>toolkit/lib/win64  |

4. Open the `server.xml` file in the same directory and add the following lines to enable the monitoring feature:

```
<featureManager>
  <feature>webProfile-7.0</feature>
```

```
<feature>monitor-1.0</feature>
<feature>usr:itcam-730.140</feature>
</featureManager>
```

5. Restart the Liberty server.

## Results

Now you can check the WebSphere Applications agent data in the Cloud APM console after you add this application component to your applications. For instructions on how to start the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#). For instructions on how to add or edit an application, see [“Managing applications” on page 1269](#).

## What to do next

After you manually configure the data collector, you cannot use the provided `unconfig` utility to unconfigure the data collector. Manually unconfigure the data collector instead. For instructions, see [“Manually unconfigure the data collector” on page 219](#).

## (Agent coexistence) Configuring the WebSphere Applications agent and the data collector

In the agent coexistence environment where both WebSphere Applications agent and ITCAM Agent for WebSphere Applications are installed, you must do some additional configuration for the agent and follow a different procedure to configure the data collector.

### About this task

In the agent coexistence environment, you configure only one data collector to send data to both WebSphere Applications agent and ITCAM Agent for WebSphere Applications. Both agents must use different ports to listen to the requests from the data collector.

### Procedure

1. If the data collector of ITCAM Agent for WebSphere Applications, which is installed in the old IBM® Tivoli® Monitoring infrastructure, exists in your environment, uninstall it.
2. Install the WebSphere Applications agent provided in IBM Cloud Application Performance Management 8.1.3 or later. It guarantees the data collector version 7.3.0.11.0 or later, which is supported for agent coexistence, is installed.
3. Make sure that the user ID that is to configure the data collector and the user ID that installed the application server have the appropriate user privileges required by the agent. For instructions, see [“Checking user access requirements” on page 937](#).
4. Make sure that the WebSphere Applications agent and ITCAM Agent for WebSphere Applications are using different port numbers to listen to the requests from the data collector. The port numbers must be unique, which cannot be used by any other component in your environment. Configure the agent again to change the port, if necessary.
  - For information about how to configure the WebSphere Applications agent, see [“Configuring WebSphere Applications agent” on page 960](#).
  - For information about how to configure the ITCAM Agent for WebSphere Applications, see ITCAM for Application Diagnostics or ITCAM for Applications documentation.
5. Use the provided configuration utility to configure the data collector. For instructions, see [“Configuring the data collector for agent coexistence environment” on page 961](#).

**Tip:** If you are familiar with the data collector configuration, you can also configure the data collector in silent mode. For instructions, see [“Configuring the data collector in silent mode” on page 949](#).

## Configuring WebSphere Applications agent

In the agent coexistence environment, the data collector is shared by both WebSphere Applications agent and ITCAM Agent for WebSphere Applications. Both agents must use different ports to listen to the requests from the data collector. You must configure the agent to change the port, if necessary.

### About this task

- On Linux or AIX systems, you can configure the agent interactively by running the configuration script and then responding to prompts, or silently by creating a silent response file and running the configuration script without interaction.
- On Windows systems, you can configure the agent by creating a silent response file and running the configuration script, or with the provided Manage Monitoring Services utility. For information about how to start Manage Monitoring Services on Windows systems, see [“Using the IBM Cloud Application Performance Management window on Windows systems”](#) on page 242.

### Procedure

- To configure the agent by editing the silent response file and running the script with no interaction, complete the following steps:

- a) Create a .txt file as the silent response file.
- b) Specify the following parameters in the silent response file. The syntax is *parameter\_name=parameter\_value*.

#### **configure\_type**

Specifies the configuration type. This parameter is required.

Valid value is `tema_configure` for agent configuration.

#### **KYN\_ALT\_NODEID**

Specifies the alternative node ID for identifying the agent. This parameter is required.

Valid value is an alphanumeric string of up to 24 characters.

#### **KYN\_PORT**

Specifies the listening port that is used by the agent. This is the TCP socket that the agent uses for listening to connection requests from the data collector. This parameter is required.

The default value is 63335.

**Remember:** In agent coexistence environment, make sure that the port number that you specified here is not being used by the ITCAM Agent for WebSphere Applications.

For example, add the following lines in the .txt file that you created.

```
configure_type=tema_configure
KYN_ALT_NODEID=WASAgent
KYN_PORT=63335
```

- c) Save and close the file, and then enter the following command to run the configuration script:

- **Linux** **UNIX** `install_dir/bin/was-agent.sh config path_to_responsefile`
- **Windows** `install_dir\bin\was-agent.bat config path_to_responsefile`

where *install\_dir* is the agent installation directory. The default is C:\IBM\APM on Windows systems, /opt/ibm/apm/agent on Linux systems and AIX systems.

- d) After configuration completes, restart the WebSphere Applications agent if it is not running with the following command:

- **Linux** **UNIX** `install_dir/bin/was-agent.sh start`
- **Windows** `install_dir\bin\was-agent.bat start`

- To configure the agent by running the script and responding to prompts, complete the following steps:

- a) From the command line, go to the `install_dir/bin` directory, where `install_dir` is the agent installation directory.

The default is `/opt/ibm/apm/agent` on Linux systems and AIX systems.

- b) Run the configuration script from the directory:

```
./was-agent.sh config
```

- c) When prompted, enter 1 and press Enter to edit the settings for the monitoring agent of WebSphere Applications agent.
- d) Press Enter until you are prompted for an alternative node ID to identify the monitoring agent.
- e) Provide the node ID and press Enter. The valid format of the node ID is an alphanumeric string of up to 24 characters.
- f) When prompted for the port number, provide the port that is used by the agent to listen to connection requests from the data collector and press Enter.

**Remember:** For agent coexistence environment, make sure that the specified port is not being used by the ITCAM Agent for WebSphere Applications.

- g) After configuration completes, restart the WebSphere Applications agent.

## Results

You have configured the WebSphere Applications agent.

## What to do next

Next, you must configure the data collector. When you configure the data collector, you will be asked to provide the port number that you configured for the WebSphere Applications agent and ITCAM Agent for WebSphere Applications. For instructions, see [“Configuring the data collector for agent coexistence environment”](#) on page 961.

## Configuring the data collector for agent coexistence environment

If you have both the WebSphere Applications agent and ITCAM Agent for WebSphere Applications in your environment, you can configure only one data collector for both agents.

## Before you begin

Make sure that you have complete other steps that are documented in [“\(Agent coexistence\) Configuring the WebSphere Applications agent and the data collector”](#) on page 959.

## About this task

Use the provided interactive configuration utility to configure the data collector for an environment where both WebSphere Applications agent and ITCAM Agent for WebSphere Applications exist and share the data collector.

**Limitation:** Integration the data collector with the following components or products are not supported for the ITCAM Agent for WebSphere Applications:

- ITCAM for Application Diagnostics Managing Server
- ITCAM for Transactions
- Tivoli Performance Viewer

**Remember:** Monitoring WebSphere Application Server Liberty is not supported by ITCAM Agent for WebSphere Applications. To monitor WebSphere Application Server Liberty, use the WebSphere Applications agent only. For information about data collector configuration for Liberty monitoring, see [“Configuring the data collector interactively”](#) on page 941 or [“Configuring the data collector in silent mode”](#) on page 949.

## Procedure

1. Log in to the system with the user ID that is used to install the application server.
2. From the command line, go to the bin directory within the *dc\_home* directory. The *dc\_home* directory is as follows:

- **Windows** `install_dir\dchome\7.3.0.14.08`
- **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08`

3. Run the following command to start the configuration utility:

- **Windows** `config.bat`
- **Linux** **UNIX** `./config.sh`

The configuration utility starts and displays the IP addresses of all network cards that are found on the local computer system.

4. Enter the number that corresponds to the IP address to use and press Enter.  
The configuration utility displays WebSphere Application Server home directories that are discovered on the system.
5. When prompted for the home directory of the application server, enter the number that corresponds to a WebSphere Application Server home directory or a full path to an application server home directory and press Enter.

The configuration utility displays all application server profiles that are discovered under the specified home directory.

6. When prompted for the application server profile to be configured, enter the number that corresponds to the WebSphere Application Server profile and press Enter.

The configuration utility indicates whether WebSphere Global Security is enabled for the WebSphere Application Server profile that you specified. If global security is not enabled, skip to Step “8” on [page 962](#).

7. Specify whether to retrieve security settings from a client properties file. Enter 1 to allow the configuration utility to retrieve the user name and password from the appropriate client properties file. Otherwise, enter 2 to enter the WebSphere administrator user name and password.

The data collector communicates with the WebSphere Administrative Services by using the Remote Method Invocation (RMI) or the SOAP protocol. If global security is enabled for a profile, you must specify the user ID and password of a user who is authorized to log in to the WebSphere Application Server administrative console for the application server profile. Alternatively, you can encrypt the user name and password and store them in client properties files before you configure the data collector. You must use the `sas.client.props` file for an RMI connection, or the `soap.client.props` file for an SOAP connection.

8. When you are prompted for the host name of WebSphere administrative console, press Enter to accept the default or specify the host name or IP address of the WebSphere administrative console. The default value is `localhost`.
9. When the configuration utility lists all the server instances that are not configured yet for data collection, select one or more application server instances from the list. Enter the number that corresponds to the application server instance to configure for data collection or enter an asterisk (\*) to configure all application server instances for data collection, and then press Enter. To specify a subset of servers, enter the numbers that represent the servers, separated by commas. For example, `1,2,3`.

### Remember:

- For a stand-alone environment, application server instances must be running during the configuration.
- For a Network Deployment environment, the Deployment Manager must be running.

- Ensure that the application server instances that you select are the actual servers that host the applications or services that you want to monitor.

The configuration utility provides an option for integrating the data collector for WebSphere Applications agent.

10. In the **Integration with Agent for WebSphere Applications** section, specify that you want to integrate the data collector with the monitoring agent. You must enter 1 to select this integration option, and then press Enter.

The selected server will be registered for PMI resource monitoring.

11. Specify whether you want to configure the data collector within the application server instance. You must enter 1 for yes, and then press Enter.
12. Specify whether to enable the data collector for diagnostics data. Enter 1 for yes, or enter 2 for no.
13. When prompted for the host name of the V8 monitoring agent component, enter the host name or IP address of the WebSphere Applications agent or accept the default.
14. When prompted for the port number of the V8 monitoring agent, enter the port number that is used by the WebSphere Applications agent.

**Remember:** The default value might not be appropriate to use if it is in use by another component. You must make sure that the specified port is not being used by any other component in your environment.

15. Specify that you want to configure the V6 monitoring agent. Enter 1 to configure the ITCAM Agent for WebSphere Applications and press Enter.
16. When prompted for the host name or IP address of the V6 monitoring agent, specify the host name or IP address of the ITCAM Agent for WebSphere Applications.
17. When prompted for the port number of the V6 monitoring agent, enter the port number that is used by the monitoring agent component of the ITCAM Agent for WebSphere Applications.

**Remember:** The default value might not be appropriate to use if it is in use by another component. You must make sure that the specified port is not being used by any other component in your environment.

18. When prompted for the server alias, do not use the default value, and specify a unique server alias that you want to use. If you are configuring several application server instances, the configuration utility prompts you for an alias for each instance.

**Important:** The alias can contain only the following characters: A-Z, a-z, underbar (\_), dash (-), and period (.). Do not use other characters in the alias.

The server alias is the first qualifier of the agent instance name (also known as MSN) that is displayed on the Cloud APM console. The default is the node name combined with the server name. For example, the **node1server1** alias indicates the server named **server1** in the node named **node1**.

19. When prompted for the TCP/IP port number for PMI resource monitoring, press Enter to accept the default or enter a new number. The default port is 63355.

The port is used for internal communication between components that are running on the same host. If the default port is in use, set a different number.

20. In the **Support for transaction tracking** section, specify whether to enable transaction tracking. Enter 1 for yes, or enter 2 for no and skip to 22.

**Remember:** To view transaction tracking information, you need to enable transaction tracking on the Agent Configuration page of the Cloud APM console.

21. Accept the default host name or IP address of the Transaction Framework Extension, which is an internal component of the WebSphere Applications agent that gathers metrics from the data collector.
22. Accept the default port number that the data collector uses to connect to the Transaction Framework Extension. The default is 5457.
23. Specify whether to integrate the data collector with Application Performance Diagnostics Lite. Press Enter to accept the default for no.

24. In the **Advanced settings** section, specify whether you want to change the garbage collection log path. Enter 1 to select a garbage collection log path. Otherwise, enter 2 and skip to step “26” on page 964.
25. Specify the garbage collection log path. Enter a file name with its full path.
- For example, if you specify `gc.log` as the file name, the actual name is set to `profile_name.cell_name.node_name.server_name.gc.log` for every configured application server instance.
- Important:** In the garbage collection log path, you can use WebSphere variables such as `${SERVER_LOG_ROOT}`. However, do not use templates, such as `%pid`.
26. In the **Data collector configuration summary** section, review the summary of the data collector configuration that is to be applied to the specified application server instances. If necessary, modify the configuration settings.
27. Enter a to accept the changes.
28. When prompted, specify whether you want to create a backup of your current configuration. Enter 1 to create a backup of the current configuration. Otherwise, enter 2.
29. Restart the application server instances as indicated by the configuration utility.
- Go to the `bin` directory under the home directory for the application server profile. For example, `opt/IBM/WebSphere/AppServer/profiles/profile_name/bin`.
  - Stop the application server by entering the **stopServer** command in the command console.
    - Linux** | **UNIX** `./stopServer.sh server_name`
    - Windows** `stopServer.bat server_name`
  - When prompted, enter the user ID and password of WebSphere administrative console administrator.
  - Start the application server again by entering the **startServer** command in the command console.
    - Linux** | **UNIX** `./startServer.sh server_name`
    - Windows** `startServer.bat server_name`
- The data collector configuration takes effect after the application server restart.
30. Log in to the Cloud APM console to view data in the dashboards.
- Open a browser window and enter the following URL where `server_host` is the IP address of the server:  
`https://server_host:9443`
  - When prompted for a logon ID, enter the following credentials for the default user or enter the credentials that were assigned by your Cloud APM console administrator:
    - User name: `apmadmin`
    - Password: `apmpass`

The initial user credentials after Cloud APM server installation are `apmadmin` with password `apmpass`.
  - Use the Applications editor to add the monitored application server to the Application Performance Dashboard. You can add it as a new component to your existing application or create an application to contain this component.
- For more information about the Applications editor, see “Managing applications” on page 1269.

## What to do next

- If the current user ID that is used to configure the data collector is not the same ID of the user running the application server, verify that the user ID for configuring the data collector has read and write permissions to the `runtime` and `logs` directories within the data collector home directory. These two

subdirectories are created by the ID of the user running the application server when the server is restarted.

- For WebSphere Applications agent, log in to the Cloud APM console to view the monitoring data in the dashboards. For ITCAM Agent for WebSphere Applications, log in to Tivoli Enterprise Portal to view data. If monitoring data is not available immediately, restart the monitoring agent by running the following commands:

– **Windows**

```
cd install_dir\bin
was-agent.bat stop
was-agent.bat start
```

– **Linux** | **UNIX**

```
cd install_dir/bin
./was-agent.sh stop
./was-agent.sh start
```

- Changing the server alias changes the agent instance name that is registered with the Cloud APM console. If this is not the first time that you configure the data collector and you changed the server alias, you must clear some cache files by completing the following steps:
  1. Stop the monitoring agent if it is running.
  2. Open the *hostname\_yn.xml* file in the following directory with a text editor, where *hostname* is the name of the host where the WebSphere Applications agent or ITCAM Agent for WebSphere Applications is installed.
    - **Windows** *install\_dir\TMAITM6\_x64* (Default is C:\IBM\APM\TMAITM6\_x64 for WebSphere Applications agent or C:\IBM\ITM\TMAITM6\_x64 for ITCAM Agent for WebSphere Applications)
    - **Linux** | **UNIX** *install\_dir/config* (Default is /opt/ibm/apm/agent/config for WebSphere Applications agent or /opt/ibm/itm/agent/config for ITCAM Agent for WebSphere Applications)
  3. Locate the line that starts with the following string and contains the previous server name. For example, *was85.win4net01Cell02.win4net01Node02.AppSrv01.server1*, where *server1* is previous name of the application server.

```
<!ENTITY was_product_code.cellname.nodename.profilename.servername
```

where *was\_product\_code* is the product code of WebSphere Application Server; *cellname* is the name of the cell; *nodename* is the node name; *profilename* is the name of the application server profile; *servername* is the previous name of the application server.

4. Locate the .XML file that is indicated in the line within the current directory and delete the file.
5. Remove the line that you located in Step 3 from the *hostname\_yn.xml* file.
6. At the end of the *hostname\_yn.xml* file, remove the line that contains the previous server names.
7. Save and close the file.
8. Restart the monitoring agent.

## Reconfiguring the data collector if you change the offering type on Cloud APM server

If you changed the offering type that you installed on the Cloud APM server from Cloud APM, Base to Cloud APM, Advanced and the WebSphere Applications agent was installed and configured with the Cloud APM, Base offering, to use the agent advanced capabilities provided in the Cloud APM, Advanced offering, you must uninstall the previous WebSphere Applications agent and install the agent again with the Cloud APM, Advanced offering. Alternatively, you can reconfigure the data collector for the capabilities to be available in the new offering.

## About this task

The WebSphere Applications agent is configured differently depending on which agent package is used to install the agent. After you change the offering type on the Cloud APM server, you have two choices to make the agent capabilities in the new offering available:

- Remove the agent that you installed with the previous offering and then install the agent in the new offering.
- Reconfigure the data collector again to use the capabilities in the new offering.

## Procedure

- Remove the agent that you installed with the previous offering and then install the agent in the new offering.
  - a) Unconfigure the data collector. For instructions, see [“WebSphere Applications agent: Unconfiguring the data collector”](#) on page 213.
  - b) Uninstall the WebSphere Applications agent that you installed with the agent package of previous offering. For instructions, see [“Uninstalling your agents”](#) on page 211.
  - c) Install the WebSphere Applications agent with the agent package in the new offering and configure the data collector again. For instructions, see [“Configuring the data collector with the simple configuration utility”](#) on page 938.
- Reconfigure the data collector again to use the capabilities in the new offering.
  - a) Edit the `offering.id` file in the data collector home directory by changing the **IOFFERING** value to one of the following values, depending on your new offering type:

### BASE

If your new offering type is Cloud APM, Base Private.

### ADVANCED

If your new offering type is Cloud APM, Advanced Private.

The data collector home directory is as follows:

- **Windows** `install_dir\dchome\7.3.0.14.08`
- **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08`

- b) Reconfigure the data collector to enable diagnostics, transaction tracking, or both in the data collector based on what is supported in the new offering type. For instructions about how to configure the data collector, see [“Configuring the data collector with the simple configuration utility”](#) on page 938.
- c) Restart the WebSphere Application Server.
- d) From any page of the Cloud APM console, click  **System Configuration > Agent Configuration** to open the **Agent Configuration** page. Ensure that the transaction tracking setting matches the capabilities available in your new offering type. If not, update the setting.

The transaction tracking setting should be enabled for Cloud APM, Advanced, but be disabled for Cloud APM, Base.

## Monitoring WebSphere Application Server Liberty inside a Docker container

To monitor a Liberty profile inside a Docker container, you must use the **docker run** command with a few options to configure the data collector before the WebSphere Application Server Liberty can be started.

## Before you begin

You must install the WebSphere Applications agent on the Docker host.

## About this task

Each Liberty profile running inside a Docker container requires a data collector to collect resource metrics, transaction metrics, and diagnostics data, and then transmit the data to the monitoring agent that is running on the Docker host. All data collectors that are configured on the same Docker host share the same monitoring agent on the host.

## Procedure

To configure the data collector for a Liberty profile container, complete the following steps:

1. Create a .txt silent response file, specify the following configuration options in the file and save it.

```
tema.host=agent_host
was.appserver.server.name=liberty_profile_name
```

where **tema.host** is used to specify the IP address of the monitoring agent host;  
**was.appserver.server.name** is used to specify the name of the Liberty profile.

**Tip:** A sample silent response file (sample\_silent\_liberty\_config.txt) is provided in the `<agent_install_dir>/agent/yndchome/7.3.0.14.08/bin` directory. You can create your own response file based on this sample file.

2. Run the following command to launch the new Docker container. Note that you must accept the license to complete the configuration by setting the **LICENSE** parameter to accept.

```
$docker run -d -e LICENSE=accept \
-e JAVA_HOME=<java_home_dir> \
-p <port_number>:<port_number> \
-v <web_app_dir>:<liberty_install_dir>/usr/servers/<liberty_profile_name> \
-v <agent_install_dir>/agent/yndchome:<agent_install_dir>/agent/yndchome
websphere-liberty /bin/bash \
-c "<agent_install_dir>/agent/yndchome/<dcversion>/bin/config.sh -silent
<absolute_path_to_silent_response_file> && <liberty_install_dir>/bin/server
run <liberty_profile_name>"
```

where:

- `<java_home_dir>` is the directory of the JRE that is used by the Liberty profile. For example, `/opt/ibm/java/jre`.
- `<port_number>` is the port number that is used for communication between the container and the host.
- `<web_app_dir>` is the directory where the web application locates.
- `<liberty_install_dir>` is the installation directory of the WebSphere Application Server Liberty. Default is `/opt/ibm/wlp`.
- `<liberty_profile_name>` is the name of the Liberty profile.
- `<agent_install_dir>` is the installation directory of the WebSphere Applications agent. Default is `/opt/ibm/apm`.
- `<dcversion>` is the version number of the data collector for WebSphere Applications agent. For example, `7.3.0.14.08`.
- `<absolute_path_to_silent_response_file>` is the absolute path to the silent response file that you created.

For example, the following command configures the data collector for the Liberty profile named newitcam. Both the WebSphere Applications agent and the Liberty profile are installed in the default directories. The version of the monitoring agent and data collector is 7.3.0.14.08.

```
$docker run -d -e LICENSE=accept \
-e JAVA_HOME=/opt/ibm/java/jre \
-p 9082:9082 \
-v /home/kub/liberty-docker/newitcam:/opt/ibm/wlp/usr/servers/newitcam \
-v /opt/ibm/apm/agent/yndchome:/opt/ibm/apm/agent/yndchome websphere-liberty
/bin/bash \
-c "/opt/ibm/apm/agent/yndchome/7.3.0.14.08/bin/config.sh -silent
```

```
/opt/ibm/wlp/usr/servers/newitcam/silent_config.txt && /opt/ibm/wlp/bin/server  
run newitcam"
```

## Results

Now you can verify that the WebSphere Applications agent data is displayed in the Cloud APM console. The **Cell name** column on the **WAS Information** widget shows the ID of the Docker container where the Liberty profile is running.

## What to do next

To unconfigure the data collector interactively, use the following command to start the unconfiguration utility:

```
docker exec -i container_id "<agent_install_dir>/yndchome/7.3.0.14.08/bin  
/unconfig.sh"
```

## Manually configuring the data collector to monitor dynamic cluster servers

You can configure the data collector to monitor application server instances in a dynamic cluster by adding some data collector configuration parameters to the server template that was used to create the dynamic cluster server instances. This is an alternative method to configure dynamic cluster server instances to creating the server templates specific for the WebSphere Applications agent.

## About this task

To configure the data collector for dynamic cluster monitoring, you must create two settings files, and then manually add settings in the WebSphere administrative console to modify the dynamic server template. The runtime directory is created automatically when the data collector is started for the application server instance. Note that any upgrade to the server template will erase these changes that you made in this way.

### Important:

- The cluster name cannot contain a space.
- You must make manual changes to the WebSphere Application Server configuration for data collectors as the WebSphere administrative user.
- You must be an experienced WebSphere administrator to make manual changes to the WebSphere Application Server for data collection. Any error in the manual configuration change can result in the application server not starting.
- If you manually configure the data collector to monitor application server instances, you cannot use the unconfiguration utility to unconfigure the data collector. To unconfigure the data collector, you must manually change the settings back.

## Procedure

1. Create the `dcManualInput.txt` file in the data collector runtime directory.  
Follow the instructions in [“Creating the dcManualInput.txt file”](#) on page 969.
2. Create the `itcam_wsBundleMetaData.xml` file in the data collector `wsBundleMetaData` directory.  
Follow the instructions in [“Creating the itcam\\_wsBundleMetaData.xml file”](#) on page 971.
3. Use WebSphere administrative console to modify the dynamic server template by adding the data collector configuration parameter. Follow the instructions in [“Adding settings with the WebSphere administrative console”](#) on page 972.

**Tip:** The dynamic cluster member name is used as the middle qualifier of the WebSphere Applications agent instance name that is displayed on the Cloud APM console. Sometimes, the cluster member name might be truncated due to the length limit on the agent instance name. In this case, you can modify the dynamic server template by adding a variable named `${MEP_NAME}` and setting the value to the JVM name for each server instance. Then, you can distinguish each cluster member by the actual

JVM name on the Cloud APM console. For instructions, see [“Optional: Showing actual JVM name to distinguish cluster members”](#) on page 975.

## Creating the `dcManualInput.txt` file

### About this task

The `dcManualInput.txt` file contains some values that are required for initial configuration of the data collector.

### Procedure

To create the `dcManualInput.txt` file, complete the following steps:

1. Check whether a file named `platform_Template.DCManualInput.txt` exists in the following directory. If it does not exist, create it.

- **Linux** | **UNIX** `install_dir/yndchome/7.3.0.14.08/runtime`
- **Windows** `install_dir\dchome\7.3.0.14.08\runtime`

The `platform` variable in the file name indicates the operating system architecture, for example, `aix32`, `xLinux64`.

You can name the file anything that you want. However, `platform_Template.DCManualInput.txt` follows the standard naming convention when the file is created by running the `configtemplate.sh` script. You will need to specify this file for the server template with WebSphere administrative console in the subsequent step.

2. Copy the contents of the following file to the `.txt` file that you found or created in the previous step.

- **Linux** | **UNIX** `dc_home/itcamdc/etc/was/dcInput_manual.properties`
- **Windows** `dc_home\itcamdc\etc\was\dcInput_manual.properties`

3. Edit the contents of the `.txt` file. You must set the parameters in section 1 of the file according to the descriptions provided in [Table 257 on page 969](#).

#### Remember:

- Do not change the parameters in section 2.
- Some of the configuration parameters that are used by the data collector to create runtime directories are always set to none. It is because in dynamic cluster monitoring, the data collector uses the WebSphere server instance configuration to create the directories when JVM starts.

| Table 257. Configuration Parameters for Section 1 |   |
|---|---|
| Parameter   | Value   |
| local.hostname                                    | The IP address or fully qualified domain name of the local system.                                  |
| was.profile.home                                  | The profile home directory.<br>Always set it to none for dynamic cluster server                     |
| was.version                                       | A short version number.<br>Always set it to none for dynamic cluster server                         |
| itcam.home  | The data collector home directory.<br>Example: <code>/opt/ibm/apm/agent/yndchome/7.3.0.14.08</code> |

| Table 257. Configuration Parameters for Section 1 (continued) |   |
|---|---|
| Parameter   | Value   |
| was.nodename  | Node name.<br>Always set it to none for dynamic cluster server  |
| was.servername  | Server name.<br>Always set it to none for dynamic cluster server  |
| was.profilename   | WebSphere profile name.<br>Always set it to none for dynamic cluster server   |
| am.camtoolkit.gpe.dc.operation.mode                           | <p>Operation mode of the data collector. Valid values are any combination of WR, TT, and DE, where:</p> <p><b>WR</b><br/>Integrates the data collector with the WebSphere Applications agent.</p> <p><b>TT</b><br/>Integrates the data collector with ITCAM for Transactions.</p> <p><b>DE</b><br/>Integrates the data collector with ITCAM Diagnostics Tool. The tool is previewed in the ITCAM for Application Diagnostics beta.</p> <p>You must specify only the operation modes required. For example, if you are connecting the data collector to the WebSphere Applications agent only, specify WR.</p> <p>Separate multiple operation modes with a comma.</p> <p>Example:<br/>am.camtoolkit.gpe.dc.operation.mode=WR, DE</p> |
| interp  | Platform code.<br>Example: interp=win64 or interp=lx6266  |
| kwj.serveralias   | WebSphere Application Server alias name.<br>Always set it to none for dynamic cluster server  |
| temagclog.path  | (Optional) Garbage Collection log file path name. Enter a unique file name with full path. The path name must not include spaces.   |
| tema.host   | <p>Host name or IP address of the WebSphere Applications agent. Mandatory if the operation mode includes WebSphere Applications agent (WR). Usually, the monitoring agent is installed on each system where the data collector is running and the loopback address can be specified.</p> <p>Example: tema.host=127.0.0.1</p>  |

Table 257. Configuration Parameters for Section 1 (continued)

| Parameter            | Value  |
|----------------------|--|
| tema.port            | Port to use for communicating with the WebSphere Applications agent. Mandatory if the operation mode includes WebSphere Applications agent (WR). The default value is 63335.<br><br>Example: tema.port=63335   |
| tt.connection.string | Host name or IP address and the port number of the transaction collector component of ITCAM for Transactions in the format of <code>tcp:host_name(IP):port</code> . Mandatory if the operation mode includes ITCAM for Transactions (TT).<br><br>Example:<br>tt.connection.string=192.38.234.77:5455 |

4. Add the following lines to the section 1 of the .txt file.

```
bcm.helper=com.ibm.tivoli.itcam.was.bcm.websphere.DefaultWASBCMHelper
BCM_HELPER=@{bcm.helper}
```

5. Save and close the file.

## Creating the itcam\_wsBundleMetaData.xml file

### About this task

The itcam\_wsBundleMetaData.xml file contains some of the values that are required initial configuration of the data collector.

### Procedure

To create this file, complete the following steps:

1. Create a directory that is named wsBundleMetaData under the following directory:
  - **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08/runtime`
  - **Windows** `install_dir\dchome\7.3.0.14.08\runtime`
2. Create a file that is named itcam\_wsBundleMetaData.xml and copy the contents of the following file into it:
  - **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08/itcamdc/etc/was/itcam_wsBundleMetaData_template.xml`
  - **Windows** `install_dir\dchome\7.3.0.14.08\itcamdc\etc\was\itcam_wsBundleMetaData_template.xml`
3. In the itcam\_wsBundleMetaData.xml file, replace the @{CONFIGHOME} variable with the full path to your data collector home directory.  
The data collector home directory on each operating system is as follows:
  - **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08`
  - **Windows** `install_dir\dchome\7.3.0.14.08`
4. Place the itcam\_wsBundleMetaData.xml file to the wsBundleMetaData directory that you created in Step 1.

## Adding settings with the WebSphere administrative console

### Procedure

Complete the following steps to modify the dynamic server template with the WebSphere administrative console.

1. Log in to the WebSphere Administrative Console.
2. Click **Servers**.
3. Expand **Clusters** and select **Dynamic Clusters**.
4. Click the name of the dynamic server cluster that you want to configure with the data collector.
5. Under the **Additional Properties** section, click **Server template**.
6. Under the **Server Infrastructure** section, expand **Java and Process Management** and click **Process Definition**.
7. Under the **Additional Properties** section, click **Java Virtual Machine**.
8. In the **Generic JVM arguments** field, add the following entries.

```
-agentlib:am_${jvm-vendor} ${jvm-version}=${WAS_SERVER_NAME}
-Xbootclasspath/p:${ITCAMDCHOME}/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=${ITCAMDCHOME}/itcamdc/etc/datacollector.policy
-verbosegc -Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=${ITCAMDCHOME}/runtime/
$platform_Template_DCManualInput.txt
-Dsun.rmi.dgc.client.gcInterval=3600000
-Dsun.rmi.dgc.server.gcInterval=3600000
-Dsun.rmi.transport.connectionTimeout=300000
-Dws.bundle.metadata=${ITCAMDCHOME}/runtime/wsBundleMetaData
-Ditcamdc.dyncluster=true
```

When you are adding the entries, take note of the following things:

- All entries must be on a single line.
- Separate different arguments by spaces before the - sign, do not use spaces anywhere else.
- Replace the following variables with the actual names:
  - *\$jvm-vendor*: The JVM vendor that is used.
  - *\$jvm-version*: The JVM version information, such as 15 based on Java 5, 16 based on Java 6, or 17 based on 7.
  - *\$platform\_Template\_DCManualInput.txt*: The .txt file that you created in the previous step.

Example:

```
-agentlib:am_ibm_16=${WAS_SERVER_NAME}
-Xbootclasspath/p:${ITCAMDCHOME}/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=${ITCAMDCHOME}/itcamdc/etc/datacollector.policy
-verbosegc -Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=${ITCAMDCHOME}/runtime/
aix64_Template_DCManualInput.txt
-Dsun.rmi.dgc.client.gcInterval=3600000
-Dsun.rmi.dgc.server.gcInterval=3600000
-Dsun.rmi.transport.connectionTimeout=300000
-Dws.bundle.metadata=${ITCAMDCHOME}/runtime/wsBundleMetaData
-Ditcamdc.dyncluster=true
```

9. Click **Apply**.
10. In the Messages dialog box, click **Save**.
11. In the Save to Master Configuration dialog box, complete the following steps:
  - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected and then click **Save**.
  - If you are not under a Network Deployment environment, click **Save**.
12. Go back to expand **Clusters**, click **Dynamic clusters**, and click the same server name.
13. In the **Configuration** tab, go to **Server Infrastructure > Java and Process Management > Process Definition > Environment Entries**.

14. Depending on the operating system, the hardware platform, and the application server JVM, set the following environment entry:

| Table 258. Environment entry   |                        |  |
|--------------------------------|------------------------|--|
| Platform                       | Environment Entry name | Environment Entry value  |
| AIX R6.1 (32-bit JVM)          | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix533:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/aix533/ttapi |
| AIX R6.1 (64-bit JVM)          | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix536:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/aix536/ttapi |
| AIX R7.1 (32-bit JVM)          | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix533:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/aix533/ttapi |
| AIX R7.1 (64-bit JVM)          | LIBPATH                | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/aix536:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/aix536/ttapi |
| Linux x86_64 R2.6 (64-bit JVM) | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lx8266:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/lx8266/ttapi |
| Linux Intel R2.6 (32-bit JVM)  | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lx6263:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/lx6263/ttapi |
| Linux ppc R2.6 (32-bit JVM)    | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lpp263:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/lpp263/ttapi |
| Linux ppc R2.6 (64-bit JVM)    | LD_LIBRARY_PATH        | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/lpp266:\$<br>{ITCAMDCHOME}/<br>toolkit/lib/lpp266/ttapi |
| Windows (32-bit JVM)           | PATH                   | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/win32;\$<br>{ITCAMDCHOME}/<br>toolkit/lib/win32/ttapi   |
| Windows (64-bit JVM)           | PATH                   | /lib:\${ITCAMDCHOME}/<br>toolkit/lib/win64;\$<br>{ITCAMDCHOME}/<br>toolkit/lib/win64/ttapi   |

15. Set the NLSPATH environment entry name to the following value:

```
${ITCAMDCHOME}/toolkit/msg/%L/%N.cat
```

16. Click **Apply** and click **Save**.

17. In the Save to Master Configuration dialog box, complete the following steps:

- If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected and then click **Save**.
  - If you are not under a Network Deployment environment, click **Save**.
- Go back to expand **Clusters**, click **Dynamic clusters**, and then click the same server name.
  - In the **Configuration** tab, go to **Server Infrastructure > Java and Process Management > Process Definition > Java Virtual Machine > Additional Properties: Custom Properties**.
  - Click **New** to add the following name and value pairs, and then click **Apply**.
    - Create an `am.home` property and set its value to the following directory:
      - **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08/itcamdc`
      - **Windows** `install_dir\dchome\7.3.0.14.08\itcamdc`
    - Create an `am.orig.wascell` property and set its value to the cell directory. For example, `am.orig.wascell =cellname1`.
    - Create a `com.ibm.tivoli.itcam.toolkit.ai.runtimebuilder.enable.rebuild` property and set its value to `true`.
    - Create an `ITCAM_DC_ENABLED` property and set its value to `true`.
    - Create a `TEMAGCCollector.gclog.path` property. If the generic JVM `verlogsegclog` argument is set, set the value of the `TEMAGCCollector.gclog.path` property to the same value. Otherwise, set the `TEMAGCCollector.gclog.path` property to `None`.

**Tip:** To identify the value of the `verlogsegclog` property, in the **Configuration** tab, click **Server Infrastructure > Java and Process Management > Process Definition > Java Virtual Machine**. The `verlogsegclog` value is in the **Generic JVM arguments** field.
  - In the Messages dialog box, click **Save**.
  - In the Save to Master Configuration dialog box, complete the following steps:
    - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected. Click **Save**.
    - If you are not under a Network Deployment environment, click **Save**.
  - In the Navigation Pane, click **Environment > WebSphere Variables**.
  - Set the following variables. For each variable, you must choose the appropriate scope level, depending on the data collector installation directory on various systems. If different systems have different installation directories for the data collector, these variables must be set correctly for each node-level scope. If they all have the same installation directory, the scope can be higher, such as at the cluster level.
    - Set `ITCAMDCHOME` to following directory:
      - **Linux** **UNIX** `install_dir/yndchome/7.3.0.14.08/itcamdc`
      - **Windows** `install_dir\dchome\7.3.0.14.08\itcamdc`
    - Set `ITCAMDCVERSION` to the version of the data collector, for example, `7.3.0.14.08`.
  - Click **Apply** and click **Save**.
  - In the Save to Master Configuration dialog box, complete the following steps:
    - If you are under a Network Deployment environment, ensure that **Synchronize changes with Nodes** is selected and then click **Save**.
    - If you are not under a Network Deployment environment, click **Save**.

After the template is modified, the values are synchronized with all the server instances in the dynamic cluster. Any new server that is dynamically created will also have the same data collector configuration parameters.
  - Restart the application server instance for the data collector to be activated. The data collector reads the settings files and creates the runtime directory.

## Optional: Showing actual JVM name to distinguish cluster members

### About this task

On the Cloud APM console, the WebSphere Applications agent instance name takes the form of *host\_name::was\_server\_name:KYNS* and has a maximum length of 32 characters. In the dynamic cluster environment, dynamic cluster member names are used for the middle qualifier *was\_server\_name*.

Sometimes, the cluster member names are truncated due to the character length limit. In this case, you can specify the actual JVM name to be used for the middle qualifier in the agent instance name.

### Procedure

Perform the following steps to show actual JVM name in the agent instance name:

1. Log in to the WebSphere Administrative Console to update the generic JVM arguments by adding a new environment variable `${MEP_NAME}` as follows:

```
-agentlib:am_${jvm-vendor}_${jvm-version}=${MEP_NAME}${WAS_SERVER_NAME}
-Xbootclasspath/p:${ITCAMDCHOME}/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=${ITCAMDCHOME}/itcamdc/etc/datacollector.policy
-verbosegc -Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=${ITCAMDCHOME}/runtime/
$platform_Template_DCManualInput.txt
-Dsun.rmi.dgc.client.gcInterval=3600000
-Dsun.rmi.dgc.server.gcInterval=3600000
-Dsun.rmi.transport.connectionTimeout=300000
-Dws.bundle.metadata=${ITCAMDCHOME}/runtime/wsBundleMetaData
-Ditcamdc.dyncluster=true
```

Example:

```
-agentlib:am_ibm_16=${MEP_NAME}${WAS_SERVER_NAME}
-Xbootclasspath/p:${ITCAMDCHOME}/toolkit/lib/bcm-bootstrap.jar
-Djava.security.policy=${ITCAMDCHOME}/itcamdc/etc/datacollector.policy
-verbosegc
-Dcom.ibm.tivoli.itcam.ai.runtimebuilder.inputs=${ITCAMDCHOME}/runtime/
aix64_Template_DCManualInput.txt
-Dsun.rmi.dgc.client.gcInterval=3600000
-Dsun.rmi.dgc.server.gcInterval=3600000
-Dsun.rmi.transport.connectionTimeout=300000
-Dws.bundle.metadata=${ITCAMDCHOME}/runtime/wsBundleMetaData
-Ditcamdc.dyncluster=true
```

2. Save and apply the changes.
3. In the Navigation Pane, click **Environment > WebSphere Variables** to define the `${MEP_NAME}` variable for each dynamic cluster member. Set the value to the actual JVM name of the cluster member.
4. Save and apply the changes.
5. Restart the application server instance.

On the Cloud APM console, a new WebSphere Applications agent instance whose name contains the `${MEP_NAME}` value that you just specified is displayed.

## Dynamically configuring data collection on Agent Configuration page

After you enable the support for transaction tracking or diagnostic data collection in the data collector, use the **Agent Configuration** page to dynamically enable or disable the data collection.

### Before you begin

- You must install and configure the Monitoring Agent for WebSphere Applications.
- To enable or disable transaction tracking for the monitored application servers, you must install Transaction Tracking. You must also enable support for transaction tracking in the agent as described in [“Configuring the data collector interactively”](#) on page 941. If you follow the simple configuration procedure, the data collector is automatically configured with support for transaction tracking.

- To enable or disable the collection of diagnostic data including method trace, you must have Cloud APM, Advanced Private. You must also enable support for the collection of diagnostic and method trace information in the data collector as described in [“Configuring the data collector interactively”](#) on page 941. (Not available for Cloud APM, Base Private).

**Tip:** The **Agent Configuration** page displays all the servers that are monitored by the agent. If any server is missing, it might not be correctly monitored. Check the agent log files on the monitored system for error messages, for example, connection errors.

**Remember:** The WebSphere Applications agent supports only Db2 and Oracle as the data source. For other types of data sources, some KPI values might appear to be null on the Transaction Tracking dashboards and group widgets.

## Procedure

Complete the following steps to configure data collection for each server:

1. From the navigation bar, click  **System Configuration** > **Agent Configuration**.  
The **Agent Configuration** page is displayed.
2. Click the **WebSphere Applications** tab.
3. Select the check boxes of the servers on which you want to configure data collection and take one of the following actions from the **Actions** list:
  - To enable transaction tracking, click **Enable Transaction Tracking**. The status in the **Current Transaction Tracking** column is updated to Yes for each selected server.
  - To enable only diagnostic data collection, click **Enable Diagnostic Mode**. The status in the **Current Diagnostic Mode** column is updated to Yes for each selected server.
  - To collect both the diagnostic data and method trace information, click **Enable Diagnostic Mode and Method Trace**. The status in the **Current Diagnostic Mode** and **Current Method Trace** columns is updated to Yes for each selected server.
  - To disable transaction tracking for the selected server, click **Disable Transaction Tracking**. The status in the **Current Transaction Tracking** column is updated to No for each selected server.
  - If only the diagnostic data collection is enabled for the selected server, to disable data collection, click **Disable Diagnostic Mode**. The status in the **Current Diagnostic Mode** column is updated to No for each selected server.
  - If both the diagnostic data and method trace data are enabled for the selected server, to disable data collection, click **Disable Diagnostic Mode and Method Trace**. The status in the **Current Diagnostic Mode** and **Current Method Trace** columns is updated to No for each selected server.

### Remember:

- Unless support for transaction tracking or diagnostic data collection is configured in the data collector, operations on the **Agent Configuration** page does not enable data collection and the column value is set to No.
- If the application server profile was configured to use 127.0.0.1 as the host name, the **IP Address** column on the **Agent Configuration** page displays the IP address of the host where the WebSphere Applications agent is installed and running.

## Results

You have configured data collection for each selected server. Transaction tracking data and diagnostic data can be displayed in the topology dashboards after you enable the data collection.

**Important:** If an application server restarts, you might need to enable transaction tracking or diagnostic data collection for the server again.

## Enabling memory leak monitoring

For the Memory Analysis dashboard to contain data, you must enable memory leak monitoring for the data collector. If the JRE that is used by the application server is supported, the memory leak monitoring function is enabled by default after you enable diagnostic data collection.

### Before you begin

- Make sure that `-Xtrace:none` is not defined in the JVM arguments for the application server.
- When memory leak monitoring is enabled, the following settings are defined in the JVM arguments for the application server. If you have defined these settings in your current JVM arguments, make sure that it is OK for the data collector configuration to change them.

```
-Xhealthcenter:level=inprocess  
-Xgc:allocationSamplingGranularity=10000
```

- Make sure the JRE that is used by the application server is one of the following versions:
  - IBM JRE 1.6.0 SR16 FP3 or later
  - IBM JRE 1.6.1 SR8 FP3 or later
  - IBM JRE 1.7.0 SR8 FP10 or later
  - IBM JRE 1.7.1 SR2 FP10 or later
  - IBM JRE 1.8 or later
  - Other IBM JRE later than 1.6.0 SR7 with iFix for APAR IV67574

### About this task

The memory leak monitoring function requires the IBM Health Center component of IBM JRE. You must make sure the JRE that is used by the application server is supported by this function.

- On AIX or Linux systems, when you configure the data collector to enable diagnostic data collection, if the current JRE is supported, the configuration utility automatically checks whether the Health Center component is eligible and upgrade the Health Center if it is not.
- On Windows systems, you must manually upgrade the Health Center component if the current version is not supported because the configuration utility cannot replace files for a running JRE.

**Remember:** The following procedure is required on Windows systems only. For AIX or Linux systems, to enable memory leak monitoring, you only need to make sure that the JRE version is supported and the diagnostic data collection is enabled. For Solaris systems, Health Center of IBM JRE is not supported, so memory leak monitoring cannot be enabled on Solaris systems.

### Procedure

1. Check the IBM Health Center version that is included in the JRE used by the application server.
  - a) At the command prompt, change to the `bin` directory within the JRE home directory.
  - b) Type `java -Xhealthcenter -version` and press Enter.  
The command returns the JRE version and the IBM Health Center version. The memory leak monitoring function requires IBM Health Center 3.0.11 or later.
2. If the IBM Health Center version is not eligible, upgrade the JRE to a version that contains IBM Health Center 3.0.11 or later.
3. Run the data collector configuration or reconfiguration utility to enable the diagnostic data collection.
  - If you have not configured the data collector, use the `simpleconfig` or `config`.
  - If you have configured the data collector, use the `reconfig` utility.

**Remember:** If you have enabled diagnostic data collection before you upgrade the JRE, you still need to run the data collection configuration utility again.

## Configuring the PMI

To view performance data in the operational monitoring dashboards, the Performance Monitoring Infrastructure (PMI) on the WebSphere Application Server must be configured to gather performance data.

### About this task

Use the WebSphere Administrative Console to enable the PMI and set the PMI level on the WebSphere Application Server.

The PMI provides four predefined levels:

1. None
2. Basic
3. Extended
4. All

You can use a custom option to selectively enable or disable individual statistics. Each level includes the statistics from the level below it.

To display data in the operational monitoring dashboards, the attributes that are used in the dashboard calculations must be included in selected level.

By default, the WebSphere Applications agent sets the PMI level high enough to collect the required attributes.

**Restriction:** To see data in some of the Process Server and Transaction Manager group widgets, you must manually set the PMI level. For more information, see the fly-over help on the group widgets.

If you modify the PMI level with the WebSphere Administrative Console, you must verify that the level is high enough to collect the required data.

### Procedure

- To enable the PMI on the application server, complete these steps:
  - a) In the WebSphere Administrative Console, expand **Monitoring and Tuning**, and then select **Performance Monitoring Infrastructure (PMI)**.
  - b) From the list of servers, click the name of your server.
  - c) Click the Configuration tab, and then select the **Enable Performance Monitoring Infrastructure (PMI)** check box.
  - d) Click **Apply** or **OK**.
  - e) Click **Save** to enable the PMI.
- To set the PMI level on the application server, complete these steps:
  - a) In the WebSphere administrative console, expand **Monitoring and Tuning**, and then select **Performance Monitoring Infrastructure (PMI)**.
  - b) From the list of servers, click the name of your server.
  - c) Click the Configuration tab, and then select the statistics set to use; Basic, Extended, All, or Custom.
  - d) Click **Apply** or **OK**.
  - e) Click **Save** to set the PMI level.

For information about the PMI level that is required for each attribute, see the "Dashboard attributes" section in the [WebSphere Applications agent Reference](#). The monitoring overhead that is incurred when you turn on the collection of each attribute is displayed.

## Restoring the application server configuration from a backup

If you configured a stand-alone application server instance for data collection either manually or with the configuration or migration utility and the application server fails to start, you must restore the application server configuration from a backup. If you did not create a backup, contact IBM Support.

### About this task

In a Network Deployment environment, if you configured an application server instance for data collection manually or with the configuration or migration utility and the application server fails to start, you have the following options:

- You can restore the application server configuration from a backup configuration. If you did not create a backup, contact IBM Support.
- You can manually unconfigure the data collector. The Deployment Manager and the Node Agent on the application server must be running. For more information, see [“Manually removing data collector configuration from an application server instance” on page 217](#).

This section applies only to the Windows, UNIX, and Linux operating systems.

### Procedure

To apply the backup configuration by using the **restoreConfig** command, use one of the following procedures:

- In a non-Network Deployment environment, complete the following steps:
  - a) Locate your backup configuration file.

The default directory is *dc\_home/data*. If several backup files are present, check the modification date and time of the file. It must be the date and time of the failed configuration. If you did not complete any other data collector configurations on the same host after the failed one, use the most recent file in the directory.
  - b) Stop all instances of the application server.
  - c) Run the **restoreConfig** command from the *appserver\_home/profiles/profile\_name/bin* directory.

The command syntax is as follows:

- **Windows** `restoreConfig.bat full_path_to_backup_file`
- **Linux** **UNIX** `./restoreConfig.sh full_path_to_backup_file`

For more information about the arguments of the **restoreConfig** command, see the topic in [WebSphere Application Server Knowledge Center](#).

- d) Start the instances of the application server again.
- In a Network Deployment environment, complete the following steps:
    - a) Locate your backup configuration file.

The default directory is *dc\_home/data*. If several backup files are present, check the modification date and time of the file; it must be the date and time of the failed configuration. If you did not complete any other data collector configurations on the same host after the failed one, use the most recent file in the directory.
    - b) Stop all instances of the application server.
    - c) Create a temporary directory in any convenient path (*temp\_directory*). On a UNIX or Linux system, create it under the */tmp* directory.
    - d) Run the **restoreConfig** command from the *appserver\_home/profiles/profile\_name/bin* directory.

The command syntax is as follows:

- **Windows** `restoreConfig.bat full_path_to_backup_file`
- **Linux** **UNIX** `./restoreConfig.sh full_path_to_backup_file`

The **restoreConfig** command restores the original application server configuration to the temporary directory.

- Copy the `server.xml`, `variables.xml`, and `pmi-config.xml` files from temporary directory to the Deployment Manager system.
  - Source directory: `temp_directory/restored_configuration_home/cells/cell_name/nodes/node_name/servers/server_name`
  - Target directory: `appserver_home/profiles/profile_name/config/cells/cell_name/nodes/node_name/servers/server_name`
- Complete a node sync from the Deployment Manager administrative console for the node.
- In the Deployment Manager administrative console, save changes to the master configuration.
- Start the instances of the application server.

## Advanced data collector configuration

You can modify data collector configuration files to change additional monitoring settings.

### Properties files for Liberty data collector

Various configuration files are provided for you to further control the data collector configuration and behavior.

After you extract the data collector package to a local directory, the data collector files are located in the `local_dir/liberty_dc/.gdc/7.3.0.14.08` directory. For example, `/opt/ibm/apm/.gdc/7.3.0.14.08`. This folder becomes the home directory of the data collector, which is referred to as `dc_home` in the following statements for simplification.

### Data collector properties files

Each application server instance that is monitored by the data collector has its own properties file. The data collector automatically creates the properties file. The name of the file is `dc_home/runtime/appserver_version.node_name.profile_name.server_name/datacollector.properties`.

To facilitate future upgrades, do not change this file.

Instead, add the settings that you want to modify to the data collector custom properties file. This file is named `dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom/datacollector_custom.properties`. Settings in the data collector custom properties file override the values that are in the data collector properties file.

**Important:** If the `dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom/datacollector_custom.properties` file does not exist, create it when you want to make changes. You might also have to create the custom directory.

### Toolkit properties file

The toolkit properties file is automatically created by the data collector at startup, using various input files. It is unique for every application server instance monitored by the data collector. Its name is `dc_home/runtime/appserver_version.node_name.profile_name.server_name/toolkit.properties`.

Because this file is re-created at each data collector startup, **do not make any changes** to this file; if you do, they will be overwritten.

Instead, add the settings that you want to modify to the toolkit custom properties file. This file is named `dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom/toolkit_custom.properties`. Settings in the toolkit custom properties file override the values in the toolkit properties file.

You can also set toolkit properties for all the application server instances that are monitored by this installation of the data collector. To do this, add the settings to the global toolkit custom properties file: `dc_home/runtime/custom/toolkit_global_custom.properties`. However, if a property is set in the instance-specific `toolkit_custom.properties` file, it overrides the value in the global file for this instance.

**Important:** If the `dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom/toolkit_custom.properties` or `dc_home/runtime/custom/toolkit_custom.properties` file does not exist, create it when you want to make changes. You might also have to create the custom directory.

## Other properties files

Besides the data collector properties file and toolkit properties file, there are other properties files that are unique for every application server instance monitored by the data collector.

**`dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/gdc/gdc_custom.properties`**

Defines the details for collecting diagnostic and method trace data. For information about changing this file, see [“Configuring collection of detailed diagnostic information”](#) on page 983.

**`dc_home/runtime/appserver_version.node_name.server_name/hc.properties`**

Defines the details for heap snapshot collection and memory allocation collection. For information about changing this file, see [“Configuring collection of detailed diagnostic information”](#) on page 983.

**`dc_home/runtime/app_server_version.node_name.profile_name.server_name/cynlogging.properties`**

Defines the log file names and logging details for the Java portion of the data collector.

**`dc_home/runtime/app_server_version.node_name.profile_name.server_name/cyncclog.properties`**

Defines the log file names and logging details for the C++ portion of the data collector.

## Data collector trace files

The data collector trace files are stored by default in the following locations:

- **Windows** `dc_home\logs\CYN\logs`.
- **Linux** | **UNIX** `dc_home/logs/CYN/logs`.

## Enabling or disabling transaction tracking and diagnostic data collection

By default, transaction tracking and method tracing are enabled for the data collector. Heap snapshot collection and memory allocation collection are disabled. You can customize the data collection or the intervals at which the diagnostic data is collected by editing the `.properties` files of the data collector.

## About this task

The properties files of the data collector are in the `dc_home` directory, for example, `/opt/ibm/apm/.gdc/7.3.0.14.08`. Use different properties to customize the data collector for the following purposes:

- Enable or disable transaction tracking.
- Enable or disable heap snapshot collection.

- Specify the interval at which the data collector takes snapshot of heap dump.
- Enable or disable memory allocation monitoring.
- Specify the interval at which the data collector collects memory allocation information.
- Enable or disable method tracing.

**Remember:** Depending on whether you have restarted the Liberty server after data collector configuration, different `.properties` files are applicable. If you have restarted the Liberty server after data collector configuration, a runtime directory is created within the `dc_home` directory. After that, you can only use the `.properties` files within the `dc_home/runtime/appserver_version.node_name.profile_name.server_name` directory to customize data collector for each application server.

## Procedure

- To enable or disable transaction tracking, set the **`com.ibm.tivoli.itcam.dc.bluemix.transaction.enabled`** property in the following file to true or false:  
  
`dc_home/runtime/appserver_version.node_name.server_name/ldc.properties` (if the runtime directory does not exist, use `dc_home/ldc/etc/ldc.properties`)  
  
After transaction tracking is enabled, you can monitor IBM Java application stack in the topologies.
- To enable or disable heap snapshot collection, set the **`com.ibm.tivoli.itcam.hc.send.heap.enable`** and **`com.ibm.tivoli.itcam.hc.snapshot.automatic.enable`** properties in the following file to true or false.  
  
`dc_home/runtime/appserver_version.node_name.server_name/hc.properties` (if the runtime directory does not exist, use `dc_home/healthcenter/etc/hc.properties`)  
  
After heap snapshot collection is enabled, the data collector can take heap snapshot at specified intervals. Heap dump information can be displayed in the Heap Dump dashboard.
- To change the interval at which heap snapshot is taken by the data collector, set the **`com.ibm.tivoli.itcam.hc.snapshot.automatic.interval`** property in the same file to a positive integer. The unit of the interval is minute and the default is 360.  
  
`dc_home/runtime/appserver_version.node_name.server_name/hc.properties` (if the runtime directory does not exist, use `dc_home/healthcenter/etc/hc.properties`)
- To enable or disable memory allocation collection, set the **`com.ibm.tivoli.itcam.hc.events.collection.automatic.enable`** property in the following file to true or false.  
  
`dc_home/runtime/appserver_version.node_name.server_name/hc.properties` (if the runtime directory does not exist, use `dc_home/healthcenter/etc/hc.properties`)  
  
**Remember:** To enable memory allocation collection, you also need to ensure the following two lines are added to the `jvm.options` file of the Liberty server.  
  

```
-Xhealthcenter:level=inprocess
-Xgc:allocationSamplingGranularity=10000
```

  
After memory allocation collection is enabled, data is available in the Memory Analysis dashboard.
- To specify the interval at which memory allocation information is collected, set the **`com.ibm.tivoli.itcam.hc.events.collection.automatic.interval`** property in the same file to a positive integer. The unit of the interval is minute and the default is 15.  
  
`dc_home/runtime/appserver_version.node_name.server_name/hc.properties` (if the runtime directory does not exist, use `dc_home/healthcenter/etc/hc.properties`)
- To enable or disable method tracing, set the **`dfe.enable.methoddata`** property in the following file to true or false:

```
dc_home/runtime/appserver_version.node_name.profile_name.server_name/  
custom/gdc/gdc_custom.properties (if the runtime directory does not exist, use  
dc_home/gdc/etc/gdc_dfe.properties)
```

## Results

After you modify the `.properties` files, restart the Liberty server for the change to take effect.

For more information about the data collector `.properties` files for each application server, see [“Properties files for Liberty data collector”](#) on page 980.

## What to do next

- After method tracing is enabled, you can set thresholds for different types of requests, so that different levels of monitoring data can be collected for different requests. For instructions, see [“Customizing the request thresholds”](#) on page 985.
- If you disabled memory allocation collection, remember to remove the following lines from the `jvm.options` file of the Liberty server:

```
-Xhealthcenter:level=inprocess  
-Xgc:allocationSamplingGranularity=10000
```

## Configuring collection of detailed diagnostic information

If you have IBM Cloud Application Performance Management, Advanced Private, you can use the data collector to collect detailed diagnostic information on the monitored application server instance. To configure the behavior of the diagnostic data collection, including the amount of diagnostic information that the data collector stores, customize the `gdc_custom.properties` configuration file.

### About this task

You can find the `gdc_custom.properties` file in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/gdc` directory.

The following examples describe how to use the properties in the `gdc_custom.properties` configuration file to do the following things:

- [Setting limits for the size and number of detailed information files](#)
- [Setting full or partial collection of request and method diagnostic data](#)

You can also set other properties in the `gdc_custom.properties` file to customize collection of diagnostic data. Refer to the comments in the file that describe the properties.

**Remember:** After you complete editing the `gdc_custom.properties` file, you must restart the monitored application server instance for the changes to take effect.

### *Setting limits for the size and number of detailed information files*

#### About this task

The data collector stores diagnostic information in a number of files. By default, it stores 100 files; if 100 files are already stored and a new file is created, the oldest file is deleted. The data collector creates a new file every 15 minutes, or when the size of the current file exceeds 200 megabytes. When the total size of the directory that contains the files exceeds 2 gigabytes, the data collector deletes the oldest file.

## Procedure

You can change the following settings in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/gdc/gdc_custom.properties` file:

- To set the maximum number of files with diagnostic information, set the `com.ibm.itcam.gdc.dfe.filelimit` property.  
For example:

```
com.ibm.itcam.gdc.dfe.filelimit=100
```

- To set the time, in minutes, after which the data collector creates a new diagnostic data file, set the `com.ibm.itcam.gdc.dfe.frequency` property.  
For example:

```
com.ibm.itcam.gdc.dfe.frequency=15
```

- To set the maximum diagnostic data file size, in megabytes, set the `dfe.file.maxlimit` property.  
For example:

```
dfe.file.maxlimit=200
```

If the current diagnostic data file reaches this size, the data collector creates a new diagnostic data file.

- To set the maximum total size of all data files, in bytes, set the `trace.dir.size.limit` property.  
For example:

```
trace.dir.size.limit=2147483648
```

If the sum of the sizes of all the diagnostic data files exceeds this value, the data collector deletes the oldest data file. The minimum total size is 25 megabytes.

## ***Setting full or partial collection of request and method diagnostic data***

### **About this task**

The data collector has the following default settings:

- The data collector collects diagnostic data only for the selected requests. The selection (sampling) of the requests aims to include all errors and some good requests.
- Method data collection is disabled at server startup.
- When method data collection is enabled, the data collector gathers method data only for some requests (of those for which diagnostic data is collected). This further selection (sampling) again aims to include all errors and some good requests.

**Important:** Changing these settings affects performance of the application server. On production servers, the performance degradation might be critical.

### **Procedure**

You can change these settings by using properties in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/gdc/gdc_custom.properties` file.

- To enable method data collection, set the property as follows:

```
dfe.enable.methoddata=true
```

**Tip:** You can also use the **Agent Configuration** page to dynamically enable or disable the method trace data collection.

- To collect diagnostic data for every request, disable the sampling by setting the property as follows:

```
dc.sampling.enable=false
```

- To enable method data collection for every request for which diagnostic data is collected, set the property as follows:

```
dc.sampling.enable=false
dc.sampling.methsamplers.enabled=false
```

**Remember:** The `dc.sampling.methsamplers.enabled` property takes effect only when method data collection is enabled on the Agent Configuration page or by the `dfe.enable.methoddata` property.

## Customizing the request thresholds

Some of the requests might not have enough information if the default thresholds are high. You can customize the request thresholds so that more requests or request context data can be captured by the data collector.

### About this task

Each request type has two threshold types, which are named **perfThreshold** and **secondaryPerfThreshold**. A request is captured by the data collector only when it takes more time than what is specified for the **perfThreshold** threshold. Context data, such as stack trace and SQL statement, is captured only when the request takes more time than what is specified for the **secondaryPerfThreshold** threshold. You can adjust these threshold values to suit your needs.

### Procedure

1. Go to the `dc_home\gdc\etc` directory, where `dc_home` is the home directory of the data collector.
2. In a text editor, open the XML file for the request type that you want to customize. You can tell which file is for which request type from the XML file name.  
For example, the `ejb.xml` file is for EJB requests, the `custom.xml` file is for custom requests, and the `appMethods.xml` file is for class and methods when method trace is enabled.

3. Set the `<collectContextData>`, `<collectStackTrace>`, and `<createDataRow>` tags to `ifThresholdExceeded`.

```
<collectContextData>ifThresholdExceeded</collectContextData>
<collectStackTrace>ifThresholdExceeded</collectStackTrace>
<createDataRow>ifThresholdExceeded</createDataRow>
```

4. Set the `<perfThreshold>` and `<secondaryPerfThreshold>` tags to the threshold values that you desire. The unit of the threshold is millisecond.  
For example, the `ejb.xml` file has the following settings for EJB requests. As a result, only the EJB requests that take more than 1 second (1000 milliseconds) are captured by the data collector. Further, the EJB request-related context data, such as stack trace and EJB home, is captured only when the EJB request takes more than 1.5 seconds (1500 milliseconds).

```
<requestProbePoint id="EJB">
<interface>com.ibm.tivoli.itcam.toolkit.ai.boot.aspectmanager.ITurboEJBEventListener</interface>
<family>EJB</family>
<collectContextData>ifThresholdExceeded</collectContextData>
<collectStackTrace>ifThresholdExceeded</collectStackTrace>
<perfThreshold>1000</perfThreshold>
<secondaryPerfThreshold>1500</secondaryPerfThreshold>
<dataToCollect>instanceAndSummary</dataToCollect>
<createDataRow>ifThresholdExceeded</createDataRow>
<requestType>EJB Method</requestType>
</requestProbePoint>
```

5. Save your changes and restart the application server.

## Disabling various types of Byte Code Instrumentation for Java EE APIs

In Byte Code Instrumentation (BCI), the data collector intercepts method entry and exit calls for various types of Java Platform Enterprise Edition (Java EE) APIs to create an execution flow of each application request. Some resources are used for the monitoring. You can tune the data collector so that some of the APIs are not monitored, reducing resource use.

To disable BCI monitoring for Java EE APIs, add the following properties to the toolkit custom properties file. For more information about this file, see [“Toolkit properties file”](#) on page 980.

| <i>Table 259. Adding lines to the toolkit custom properties file</i> |  |
|--|--|
| <b>Type of Java EE API</b>   | <b>Line to add to toolkit_custom.properties file</b>                     |
| Enterprise JavaBeans (EJB)   | <code>com.ibm.tivoli.itcam.toolkit.ai.enableejb=false</code>             |
| Java Connector Architecture (JCA)                                    | <code>com.ibm.tivoli.itcam.toolkit.ai.enablejca=false</code>             |
| Java Database Connectivity (JDBC)                                    | <code>com.ibm.tivoli.itcam.toolkit.ai.enablejdbc=false</code>            |
| Java Naming and Directory Interface (JNDI)                           | <code>com.ibm.tivoli.itcam.toolkit.ai.enablejndi=false</code>            |
| Java Message Service (JMS)   | <code>com.ibm.tivoli.itcam.toolkit.ai.enablejms=false</code>             |
| Web containers for Servlets/JavaServer Pages (JSP)                   | <code>com.ibm.tivoli.itcam.dc.was.webcontainer=false</code>              |
| HTTP session count tracking  | <code>com.ibm.tivoli.itcam.toolkit.ai.enablesessioncount=false</code>    |
| CICS® Transaction Gateway (CTG)                                      | <code>com.ibm.tivoli.itcam.dc.ctg.enablectg=false</code>                 |
| IMS  | <code>com.ibm.tivoli.itcam.dc.mqi.enableims=false</code>                 |
| Java Data Objects (JDO)  | <code>com.ibm.tivoli.itcam.dc.mqi.enablejdo=false</code>                 |
| Message Queue Interface (MQI)  | <code>com.ibm.tivoli.itcam.dc.mqi.enablemqi=false</code>                 |
| Axis web service   | <code>com.ibm.tivoli.itcam.toolkit.ai.axis.enablewebservice=false</code> |
| Remote Method Invocation (RMI)                                       | <code>am.ejb.rmilistener.enable=false</code>                             |
| WebSphere Application Server EJB container                           | <code>com.ibm.tivoli.itcam.dc.was.enableEJBContainer=false</code>        |

## Disabling transaction tracking for a certain type of transactions

When transaction tracking is enabled for the data collector, all types of transactions are by default monitored. You can use the toolkit properties file to disable transaction tracking for specific types of transactions.

### About this task

Edit the `toolkit_custom.properties` file to customize transaction tracking for each application server or edit the `toolkit_global_custom.properties` file for all the application server instances.

The `toolkit_custom.properties` file is used in the following procedure for a single application server. The properties are also supported in the `toolkit_global_custom.properties` file. For more information about the toolkit properties files, see [Property files for Liberty data collector](#).

## Procedure

1. Open the `toolkit_custom.properties` file of the application server with a text editor. This file can be found in the following directory:

`dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom`

2. According to your needs, specify one or more of the following properties and set the property value to `false` to disable transaction tracking for a certain type of transactions.

### For CICS requests

`com.ibm.tivoli.itcam.dc.ttapi.cics.enabled=false`

### For custom requests

`com.ibm.tivoli.itcam.dc.ttapi.ims.enabled=false`

### For EJB requests

`com.ibm.tivoli.itcam.dc.ttapi.ejb.enabled=false`

### For HTTP Client calls

`com.ibm.tivoli.itcam.dc.ttapi.httpclient.enabled=false`

**Exception:** To disable transaction tracking for Apache HTTP Client calls, specify `com.ibm.tivoli.itcam.toolkit.dc.enable.apache.httpclient=false`.

### For IMS requests

`com.ibm.tivoli.itcam.dc.ttapi.ims.enabled=false`

### For JDBC requests

`com.ibm.tivoli.itcam.dc.ttapi.jdbc.enabled=false`

### For JMS requests

`com.ibm.tivoli.itcam.dc.ttapi.jms.enabled=false`

### For JNDI requests

`com.ibm.tivoli.itcam.dc.ttapi.jndi.enabled=false`

### For MQI requests

`com.ibm.tivoli.itcam.dc.ttapi.mqi.enabled=false`

### For Portal requests

`com.ibm.tivoli.itcam.dc.ttapi.portal=false`

### For RMI-IIOP requests

`com.ibm.tivoli.itcam.dc.ttapi.rmiiop.enabled=false`

### For Servlet requests

`com.ibm.tivoli.itcam.dc.ttapi.arm.servlet.enabled=false`

### For Web service requests

`com.ibm.tivoli.itcam.dc.ttapi.webservice.enabled=false`

**Tip:** For more information about these properties, refer to the `dc_home/ttdc/etc/ttdc.properties` file.

3. Save and close the `toolkit_custom.properties` file.
4. Restart the application server for the changes to take effect.

## Excluding classes from being monitored

You can customize data collection by excluding certain classes from being monitored. Use the toolkit properties file for this customization.

## About this task

Edit the `toolkit_custom.properties` file to customize transaction tracking for each application server or edit the `toolkit_global_custom.properties` file for all the application server instances.

The `toolkit_custom.properties` file is used in the following procedure for a single application server. The properties are also supported in the `toolkit_global_custom.properties` file. For more information about the toolkit properties files, see [Property files for Liberty data collector](#).

## Procedure

1. Open the `toolkit_custom.properties` file of the application server with a text editor. This file can be found in the following directory:

`dc_home/runtime/app_server_version.node_name.profile_name.server_name/custom`

2. Edit the file to add the following property and save your changes.

```
am.camtoolkit.gpe.customxml.exclude=excludes.xml
```

3. In the same custom directory, create the `excludes.xml` file with the following content and specify the class name to be excluded within the `<exclude>` tag. You can add as many classes as needed and the asterisk wildcard (\*) is supported.

```
<gpe>
  <bci>
    <classExcludes>
      <exclude>class_name_to_be_excluded</exclude>
      <exclude>class_name_to_be_excluded</exclude>
    </classExcludes>
  </bci>
</gpe>
```

Example:

```
<gpe>
  <bci>
    <classExcludes>
      <exclude>org.apache.struts.action.ActionServlet</exclude>
      <exclude>com.company.package.*</exclude>
    </classExcludes>
  </bci>
</gpe>
```

4. Restart the application server.

## What to do next

To verify that the class are excluded, look in the `toolkit.xml` file and the class name should be listed in the `<classExcludes>` section.

**Remember:** The `toolkit.xml` file contains runtime settings and it is refreshed every time the application server is restarted.

## Changing the host name used in MSN

The managed system name (MSN) is the instance name that you see on the Resources Dashboard. The host name used in MSN has a maximum limit of 19 characters. If the length exceeds 19 characters, the instance property value is truncated in the Resources Dashboard. Then you must change the host name.

## About this task

When the WebSphere Applications agent is started, it registers the following MSN for each agent instance:

`serveralias:hostname:KYNS`

Where:

- `serveralias` is the alias that you assign to the application server during data collector configuration.
- `hostname` is the name of the host where the agent is running.
- `KYNS` is the fixed string that identifies the WebSphere Applications agent.

**Important:**

- MSN has a maximum length limit of 32 characters.
- KYNS is fixed and cannot be changed.
- The maximum length of hostname is 19 characters. If the length exceeds 19 characters, the instance property value is truncated in the Resources Dashboard.
- The maximum length of *serveralias* equals 26 minus the length of *hostname*. If the length exceeds, the instance property value is truncated in the Resources Dashboard.
- Any truncation of the MSN attributes causes the incorrect display of resources names and property values.

If the length of *hostname* or *serveralias* exceeds, the specified string is truncated.

To avoid the truncation issue, you can follow the steps to change the *hostname* value.

**Procedure**

1. Stop the WebSphere Applications agent.
2. Open the following agent environment file with a text editor. If the file does not exist, create it by yourself.
  - Linux: *agent\_install\_dir/config/yn.environment*
  - Windows: *agent\_install\_dir/Config/KYNNENV*
3. Add the following variable to set the new host name in the agent environment file, where *newhostname* is the new host name with a maximum length of 19 characters.

```
CTIRA_HOSTNAME=newhostname
```

4. Back up the following xml file in the *agent\_install\_dir/config/* directory and then remove the original one:

```
hostname_yn_wasversion.cellname.nodename.profilename.servername.xml
```

For example,

```
/opt/ibm/apm/agent/config/tivvm123_yn_was85.tivvm123Node01Cell.  
tivvm123Node01.AppSrv01.server1.xml
```

**Remember:**

If you configured multiple data collector instances for the WebSphere Applications agent, there will be multiple xml files. Each application server has its own xml file. You must remove all the xml files.

5. Open the *agent\_install\_dir/config/hostname\_yn.xml* file and make the following changes:
  - In the `<!DOCTYPE AgentConfig[]>` section, remove the following entry:

```
<!ENTITY wasversion.cellname.nodename.profilename.  
servername SYSTEM "hostname_yn_was_version.cellname.  
nodename.profilename.servername.xml">
```

For example, remove:

```
<!ENTITY was85.tivvm123Node01Cell.tivvm123Node01.AppSrv01.  
server1 SYSTEM "tivvm123_yn_was85.  
<tivvm123Node01Cell.tivvm123Node01.AppSrv01.server1.xml">
```

- Between the `</defaultServerSettings>` and `</AgentConfig>` tags, remove the `"&was_version.cellname.nodename.profilename.servername"` line.

For example, remove `&was85.tivvm123Node01Cell.tivvm123Node01.AppSrv01.server1;`.

6. Start the WebSphere Applications agent. An error might occur, saying that data is not sent due to the missing xml file. You can ignore this error and try starting the agent again.

7. Stop the WebSphere Applications agent. The previously removed xml file in Step 4 is created again.
8. Go to the *agent\_install\_dir/logs* directory and verify that the new host name is applied to the data collector instance in the log files.

For example, on a Linux system, you can issue `grep <newhostname>:KYNS ' *asf*` to check whether there is any result returned.

9. Start the WebSphere Applications agent again. The agent instance will work under the new MSN.

## Example

A real example of modifying the *hostname\_yn.xml* file, for example, *tivvm123\_yn.xml* in Step 5.

Original content:

```
<!DOCTYPE AgentConfig [
  <!ENTITY was85.tivvm123Node01Cell.tivvm123Node01.AppSrv01.server1 SYSTEM
    "tivvm123_yn_was85.tivvm123Node01Cell.tivvm123Node01.AppSrv01.server1.xml">

    </applicationMonitoringSettings>
</defaultServerSettings>
</AgentConfig>

```

## Customizing request information mapping

In some cases, you might have to change the information that identifies the requests monitored by the agent. This information includes the request name, and any data that can be displayed for the request (for example, the query text for an SQL request). To change the information, set up a custom request mapper configuration.

### About this task

To customize request information mapping, you must define a custom request mapper configuration in an XML file.

In this file, some built-in *symbols* represent values from the runtime context of the request. You can create extra symbols, which calculate new values. The calculation can include original request values, expressions, calls to Java methods (including methods in the monitored application), conditionals, and iteration over a set of values.

Then, you can *map* the contents of the symbols into the new request data that is provided to Cloud APM server. If a particular variable in the request data is not mapped, the original value is retained.

Because different data is collected for request types, a custom request mapper configuration must be specific for a request type. You can configure different request mappers for different request types on the same data collector.

### Procedure

To set a custom request mapper configuration for a request type, complete the following steps:

1. Define a custom request mapper configuration in an XML file.  
For information about the XML syntax, see [“XML file syntax” on page 992](#).
2. Place the XML file in the `dc_home/runtime/custom` directory to use it for all application server instances, or in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom` directory to use it for one application server instance.
3. Enable custom request mapping for this type in the toolkit custom configuration file, `toolkit_custom.properties`, or `toolkit_global_custom.properties`.  
For instructions, see [“Enabling a request mapper” on page 1002](#).
4. Reference the XML file that you defined from the same toolkit custom configuration file.  
For instructions, see [“Enabling a request mapper” on page 1002](#).

### XML file syntax

The XML file that you create for request mapper configuration must be valid XML and must remain available when the configuration is in use. Place the XML file in the `dc_home/runtime/custom` directory to use it for all application server instances, or in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom` directory to use it for one application server instance.

### Top level

The top-level tag is `<gpe>`. Within this tag, use the `<runtimeConfiguration>` tag. These tags have no attributes.

Within the `<runtimeConfiguration>` tag, create a `<requestMapperDefinition>` tag. This tag must have a `type` attribute. Set it to the request mapper type name for the required request type. For more information, see [Table 261 on page 1004](#).

Within the `<requestMapperDefinition>` tag, the following two tags must be present:

#### **<symbolDefinitions>**

Contains all definitions of symbols. Symbols represent values that the agent calculates every time a request of this type is detected.

#### **<selection>**

Contains the mapping of context keys to values. The keys represent the custom data that is passed to the agent. They are predefined for each request type. The mapping can be conditional.

For more information about request mapper enabling properties and type names, see [Table 261 on page 1004](#).

Also, within the `<runtimeConfiguration>` tag, you can create a `<requestMapperClassPath>` tag. Within this tag, you can define JAR files. You can reference Java classes in these JAR files within Request Mapper definitions.

#### *Defining an expression*

To define symbols, you must use expressions. The agent evaluates the expressions to assign values to symbols.

### **Using data in an expression**

An expression can use the following data:

- The input data symbols for the request type
- Other symbols described in the same request mapper definition
- Numeric constants
- String constants (delimited with `"`, for example, `"string"`)
- Boolean constants (`true`, `TRUE`, `false`, `FALSE`)
- The null constant

For more information about input data symbols, see [Table 262 on page 1005](#).

If the value of a symbol is an instantiation of a Java class, expressions can contain references to fields and methods that are defined within the class. To refer to a field, use `symbol.fieldname`. To refer to a method, use `symbol.methodname(parameters)`. The method call must return a value. For example, you can use the Java String methods with a symbol that has a String value.

To refer to a static field or method of a class, you can also use `classname.fieldname` and `classname.methodname(parameters)`.

If a symbol refers to an array object, the expression can select an element (`symbol[selector]`) and determine the length of the array (`symbol.length`)

### **Operators**

You can use the following operators in an expression:

- Boolean operators: AND, &, OR, |, NOT, !
- Comparison: ==, !=, GT, >, LT, <, GE, >=, LE, <=
- Numeric operators: +, -, \*, /
- Parentheses to force order of evaluation: (, )

**Important:** You must escape the symbols `<`, `>`, and `&` in XML. Alternatively, you can use the GT (greater than), GE (greater than or equal), LT (less than), LE (less than or equal), and AND operators.

The expression can evaluate whether a value is an instance of a class, by using the `instanceof` operator:

```
expression instanceof java.class.name
```

This operator, similar to the Java `instanceof` operator, produces a Boolean value. In this example, the value is true if the class to which the *expression* value belongs meets any of the following conditions:

- Is named *java.class.name*
- Is a direct or indirect subclass of the class identified by *java.class.name*.
- Implements, directly or indirectly, the interface identified by *java.class.name*.

The expression can also instantiate a new object of a Java class, by using the `new` operator. This operator is similar to the Java `new` operator:

```
new java.class.name(expression1, expression2, ... expressionN)
```

## Operator precedence

Operators are evaluated in order of precedence. Operators of the same order of precedence are evaluated from left to right. You can change the order of evaluation by using parentheses ( and ).

The order of precedence is as follows:

1. . operator (method call or field reference)
2. [ ] (array element selector)
3. new
4. !, NOT
5. \*, /
6. +, -
7. GT, >, LT, <, GE, >=, LE, <=, instanceof
8. ==, !=
9. AND, &
10. OR, |

## Example

```
$s1 >= ( 2 * ($s2.sampMethod($s3, true) + 1))
```

The agent evaluates this expression in the following way:

1. The `$s1` symbol is evaluated. It must yield a numeric value.
2. The `$s2` symbol is evaluated. It must yield a Java object.
3. The `$s3` symbol is evaluated.
4. The `sampMethod` method for the object that results from the evaluation of `$s2` is called. The result of the evaluation of `$s3` is passed as the first parameter, and the Boolean value `true` is passed as the second parameter. The call to `sampMethod` must return a numeric value.
5. 1 is added to the result of step “4” on page 994.
6. The result of step “5” on page 994 is multiplied by 2.
7. The result of step “1” on page 994 is compared with the result of step “6” on page 994. If the result of step “1” on page 994 is greater than or equal to the result of step “6” on page 994, `true` is returned. Otherwise, `false` is returned.

### Defining basic symbols

To define symbols, you must use expressions. The agent evaluates the expressions to assign values to symbols.

Within the `<symbol>` tag, use the following tags:

#### **<name>**

The name of the symbol. It is a string and must start with the `$` character.

#### **<eval>**

The expression that the agent must evaluate to produce the value for this symbol. For more information about defining expressions, see [“Defining an expression” on page 993](#).

#### **<type>**

The type of the value that the symbol returns. Specify this value as a fully qualified Java class name, or a Java primitive. Specifying the type for the symbol is optional. If it is not defined, the request mapper attempts to establish the field type based on the expression. If the request mapper is unable to determine the symbol type before it evaluates the expression, performance is affected. Therefore, for best performance, it is better to specify the type.

#### **<args>**

The arguments for the symbol. This tag is optional; if it is specified, arguments must be supplied for evaluating the symbol. For more information, see [“Defining symbol arguments” on page 995](#).

### Example

```
<symbol>
  <name>$doubles1</name>
  <eval>$s1*2</eval>
  <type>int</type>
</symbol>
```

This symbol returns double the value of another symbol, `$s1`.

### Defining symbol arguments

Within the `<args>` tag of a symbol definition, you can define argument types for the symbol.

In this tag, use the `<type>` tag to specify the types of arguments. Specify this value as a fully qualified Java class name, or a Java primitive. You can specify any number of `<type>` tags; each of these tags defines an argument.

In this case, the symbol must be referenced with arguments in parentheses:

```
$symbol(argument1,argument2...)
```

The number of arguments must be the same as the number of argument type definitions.

Within the symbol definition, refer to the first argument as `$p0`, the second argument as `$p1`, and so on.

A symbol with arguments works like a Java method. It takes input arguments, and returns a value that depends on the values of the arguments.

### Example

```
<symbol>
  <name>$double</name>
  <eval>$p0*2</eval>
  <type>int</type>
  <args>
    <type>int</type>
  </args>
</symbol>
```

This symbol returns double the value of the argument. To evaluate it, supply a numeric argument: `$double(2)`, `$double($s1)`.

### Defining iteration symbols

Within the `<symbolDefinitions>` tag, you can define an iteration symbol by using the `<iterationSymbol>` tag. An iteration symbol represents a value that is acquired by iterating through a set of objects in a Java array, enumeration, or collection. For each of the members, the request mapper evaluates one or more condition expressions. If an expression returns `true`, request mapper uses the member to calculate the return value. When a member meets the condition expression, the request mapper does not evaluate the rest of the members.

Within the `<iterationSymbol>` tag, use the following tags.

#### **`<name>`**

The name of the symbol. It is a string and must start with the `$` character.

#### **`<type>`**

The type of the value that the symbol returns. Specify this value as a fully qualified Java class name or a Java primitive. Specifying the type for the symbol is optional. If it is not defined, the request mapper attempts to establish the field type based on the expression. If the request mapper is unable to determine the symbol type before it evaluates the expression, performance is affected. Therefore, for best performance, it is better to specify the type.

#### **`<args>`**

The arguments for the symbol. This tag is optional; if it is specified, arguments must be supplied for evaluating the symbol. For more information, see [“Defining symbol arguments” on page 995](#).

#### **`<iterate over="expression">`**

Defines the object (array, Enumeration, or Collection) that contains the members to iterate through. The expression must return such an object. request mapper iterates over its members until either one of them causes a condition expression to return `true`, or no more members remain. Define the set of iteration expressions in tags within this tag:

##### **`<test>`**

Define the condition and return expression within this tag. An `<iterate>` tag can contain several `<test>` tags. In this case, request mapper evaluates all of them. If any condition expression is true, the symbol returns a value using the result expression in the same `<test>` tag, and no further evaluation is performed.

##### **`<castTo>`**

Optional: If this tag is present, specify the name of a Java type within it, as a fully qualified Java class name or a Java primitive. The request mapper casts the iterated element to this type before it evaluates the condition and return expressions. If this tag is not present, request mapper casts a member of an array to the array base type, and a member of an Enumeration or Collection to `java.lang.Object`. For an array member, the array base type is usually the correct choice; therefore, use this tag for request mapper to iterate over an enumeration or collection.

##### **`<condition>`**

An expression that must yield a Boolean value. Use `$iterElement` to refer to the element that is being iterated.

##### **`<return>`**

If the expression in the `<condition>` tag returns `true`, request mapper evaluates the expression in the `<return>` tag. The iteration symbol returns the value that this expression produces. Use `$iterElement` to refer to the element that is being iterated.

#### **`<defaultValue>`**

Optional. If the request mapper has iterated over all members of the object, but no condition expression has returned `true`, the request mapper evaluates the expression in the `<defaultValue>` tag. The iteration symbol returns the value that the expression produces. If this tag is not present, the default value is `null`.

### Examples

```
<iterationSymbol>
  <name>$userNameCookieValue</name>
```

```

<iterate over="$HttpServletRequest.getCookies()">
  <test>
    <condition>$iterElement.getName().equals("userName")</condition>
    <return>$iterElement.getValue()</return>
  </test>
</iterate>
</iterationSymbol>

```

This symbol finds the cookie named "username", and returns its value.

`HttpServletRequest.getCookies()` returns an array, so there is no need for the `<castTo>` element.

```

<iterationSymbol>
  <name>$headerNameStartingWithA</name>
  <iterate over="$HttpServletRequest.getHeaderNames()">
    <test>
      <castTo>java.lang.String</castTo>
      <condition>$iterElement.startsWith("A")</condition>
      <return>$iterElement</return>
    </test>
  </iterate>
</iterationSymbol>

```

This symbol finds the header with a name starting with "A", and returns its name.

`HttpServletRequest.getHeaderNames()` returns an Enumeration, so the `<castTo>` element is required.

```

<iterationSymbol>
  <name>$determined_gender</name>
  <iterate over="$children">
    <test>
      <castTo>java.lang.String</castTo>
      <condition>$iterElement.equals("male")</condition>
      <return>"It's a boy"</return>
    </test>
    <test>
      <castTo>java.lang.String</castTo>
      <condition>$iterElement.equals("female")</condition>
      <return>"It's a girl"</return>
    </test>
  </iterate>
  <defaultValue>"unknown"</defaultValue>
</iterationSymbol>

```

This symbol iterates over `$children`, which must be an array, Enumeration, or Collection of strings. If any of the strings equals "male", it returns "it's a boy". If any of the strings equals "female", it returns "it's a girl". Finally, if no string in the `$children` object equals either "male" or "female", the symbol returns "unknown".

### Defining conditional symbols

Within the `<symbolDefinitions>` tag, you can define a conditional symbol by using the `<conditionalSymbol>` tag. A conditional symbol represents a value that is acquired by evaluation a series of condition expressions. If any expression returns `true`, request mapper uses the member to calculate the return value. When a member meets the condition expression, request mapper evaluates a corresponding return expression, and return the result. After the request mapper finds a result to return, it does not evaluate any further expressions.

Within the `<conditionalSymbol>` tag, use the following tags.

#### **<name>**

The name of the symbol. It is a string and must start with the `$` character.

#### **<type>**

The type of the value that the symbol returns. Specify this value as a fully qualified Java class name, or a Java primitive. Specifying the type for the symbol is optional. If it is not defined, the request mapper attempts to establish the field type based on the expression. If the request mapper is unable to determine the symbol type before it evaluates the expression, performance is affected. Therefore, for best performance, it is better to specify the type.

### <args>

The arguments for the symbol. This tag is optional; if it is specified, arguments must be supplied for evaluating the symbol. For more information, see [“Defining symbol arguments”](#) on page 995.

### <if condition="expression">

The condition attribute defines a condition expression to evaluate. The expression must yield a Boolean value. If the value is true, request mapper uses the contents of the <if> tag to try to determine the return value. The <if> tag must contain either, but not both, of the following contents:

- A <return> tag. This tag contains an expression. If the condition expression is true, request mapper evaluates the expression and returns the result.
- Any number of <if> tags, nested within this <if> tag. If the condition expression is true, request mapper processes the nested <if> tags in the same way as a top-level <if> tag. That is, it evaluates the expression in the condition attribute, and if the expression is true, uses the contents of the tag to try and determine the return value.

**Important:** If a return value is determined, request mapper does not evaluate any further expressions. However, if a condition expression in an <if> tag is true, but it contains nested <if> tags and none of their condition expressions are true, no value is determined. In this case, request mapper continues to evaluate subsequent expressions.

### <defaultValue>

Optional. If request mapper has evaluated all condition expressions, but none of the condition expression has returned true, request mapper evaluates the expression in the <defaultValue> tag. The conditional symbol returns the value that the expression produces. If this tag is not present, the default value is null.

### Example

```
<symbol>
  <name>$GET</name>
  <eval>"GET"</eval>
</symbol>
<symbol>
  <name>$PUT</name>
  <eval>"PUT"</eval>
</symbol>
<conditionalSymbol>
  <name>$sessionAttribute</name>
  <if condition="$HttpServletRequest.getSession(false) != null">
    <if condition="$HttpServletRequest.getSession(false).getAttribute($GET)
    != null">
      <return>$HttpServletRequest.getSession(false).getAttribute($GET)</return>
    </if>
    <if condition="true">
      <return>$HttpServletRequest.getSession(false).getAttribute($PUT)</return>
    </if>
  </if>
</conditionalSymbol>
```

This symbol is assumed to be a part of the servlet request mapper. First, it checks whether an HTTP session exists for the servlet; if not, the symbol returns null. If a session is present, the symbol checks whether the servlet has a GET attribute, it returns the value of that attribute. Otherwise, it returns the value of the PUT attribute. The second condition expression is true; this value is used as an else clause. If the first condition is true, the request mapper does not evaluate any further expressions; otherwise, it continues to the second expression.

### Defining external class symbols

Within the <symbolDefinitions> tag, you can define an external class by using the <externalClassSymbol> tag. An external class symbol represents an external Java class. External class symbol definition is optional; you can use external Java classes in expressions directly. However, it might enhance the readability of the request mapper configuration.

Within the <externalClassSymbol> tag, use the following tags.

**<name>**

The name of the symbol. It is a string and must start with the \$ character.

**<className>**

The name of the customer defined class.

**Important:** To refer to any Java class in request mapper configuration, whether in an external class symbol definition or in any expression, you must add the full path and name of the JAR file that contains the class to the `<requestMapperClassPath>` tag within the `<runtimeConfiguration>` tag.

After defining an external symbol, you can refer to the class by the name of the symbol. You can also refer to static methods and fields of the class by using the symbol.

**Example**

```
<externalClassSymbol>
  <name>$rand</name>
  <className>user.class.Random</className>
</externalClassSymbol>
```

This symbol refers to a user-written class, generating a random number. The full path and name of the JAR file that contains this class must be present in the `<requestMapperClassPath>` tag within the `<runtimeConfiguration>` tag.

To refer to the static method `user.class.Random.generate()` in an expression, you can use the external symbol:

```
$rand.generate()
```

*Mapping values to context keys*

Within the `<requestMapperDefinition>` tag, map values to context keys by using the `<selection>` tag. This mapping provides the changes in the monitoring information.

You can map values to the output keys defined for the request type. For more information, see [Table 261 on page 1004](#).

If no value is mapped to a key after the evaluation of the request mapper configuration, ITCAM uses the original value extracted from the request.

Within the `<selection>` tag, use the following tags.

**<matchCriteria>**

An expression that must return a Boolean value. The mapping that is defined within this tag is only used if this expression returns `true`.

**<mapTo>**

Defines a key and the value to map to it. Within this tag, a `<key>` tag contains the key, and a `<value>` tag contains the value.

**<selection>**

You can nest `<selection>` tags, placing one within another.

If `<selection>` tags are nested, then the nested mapping is only used if both the outer and the nested `<matchCriteria>` expressions return `true`.

You can use multiple `<selection>` tags within a `<requestMapperDefinition>` tag or within another `<selection>` tag. If the same key is mapped several times in several `<selection>` tags on the same nesting level (that is, within the same parent tag), then the first mapping for which the `<matchCriteria>` expression returned `true` is used.

Do not map the same key both in the outer and nested `<selection>` tags.

Typically, use the `<matchCriteria>` value of `true` as an "else" value for the last selection tag on a nesting level. If you want to map different values in different cases, use several `<selection>` tags within this outer tag; each of them can contain the criteria and values for a particular case. The last tag, with a value of `true`, covers the case when the available data meets none of the criteria.

## Examples

```
<selection>
  <matchCriteria>true</matchCriteria>
  <mapTo>
    <key>Result</key>
    <value>$s1</value>
  </mapTo>
</selection>
```

In this mapping configuration, Result is set to the value of the symbol \$s1.

```
<matchCriteria>true</matchCriteria>
  <selection>
    <matchCriteria>$b1</matchCriteria>
    <mapTo>
      <key>Result</key>
      <value>1</value>
    </mapTo>
  </selection>
  <selection>
    <matchCriteria>true</matchCriteria>
    <mapTo>
      <key>Result</key>
      <value>2</value>
    </mapTo>
  </selection>
```

In this mapping configuration, the symbol \$b1 must return a Boolean value. Result is set to 1 if \$b1 returns true, and to 2 if \$b1 returns false. If \$b1 returns true, request mapper uses the mapping for Result in the first <selection> tag; the mapping for the same key in the second tag is not used.

## Defining custom requests

By default, only certain types of Java classes and methods are monitored as requests by the data collector. Servlets, JSPs, EJB business methods, and certain standard Java EE APIs are recognized as requests. You can designate extra classes and methods as *custom requests*.

## About this task

To enable monitoring of custom requests by the data collector, define the custom requests in an XML file and set the `am.camtoolkit.gpe.customxml.custom` property in the toolkit custom properties file.

For example, the data collector does not recognize Struts Action classes as requests by default. However, you can set up custom request definitions and cause the actions to be recognized as Nested Requests.

## Procedure

Complete the following procedure to enable monitoring of custom requests and designate one or more methods as custom requests:

1. Make a copy of the `dc_home/itcamdc/etc/custom_requests.xml` file in a temporary location. Then, open the copy in a text editor.
2. Modify the parameters in the file.

The following table describes the parameters that you can modify:

| Table 260. Parameters for the custom requests configuration file |  |
|--|--|
| Tag name   | Description  |
| edgeRequest  | Identifies one or more application methods that are to be Byte-Code-Instrumented for custom request processing. By modifying the <code>requestName</code> , <code>Matches</code> , <code>type</code> , and <code>methodName</code> tags within the <code>edgeRequest</code> tag, you can customize the selection.<br><br>Each <code>edgeRequest</code> tag must contain exactly one <code>methodName</code> tag, and one or more <code>Matches</code> tags. Multiple <code>edgeRequest</code> tags can be specified. |

Table 260. Parameters for the custom requests configuration file (continued)

| Tag name      | Description  |
|---------------|--|
| requestName   | Defines a unique name for this request. The request name is displayed to the user when the method entry and exit are traced.   |
| Matches       | Identifies a class or classes that contain the methods that are to be Byte-Code-Instrumented for custom request processing. Multiple Matches tags can be present within a single edgeRequest tag.  |
| type          | Indicates whether a class must be a system or application class to match the edgeRequest tag.  |
| methodName    | Identifies the names of the methods within one of the classes identified by the Matches tag that are to be Byte-Code-Instrumented for custom request processing. Exactly one methodName tag can be specified in each edgeRequest tag.  |
| requestMapper | Optional. If this tag is specified, the data collector uses a request mapper to determine information that identifies the request. You can define nonstandard ways of extracting this information. For more information about enabling and defining request mappers, see <a href="#">“Customizing request information mapping” on page 992</a> . |

**Remember:** The Matches and methodName tags can include wildcard characters. How the wildcard characters works is described as follows:

- Asterisk (\*) stands for zero or more occurrences of any character when used by itself. When embedded within a sequence of characters (for example, java.\*.String), it matches zero or more occurrences of any character except the package separator (.).
- Two periods (..) can be used to specify all sub-packages. It matches any sequence of characters that starts and ends with the package separator (.). For example, java..String matches java.lang.String and com.ibm..\* matches any declaration beginning with com.ibm.

For example, an application with a package name of com.mycompany.myapp has the following requirements:

- Within the Customer class, the creditCheck() method must be treated as a custom request called CreditCheck.
- Within the Supplier class, the inventoryCheck() method must be treated as a custom request called SupplyCheck.

The contents of the customized custom\_requests.xml file that accomplishes the requirements are as follows:

```
<customEdgeRequests>
  <edgeRequest>
    <requestName>CreditCheck</requestName>
    <Matches>com.mycompany.myapp.Customer</Matches>
    <type>application</type>
    <methodName>creditCheck</methodName>
  </edgeRequest>
  <edgeRequest>
    <requestName>SupplyCheck</requestName>
    <Matches>com.mycompany.myapp.Supplier</Matches>
    <type>application</type>
    <methodName>inventoryCheck</methodName>
  </edgeRequest>
</customEdgeRequests>
```

3. Complete one of the following steps:

- Save the file in the dc\_home/runtime/app\_server\_version.node\_name.profile\_name.server\_name/custom directory. Then, in the toolkit custom properties file, set the property am.camtoolkit.gpe.customxml.custom to the name (without path) of the file that you modified in Step “2” on page 1000.

- Save the file in any directory on your computer. Then, in the toolkit custom properties file, set the property `am.camtoolkit.gpe.customxml.custom` to the path and name for the file that you modified in Step “2” on page 1000.

For more information about the toolkit custom properties file, see [“Toolkit properties file” on page 980](#).

## Enabling a request mapper

To enable a request mapper for a request type, edit the toolkit custom configuration file or the toolkit global custom configuration file. Procedures are different for common request types and for custom requests.

## Before you begin

Define the request mapper configuration in an XML file. Then, place the XML file that contains request mapper configuration in the same directory as the toolkit properties file.

- To enable the request mapper for all application server instances, place it in the `dc_home/runtime/custom` directory.
- To enable the request mapper for one application server instance, place it in the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/` directory.

For information about the XML file syntax, see [“XML file syntax” on page 992](#).

## About this task

Edit the `toolkit_custom.properties` file or the `toolkit_global_custom.properties` file to enable the request mapper for one or all application server instances.

## Procedure

- To enable a request mapper for common requests, complete the following steps:
  - a) In a text editor, open one of the following toolkit custom configuration files:
    - To enable the request mapper for all application server instances, open the `dc_home/runtime/custom/toolkit_global_custom.properties` file.
    - To enable the request mapper for one application server instance, open the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/toolkit_custom.properties` file.
  - b) Edit the toolkit properties file as follows:
    - Add a line setting the enabling property for this request type to `true`. For more information, see [Table 261 on page 1004](#).
    - Add a line setting the `am.camtoolkit.gpe.customxml.*` property to the name of the mapper XML file. Use any unique value instead of the `*` symbol. For more information, see [“XML file syntax” on page 992](#).
  - c) Save and close the properties file.

## Example:

To enable a request mapper that is defined in `renameDataSource.xml` for the SQL request type, add the following lines to the toolkit custom configuration file or the toolkit global custom configuration file:

```
com.ibm.tivoli.itcam.toolkit.ai.enable.sqlrequestmapper=true
am.camtoolkit.gpe.customxml.renameDataSource=renameDataSource.xml
```

- To enable a request mapper for custom requests, complete the following steps:
  - a) Under the `<edgerequest>` tag in the custom request definition XML file, create a `<requestMapper>` tag. Place a unique request map type name in this tag. For information about defining custom requests, see [“Defining custom requests” on page 1000](#).

- b) In the request mapper XML file, use the unique request map type name in the type attribute of the `<requestMapperDefinition>` tag.
- c) In a text editor, open one of the following toolkit custom configuration files:
  - To enable the request mapper for all application server instances, open the `dc_home/runtime/custom/toolkit_global_custom.properties` file.
  - To enable the request mapper for one application server instance, open the `dc_home/runtime/appserver_version.node_name.profile_name.server_name/custom/toolkit_custom.properties` file.
- d) Edit the toolkit properties file to add a line setting the `am.camtoolkit.gpe.customxml.*` property to the name of the mapper XML file. Use any unique value instead of the `*` symbol. For more information, see [“XML file syntax”](#) on page 992.
- e) Save and close the properties file.

### Example:

To enable a request mapper that is defined in `customMapper.xml` for the SupplyCheck custom request type that is defined in the `custom_requests.xml` file, complete the following steps:

1. Use the following definition in the `custom_requests.xml` file:

```
<customEdgeRequests>
  <edgeRequest>
    <requestName>SupplyCheck</requestName>
    <Matches>com.mycompany.myapp.Supplier</Matches>
    <type>application</type>
    <methodName>inventoryCheck</methodName>
    <requestMapper>customMapper</requestMapper>
  </edgeRequest>
</customEdgeRequests>
```

2. In the `customMapper.xml` file, make sure that the type name is set:

```
<requestMapperDefinition type="customMapper">
```

3. Add the following line to the toolkit custom configuration file or the toolkit global custom configuration file:

```
am.camtoolkit.gpe.customxml.customMapper=customMapper.xml
```

## ***Request mapper type names, input, and output data***

The following tables list the information necessary to configure and enable request mappers for different request types.

The meaning of each table header is explained as follows:

### **Request type**

The request type.

### **Enabling property**

To enable the request mapper, set this property to true in the `toolkit_custom.properties` or `toolkit_global_custom.properties` file.

**Important:** If you copy this value from the table, remove any spaces and line breaks.

### **Request mapper type name**

Assign this value to the type attribute of the `<requestMapperDefinition>` tag in the request mapper definition XML file.

### **Input data symbol names**

The symbols that represent the request information. You can use these symbols in expressions within the request mapper definitions. For more information, see [“Defining an expression”](#) on page 993.

### Output data context keys

To provide changes in the monitoring information, assign values to these keys in the request mapper definition. For more information, see [“Mapping values to context keys”](#) on page 999.

| Table 261. Request mapper enabling properties and type names                            |   |   |
|---|---|---|
| Request type  | Enabling property   | Request mapper type name                      |
| Servlet   | com.ibm.tivoli.itcam.toolkit.ai.enable.servletrequestmapper           | servlet                                       |
| JNDI  | com.ibm.tivoli.itcam.toolkit.ai.enable.jndirequestmapper              | jndiLookup                                    |
| Custom Request  |   | Defined by user in the edgeRequest definition |
| EJB   | com.ibm.tivoli.itcam.toolkit.ai.enable.ejbrequestmapper               | ejb   |
| JCA   | com.ibm.tivoli.itcam.toolkit.ai.enable.jcarequestmapper               | jca   |
| JDBC data source  | com.ibm.tivoli.itcam.toolkit.ai.enable.datasourcerequestmapper        | dataSource                                    |
| JDBC SQL statement  | com.ibm.tivoli.itcam.toolkit.ai.enable.sqlrequestmapper               | sqlStatement                                  |
| JMS   | com.ibm.tivoli.itcam.toolkit.ai.enable.jmsrequestmapper               | jms   |
| JAX-RPC web service   | com.ibm.tivoli.itcam.toolkit.ai.enable.webservicesrequestmapper       | webServices                                   |
| Axis web service  | com.ibm.tivoli.itcam.toolkit.ai.enable.webservicesrequestmapper       | webServices                                   |
| MQI   | com.ibm.tivoli.itcam.toolkit.ai.enable.mqrequestmapper                | mqi   |
| EJB   | com.ibm.tivoli.itcam.toolkit.ai.enable.ejbrequestmapper               | ejb   |
| JDBC connection factory   | com.ibm.tivoli.itcam.toolkit.ai.enable.sqlconnectfactoryrequestmapper | connectionFactory                             |
| SCA   | com.ibm.tivoli.itcam.toolkit.ai.enable.scarequestmapper               | sca   |
| JAX-WS web service  | com.ibm.tivoli.itcam.toolkit.ai.enable.webservicesrequestmapper       | webServices                                   |
| WebSphere Portal Server Portal (extending the org.apache.jsp.eed.portlet.Portlet class) | com.ibm.tivoli.itcam.toolkit.ai.enable.portalrequestmapper            | portalPortal                                  |

| Table 261. Request mapper enabling properties and type names (continued)                                |   |                          |
|---|---|--------------------------|
| Request type  | Enabling property   | Request mapper type name |
| WebSphere Portal Server version 6.1, 7, and 8 Portal (implementing the javax.portlet.Portlet interface) | com.ibm.tivoli.itcam.toolkit.ai.enable.portal6requestmapper | Portal6Portal            |

**Important:** There is no meaningful way to configure the custom request mapper for the request types that are not listed in [Table 261 on page 1004](#).

| Table 262. Request mapper input and output data |   |  |
|---|---|--|
| Request type                                    | Input data symbol names   | Output data context keys   |

For servlet requests, a larger number of input data symbols is provided.

Table 263. Input data symbol names for servlet requests

| Symbol Name           | Value Type                             | Symbol Contents  |
|-----------------------|--|--|
| \$context             | String                                 | "ServletMethod"  |
| \$servlet             | javax.servlet.http.HttpServlet         | The HttpServlet object associated with the servlet request         |
| \$HttpServletRequest  | javax.servlet.http.HttpServletRequest  | The HttpServletRequest object associated with the servlet request  |
| \$HttpServletResponse | javax.servlet.http.HttpServletResponse | The HttpServletResponse object associated with the servlet request |
| \$appName             | java.lang.String                       | The application name associated with the servlet                   |

| Table 263. Input data symbol names for servlet requests (continued) |                                |   |
|---|--------------------------------|---|
| Symbol Name   | Value Type                     | Symbol Contents   |
| \$URL   | java.lang.StringBuffer         | The URL that the client used to make the request  |
| \$RemoteUser  | java.lang.String               | The login name of the user making this request, if authenticated  |
| \$URI   | java.lang.String               | The part of the request URL from the protocol name up to the query string   |
| \$ServletPath   | java.lang.String               | The part of the request URL that calls the servlet.   |
| \$SessionID   | javax.servlet.http.HttpSession | The current session associated with this request  |
| \$QueryString   | java.lang.String               | The query string that is contained in the request URL after the path.   |
| \$SessionAttribute  | java.lang.String               | <p>This parameterized symbol returns a session attribute value. It has one parameter, the attribute name (must be a string).</p> <p>For example, <code>\$SessionAttribute("attr1")</code> returns the value of the attribute named attr1.</p> |
| \$cookie  | javax.servlet.http.Cookie      | <p>This parameterized symbol returns a named cookie. It has one parameter, the cookie name (must be a string).</p> <p>For example, <code>\$cookie("cookie1")</code> returns the value of the attribute named cookie1.</p>                     |

### Example request mapper definitions

The following examples illustrate usage of the request mapper functionality.

#### Changing the servlet application name

In this example, the application name in a servlet request is replaced by the URI and the query string.

The `dc_home/runtime/changeAppname.xml` file contains the following request mapper definition:

```
<gpe>
  <runtimeConfiguration>
    <requestMapperDefinition type="servlet">
      <selection>
        <matchCriteria>true</matchCriteria>
        <mapTo>
          <key>appName</key>
          <value>$URI + "." + $QueryString</value>
        </mapTo>
      </selection>
    </requestMapperDefinition>
  </runtimeConfiguration>
</gpe>
```

### Renaming a data source

In this example, the data source name in an SQL request is changed to a version that a user can understand more easily.

The `dc_home/runtime/renameDataSource.xml` file contains the following request mapper definition:

```
<gpe>
  <runtimeConfiguration>
    <requestMapperDefinition type="sqlStatement">
      <selection>
        <matchCriteria>$dataSourceName != null</matchCriteria>
        <selection>
          <matchCriteria>$dataSourceName.equals("jdbc/TradeDataSource")
</matchCriteria>
          <mapTo>
            <key>dataSourceName</key>
            <value>"Daytrader Data Source"</value>
          </mapTo>
        </selection>
        <selection>
          <matchCriteria>$dataSourceName.equals("jdbc/LongDataSource")
</matchCriteria>
          <mapTo>
            <key>dataSourceName</key>
            <value>"Long term trader Data Source"</value>
          </mapTo>
        </selection>
      </selection>
    </requestMapperDefinition>
  </runtimeConfiguration>
</gpe>
```

The first `<selection>` tag ensures that `$dataSourceName` is not null. Then, the second `<selection>` tag can safely evaluate `$dataSourceName.equals()`.

If the first `<selection>` tag was not present, and a null `$dataSourceName` was passed, the request mapper would generate an exception. Such an exception might result in missing monitoring information.

To enable this request mapper, the file `dc_home/runtime/toolkit_global_custom.properties` contains the following lines:

```
com.ibm.tivoli.itcam.toolkit.ai.enable.sqlrequestmapper=true
am.camtoolkit.gpe.customxml.renameDataSource=renameDataSource.xml
```

### Removing sensitive information from an SQL request

In this example, an application includes social security numbers in SQL requests. The request mapper removes the numbers from the version of the request that the user can see.

In the SQL requests, the social security number is listed with the SS column name, `SS = number`. The request mapper looks for the `SS =` string and removes the nine symbols after it.

The `dc_home/runtime/removeSSN.xml` file contains the following request mapper definition:

```
<gpe>
  <runtimeConfiguration>
    <requestMapperDefinition type="sqlStatement">
      <symbolDefinitions>
        <symbol>
          <name>$offsetOfSS</name>
          <eval>$sqlText.indexOf("SS = ")</eval>
        </symbol>
        <symbol>
          <name>$sqlTextContainsSS</name>
          <eval>$sqlText != null AND $offsetOfSS > 0 AND $sqlText.length() GE
$offsetOfSS+16</eval>
        </symbol>
        <conditionalSymbol>
          <name>$sqlTextPriorToSSKeyword</name>
          <type>java.lang.String</type>
          <defaultValue>"</defaultValue>
          <if condition="$sqlTextContainsSS">
            <return>$sqlText.substring(0, $offsetOfSS+5)</return>
          </if>
        </conditionalSymbol>
      </symbolDefinitions>
    </requestMapperDefinition>
  </runtimeConfiguration>
</gpe>
```

```

        <conditionalSymbol>
            <name>$sqlTextAfterSS</name>
            <type>java.lang.String</type>
            <defaultValue>"</defaultValue>
            <if condition="$sqlTextContainsSS">
                <return>$sqlText.substring($offsetOfSS+16)</return>
            </if>
        </conditionalSymbol>
    </symbolDefinitions>
    <selection>
        <matchCriteria>$sqlText != null AND $sqlText.length() >
0</matchCriteria>
        <selection>
            <matchCriteria>$sqlTextContainsSS</matchCriteria>
            <mapTo>
                <key>sqlText</key>
                <value>$sqlTextPriorToSSKeyword + "?" +
$sqlTextAfterSS</value>
            </mapTo>
        </selection>
    </selection>
</requestMapperDefinition>
</runtimeConfiguration>
</gpe>

```

To enable this request mapper, the file `dc_home/runtime/toolkit_global_custom.properties` contains the following lines:

```

com.ibm.tivoli.itcam.toolkit.ai.enable.sqlrequestmapper=true
am.camtoolkit.gpe.customxml.renameDataSource=removeSSN.xml

```

## Configuring the WebSphere Applications agent to monitor WebSphere Extreme Scale

After you install WebSphere Applications agent, you can make extra configuration to monitor WebSphere Extreme Scale (WXS) in a stand-alone or WebSphere Application Server environment.

### About this task

Configuration steps are different depending on the installation mode of WebSphere Extreme Scale and whether security is enabled. Do the following steps before you run the configuration process.

### Procedure

1. Confirm the installation mode of WebSphere Extreme Scale.

#### Stand-alone mode

WebSphere Extreme Scale is installed in an environment that does not have WebSphere Application Server.

#### Embedded WAS mode

WebSphere Extreme Scale is installed in a WebSphere Application Server environment.

2. Confirm whether the security is enabled for WebSphere Extreme Scale. If a secure Java™ client is used in embedded WebSphere Application Server mode, you must complete security connection steps.
3. Click the links for instructions.
  - To configure WebSphere Extreme Scale in stand-alone environment, click [“Configuring WebSphere Extreme Scale monitoring in stand-alone environment”](#) on page 1013.
  - To configure WebSphere Extreme Scale in embedded environment without security, click [“Configuring WebSphere Extreme Scale monitoring in WebSphere environment without security enabled”](#) on page 1014.
  - To configure WebSphere Extreme Scale in embedded environment with security enabled, click [“Configuring WebSphere Extreme Scale monitoring in security-enabled WebSphere environment”](#) on page 1015.

## Configuring WebSphere Extreme Scale monitoring in stand-alone environment

Learn how to configure the WebSphere Applications agent when your WebSphere Extreme Scale is installed in an environment that does not have WebSphere Application Server.

### Procedure

1. Stop the WebSphere Applications agent.
  - a) Go to the directory *install\_dir* where you install the WebSphere Applications agent.
  - b) Run command `bin/was-agent.sh stop`.
2. Run the configuration script.

```
install_dir/platform_code/yn/bin/wxs-agent-config.sh config
```

Where

- *install\_dir* is the installation directory of the WebSphere Applications agent.
- *platform\_code* is the platform code where you install the agent, for example, lx8266 represents Linux x86\_64 R2.6 (64 bit), aix536 represents AIX R5.3 (64 bit).

Example command:

```
/opt/ibm/apm/agent/lx8266/yn/bin/wxs-agent-config.sh config
```

```
/opt/ibm/apm/agent/aix536/yn/bin/wxs-agent-config.sh config
```

3. When prompted for the agent installation path, specify the home directory of WebSphere Applications agent.

**Note:** The script looks for the configuration file name based on the installation path you specify. The default is *install\_dir*/config/\${hostname}\_yn.xml. If prompted that the file does not exist, it might be because you did not start WebSphere Applications agent before you do this configuration. Start the WebSphere Applications agent and then stop it at least once.
4. When prompted for WebSphere Extreme Scale Catalog Server connector type, enter 1 to continue.
5. When prompted to Input a node name to identify this agent node on UI, enter the node name.

The node name is used to identify the monitored WebSphere Extreme Scale zone and it is displayed in the instance name that you can see in the Application Performance Dashboard UI.
6. When prompted for WebSphere Extreme Scale Catalog Server security enabled?, enter 1 if there is enabled security. Then, enter the user name and password. If there is no enabled security, enter 2.
7. Specify the host name and port number of the catalog server. If there are multiple catalog servers, you can add them one by one. You can also add multiple zones one after another.
  - The host name is the name of the system where the catalog server is located. Make sure the host name can be accessed. If not, use the IP address as the host name.
  - The port number is the **JMXServicePort** number of the WebSphere Extreme Scale catalog server. The default value is 1099. More details about the port number can be found in [WebSphere Extreme Scale Knowledge Center](#).
8. To start the agent, run the following command.

```
install_dir/bin/was-agent.sh start
```

**Note:**

- Agent configuration is stored in *install\_dir/config/\${hostname}\_yn.xml*. If you want to change any configuration, run this script again or modify the .xml file directly.
- Previous configuration is backed up as *install\_dir/config/\${hostname}\_yn.xml.bak*. You can restore previous configuration if necessary.
- You can press Ctrl-C to exit the script when you run *install\_dir/platform\_code/yn/bin/wxs-agent-config.sh config*. Your existing configuration is not changed.

## Configuring WebSphere Extreme Scale monitoring in embedded WebSphere environment

Learn how to configure the WebSphere Applications agent when your WebSphere Extreme Scale is installed in a WebSphere Application Server environment.

### About this task

If security is not enabled for the WebSphere Extreme Scale server, you can directly run the configuration process. Otherwise, you must first complete “Configuring WebSphere Extreme Scale monitoring in security-enabled WebSphere environment” on page 1015.

### Configuring WebSphere Extreme Scale monitoring in WebSphere environment without security enabled

If you install WebSphere Extreme Scale in a WebSphere Application Server environment without security enabled, you can directly configure the WebSphere Applications agent.

### Procedure

1. Stop the WebSphere Applications agent.
  - a) Go to the directory *install\_dir* where you install the WebSphere Applications agent.
  - b) Run command *bin/was-agent.sh stop*.
2. Run the configuration script.

```
install_dir/platform_code/yn/bin/wxs-agent-config.sh config
```

Where

- *install\_dir* is the installation directory of the WebSphere Applications agent.
- *platform\_code* is the platform code where you install the agent, for example, lx8266 represents Linux x86\_64 R2.6 (64 bit), aix536 represents AIX R5.3 (64 bit).

Example command:

```
/opt/ibm/apm/agent/lx8266/yn/bin/wxs-agent-config.sh
```

```
/opt/ibm/apm/agent/aix536/yn/bin/wxs-agent-config.sh
```

3. When prompted for the agent installation path, specify the home directory of WebSphere Applications agent.
 

**Note:** The script looks for the configuration file name based on the installation path you specify. The default is *install\_dir/config/\${hostname}\_yn.xml*. If prompted that the file does not exist, it might be because you did not start WebSphere Applications agent before you do this configuration. Start the WebSphere Applications agent and then stop it at least once.
4. When prompted for WebSphere Extreme Scale Catalog Server connector type, enter 2 to continue.
5. When prompted to Input a node name to identify this agent node on UI, enter the node name.

The node name is used to identify the monitored WebSphere Extreme Scale zone and it is displayed in the instance name that you can see in the Application Performance Dashboard UI.

6. When prompted for WebSphere Extreme Scale Catalog Server security enabled?, enter 2 to continue.
7. Specify the host name and port number of the catalog server. If there are multiple catalog servers, you can add them one by one. You can also add multiple zones one after another.
  - The host name is the name of the system where the catalog server is located. Make sure the host name can be accessed. If not, use the IP address as the host name.
  - The port number indicates the **JMXServicePort** number of the WebSphere Extreme Scale catalog server. It is inherited from the **BOOTSTRAP\_ADDRESS** value for each WebSphere Application Server. More details about the port number can be found in [WebSphere Extreme Scale Knowledge Center](#).
8. To start the agent, run the following command.

```
install_dir/bin/was-agent.sh start
```

**Note:**

- Agent configuration is stored in `install_dir/config/${hostname}_yn.xml`. If you want to change any configuration, run this script again or modify the `.xml` file directly.
- Previous configuration is backed up as `install_dir/config/${hostname}_yn.xml.bak`. You can restore previous configuration if necessary.
- You can press Ctrl-C to exit the script when you run `install_dir/platform_code/yn/bin/wxs-agent-config.sh config`. Your existing configuration is not changed.

## **Configuring WebSphere Extreme Scale monitoring in security-enabled WebSphere environment**

If you install WebSphere Extreme Scale in a WebSphere Application Server environment with security enabled, you must complete initial setup steps before you configure the WebSphere Applications agent.

### **About this task**

If you want to monitor WebSphere Extreme Scale servers in WebSphere Application Server security enabled environments, it is necessary to configure security settings manually.

The procedure applies to the following case:

- WebSphere Extreme Scale servers must be deployed inside the WebSphere Application Server application servers (or node agent or DMGR processes).
- WebSphere Applications agent must be deployed on a node where a WebSphere Extreme Scale zone catalog service is running. Configure the Agent for WebSphere Extreme Scale monitoring under this node, and set it to connect to this catalog service instance.
- One Agent instance must be used to monitor only one WebSphere Extreme Scale zone.

### **Procedure**

1. If the JDK version of your WebSphere Application Server is prior to 1.7, you must reconfigure the WebSphere Applications agent to use the same JRE as WebSphere Application Server.
  - a) Open the `install_dir/config/.yn.environment` file.
  - b) Add the following value to the first line.

```
#JAVAHOME=/opt/IBM/WebSphere/AppServer/java/8.0/jre
```

2. Configure the WebSphere Applications agent security properties file.  
For instructions, see [“Configuring the agent to work with JAR files and security properties of WebSphere Application Server”](#) on page 1016.

3. Optional: If a secure Java™ client is used, you must ensure that the authentication is properly configured. You must edit the client properties file and SSL properties file. For instructions, see [“Setting up connection credentials” on page 1017](#).

**Note:** If the key is not secured by SSL settings, you need to enter a password and user name only, then you can skip this step.

4. Run the configuration script to launch the configuration console. See [“Running the configuration” on page 1019](#).

*Configuring the agent to work with JAR files and security properties of WebSphere Application Server*

Configure the WebSphere Applications agent to work with WebSphere Application Server JAR files and security properties.

## About this task

To do this configuration, edit the `kynwb.properties` file.

## Procedure

1. Open the file `install_dir/platform_code/yn/config/kynwb.properties`. If this file does not exist, create one.
  - `install_dir` is the installation directory of the WebSphere Applications agent.
  - `platform_code` is the platform code where you install the agent, for example, `lx8266` represents Linux x86\_64 R2.6 (64 bit), `aix536` represents AIX R5.3 (64 bit).
2. In the beginning of the file, the class path is listed. Add the following lines before the existing lines.
  - For WebSphere Application Server 9.0:

```
appserver_home/plugins/com.ibm.ws.runtime.jar:\
appserver_home/lib/bootstrap.jar:\
appserver_home/runtimes/com.ibm.ws.admin.client_9.0.jar:\
appserver_home/lib/wsogclient.jar:\
```

- For WebSphere Application Server 8.5:

```
appserver_home/plugins/com.ibm.ws.runtime.jar:\
appserver_home/lib/bootstrap.jar:\
appserver_home/runtimes/com.ibm.ws.admin.client_8.5.0.jar:\
appserver_home/lib/wsogclient.jar:\
```

Example of a modified class path:

```
/opt/IBM/WebSphere/plugins/com.ibm.ws.runtime.jar:\
/opt/IBM/WebSphere/lib/bootstrap.jar:\
/opt/IBM/WebSphere/runtimes/com.ibm.ws.admin.client_8.5.0.jar:\
/opt/IBM/WebSphere/lib/wsogclient.jar:\
lib/kynwb.jar:\
lib/kynwssec_api.jar:\
lib/itcam.cg.mbean.jar:\
wasdc/7.3/installer/lib/itcamfwas.jar:\
```

3. At the end of the `install_dir/platform_code/yn/config/kynwb.properties` file, add the lines that indicate the security property files for use by the agent. Typically, these files are the ones that are used by the `wsadmin` utility:

```
-Dcom.ibm.CORBA.ConfigURL=file:/appserver_profile/properties/sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:/appserver_profile/properties/ssl.client.props
```

If the agent required security settings are different from those settings that are used by the `wsadmin` utility, create separate copies of the files and provide paths to them instead, for example:

```
-Dcom.ibm.CORBA.ConfigURL=file:/opt/IBM/ITM/config/sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:/opt/IBM/ITM/config/ssl.client.props
```

**Note:** When you install a fix pack or interim fix for WebSphere Applications agent, the changes that are made in the `yn.ini` and `kynwb.properties` files are overwritten. Therefore, after you install a fix pack or interim fix, you must complete the changes in these two files again.

#### *Setting up connection credentials*

When a secure Java client is used, it needs to read a properties file that contains a list of CSIV2 settings. These settings determine how the client authenticates to a server. You must ensure that the authentication is properly configured.

### About this task

Typically, the file with these settings is specified in the `com.ibm.CORBA.ConfigURL` JVM property. More SSL settings can be found in file specified in the `com.ibm.SSL.ConfigURL` JVM property.

When WebSphere Applications agent is configured to monitor eXtreme Scale servers embedded in WebSphere Application Server, it acts as secure Java client. For that reason, - `Dcom.ibm.CORBA.ConfigURL` and - `Dcom.ibm.SSL.ConfigURL` must be specified in the `kynwb.properties` file.

In most cases, these properties point to the `sas.client.props` and `ssl.client.props` files in the `appserver_profile/properties` directory. These files are used by tools like `wsadmin` or `xscmd`. Therefore, if you can use one of these tools to connect to an Extreme Scale catalog server without the need to enter any credentials, you do not need to customize the settings.

If the connection fails or requires entering a username or password, you must complete extra configuration.

#### *Modifying client properties file*

Edit the `sas.client.props` file to be used by the WebSphere Applications agent.

### About this task

The full path to the `sas.client.props` file is specified in `kynwb.properties`, in the - `Dcom.ibm.CORBA.ConfigURL` property. Provide the connection and security information for the WebSphere Application Server instance running the Catalog Services instance for which the agent is configured.

### Procedure

1. Open the `appserver_profile/properties/sas.client.props` file.
2. Change the value of the `com.ibm.CORBA.loginSource` property to properties:

```
com.ibm.CORBA.loginSource=properties
```

3. Set the property `com.ibm.CORBA.securityServerHost` to the host name of an application server within the WebSphere Extreme Scale zone. The server can be the local server or a different one. The server must be always available when the agent starts up. For example:

```
com.ibm.CORBA.securityServerHost=server.company.com
```

4. Set the `com.ibm.CORBA.securityServerPort` property to the RMI port for the application server profile, for example:

```
com.ibm.CORBA.securityServerPort=2819
```

5. Set the property `com.ibm.CORBA.loginUserId` to the login name for communicating with the application server, and the property `com.ibm.CORBA.loginPassword` to the password, for example:

```
com.ibm.CORBA.loginUserId=admin
com.ibm.CORBA.loginPassword=password
```

6. Set the following properties to true or false, corresponding to the **CSIV2 inbound communications** settings in the WebSphere administrative console:

```
com.ibm.CSI.performTLClientAuthenticationRequired
com.ibm.CSI.performTLClientAuthenticationSupported
com.ibm.CSI.performTransportAssocSSLTLSRequired
com.ibm.CSI.performTransportAssocSSLTLSSupported
```

The `com.ibm.CSI.performTLClientAuthentication*` properties are related to **Client certificate authentication** settings. The `com.ibm.CSI.performTransportAssocSSLTLS*` are related to **Transport** settings.

- Optional: If the default SSL alias (`DefaultSSLSettings`) is not used, set the SSL configuration alias name in the `com.ibm.ssl.alias` property.
- Save the file, and then encrypt the password within the `sas.client.props` file. To encrypt the password, run the following command:
  - On Linux and UNIX systems, run `appserver_profile/bin/PropFilePasswordEncoder.sh sas.client.props com.ibm.CORBA.loginPassword`

**Important:** When client certificate authentication is required and basic authentication is enabled, you might also need to set the property `com.ibm.CORBA.validateBasicAuth=false`.

#### *Modifying client SSL properties file*

Modify the SSL properties file that the WebSphere Applications agent uses to access server certificates.

### About this task

Edit the `ssl.client.props` file to be used by the agent. The full path to the file is specified in the `kynwb.properties` file, in the `-Dcom.ibm.SSL.ConfigURL` property. Provide the SSL truststore and keystore information for the WebSphere Application Server instance running the Catalog Services instance for which the agent is configured.

You can create and manage certificates by using the WebSphere administrative console (**Security > SSL certificate and key management > Key stores and certificates**) or by using the iKeyman tool.

### Procedure

- Open the `appserver_profile/properties/ssl.client.props` file.
- Change the value of the `com.ibm.ssl.alias` property to match the value of the same property in the `sas.client.props` file.

**Tip:** The `ssl.client.props` file can contain several SSL configurations. Each configuration starts with the `com.ibm.ssl.alias` property.

- Set the `com.ibm.ssl.enableSignerExchangePrompt` property to `false`.
- Set the following keystore properties to enable the client application to access the encryption key:

**com.ibm.ssl.keyStoreName**

The name that identifies this keystore

**com.ibm.ssl.keyStore**

The full path and name of the keystore file

**com.ibm.ssl.keyStorePassword**

The password for the keystore

**com.ibm.ssl.keyStoreType**

The keystore type. Use the default PKCS12 type because of its interoperability with other applications.

**Important:** If client certificate authentication is not required, the keystore can contain any self-signed key. Otherwise, the keystore must contain a key that is signed by a certificate that is in the server truststore.

- Set the following truststore properties to enable the client application to access signer certificates:

**com.ibm.ssl.trustStoreName**

The name that identifies this truststore

**com.ibm.ssl.trustStore**

The full path and name of the truststore file

**com.ibm.ssl.trustStorePassword**

The password for the truststore

**com.ibm.ssl.trustStoreType**

The truststore type. Use the default PKCS12 type because of its interoperability with other applications.

**Important:** If the client is to use an SSL connection, the server signer certificate must be in its truststore.

*Running the configuration*

After you check the environment and security, you can run the configuration process.

**Procedure**

1. Stop the WebSphere Applications agent.
  - a) Go to the directory *install\_dir* where you install the WebSphere Applications agent.
  - b) Run command `bin/was-agent.sh stop`.
2. Run the configuration script.

```
install_dir/platform_code/yn/bin/wxs-agent-config.sh config
```

Where

- *install\_dir* is the installation directory of the WebSphere Applications agent.
- *platform\_code* is the platform code where you install the agent, for example, lx8266 represents Linux x86\_64 R2.6 (64 bit), aix536 represents AIX R5.3 (64 bit).

Example command:

```
/opt/ibm/apm/agent/lx8266/yn/bin/wxs-agent-config.sh config
```

```
/opt/ibm/apm/agent/aix536/yn/bin/wxs-agent-config.sh config
```

3. When prompted for the agent installation path, specify the home directory of WebSphere Applications agent.

**Note:** The script looks for the configuration file name based on the installation path you specify. The default is *install\_dir/config/\${hostname}\_yn.xml*. If prompted that the file does not exist, it might be because you did not start WebSphere Applications agent before you do this configuration. Start the WebSphere Applications agent and then stop it at least once.

4. When prompted for WebSphere Extreme Scale Catalog Server connector type, enter 2 to continue.
5. When prompted to Input a node name to identify this agent node on UI, enter the node name.  
The node name is used to identify the monitored WebSphere Extreme Scale zone and it is displayed in the instance name that you can see in the Application Performance Dashboard UI.
6. When prompted for WebSphere Extreme Scale Catalog Server security enabled?, enter 1 to continue. Then, enter the user name and password.
7. Specify the host name and port number of the catalog server. If there are multiple catalog servers, you can add them one by one. You can also add multiple zones one after another.
  - The host name is the name of the system where the catalog server is located. Make sure the host name can be accessed. If not, use the IP address as the host name.
  - The port number indicates the **JMXServicePort** number of the WebSphere Extreme Scale catalog server. It is inherited from the **BOOTSTRAP\_ADDRESS** value for each WebSphere Application Server. More details about the port number can be found in [WebSphere Extreme Scale Knowledge Center](#).

8. To start the agent, run the following command.

```
install_dir/bin/was-agent.sh start
```

**Note:**

- Agent configuration is stored in *install\_dir*/config/\${hostname}\_yn.xml. If you want to change any configuration, run this script again or modify the .xml file directly.
- Previous configuration is backed up as *install\_dir*/config/\${hostname}\_yn.xml.bak. You can restore previous configuration if necessary.
- You can press Ctrl-C to exit the script when you run *install\_dir*/bin/wxs-agent-config.sh config. Your existing configuration is not changed.

## Unconfiguring the WebSphere Extreme Scale monitoring

When you do not want to monitor WebSphere Extreme Scale, you can unconfigure the WebSphere Applications agent.

### Procedure

1. Stop the WebSphere Applications agent.
  - a) Go to the directory *install\_dir* where you install the WebSphere Applications agent.
  - b) Run command `bin/was-agent.sh stop`.
2. Run the unconfiguration script.

```
install_dir/bin/wxs-agent-config.sh unconfig
```

Where

- *install\_dir* is the installation directory of the WebSphere Applications agent.
- *platform\_code* is the platform code where you install the agent, for example, lx8266 represents Linux x86\_64 R2.6 (64 bit), aix536 represents AIX R5.3 (64 bit).

Example command:

```
/opt/ibm/apm/agent/lx8266/bin/wxs-agent-config.sh unconfig
```

```
/opt/ibm/apm/agent/aix536/bin/wxs-agent-config.sh unconfig
```

## Configuring WebSphere Infrastructure Manager monitoring

Configure the WebSphere Infrastructure Manager agent to monitor the performance of WebSphere Deployment Manager and Node Agent.

### About this task

The WebSphere Infrastructure Manager agent is a multiple instance agent. You must create the first instance and start the agent manually.

### Procedure

1. To configure the agent, run the following command.

```
install_dir/bin/wim-agent.sh config instance_name
```

Where *instance\_name* is the name you want to give to the instance, and *install\_dir* is the installation directory of WebSphere Infrastructure Manager agent. The default installation directory is `/opt/ibm/apm/agent`.

2. When prompted to Edit 'Monitoring Agent for WebSphere Infrastructure Manager' settings, enter 1 to continue.
3. When prompted for Java home, specify the directory where Java is installed.  
The default value is /opt/ibm/apm/agent/JRE/1x8266/jre.
4. When prompted for DMGR Profile Home, specify the home directory of the Deployment Manager profile.  
The default directory is /opt/IBM/WebSphere/AppServer/profiles/Dmgr01.
5. When prompted for JMX user ID, specify the user ID that is used to connect to the MBean server.
6. When prompted to Enter JMX password, specify the password for the user.
7. When prompted to Re-type JMX password, enter the password again.
8. To start the agent, run the following command.

```
install_dir/bin/wim-agent.sh start instance_name
```

## Results

You created a WebSphere Infrastructure Manager agent instance and started the monitoring agent to begin collecting data samples for resource monitoring.

## Configuring WebSphere MQ monitoring

---

Before you can start the agent, you must assign an instance name to the agent and complete the several configuration tasks for the user ID and managed system names. Optionally you can also enable transaction tracking for the agent.

### Before you begin

- The directions here are for the most current release of this agent. For information about how to check the version of an agent in your environment, see [Agent version command](#). For detailed information about the agent version list and what's new for each version, see [“Change history” on page 58](#).
- Make sure that the system requirements for the WebSphere MQ agent are met in your environment. For the up-to-date system requirement information, see the [Detailed System Requirements Report for the WebSphere MQ agent](#).

### About this task

To set up the environment for the WebSphere MQ agent, you must first make sure the agent user ID can access IBM MQ (WebSphere MQ) objects, configure IBM MQ (WebSphere MQ) for data enablement, and then configure the WebSphere MQ agent.

The following procedure is a roadmap for configuring WebSphere MQ agent, which includes both required and optional steps. Complete the necessary steps according to your needs.

### Procedure

1. Authorize the user ID that is used to configure, start, and stop the agent to access IBM MQ (WebSphere MQ) objects. See [“Authorizing the user IDs to run the agent” on page 1022](#).
2. Configure IBM MQ (WebSphere MQ) to enable the data that you want to monitor. See [“Configuring IBM MQ \(WebSphere MQ\) for data enablement” on page 1023](#).
3. Configure the agent by providing an agent instance name, a queue manager name, and optionally an agent name. See [“Configuring the WebSphere MQ agent” on page 1026](#).
4. Optional: Depending on your monitoring requirements, you might require a unique managed system name to distinguish different monitoring agents. Use the Agent Name option in the `mq-agent.sh config` command to specify the middle qualifier of the managed system name. See [“Specifying unique managed system names for multiple queue managers” on page 1028](#).

5. Optional: To configure the agent to collect transaction tracking data of the monitored queue manager, use the **Agent Configuration** page. For instructions, see [“Configuring transaction tracking for the WebSphere MQ agent” on page 1030](#).
6. Optional: Enable the agent to collect the long-term history data for queues and channels. For instructions, see [“Enabling data collection for queue and channel long-term history” on page 1031](#).
7. Optional: To remotely monitor queue manager on MQ Appliance, additional configuration of both the agent and IBM MQ (WebSphere MQ) is required. For instructions, see [“Remotely monitoring queue managers on MQ Appliance” on page 1033](#) or [“Remotely monitoring HA queue managers on MQ Appliance” on page 1034](#).

## Authorizing the user IDs to run the agent

For a user ID to configure, start, and stop the WebSphere MQ agent, the user ID must belong to the **mqm** group, which has full administrative privileges over IBM MQ (WebSphere MQ). Also, for a non-root user or a non-administrator user, you must grant users the access to the IBM MQ (WebSphere MQ) objects by using the IBM MQ (WebSphere MQ) control command.

### About this task

On AIX or Linux system, you must add the user ID to the **mqm** group and then grant the user ID appropriate access to the IBM MQ (WebSphere MQ) objects with the **setmqaut** command.

On Windows systems, you must add the user ID to the **mqm** group. If the user ID does not belong to the Administrator user group, you must also use the Registry Editor to grant permissions to the user ID to start or stop the agent.

### Procedure

- **Linux** **UNIX**  
On AIX or Linux system, complete the following steps:
  - a) Log on to the AIX or Linux system by using the root ID.
  - b) Add the user ID that is used to run the agent to the **mqm** group.
  - c) (WebSphere MQ V7.5 or later): If the user ID is a non-root user on the AIX or Linux system, set the appropriate level of authority for the user ID to access the IBM MQ (WebSphere MQ) objects by running the following command:

```
setmqaut -m queue_manager -t qmgr -p user_ID +inq +connect +dsp +setid
```

where *queue\_manager* is the name of the queue manager of WebSphere MQ V7.5 or later and *user\_ID* is the non-root or non-administrator user ID to run the agent.
- **Windows**  
On Windows systems, complete the following steps:
  - a) Log on to the Windows systems as a system administrator.
  - b) Add the user ID that is used to run the agent to the **mqm** group.
  - c) If the user ID that you use to start, run, and stop the agent is not a member of the Administrators group, use the Registry Editor to set permissions for a user ID to ensure that the agent can be started and stopped successfully:
    - a. Click **Start > Run**, and then type `regedit.exe` to open the Registry Editor.
    - b. In the Registry Editor, locate the key, `HKEY_LOCAL_MACHINE\SOFTWARE\Candle`.
    - c. Right-click the key and click **Permissions**.
    - d. If the user ID for the WebSphere MQ agent is not in the Group or user names list, click **Add** to add the user ID to the list.
    - e. Click the user ID in the list.

- f. In the Permissions for the *user-ID* list, where *user-ID* is the user ID of WebSphere MQ agent, select **Full Control** in the Allow column and click **OK**.
- g. In the Registry Editor, locate the key, HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib.
- h. Right-click the key and click **Permissions**.
- i. If the user ID for the WebSphere MQ agent is not in the Group or user names list, click **Add** to add the user ID to the list.
- j. Click the user ID in the Group or user names list.
- k. In the Permissions for the *user-ID* list, where *user-ID* is the user ID of WebSphere MQ agent, select **Read** in the Allow column and click **OK**.
- l. Close the Registry Editor.
- m. Locate the *install\_dir* directory, where *install\_dir* is the agent installation directory.
- n. Right-click the directory and click **Properties**.
- o. On the Security tab, if the user ID for WebSphere MQ agent is not in the Group or user names list, click **Edit** and then **Add** to add the user ID to the list.
- p. Click the user ID in the Group or user names list.
- q. In the Permissions for the *user-ID* list, select **Full Control** in the Allow column, where **user-ID** is the user ID of WebSphere MQ agent.
- r. Click **OK**.

### What to do next

The next step to configure IBM MQ (WebSphere MQ) for data enablement. See [“Configuring IBM MQ \(WebSphere MQ\) for data enablement”](#) on page 1023.

## Configuring IBM MQ (WebSphere MQ) for data enablement

Before you configure the WebSphere MQ agent, it is recommended to the configure IBM MQ (WebSphere MQ) first to enable the data that you want to monitor.

### About this task

Decide what type of data that you want the WebSphere MQ agent to monitor. Enable the data at the queue manager by using the MQSC commands if the data is not produced by the queue manager by default.

**Remember:** You must start MQSC for the target queue manager before you issue the MQSC commands. To get a list of the queue manager, issue the **dspmq** command from the bin directory within the IBM MQ (WebSphere MQ) installation directory. To start MQSC for a queue manager, issue the following command from the bin directory, where *<qmgr\_name>* is the name of the queue manager that you want to configure.

```
runmqsc <qmgr_name>
```

### Procedure

- To see the age of the oldest message on a queue, complete the steps as documented in [“Enabling real-time monitoring for queues”](#) on page 1024.
- To monitor certain queue manager events that are not generated by the queue manager by default, complete the steps as documented in [“Enabling event monitoring for the queue manager”](#) on page 1024.
- To get the transaction tracking data, complete the steps as documented in [“Enabling MQI application activity trace”](#) on page 1025.

- To monitor a remote queue manager, ensure that the WebSphere MQ agent can collect monitoring data through a channel on the remote system. For more information, see [“Security settings for remote monitoring”](#) on page 1025.

## Enabling real-time monitoring for queues

### About this task

To see the age of the oldest message (in seconds) on a queue, you must enable the real-time monitoring for the queue.

### Procedure

Use the following commands to enable real-time monitoring for the queues in your environment.

- To enable real-time monitoring for all the queues whose MONQ attribute is set to QMGR, issue the following command:

```
ALTER QMGR MONQ(collection_level)
```

where *collection\_level* specifies the collection level of monitoring data for the queues. You can set it to LOW, MEDIUM, or HIGH to suit the requirements of your environment.

- To enable real-time monitoring for individual queue, issue the following command:

```
ALTER QLOCAL(queue_name) MONQ(collection_level)
```

where *queue\_name* is the name of the queue; *collection\_level* specifies the collection level of monitoring data for the queues. You can set it to LOW, MEDIUM, or HIGH to suit the requirements of your environment.

### Results

The data can be displayed in the Oldest Message Age for Queue group widget after the WebSphere MQ agent is started.

## Enabling event monitoring for the queue manager

### About this task

Event monitoring is one of the monitoring techniques that are available to monitor your IBM MQ network. After you enable the queue manager to emit certain types of events, event messages are put on event queues when the event occurs. So that these event messages can be monitored and displayed by the WebSphere MQ agent.

The following types of events are not monitored and displayed with the default queue manager configuration. Use the **ALTER QMGR** command to enable the queue manager to generate these events so that they can be displayed on the Application Performance Dashboard.

- Channel events
- Performance events

### Procedure

Use the following commands to enable the queue manager to generate the events that you care:

- To generate channel events, issue **ALTER QMGR CHLEV(ENABLED)**.
- To generate performance events, issue **ALTER QMGR PERFMEV(ENABLED)**.

## Results

The monitored events can be displayed in the Queue Manager Events group widget after the WebSphere MQ agent is started.

## Enabling MQI application activity trace

### About this task

For transaction tracking data to be displayed in the middleware and topology dashboards, the MQI application activity trace must be enabled at the queue manager.

### Procedure

- To enable MQI application activity trace information collection, issue the following MQSC command:

```
ALTER QMGR ACTVTRC(ON)
```

## Security settings for remote monitoring

### About this task

To use the WebSphere MQ agent to monitor a remote queue manager, you must make sure that the security settings of IBM MQ (WebSphere MQ) does not prevent the agent from collecting monitoring data through a channel on the remote system.

The following procedure provides an example of a simple security setting for remote monitoring. To exercise more precise control over the access granted to connecting systems at a channel level, you can use channel authentication records. For more information, refer to [IBM MQ security mechanisms documentation](#).

### Procedure

1. Disable channel authentication by running the following MQSC command:

```
ALTER QMGR CHLAUTH(DISABLED) CONNAUTH(' ')
```

2. Change the channel settings as follows, where *channel\_for\_remote\_monitor* is the name of the channel used for remote monitoring.

- Linux | UNIX

```
ALTER CHANNEL(channel_for_remote_monitor) CHLTYPE(SVRCONN) MCAUSER('mqm')
```

- Windows

```
ALTER CHANNEL(channel_for_remote_monitor) CHLTYPE(SVRCONN) MCAUSER(MUSR_MQADMIN)
```

3. Refresh the security settings.

```
REFRESH SECURITY
```

## Configuring the WebSphere MQ agent

You must assign an instance name to the WebSphere MQ agent and configure the agent before it can start monitoring your IBM MQ (WebSphere MQ) environment.

### Before you begin

- Make sure that the agent user ID has appropriate permission to access IBM MQ (WebSphere MQ) objects. If you have not done it, follow the instructions in [“Authorizing the user IDs to run the agent” on page 1022](#).
- Configure IBM MQ (WebSphere MQ) to enable the required data collection. If you have not done it, see [“Configuring IBM MQ \(WebSphere MQ\) for data enablement” on page 1023](#).
- You must provide the name of queue manager to be monitored by the WebSphere MQ agent. Contact the IBM MQ (WebSphere MQ) administrator if you do not know the appropriate queue manager name. Alternatively, issue the **dspmqr** command from the `bin` directory within the IBM MQ (WebSphere MQ) installation directory to get a list of the queue managers. The returned QMNAME value is what you must provide when you configure the WebSphere MQ agent.

### About this task

The WebSphere MQ agent is a multiple instance agent; you must create the first instance and manually start the agent.

On UNIX or Linux systems, you can choose to configure the agent with or without interactions. On Windows systems, you can configure the agent without interactions only.

- To configure the agent with interaction, run the configuration script and respond to prompts. See [“Interactive configuration” on page 1026](#).
- To configure the agent without interaction, edit the silent response file and then run the configuration script. See [“Silent configuration” on page 1027](#).

**Important:** If you also installed Monitoring Agent for WebSphere MQ, which is delivered as one component of the ITCAM for Applications product, on the same system as the WebSphere MQ agent, which is delivered in Cloud APM, do not use them to monitor the same queue manager on the system.

## Interactive configuration

### Procedure

To configure the agent by running the script and responding to prompts, complete the following steps:

1. Enter the following command to create an agent instance:

```
install_dir/bin/mq-agent.sh config instance_name
```

where *instance\_name* is the name you want to give to the instance.

2. When prompted for Queue Manager Name, specify the name of the queue manager to be monitored.
3. When prompted for Agent Name, specify the agent name to be used as the middle qualifier of the managed system name. Do not press Enter to skip specifying this parameter.

**Remember:** This agent name is different from the agent instance name. The agent instance name is used in the agent configuration file name to distinguish the configuration files between agents, for example, *hostname\_mq\_instancename.cfg*. The agent name is used as a short identifier to create unique managed system names. To understand when a unique managed system name is required, see [“Specifying unique managed system names for multiple queue managers” on page 1028](#).

4. If you want to monitor a remote queue manager, specify the following configuration parameters. If you want to monitor a local queue manager, press Enter to proceed.
  - Connection Name: The connection name for remote monitoring. The format is *IP\_address (port\_number)*, for example, *127.0.0.1(1414)*. If this is the first time you configure the agent

instance, you can press Enter to accept the default of null. The appropriate connection name can be automatically discovered.

- **Channel1:** The name of channel used for remote data collection. If this is the first time you configure the agent instance, you can press Enter to accept the default of null. The SYSTEM.DEF.SVRCONN channel will be used.

**Limitation:** Error logs of a remote queue manager cannot be monitored. When the agent is monitoring a remote queue manager, the MQ Errors Details dashboard contains no data.

5. When prompted for WebSphere MQ library path, press Enter to accept the default value, which is the 64-bit library path of IBM MQ (WebSphere MQ) automatically discovered by the WebSphere MQ agent. If no default value is displayed, you must provide the 64-bit library path of IBM MQ (WebSphere MQ) to proceed.

An example of the 64-bit library path is /opt/mqm8/lib64 for a Linux system.

6. To start the agent, enter the following command:

```
install_dir/bin/mq-agent.sh start instance_name
```

## Silent configuration

### Procedure

To configure the agent by editing the silent response file and running the script without interaction, complete the following steps:

1. Open the mq\_silent\_config.txt file in a text editor.

- **Linux** | **UNIX** `install_dir/samples/mq_silent_config.txt`
- **Windows** `install_dir\tmaitm6_x64\samples\mq_silent_config.txt`

where *install\_dir* is the installation directory of WebSphere MQ agent.

2. Required: For **QMNAME**, specify the name of the queue manager to be monitored.
3. Required: For **AGTNAME**, specify the agent name to be used as the middle qualifier of the managed system name.

**Remember:** This agent name is different from the agent instance name. The agent instance name is used in the agent configuration file name to distinguish the configuration files between agents, for example, *hostname\_mq\_instancename.cfg*. The agent name is used as a short identifier to create unique managed system names. To understand when a unique managed system name is required, see [“Specifying unique managed system names for multiple queue managers”](#) on page 1028.

4. If you want to monitor a remote queue manager, specify the following configuration parameters:

- **CONNAME:** The connection name for remote monitoring. The format is *IP\_address (port\_number)*, for example, 127.0.0.1(1414).
- **CHANNEL:** The name of channel used for remote data collection. If not specified, the SYSTEM.DEF.SVRCONN channel will be used.

**Limitation:** Error logs of a remote queue manager cannot be monitored. When the agent is monitoring a remote queue manager, the MQ Errors Details dashboard contains no data.

5. Optional: For **WMQLIBPATH**, specify the 64-bit library path of IBM MQ (WebSphere MQ). For example, /opt/mqm8/lib64. If no value is specified, the path can be automatically discovered during agent configuration.
6. Save and close the mq\_silent\_config.txt file, and then run the following command from the command line:

- **Linux** | **UNIX** `install_dir/bin/mq-agent.sh config instance_name path_to_responsefile`
- **Windows** `install_dir\BIN\mq-agent.bat config instance_name "path_to_responsefile"`

where *instance\_name* is the name of the instance that you configure, and *path\_to\_responsefile* is the full path of the silent response file.

**Remember:** On Windows systems, do not omit the double quotation marks ("" ) that enclose the path to the silent response file, especially when the path contains special characters.

For example, if the response file is in the default directory, run the following command.

- Linux | UNIX

```
/opt/ibm/apm/agent/bin/mq-agent.sh config instance_name
/opt/ibm/apm/agent/samples/mq_silent_config.txt
```

- Windows

```
C:\IBM\APM\BIN\mq-agent.bat config instance_name
"C:\IBM\APM\tmaitm6_x64\samples\mq_silent_config.txt"
```

7. To start the agent, enter the following command:

- Linux | UNIX

```
install_dir/bin/mq-agent.sh start instance_name
```

- Windows

```
install_dir\bin\mq-agent.bat start instance_name
```

## Results

Now, you can log in to the Cloud APM console and use the Applications editor to add the WebSphere MQ agent instance to the Application Performance Dashboard. For instructions on how to start the Cloud APM console, see [“Starting the Cloud APM console” on page 1109](#). For information about using the Applications editor, see [“Managing applications” on page 1269](#).

## What to do next

- If you have enabled MQI application activity trace information collection at the queue manager, use the **Agent Configuration** page to configure the WebSphere MQ agent to collect transaction tracking data of the monitored queue manager. See [“Configuring transaction tracking for the WebSphere MQ agent” on page 1030](#). If the agent does not show up on the **Agent Configuration** page, restart the Cloud APM server.
- Depending on your monitoring requirements, you might require a unique managed system name to distinguish different monitoring agents. Use the Agent Name option in the `mq-agent.sh config` command to specify the middle qualifier of the managed system name. See [“Specifying unique managed system names for multiple queue managers” on page 1028](#).
- To configure the WebSphere MQ agent for remote monitoring, you must do some manual configuration after you create an agent instance. For instructions, see the following topics:
  - [“Remotely monitoring queue managers on MQ Appliance” on page 1033](#)
  - [“Remotely monitoring HA queue managers on MQ Appliance” on page 1034](#)

## Specifying unique managed system names for multiple queue managers

Unique managed system names are required sometimes to distinguish different monitoring agents that connect to the same Cloud APM server. Use the **AGTNAME** parameter in the silent response file or the

Agent Name option in the **mq-agent.sh config** command to specify the middle qualifier that is used in the managed system name.

## About this task

When the WebSphere MQ agent is started, it registers the following managed system:

```
monitoredqueuemanagename:agentname:MQ
```

where

- *monitoredqueuemanagename* is the name of the queue manager that is monitored by the agent.
- *agentname* is the middle qualifier of the managed system name. If the *agentname* value is not specified, no value is used.

Specifying the agent name value is useful in the following circumstances:

- If your site has multiple queue managers with the same name that are running on different nodes, specify the agent name for each queue manager, so that the WebSphere MQ agent can create unique managed system names.
- If the length of the managed system name exceeds 32 characters, 2 different queue manager names might resolve to the same name because of truncation. To distinguish the managed system names for queue managers, specify the agent name for each queue manager.
- If you want to group and identify queue manager names by something other than the host name and queue manager name, such as a high-availability cluster name.
- If you want to enable multiple agents that are connected to the same Cloud APM server to monitor the queue managers with the same name on different hosts.

## Interactive configuration

### Procedure

To use the Agent Name option in the **mq-agent.sh config** command, complete the following steps:

1. In the command line, run the following command to start configuring the WebSphere MQ agent.

```
./mq-agent.sh config instance_name
```

where *instance\_name* is the name of the instance that you started.

2. Follow the options to configure the agent instance.

The name of the queue manager is required. For other options, if no change is needed, use the default value.

3. When the Agent Name option appears, specify the middle qualifier for the managed system name.

**Remember:** The complete managed system name is *monitoredqueuemanagename:agentname:MQ*. The maximum length for the complete managed system name is 32 characters, so the maximum length for the middle qualifier *agentname* depends on the length of the queue manager name. If the value that is specified for the Agent Name option exceeds the maximum length, the value for *agentname* is truncated to no less than 8 characters.

For example, to monitor a queue manager that is named PERSONNEL on the AIX1 node while another queue manager that is named PERSONNEL is on a node that is named LINUX2, run the following command first for the AIX1 node:

```
./mq-agent.sh config PERSONNEL
```

Then specify the agent name when the *Agent Name* option appears:

```
Agent Name (default is: ): AIX1
```

To simultaneously monitor the PERSONNEL queue manager on the LINUX2 node, run the following command first:

```
./mq-agent.sh config PERSONNEL
```

Then specify the agent name:

```
Agent Name (default is: ): LINUX2
```

**Remember:** The names of the agent nodes are used for the Agent Name option in the code samples for explanatory purpose only. You can specify other strings for the Agent Name option.

## Silent configuration

### Procedure

To use the **AGTNAME** parameter in the silent response file, complete the following steps:

1. Open the `mq_silent_config.txt` silent response file in a text editor.
2. Specify an agent name for the **AGTNAME** parameter.

**Remember:** The complete managed system name is *monitoredqueueanagername:agentname:MQ*. The maximum length for the complete managed system name is 32 characters, so the maximum length for the middle qualifier *agentname* depends on the length of the queue manager name. If the value that is specified for the **AGTNAME** parameter exceeds the maximum length, the value for *agentname* is truncated to no less than 8 characters.

3. Save and close the `mq_silent_config.txt` file, and then run the following command from the command line:

```
install_dir/BIN/mq-agent.sh config instance_name path_to_responsefile
```

where *instance\_name* is the name of the instance that you configure, and *path\_to\_responsefile* is the full path of the silent response file.

### What to do next

Log in to the Cloud APM console. If the agent instance with previous MSN is still displayed as offline, edit your application to remove it and then add the new agent instance with the assigned agent name.

## Configuring transaction tracking for the WebSphere MQ agent

Transaction tracking data for IBM MQ (WebSphere MQ) can be displayed in the middleware and topology dashboards after you enable the data collection on the **Agent Configuration** page for the WebSphere MQ agent.

### Before you begin

- Make sure that MQI application activity trace information collection is enabled at the queue manager. If you have not done it before the WebSphere MQ agent is configured and started, follow the instructions in [“Enabling MQI application activity trace” on page 1025](#) and then restart the agent.
- Make sure that the version of IBM MQ (WebSphere MQ) that you are using is supported by the transaction tracking feature. For the up-to-date information about supported IBM MQ (WebSphere MQ), see the prerequisites statement in the [Detailed System Requirements Report for the WebSphere MQ agent](#).
- Make sure that the WebSphere MQ agent is configured to monitor the queue manager. For instructions, see [“Configuring the WebSphere MQ agent” on page 1026](#).

**Remember:** Ensure that you have upgraded the WebSphere MQ agent to the latest version. For Cloud APM, Private, you need V8.1.2 or later. You must upgrade the agent, and configure and enable transaction tracking to see data in some of the widgets, such as the Message Volume widget.

## Procedure

To configure transaction tracking for the WebSphere MQ agent, complete the following steps:

1. From the navigation bar, click  **System Configuration > Agent Configuration**.  
The **Agent Configuration** page is displayed.
2. Click the **WebSphere MQ** tab.
3. Select the check boxes for the queue managers that you want to monitor and take one of the following actions from the **Actions** list:
  - To enable transaction tracking, click **Set Transaction Tracking > Enabled**. The status in the **Transaction Tracking** column is updated to Enabled.  
**Tip:** Tracking alias queues and remote queues is enabled by default. To reduce the volume of data that is being tracked, you can disable the tracking of alias and remote queues by clicking **Set Alias Queue Tracking > Disabled** from the **Actions** list. After tracking alias and remote queues is disabled, alias queues and remote queues are eliminated from the Transaction Topology view.
  - To disable transaction tracking, click **Set Transaction Tracking > Disabled**. The status in the **Transaction Tracking** column is updated to Disabled.

## Results

You have configured the WebSphere MQ agent for tracking the selected queue managers. Transaction tracking data can be displayed in the middleware and topology dashboards. For more information, see [“Adding middleware applications to the Application Performance Dashboard”](#) on page 126.

## Enabling data collection for queue and channel long-term history

By default, the queue long-term history and channel long-term history is not collected and is not displayed on any predefined dashboards or group widgets. However, you can enable the agent to collect the long-term history data and then use the **Attribute Details** tab to query the collected data.

### Before you begin

Ensure the WebSphere MQ agent is installed and configured. For information, see [“Configuring the WebSphere MQ agent”](#) on page 1026.

### About this task

The channel long-term history or the queue long-term history data can be useful for detecting problems with individual channels or queues.

If you are a user of Tivoli Data Warehouse, the agent can also send the long-term history data to Tivoli Data Warehouse for further processing.

## Procedure

Complete the following steps to enable the WebSphere MQ agent to collect queue long-term history and channel long-term history data:

1. Open the following agent environment file with a text editor. If the `mq.environment` file does not exist, create it by yourself.

- **Linux** | **UNIX** `install_dir/config/mq.environment`
- **Windows** `install_dir\Config\KMQENV_instance`

where:

- `install_dir` is the agent installation directory. The default is `/opt/ibm/apm` on Linux and AIX systems, and `C:\IBM\APM` on Windows systems.
- `instance` is the agent instance name.

2. Enable the data collection by setting the **LH\_COLLECTION** value to ENABLED.

```
LH_COLLECTION=ENABLED
```

3. Optional: If you are a user of Tivoli Data Warehouse and you want the agent to send the collected data to Tivoli Data Warehouse, set the **LH\_PVTHISTORY** value to ENABLED.

```
LH_PVTHISTORY=ENABLED
```

**Remember:** Enable this option only if you need the collected data to be sent to Tivoli Data Warehouse.

4. Save your change and restart the agent.

## Results

The WebSphere MQ agent starts to collect the queue long-term history and channel long-term history data. If you specified LH\_PVTHISTORY=ENABLED, the collected long-term history data can also be sent to Tivoli Data Warehouse.

## What to do next

Use the **Attribute Details** tab to view the collected data on the dashboard for the configured agent instance. Select **Channel\_Long-Term\_History** or **Queue\_Long-Term\_History** from the **Data Set** list. For more information about the **Attribute Details** tab, see [“Creating a custom chart or table page” on page 1264](#).

# Enabling queue statistics monitoring for the queue manager of IBM MQ

By default, the queue statistics are not collected and are not displayed on any predefined dashboards or group widgets. However, you can enable the agent to collect statistics for the queue manager and then view the collected data.

## Before you begin

Ensure the WebSphere MQ agent is installed and configured. For information, see [“Configuring the WebSphere MQ agent” on page 1026](#).

## Procedure

Complete the following steps to enable the WebSphere MQ agent to collect statistics data:

1. Configure the queue manager to collect queue statistics information. Run the following MQSC command:

```
ALTER QMGR STATQ(ON)
```

2. Set the interval over which the accounting data is collected. Run the following command:

```
ALTER QMGR STATINT(n)
```

Where **n** is the number of seconds over which the accounting data is collected.

3. Enable statistics information collection for a specific queue. Run the following MQSC command:

```
ALTER QLOCAL(queue_name) STATQ(QMGR)
```

Where **queue\_name** is the name of the queue for which you want to collect statistics information.

## What to do next

Use one of the following methods to view the MQ Queue statistics monitoring data:

- View the monitoring data from the **Attribute Details** tab of **MQ\_Queue\_Statistics** Data Set. For more information about the **Attribute Details** tab, see [“Creating a custom chart or table page” on page 1264](#).

- Define the thresholds based on **Expired Message Count** and other metrics of **MQ\_Queue\_Statistics**. For more information about thresholds, see [“Thresholds and resource groups”](#) on page 1110.

## Remotely monitoring queue managers on MQ Appliance

You can use the WebSphere MQ agent to monitor remote queue manager on MQ Appliance environment.

### Before you begin

- Install WebSphere MQ agent on a supported platform.
- Install IBM MQ Client. The version of MQ client must be same as the version of the remote MQ Queue Manager.

### Procedure

1. Set up connection to the remote queue manager. On the remote queue manager, define a server connection channel and a listener that is used for communication with the monitoring agent. Run the following command:

```
M2000# mqcli
M2000(mqcli)#runmqsc qmgr_remote
> DEFINE LISTENER(listener) TRPTYPE(TCP) PORT(port_NO)
> DEFINE CHANNEL(chl_name)CHLTYPE(SVRCONN) TRPTYPE(TCP)
CONNAME('host_IP(port_NO)') QMNAME(Qmgr_remote)
> END
```

where:

- *qmgr\_remote* is the name of the remote queue manager.
  - *listener* is the name of the listener on the remote queue manager.
  - *port\_NO* is the port number to be used for the listener.
  - *chl\_name* is the name that you assign to both the server channel and the client channel.
  - *host\_IP* is the IP address of the remote system.
2. Configure the listener to start automatically and then start the listener on the remote queue manager by running the following commands on the remote system:

```
M2000# mqcli
M2000(mqcli)#runmqsc qmgr_remote
> ALTER LISTENER(listener) TRPTYPE(tcp) CONTROL(qmgr_remote)
> START LISTENER(listener)
> END
```

3. Make sure that channel authentication settings are configured appropriately for the user ID that is used to start the MQ agent instance. For more information, see [Setting up a queue manager to accept client connections](#) in IBM MQ Appliance Knowledge Center.
4. Create an instance of the WebSphere MQ agent for remote monitoring by following instructions in [“Configuring the WebSphere MQ agent”](#) on page 1026 and provide remote queue manager connection information in prompts following **Remote Monitoring Settings**.

```
Remote Monitoring Settings (For a local queue manager, just press Enter in
this section) :
Connection name for remote monitoring, for example: 192.168.1.1(1415)
Connection Name (default is: null):
Channel name for remote monitoring, SYSTEM.DEF.SVRCONN is as default.
Channels (default is: null):
```

5. Start the WebSphere MQ agent instance.

## Remotely monitoring HA queue managers on MQ Appliance

To remotely monitor HA queue manager on MQ Appliance, you have two options. One is to use a single agent instance to connect to whichever system that has the active queue manager. The other option is to use separate agent instance for each appliance that the queue manager might be running on.

### About this task

Only the second option is explained here. To use different agent instances, you need two installations of the WebSphere MQ agent on Linux or UNIX systems. On Windows systems, you only need one installation of the agent and create separate agent instances.

### Procedure

- Linux UNIX  
Perform the following steps to use the WebSphere MQ agent installed on Linux or UNIX systems for remote monitoring:
  - a) Install the WebSphere MQ agent in different directories on the system.
  - b) Create an instance of each installed WebSphere MQ agent. For instructions, see [“Configuring the WebSphere MQ agent”](#) on page 1026.
  - c) Modify the configuration file of each agent instance to enable remote monitoring by replacing the content with the following lines:

```
SET GROUP NAME (GROUP1) -  
DEFAULT(YES) -  
RETAINHIST(120) -  
COMMAND (YES) -  
MSGACCESS(DESC) -  
EVENTS(REMOVE) -  
ACCOUNTINGINFO(REMOVE) -  
STATISTICSINFO(REMOVE)  
  
SET MANAGER NAME(qmgr_name) REMOTE(YES)  
SET AGENT NAME(agentID)  
SET QUEUE NAME(*) MGRNAME(qmgr_name) QDEFTYPE(PREDEFINED)  
SET CHANNEL NAME(*) MGRNAME(qmgr_name)  
PERFORM STARTMON SAMPINT(300) HISTORY(NO)
```

where:

- *qmgr\_name* is the name of the HA queue manager.
- *agentID* is the ID to identify the queue manager system. It is usually the host name or the IP address of the remote system where the HA queue manager is running.

The configuration file name and path is *install\_dir/config/hostname\_mq\_qmgr\_name.cfg*.

- d) Create a pair of client and server channels between the primary queue manager and the WebSphere MQ agent, between the secondary queue manager and the WebSphere MQ agent on the remote system where the primary queue manager is installed.

**Remember:** You must run all the following commands before you proceed to the next step.

- a. Run the following commands for the primary queue manager:

```
M2000# mqcli  
M2000(mqcli)#runmqsc qmgr_primary  
>DEFINE LISTENER(listener_primary) TRPTYPE(TCP) PORT(port_no_primary)  
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(SVRCONN) TRPTYPE(TCP)  
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)  
CONNNAME('host_IP(port_no_primary)') QMNAME(qmgr_primary)
```

where:

- *qmgr\_primary* is the name of the primary queue manager.
- *listener\_primary* is the name of the listener for the primary queue manager.

- *port\_no\_primary* is the port number that is used by the listener.
  - *chl\_name\_primary* is the name that you want to assign to both the server channel and the client channel.
  - *host\_IP* is the IP address of the system where the primary queue manager is installed.
- b. Run the following commands for the secondary queue manager on the primary queue manager. This is to add the connection information for the secondary queue manager to the client channel definition table file of the primary queue manager. The same agent can then connect to the secondary queue manager automatically when the primary queue manager fails over.

```
>DEFINE LISTENER(listener_secondary) TRPTYPE(TCP) PORT(port_no_secondary)
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(SVRCONN) TRPTYPE(TCP)
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)
CONNAME('host_IP(port_no_secondary)') QMNAME(qmgr_secondary)
```

where:

- *qmgr\_secondary* is the name of the secondary queue manager on the remote system. It is the same as the primary queue manager name.
  - *listener\_secondary* is the name of the listener for the secondary queue manager.
  - *port\_no\_secondary* is the port number that is used by the listener.
  - *chl\_name\_secondary* is the name that you want to assign to both the server channel and the client channel.
  - *host\_IP* is the IP address of the system where the secondary queue manager is installed.
- c. Finally, run the following command:

```
>END
>EXIT
```

- e) Create the client channel definition table file (AMQCLCHL . TAB) for the WebSphere MQ agent instance on the 1st MQ appliance.

- a. Use the **runmqsc** command or the **runmqsc -n** command to create the AMQCLCHL . TAB file for the queue manager on the 1st MQ appliance:

```
runmqsc -n
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)+
>CONNAME('host_IP_appliance1(port_no_primary)') QMNAME(qmgr_name)
```

where *host\_IP\_appliance1* is the IP address of the 1st MQ appliance; *chl\_name\_primary* and *port\_no\_primary* are the same as the ones that you defined in Step 4.

**Tip:** By default, the AMQCLCHL . TAB file is created in the *var/mqm/qmgrs/qmgr\_name/@ipcc* directory.

- b. Move the primary AMQCLCHL . TAB file to the *agent\_install\_dir/arch/mq/bin* directory on the system where the WebSphere MQ agent is installed for the primary queue manager.

- f) Create the client channel definition table file (AMQCLCHL . TAB) for the WebSphere MQ agent instance on the 2nd MQ appliance.

- a. Use the **runmqsc** command or the **runmqsc -n** command to create the AMQCLCHL . TAB file for the queue manager on the 2nd MQ appliance:

```
runmqsc -n
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)+
>CONNAME('host_IP_appliance2(port_no_secondary)') QMNAME(qmgr_name)
```

where *host\_IP\_appliance2* is the IP address of the 2nd MQ appliance; *chl\_name\_secondary* and *port\_no\_secondary* are the same as the ones that you defined in Step 4.

- b. Move the secondary AMQCLCHL . TAB file to the *agent\_install\_dir/arch/mq/bin* directory on the system where the WebSphere MQ agent is installed for the secondary queue manager.

- g) Make sure that channel authentication settings are configured appropriately for the user ID that is used to set up connection between agent instance and queue manager.
- h) Start all listeners for both remotely monitored queue manager and start all the WebSphere MQ agent instances.

- **Windows**

Perform the following steps to use the WebSphere MQ agent installed on Windows systems for remote monitoring:

- a) Install the WebSphere MQ agent on the Windows system.
- b) Create two instances of the WebSphere MQ agent for each HA queue manager.
- c) Modify the configuration file of each agent instance to enable remote monitoring by replacing the content with the following lines:

```
SET GROUP NAME (GROUP1) -
DEFAULT(YES) -
RETAINHIST(120) -
COMMAND (YES) -
MSGACCESS(DESC) -
EVENTS(REMOVE) -
ACCOUNTINGINFO(REMOVE) -
STATISTICSINFO(REMOVE)

SET MANAGER NAME(qmgr_name) REMOTE(YES)
SET AGENT NAME(agentID)
SET QUEUE NAME(*) MGRNAME(qmgr_name) QDEFTYPE(PREDEFINED)
SET CHANNEL NAME(*) MGRNAME(qmgr_name)
PERFORM STARTMON SAMPINT(300) HISTORY(NO)
```

where:

- *qmgr\_name* is the name of the HA queue manager.
- *agentID* is the ID to identify the queue manager system. It is usually the host name or the IP address of the remote system where the HA queue manager is running.

**Tip:** The configuration file name and path is *install\_dir* \TMAITM6\_x64\mq\_<instance\_name>.cfg.

- d) Create a pair of client and server channels between the primary queue manager and the WebSphere MQ agent, between the secondary queue manager and the WebSphere MQ agent on the remote system where the primary queue manager is installed.

**Remember:** You must run all the following commands before you proceed to the next step.

- a. Run the following commands for the primary queue manager:

```
M2000# mqcli
M2000(mqcli)#runmqsc qmgr_primary
>DEFINE LISTENER(listener_primary) TRPTYPE(TCP) PORT(port_no_primary)
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(SVRCONN) TRPTYPE(TCP)
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)
CONNNAME('host_IP(port_no_primary)') QMNAME(qmgr_primary)
```

where:

- *qmgr\_primary* is the name of the primary queue manager.
  - *listener\_primary* is the name of the listener for the primary queue manager.
  - *port\_no\_primary* is the port number that is used by the listener.
  - *chl\_name\_primary* is the name that you want to assign to both the server channel and the client channel.
  - *host\_IP* is the IP address of the system where the primary queue manager is installed.
- b. Run the following commands for the secondary queue manager on the primary queue manager. This is to add the connection information for the secondary queue manager to the client channel definition table file of the primary queue manager. The same agent can then connect to the secondary queue manager automatically when the primary queue manager fails over.

```
>DEFINE LISTENER(listener_secondary) TRPTYPE(TCP) PORT(port_no_secondary)
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(SVRCONN) TRPTYPE(TCP)
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)
CONNAME('host_IP(port_no_secondary)') QMNAME(qmgr_secondary)
```

where:

- *qmgr\_secondary* is the name of the secondary queue manager on the remote system. It is the same as the primary queue manager name.
- *listener\_secondary* is the name of the listener for the secondary queue manager.
- *port\_no\_secondary* is the port number that is used by the listener.
- *chl\_name\_secondary* is the name that you want to assign to both the server channel and the client channel.
- *host\_IP* is the IP address of the system where the secondary queue manager is installed.

c. Finally, run the following command:

```
>END
>EXIT
```

e) Create the client channel definition table file (AMQCLCHL . TAB) for each WebSphere MQ agent instance.

- a. Use the **runmqsc** command or the **runmqsc -n** command to create the AMQCLCHL . TAB file for the queue manager on the 1st MQ appliance:

```
runmqsc -n
>DEFINE CHANNEL(chl_name_primary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)+
>CONNAME('host_IP_appliance1(port_no_primary)') QMNAME(qmgr_name)
```

where *host\_IP\_appliance1* is the IP address of the 1st MQ appliance; *chl\_name\_primary* and *port\_no\_primary* are the same as the ones that you defined in Step 4.

- b. Create the AMQCLCHL . TAB file for the queue manager on the 2nd MQ appliance:

```
runmqsc -n
>DEFINE CHANNEL(chl_name_secondary) CHLTYPE(CLNTCONN) TRPTYPE(TCP)+
>CONNAME('host_IP_appliance2(port_no_secondary)') QMNAME(qmgr_name)
```

where *host\_IP\_appliance2* is the IP address of the 2nd MQ appliance; *chl\_name\_secondary* and *port\_no\_secondary* are the same as the ones that you defined in Step 4.

- f) Rename the two AMQCLCHL . TAB file to different names, for example, NODE1 . TAB and NODE2 . TAB. Transfer them to the directory of *install\_dir*\TMAITM6\_x64, where *install\_dir* is the installation directory of the WebSphere MQ agent.
- g) Modify the *kmqma\_instance\_name* . ini file to set the **MQCHLTAB** value to the client channel definition table file for each agent instance.  
For example, set MQCHLTAB=NODE1 . TAB in the *kmqma\_instance1* . ini file and set MQCHLTAB=NODE2 . TAB in the *kmqma\_instance2* . ini file.
- h) Open the Windows Register Editor, locate the following key of **MQCHLTAB** and change it from AMQCLCHL . TAB to the appropriate client channel definition table file name for each agent instance.
- **HKEY\_LOCAL\_MACHINE\SOFTWARE\Candle\KMQ\Ver730\instance1\Environment**  
MQCHLTAB=NODE1 . TAB
  - **HKEY\_LOCAL\_MACHINE\SOFTWARE\Candle\KMQ\Ver730\instance2\Environment**  
MQCHLTAB=NODE2 . TAB
- i) Make sure that channel authentication settings are configured properly for the user ID that is used to set up connection between agent instance and the queue manager.
- j) Start all listeners for both remotely monitored queue manager and start all the WebSphere MQ agent instances.

---

## Chapter 9. Integrating with other products and components

You can integrate other products and components with IBM Cloud Application Performance Management to provide you with a robust solution.

### Integrating with Cloud Event Management

---

Cloud Event Management provides real-time incident management across your services, applications, and infrastructure. When you set up the integration between Cloud Event Management and IBM Cloud Application Performance Management, all the events that are generated in Cloud APM are sent to Cloud Event Management.

#### About this task

Configure a webhook URL in Cloud Event Management. Then, configure Cloud APM to use the webhook URL to send events to Cloud Event Management. For additional information about Cloud Event Management, see the [IBM Cloud Event Management Knowledge Center](#).

To use the Cloud Event Management integration support, you must install the Cloud APM Version 8.1.4.0 Server Interim Fix 7 or later.

#### Procedure

1. Click **Integrations** on the Cloud Event Management **Administration** page.
2. Click **Configure an integration**.
3. Go to the **IBM Cloud Application Performance Management** tile and click **Configure**.
4. Enter a name for the integration and click **Copy** to add the generated webhook URL to the clipboard. Ensure that you save the generated webhook to make it available later in the configuration process. For example, you can save it to a file.
5. To start receiving alert information from Cloud APM, ensure that **Enable event management from this source** is set to On in Cloud Event Management.
6. Click **Save**.
7. Log in to your Cloud APM subscription.
8. Navigate to **System Configuration > Advanced Configuration > Event Manager**. For more information, see [Advanced Configuration](#).
9. Paste the webhook URL into the **Cloud Event Management Webhook** field.
10. Click **Save**.

### Integrating with IBM Tivoli Monitoring V6.3

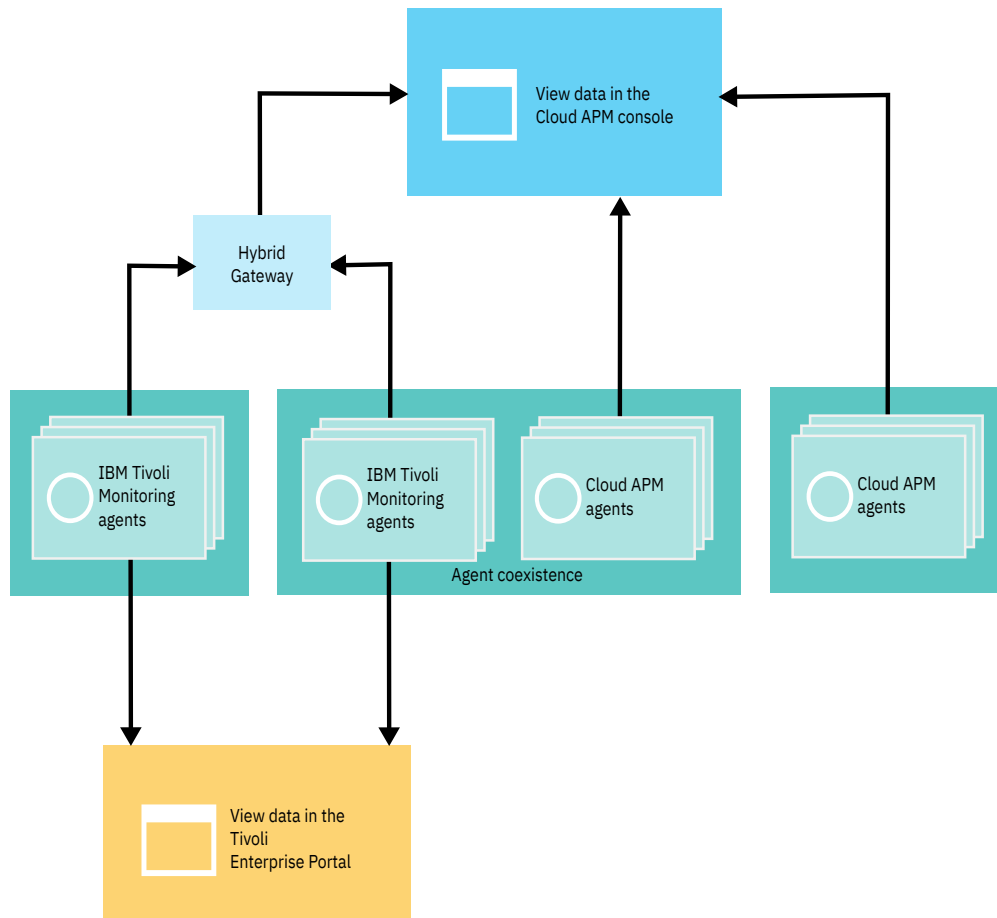

---

In an environment that includes both IBM Tivoli Monitoring and IBM Cloud Application Performance Management products, you can use these products together in several ways.

The following options are available to integrate with IBM Tivoli Monitoring:

- You can install the IBM Cloud Application Performance Management Hybrid Gateway to provide a consolidated view of managed systems from one or more Tivoli Monitoring domains and your Cloud APM domain in the Application Performance Dashboard pages. For more information about integrating agents, see [“Hybrid Gateway” on page 1043](#).
- You can configure Cloud APM agents to send history data to Tivoli Data Warehouse in order to use Tivoli Monitoring historical reporting tools. For more information about Tivoli Data Warehouse, see [“Tivoli Data Warehouse for historical reporting” on page 1055](#).

- You can install Tivoli Monitoring and Cloud APM agents on the same system. When agents coexist on the same computer, but not in the same directory, data from Cloud APM agents is available in the Cloud APM console and data from Tivoli Monitoring agents is available in the Tivoli Enterprise Portal. If coexisting agents are monitoring the same resources, certain limitations apply. For more information about agent coexistence, see [“Cloud APM agent and Tivoli Monitoring agent coexistence”](#) on page 1040.

## Cloud APM agent and Tivoli Monitoring agent coexistence

Agent coexistence is supported. You can install IBM Cloud Application Performance Management agents on the same computer where IBM Tivoli Monitoring agents are installed. However, both agent types cannot be installed in the same directory.

Cloud APM agents are referred to as version 8 agents. Tivoli Monitoring agents are referred to as version 6 or 7 agents.

When agents coexist on the same computer, data from version 8 agents is available in the Cloud APM console and data from version 6 or 7 agents is available in the Tivoli Enterprise Portal.

When version 6 or 7 agents, which coexist on the same computer as version 8 agents and monitor different resources, are integrated with the IBM Cloud Application Performance Management Hybrid Gateway, data from both agents is available in the Cloud APM console. For more information, see [“Hybrid Gateway”](#) on page 1043.

The following table lists the Tivoli Monitoring agents with documentation links:

| <i>Table 264. Documentation links for Tivoli Monitoring agents</i>                           |  |
|--|--|
| <b>Tivoli Monitoring agents</b>  | <b>IBM Knowledge Center topic collection links</b>             |
| IBM Monitoring Agent for Citrix Virtual Desktop Infrastructure                               | <a href="#">IBM Tivoli Monitoring for Virtual Environments</a> |
| IBM Tivoli Monitoring for Virtual Environments Agent for Cisco UCS                           | <a href="#">IBM Tivoli Monitoring for Virtual Environments</a> |
| IBM Tivoli Monitoring for Virtual Environments Agent for Linux Kernel-based Virtual Machines | <a href="#">IBM Tivoli Monitoring for Virtual Environments</a> |
| IBM Tivoli Monitoring for Virtual Environments Agent for VMware VI                           | <a href="#">IBM Tivoli Monitoring for Virtual Environments</a> |
| IBM Tivoli Monitoring: HMC Base Agent  | <a href="#">IBM Tivoli Monitoring</a>                          |
| IBM Tivoli Monitoring: Linux OS Agent  | <a href="#">IBM Tivoli Monitoring</a>                          |
| IBM Tivoli Monitoring: UNIX OS Agent   | <a href="#">IBM Tivoli Monitoring</a>                          |
| IBM Tivoli Monitoring: Windows OS Agent  | <a href="#">IBM Tivoli Monitoring</a>                          |
| ITCAM Agent for DB2  | <a href="#">ITCAM for Applications</a>                         |
| ITCAM Agent for HTTP Servers   | <a href="#">ITCAM for Applications</a>                         |
| ITCAM Agent for J2EE   | <a href="#">ITCAM for Applications</a>                         |
| ITCAM for Microsoft Applications: Microsoft Active Directory Agent                           | <a href="#">ITCAM for Microsoft Applications</a>               |
| ITCAM for Microsoft Applications: Microsoft Cluster Server Agent                             | <a href="#">ITCAM for Microsoft Applications</a>               |
| ITCAM for Microsoft Applications: Microsoft Exchange Server Agent                            | <a href="#">ITCAM for Microsoft Applications</a>               |
| ITCAM for Microsoft Applications: Microsoft Hyper-V Server Agent                             | <a href="#">ITCAM for Microsoft Applications</a>               |

| <i>Table 264. Documentation links for Tivoli Monitoring agents (continued)</i>  |   |
|---|---|
| <b>Tivoli Monitoring agents</b>   | <b>IBM Knowledge Center topic collection links</b>  |
| ITCAM for Microsoft Applications: Microsoft Internet Information Services Agent | <a href="#">ITCAM for Microsoft Applications</a>  |
| ITCAM for Microsoft Applications: Skype for Business Server Agent               | <a href="#">ITCAM for Microsoft Applications</a>  |
| ITCAM for Microsoft Applications: Microsoft .NET Framework Agent                | <a href="#">ITCAM for Microsoft Applications</a>  |
| ITCAM for Microsoft Applications: Microsoft SharePoint Server Agent             | <a href="#">ITCAM for Microsoft Applications</a>  |
| Monitoring Agent for Microsoft SQL Server                                       | <a href="#">ITCAM for Microsoft Applications</a>  |
| ITCAM Agent for SAP Applications  | <a href="#">ITCAM for Applications</a>  |
| ITCAM Agent for WebSphere Applications  | IBM Tivoli Composite Application Manager for Application Diagnostics for version 7.1 and earlier and in the <a href="#">ITCAM for Applications</a> for version 7.2 and later. |
| ITCAM Agent for WebSphere DataPower Appliance                                   | <a href="#">ITCAM for Applications</a>  |
| Monitoring Agent for WebSphere Message Broker                                   | <a href="#">ITCAM for Applications</a>  |
| Monitoring Agent for WebSphere MQ   | <a href="#">ITCAM for Applications Knowledge Center</a>   |
| ITCAM Extended Agent for Oracle Database  | <a href="#">ITCAM for Applications</a>  |
| ITCAM Monitoring Agent for SAP HANA Database                                    | <a href="#">ITCAM Monitoring Agent for SAP HANA Database Reference</a>  |
| ITCAM Web Response Time Agent   | <a href="#">IBM Tivoli Composite Application Manager for Transactions</a>   |

If coexisting agents are monitoring the same resources, the following scenarios are not supported:

- Both agents store data in the same IBM Tivoli Data Warehouse. For example, if both agents send data to the same Tivoli Data Warehouse, do not use the version 8 WebSphere MQ agent and the version 6 or 7 WebSphere MQ agent to monitor the same queue manager on your system. This scenario also applies to multi-instance agents. For more information, see [“Tivoli Data Warehouse for historical reporting” on page 1055](#).
- Version 6 or 7 agents are integrated with the Hybrid Gateway to display data from both agents in the Cloud APM console. For example, if version 6 or 7 agents are connected to the same Cloud APM server through the Hybrid Gateway, do not use the version 8 IBM Integration Bus agent and the version 6 or 7 Monitoring Agent for WebSphere Message Broker to monitor the same broker on your system.

If a Tivoli Monitoring agent, which is integrated with the Hybrid Gateway to display data in the Cloud APM console, is monitoring a resource and you want your Cloud APM agent to monitor that resource, complete the following steps:

1. Remove the Tivoli Monitoring agent from any applications that include it.
2. Remove the Tivoli Monitoring agent from the Tivoli Monitoring managed system group that Cloud APM is configured to use.
3. Wait at least 24 hours and then install the Cloud APM agent and add it to an application.

When multi-instance agents that coexist on the same computer are integrated with the Hybrid Gateway and monitor the same resources, use different names for each instance to display data from both agents in the Cloud APM console.

For agents with a data collector, two agents of the same type are supported. Deep-dive diagnostics, resource, and transaction tracking data is displayed in the Cloud APM console. Resource data is displayed in the Tivoli Enterprise Portal. The following agents share a data collector:

#### **Monitoring Agent for HTTP Server**

The HTTP Server agent is a Cloud APM agent and the ITCAM Agent for HTTP Servers is an IBM Tivoli Monitoring agent. If you have both agents in your environment, you can configure both data collectors on the same HTTP Server for both agents. For more information about the HTTP Server agent, see [“Configuring HTTP Server monitoring” on page 344](#).

#### **Microsoft .NET agent**

For more information about Microsoft .NET agent coexistence, see [“Enabling transaction tracking in agent coexistence environment” on page 623](#).

#### **WebSphere Applications agent**

For more information about WebSphere Applications agent coexistence, see [“Configuring WebSphere Applications agent” on page 960](#) and [“Configuring the data collector for agent coexistence environment” on page 961](#).

## **Hybrid Gateway**

To view monitoring data and events for your IBM Tivoli Monitoring and OMEGAMON agents in the Cloud APM console, you must create a managed system group and install the IBM Cloud Application Performance Management Hybrid Gateway in your Tivoli Monitoring domain, and configure communications in the Cloud APM console **Hybrid Gateway Manager**. Review the background information to help you plan for installing and configuring one or more Hybrid Gateways in your Tivoli Monitoring and Cloud APM environments.

For a video demonstration of installing and configuring the Hybrid Gateway, and then viewing data from your hybrid environment in the Cloud APM console, see [Integrating with Tivoli Monitoring - Hybrid Gateway](#).

#### **Where to install the Hybrid Gateway**

You can install the Hybrid Gateway in one or more Tivoli Monitoring domains: one hub Tivoli Enterprise Monitoring Server per domain. For details about where to install the Hybrid Gateway, see the [Preparing to install the Hybrid Gateway](#) information. For Hybrid Gateway system requirements, which includes Tivoli Enterprise Portal Server, see the [Hybrid Gateway Software Product Compatibility report](#), **Prerequisites** tab.

#### **Tivoli Monitoring and OMEGAMON agents in the Cloud APM console**

After you select the "My Components" predefined application or a defined application in the Application Performance Dashboard that includes Tivoli Monitoring or OMEGAMON managed systems (or both), you can see a summary status dashboard of all managed systems and you can see a detailed dashboard of a single managed system instance. You can also create dashboard pages in **Custom Views** tab.

You can view situation events for these agents in the **Events** tab. However, you cannot create new thresholds for Tivoli Monitoring and OMEGAMON agents in the Threshold Manager. Instead, create new situations in Tivoli Monitoring.

Not all possible Tivoli Monitoring and OMEGAMON events are available in the Events dashboard. Only events from agent nodes that can be added to an application are displayed. For example, for the Tivoli Monitoring agent for WebSphere Application Servers, events that are associated with a particular server instance are displayed, but events from the agent as a whole are not displayed.

#### **View up to 1500 managed systems from each Tivoli Monitoring domain**

The maximum number of managed systems, including subnodes, that you can view from a Tivoli Monitoring domain is 1500. By default, the limit is 200 systems. You can plan for supporting an increased amount of systems. For instructions, see [“Planning for a large number of managed systems” on page 1052](#).

The limit for all Tivoli Monitoring domains must be within the maximum supported by Cloud APM. For more information see [“Architecture overview” on page 51](#).

### Resource monitoring only

Resource monitoring is available for your Tivoli Monitoring agents. For more information about resource monitoring, see [“Offerings and add-ons”](#) on page 54 and [“Capabilities”](#) on page 60. If you have the IBM Cloud Application Performance Management, Advanced Private offering, transaction tracking and diagnostics dashboards are not available for managed systems from your Tivoli Monitoring environment.

### Tivoli Authorization Policy Server affects the availability of Tivoli Monitoring managed systems

For Tivoli Monitoring environments that include the Tivoli Authorization Policy Server, the managed systems that are available through the Hybrid Gateway are affected by the authorization policies. For more information, see [Using role-based authorization policies](#) in the Tivoli Monitoring Knowledge Center.

### Supported Tivoli Monitoring and OMEGAMON agents

For a Tivoli Monitoring agent to be available for the Hybrid Gateway, it must also be supported in Cloud APM, with the exception of the iOS and OMEGAMON agents. The available Tivoli Monitoring agents and versions are listed here:

| Product name   | Product code | Supported version   |
|--|--------------|---|
| IBM iOS agent  | KA4          | v6.30: 06.30.00.00 and later                                |
| ITCAM for Microsoft Applications: Microsoft SQL Server agent | KOQ          | 6.3.1.8, or later   |
| ITCAM Agent for WebSphere Applications                       | KYN          | 07.20.00  |
| TCAM Extended Agent for Oracle Database                      | KRZ          | 06.31.02.00   |
| ITCAM Agent for DB2  | KUD          | 07.10.00  |
| IBM Tivoli Monitoring: Linux OS Agent                        | KLZ          | v6.2.3: 06.23.01.00 and later v6.3.0: 06.30.01.00 and later |
| IBM Tivoli Monitoring: Windows OS Agent                      | KNT          | v6.2.3: 06.23.01.00 and later v6.3.0: 06.30.02.00 and later |
| IBM Tivoli Monitoring: UNIX OS Agent                         | KUX          | v6.2.3: 06.23.01.00 and later v6.3.0: 06.30.02.00 and later |
| ITCAM Agent for WebSphere MQ <sup>1</sup>                    | KMQ          | 07.10.01  |
| ITCAM Agent for WebSphere Message Broker <sup>1</sup>        | KQI          | 07.10.01  |

<sup>1</sup>Not available if you are using the Cloud APM, Base offering. For a list of agents in the Cloud APM, Base and Advanced offerings, see [Capabilities](#).

If you have custom Tivoli Monitoring agents that you created using Agent Builder, you can add support for them to the Cloud APM environment. For instructions, see [Configuring support for custom agents created with Agent Builder](#) in the [IBM Agent Builder User's Guide](#).

For a list of OMEGAMON agents that you can display in the Cloud APM console, see the [Getting started](#) topic for your release in the [IBM OMEGAMON for Application Performance Management topic collection](#) on IBM Knowledge Center.

## Preparing to install the Hybrid Gateway

To install the IBM Cloud Application Performance Management Hybrid Gateway, you must first ensure that your environment is set up correctly. Review the information to help you plan your Hybrid Gateway installation.

## Where to install the Hybrid Gateway

The Hybrid Gateway must be installed on a Red Hat Enterprise Linux v6.2 (or later) x86-64 system that has a network connection with IBM Tivoli Monitoring and IBM Cloud Application Performance Management.

The Hybrid Gateway can be installed on the same system as your Tivoli Enterprise Portal Server or on a separate system from the Tivoli Enterprise Portal Server if the systems are running on Red Hat Enterprise Linux. However, the Hybrid Gateway cannot be installed on the same system as your Cloud APM server.

A Tivoli Monitoring domain has one hub Tivoli Enterprise Monitoring Server. When your Tivoli Monitoring environment consists of multiple domains, you can install the Hybrid Gateway in more than one domain.

For system requirements related to the Hybrid Gateway, click the **Hardware** tab in the [Software Product Compatibility Report for Hybrid Gateway](#).

## Setting up the Tivoli Enterprise Portal Server for the Hybrid Gateway

For Tivoli Monitoring environments where the portal server has a heavy load, you should install a separate dedicated portal server to service the requests from the Hybrid Gateway. If you set up a separate portal server:

- You can use the same host for the portal server and the Hybrid Gateway if the portal server is running Red Hat Enterprise Linux.
- Ensure that the separate portal server has the application support for the agents whose data is displayed in the Cloud APM console.
- Ensure that Tivoli Enterprise Portal clients are not connected to the separate portal server to complete administrative tasks such as creating custom workspaces, creating situations, and creating managed system groups.

The Tivoli Enterprise Portal Server must be at V6.3 Fix Pack 6 or higher. If your portal server is at an earlier version, the integrated Tivoli Monitoring agents might not be available for adding to an application in the Cloud APM console.

The IBM Tivoli Monitoring dashboard data provider must be enabled on the Tivoli Enterprise Portal Server. For details, see [Verifying the dashboard data provider is enabled](#) in the IBM Tivoli Monitoring topic collection on IBM Knowledge Center.

## The TCP ports that must be opened on the Hybrid Gateway

The following TCP ports must be open on the Hybrid Gateway. For each port, one side sends a request and the other side provides a response. The side that initiates the connection is indicated.

- If you use HTTP to communicate with the Cloud APM server, open port 80. If you use HTTPS, open port 443. The Hybrid Gateway initiates a unidirectional connection with the Cloud APM server on either port 80 or 443. HTTP communication is the default option.

Alternatively, if the Hybrid Gateway uses a pass-through forwarding proxy to connect to the Cloud APM server, configure the Hybrid Gateway to use the proxy port instead of either port 80 or 443 for unidirectional connections that it initiates with the Cloud APM server. For instructions, see [“Using a forward proxy to communicate with the Cloud APM server” on page 1047](#).

- If you use HTTP to communicate with the portal server, open port 15200. If you use HTTPS, open port 15201. The Hybrid Gateway initiates a unidirectional connection with the portal server on either port 15200 or 15201. To use a custom port, update the value of the **Portal Server Port** setting. For more information, see [“Hybrid Gateway Manager” on page 1054](#).

Alternatively, if the Hybrid Gateway uses a pass-through forwarding proxy to connect to the portal server, configure the Hybrid Gateway to use the proxy port instead for unidirectional connections that it initiates with the portal server. Set the value of the **Pass-through Proxy Port** setting. For more information, see [“Hybrid Gateway Manager” on page 1054](#).

- For the Hybrid Gateway to listen to inbound EIF events from the Tivoli Enterprise Monitoring Server, open port 9998. The monitoring server initiates a unidirectional connection with the Hybrid Gateway on port 9998. The installation utility displays a warning if this port is not open.

## Root privileges required to run the Hybrid Gateway installation script

You must run the Hybrid Gateway installation script with root privileges. For a list of supported operating systems, see IBM Software Product Compatibility Reports for [IBM Cloud Application Performance Management - Agents V8.1](#).

## Configure the Hybrid Gateway images

Before you install the Hybrid Gateway, you must configure the Hybrid Gateway images with the connection details for the Cloud APM server. For more information, see [“Configuring the downloaded images”](#) on page 182.

## Installing the Hybrid Gateway

Download and install the IBM Cloud Application Performance Management Hybrid Gateway to view managed systems from your IBM Tivoli Monitoring domain in the Cloud APM console.

## Before you begin

Review and complete the required preparation tasks in [Preparing to install the Hybrid Gateway](#).

## Procedure

Complete the following steps to install the Hybrid Gateway in your Tivoli Monitoring domain:

1. Navigate to the directory where the configured Hybrid Gateway image is located.

The default location on the Cloud APM server is `install_dir/ccm/depot/`. (For more information, see [“Configuring the downloaded images”](#) on page 182.)

2. Enter the following command to extract the files:

```
tar -xvf
apm_hybrid_gateway_8.1.4.0.tar
```

The archive file contains a script that is used to deploy the Hybrid Gateway. The installation script is extracted into the directory and Hybrid Gateway files are extracted into subdirectories.

3. Change to the Hybrid Gateway directory and run the installation script with root user privileges:

```
cd APM_Hybrid_Gateway_Install_version
./install.sh
```

where *version* is the current version, such as 8.1.4.0.

A prerequisite scan of your environment starts and takes a few moments to complete. If any requirements are missing, a message directs you to a log file with the reason for the failure. A prerequisite, such as insufficient disk space, stops the installation. You must address the failure, and start the installation again. You can also turn off the prerequisite check as described in [Bypassing the prerequisite scanner](#).

4. After the system passes the prerequisite scan, respond to the prompt to accept the license agreement by selecting 1 for yes.

A message then instructs you to log in to the Cloud APM console and configure the Hybrid Gateway before continuing. The default profile name, which is derived from the host name, is also displayed.

5. Press Enter to accept the default name or enter a profile name.

If you already created a profile for this Tivoli Monitoring domain, use the identical name that you provided in the Hybrid Gateway Manager. If you haven't yet created a profile, you can accept the default name or provide a new name, but be sure to keep track of the name because you must use this name when you create the profile later. (See [“Configuring the Hybrid Gateway using the Cloud APM console”](#) on page 1049.)

After you press Enter, the Hybrid Gateway installation continues.

## Results

The Hybrid Gateway is installed in the `/opt/ibm/hybridgateway` directory and starts automatically. The installation log file is at `/opt/ibm/hybridgateway/logs/install-hybridgateway-timestamp.log`. The Hybrid Gateway log files are in the `/opt/ibm/wlp/usr/servers/hybridgateway/logs` directory. Be aware that until the connection to the Tivoli Enterprise Portal Server is configured, connection failures are logged.

## What to do next

- You can configure the Hybrid Gateway to use a forward proxy to communicate with the Cloud APM server. For instructions, see [“Using a forward proxy to communicate with the Cloud APM server” on page 1047](#).
- You can check the status of the Hybrid Gateway with the following command: `install_dir/hybridgateway/bin/hybridgateway.sh status`. For more options, see [“Managing the Hybrid Gateway” on page 1054](#).
- If you haven't already created the managed system group for the Hybrid Gateway, follow the instructions in [“Creating the managed system group” on page 1047](#).
- If you haven't already created a Hybrid Gateway profile for the Tivoli Monitoring domain, follow the instructions in [“Configuring the Hybrid Gateway using the Cloud APM console” on page 1049](#).
- If your Tivoli Monitoring environment has more than one hub domain, you can install the Hybrid Gateway in other domains. Repeat the steps in this procedure to install the Hybrid Gateway in another Tivoli Monitoring domain.

## Using a forward proxy to communicate with the Cloud APM server

You can configure the IBM Cloud Application Performance Management Hybrid Gateway to use a forward proxy to communicate with the Cloud APM server.

### Procedure

1. On the host where you installed the Hybrid Gateway, edit the `/opt/ibm/wlp/usr/servers/hybridgateway/bootstrap.properties` file:

- If the Hybrid Gateway uses HTTP to communicate with the Cloud APM server, add the lines:

```
http.proxyHost=proxy_host
http.proxyPort=proxy_port
```

- If the Hybrid Gateway uses HTTPS to communicate with the Cloud APM server, add the lines:

```
https.proxyHost=proxy_host
https.proxyPort=proxy_port
```

where *proxy\_host* is the host name or IP address of the proxy, accessible from the Hybrid Gateway host, and *proxy\_port* is the port of the proxy.

2. Restart the Hybrid Gateway.

## Creating the managed system group

Use the Object group editor in the Tivoli Enterprise Portal client to create a managed system group of managed systems that you want to view in the Cloud APM console.

### Before you begin

- The types of IBM Tivoli Monitoring and OMEGAMON agents that you can include in the managed system group must be one of the supported agents. For example, for Tivoli Monitoring, some supported agents are Monitoring Agent for Oracle Database or Monitoring Agent for Linux OS.

For the current list of supported Tivoli Monitoring agents, see [“Supported Tivoli Monitoring and OMEGAMON agents”](#) on page 1044. For a list of OMEGAMON agents that you can display in the Cloud APM console, see the Getting started topic in the [IBM OMEGAMON for Application Performance Management](#) topic collection on IBM Knowledge Center.

- The Tivoli Monitoring and OMEGAMON agents must be connected to the same IBM Tivoli Monitoring infrastructure. If your environment has multiple Tivoli Monitoring domains, create a managed system group for each hub Tivoli Enterprise Monitoring Server for which a Hybrid Gateway is installed.
- By default, you can add up to 200 managed systems to the managed system group for viewing from the Tivoli Monitoring domain in the Application Performance Dashboard. You can increase the limit to as many as 1500 systems by taking several planning steps. For more information, see [“Planning for a large number of managed systems”](#) on page 1052. If you have multiple Hybrid Gateways for Tivoli Monitoring a environment with multiple hubs, the managed system group for each domain must be within the maximum supported by Cloud APM. For more information see [“Architecture overview”](#) on page 51.
- The default for handling subnodes changed in the Cloud APM Version 8.1.4 release. In previous releases, if you had agents with subnodes such as the WebSphere Applications agent, you had to assign the managing node to the managed system group and all the subnodes were included automatically. Although, you assigned one managing node to the managed system group, any subnodes were included in the count towards the managed system maximum.

In the Cloud APM Version 8.1.4 release and later, subnodes whose metric data that you want to display in the Cloud APM console must be specifically assigned to the managed system group. The managing agent is discovered automatically if any of its subnodes are clearly assigned to the managed system group. For monitoring applications based on subnodes, Cloud APM might need to query the managing agent for information that is required to clearly identify the monitoring resources that appear in the Cloud APM dashboard navigator. It is for this reason that, with the current version of discovery mode, the managing agent is included automatically and at least one associated subnode is assigned to the managed system group configured for the Hybrid Gateway to use. The current discovery mode supports precise control over the subnode resources that can be viewed in the Cloud APM console and is better aligned with how Cloud APM applications are constructed, particularly for applications that involve large sets of subnode resource instances. Always use the current default discovery mode when you are integrating OMEGAMON agents with Cloud APM.

You can specify which discovery mode version the Hybrid Gateway uses by assigning the appropriate value to an external property called `MSN_DISCOVERY_MODE`, which is processed by the Hybrid Gateway during initialization. To control which discovery mode is used by the Hybrid Gateway, add the `MSN_DISCOVERY_MODE` property (or change its current value) in the following properties file on the system where the Hybrid Gateway is installed and then restart the Hybrid Gateway.

```
HG_install_dir/wlp/usr/servers/hybridgateway/bootstrap.properties
```

The possible values are for the `MSN_DISCOVERY_MODE` property are:

- `MSN_DISCOVERY_MODE=1` forces the Hybrid Gateway to use the original agent discovery mode where all subnodes are discovered automatically for any managing agent that is assigned to the Tivoli Monitoring managed system group.
- `MSN_DISCOVERY_MODE=2` forces the Hybrid Gateway to use the new default agent discovery mode where only the subnodes that are clearly assigned to the managed system group are queried by the Hybrid Gateway. The associated managing agent or agents are discovered automatically.
- If you prefer to create the managed system group with the **`tacmd createsystemlist`** and **`tacmd editsystemlist`** IBM Tivoli Monitoring commands, see the *IBM Tivoli Monitoring Command Reference* ([https://www.ibm.com/support/knowledgecenter/SSTFXA\\_6.3.0/com.ibm.itm.doc\\_6.3/cmdref/itm\\_cmdref.htm](https://www.ibm.com/support/knowledgecenter/SSTFXA_6.3.0/com.ibm.itm.doc_6.3/cmdref/itm_cmdref.htm)) for information about how to run the commands.

## Procedure

Complete these steps to create a managed system group in the Tivoli Enterprise Portal client.

1. Start the Tivoli Enterprise Portal client with a user ID and password that has full access to all the managed system types (**Allowed Applications** is set to **All Applications** for the user ID.)

2. Click  **Object group editor**.
3. Expand the  **Managed system** object and select  **All Managed Systems** to combine multiple agent types (such as Windows OS and Oracle) in the managed system group. If you prefer that the managed system group contain only one monitoring agent type, such as Linux OS or WebSphere Applications, select the agent type.
4. Click  **Create new group** and enter a name for the managed system group.

The name can consist of letters and numbers, and must have no spaces, punctuation, or special characters other than the underscore (\_).

After you click **OK**, the new managed system group is displayed in the managed system folder.
5. Select the managed systems from the **Available Managed Systems** list and  to move them to the **Assigned** list.

You can select multiple managed systems by holding down the Ctrl key while you are clicking each managed system. After you select a managed system, you can use press Shift+click to select all managed systems between this selection and the first selection.
6. After you added managed systems to the group, click **OK** to save your changes and close the Object group editor.

## What to do next

- After you create the managed system group and installed the Hybrid Gateway, you must configure the Hybrid Gateway in the Cloud APM console.
- For the configuration, specify the managed system group name that you created, the Tivoli Enterprise Portal user ID that is allowed access to all agent types, and the host name and port of the Tivoli Enterprise Portal Server.
- For installation instructions, see [“Installing the Hybrid Gateway” on page 1046](#).
- For configuration instructions, see [“Configuring the Hybrid Gateway using the Cloud APM console” on page 1049](#).

## Configuring the Hybrid Gateway using the Cloud APM console

Use the **Hybrid Gateway Manager** page in the Cloud APM console to configure the IBM Cloud Application Performance Management Hybrid Gateway to connect to the Tivoli Enterprise Portal Server and to specify the managed system group. You can create a Hybrid Gateway profile for each hub Tivoli Enterprise Monitoring Server in your environment.

### Procedure

Complete the following steps to configure the Hybrid Gateway in the Cloud APM console.

1. If you are not already logged in to the Cloud APM console, log in now.

(See [“Starting the Cloud APM console” on page 1109](#).)
2. Click  **System Configuration > Hybrid Gateway Manager**.

The page displays with a table of any the Hybrid Gateways that were configured for your Tivoli Monitoring domains. If a profile with a blank name is displayed, it is for the Hybrid Gateway that was installed before the V8.1.4 release. For more information, see [“Profile Name” on page 1054](#).
3. Click  **Add** to open the **Add Hybrid Gateway** window, enter a new name in the **Profile Name** field, and click **Add**.

If you already installed the Hybrid Gateway on the Tivoli Monitoring domain, be sure to use the same name that you provided or accepted during Hybrid Gateway installation. The profile name entered during installation and the name you enter here must be an exact match.

The **Edit Hybrid Gateway** window opens.
4. In the **Managed System Group Name** field, enter the name of the manage system group for the Hybrid Gateway.

This is the name that you used in [“Creating the managed system group”](#) on page 1047.

5. Specify the address, port, and web communications protocol of the Tivoli Enterprise Portal Server:

| Option                         | Description   |
|--------------------------------|---|
| <b>Portal Server Host Name</b> | Enter the portal server host IP address or fully qualified host or domain name.   |
| <b>Portal Server Port</b>      | Enter the port number that is used by the portal server for web communications. The default port is 15200 for HTTP or 15201 for HTTPS. A value of 0 sets the port to the default 15200 for HTTP or 15201 for HTTPS. |
| <b>Portal Server Protocol</b>  | Select the <b>HTTP</b> Internet Protocol or the secure <b>HTTPS</b> Internet Protocol to connect to the portal server.  |

6. Complete the **Portal Server User Name** and **Portal Server Password** fields with the logon user name and corresponding password for starting the Tivoli Enterprise Portal client.

The user ID must have access to all monitoring agent types (**Allowed Applications** is set to **All Applications**), such as the sysadmin ID. For more information, see [Administer Users](#) in the Tivoli Monitoring IBM Knowledge Center.

7. If access to the portal server goes through a proxy server, specify the address, port, and web protocol:

| Option                              | Description  |
|-------------------------------------|--|
| <b>Pass-Through Proxy Host Name</b> | Enter the IP address or fully qualified name of the proxy host system.               |
| <b>Pass-Through Proxy Port</b>      | Enter the port number of the proxy host system.                                      |
| <b>Pass-Through Proxy Protocol</b>  | Select the protocol that is used for communications through the proxy: HTTP or HTTPS |

## Results

After you click **Save**, a connection is established with the Hybrid Gateway service and the managed systems from your Tivoli Monitoring domain are discovered. The managed system group is polled every 5 minutes for resource monitoring data.

## What to do next

- You must configure Tivoli Monitoring to interact with Cloud APM. For instructions, see [“Configuring Tivoli Monitoring to integrate with Cloud APM”](#) on page 1051.
- You can repeat these steps to add a profile for each Tivoli Monitoring domain that you want to monitor managed systems from Cloud APM.
- You can manage existing profiles with the **Hybrid Gateway Manager** tools:

Select a Hybrid Gateway and click  **Edit** to open the **Edit Hybrid Gateway** window.

Select a Hybrid Gateway that you no longer want and click  **Delete**. After you confirm that you want to delete the Hybrid Gateway, the profile is permanently removed.

Click a column heading to sort the table by that column; Ctrl + Click another column to add a secondary sort.

Click inside the filter text box  and type the beginning of the value to filter by. As you type, the rows that do not fit the criteria are filtered out. To clear the filter, click the  in the filter box

  or press the Backspace key.

## Configuring Tivoli Monitoring to integrate with Cloud APM

To integrate your IBM Tivoli Monitoring domain with Cloud APM, you must complete such tasks as configuring the Tivoli Enterprise Portal Server and configuring the hub Tivoli Enterprise Monitoring Server.

### Procedure

For each Tivoli Monitoring domain that you have a Hybrid Gateway installed on, complete these steps:

1. Configure the Tivoli Enterprise Portal Server to enable the dashboard data provider.

The data provider is required to integrate Cloud APM with the Hybrid Gateway. For instructions, see the following topics:

-  [Windows: Installing the portal server \(step 16c\).](#)
-   [Configuring the portal server on Linux or AIX: command-line procedure \(step 14\).](#)

If you are using the Hot Standby feature, you must specify a domain override. The Hybrid Gateway uses the domain name to collect data from both hub monitoring servers, regardless of the hub to which the portal server is connected.

2. If you want to view situation events from Tivoli Monitoring agents in the Cloud APM console, configure the hub monitoring server for one of the following scenarios:
  - To send events to the Hybrid Gateway only.
  - To send events to the Hybrid Gateway and additional EIF receivers such as Netcool/OMNIBus servers.

Complete one of the following steps depending on your applicable scenario.

- a) To configure the hub Tivoli Enterprise Monitoring Server to send events to the Hybrid Gateway only, complete the steps in the [Configuring the hub monitoring server to forward events](#) topic.  
Specify port number 9998 for the **ServerPort** parameter.  
Cloud APM does not forward Tivoli Monitoring events to Netcool/OMNIBus. If you want to view Tivoli Monitoring events in Cloud APM and in Netcool®/OMNIBus, you must configure Tivoli Monitoring to send the events to both systems.
- b) To configure the hub Tivoli Enterprise Monitoring Server to send events to the Hybrid Gateway and another EIF receiver such as a Netcool/OMNIBus server, configure the default EIF receiver using the steps in the [Configuring the hub monitoring server to forward events](#) topic.  
The topic also provides information about creating additional EIF destinations by using the **tacmd createEventDest** command. Specify port 9998 as the EIF port number for the Hybrid Gateway destination.
- c) Configure any situations that exist for the agents in the Hybrid Gateway managed system group to ensure that the situation events are sent to the EIF destination for the Hybrid Gateway. For instructions, see the [Specifying which situations forward events to Netcool/OMNIBus](#) topic.

### What to do next

Review the Application Performance Dashboard to confirm that the managed systems from your Tivoli Monitoring domain are passed through the Hybrid Gateway:

1. Click  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard.
2. In the summary box for "My Components", click  **Components** to open the status summary dashboard for all component-managed systems (except for the WebSphere Applications agent). If you don't have a "My Components" application, add an application as described in ["Managing applications" on page 1269](#).
3. Look for managed systems from your Tivoli Monitoring domain, indicated by an  **ITM** (IBM Tivoli Monitoring) domain icon in the status summary group widget title. If any managed systems are

missing, go to the [Cloud Application Performance Management Forum](#) and search on "Hybrid Gateway".

You can create applications with managed systems from your Tivoli Monitoring domains and include managed systems from your Cloud APM domain. For more information, see [“Managing applications”](#) on page 1269.

## Configuring support for custom agents created with Agent Builder

If you have custom IBM Tivoli Monitoring agents that you created using Agent Builder, you can use the new version of Agent Builder to create support files for Cloud APM. Then install them on the Cloud APM server to display information from your agent in the Cloud APM console.

### Procedure

1. If you have not done so previously, install Agent Builder on any computer. For instructions, see *Installing and starting Agent Builder* in the [IBM Agent Builder User's Guide](#).
2. Copy the full Agent Builder source subdirectory into the workspace directory of your Agent Builder installation.
3. Start Agent Builder and select your agent in the Agent Editor. For instructions, see *Using the Agent Editor to modify the agent* in the [IBM Agent Builder User's Guide](#).
4. Click the Dashboards link on the summary page or right-hand navigation panel, then configure the Cloud APM dashboards and resources. For instructions, see *Preparing the agent for IBM Cloud Application Performance Management* in the [IBM Agent Builder User's Guide](#).
5. Create the agent image in any directory. Do not select **Create a ZIP file** or **Create a TAR file**. For instructions, see *Creating the agent image* in the [IBM Agent Builder User's Guide](#).
6. In the agent image directory, find the `support/product_code_sda_version.jar` file. Copy this file to the Cloud APM server, into the `/opt/ibm/ccm` directory.
7. On the Cloud APM server, in the `/opt/ibm/ccm` directory, run the following command:

```
install_app_support.sh [-force] [-verbose] filename.jar
```

where `filename.jar` is the name of the file that you copied.

The `-force` argument installs support for this agent even if support for the same or newer version of the agent is already installed.

The `-verbose` argument displays detailed progress messages.

### Results

If you have installed the Hybrid Gateway and included your custom agent in the managed system group for Cloud APM, within 30 minutes the Cloud APM console displays information from the agent.

### What to do next

Restart the `apmui` service on the Cloud APM server so that agent online help updates are displayed in the Cloud APM console. The `apmui` service is restarted by using the `apm restart apmui` command.

## Planning for a large number of managed systems

The maximum number of managed systems that you can view from your IBM Tivoli Monitoring domain is 1500. If you include an agent that has subnodes in the managed system group that you created for the Hybrid Gateway profile, all the subnodes, as well as the agent, count towards the limit. By default, this limit is 200 managed systems, but you can take a number of planning steps to extend the limit. The limit for all Tivoli Monitoring domains must be within the maximum supported by Cloud APM. For more information see [“Architecture overview”](#) on page 51.

- Set the value of the Tivoli Enterprise Portal Server **KFW\_REPORT\_NODE\_LIMIT** environment variable to a number greater than or equal to the number of managed systems for the Hybrid Gateway. The default value is 200. For instructions, see [Tivoli Enterprise Portal Server configuration settings](#). If the managed systems exceed this setting, the Tivoli Enterprise Portal Server KfwServices message log displays a message similar to the following example:  
56C6246F.0000-10:ctreportmanager.cpp,2864,"CTReport::Manager::executeDefinitionOnDual") Query is targeting 1497 nodes which exceeds the current limit of 200 nodes.
- If you are viewing a large number of systems, performance might degrade depending on the type of agents, the network latency between the Hybrid Gateway and the managed systems, and the size of the environment monitored by each agent (amount of data collected and posted). To avoid this effect, select only the agents that provide necessary data and ensure fast networking connectivity between the monitored systems and the Hybrid Gateway host.
- As the network latency increases, the time to collect data from a given number of agents increases. The Hybrid Gateway attempts to gather data from each agent every 5 minutes. If the time to collect data from all agents exceeds 5 minutes, the Hybrid Gateway misses data samples, and therefore metrics are unavailable for some of the managed systems on the Application Performance Dashboard pages.
- To compensate for very slow network speeds, you can try increasing the number of threads used by the Hybrid Gateway to gather data samples. The **MAX\_COLLECTOR\_THREADS** parameter of the Hybrid Gateway bootstrap.properties file controls the thread number. The default value is 50.

## Uninstalling the Hybrid Gateway

If you no longer want to view the IBM Tivoli Monitoring managed systems in the Cloud APM console, uninstall the IBM Cloud Application Performance Management Hybrid Gateway.

### Procedure

1. In the Hybrid Gateway *install\_dir*/hybridgateway/bin directory (such as /opt/ibm/hybridgateway/bin), run the following command:

```
./hybridgateway.sh uninstall
```

The Hybrid Gateway is removed and a message confirms that it has been uninstalled successfully. If you have any applications in the Cloud APM console that include hybrid agents, the hybrid agents continue to appear until the monitoring infrastructure processes their removal.

2. In the Cloud APM console, Click  **System Configuration > Hybrid Gateway Manager**.
3. Select the Hybrid Gateway profile that you no longer want and click  **Delete**.

After you confirm that you want to delete the Hybrid Gateway, the profile is permanently removed.

### What to do next

- To remove any hybrid agent managed systems from an application in the Cloud APM console, follow the instructions in [“Managing applications” on page 1269](#) for editing an application.
- If, instead of successful removal of the software, you get an error message similar to the one shown in this example, review the log file for the possible causes:

```
error: Failed dependencies:
ibm-java-x86_64-jre is needed by (installed) smai-kafka-00.08.00.00-1.el6.x86_64
Uninstallation failed. The uninstaller was unable to remove some of the components,
please inspect the
log file ("/tmp/hybridgateway/logs/uninstall-hybridgateway-20150228080551.log")
for more information.
```

The error shown in the example occurred because the ibm-java-x86\_64-jre is required by an externally installed package on the system. The installer does not remove the JRE because it would likely render the other package nonfunctional. As a workaround, uninstall the products with the dependency on ibm-java-x86-64-jre before uninstalling the Hybrid Gateway.

## Managing the Hybrid Gateway

Use the commands available for the IBM Cloud Application Performance Management Hybrid Gateway service to start or stop it, to check the status, to uninstall the Hybrid Gateway, and to collect the log files if instructed by IBM Support.

### About this task

These steps assume that the Hybrid Gateway installation directory is `/opt/ibm/`. On the system where the Hybrid Gateway is installed, take any of the following steps from the command prompt:

### Procedure

- To start the Hybrid Gateway service, enter **`/opt/ibm/hybridgateway/bin/hybridgateway.sh start`**.
- To stop the Hybrid Gateway service, enter **`/opt/ibm/hybridgateway/bin/hybridgateway.sh stop`**.
- To check the status of the Hybrid Gateway service, enter **`/opt/ibm/hybridgateway/bin/hybridgateway.sh status`**.
- To uninstall the Hybrid Gateway, enter **`/opt/ibm/hybridgateway/bin/hybridgateway.sh uninstall`**.  
See also [“Uninstalling the Hybrid Gateway”](#) on page 1053.
- To check the Hybrid Gateway log files, go to `/opt/ibm/wlp/usr/servers/hybridgateway/logs`.
- To collect the Hybrid Gateway log files for IBM Support, enter **`/opt/ibm/hybridgateway/collectLogs.sh`**.

The log files are collected and a message shows the location of the compressed log files and asks you to return them to IBM Support.

## Hybrid Gateway Manager

Configure the IBM Cloud Application Performance Management Hybrid Gateway for viewing monitoring data from your IBM Tivoli Monitoring domain in the Cloud APM console. You can create a Hybrid Gateway profile for each hub Tivoli Enterprise Monitoring Server in your environment.

After you click  **System Configuration** > **Hybrid Gateway Manager**, the page is displayed with a list of the defined Hybrid Gateways.

The page has a table of all the hybrid gateways that were configured for your Tivoli Monitoring domains, and has tools for managing the Hybrid Gateway profiles:

-  **Add** opens the **Add Hybrid Gateway** window for naming the new profile. After you enter a name and click **Add**, the **Edit Hybrid Gateway** window opens.
- Select a hybrid gateway and click  **Edit** to open the **Edit Hybrid Gateway** window.
- Select a hybrid gateway that you no longer want and click  **Delete**. After you confirm that you want to delete the hybrid gateway, the profile is permanently removed.
- Click a column heading to sort the table by that column; Ctrl + Click another column to add a secondary sort.
- Click inside the filter text box  and type the beginning of the value to filter by. As you type, the rows that do not fit the criteria are filtered out. To clear the filter, click the  in the filter box  or press the Backspace key.

The mandatory fields that you must populate to configure the Hybrid Gateway are marked with an asterisk (\*) in the **Edit Hybrid Gateway** window.

### Profile Name

The given name for the Hybrid Gateway profile, which can be up to 128 letters, numbers and underscores (\_).

The profile name is requested during Hybrid Gateway installation. If you already installed the Hybrid Gateway on the Tivoli Monitoring domain, use the name that you provided or accepted during Hybrid Gateway installation.

Older versions of the Hybrid Gateway don't use a named profile to access their configuration data. If you installed the Hybrid Gateway before the Cloud APM, Private V8.1.4 release, you have a special, unnamed (blank) profile name. Only one older version of the Hybrid Gateway is allowed to connect to the Cloud APM server. If you configured the earlier version Hybrid Gateway, the unnamed profile shows the configured values. If you did not configure the earlier version Hybrid Gateway, the unnamed profile shows the default values. You can keep the unnamed profile, or delete and add it again later as needed, and it can be used only for the V8.1.3 (or earlier) version Hybrid Gateway.

#### **Managed System Group Name**

The Tivoli Enterprise Portal Server managed system group that you created for viewing supported monitoring agents in the Cloud APM console. Any monitoring agent types that are not supported by your Cloud APM offering are not shown in the console regardless of their inclusion in the managed system group.

For guidance and limitations when creating the managed system group for hybrid enablement, see .

#### **Portal Server Host name**

The Tivoli Enterprise Portal Server host IP address or fully qualified domain name.

#### **Portal Server Port**

The port number used by the Tivoli Enterprise Portal Server for communications. The default port is 15200 for HTTP or 15201 for HTTPS. A value of 0 sets the port to the default 15200 for HTTP or 15201 for HTTPS.

#### **Portal Server Protocol**

Determines whether to use the HTTP Internet protocol or the secure HTTPS protocol to connect to the Tivoli Enterprise Portal Server. Default: `http`.

#### **Portal Server User Name**

The user name for starting the Tivoli Enterprise Portal client. This user ID must have access to all monitoring agent types (**Allowed Applications** is set to **All Applications**). For more information, see [Administer Users](#) in the Tivoli Monitoring Knowledge Center.)

#### **Portal Server User Password**

The password that is associated with the Tivoli Enterprise Portal login user name.

#### **Pass-Through Proxy Host Name**

Used if the Tivoli Enterprise Portal Server communicates through a pass-through proxy server. Enter the IP address or fully qualified name of the proxy host system.

#### **Pass-Through Proxy Port**

Used if the Tivoli Enterprise Portal Server communicates through a pass-through proxy server. Enter the port number for communicating with the proxy.

#### **Pass-Through Proxy Protocol**

Used if the Tivoli Enterprise Portal Server communicates through a pass-through proxy server. Enter the protocol used for communications through the proxy. Default: `http`.

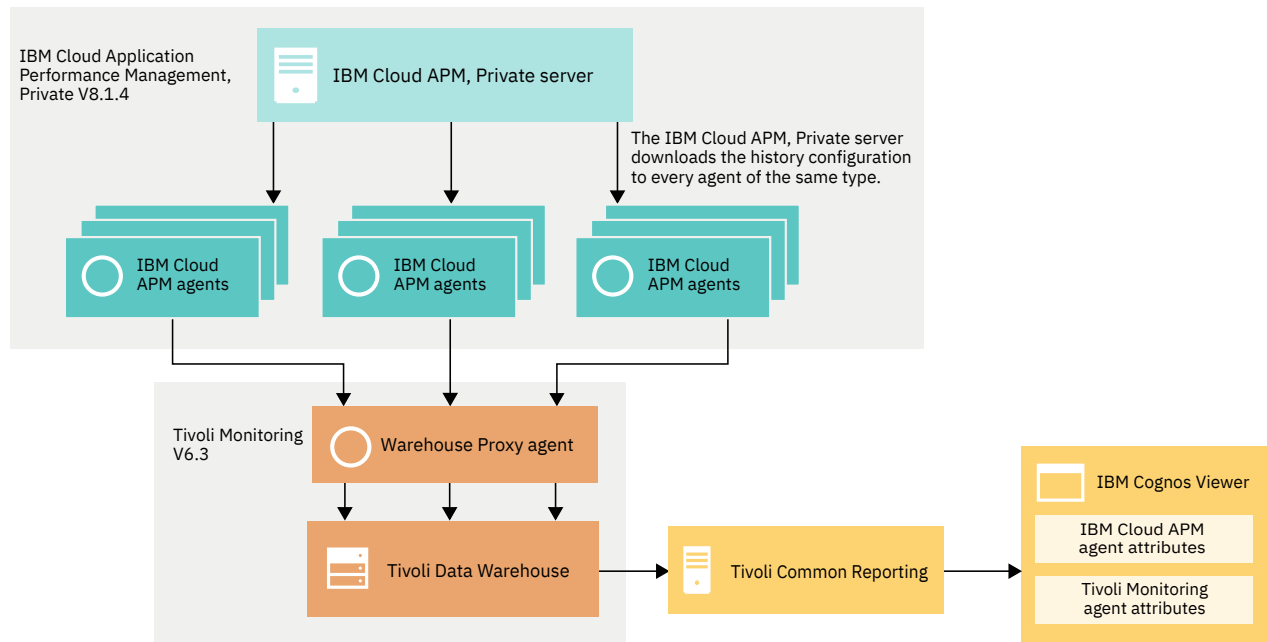

The Tivoli Monitoring agents that you are viewing in the Cloud APM console are in your IBM Tivoli Monitoring environment. You can view them in the Application Performance Dashboard pages, but you cannot create thresholds for these agents in the **Threshold Manager**.

## **Tivoli Data Warehouse for historical reporting**

When your managed environment includes an IBM Tivoli Monitoring domain with a Tivoli Data Warehouse, you can send data samples to the data warehouse from Cloud APM agents. You can then access the data to generate Cognos reports in Tivoli Common Reporting. For example, if you have Windows OS agents in your Tivoli Monitoring and Cloud APM domains, you can generate a Windows OS report of historical data from both domains.

To enable sending historical data to Tivoli Data Warehouse, you must complete configuration for each agent type. You configure the Warehouse Proxy agent address, the data sets to collect samples from, the frequency of data collection, and how long to keep the data locally.

This configuration is stored on the Cloud APM server. The server distributes the configuration information to the agents. The agents send historical data to the Warehouse Proxy agent, which stores it in Tivoli Data Warehouse.

In your IBM Cloud Application Performance Management environment, historical data is available for viewing up to 24 hours and comparing with up to 7 days in dashboards with historical charts and tables, described in “Adjusting and comparing metrics over time” on page 1263. When you also have an IBM Tivoli Monitoring environment, you can save historical data from Cloud APM agents in your Tivoli Data Warehouse for long term storage. The data can then be retrieved from the data warehouse for generating reports with Tivoli Common Reporting and other applications.

For every agent that can send historical data to Tivoli Data Warehouse, you can find a sample history configuration file on your Cloud APM server. To configure agents of this type to send data to Tivoli Data Warehouse, create a copy of this file, modify it to provide the necessary configuration information, and save it on the server.

## Eligible Cloud APM agents for historical data collection

Tivoli Data Warehouse integration is available only for agents that also exist in Tivoli Monitoring. Only the data sets (attribute groups) that are also available in Tivoli Monitoring can be sent to Tivoli Data Warehouse.

The following agents are eligible:

- Monitoring Agent for Cisco UCS (v6)
- Monitoring Agent for Citrix Virtual Desktop Infrastructure (vd)
- Monitoring Agent for DataPower (bn)
- Monitoring Agent for Db2 (ud)
- Monitoring Agent for HMC Base (ph)
- Monitoring Agent for IBM Integration Bus (qi)
- Monitoring Agent for Linux KVM (v1)
- Monitoring Agent for Linux OS (lz)
- Monitoring Agent for Microsoft Active Directory (3z)

- Monitoring Agent for Microsoft Cluster Server (q5)

## Configuring historical data collection for Performance Management agents

Sample history files for agents are available on your Cloud APM server. Use the sample file for your agent as the basis for creating the history configuration xml file on the Cloud APM server. The server propagates the configuration to all agents of this type. The history file specifies the Warehouse Proxy agent address, the data sets to collect samples from, the frequency of data collection, and how long to keep the data locally.

### Before you begin

Before configuring any Cloud APM agent to send data to Tivoli Data Warehouse, ensure that the equivalent Tivoli Monitoring agent is installed in your Tivoli Monitoring environment. Otherwise, reporting functions can fail.

### About this task

For every agent that can send historical data to Tivoli Data Warehouse, you can find a sample history configuration file on your Cloud APM server. Create your configuration file by copying the sample file and editing the copy.

The file includes the data sets (attribute groups) of the agent that can send historical data to Tivoli Data Warehouse. If a particular data set that you are interested in does not exist in the sample file, it is likely because this exact data set does not also exist in the Tivoli Monitoring V6.3 agent product or it is not available for historical data collection. You can remove some of the data sets if you do not want to collect data for them.

The file also contains other sample or default settings. You must modify these settings to configure historical data collection.

Do not modify the sample history configuration file, because the next Cloud APM server upgrade installation can overwrite it. Instead, create a copy of the file.

### Procedure

1. Locate the *product\_name\_sample\_history.xml* file on the Cloud APM server system:

```
install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/data_source/pc
```

where *install\_dir* is */opt/ibm* or the directory specified during server installation and *pc* is the two-character product code. The product codes are shown in parentheses after the product name in [“Eligible Cloud APM agents for historical data collection” on page 1056](#).

2. Create a copy of the `product_name_sample_history.xml` file in the same directory with the following name:

```
pc_history.xml
```

where `pc` is the two-character product code. For example, `ud_history.xml` for the Db2 agent and `lz_history.xml` for the Linux operating system agent.

**Tip:** A file with the name `pc_history.xml` already exists by default in the location. You can overwrite the file with your new configuration file.

3. Open `pc_history.xml` in a text editor.
4. Specify the Warehouse Proxy agent location. The default value is:

```
<WAREHOUSE LOCATION="ip.pipe:#netaddress[port#]" />
```

Modify the following parts of this value:

#### **ip.pipe:**

For non-secure RPC communication between the agent and the Warehouse Proxy Agent, leave at `ip.pipe:.` For secure RPC communication, change to `ip.spipe:.`

**Attention:** Because of certificate compatibility issues, secure communication (`ip.spipe`) between Cloud APM agents and the Warehouse Proxy agent requires significant additional configuration. For instructions, see [“Configuring secure communications for historical data collection” on page 1060](#). If you want to enable integration with Tivoli Data Warehouse without additional configuration procedures, use the non-secure `ip.pipe` setting.

#### **#netaddress**

Set the IP address or fully qualified host name of the system where the Warehouse Proxy agent is installed. All hosts where your Cloud APM agents run must be able to establish a direct outbound connection to the system using this address or host name.

**Attention:** If you use an IP address, add the `#` sign before the address. If you use a fully qualified host name, make sure the `#` sign is not present before the host name.

#### **port#**

Enter the listening port of the Warehouse Proxy agent. The default port is 63358 for the `ip.pipe` protocol and 65100 for the `ip.spipe` protocol.

**Tip:** You can find the value of the warehouse location string in the RAS1 log file on the Warehouse Proxy agent host. The RAS1 log file is located in the `Install_Home/logs` directory. The file name format is `hostname_hd_timestamp-#.log` (for example, `myhost01_hd_56d4db3c-01.log`). Search the log file for the `register_interface` message.

A RAS1 log message can look like this:

```
"register_interface") Registering "Candle_Warehouse_Proxy": ip.pipe:#9.48.147.34[63358]
```

In this example, set the following value in the file:

```
<WAREHOUSE LOCATION="ip.pipe:#9.48.147.34[63358]" />
```

5. If you want to specify more than one destination or protocol, separate each with a semi-colon (;). For example, you can set the value:

```
<WAREHOUSE LOCATION="ip.spipe:#9.11.123.45[65100];ip.pipe:#9.11.123.45[63358];ip.pipe:tdw.example.com[63358]" />
```

In this case, when an agent initiates communications with the Warehouse Proxy agent, it attempts secure RPC communication, then falls back to non-secure RPC communication.

6. Optional: Delete the HISTORY EXPORT rows of the data sets that you do not want to collect history from:

```
<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="TABLENAME"/>
```

where *TABLENAME* is the data set name.

For example, if you do not want to send Linux\_IP\_Address data samples to the Tivoli Data Warehouse, delete the `<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="Linux_IP_Address"/>` row.

Data sets are described in the "Attributes" section of the agent help and the reference PDF.

7. In the rows that remain, specify the interval for exporting the data, the interval for collecting the data, and how long to keep the collected samples locally:

#### **EXPORT**

This parameter specifies the interval in minutes for exporting historical data to the Tivoli Data Warehouse. Valid export intervals are 15, 30, and values divisible by 60; an interval greater than 60 could be 120, 180, 240, and so on, up to 1440. The export interval must also be divisible by the **INTERVAL** parameter value. If you enter an invalid value, no historical data is collected nor exported for the specified data set. Default: 60 minutes.

#### **INTERVAL**

This parameter specifies the historical data collection interval in minutes. The minimum collection interval is 1 minute and the maximum is 1440 (24 hours). Valid intervals must divide evenly into 60 or are divisible by 60: 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, and 30; an interval greater than 60 could be 120, 180, 240, and so on, up to 1440. If you enter an invalid value, no history is collected for the specified data set. Default: 15.

#### **RETAIN**

This parameter defines the short-term history data retention period in hours, with a one-hour minimum. There is no limit other than that imposed by storage space on the system. After the retention limit has been reached, the agent deletes oldest data samples as new samples arrive. This retention period ensures that, if the agent loses communication with the Tivoli Data Warehouse for some time, history data is not lost. Default: 6 hours.

8. Save the *pc\_history.xml* file.
9. Repeat these steps for each agent that you want to configure for historical data collection.

## **Results**

After you save the *pc\_history.xml* file, the Cloud APM server processes the file and distributes the configuration to all online agents of the same type. The time it takes for an agent to receive and process the file and begin historical data collection varies depending on server work load conditions. It might take 15 minutes or more in some cases. As new agents of the applicable type come online, the server automatically distributes the configuration to them.

After your agents receive the configuration, they continue to send history data to the Tivoli Data Warehouse even if connection to the Cloud APM server is disrupted.

## **Example**

The following example is the content of the *ud\_history.xml* configuration file for the Db2 agent. With this configuration, the agent collects samples from the KUDINF000 attributes every 15 minutes, transmits the collected data every hour to the Warehouse Proxy agent at IP address 9.88.765.432, port 63358, and retains the collected data locally for 6 hours:

```
<PRIVATECONFIGURATION>
  <WAREHOUSE LOCATION="ip.pipe:#9.88.765.432[63358]"/>
  <HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KUDINF000"/>
</PRIVATECONFIGURATION>
```

This is the *linux\_os\_sample\_history.xml* sample history file for the Linux OS agent:

```
<PRIVATECONFIGURATION>
  <WAREHOUSE LOCATION="ip.pipe:#netaddress[port#]"/>
  <HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_CPU"/>
  <HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_DISK"/>
```

```
<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_VM_STATS"/>
<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_NETWORK"/>
<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_SYSTEM_STATISTICS"/>
<HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="Linux_IP_Address"/>
</PRIVATECONFIGURATION>
```

The `lz_history.xml` historical configuration file that you create from the sample might look like this:

```
<PRIVATECONFIGURATION>
  <WAREHOUSE LOCATION=
    "ip.spipe:#9.11.123.45[65100];ip.pipe:#9.11.123.45[63358];ip.pipe:tdw.example.com[63358]"/>
  <HISTORY EXPORT="60" INTERVAL="15" RETAIN="6" TABLE="KLZ_CPU"/>
  <HISTORY EXPORT="240" INTERVAL="60" RETAIN="24" TABLE="KLZ_DISK"/>
  <HISTORY EXPORT="120" INTERVAL="15" RETAIN="6" TABLE="KLZ_SYSTEM_STATISTICS"/>
</PRIVATECONFIGURATION>
```

## Disabling and re-enabling history data communication protocols for an agent host

By default, all installed agents can use all the RPC communication protocols that are configured for the agent type to send data to the Warehouse Proxy agent. The history warehousing configuration for an agent can include both IP.PIPE and IP.SPIPE communication protocols. You can disable one of the protocols on an individual agent host. Normally, this action is not required.

### About this task

If you want to disable a history data communication protocol for a particular host where the agent is installed, or to re-enable a protocol on an agent host where it was disabled, complete the following procedure on the agent host.

**Important:** This setting applies only to communication between the agent and the Warehouse Proxy agent. It does not affect communication between the agent and the Cloud APM server.

### Procedure

1. Change to the following directory:

- **Windows** `install_dir\BIN`, by default, `C:\IBM\APM\BIN`
- **Linux** `install_dir/bin`, by default, `/opt/ibm/apm/bin`
- **AIX** `install_dir/bin`, by default, `/opt/ibm/apm/bin`

2. Run the following command:

- **Windows** `enableprotocols.bat pipe=yes/no spipe=yes/no`
- **Linux** **UNIX** `./enableprotocols.sh pipe=yes/no spipe=yes/no`

Where *yes/no* is yes to enable a protocol or no to disable it,

For example, to enable IP.SPIPE and disable IP.PIPE on a Windows system, use the command:

```
enableprotocols.bat pipe=no spipe=yes
```

**Tip:** Run the `enableprotocols` command without parameters to see which protocols are currently enabled and disabled.

## Configuring secure communications for historical data collection

If you want to use secure communications (IP.SPIPE) between Cloud APM agents and the Tivoli Monitoring Warehouse Proxy agent, you must complete additional configuration steps on the Cloud APM, Warehouse Proxy agent, all Cloud APM agents that are to use secure communications for historical data, and possibly other Tivoli Monitoring components.

In order for any two sides to communicate using the secure communications protocol (IP.SPIPE), both of the sides must have matching certificates that use the same encryption type.

Each side must present a certificate to the other side. The other side must recognize the signature of a certifying authority (CA) on that certificate. To recognize the signature, that side must have a root certificate of the CA.

So, for example, side A must have its own certificate and the root CA certificate matching the certificate of side B. Side B, in turn, must have its own certificate and the root CA certificate matching side A. (They can also have the same certificate and the same root CA certificate, but this is not required).

However, because of different default configurations of Tivoli Monitoring and Cloud APM, certificate encryption types do not match. When Cloud APM infrastructure is installed, it is configured to use TLS1.2 Elliptic Curve (ECDSA) digital certificates. However, Tivoli Monitoring infrastructure, including Warehouse Proxy agents, is configured to use RSA certificates.

**Important:** Non-secure communication (IP.PIPE) is not affected by this issue. You can use IP.PIPE communication between any components without additional configuration.

**Important:** An installed instance of a component can use ECDSA certificates and RSA certificates for communication. It can not use ECDSA certificates for communication with one component and RSA certificates for communicating with another component.

In order to enable secure communication between Cloud APM agents and the Warehouse Proxy agent, you must complete, as a minimum, the following actions:

- Install one or more Tivoli Monitoring Warehouse Proxy agents. These agents must communicate with Cloud APM agents, not with Tivoli Monitoring agents.
- Generate a new ECDSA digital certificate. Sign this certificate with a self-signed certifying authority or get it signed by a third-party certifying authority of your choice. This certificate is for use on certain Tivoli Monitoring components.
- Extract the ECDSA certifying authority certificates that the Cloud APM agents use.
- On the Warehouse Proxy agents, install the new certificate and the CA certificate matching the agents.
- On all Cloud APM agents that must use secure communications with the Warehouse Proxy agent, install the root certificate for the CA that signed your new certificate (either the self-signed CA or the third-party CA).

After these steps, the Warehouse Proxy agents are not able to communicate with the Tivoli Enterprise Monitoring Server using a secure protocol, because the Monitoring Server has RSA certificates.

You can use non-secure communication (IP.PIPE) between the Warehouse Proxy agents and the Monitoring Server. For example, you can deploy a separate remote Monitoring Server on the same host as the Warehouse Proxy agents, and use IP.PIPE to connect the Proxy Agents to the Monitoring Server on `localhost`. In this way, all actual network communications can remain secure.

Alternatively, you can install the new ECDSA certificate on the Tivoli Enterprise Monitoring Server. In this case, however, all other Tivoli Monitoring components (including monitoring agents) connecting to this server using SPIPE must also be reconfigured for this certificate, as well as any components connecting to these components using SPIPE, and so on.

You can use non-secure communication (PIPE) to link the part of your infrastructure using ECDSA certificates with the part using RSA certificates at any point. In the absence of any non-secure communications, you would need to install the new certificate on your entire Tivoli Monitoring infrastructure.

### ***Creating and signing the new certificate***

You must create an ECDSA certificate and use either a self-signed or third-party Certification Authority (CA) to sign it.

### **About this task**

The certificate must also be signed. You can create a self-signed CA on the same host in order to sign the certificate. Alternatively, you can submit the certificate to a third-party CA of your choice (whether in your organization or elsewhere) for signature. In this case, you must have the root certificate from this CA.

## Procedure

1. Log on to any host where Cloud APM agents are installed.

**Important:** These instructions are based on the following presuppositions:

- The host runs the Linux operating system. For a Windows or AIX system, adjust the paths and commands.
- The agents are installed in the default path (/opt/ibm/apm/agent). If you are using a custom path, replace this path with your custom path.

2. Create a working directory for all keyfiles that you are going to create. Set the KEYFILES\_DIR environment variable to the fully qualified path to this directory. For example:

```
mkdir -v -p ~/itm_keystore
export KEYFILES_DIR=~/itm_keystore
```

**Tip:** You must install these keyfiles on certain Tivoli Monitoring components later. For this reason, these keyfiles are known as the *ITM keyfiles*, and the certificate you are creating is known as the *ITM certificate*.

3. Configure the host to use the GSKit tools. The tools are located in the /opt/ibm/apm/agent/1x8266/gsdirectory. Make the following changes to environment variables using the shell:

```
export GSK_HOME=/opt/ibm/apm/agent/1x8266/gs
export PATH=$GSK_HOME/bin:$PATH
export LD_LIBRARY_PATH=$GSK_HOME/lib64:$LD_LIBRARY_PATH
```

**Important:** In this example, 1x8266 is the platform code for a 64-bit Linux system. If you are using a different operating system, change the platform code according to [IBM Tivoli product, platform, and component codes](#).

**Important:** Subsequent instructions use the gsk8capicmd\_64 command. On a 32-bit platform, the command name is gsk8capicmd.

4. If you are not using a third-party Certifying Authority (CA), create your own CA.

**Tip:** Because this CA signs the ITM certificate, it is known as the *ITM Root CA*. However, it is not the same CA as the one used for your existing Tivoli Monitoring environment.

- a) Choose a password for the new CA keystore. The password enciphers the CA private key and keystore. Set the ROOTCAPASS environment variable to this password. For example:

```
export ROOTCAPASS="your_ITM_Root_CA_password"
```

- b) Create the subdirectory to hold the keys for the new CA under the keyfiles directory that you have created:

```
mkdir -v -p ${KEYFILES_DIR}/apmCA
mkdir -v -p ${KEYFILES_DIR}/apmCA/keyfiles
mkdir -v -p ${KEYFILES_DIR}/apmCA/exports
```

- c) Create the ITM root CA keystore:

```
gsk8capicmd_64 -keydb -create -db ${KEYFILES_DIR}/apmCA/keyfiles/
keyfile.kdb -pw $ROOTCAPASS -expire 3650 -fips -stash
```

- d) Create the ITM root CA certificate:

```
gsk8capicmd_64 -cert -create -db ${KEYFILES_DIR}/apmCA/keyfiles/
keyfile.kdb -stashed -label ITM_Root_CA_Certificate -ca true -size 256 -dn
"CN=ITM_Root_CA,O=my_corp,OU=my_div" -default_cert yes -expire 3695 -
sigalg EC_ecdsa_with_SHA256 -fips
```

**Tip:** The -dn option provides a distinguished name for your certificate. You can change it to the values appropriate for your environment:

- Change CN=ITM\_Root\_CA to a different identifier, for example, CN=Example\_ITM\_CA

- Change O=my\_corp to the name of your company, for example, CN=Example\_Co
- Change OU=my\_div to the name of your division, for example, CN=Example\_Div

**Attention:** You can also change the -label ITM\_Root\_CA\_Certificate name. However., in this case, you must modify all subsequent commands to match the new label name. Failure to modify any of the commands correctly causes failure of secure communication.

- e) Make the ITM Root CA certificate the default in the new keystore:

```
gsk8capicmd_64 -cert -setdefault -db ${KEYFILES_DIR}/apmCA/keyfiles/
keyfile.kdb -stashed -label ITM_Root_CA_Certificate -fips
```

**Attention:** If you have changed the -label option in step “4.d” on page 1062, you must change the -label setting in this command and all subsequent commands to the same name.

- f) Export the new ITM Root CA Certificate so you can import it into other keystores:

```
gsk8capicmd_64 -cert -extract -target ${KEYFILES_DIR}/apmCA/exports/
apmCA.cer -db ${KEYFILES_DIR}/apmCA/keyfiles/keyfile.kdb -stashed -label
ITM_Root_CA_Certificate -fips
```

- g) To display the ITM Root CA certificate that you created in the ITM Root CA keystore, use the following commands.

- Display the names of all certificates found in the Root CA keystore:

```
gsk8capicmd_64 -cert -list -db ${KEYFILES_DIR}/apmCA/keyfiles/
keyfile.kdb -stashed
```

- Display the details of a specific certificate in the ITM Root CA keystore:

```
gsk8capicmd_64 -cert -details -showOID -label "ITM_Root_CA_Certificate"
-db ${KEYFILES_DIR}/apmCA/keyfiles/keyfile.kdb -stashed
```

At this point, the new ITM Root CA is created in the "\${KEYFILES\_DIR}"/apmCA directory. It contains two subdirectories: keyfiles and exports. The keyfiles subdirectory contains the root CA keystore and the exports subdirectory contains the root CA public certificate.

## 5. Use the GSKit tools to create a new digital certificate and a Certificate Signing Request (CSR).

This certificate is to be used by Tivoli Monitoring components (as the minimum, the Warehouse Proxy agents). It is, therefore, known as the *ITM certificate*.

The certificate is identified by a host name. The host name does not have to correspond to a real host. These instructions use the default.itm hostname. You can set any other hostname if you want.

- a) Choose a password for the new ITM keystore. The password enciphers the ITM private key and keystore. Set the ITMPASS environment variable to this password. For example:

```
export ITMPASS="your_ITM_password"
```

- b) Create the subdirectory to hold the ITM keys under the keyfiles directory that you have created:

```
mkdir -v -p ${KEYFILES_DIR}/default.itm
mkdir -v -p ${KEYFILES_DIR}/default.itm/keyfiles
mkdir -v -p ${KEYFILES_DIR}/default.itm/exports
```

- c) Create the ITM keystore:

```
gsk8capicmd_64 -keydb -create -db ${KEYFILES_DIR}/default.itm/keyfiles/
keyfile.kdb -pw $ITMPASS -expire 3650 -fips -stash
```

- d) Import the root CA public key into the ITM keystore. If you are using a self-signed CA, import the ITM root CA was created and exported in Step “4” on page 1062. Use the following command:

```
gsk8capicmd_64 -cert -add -file ${KEYFILES_DIR}/apmCA/exports/apmCA.cer -  
trust enable -label ITM_Root_CA_Certificate -db ${KEYFILES_DIR}/  
default.itm/keyfiles/keyfile.kdb -stashed -fips
```

**Attention:** If you have changed the value of the `-label` option in your ITM Root CA certificate, set the value of the `-label` option in this command to the same name.

If you are using a third-party CA, you must have a root certificate from this CA. Use the file name of this certificate instead of `${KEYFILES_DIR}/apmCA/exports/apmCA.cer`. Use the label supplied by the CA in the `-label` option.

- e) Create the new digital certificate and the certificate signing request (CSR) for it:

```
gsk8capicmd_64 -certreq -create -db ${KEYFILES_DIR}/default.itm/keyfiles/  
keyfile.kdb -stashed -label IBM_Tivoli_Monitoring_Certificate -size 256 -  
file ${KEYFILES_DIR}/default.itm/keyfiles/default.itmReq.arm -dn  
"CN=ITM_Hostname,O=my_corp,OU=my_div" -sigalg EC_ecdsa_with_SHA256 -fips
```

**Tip:** The `-dn` option provides a distinguished name for your certificate. You can change it to the values appropriate for your environment:

- Change `CN=ITM_Hostname` to a different identifier, for example, `CN=Example_ITM_Hostname`
- Change `O=my_corp` to the name of your company, for example, `O=Example_Co`
- Change `OU=my_div` to the name of your division, for example, `OU=Example_Div`

**Attention:** You can also change the `-label IBM_Tivoli_Monitoring_Certificate` name. However., in this case, you will need to reconfigure any Tivoli Monitoring components (as the minimum, the Warehouse Proxy agents) to use this label. For details, see [“Configuring Tivoli Monitoring components with the new certificate” on page 1067](#). Also, in this case you must modify all subsequent commands to match the new label name. Failure to modify any of the commands correctly causes failure of secure communication.

6. Sign the certificate. Depending on the CA that you are using:

- If you are using a self-signed CA, run the following command:

```
gsk8capicmd_64 -cert -sign -db ${KEYFILES_DIR}/apmCA/keyfiles/keyfile.kdb  
-stashed -expire 3650 -label ITM_Root_CA_Certificate -file $  
{KEYFILES_DIR}/default.itm/keyfiles/default.itmReq.arm -target $  
{KEYFILES_DIR}/default.itm/keyfiles/default.itmSigned.arm
```

**Attention:** If you have changed the value of the `-label` option in your ITM Root CA certificate, set the value of the `-label` option in this command to the same name.

- If you are using a third-party CA, send the `${KEYFILES_DIR}/default.itm/keyfiles/default.itmReq.arm` file to the CA, and wait to receive the signed certificate. Save the signed certificate as `${KEYFILES_DIR}/default.itm/keyfiles/default.itmSigned.arm`

7. Receive the newly signed certificate into the ITM keystore:

```
gsk8capicmd_64 -cert -receive -file ${KEYFILES_DIR}/default.itm/keyfiles/  
default.itmSigned.arm -db ${KEYFILES_DIR}/default.itm/keyfiles/keyfile.kdb -  
stashed -fips
```

8. Make the newly signed certificate the default certificate for the ITM keystore.

```
gsk8capicmd_64 -cert -setdefault -db ${KEYFILES_DIR}/default.itm/keyfiles/  
keyfile.kdb -stashed -label IBM_Tivoli_Monitoring_Certificate -fips
```

**Attention:** If you have changed the value of the `-label` option in your ITM certificate, set the value of the `-label` option in this command to the same name.

## Extracting and importing agent CA certificates

You must create a copy of the keyfiles directory that your Cloud APM agents use. Then you must use this copy to extract CA certificates. Import these CA certificates into the ITM keystore.

### Before you begin

Complete all actions in [“Creating and signing the new certificate” on page 1061](#). In particular, if you use a third-party CA, wait for the signed certificate and receive it into the keystore.

### About this task

The key store for your Cloud APM agents includes the CA certificates that they use. In order to enable secure communications, you must complete the following actions:

- Determine the default certificate for the agents.
- Determine which certificate signed the default certificate.
- Check if that certificate is a root certificate.
- If that certificate is not a root certificate, determine which certificate signed it. If that certificate is also not the root certificate, check which certificate signed it. Continue until you find the root certificate.
- Extract the public key for each signing certificate (not only the root certificate).
- Import each public key into the ITM keystore.

In a later step, you need to modify the keystore for the Cloud APM agents (see [“Modifying the keystore for Cloud APM agents” on page 1068](#)). Therefore, ensure that the copy of the keyfiles directory remains available.

Complete this procedure on the same host that you used for [“Creating and signing the new certificate” on page 1061](#). Cloud APM agents must be installed on this host.

**Attention:** You might have Cloud APM agents that connect to different Cloud APM servers. For example, you might have different on-premises servers, or different cloud Cloud APM subscriptions, or different agents connecting to on-premises servers and cloud servers. Such agents have different CA certificates. In this case, you must create a copy of the keystores for each of these agent kinds, and extract the CA certificates from each of the copies.

### Procedure

1. Copy the Cloud APM agent keystore files into a working directory:

```
mkdir -v -p ~/apm_agent_keystore/keyfiles
cp /opt/ibm/apm/agent/keyfiles/* ~/apm_agent_keystore/keyfiles
```

**Attention:** if you have Cloud APM agents that connect to different Cloud APM servers, you must also get a copy of the keyfiles directory from one agent host for each server and place it in a separate working directory on the host you are completing the configuration on. For example, ~/apm\_agent\_onprem1\_keystore/keyfiles, ~/apm\_agent\_cloud1\_keystore/keyfiles, and so on.

2. Set the environment variable APM\_AGENT\_KEYFILES\_DIR to point to the specific agent keyfiles working directory that you created, for example:

```
export APM_AGENT_KEYFILES_DIR=~/apm_onprem_keystore
```

3. Issue the certificate list command to inspect the certificate names in the agent keystore:

```
gsk8capicmd_64 -cert -list -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/
keyfile.kdb -stashed
```

Review the output of the command and find the name of the default certificate, which is marked with the \* sign, For example, the output might be:

```
Certificates found
* default, - personal, ! trusted, # secret key
!      apmCA
!      server_key
*-     IBM_Tivoli_Monitoring_Certificate
```

In this example, the name of the default certificate is IBM\_Tivoli\_Monitoring\_Certificate.

**Tip:** Cloud APM agents can use the words "Tivoli Monitoring" in certificate names. This is normal.

4. To examine the default certificate, use the certificate details command, for example:

```
gsk8capicmd_64 -cert -details -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/
keyfile.kdb -stashed -label "IBM_Tivoli_Monitoring_Certificate"
```

Use the label of the default certificate in the -label option. Enclose the label in double quotes.

5. Examine the first part of the command output, for example:

```
Label : IBM_Tivoli_Monitoring_Certificate
Key Size : 256
Version : X509 V3
Serial : 0a5936d9a7b572cb
Issuer : CN=APM_MIN_server
Subject : CN=default.agent
```

Compare the contents of the Issuer and Subject fields. They are the same for a root certificate. The default certificate is normally not the root certificate. (If the contents of the Issuer and Subject fields of the default certificate are the same, contact IBM support).

6. Use the Issuer field to determine the signing certificate for this certificate. The field contains a *signing certificate name*, which is either the label or the value of the Subject field of the signing certificate.

Review the list displayed in Step “3” on page 1065. Take one of the following steps:

- If you find the signing certificate name in the list of labels, examine the signing certificate.
- If the list does not contain the signing certificate name, examine every other certificate in the list, until you find one where the Subject field matches the signing certificate name.

To examine a certificate, use the following command:

```
gsk8capicmd_64 -cert -details -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/
keyfile.kdb -stashed -label "label"
```

Set the -label option to the label of the certificate you are examining. Enclose the label in double quotes.

In this example, the list does not contain the signing certificate name. We start with the first listed label, apmCA:

```
gsk8capicmd_64 -cert -details -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/
keyfile.kdb -stashed -label "apmCA"
```

The output is:

```
Label : apmCA
Key Size : 256
Version : X509 V3
Serial : 5b023cefbfbf4076e
Issuer : CN=APM_MIN_server
Subject : CN=APM_MIN_server
```

Because the value of the Subject field matches the signing certificate name, this is the correct certificate.

7. Extract the signing certificate that you have identified in Step “6” on page 1066:

```
gsk8capicmd_64 -cert -extract -target ${KEYFILES_DIR}/default.itm/exports/  
apm_agentCA.cer -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/keyfile.kdb -stashed  
-label "apmCA"
```

Set the `-label` option to the label of the signing certificate. Enclose the label in double quotes.

8. Import the extracted certificate file into the ITM keystore.

```
gsk8capicmd_64 -cert -add -file ${KEYFILES_DIR}/default.itm/exports/  
apm_agentCA.cer -trust enable -label "apmCA" -db ${KEYFILES_DIR}/  
default.itm/keyfiles/keyfile.kdb -stashed
```

Set the `-label` option to the label of the signing certificate. Enclose the label in double quotes.

9. In the signing certificate information that you displayed in Step “6” on page 1066, compare the values of the Issuer and Subject fields. If they are the same, this is the root certificate; proceed to the next step. If the values differ, you need to find the signing certificate for this certificate. The signing certificate name is in the Issuer field. Repeat the procedure starting from Step “6” on page 1066 to find and process the signing certificate.

**Important:** You must extract every signing certificate you find, including the root certificate, and add it to the ITM keystore.

In this example, the Issuer and Subject fields of the “apmCA” certificate match. Therefore, it is the root certificate.

10. If you have Cloud APM agents that connect to different Cloud APM servers, repeat the procedure starting with Step “2” on page 1065 for the agent keystore from each of those servers.
11. To display the certificates that you have added to the ITM keystore, you can use the following commands:

- To display the names of all certificates in the ITM keystore:

```
gsk8capicmd_64 -cert -list -db ${KEYFILES_DIR}/default.itm/keyfiles/  
keyfile.kdb -stashed
```

- To examine the details of a specific certificate in the ITM keystore:

```
gsk8capicmd_64 -cert -details -label "label" -db ${KEYFILES_DIR}/  
default.itm/keyfiles/keyfile.kdb -stashed
```

Set the `-label` option to the label of the certificate you are examining. Enclose the label in double quotes.

## ***Configuring Tivoli Monitoring components with the new certificate***

You must configure certain Tivoli Monitoring components to use the new ITM certificate. As a minimum, you must complete this configuration for Warehouse Proxy agents.

### **Before you begin**

You must determine the Tivoli Monitoring components that must use the new certificate and install these components. The following rules apply:

- Tivoli Monitoring Warehouse Proxy agents that use secure communication with Cloud APM agents must use the new certificate.
- Components that use the new certificate can not use secure (SPIPE) communication with components that do not use the new certificate, because the new certificate uses ECDSA encryption and existing Tivoli Monitoring certificates use RSA encryption. They can still use non-secure (PIPE) communication with any components.
- Components installed in the same installation location use the same certificate. However, you can install components into different locations on the same host. These components can use different certificates.

To avoid installing the new certificate across a large part of your infrastructure, install new Warehouse Proxy agents that receive historical data from Cloud APM agents and not Tivoli Monitoring agents. Configure these Warehouse Proxy agents to use the new certificate. Use the non-secure (IP.PIPE)

communication protocol to connect these Warehouse Proxy agents to a Tivoli Enterprise Monitoring Server.

If you need to ensure that all network connections are secure, you can install a remote Tivoli Enterprise Monitoring Server on each host where the new Warehouse Proxy agents are installed. Use different installation locations for the Warehouse Proxy agents and the Monitoring Server. Do **not** configure the Monitoring Server to use the new certificate. Configure IP.PIPE communication on the local host between the Warehouse Proxy agents and the Monitoring Server. In this case, the Monitoring Server can use existing certificates to communicate with the rest of the Tivoli Monitoring infrastructure.

Alternatively, you can use the new certificate to communicate between the Warehouse Proxy agents and a Monitoring Server. In this case, however, you might need to deploy the new certificate to a large part of your Tivoli Monitoring infrastructure. This solution can involve a lot of manual operations.

## About this task

Complete the following procedure on Tivoli Monitoring Warehouse Proxy agents that communicate with Cloud APM agents. If your planning requires it, you can also complete the procedure on any other Tivoli Monitoring components.

## Procedure

1. Log on to the host where the Tivoli Monitoring component is installed.
2. Change to the installation directory of the component.
3. Back up the `keyfiles` subdirectory.
4. Copy the files from the ITM keystore that you created (`${KEYFILES_DIR}/default.itm/keyfiles` on the host where you created the keystore, see [“Creating and signing the new certificate”](#) on page 1061) into the `keyfiles` subdirectory, overwriting any existing files.
5. Copy the `KAES256.ser` file from the backup that you created in Step [“3”](#) on page 1068 into the `keyfiles` subdirectory.
6. Set the following Tivoli Monitoring configuration variables. For instructions about setting configuration variables, see [Editing your environment configuration settings](#). If any of the variables is not present in the list, create it.
  - a) Change the `KDEBE_FIPS_MODE_ENABLED` variable to `SuiteB-128`.
  - b) Change the `ITM_AUTHENTICATE_SERVER_CERTIFICATE` variable to `Y`.
  - c) Change the `ITM_AUTHENTICATE_CLIENT_CERTIFICATE` variable to `Y`.
  - d) If you used a custom value for the label of the new ITM certificate, you must configure the Tivoli Monitoring component to use the new label. The default label in the instructions is `IBM_Tivoli_Monitoring_Certificate`; the components are already configured to use this label.

For a custom label, change the `KDEBE_KEY_LABEL` variable to the label.

## Modifying the keystore for Cloud APM agents

You must import the CA certificate for your new ITM certificate to the keystore for Cloud APM agents. You must deploy the new keystore to every agent host that must use secure communications to send historical data.

## About this task

In a previous step, [“Extracting and importing agent CA certificates”](#) on page 1065, you created a copy of the Cloud APM agent keystore.

You must import the CA certificate for your new ITM certificate to this copy. You created and signed this certificate in [“Creating and signing the new certificate”](#) on page 1061.

If you created a self-signed ITM CA, import the ITM Root CA certificate that you created. If a third-party CA signed the certificate, import the root certificate that is supplied by the third-party CA. Then you must

deploy the new keystore to all Cloud APM agent that must use secure communications with a Tivoli Monitoring Warehouse Proxy agent.

**Attention:** If you have Cloud APM agents that connect to different Cloud APM servers, you must complete this procedure separately for each of the servers. Modify each keystore and deploy the new keystores to the agents. Take care to deploy each keystore to the correct agents. If you copy a keystore for agents using one Cloud APM server into an agent host that connects to another Cloud APM server, the agent ceases to communicate with the server.

## Procedure

1. Set the `APM_AGENT_KEYFILES_DIR` environment variable to the full path of the working directory with a copy of the agent keystore files, for example:

```
export APM_AGENT_KEYFILES_DIR="/apm_agent_keystore/keyfiles"
```

2. Import the Certifying Authority public key into the agent keystore. If you used a self-signed ITM CA, use the ITM Root CA that you created. Use the following command:

```
gsk8capicmd_64 -cert -add -file ${KEYFILES_DIR}/apmCA/exports/apmCA.cer -trust enable  
-label ITM_Root_CA_Certificate -db ${APM_AGENT_KEYFILES_DIR}/keyfiles/keyfile.kdb -stashed
```

Ensure that the value of the `-label` option is the same as the label you used for the ITM Root CA certificate.

If a third-party CA signed the certificate, replace `${KEYFILES_DIR}/apmCA/exports/apmCA.cer` with the path and name of the file that contains the root certificate provided by the CA. Use the label provided by the CA in the `-label` option.

3. On every host where the Cloud APM agents are installed and must use secure communications to send historical data, back up the contents of the *agent\_install\_directory*/keyfiles directory.
4. Copy the files in the `${APM_AGENT_KEYFILES_DIR}/keyfiles` directory into the *agent\_install\_directory*/keyfiles directory on every host where the Cloud APM agents are installed and must use secure communications to send historical data. Overwrite existing files of the same name. Do not remove any files that are not overwritten by new files.
5. Preserve the working copy of the keystore. When you install Cloud APM agents in the future, you can copy the new keystore files onto the agent hosts to enable secure communications for historical data.

## Keystore files and environment variables

Both Tivoli Monitoring and Cloud APM components use the GSKit component to manage secure communications using certificates. They store the certificates in a directory and require certain configuration variables.

## Certificate keystore files

Both Tivoli Monitoring and Cloud APM components store their secret keys and certificates in the *install\_home*/keyfiles firectory. This directory is shared between all components installed in the same path. It contains the following files:

### keyfile.kdb

Default Key certificate database. The certificate named `IBM_Tivoli_Monitoring_Certificate` is used for negotiation by default.

### keyfile.sth

Stash file that holds the obfuscated password for the key database. Ensure that permissions for this file are locked down so that only agent user identifiers and administrators can read them.

### keyfile.crl

Legacy file for storing certification revocation lists. No longer used.

### keyfile.jks

Java version of the keyfile.kdb keystore file. Present in Cloud APM components.

**server.jks**

This file is present only on Cloud APM server installations and is used by the server. It is the Java version of the `keyfiles/default.server/keyfiles/keyfile.kdb` keystore file. The `default.server` directory name is used when the Cloud APM server is installed.

**KAES256.ser**

256-bit AES Key used to encrypt locally encrypted configuration data or decrypting credentials passed through remote deployment functions. This key is not used for communication encryption.

**Configuration variables**

Both Tivoli Monitoring and Cloud APM components use configuration variables to manage secure connections. For Tivoli Monitoring components, you can use the Manage Tivoli Enterprise Monitoring Services utility to modify the variables. Cloud APM components store the variables in configuration files.

**KEYFILE\_DIR**

The keyfile directory where the key database is stored.

Default value: `install_home/keyfiles`

**KDEBE\_KEYRING\_FILE**

The Key certificate database file.

Default value: `install_home/keyfiles/keyfile.kdb`

**KDEBE\_KEYRING\_STASH**

The stash file that holds the obfuscated password for the key database.

Default value: `install_home/keyfiles/keyfile.sth`

**KDEBE\_KEY\_LABEL**

The label of the specific certificate to use for authentication. A certificate must be present even when no validation is enabled.

Default Value: `IBM_Tivoli_Monitoring_Certificate`

The following variables specify how the certificates are handled:

**KDEBE\_FIPS\_MODE\_ENABLED**

FIPS compliance mode of operation.

Default value (Cloud APM): `SuiteB-128`

Default value (Tivoli Monitoring): `not set`.

**ITM\_AUTHENTICATE\_SERVER\_CERTIFICATE**

If set to Y, the server receiving the call must present a valid signed certificate to the client, or the connection will not complete.

Default value (Cloud APM): `Y`

Default value (Tivoli Monitoring): `N`

**ITM\_AUTHENTICATE\_CLIENT\_CERTIFICATE**

If set to Y, the client making the call must present a valid signed certificate to the server, or the connection will not complete.

Default value (Cloud APM): `Y`

Default value (Tivoli Monitoring): `N`

## Integrating with OMEGAMON

---

You can view data and events for your OMEGAMON application components in the Cloud APM console by purchasing OMEGAMON for APM and using the Hybrid Gateway to connect one or more deployed OMEGAMON agents to Cloud APM.

### Before you begin

- To use OMEGAMON for APM, you must have either the IBM Cloud Application Performance Management, Advanced or IBM Cloud Application Performance Management, Base offering.
- One or more licensed OMEGAMON agents must be running on z Systems LPARS that are being monitored.
- The OMEGAMON agents are connected to the IBM Tivoli Monitoring infrastructure.

For a list of OMEGAMON agents that you can display in the Cloud APM console, see the [Getting started](#) topic for your release in the [IBM OMEGAMON for Application Performance Management](#) topic collection on IBM Knowledge Center.

### Procedure

To integrate OMEGAMON with Cloud APM, complete the following steps:

1. Install OMEGAMON for APM. For details, see the Installing topics in the [IBM OMEGAMON for Application Performance Management](#) topic collection on IBM Knowledge Center. After OMEGAMON for APM is installed, complete the following Hybrid Gateway tasks:
  - a) Install the Hybrid Gateway.
  - b) Create the managed system group that you want to view in the Cloud APM console.
  - c) Configure the Hybrid Gateway in the Cloud APM console so that you can connect the Hybrid Gateway to the Tivoli Enterprise Portal Server and specify a managed system group.For more information, see the required topics in the [“Hybrid Gateway”](#) on page 1043 section.
2. To view the status of your applications in the dashboard, log in to the Cloud APM console from your browser. For more information, see [“Starting the Cloud APM console”](#) on page 1109.

## Integrating with Netcool/OMNIBus

---

You can forward events from IBM Cloud Application Performance Management into your on-premises IBM Tivoli Netcool/OMNIBus event manager.

### Procedure

1. Configure the integration for Netcool/OMNIBus.
2. After you configure the integration with Netcool/OMNIBus, you can customize how threshold events are mapped to forwarded events.

## Configuring the integration for Netcool/OMNIBus

After you install the Cloud APM server, you must copy the event rules to the Probe for Tivoli EIF and modify them. You must also update the Netcool/OMNIBus ObjectServer and the database schema.

### About this task

After you install the Cloud APM server, the following configuration files are in the `install_dir/ccm/omnibus` directory (where `install_dir` is the default `/opt/IBM/` or `C:\IBM\` or the directory that you specified during the Cloud APM server installation):

- `itm_apm_db_update.sql`
- `itm_event.rules`

- itm\_apm\_event.rules
- multitier/collection\_itm\_apm.sql
- multitier/display\_itm\_apm.sql
- multitier/GATE\_itm\_apm.map

You must copy the files to the computer systems where the Netcool Probe for Tivoli EIF and Netcool/OMNIBus ObjectServers are installed. If your Netcool/OMNIBus environment is configured for the single tiered architecture, which is the default, you only need the first three files. However, if your Netcool/OMNIBus environment is configured for the multitiered architecture, you also need to deploy the files in the multitier directory.

You must install [IBM Cloud Application Performance Management, V8.1.4.0 interim fix 10](#), or a later server interim fix, to obtain the files in the multitier directory. Interim fixes for the Cloud APM server V8.1.4 are available to download from [IBM Fix Central](#).

**Important:** You must complete these steps even if your Probe for Tivoli EIF and Netcool/OMNIBus ObjectServer are already integrated with IBM Tivoli Monitoring, Probe for Tivoli EIF, IBM SmartCloud Monitoring - Application Insight®, IBM SmartCloud Application Performance Management, or a previous version of Cloud APM.

## Procedure

In this procedure, when you follow links to the IBM Tivoli Monitoring documentation, complete only the steps that are provided on the linked page.

1. Copy the itm\_event.rules and itm\_apm\_event.rules files to the Probe for Tivoli EIF installation directory.

**Linux** `install_dir/tivoli/netcool/omnibus/probes/linux2x86`

**Windows** `install_dir\Tivoli\Netcool\omnibus\probes\win32`

Where `install_dir` is the directory where you install the Probe for Tivoli EIF.

2. Open the Probe for Tivoli EIF `tivoli_eif.rules` file in a text editor and complete one of the following steps:
  - If you are an existing IBM Tivoli Monitoring customer and have completed the OMNIBus integration already, add this line to your `itm_event.rules` file: `include "itm_apm_event.rules"`.
  - If you have not set up the OMNIBus integration already, uncomment the include statement for the `itm_event.rules` file.

For detailed steps, see [Updating the rules files of the EIF probe](#) in the IBM Tivoli Monitoring documentation.

3. Update the Netcool/OMNIBus ObjectServer database schema by loading the `itm_apm_db_update.sql` file into the database if you configured a single tiered Netcool/OMNIBus architecture, which is the default architecture. If you configured a multitiered Netcool/OMNIBus architecture then load the `itm_apm_db_update.sql` file into the database of each Netcool/OMNIBus ObjectServer in the aggregation tier.

**Linux**

```
$OMNIHOME/bin/nco_sql -user user_name -password password
-server server_name < itm_apm_db_update.sql
```

Example:

```
$OMNIHOME/bin/nco_sql -user smadmin -password passw0rd -server NCOMS <
/tmp/apm/itm_apm_db_update.sql
```

**Windows**

```
itm_apm_db_update.sql | %OMNIHOME%\..\bin\isql -U user_name
```

```
-P password -S server_name
```

Example:

```
\temp\apm\itm_apm_db_update.sql | %OMNIHOME%\..\bin\isql -U smadmin  
-P passwd -S NCOMS
```

The following error messages might be displayed when you are running the scripts and these messages are harmless:

- Object exists and Attempt to insert duplicate row, if the scripts were run previously (for example, for integration with an earlier version of Cloud APM or with Tivoli Monitoring).
  - ERROR=Object not found on line 4 of statement "-- A workspace table for the ITM event clear automation..." at or near itm\_event\_clear.
  - ERROR=Object not found on line 1 of statement "delete from alerts.itm\_problem\_events;..." at or near itm\_problem\_events.
  - ERROR=Object not found on line 1 of statement "drop table alerts.itm\_problem\_events;..." at or near itm\_problem\_events.
4. Repeat step 3 so that the file is loaded into the Object Server twice to ensure that all dependencies are loaded correctly.
  5. If you have a multitiered Netcool/OMNIBus architecture configured, perform the following steps:
    - a) Copy the GATE\_itm\_apm.map file to the computer systems where the Netcool/OMNIBus uni-directional gateways are installed. You need to update all uni-directional gateways that transfer data between the Netcool/OMNIBus ObjectServers.
    - b) Copy the mappings in the GATE\_itm\_apm.map file into the gateway map definition file that also uses the .map extension.

The attributes should be added to the STATUSMAP mapping entry in the gateway map definition file. Your gateway map file might contain the following comment block to identify where to add these custom attributes:

```
#####  
#  
# CUSTOM alerts.status FIELD MAPPINGS GO HERE  
# #####
```

- c) Copy the collection\_itm\_apm.sql file to the computer systems where the Netcool/OMNIBus ObjectServers in the collection tier are installed.
- d) Update the Object Server database in the collection tier with the following command, which pipes the SQL command set into the SQL command-line tool and performs the updates to the ObjectServer database.

- **Windows**

```
type path_to_file\collection_itm_apm.sql | %OMNIHOME%\..\bin\redis\isql  
-U username  
-P password  
-S server_name
```

where:

**\$OMNIHOME**

Is the system-defined variable defining the installation location of OMNIBus.

**username**

Is the OMNIBus Object Server user name.

**password**

Is the OMNIBus Object Server password.

**server\_name**

Is the OMNIBus Object Server name defined for process control.

**path\_to\_file**

Is the fully qualified path to the specified SQL file.

- **UNIX**

```
$OMNIHOME/bin/ncs_sql -user username
                        -password password
                        -server server_name
                        < path_to_file/collection_itm_apm.sql
```

where:

**\$OMNIHOME**

Is the system-defined variable defining the installation location of OMNIBus.

**username**

Is the OMNIBus Object Server user name.

**password**

Is the OMNIBus Object Server password.

**server\_name**

Is the OMNIBus Object Server name defined for process control.

**path\_to\_file**

Is the fully qualified path to the specified SQL file.

- e) If the Netcool/OMNIBus architecture includes a display tier, copy the `display_itm_apm.sql` file to the computer systems where the Netcool/OMNIBus ObjectServers in the display tier are installed. Update the Object Server database in the display tier with the following command, which pipes the SQL command set into the SQL command-line tool and performs the updates to the ObjectServer database.

- **Windows**

```
type path_to_file\display_itm_apm.sql | %OMNIHOME%\..\bin\redist\isql
-U username
-P password
-S server_name
```

where:

**\$OMNIHOME**

Is the system-defined variable defining the installation location of OMNIBus.

**username**

Is the OMNIBus Object Server user name.

**password**

Is the OMNIBus Object Server password.

**server\_name**

Is the OMNIBus Object Server name defined for process control.

**path\_to\_file**

Is the fully qualified path to the specified SQL file.

- **UNIX**

```
$OMNIHOME/bin/ncs_sql -user username
                        -password password
                        -server server_name
                        < path_to_file/collection_itm_apm.sql
```

where:

**\$OMNIHOME**

Is the system-defined variable defining the installation location of OMNIBus.

**username**

Is the OMNIBus Object Server user name.

**password**

Is the OMNIbus Object Server password.

**server\_name**

Is the OMNIbus Object Server name defined for process control.

**path\_to\_file**

Is the fully qualified path to the specified SQL file.

- f) Restart the Netcool/OMNIbus uni-directional gateways between the collection and aggregation tiers.
  - g) If the Netcool/OMNIbus architecture includes a display tier, restart the uni-directional gateways between the aggregation and display tiers.
6. If you have a multitiered Netcool/OMNIbus architecture, and you have a bidirectional failover gateway for high availability, modify the `agg_deduplication` trigger on each ObjectServer in the aggregation tier: The `agg_deduplication` trigger is defined in this file:

**Linux**

```
$OMNIHOME/extensions/multitier/objectserver/aggregation.sql
```

**Windows**

```
%OMNIHOME%\extensions\multitier\objectserver\aggregation.sql
```

- a) Copy the `aggregation.sql` file to a temporary file. In this example, the temporary file name is `/tmp/agg_dedup.sql`.
- b) Edit `/tmp/agg_dedup.sql`, and add the line **when (new.Type != 20) and (new.Type != 21)** in the following example so that the trigger ignores Cloud IBM APM events.

```
CREATE OR REPLACE TRIGGER agg_deduplication
GROUP default_triggers
PRIORITY 2 COMMENT 'Replacement reinsert trigger (alerts.status) for multi-ObjectServer
environments.'
BEFORE REINSERT ON alerts.status FOR EACH ROW
when (new.Type != 20) and (new.Type != 21)
declare
now utc;
begin
```

**Note:** Only the beginning portion of the `agg_deduplication` trigger is shown in the example that follows. The remaining logic is not shown because it does not need any modifications. Your `agg_deduplication` trigger might be different than what is shown in the following example depending on the Netcool/OMNIbus releases that you are using or if you have customized the trigger.

- c) Save the file, and run the following command to update the `agg_deduplication` trigger:

**Linux**

```
$OMNIHOME/bin/nco_sql -user username -password password -server server_name < /tmp/agg_dedup.sql
```

**Windows**

```
%OMNIHOME%\..\bin\redisql -U username -P password -S server_name < C:\tmp\agg_dedup.sql
```

Where:

- i) `$OMNIHOME` is the system-defined variable that defines the installation location of Netcool/OMNIbus ObjectServer.
- ii) `username` is the Netcool/OMNIbus ObjectServer user name.
- iii) `password` is the Netcool/OMNIbus ObjectServer password.

- iv) *server\_name* is the Netcool/OMNIBus ObjectServer name that is defined for process control.
- 7. Start (or restart) the Probe for Tivoli EIF.
- 8. Configure the Cloud APM server to forward events to Netcool/OMNIBus:
  - a) Log in to the Cloud APM console.
  - b) Select  **System Configuration > Advanced Configuration**.
  - c) In the **Event Manager** category, set the **EIF Event Target(s)** field to include the host name or IP address of the host where Netcool/OMNIBus is installed.
  - d) If necessary, change the **EIF Port** setting to match your environment.
  - e) Click **Save**.
- 9. Optional: As you create or edit a threshold in the Threshold Editor, set **Forward EIF Event** to No if you do not want to forward events to the EIF receiver. For more information, see [Forward EIF Event](#).

## Results

Your Netcool/OMNIBus integration is now complete.

If your Probe for Tivoli EIF and Netcool/OMNIBus ObjectServer are already integrated with IBM Tivoli Monitoring, IBM SmartCloud Monitoring - Application Insight, IBM SmartCloud Application Performance Management, or Cloud APM, this configuration enables new fields.

## What to do next

To customize how thresholds are mapped to forwarded events, thus overriding the default mapping between thresholds and events forwarded to the event server, in the **Threshold Editor**, click **EIF Slot Customization**. For more information, see [Customizing an event to forward to an EIF receiver](#).

# Integrating with Operations Analytics - Log Analysis

---

When your environment includes IBM Operations Analytics - Log Analysis, you can integrate it to enable searching through application logs in the Cloud APM console.

## About this task

Integrating with your installed Log Analysis application involves configuring the Cloud APM server with the URL. For more information about Log Analysis, see the [IBM Operations Analytics - Developers Community](#).

You must provide the top level URL for your Log Analysis installation, for example:

```
https://loganalysis.example.com:9987/Unity
```

## Procedure

1. In the Cloud APM console, click  **System Configuration > Advanced Configuration**.
2. Select the **UI Integration** category.
3. In the **Log Analysis URL** field, enter the URL that is used to launch your Log Analysis application.

## Results

The Log Analysis application is integrated and the feature is enabled for you to search through application logs from the Application Performance Dashboard.

## What to do next

Select  **Performance > Application Performance Dashboard**. Optionally select an application, then use the   search box to search log files. By default, entries for the last hour are searched,

but you can change this time period. If you select an application, only the logs on servers associated with this application are searched. For detailed instructions, see [“Searching log files”](#) on page 1253.

## Integrating with Operations Analytics - Predictive Insights

---

When you integrate IBM Cloud Application Performance Management with Operations Analytics - Predictive Insights, Operations Analytics - Predictive Insights analyzes the metric data collected by Cloud APM and generates alarms when it identifies anomalies in the data.

Anomalies are displayed as events in the Cloud APM Dashboard, as described in [“Investigating anomalies with Operations Analytics - Predictive Insights”](#) on page 1282. You can then drill down to the Operations Analytics - Predictive Insights User Interface to view more details on an anomaly.

For instructions about configuring integration between Operations Analytics - Predictive Insights and Cloud APM, see [Configuring integration with IBM Performance Management](#) in the IBM Operations Analytics - Predictive Insights Knowledge Center.

## Integrating with IBM® License Metric Tool

---

IBM® License Metric Tool helps you to manage your license compliance. If you want to track Cloud APM agents' license consumption, you can integrate Cloud APM with IBM® License Metric Tool by installing the APM ILMT tool on Cloud APM Server side.

### About this task

For how to install the APM ILMT tool and how the integration goes, see the [Integrating IBM Cloud Application Performance Management \(Cloud APM\) with IBM License Metric Tool](#) technote.

## Integrating with IBM Cloud

---

You can view monitoring information for your applications within the IBM Cloud environment by using selected data collectors.

When configured to collect data from an IBM Cloud application, a data collector enables the integration of monitoring capabilities with IBM Cloud. Data collectors transfer resource monitoring and diagnostics data about your IBM Cloud applications to the Cloud APM server. The Cloud APM server receives and processes monitoring information that is collected by the data collectors. The following types of IBM Cloud applications can be monitored:

- Liberty applications
- Node.js applications
- Python applications
- Ruby applications

After proper configurations of a data collector, you can view monitoring data on the Cloud APM console. For configuration instructions, see [“General procedure for configuring data collectors”](#) on page 257.

## Monitoring IBM Cloud Private

---

You can use IBM Cloud Application Performance Management, Private to monitor your IBM Cloud Private environment, thus enabling you to manage traditional and container-based workloads from the Cloud APM console.

### Monitoring your IBM Cloud Private containers

Use IBM Cloud Application Performance Management, Private to monitor the IBM Cloud Private containers where your workloads are running.

The setup involves some basic steps:

## Install the Linux OS agent on your Cloud Private nodes

You install the Cloud APM Linux OS agent on both the Cloud Private master and worker nodes. As a best practice, include the installed Linux OS agent for each virtual machine that is created for IBM Cloud Private. For more information, see [“Installing agents on Linux systems”](#) on page 191.

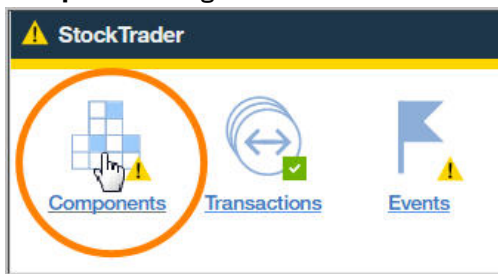

## Create an application to group the OS resources

To manage the nodes that comprise the Cloud Private container, create an application to group them. Launch the Cloud APM console and create an application with the Linux OS managed resources that you installed in your Cloud Private environment. For more information, see [“Managing applications”](#) on page 1269.

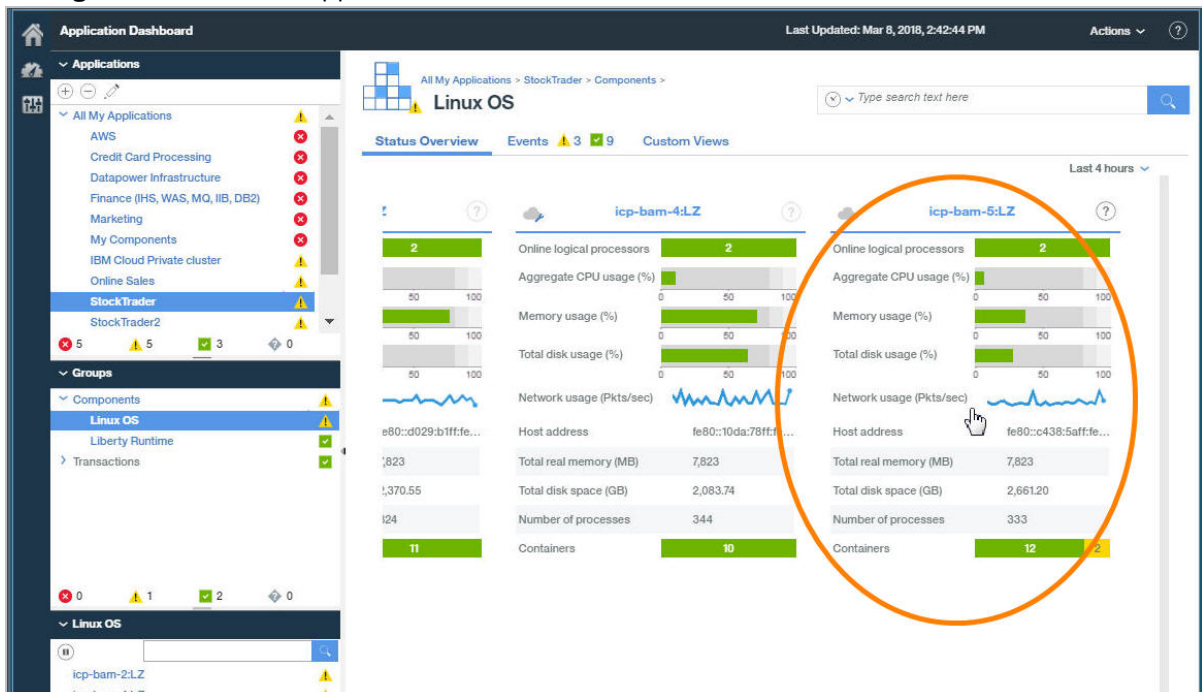

## Start monitoring your Cloud Private container

Now you're ready to use the Cloud APM console for monitoring your Linux OS container. Take a look at the dashboards for the application that you created. The examples in these screens present the StockTrader application that was created for monitoring the Cloud APM container.

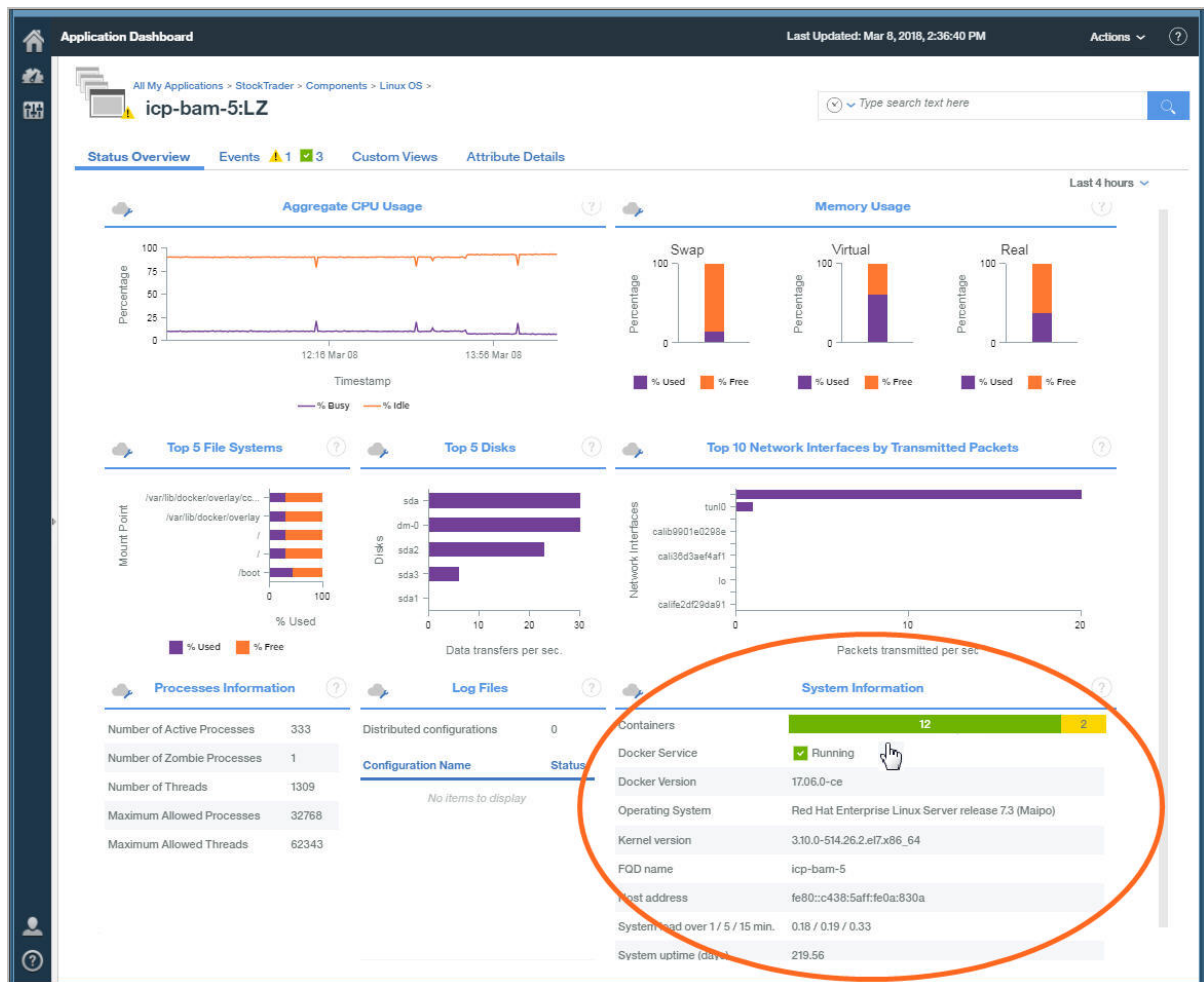

After starting the Cloud APM console, click  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard. Find the summary status box for **StockTrader** and select **Components** to get a status overview of all the managed resources.

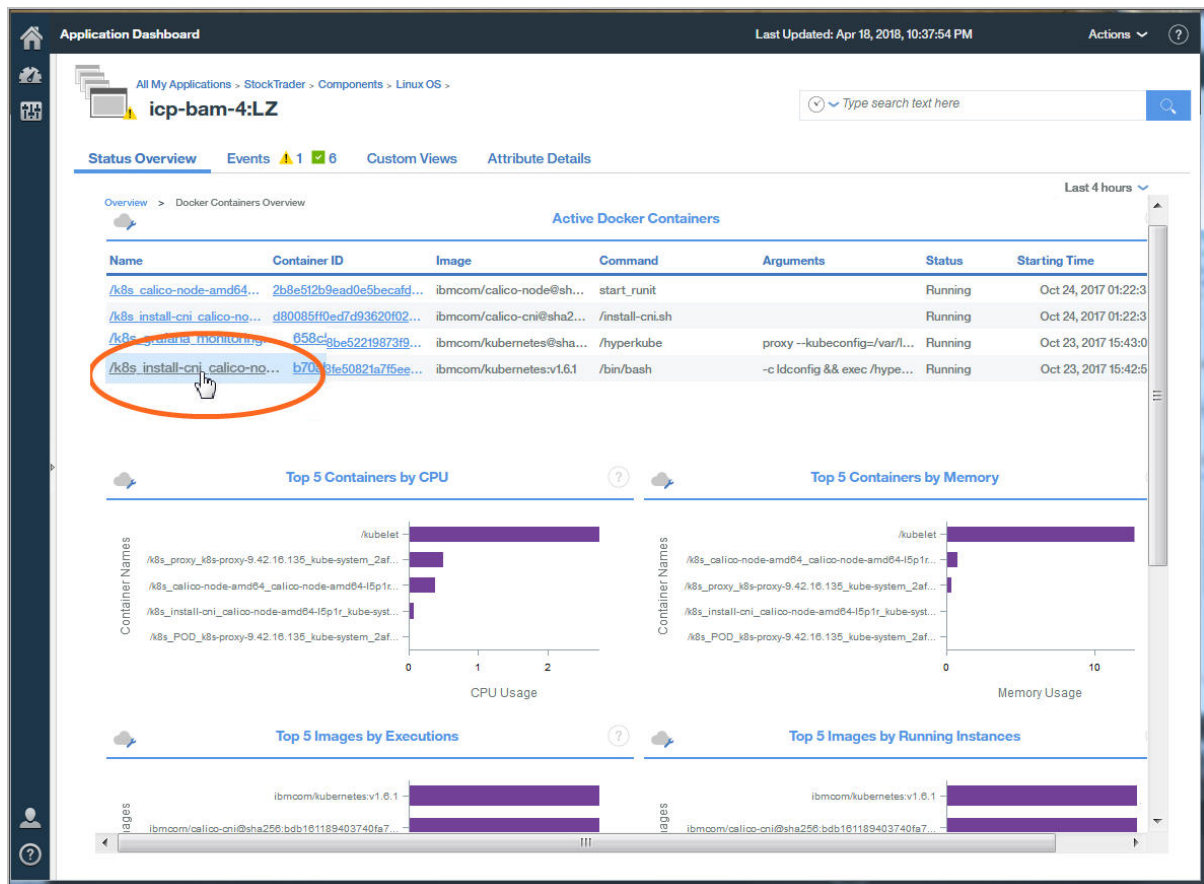

The Status Overview is displayed with a group widget for each managed resource in the StockTrader application. You can hover the mouse over any of the widgets to see the exact value, such as the **Aggregate CPU usage** percentage. At the group level of the navigator, the status is shown for each managed resource in the application.

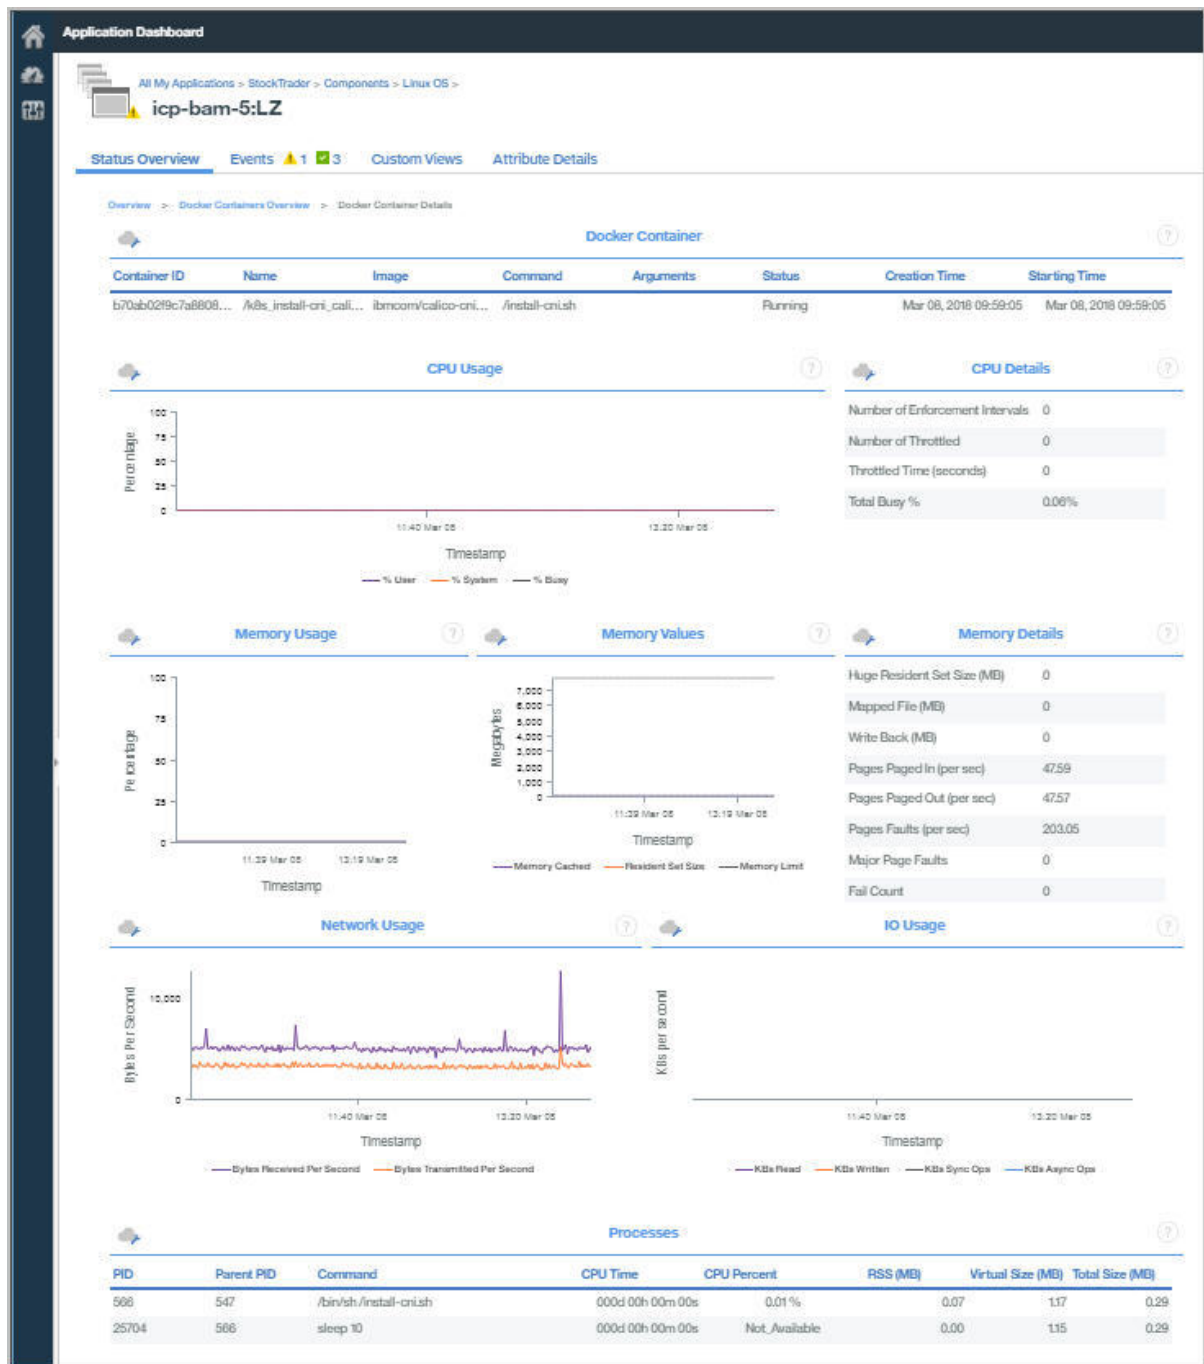

Click inside the Linux OS group widget to open the dashboard for the node. The **Overview** dashboard presents Linux OS statistics of most interest. For example, the **System Information** group widget shows the status of all the containers, including system load and up time.

Click the Containers gauge or Docker Service widget to open the **Docker Containers Overview**. The table lists all the active Docker containers and shows which are consuming the most CPU and memory, as well as the images with the most executions and running instances.

Click a row of the **Active Docker Containers** table to see more details about the container. The **Docker Container Details** dashboard displays information about the Docker container, performance statistics over the past four hours that you can extend to a full day or compare the values with a different day, and other details such as the processes that are running and how much CPU they consume.

You can also use predefined thresholds to monitor the Linux OS resource consumption by the Cloud Private container. Create thresholds for early detection of issues. For more information about adding thresholds, see [“Tutorial: Defining a threshold”](#) on page 1116.

## Monitoring your IBM Cloud Private applications

Use IBM Cloud Application Performance Management, Private to monitor your IBM Cloud Private Liberty-based applications.

The setup involves some basic steps:

### Configure the Liberty data collector to connect to the Cloud APM server

When you set up a Microservice Builder pipeline and push a Liberty application into Cloud Private, the Liberty data collector is automatically installed. The data collector is initially in a disabled state and

gets activated after it discovers the Cloud APM server information. You use the Kubernetes Secrets to provide the server information.

You can also deploy the Liberty data collector into Cloud Private without using Microservice Builder.

For more information, see [“Configuring Liberty monitoring”](#) on page 548.

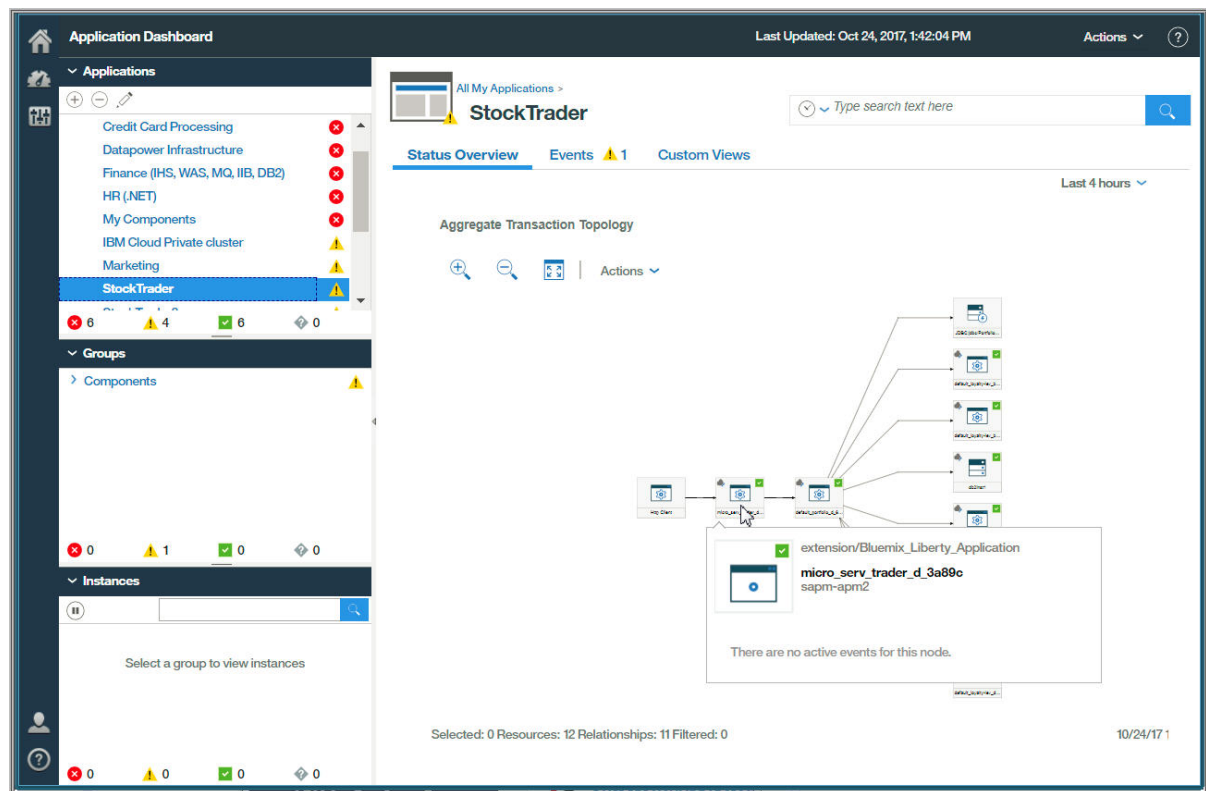

### Add an application for managing your Cloud Private applications

To manage your Liberty-based applications, group them by adding an application in the Application Performance Dashboard to group them. Launch the Cloud APM console and create an application with the Liberty managed resources that you configured in your Cloud Private environment. For more information, see [“Managing applications”](#) on page 1269.

### Start monitoring your Cloud Private applications

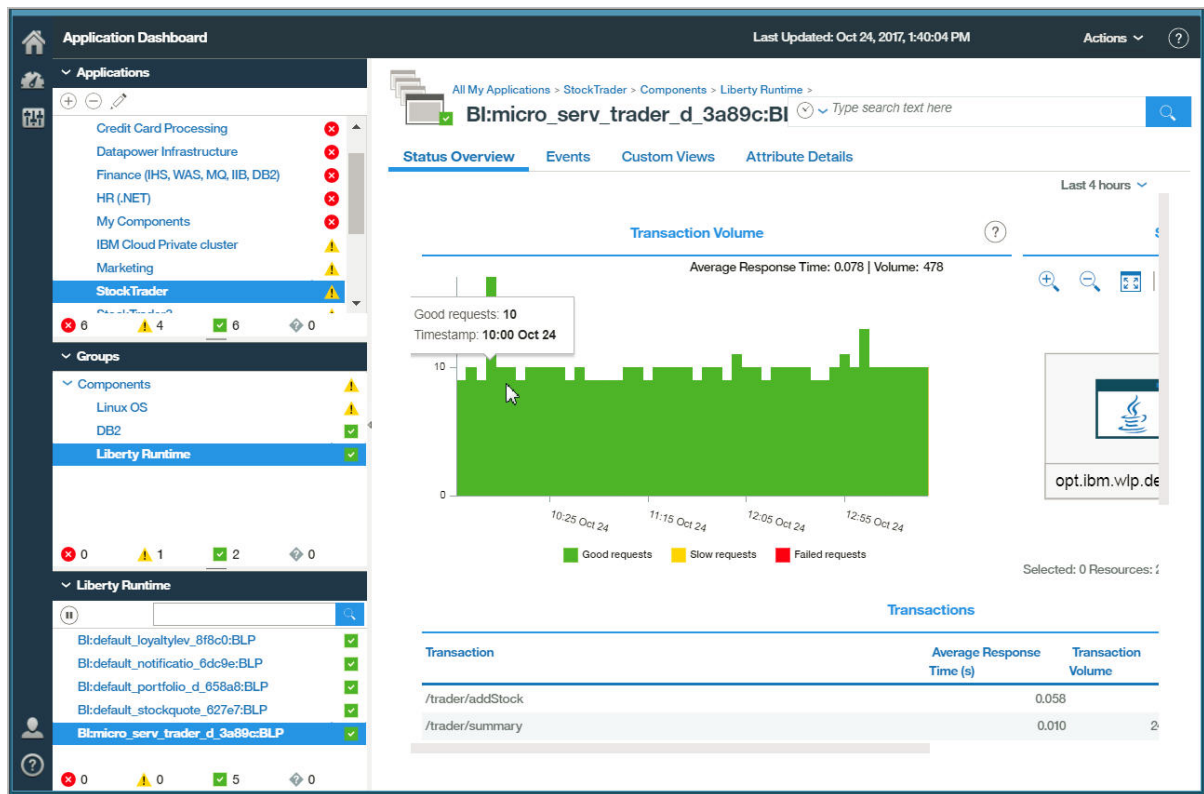

Now you're ready to use the Cloud APM console for monitoring your Liberty-based microservice applications. Take a look at the dashboards for the application that you created. You can quickly learn where problems with your microservices are occurring. The examples in these screens present the StockTrader application that was created for monitoring the Cloud Private Liberty-based applications.

The application-level dashboard shows the Aggregate Transaction Topology view. Hover your mouse over a node to see more details.

Right-click a node and select **Go to Transaction Summary Page**.

Details about the transactions are displayed for the Liberty Runtime instance in the dashboard. The Transaction Volume bar chart shows the volume and average response time. In the Transactions table, you can click a transaction to get a closer look at the details.

You can use the predefined thresholds to monitor your Cloud Private Liberty-based applications. Add additional thresholds for early detection of issues, such as a high transaction failure rate on Liberty. For more information about adding thresholds, see [“Tutorial: Defining a threshold”](#) on page 1116.

## Integrating with IBM Cognos Analytics

You can run your installed IBM Cloud APM reports from the IBM Cognos Analytics user interface. Cognos Analytics 11.x is the replacement for Tivoli Common Reporting (TCR), which is at end of service.

For more information on installing the Cloud APM reports in a Cognos Analytics 11.x environment, see the IBM Support technote at <https://www.ibm.com/support/pages/node/6257869>

## Integrating with Tivoli Common Reporting

Integrate Tivoli Common Reporting with Cloud APM to generate reports on data that is collected by the Response Time Monitoring Agent, the Synthetic Playback agent, and the WebSphere Applications agent.

**Notice:** Tivoli Common Reporting is at end of service as of May 2020. Cognos Analytics 11.x is the replacement. For more information, see the following technote: [How to install the IBM Cloud Application Performance Management reports in an IBM Cognos Analytics 11.x environment](#).

Reports are available only for Tivoli Common Reporting running on Linux and AIX systems. If you plan to integrate Tivoli Common Reporting with Cloud APM, use Tivoli Common Reporting V3.1.2.1 or V3.1.3 on Linux or AIX systems.

Tivoli Common Reporting V3.1.2.0 is included in Jazz for Service Management V1.1.2.0. Jazz for Service Management V1.1.2.0 is a component of Tivoli Monitoring V6.3.0.7, which is provided with Cloud APM V8.1.4. You must install Fix Pack 1 of Jazz for Service Management V1.1.2, which upgrades Jazz for Service Management to V1.1.2.1 and upgrades Tivoli Common Reporting to V3.1.2.1. For the relevant eAssembly and eImage part numbers, see [“Part numbers”](#) on page 135.

Tivoli Common Reporting V3.1.3 is included in Jazz for Service Management V1.1.3. See the latest [Jazz for Service Management Version 1.1.3.0 Knowledge Center](#).

To integrate Tivoli Common Reporting, you must complete the following tasks:

1. Download and install Tivoli Common Reporting.
2. Check that the Tivoli Common Reporting server is connected to the Cloud APM Db2 machine. If not, configure an ODBC connection between the Tivoli Common Reporting server and the Cloud APM Db2 machine.
3. Configure the reports installation image to create the reports package.
4. Install the reports package on the Tivoli Common Reporting server.
5. Enable single sign-on between Cloud APM and Tivoli Common Reporting.

For a list of reports available for each agent, see [“Reports” on page 1294](#).

## Downloading and installing Tivoli Common Reporting

Before you integrate Tivoli Common Reporting with Cloud APM, you must download and install Tivoli Common Reporting.

Tivoli Common Reporting is a component of Jazz for Service Management. It is a prerequisite for Response Time Monitoring Agent, Synthetic Playback agent, and WebSphere Applications agent reports. Cloud APM reports are supported only on Tivoli Common Reporting Linux systems.

Tivoli Common Reporting is part of IBM Tivoli Monitoring, and is bundled with Cloud APM offerings. The download image is available from the IBM Passport Advantage website. For information about how to download, see [“Download instructions” on page 131](#). For more information about Tivoli Common Reporting, see the latest [Jazz for Service Management Version 1.1.3.0 Knowledge Center](#).

## Configuring an ODBC connection

Before you install Cloud APM reports, you must configure an ODBC connection between the Tivoli Common Reporting server and the Cloud APM Db2 machine. The purpose of this configuration is to enable Tivoli Common Reporting to retrieve the required data from the Cloud APM Db2 database by using a local Db2 client.

### Procedure

1. On the Tivoli Common Reporting server, connect to the Cloud APM Db2 database by using the Db2 client and catalog a node. Run the following command:

```
su - local_db_instance_User
db2 catalog tcpip node apm_db2_node_name remote apm_db2_ip_address server
    apm_db2_instance_port
```

Example:

```
su - dbinst1
db2 catalog tcpip node DB2_SRVR remote 123.456.789.123 server 50000
```

The *apm\_db2\_node\_name* must be no longer than 8 characters.

2. On the Tivoli Common Reporting server, connect to the local Db2 instance and catalog the Cloud APM Db2 WAREHOUS and DATAMART databases:

If you want to create a connection to generate reports for the WebSphere Applications agent, run the following command:

```
su - local_db_instance_User db2 catalog db WAREHOUS as WAREHOUS at node apm_db2_node_name
```

Example:

```
su - dbinst1
db2 catalog db WAREHOUS as WAREHOUS at node DB2_SRVR
```

If you want to create a connection to generate reports for the Synthetic Playback agent or the Response Time Monitoring Agent, you must catalog the Db2 DATAMART. Run the following command:

```
su - db2inst1
db2 catalog db DATAMART as DATAMART at node apm_db2_node_name
```

Example:

```
su - dbinst1
db2 catalog db DATAMART as DATAMART at node DB2_SRVR
```

If you're using custom database names instead of the default database names WAREHOUSE and DATAMART, catalog WAREHOUS and DATAMART as shown here:

```
su - local_db_instance_User
db2 catalog db CUSTOM_WAREHOUS_DBNAME as WAREHOUS at node apm_db2_node_name
db2 catalog db CUSTOM_DATAMART_DBNAME as DATAMART at node apm_db2_node_name
```

## Results

An ODBC connection is now configured between the Tivoli Common Reporting server and the Db2 client.

## What to do next

Configure the reports installation image. For more information, see [“Configuring the reports installation image” on page 1085](#).

## Configuring the reports installation image

Before you install Cloud APM reports, you need to configure the reports installation image to connect to the Cloud APM server. When you complete the configuration, a reports package for installation is created.

### Before you begin

1. Ensure that you configured the ODBC connection between the Tivoli Common Reporting server and the Cloud APM Db2 machine. For details, see [“Configuring an ODBC connection” on page 1084](#).
2. Download the reports image to your Cloud APM server. For details, see [“Download instructions” on page 131](#). The following reports installation images are available depending on your offering:
  - `apm_advanced_reports_8.1.4.0.zip`
  - `apm_base_reports_8.1.4.0.zip`

### Procedure

1. Run the `configure_reports_images.sh` script with root privileges to configure the reports installation image:

```
/opt/ibm/ccm/configure_reports_images.sh
```

Where `/opt/ibm/` is the default installation folder for the Cloud APM server. If you have a different Cloud APM server installation folder, replace `/opt/ibm/` with your installation folder location.

2. Enter 1 to confirm that you want to configure the reports installation image.
3. Enter the directory path where you downloaded the reports installation image.
4. Enter the password of the Cloud APM smadmin user.

**Important:** This password is the password of the Internal Cloud APM smadmin user. The smadmin password is the same as the apmadmin user password that you specified at installation. The default

value is `ampass`. If you cannot remember the `smadmin` password, you can change it using the script that is described in the following topic: [“Default users and passwords” on page 1194](#).

After you enter the correct password, the configuration script configures the reports installation image and copies the reports package to another directory.

5. Enter the path where you want to store the reports package, or accept the default value of `/opt/ibm/ccm/depot`.
6. Enter the fully qualified hostname of the Cloud APM server that the Tivoli Common Reporting server communicates with for retrieving data for reports.  
For more information about Tivoli Common Reporting, see [“Downloading and installing Tivoli Common Reporting” on page 1084](#).

## Results

A message is displayed indicating the directory where the reports installation package is available.

The reports installation package is available in the directory that you specified in step “5” on page 1086. The reports installation package has the same name as the reports installation image that you downloaded. For example, if you downloaded `apm_advanced_reports_8.1.4.0.zip` and completed the configuration successfully, the `apm_advanced_reports_8.1.4.0.zip` reports installation package is available in the directory you specified in step “5” on page 1086.

## What to do next

Install the reports packages, for details, see [“Installing reports” on page 1086](#).

## Installing reports

Install the reports package on the Tivoli Common Reporting server.

### Before you begin

Before you install reports, you must complete the following steps:

- Configure the reports installation image. If you configured the reports installation image, you see one of the following reports installation packages in the directory that you specified during configuration. The default folder for the reports installation package is `/opt/ibm/ccm/depot`.
  - `apm_advanced_reports_8.1.4.0.zip`
  - `apm_base_reports_8.1.4.0.zip`

For more information, see [“Configuring the reports installation image” on page 1085](#).

- Ensure that network connectivity exists between the Tivoli Common Reporting server and the Cloud APM server. The `install_reports.sh` script uses port 8091 to send HTTP requests to the Cloud APM server.

## Procedure

1. Copy the reports installation package from the Cloud APM server to the Tivoli Common Reporting server and extract the reports installation package.
2. On the Tivoli Common Reporting server, run the installation script with root user privileges:

```
./installReports.sh
```

**Note:**  If you want to install reports packages on an AIX system with the Korn shell set as default, you must ensure that the Bash shell is available. You must also edit the `./installReports.sh` script to change the line

```
#!/bin/sh
```

to

```
#!/bin/bash
```

3. Select packages to install from the following reports packages by entering the corresponding numbers:
  - Response Time Monitoring Agent Reports (not available in IBM Cloud Application Performance Management, Base Private)
  - Monitoring Agent for WebSphere Applications Reports
  - Monitoring Agent for Synthetic Playback Reports (not available in IBM Cloud Application Performance Management, Base Private)
4. Enter the installation path for Jazz for Service Management.
5. Enter the user name and password for a Jazz for Service Management user with administrator privileges.
6. Enter the password of a Cloud APM administrator.

**Important:** This password is the password of the Internal Cloud APM smadmin user. The smadmin password is the same as the apmadmin user password that you specified at installation. The default value is apmpass. If you cannot remember the smadmin password, you can change it using the script that is described in the following topic: [“Default users and passwords” on page 1194](#).

7. Enter the fully qualified hostname for Tivoli Common Reporting. For more information about Tivoli Common Reporting, see [“Downloading and installing Tivoli Common Reporting” on page 1084](#).
8. Verify Cognos Application Firewall and Cross Site Scripting (XSS) settings in IBM Cognos and Cloud APM to allow access to reports from the Application Performance Dashboard.
  - a) Navigate to the installation location of Tivoli Common Reporting and run Cognos Configuration. The default location is `/opt/IBM/JazzSM/reporting/cognos/bin64/tcr_cogconfig.sh`.
  - b) In the **Component Properties** table, ensure that **Enable CAF validation?** and **Is third party XSS checking enabled?** are set to True.  
For more information, see [Configure IBM Cognos Components to Use IBM Cognos Application Firewall](#).
  - c) Restart the Tivoli Common Reporting server.  
For more information, see [Restarting Jazz for Service Management application servers](#).
  - d) In the Cloud APM console Console, click **Advanced Configuration > UI Integration > Parameters** and set **Cognos Reporting Requires XSS Validation** as True.

## Results

The reports packages are installed successfully. The Tivoli Common Reporting URL is added to the **Cognos Reporting URL** field in **Advanced Configuration > UI Integration > Parameters** in the Performance Management console. The Cognos Reporting URL format is `https://reporting-server-hostname:port/tarf/servlet/dispatch/secured`.

For Tivoli Common Reporting 3.1.1 and higher, the Cognos Reporting URL format is `https://reporting-server-hostname:port/tarf/servlet/reporting/secured`.

If you are using Tivoli Common Reporting 3.1.1 or later, you must use the Cloud APM console to manually set the **Cognos Reporting URL** field in the **Advanced Configuration > UI Configuration > Parameters** section.

**Important:** If the installation script does not complete successfully, review the error messages in the latest log file in the `/tmp/apm_reports_installer` directory.

## What to do next

You are now ready to view reports in the Application Dashboard. For more information, see [“Reports” on page 1294](#).

## Configuring single sign-on with Tivoli Common Reporting

Disable OIDC and configure Tivoli Common Reporting and IBM Cloud Application Performance Management to enable single sign-on (SSO) and prevent repeated login requests.

To enable single sign-on between Tivoli Common Reporting and Cloud APM, you must complete the following tasks:

1. Disable OpenID Connect authentication for the Cloud APM UI.
2. Enable single sign-on between Cloud APM and Tivoli Common Reporting.
3. Ensure the **Cognos Reporting URL** host is the fully qualified Tivoli Common Reporting server hostname under **Advanced Configuration > UI Integration**. For more information, see [“Installing reports” on page 1086](#).

### Disabling OpenID Connect authentication for the Cloud APM console

You must disable the OpenID Connect authentication for the Cloud APM console before you can enable single sign-on (SSO) between Cloud APM and another IBM product that requires LTPA for SSO.

Although OIDC is no longer used for UI authentication after you complete this procedure, the RESTful APIs continue to rely on OIDC. The RESTful APIs do not interfere with SSO (see [“Exploring the APIs” on page 1237](#)).

### Procedure

Complete these steps to disable OIDC authentication for the Cloud APM console.

1. Stop all servers with the command `apm stop_all`.

For more information, see [“Starting, stopping, and checking the status of server components” on page 1210](#).

2. If LDAP is already configured for Cloud APM, you must temporarily modify the `commonRegistry.xml` file at `install_dir/wlp/usr/shared/config/` to include `basicRegistry.xml` instead of `ldapRegistry.xml`:

- a) Comment out the line that refers to the LDAP registry file as follows:

```
<!--include optional="false" location="${shared.config.dir}/ldapRegistry.xml"/-->
```

- b) Remove the comment tags from the line that refers to the basic registry file as follows:

```
<include optional="false" location="${shared.config.dir}/basicRegistry.xml"/>
```

3. Change the value of the `oauthRealm` attribute in the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file to match the value of the `realm` attribute in the `basicRegistry.xml` file.
4. Edit the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to temporarily remove the **systemUser** property, complete these steps:
  - a) Make a backup copy of the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file.
  - b) Open the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file and search for the line that begins with `<properties`. Delete the **systemUser** property.
5. Edit the `install_dir/wlp/usr/servers/apmui/server.xml` file and comment out this line as follows:

```
<!--include optional="true" location="server-relying-party.xml"/-->
```

6. Edit the `install_dir/wlp/usr/servers/apmui/server-itportal.xml` file to change the following line:

```
<application type="eba" id="Blaze" name="Blaze"  
  location="${server.config.dir}/apps/com.ibm.tivoli.blaze_2.3.0.7.eba">
```

Change the line as shown in the following code:

```
<application type="eba" id="Blaze" name="Blaze"
  location="${server.config.dir}/apps/com.ibm.tivoli.blaze_2.3.0.7.ltpasso.eba">
```

7. Edit the `install_dir/wlp/usr/servers/uviews/server.xml` file and comment out this line as follows:

```
<!--include optional="true" location="server-relying-party.xml"-->
```

You must use the exact format that is shown here to comment out the `include` statement for the `server-relying-party.xml` file.

8. Run the following command with the correct password for the **apmadmin** user:

```
install_dir/ccm/configureConsole_ltpasso.sh apmadmin password
```

The default *password* is **apmpass**.

9. If you disabled LDAP in step “2” on page 1088, re-enable the LDAP registry in the `commonRegistry.xml` file:

- a) Comment out the line that refers to the basic registry as follows:

```
<!--include optional="false" location="${shared.config.dir}/basicRegistry.xml"-->
```

- b) Remove the comment tags from the line that refers to the LDAP registry file as follows:

```
<include optional="false" location="${shared.config.dir}/ldapRegistry.xml"/>
```

10. If you changed the value of the `oauthRealm` attribute in step “3” on page 1088, update it to match the value of the `realm` attribute in the `ldapRegistry.xml` file.
11. If you removed the **systemUser** property in step “4” on page 1088, replace the current `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file with the backup file that you created in step 4a.
12. Start all servers with the command `apm restart_all`.

For more information, see “Starting, stopping, and checking the status of server components” on page 1210.

## Results

OpenID Connect authentication for the Cloud APM console is now disabled.

## Enabling single sign-on between Cloud APM and Tivoli Common Reporting

Configure Tivoli Common Reporting and IBM Cloud APM to enable single sign-on (SSO) and prevent repeated login requests.

### Before you begin

Ensure that OpenID connect (OIDC) authorization is disabled for the Cloud APM console. For more information, see “Disabling OpenID Connect authentication for the Cloud APM console” on page 1088.

### About this task

To configure SSO between Tivoli Common Reporting and Cloud APM, you must use a common Lightweight Directory Access Protocol (LDAP) server that contains defined users who can access the Cloud APM UI and who are authorized to run reports.

### Procedure

Complete the following steps to enable SSO on the Tivoli Common Reporting server:

1. Configure Tivoli Common Reporting to use the common LDAP server.

For more information, see [Configuring the LDAP federated repository](#).

2. Enable SSO on the server where Tivoli Common Reporting is located.

For more information, see [Configuring SSO on the application server](#).

3. Configure which LDAP users have access to Tivoli Common Reporting and Jazz for Service Management and have permission to run reports.

For more information, see [Adding users by using the WebSphere administrative console and Managing roles for users](#).

On the Cloud APM server, complete the following steps:

4. Configure the Cloud APM server to use the common LDAP server if LDAP is not already configured. For more information, see ["Integrating with LDAP" on page 1097](#).

5. Update the Cloud APM realm in the following files to ensure that the realm matches the Tivoli Common Reporting and Jazz for Service Management realm (the Jazz for Service Management realm can be customized; the default is **defaultWIMFileBasedRealm**):

- `oauthVariables-onprem.xml`
- `cscsRoleAdmin.conf` To update this file, you must create a `cscsRoleAdmin.new` file, which is similar to changing a default Role Administrator user as described in ["Updating the primary role administrator" on page 1104](#).
- `ldapRegistry.xml`

6. Edit the Cloud APM server `ltpa.keys` file:

- a) Locate the `ltpa.keys` file at the location `install_dir/usr/servers/apmui/resources/security/` and create a copy of that file.
- b) Open the copy in a text editor and change the line  
`com.ibm.websphere.CreationHost=localhost`  
to  
`com.ibm.websphere.CreationHost=fully_qualified_apm_server_hostname`.  
Example: `com.ibm.websphere.CreationHost=apmhost.example.com`
- c) Copy the modified `ltpa.keys` file to the Tivoli Common Reporting server.

On the Tivoli Common Reporting server, complete the following steps:

7. Import the modified `ltpa.keys` file into the Tivoli Common Reporting server.

The password for the default `ltpa.keys` file is WebAS. For more information, see [Importing LTPA keys](#).

8. Restart Tivoli Common Reporting.

For more information, see [Restarting Jazz for Service Management application servers](#).

On the Cloud APM server, complete the following steps:

9. Edit the `install_dir/wlp/usr/servers/apmui/user-exit.xml`:

- Add or update the line `<webAppSecurity ssoRequiresSSL="true" />` to add or edit the attribute `ssoDomainNames=".common_domain"` to the element, where `common_domain` is the domain name that is common to Tivoli Common Reporting server and the Cloud APM server.

Example:

```
<webAppSecurity ssoRequiresSSL="true" ssoDomainNames=".example.com" />
```

Ensure that the `ssoDomainNames=".common_domain"` name starts with a period.

If the **webAppSecurity** element exists in the `apmui/server.xml` file, remove it.

10. Edit the `install_dir/wlp/usr/servers/uviews/user-exit.xml`:

- Add or update the line `<webAppSecurity ssoRequiresSSL="true" postParamSaveMethod="Session" />` to add or edit the attribute `ssoDomainNames=".common_domain"` to the element, where `common_domain` matches the domain name used in the previous step.

Example:

```
<webAppSecurity ssoRequiresSSL="true" postParamSaveMethod="Session"
ssoDomainNames=".example.com" />
```

Ensure that the `ssoDomainNames=".common_domain"` name starts with a period.

If the **webAppSecurity** element exists in the `uviews/server.xml` file, remove it.

11. If the ltpa expiration value in `install_dir/wlp/usr/servers/apmui/server.xml` and `install_dir/wlp/usr/servers/uviews/server.xml` are different, update them to match:
  - a) Edit the `install_dir/wlp/usr/servers/apmui/user-exit.xml` to add or update the ltpa expiration value for the apmui server.  
Example:

```
<ltpa expiration="200m" />
```

If the **ltpa** element exists in the `apmui/server.xml` file, remove it.

- b) Edit the `install_dir/wlp/usr/servers/uviews/user-exit.xml` to add or update the ltpa expiration value for uviews server.  
Example:

```
<ltpa expiration="200m" />
```

If the **ltpa** element exists in the `uviews/server.xml` file, remove it.

12. Import the apmui server ltpa key into the uviews server:
  - a) Make a backup copy of the uviews server ltpa key in `install_dir/wlp/usr/servers/uviews/resources/security/ltpa.keys`.
  - b) Copy the apmui server ltpa key to the uview server:

```
cp install_dir/wlp/usr/servers/apmui/resources/security/ltpa.keys
install_dir/wlp/usr/servers/uviews/resources/security/
```

13. Restart all Cloud APM services with the **apm restart\_all** command.  
For more information, see [“Starting, stopping, and checking the status of server components” on page 1210](#).

## Results

Single sign-on is now enabled between Tivoli Common Reporting and Cloud APM.

## Integrating with Dashboard Application Services Hub

Integrate Dashboard Application Services Hub with Cloud APM to create a single console or to create your own custom dashboards.

For more information about integrating with Dashboard Application Services Hub, see [Integrating with Jazz for Service Management](#) in the Jazz for Service Management documentation.

## Configuring single sign-on with Jazz for Service Management V1.1.2.0 or later

Disable OIDC and configure Jazz for Service Management V1.1.2.0 or later and IBM Cloud Application Performance Management to enable single sign-on (SSO) and prevent repeated login requests.

To enable single sign-on between with Jazz for Service Management V1.1.2.0 or later and Cloud APM, you must complete the following tasks:

1. Disable OpenID Connect authentication for the Cloud APM console.
2. Enable single sign-on between Cloud APM and Jazz for Service Management V1.1.2.0 or later.

## Disabling OpenID Connect authentication for the Cloud APM console

You must disable the OpenID Connect authentication for the Cloud APM console before you can enable single sign-on (SSO) between Cloud APM and another IBM product that requires LTPA for SSO.

Although OIDC is no longer used for UI authentication after you complete this procedure, the RESTful APIs continue to rely on OIDC. The RESTful APIs do not interfere with SSO (see [“Exploring the APIs” on page 1237](#)).

### Procedure

Complete these steps to disable OIDC authentication for the Cloud APM console.

1. Stop all servers with the command `apm stop_all`.

For more information, see [“Starting, stopping, and checking the status of server components” on page 1210](#).

2. If LDAP is already configured for Cloud APM, you must temporarily modify the `commonRegistry.xml` file at `install_dir/wlp/usr/shared/config/` to include `basicRegistry.xml` instead of `ldapRegistry.xml`:

- a) Comment out the line that refers to the LDAP registry file as follows:

```
<!--include optional="false" location="${shared.config.dir}/ldapRegistry.xml"-->
```

- b) Remove the comment tags from the line that refers to the basic registry file as follows:

```
<include optional="false" location="${shared.config.dir}/basicRegistry.xml"/>
```

3. Change the value of the `oauthRealm` attribute in the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file to match the value of the `realm` attribute in the `basicRegistry.xml` file.
4. Edit the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to temporarily remove the **systemUser** property, complete these steps:
  - a) Make a backup copy of the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file.
  - b) Open the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file and search for the line that begins with `<properties`. Delete the **systemUser** property.
5. Edit the `install_dir/wlp/usr/servers/apmui/server.xml` file and comment out this line as follows:

```
<!--include optional="true" location="server-relying-party.xml"-->
```

6. Edit the `install_dir/wlp/usr/servers/apmui/server-itportal.xml` file to change the following line:

```
<application type="eba" id="Blaze" name="Blaze"
  location="${server.config.dir}/apps/com.ibm.tivoli.blaze_2.3.0.7.eba">
```

Change the line as shown in the following code:

```
<application type="eba" id="Blaze" name="Blaze"
  location="${server.config.dir}/apps/com.ibm.tivoli.blaze_2.3.0.7.ltpasso.eba">
```

7. Edit the `install_dir/wlp/usr/servers/uviews/server.xml` file and comment out this line as follows:

```
<!--include optional="true" location="server-relying-party.xml"-->
```

You must use the exact format that is shown here to comment out the `include` statement for the `server-relying-party.xml` file.

8. Run the following command with the correct password for the **apmadmin** user:

```
install_dir/ccm/configureConsole_ltpasso.sh apmadmin password
```

The default *password* is **apmpass**.

9. If you disabled LDAP in step “2” on page 1092, re-enable the LDAP registry in the `commonRegistry.xml` file:

- a) Comment out the line that refers to the basic registry as follows:

```
<!--include optional="false" location="${shared.config.dir}/basicRegistry.xml"/-->
```

- b) Remove the comment tags from the line that refers to the LDAP registry file as follows:

```
<include optional="false" location="${shared.config.dir}/ldapRegistry.xml"/>
```

10. If you changed the value of the `oauthRealm` attribute in step “3” on page 1092, update it to match the value of the `realm` attribute in the `ldapRegistry.xml` file.
11. If you removed the **systemUser** property in step “4” on page 1092, replace the current `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file with the backup file that you created in step 4a.
12. Start all servers with the command `apm restart_all`.  
For more information, see “Starting, stopping, and checking the status of server components” on page 1210.

## Results

OpenID Connect authentication for the Cloud APM console is now disabled.

## Enabling single sign-on between Cloud APM and Jazz for Service Management V1.1.2.0 or later

Configure Jazz for Service Management and IBM Cloud Application Performance Management to enable single sign-on (SSO) and prevent repeated login requests.

### Before you begin

Ensure that OpenID connect (OIDC) authorization is disabled for the Cloud APM console. For more information, see “Disabling OpenID Connect authentication for the Cloud APM console” on page 1088.

### About this task

To configure SSO between Jazz for Service Management and Cloud APM, you must use a common Lightweight Directory Access Protocol (LDAP) server that contains defined users who can access the Cloud APM console and who are authorized to view dashboards in the Dashboard Application Services Hub (DASH).

### Procedure

On the Jazz for Service Management server, complete the following steps to enable SSO.:

1. Configure Jazz for Service Management V1.1.2.0 or later to use the common LDAP server.  
For more information, see [Configuring the LDAP federated repository](#).
2. Enable SSO on the server where Jazz for Service Management V1.1.2.0 or later is located.  
For more information, see [Configuring SSO on the application server](#).
3. Configure which LDAP users have access to Jazz for Service Management and have permission to view dashboards.  
For more information, see [Adding users by using the WebSphere administrative console and Managing roles for users](#).

On the Cloud APM server, complete the following steps:

4. Configure the Cloud APM server to use the common LDAP server if LDAP is not already configured. For more information, see [“Integrating with LDAP”](#) on page 1097.
5. Ensure the Cloud APM realm matches the Jazz for Service Management realm. The Jazz for Service Management realm can be customized. The default is **defaultWIMFileBasedRealm**. Update the realm in the following files:
  - `oauthVariables-onprem.xml`
  - `cscsRoleAdmin.conf` To update this file, you must create a `cscsRoleAdmin.new` file, which is similar to changing a default Role Administrator user as described in [“Updating the primary role administrator”](#) on page 1104.
  - `ldapRegistry.xml`
6. Edit the Cloud APM server `ltpa.keys` file:
  - a) Locate the `ltpa.keys` file at the location `install_dir/usr/servers/apmui/resources/security/` and create a copy of that file.
  - b) Open the copy in a text editor and change the line  
`com.ibm.websphere.CreationHost=localhost`  
to  
`com.ibm.websphere.CreationHost=fully_qualified_apm_server_hostname`.  
Example: `com.ibm.websphere.CreationHost=apmhost.example.com`
  - c) Copy the modified `ltpa.keys` file to the Jazz for Service Management server.

On the Jazz for Service Management server, complete the following steps:

7. Import the modified `ltpa.keys` file into the Jazz for Service Management server.  
The password for the default `ltpa.keys` file is WebAS. For more information, see [Importing LTPA keys](#).
8. Restart Jazz for Service Management V1.1.2.0 or later.  
For more information, see [Restarting Jazz for Service Management application servers](#).

On the Cloud APM server, complete the following steps:

9. Edit `install_dir/wlp/usr/servers/apmui/user-exit.xml`:
  - Add or update the line `<webAppSecurity ssoRequiresSSL="true" />` to add or edit the attribute `ssoDomainNames=".common_domain"` to the element, where `common_domain` is the domain name of the Jazz for Service Management server and the Cloud APM server.

Example:

```
<webAppSecurity ssoRequiresSSL="true" ssoDomainNames=".example.com" />
```

Ensure that the `ssoDomainNames=".common_domain"` name starts with a period.

If the `webAppSecurity` element exists in the `apmui/server.xml` file, remove it.

10. Edit the `install_dir/wlp/usr/servers/uviews/user-exit.xml`:

- Add or update the line `<webAppSecurity ssoRequiresSSL="true" postParamSaveMethod="Session" />` to add or edit the attribute `ssoDomainNames=".common_domain"` to the element, where `common_domain` matches the domain name used in the previous step.

Example:

```
<webAppSecurity ssoRequiresSSL="true" postParamSaveMethod="Session" ssoDomainNames=".example.com" />
```

Ensure that the `ssoDomainNames=".common_domain"` name starts with a period.

If the **webAppSecurity** element exists in the `uviews/server.xml` file, remove it.

11. If the `ltpa` expiration value in `install_dir/wlp/usr/servers/apmui/server.xml` and `install_dir/wlp/usr/servers/uviews/server.xml` are different, update them to match:

- a) Edit the `install_dir/wlp/usr/servers/apmui/user-exit.xml` to add or update the ltpa expiration value for the apmui server.  
Example:

```
<ltpa expiration="200m" />
```

If the **ltpa** element exists in the `apmui/server.xml` file, remove it.

- b) Edit the `install_dir/wlp/usr/servers/uviews/user-exit.xml` to add or update the ltpa expiration value for uviews server.  
Example:

```
<ltpa expiration="200m" />
```

If the **ltpa** element exists in the `uviews/server.xml` file, remove it.

12. Import the apmui server ltpa key into the uviews server:

- a) Make a backup copy of the uviews server ltpa key in `install_dir/wlp/usr/servers/uviews/resources/security/ltpa.keys`.  
b) Copy the apmui server ltpa key to the uview server:

```
cp install_dir/wlp/usr/servers/apmui/resources/security/ltpa.keys  
install_dir/wlp/usr/servers/uviews/resources/security/
```

13. Restart all Cloud APM services with the **apm restart\_all** command.

For more information, see [“Starting, stopping, and checking the status of server components” on page 1210](#).

## Results

Single sign-on is now enabled between Jazz for Service Management V1.1.2.0 or later and Cloud APM.

## Configuring console integration

To display external content from the Cloud APM console in the Jazz for Service Management Dashboard Application Services Hub console, configure a new console integration.

For more information about configuring a new console integration, see [Configuring a new console integration](#) in the Jazz for Service Management documentation.

### Note:

- Do not use the default console integration URL as described in the Jazz for Service Management documentation. Use the following console integration URL for Cloud APM: `http://fully_qualified_APM_hostname:9443/rest`
- The **Role Based Access Control** page cannot be used when the Cloud APM console is accessed in the **Dashboard Application Services Hub** console.
- The **Synthetic Script Manager** page cannot be used when the Cloud APM console is accessed in the **Dashboard Application Services Hub** console.
- If the Dashboard Application Services Hub is using WebSphere Application Server 8.5 Fix Pack 14 or later and the existing Cloud APM console integration stops working or you are unable to configure a new one, then complete the following steps:

1. Verify that you are getting these errors:

#### DASH Console Integration Error

Unable to connect to the remote console. Please check the console URL externally to ensure it works.

#### Cloud APM UI Server Error (messages.log)

CWWK00801E: Unable to initialize SSL connection. Unauthorized access was denied or security settings have expired. Exception is

```
javax.net.ssl.SSLHandshakeException: Client requested protocol TLSv1 not enabled or not supported
```

2. Change the Dashboard Application Services Hub SSL configuration to use protocol TLSv1.2:

- a. Log in to the Dashboard Application Services Hub.
- b. In the navigation pane, click **Console Settings > Websphere Administrative Console** and click **Launch Websphere administrative console**.
- c. In the WebSphere administrative console navigation pane, click **Security > SSL certificate and key management > SSL configurations > NodeDefaultSSLSettings > Quality of protection (QoP) settings**, open the **Protocol** drop-down menu, and select **TLSv1.2**.
- d. Open the `WAS_Install_Dir/JazzSM/profile/properties/ssl.client.prop` file in a text editor, locate the `com.ibm.ssl.protocol=SSL_TLS` entry, and update it:

```
com.ibm.ssl.protocol=TLSv1.2
```

- e. Restart the Dashboard Application Services Hub.

3. Add the Cloud APM server signer certificates to the NodeDefaultTrustStore:

- a. Log in to the Dashboard Application Services Hub.
- b. In the navigation pane, click **Console Settings > Websphere Administrative Console** and click **Launch Websphere administrative console**.
- c. In the WebSphere administrative console navigation pane, click **Security > SSL certificate and key management > Key stores and certificates > NodeDefaultTrustStore > Signer certificates > Retrieve from port** and update the following fields.

**Host** is the fully qualified host name of the Cloud APM server  
(`APMServer.domainname.com`)

**Port** is 9443

**Alias** can be anything that you choose to represent the Cloud APM server that the certificate belongs to (`APMServer.domainname.com_cert`)

- If your Cloud APM server has the IBM Cloud Application Performance Management V8.1.4.0 interim fix 9, or a later server interim fix, you must set the **DASH Console Integration Enabled** field to True. For more information, see [“Advanced Configuration” on page 1239](#), category [“UI Integration” on page 1239](#).

## Connect to the IBM Cloud Application Performance Management data provider

To display Cloud APM data in custom dashboards in the Dashboard Application Services Hub console, you must create a connection to the Cloud APM data provider.

For more information about creating a connection to a remote data provider, see [Creating a connection](#) in the Jazz for Service Management documentation ([http://www.ibm.com/support/knowledgecenter/SSEKCU\\_1.1.2.1/com.ibm.psc.doc/tip\\_original/cmdoc/connection\\_creating.html](http://www.ibm.com/support/knowledgecenter/SSEKCU_1.1.2.1/com.ibm.psc.doc/tip_original/cmdoc/connection_creating.html)).

For more information about what details to specify when creating a connection, see the Cloud APM and DASH configuration section in the *Creating custom monitoring dashboards* PDF file, available from the [IBM-cloud-apm-samples github repository](#).

**Note:** When you create the data provider connection, you must specify the smadmin user and its password. smadmin is an internal user for Cloud APM. The default password is apmpass. If you created a custom password for the apmadmin user during the Cloud APM server installation, or used the smapasswd.sh script to change the password of the smadmin user, then you need to specify your custom password to replace the default password apmpass.

After you create the connection to the Cloud APM data provider, you can create custom dashboards. For more information, see [“Create custom dashboards with IBM Cloud Application Performance Management data” on page 1097](#).

## Create custom dashboards with IBM Cloud Application Performance Management data

To display Cloud APM data in the Dashboard Application Services Hub console, you can create custom dashboards.

Information about creating custom dashboards is in the Cloud APM and DASH configuration section of the *Creating custom monitoring dashboards* PDF file, available from the [IBM-cloud-apm-samples github repository](#). General information about creating dashboards and adding widgets is in [Working with dashboards or pages](#) in the Jazz® for Service Management documentation.

When you create widgets with attributes from Cloud APM agents, you can see an agent's attributes, but not all of them are available for display in the dashboard. If no data is displayed from an attribute in the widget, it might be because you specified an unsupported attribute or data set. To see a list of the attributes that are suitable for inclusion in the widget, complete the following steps. Log in to the Cloud APM console. Select **Performance > Application Performance Dashboard**. Drill down to the dashboard of an agent instance. Select the **Attribute Details** tab. To see which attributes are available, create a table with the data set that you intend to use in your Dashboard Application Services Hub widget.

The Cloud APM data provider can be used with the following Dashboard Application Services Hub widgets:

- List widget
- Simple table
- Gauges:
  - Analog gauge
  - Status gauge
  - Volume bar value status gauge
- Charts:
  - Bar
  - Column
  - Line
  - Pie

When configuring a DASH widget to retrieve Cloud APM metric data, a managed system name or system resource group identifier must be specified. When you specify a system resource group identifier for your DASH widget, the list of group members is displayed. Select the agents that you want to retrieve data from.

**Note:** Custom resource group names cannot be specified.

For the system resource group identifier, you cannot specify the name that you see in the Resource Group Manager. Instead, you must specify the internal identifier for the system resource group. To determine the system resource group identifier, use the Resource Group Management Service API to query for system resource groups. The system resource group identifier is in the **keyIndexName** field, which is returned by the API. For more information about the Resource Group Management Service API, see [Using the Resource Group Management Service API](#).

## Integrating with LDAP

To leverage your LDAP user repository in Cloud APM, you must integrate your LDAP server with your Cloud APM server.

Cloud APM uses the WebSphere Application Server Liberty profile basic registry as the default method for user authentication. Alternatively, you can use an LDAP registry for user authentication.

When you integrate Cloud APM with LDAP, you can use SSL or non-SSL. Complete the following steps to integrate Cloud APM with LDAP:

- Create a copy of the following files:

- `install_dir/wlp/usr/shared/config/basicRegistry.xml`
- `install_dir/wlp/usr/shared/config/commonRegistry.xml`
- `install_dir/wlp/usr/servers/server1/cscs/conf/cscsRoleAdmin.conf`
- `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml`

You might need to restore these files later if you are troubleshooting the configuration, see [“Troubleshooting changing the primary role administrator”](#) on page 1106, and [“Troubleshooting the LDAP configuration”](#) on page 1102.

- (SSL only) [Add the LDAP server certificate.](#)
- [“Updating the LDAP registry file”](#) on page 1099.
- [Updating the primary role administrator.](#)

## Adding LDAP server certificate

To enable SSL communication between the Cloud APM server and LDAP server, the signer certificate for the LDAP server must be added to a trust store on the Cloud APM server.

### Before you begin

Obtain the signer certificates for your LDAP server from the LDAP administrator.

### About this task

The signer certificate for the LDAP server must be added to the trust store that is referenced by the **sslAlias** attribute of the `<ldapRegistry>` element in the Cloud APM server `ldapRegistry.xml` file. In the Procedure below and in the `ldapregistry.xml` samples topic ([“ldapregistry.xml samples”](#) on page 1102) `LdapSSLTrustStore.jks` is used as the trust store filename.

### Procedure

Complete these steps on your Cloud APM server:

1. Change to the `install_dir/wlp/usr/shared/resources/security` directory.
2. If the `install_dir/wlp/usr/shared/resources/security/LdapSSLTrustStore.jks` file already exists, rename it to `LdapSSLTrustStore.jks.sav`.
3. Enter the following command to create a new truststore:

```
install_dir/java/bin/keytool -importcert -keystore LdapSSLTrustStore.jks -file cert.name -alias ldap
```

where `cert.name` is the name of the signer certificate for the LDAP server. Example:

```
install_dir/java/bin/keytool -importcert -keystore LdapSSLTrustStore.jks -file ldap-signer.cer -alias ldap
```

4. When prompted, enter a password for the trust store.  
Enter the same password that is used for the Cloud APM shared truststore (`trust.jks`). The default password is `ccmR0cKs!`.
5. After the certificate is printed and you are prompted to confirm that you trust the certificate, enter Yes to trust the certificate.
6. You can check the content with the following command, which lists the certificates:

```
install_dir/java/bin/keytool -list -v -keystore LdapSSLTrustStore.jks
```

### Results

You added the LDAP server's certificate to the shared truststore.

## What to do next

Now that you have added the LDAP server signer certificate to a trust store, you must update the LDAP registry file as described in [“Updating the LDAP registry file” on page 1099](#). The [“ldapregistry.xml samples” on page 1102](#) topic shows how to specify the ssl attributes to reference the trust store that you just created.

## Updating the LDAP registry file

To configure Cloud APM to use LDAP for user authentication, update the `ldapRegistry.xml` file with your LDAP server information and then update the `commonRegistry.xml` to reference `ldapRegistry.xml`.

### Before you begin

If you are configuring using SSL, to enable SSL communication between Cloud APM and LDAP, the Signer certificate for the LDAP server must be added to the Cloud APM server.

### Procedure

1. Update the `ldapRegistry.xml` in the `install_dir/wlp/usr/shared/config/` directory. Choose the Non-SSL or SSL template. Both are identical except for the additional SSL settings. Samples are available in [“ldapregistry.xml samples” on page 1102](#).

The following list describes the fields that must be updated and the fields that might need to be updated depending on your environment:

#### Fields that must be updated for IBM Tivoli Directory Server

- `realm` – This can be any name without spaces or special characters. The same realm name is specified in the `ldapRegistry.xml` and `oauthVariables-onprem.xml` files.
- `host` – The host name or the IP address of the LDAP server.
- `port` – The port number of the LDAP server. By default, the LDAP server uses port 389 for non-SSL, and 636 for SSL.
- `baseDN` - The starting point in the LDAP directory where the LDAP server should start searching for your users and groups. The Cloud APM server treats user distinguished names as case sensitive strings when performing role based authorization. Since user distinguished names include the baseDN, the baseDN value is case sensitive even if the `ignoreCase` property is set to `true` in the `ldapRegistry.xml` file. The baseDN must match the format in your LDAP directory.
- `bindDN` - The fully qualified DN, which has the authority to bind to your LDAP server and perform the requested queries. If your LDAP server allows anonymous queries, this field is not required.
- `bindPassword` - The password for bindDN. If your LDAP server allows anonymous queries, this field is not required.

#### Fields that might need to be updated for IBM Tivoli Directory Server (check with your LDAP administrator)

- `userFilter` and `groupFilter` - Check with your LDAP administrator to verify that the `objectclass` for `userFilter` and `groupFilter` are correct.

#### Fields that must be updated for Microsoft Active Directory

- `realm` – This can be any name without spaces or special characters. The same realm name is specified in the `ldapRegistry.xml` and `oauthVariables-onprem.xml` files.
- `host` – The host name or the IP address of the LDAP server.
- `port` – The port number of the LDAP server. By default, the LDAP server uses port 389 for non-SSL, and 636 for SSL.
- `baseDN` - The starting point in the LDAP directory where the LDAP server should start searching for your users and groups. The Cloud APM server treats user distinguished names as case sensitive strings when performing role based authorization. Since user distinguished names

include the baseDN, the baseDN value is case sensitive even if the ignoreCase property is set to true in the ldapRegistry.xml file. The baseDN must match the format in your LDAP directory.

- bindDN – The fully qualified DN, which has the authority to bind to your LDAP server and perform the requested queries. If your LDAP server allows anonymous queries, this field is not required.
- bindPassword – The password for bindDN. If your LDAP server allows anonymous queries, this field is not required.

#### Fields that might need to change for Microsoft Active Directory (check with your LDAP administrator)

- userFilter and groupFilter - Check with the LDAP administrator to verify that the objectcategory for userFilter and groupFilter are correct.
2. (Optional) To encode the value of the bindPassword property in the ldapRegistry.xml file, run the securityUtility from the *install\_dir/wlp/bin* directory. Enter the bindPassword password as an argument from the command line or when prompted. The securityUtility then outputs the encoded value. Copy the encoded value, and use that value for the bindPassword password in the ldapRegistry.xml file.
  3. Comment out the login property line from the ldapRegistry.xml file if it exists and is enabled.  
Active Directory: comment out <loginProperty>sAMAccountName;cn</loginProperty>  
Tivoli Directory Service: comment out <loginProperty>uid;cn</loginProperty>
  4. (Optional) If your LDAP directory contains thousands of users, use the userFilter parameter to limit the number of users that are returned when the Cloud APM server requests the list of users from the LDAP server. Specify a filter that returns the set of users that may require access to the Cloud APM console. If you do not specify a userFilter, when there are a very large number of users, the Cloud APM console displays the message "Failed to load Users" when you select **Individual Users** on the **Role Based Access Control** page.

If your LDAP directory contains thousands of groups, you should also use the groupFilter parameter to reduce the number of groups that are returned when the Cloud APM server requests the list of groups from the LDAP server. If you do not specify a groupFilter, when there are a very large number of users, the Cloud APM console displays the message "Failed to load Groups" when you select **User Groups** on the **Role Based Access Control** page.

If you only want users in certain LDAP groups to access the Cloud APM console, you can specify (memberOf=groupDN) in the userFilter where groupDN is the group distinguished name. If you want to include a nested LDAP group in the userFilter value, then you must include memberOf with the parent group DN and memberOf for each child group DN in the userFilter value. If you only specify memberOf with the parent group DN, then users in the child groups cannot log into the Cloud APM console.

This example shows a filtering on groups when a Microsoft Active Directory server is used:

```
userFilter="(&(sAMAccountName=%v)(objectcategory=user)(|
(memberOf=cn=Admins,ou=Groups,dc=mycity,dc=mycompany,dc=com)
(memberOf=cn=Operators,ou=Groups,dc=mycity,dc=mycompany,dc=com)))"
groupFilter="(&(cn=%v)(objectcategory=group)(|
(cn=Admins,ou=Groups,dc=mycity,dc=mycompany,dc=com)
(cn=Operators,ou=Groups,dc=mycity,dc=mycompany,dc=com)))"
userIdMap="user:sAMAccountName"
groupIdMap="*:cn"
groupMemberIdMap="memberOf:member"
```

This example shows filtering on uid and department:

```
userFilter="(&(uid=%v)(dept=CNNA)(objectclass=ibmPerson)))"
groupFilter="(&(cn=%v)(objectclass=groupOfUniqueNames))"
userIdMap="*:uid"
groupIdMap="*:cn"
groupMemberIdMap="groupOfNames:member;groupOfUniqueNames:uniqueMember"
```

This example shows filtering on uid or emailaddress, and department. This means either the uid or emailaddress can be used in 'userIdMap' for login:

```

    userFilter="( &(|(emailaddress=%v)(uid=%v))(dept=CNNA)
(objectclass=ibmPerson)))"
    groupFilter="( &(|(cn=%v)(objectclass=groupOfUniqueNames)))"
    userIdMap="*:emailaddress"
    groupIdMap="*:cn"
    groupMemberIdMap="groupOfNames:member;groupOfUniqueNames:uniqueMember"

```

This example shows filtering on country:

```

    userFilter="( &(|(uid=%v)(c=us)(objectclass=ibmPerson)))"
    groupFilter="( &(|(cn=%v)(objectclass=groupOfUniqueNames)))"
    userIdMap="*:uid"
    groupIdMap="*:cn"
    groupMemberIdMap="groupOfNames:member;groupOfUniqueNames:uniqueMember"

```

5. (Optional) To reduce the number of users returned in the search results, uncomment the `federatedRepository` property, and edit the **maxSearchResults** and **searchTimeOut** parameters. If you fail to edit the **maxSearchResults** parameter, you might get a **Not Authorized** message when you attempt to access users and user groups in the **Role Based Access Control** window. In addition, you might see `MaxResultsExceededException` in your log files.
6. Update the realm name in the `oauthVariables-onprem.xml` file in the `install_dir/wlp/usr/shared/config/` directory so that it matches the realm name in the `ldapregistry.xml` file. For example, if the `ldapregistry.xml` file has the following realm: `<ldapRegistry id="ldap" realm="SampleLdapIDSRealm"`, then the `oauthVariables-onprem.xml` file should have the same realm as follows: `<variable name="oauthRealm" value="SampleLdapIDSRealm" />`.
7. Update the `commonRegistry.xml` file in the `install_dir/wlp/usr/shared/config/` directory to use `ldapRegistry.xml`. Complete the following steps:

- a) Comment out the line that refers to the basic registry as follows:

```
<!--include optional="false" location="${shared.config.dir}/basicRegistry.xml"-->
```

- b) Remove the comment tags from the line that refers to the LDAP registry file as follows:

```
<include optional="false" location="${shared.config.dir}/ldapRegistry.xml"/>
```

- c) Save the `commonRegistry.xml` file.

8. To verify that the configuration is complete, go to `https://hostname:9443` and try logging in with the LDAP user account that will be the new Role Administrator.

- If you see the following message, your LDAP configuration is successful:

```

Not Authorized. You do not have permission to view this application.
If you require access to this application, please send the URL that you are attempting to
access
to your monitoring administrator.

```

The final step that you need to complete is to set the new Role Administrator user account from the LDAP repository as the default Cloud APM user, see [Updating the primary role administrator](#).

- If you see the following message, your LDAP configuration failed:

```
login failed
```

You might need to revert to basic registry authentication and/or troubleshoot the LDAP configuration, see [“Troubleshooting the LDAP configuration” on page 1102](#).

## Results

You configured Cloud APM to use LDAP for user authentication.

## What to do next

After you change user authentication to LDAP, you need to change the primary role administrator user. For information on changing the default user, see [“Updating the primary role administrator” on page 1104](#).

## Troubleshooting the LDAP configuration

You might need to troubleshoot your LDAP configuration.

### Procedure

1. If some or all of the following conditions are true, your LDAP configuration failed:

- You can still log in as apmadmin, or as any user defined in basic registry.
- You get the following error when you attempt to log in to `https://host_name:9443`

```
login failed
```

Complete the following checks:

- Check that the `commonRegistry.xml` file was updated correctly to point to `ldapRegistry.xml`.
  - Check that the LDAP server address, port, and bind credential are referenced correctly in the `ldapRegistry.xml` file. Any edits that you make and save take effect immediately.
  - Check that the correct ID is used in the `ldapRegistry.xml` file. Typically the uid for Tivoli Director Server or the sAMAccountName for Microsoft Active Directory is a single string with no spaces, and is different from the CN. For example, a user named John Smith might have a uid called johnsmith. The sample `ldapRegistry.xml` files are set up to use uid or sAMAccountName as the login ID. However, once logged in, the first CN is used to display the user name.
2. If you need to revert to basicRegistry, complete the steps in [“Switching from LDAP back to basicRegistry”](#) on page 1105.

### ldapregistry.xml samples

Review the LDAP registry examples of SSL and non-SSL configurations for IBM Tivoli Directory Server and Microsoft Active Directory.

SSL example for IBM Tivoli Directory Server

```
<server>
  <ldapRegistry id="ldap" realm="SampleLdapIDSRealm"
    host="ldapsrvr.mycity.mycompany.com" port="636" ignoreCase="true"
    baseDN="o=mycompany,c=us"
    ldapType="IBM Tivoli Directory Server"
    recursiveSearch="true"
    sslEnabled="true" sslRef="LDAPSSLSettings">

    <idsFilters userFilter="(&(uid=%v)(objectclass=ePerson))"
      groupFilter="(&(cn=%v)(!(objectclass=groupOfNames)
        (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))"
      userIdMap="*:uid"
      groupIdMap="*:cn"
      groupMemberIdMap="mycompany-allGroups:member;mycompany-allGroups:uniqueMember;
        groupOfNames:member;groupOfUniqueNames:uniqueMember">

    </idsFilters>

    <!-- Set up mapping between uid and cn -->
    <!--loginProperty>uid;cn</loginProperty-->

  </ldapRegistry>

  <!-- SSL Settings -->

```

## Non-SSL example for IBM Tivoli Directory Server

```
<server>
  <ldapRegistry id="ldap" realm="SampleLdapIDSRealm"
    host="ldapserver.mycity.mycompany.com" port="389" ignoreCase="true"
    baseDN="o=mycompany,c=us"
    ldapType="IBM Tivoli Directory Server"
    recursiveSearch="true">

    <idsFilters userFilter="(&(uid=%v)(objectclass=ePerson))"
      groupFilter="(&(cn=%v)(|(objectclass=groupOfNames)
        (objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))"
      userIdMap="*:uid"
      groupIdMap="*:cn"
      groupMemberIdMap="mycompany-allGroups:member;mycompany-allGroups:uniqueMember;
        groupOfNames:member;groupOfUniqueNames:uniqueMember">

    </idsFilters>

    <!-- Set up mapping between uid and cn -->
    <!--loginProperty>uid;cn</loginProperty-->

  </ldapRegistry>

  <!-- Max entries and timeout (in milliseconds) -->
  <!--federatedRepository maxSearchResults="4500" -->

</server>
```

## SSL example for Microsoft Active Directory

```
<server>
  <ldapRegistry id="ldap" realm="SampleLdapADRealm"
    host="ldapserver.mycity.mycompany.com" port="636" ignoreCase="true"
    baseDN="dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindDN="cn=testuser,cn=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindPassword="testuserpwd"
    ldapType="Microsoft Active Directory"
    recursiveSearch="true"
    sslEnabled="true" sslRef="LDAPSSLSettings">

    <activatedFilters userFilter="(&(sAMAccountName=%v)(objectcategory=user))"
      groupFilter="(&(cn=%v)(objectcategory=group))"
      userIdMap="user:sAMAccountName"
      groupIdMap="*:cn"
      groupMemberIdMap="memberOf:member">

    </activatedFilters>

    <!-- Set up mapping between sAMAccountName and cn -->
    <!--loginProperty>sAMAccountName;cn</loginProperty-->

  </ldapRegistry>

  <!-- SSL Settings -->

  <ssl id="LDAPSSLSettings" keyStoreRef="defaultKeyStore" trustStoreRef="LDAPTrustStore"/>
  <keyStore id="LDAPTrustStore" location="{shared.resource.dir}/security/LdapSSLTrustStore.jks"
    password="{trust.store.password}" type="JKS"/>

  <!-- Max entries and timeout (in milliseconds) -->
  <!--federatedRepository maxSearchResults="4500" -->

</server>
```

## Non-SSL example for Microsoft Active Directory

```
<server>
  <ldapRegistry id="ldap" realm="SampleLdapADRealm"
    host="ldapserver.mycity.mycompany.com" port="389" ignoreCase="true"
    baseDN="dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindDN="cn=testuser,cn=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
    bindPassword="testuserpwd"
    ldapType="Microsoft Active Directory"
    recursiveSearch="true">

    <activatedFilters
```

```

        userFilter="( &(sAMAccountName=%v)(objectcategory=user))"
        groupFilter="( &(cn=%v)(objectcategory=group))"
        userIdMap="user:sAMAccountName"
        groupIdMap="*:cn"
        groupMemberIdMap="memberOf:member" >
    </activatedFilters>

    <!-- Set up mapping between sAMAccountName and cn -->
    <!--loginProperty>sAMAccountName;cn</loginProperty-->

</ldapRegistry>

<!-- Max entries and timeout (in milliseconds) -->
<!--federatedRepository maxSearchResults="4500" -->

</server>

```

## Updating the primary role administrator

The default user for Cloud APM is apmadmin, and the default realm is customRealm. By default apmadmin is also the primary role administrator. When you configure LDAP to authenticate Cloud APM console users, you must change the primary role administrator from apmadmin to a LDAP user.

### About this task

The primary role administrator is responsible for assigning other Cloud APM console users to roles by using the **Role Based Access Control** page. The primary role administrator username and password are also used when backing up and restoring data for the Cloud APM server. You might need to change the primary role administrator for one of the following reasons:

- You are changing user authentication from basic registry to LDAP or you are switching to a different LDAP registry.
- You want to use a different LDAP user as the primary role administrator.
- You want to use a different realm name for the user registry.

If you are using basic registry, you cannot change the primary role administrator from apmadmin to another user. This is because Cloud APM procedures, such as backup and restore, assume apmadmin is the primary role administrator when the basic registry is configured. If you are switching from LDAP back to the basic registry, then see this topic ([Switching from LDAP back to basicRegistry](#)) for details on changing the primary role administrator back to the apmadmin user.

### Procedure

1. Navigate to the `install_dir/wlp/usr/servers/server1/cscs/conf` directory and create a file called `cscsRoleAdmin.new`.  
Do not edit or remove the `cscsRoleAdmin.conf` file directly. Any change should be done by creating a `cscsRoleAdmin.new` file.
2. Add a new default user to `cscsRoleAdmin.new` using syntax similar to the following (contact your LDAP administrator for the exact syntax):

```
user:SampleLdapADRealm/CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com
```

where:

#### SampleLdapADRealm

This is the realm name for your registry. Replace `SampleLdapADRealm` with the realm name from the registry configuration file (`basicRegistry.xml` or `ldapRegistry.xml`)

#### CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com

Replace `CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com` with the user that is being designated the primary role administrator. The primary role administrator user has authorization to perform all actions in the Cloud APM console including assigning other users or user groups to roles.

When you are switching from basic registry to LDAP, the primary role administrator must log into the Cloud APM console after this procedure is complete and assign roles to other LDAP users so that they are authorized to access the Cloud APM console.

Specify the user's distinguished name exactly as it is defined in the LDAP directory. The best practice is to specify a different user distinguished name from the bindDN user specified in the `ldapRegistry.xml` file.

**Note:** The realm name and user name are case sensitive.

3. Save the `cscsRoleAdmin.new` file.
4. Update the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to add the user from step “2” on page 1104:
  - a) Find the properties line, `<properties>`, and its closing tag, `</>`.
  - b) Add a new line before the `</>` closing tag with the following content: `systemUser="testuser LDAP distinguished name"` where `testuser` matches the user string from step “2” on page 1104, for example:  
`systemUser="CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"`  
**Note:** Do not include the `user:` prefix or realm name that was specified in step “2” on page 1104.
  - c) Confirm that the `</>` closing tag was not deleted, then save and close the file.
5. Update the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file and set the value of the `oauthRealm` attribute to the value of the `realm` property in the `install_dir/wlp/usr/shared/config/ldapRegistry.xml` file.
6. Restart the Cloud APM server by using the following command in the `/user/bin/` directory:

```
apm restart_all
```

7. To verify that you have successfully changed the primary role administrator, attempt to log in with your new Role Administrator user account.
  - If you can log in successfully, you have successfully changed the primary role administrator account. Go to the Role Based Access Control page to assign other LDAP users to roles so that they are authorized to log in to the Cloud APM console. For more information, see the Working with roles, users, and permissions topic ([Working with roles, users, and permissions](#)).
  - If you receive the message "You do not have permission to view this application. If you require access to the application, please send the URL that you are attempting to access to your monitoring system administrator", see [Troubleshooting changing the primary role administrator](#).

## Results

The Cloud APM integration with your LDAP server is now complete.

## Switching from LDAP back to basicRegistry

Cloud APM uses the WebSphere Application Server Liberty profile basic registry as the default method for user authentication.

## Procedure

1. Stop all components and services: `apm stop_all`
2. Open `install_dir/wlp/usr/shared/config/commonRegistry.xml` and comment out the `ldapRegistry` entry and uncomment the `basicRegistry` entry, or alternatively revert to a backup copy.
3. Open `install_dir/wlp/usr/shared/config/oauth_variables_onPrem.xml` and update the `oauthRealm` value to `CustomRealm`, or alternatively revert to a backup copy.
4. Navigate to the `install_dir/wlp/usr/servers/server1/cscs/conf` directory. Create a file called `cscsRoleAdmin.new`. Add a user: `user:customRealm/apmadmin`.  
**Note:** Do not modify the `cscsRoleAdmin.conf` file directly.
5. Start all component and services: `apm start_all`

## Troubleshooting changing the primary role administrator

If you cannot log into the Cloud APM console after changing the primary role administrator, follow the steps to troubleshoot the configuration.

### Before you begin

After you change the primary role administrator user, if you still receive the following error:

You do not have permission to view this application. If you require access to the application, please send the URL that you are attempting to access to your monitoring system administrator

you need to troubleshoot the configuration.

### Procedure

1. Check the `messages.log` file in the `install_dir/wlp/usr/servers/apmui/logs/` directory for any LDAP related errors. A search for the word 'RBAC2' should return several entries with the expected Distinguished Name, for example:

```
[3/8/16 12:40:17:976 CET] 000028c5 com.ibm.tivoli.ccm.rbac.RBACPermissions E **  
RBAC2: user:LdapRealm/cn=John Smith,dc=ibm,dc=com, /ui/tasks/information, task, view,  
false
```

In this example the expected Distinguished Name is `user: LdapRealm/cn=John Smith,dc=ibm,dc=com`

2. Verify the user and Distinguished Name that are specified in the `cscsRoleAdmin.conf` match exactly with your LDAP server entry. If updates are necessary, create a `cscsRoleAdmin.new` file with the correct entry, and run **apm restart\_all**.
3. Verify the realm that is specified in the `cscsRoleAdmin.conf` file matches exactly with the realm in the `ldapRegistry.xml` file. If updates are necessary, create a `cscsRoleAdmin.new` file with the correct entry, and run **apm restart\_all** command.
4. Verify that you have completed all the steps outlined in these sections, “Adding LDAP server certificate” on page 1098 “Updating the LDAP registry file” on page 1099.
5. If you need to revert to having `apmadmin` as the default user, you must also revert to using `customRealm` and `basicRegistry`. Complete the steps in “Switching from LDAP back to `basicRegistry`” on page 1105.

## Integrating with IBM Agent Builder

---

You can create, modify, debug, and package agents using Agent Builder that extend the monitoring capabilities of an IBM Tivoli Monitoring or IBM Cloud Application Performance Management environment. A custom agent uses either of these environments to monitor any type of in-house or customized software.

For details, see the [IBM Agent Builder User's Guide](#).

## IBM Cloud Application Business Insights

---

Use Cloud Application Business Insights application to create and view custom dashboards that provide a comprehensive performance overview of all your applications. You can create complex, dynamic, and interactive visual representations from Cloud APM and Tivoli Monitoring data sources to display real-time data. You can also connect to other third-party data sources.

### Components in Cloud Application Business Insights

It consists of the following components:

## **Dashboard Designer**

Dashboard builder component. A web-based tool with intuitive drag interface that helps to create and share live dashboards with real-time data. You can convert the business-critical data into interactive dashboards, and then customize them.

## **Engine**

Data visualization component. Engine is deployed as a web application on WebSphere Application Server Liberty.

## **Connector**

Data query component that connects to a data source and retrieves the data for visual representations in the widgets. By default, Cloud Application Business Insights has connectors to Cloud APM and Tivoli Monitoring data sources.

You can also connect to third-party data sources by using the JDBC drivers for most relational databases.

## **More information**

For more information about installing, administering, and using the application, see the following links:

- [Cloud Application Business Insights overview](#)
- [Installing Cloud Application Business Insights](#)
- [Administering Cloud Application Business Insights](#)
- [Using Cloud Application Business Insights](#)

---

## Chapter 10. Administering

Administering the Cloud APM infrastructure and agents involves maintenance tasks such as changing passwords and customization tasks such as adding and editing applications.

### Starting the Cloud APM console

---

Log in to the Cloud APM console from your browser to review the health status of your applications in the dashboards.

#### Before you begin

- The URL for the login is the IP address of the Cloud APM server.
- To ensure that the user interface is not truncated, use a minimum resolution of 1280 x 1024.
- For optimal performance, use one of the supported browsers. For a list of the supported browsers, open the IBM Cloud Application Performance Management [Software Product Compatibility Report](#), select the Prerequisites tab, and scroll down to Web Browsers.

#### Procedure

1. Open a browser window and enter the following URL where *server\_host* is the IP address of the server:

```
https://server_host:9443
```

You can also enter `http://server_host:8080`, although the URL is changed to the secure https and port number 9443 automatically.

2. After you are prompted for a logon ID, enter the following credentials for the default user or enter the credentials that were assigned by your administrator:
  - **User name** *apmadmin*
  - **Password** *apmpass*

The initial user credentials after Cloud APM server installation are *apmadmin* with password *apmpass*.

#### Results

After you log in, the **Getting Started** page is displayed with learning options for **User Tasks** and **Administrator Tasks**, and links to **Community Resources**.

#### What to do next

- Familiarize yourself with the user interface elements by clicking the hypertext link to take a tour of the Cloud APM dashboard. Watch videos of the user tasks and administrator tasks to help you get started using and customizing your Cloud APM environment.
- Add applications for viewing dashboards of your resources in logical groupings such as Online Ordering. For instructions, see [“Managing applications” on page 1269](#).
- Create thresholds to test for conditions that, when met, cause an event to open. For example, you can have a threshold that opens an event after storage capacity reaches 90%. For instructions, see [“Threshold Manager” on page 1119](#).
- Add and assign users to user groups and roles to control access to the Cloud APM console features and managed resources. For more information, see [“Managing user access” on page 1136](#).
- To learn about monitoring the IBM Java application stack and IBM integration stack, see [“Scenarios” on page 116](#).

- If, instead of the Getting Started page or the Application Performance Dashboard, your browser goes to the IBM website, your user ID has no permissions to the Cloud APM console. You must request access from your administrator.
- If no metrics are shown for a data source, consult the [Cloud Application Performance Management Forum](#) on developerWorks®. Search the forum for "dashboard", reply to an entry to ask a related question, or create a new entry and describe the symptom.
- If you are starting the Cloud APM console from Internet Explorer 8, 9, or 10 and you get a This page can't be displayed error, you might need to enable the security option, TLS 1.2. For more information, go to the [Cloud Application Performance Management Forum](#) and search on "tls".

## Thresholds and resource groups

Thresholds test for certain conditions, such as number of transactions per minute fewer than 100, and open an event when the conditions have been met. Use thresholds to monitor for real and potential issues with your monitored resources. Assign thresholds to resource groups for monitoring on all managed systems of the same type the belong to the group.

## Background information

Review the background information to learn about thresholds, predefined thresholds for your agents, the resource groups that they are assigned to, and customizing thresholds.

### Predefined thresholds

Your monitoring agents come with *predefined thresholds* that are enabled and started with the agent. The first time that you open the **Threshold Manager** after agent installation, the thresholds that are listed for the selected data source type are the predefined thresholds. These predefined thresholds are assigned to the default system resource group for the agent and shown in the **Assigned groups** column.

If you edit a predefined threshold, such as to change the name or condition, the threshold is no longer treated as a predefined threshold but considered a *custom threshold*. However, you can change the assigned resource group for a predefined threshold from the default system group to a user-defined group and it remains a predefined threshold.

If you prefer not to use the predefined thresholds, you can turn them off in the **Advanced Configuration** page (see “Thresholds Enablement” on page 1243). Disabling the predefined thresholds doesn't remove them from the **Threshold Manager**; it only removes their group assignment, rendering them inactive. After disabling the predefined thresholds, you can open the **Threshold Manager** and see that the **Assigned groups** column is empty for every predefined threshold (see “Examples of disabled thresholds” on page 1112).

You can enable the threshold as a custom threshold by assigning it to any available resource group.

### Custom thresholds

New thresholds that you create are custom thresholds, as indicated in the **Threshold Manager Origin** column. If you edit a predefined threshold, it also becomes a custom threshold and its origin changes from "Predefined" to "Custom".

### Execute command

After an event is opened for a threshold that evaluates to true, you can have a command or script of commands run automatically. For example, you might want to log information, trigger an audible beep, or stop a job that is overusing resources when an event is opened. The command or script is run on the system of the monitoring agent that opened the event.

The command uses the following syntax:

```
&{data_set.attribute}
```

where *data\_set* is the data set name and *attribute* is the attribute name as shown in the Threshold Editor. If the data set or attribute name contains a space, replace with an underscore. The *data\_set* must be the same data set that you select in the Data set selection field.

The following example shows how you can pass the disk name parameter to your managed resource:

```
/scripts/clean_logs.sh &{KLZ_Disk.Disk_Name}
```

You can pass in one or more attributes from the data set. If specified, multiple attributes are passed into the command in order (\$1, \$2, and so on).

You must ensure the script or programs executed by the command are installed on the agent system since Cloud APM does not provide a mechanism to distribute scripts or programs. The command runs from the command line with the same user account that the agent was started with. Ensure the user that starts the agent has permission to execute the command. For example, if the agent is running as root, then root runs the command on the managed system.

The following options control how often the command is run:

Select ☐ **On first event only** if the data set returns multiple rows and you want to run the command for only the first event occurrence in the data sample. Clear the check box to run the command for every row that causes an event.

Select ☐ **For every consecutive true interval** to run the command every time the threshold evaluates to true. Clear the check box to run the command when the threshold is true, but not again until the threshold evaluates to false, followed by another true evaluation in a subsequent interval.

### Resource groups

Resource groups represent a collection of managed systems and control how thresholds are distributed. You assign a threshold to the resource group that includes the managed systems where you want it to run.

All predefined thresholds have a default resource group assignment, which is the system defined group for the agent type, such as Db2 and Microsoft IIS.

You can create custom resource groups and select the managed systems to include in each group. You can have multiple agent types in a custom resource group; thresholds that are assigned to the group are distributed only to the managed systems of the same agent type. For example, a threshold that is created with Linux OS attributes and assigned to a resource group of Linux OS, MongoDB, and Python managed systems, is distributed to only the Linux OS managed systems.

For more information, see [“Resource Group Manager” on page 1114](#).

### Application Performance Dashboard event status

The status severities that are shown in the Application Performance Dashboard indicate the highest event severity of the selected application, group, subgroup, and managed system instance.

After you select an application from the navigator or from a summary box in the **All My Applications** dashboard, a tabbed dashboard presents different facets of your application. The **Events** tab provides information about the events for the selected navigator item, as described in [“Event Status” on page 1280](#).

### Threshold changes affect other thresholds that are assigned to the same monitoring agent

After you create, modify, or delete a threshold definition or change the list of thresholds that are distributed to a monitoring agent, all sampled events are closed for the agents that the threshold is distributed to. After the event closure, the monitoring agents reopen events for any threshold conditions that evaluate to true. On the Cloud APM console, the closed events disappear from the console until they are reopened with a new **Timestamp** value. If you are receiving email notifications for events, you receive close event and open event email notifications.

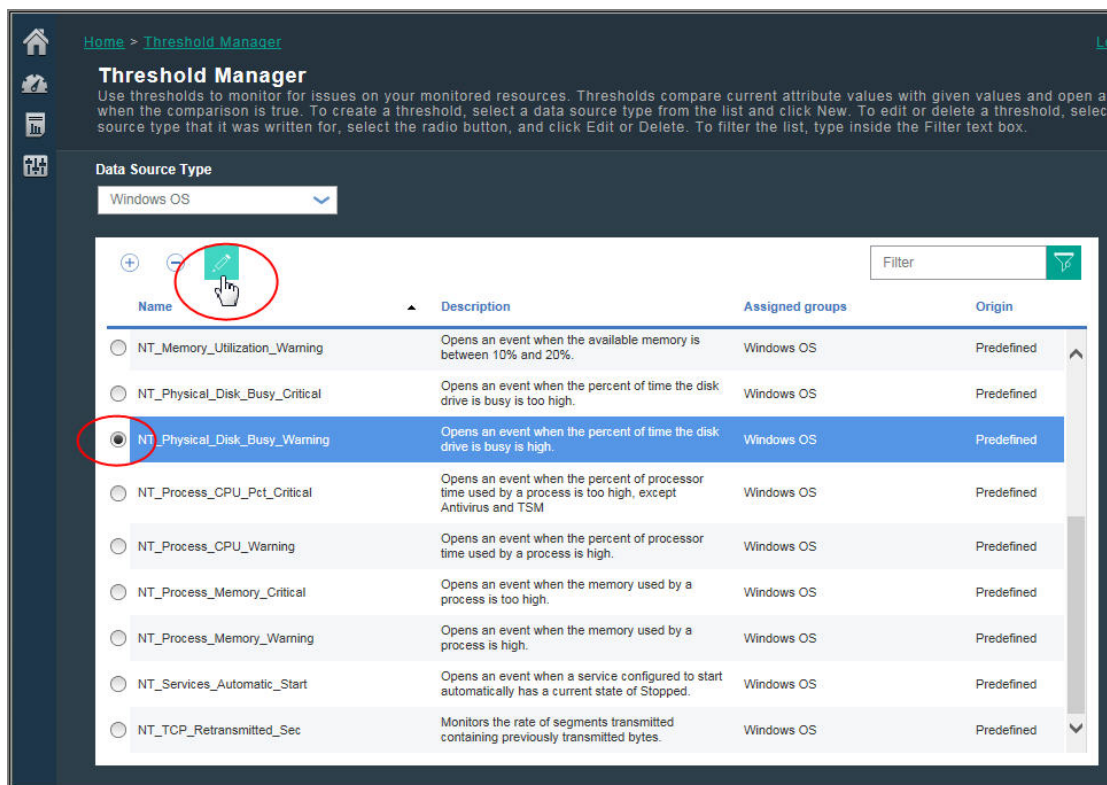

Consider, for example, that you have a custom resource group named Site Systems with Linux OS and WebSphere Applications thresholds and agents assigned. You create a new Linux OS threshold and assign it to Site Systems. Any open sampled events on the Linux OS agents that are assigned to Site Systems are closed. Then the sampled events are reopened if the threshold conditions are still true.

## Examples of disabled thresholds

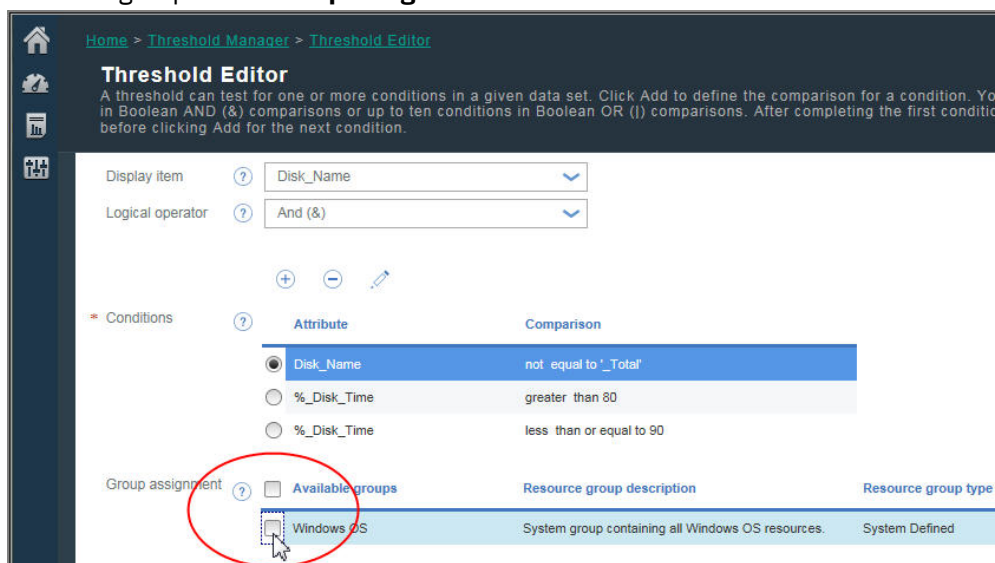

You can disable the predefined thresholds for all agents in your environment. You can also disable thresholds individually, whether predefined or custom. When a threshold is disabled it is not running on managed systems and no events are opened. You disable a threshold by removing its resource group assignment (or assignments). An **Advanced Configuration** setting is also available for disabling the predefined thresholds for all agents.

### Disabling a single threshold

In this image, the threshold to be disabled is selected in the **Threshold Manager** and the user clicks **Edit**:

The threshold is opened in the Threshold Editor. The user clears the check box of the assigned resource group in the **Group assignment** field:

After the user clicks **Save**, the **Threshold Manager** is displayed. The threshold is disabled, and the **Assigned groups** column is empty:

**Threshold Manager**

Use thresholds to monitor for issues on your monitored resources. Thresholds compare current attribute values with given values and open an event when the comparison is true. To create a threshold, select a data source type from the list and click New. To edit or delete a threshold, select source type that it was written for, select the radio button, and click Edit or Delete. To filter the list, type inside the Filter text box.

Data Source Type: Windows OS

| Name   | Description   | Assigned groups | Origin     |
|--|---|-----------------|------------|
| <input type="radio"/> NT_Memory_Utilization_Warning  | Opens an event when the available memory is between 10% and 20%.  | Windows OS      | Predefined |
| <input type="radio"/> NT_Physical_Disk_Busy_Critical | Opens an event when the percent of time the disk drive is busy is too high.                               | Windows OS      | Predefined |
| <input type="radio"/> NT_Physical_Disk_Busy_Warning  | Opens an event when the percent of time the disk drive is busy is high.                                   |                 | Predefined |
| <input type="radio"/> NT_Process_CPU_Pct_Critical    | Opens an event when the percent of processor time used by a process is too high, except Antivirus and TSM | Windows OS      | Predefined |
| <input type="radio"/> NT_Process_CPU_Warning         | Opens an event when the percent of processor time used by a process is high.                              | Windows OS      | Predefined |
| <input type="radio"/> NT_Process_Memory_Critical     | Opens an event when the memory used by a process is too high.   | Windows OS      | Predefined |
| <input type="radio"/> NT_Process_Memory_Warning      | Opens an event when the memory used by a process is high.   | Windows OS      | Predefined |
| <input type="radio"/> NT_Services_Automatic_Start    | Opens an event when a service configured to start automatically has a current state of Stopped.           | Windows OS      | Predefined |
| <input type="radio"/> NT_TCP_Retransmitted_Sec       | Monitors the rate of segments transmitted containing previously transmitted bytes.                        | Windows OS      | Predefined |

### Disabling all predefined thresholds

Turn off all predefined thresholds for all monitoring agents in **Advanced Configuration** page, as described in “Thresholds Enablement” on page 1243. When you next open the **Threshold Manager**, the **Assigned groups** column is empty for every predefined threshold, indicating that the thresholds are inactive:

**Threshold Manager**

Use thresholds to monitor for issues on your monitored resources. Thresholds compare current attribute values with given values and open an event when the comparison is true. To create a threshold, select a data source type from the list and click New. To edit or delete a threshold, select source type that it was written for, select the radio button, and click Edit or Delete. To filter the list, type inside the Filter text box.

Data Source Type: Windows OS

| Name   | Description   | Assigned groups | Origin     |
|--|---|-----------------|------------|
| <input type="radio"/> NT_Memory_Utilization_Warning  | Opens an event when the available memory is between 10% and 20%.  |                 | Predefined |
| <input type="radio"/> NT_Physical_Disk_Busy_Critical | Opens an event when the percent of time the disk drive is busy is too high.                               |                 | Predefined |
| <input type="radio"/> NT_Physical_Disk_Busy_Warning  | Opens an event when the percent of time the disk drive is busy is high.                                   |                 | Predefined |
| <input type="radio"/> NT_Process_CPU_Pct_Critical    | Opens an event when the percent of processor time used by a process is too high, except Antivirus and TSM |                 | Predefined |
| <input type="radio"/> NT_Process_CPU_Warning         | Opens an event when the percent of processor time used by a process is high.                              |                 | Predefined |
| <input type="radio"/> NT_Process_Memory_Critical     | Opens an event when the memory used by a process is too high.   |                 | Predefined |
| <input type="radio"/> NT_Process_Memory_Warning      | Opens an event when the memory used by a process is high.   |                 | Predefined |
| <input type="radio"/> NT_Services_Automatic_Start    | Opens an event when a service configured to start automatically has a current state of Stopped.           |                 | Predefined |
| <input type="radio"/> NT_TCP_Retransmitted_Sec       | Monitors the rate of segments transmitted containing previously transmitted bytes.                        |                 | Predefined |

[“Threshold Manager” on page 1119](#)

# Resource Group Manager

Your monitored environment might have multiple managed systems that can be categorized by their purpose. Such systems often have the same threshold requirements. Use the **Resource Group Manager** to organize managed systems into groups that you can assign thresholds to. You can also create resource groups that correlate with your role-based access control (RBAC) policies.

After you click  **System Configuration** > **Resource Group Manager**, the page opens with a table of defined resource groups. Initially, one predefined system group is shown for each monitoring agent type that is installed, such as Windows OS. Each system group contains all the predefined thresholds for the agent.

Your access to the **Resource Group Manager** and resource groups is controlled by your user permissions. You must have View permission for a resource group to see it; you must have Modify permission to create, edit, or delete a resource group.

The table has tools for managing resource groups:

-  **New** opens the **Resource Group Editor** for assigning managed systems and thresholds.
- Select a resource group to see the assigned resources and thresholds that are assigned to the group in the adjacent pane.
- Select a resource group and click  **Edit** to open the **Resource Group Editor** for changing the managed system and threshold assignments.
- Select a resource group that you no longer want and click  **Delete**. After you confirm the deletion, any thresholds that were assigned to the group must be assigned to another group if you want them to continue to run on your managed systems.
- You can click inside the filter text box  and type the value to filter by. As you type, the rows that do not fit the criteria are filtered out. To clear the filter, click the  in the filter box  or press the Backspace key.

The table displays the available resource groups:

## Resource group name

Predefined groups are named for their agent type; custom groups are named by the author.

## Resource group description

A predefined group is described as a *system group* for the monitored resource; custom groups are described by the author.

A system group, such as Linux OS, includes all the predefined thresholds for the agent and all managed systems where the agent is installed. You can edit a system group to assign or remove thresholds but you cannot assign or remove managed systems. Managed systems are automatically assigned to a system group of the same type, including any from your Tivoli Monitoring domain if you have a Hybrid Gateway configured.

Some system resource groups relate to agents that support subnodes. Depending on the agent type, the subnodes, the agent node, or both can be added to applications. If only the subnodes can be added to defined applications, you are not able to see events for any thresholds that were defined for the agent node. However, the events can be forwarded to an event manager such as Netcool/OMNIBus.

## Resource group type

Predefined groups are type *System Defined*. You have a predefined group for every type of agent that you have installed in your environment.

Custom groups that you or others in your environment create are type *User Defined*.

## Resource Group Editor

After you click  **New** to add a group, or after you select a group and click  **Edit** to edit a group, the **Resource Group Editor** is displayed with the following fields:

### Group name

The name of the group is required. You can change an existing custom group name, and all references to the group are updated automatically after you save your changes.

### Group description

Optional for custom groups. Add a description of the group organization. The description is displayed in the **Resource Group Manager**.

### Resource assignment

All the managed systems that are available for adding to the group are shown in the agent list by their managed system name, host name, agent type, and their domain. You can click a column heading to sort the list by agent name, host name, type, or domain.

To populate the group, select the check box of one or more managed systems.

You can select ☐ **Show only selected resources** to hide the unassigned managed systems.

If you have configured the IBM Cloud Application Performance Management Hybrid Gateway, you can add managed systems from your IBM Tivoli Monitoring domain to user defined resource groups. You cannot add Tivoli Monitoring managed systems to system defined groups nor can you create thresholds for them.

### Threshold assignment

All the thresholds that are predefined or were added through the **Threshold Manager** are shown in the threshold list by their name and agent type. You can click a column heading to sort the list.

To add a threshold to the group, select the check box next to the name; to remove a threshold from the group, clear the check box. You must have View permission for the **Threshold Manager** to add or remove thresholds. When adding thresholds to a system group, the available thresholds are limited to those whose data set is suitable for the system group.

The thresholds that you assign to the group are distributed to every managed system in the group of the same agent type. Although you can assign thresholds of any monitoring agent type to a group, the assigned thresholds are distributed only to managed systems of the same type that are members of the group. For example, if you assign the MySQL\_Process\_Down threshold to the group, it is included in the group, but is distributed only to the Monitoring Agent for MySQL managed systems that belong to the group.

You can select ☐ **Show only selected thresholds** to hide the unassigned thresholds. If you are filtering the list, click the  in the filter box   to clear the filter and enable the check box.

You can also assign a resource group to a threshold from the **Threshold Manager**.

After you click **Save**, the resource group is saved with the list of resource groups and displayed in the **Resource Group Manager** table.

## Tutorial: Defining a threshold

Thresholds are the alerting mechanism for potential and actual problems with your managed resources. Use the tutorial to learn the basic steps for defining a threshold to raise an alarm when the condition occurs.

### About this task

This tutorial uses the Linux OS agent for showing you how to define a threshold in the **Threshold Manager** and view the raised alarm in the Application Performance Dashboard. Your user ID must have View permission for the **Threshold Manager** to complete these steps.

### Procedure

1. From the navigation bar, click  **System Configuration** > **Threshold Manager**.
2. Click the **Data Source Type** list box and select the **Linux OS** data type.  
The thresholds that were defined for the Linux OS agent are displayed in the table.
3. Click  **New** to open the **Threshold Editor** for defining the threshold.
4. Define a threshold to raise an alarm of  Unknown severity when the average CPU is under 75%:
  - a) In the **Name** field, enter CPU\_average\_below\_75\_percent.
  - b) In the **Description** field, enter Threshold tutorial
  - c) Leave the **Severity**, **Interval**, and **Required consecutive samples** fields at their default values.
  - d) In the **Data set** field, select **KLZ CPU Averages**.
  - e) In the **Conditions** field, click  **New** and add the comparison in the dialog box that pops up:
    - i) In the **Attribute** field, select **CPU\_Usage\_Current\_Average**
    - ii) In the **Operator** field, select **Less than**
    - iii) In the **Value** field, enter 75After you click **OK**, the attribute and comparison are displayed in the **Conditions** field.
  - f) In the **Group assignment** field, select the **Linux OS** system group.
  - g) Click **Save** to complete the definition and return to the **Threshold Manager** page.  
CPU\_average\_below\_75\_percent is displayed in the list of thresholds that are defined for the Linux OS data source.

### Results

You defined a threshold that raises an alarm when the average CPU usage on any of your Linux OS managed systems is under 75%.

### What to do next

- View the event:
  1. From the navigation bar, click  **Performance** > **Application Performance Dashboard**.
  2. In the **My Components** summary box, click the **Events** link.

3. In the **Events** tab that opens, look for the CPU\_average\_below\_75\_percent threshold in the list. It can take 1 or 2 minutes for the alarm to be raised. If the CPU average is over 75 percent, however, no alarm is raised.
- Edit the threshold:
  1. From the navigation bar, click  **System Configuration** > **Threshold Manager**.
  2. Click the **Data Source Type** list box and select the **Linux OS** data type.
  3. Select the CPU\_average\_below\_75\_percent threshold from the list and click  **Edit**.
  4. Change any of the fields for a condition that you want to be alerted of. For example, you might change **Name** to CPU\_high\_warning, change **Severity** to **Warning**, edit the condition to be **Greater than 75**, and add a condition: **Less than 95**. To edit the comparison, click  **Edit**, change **Operator** to **Greater than** and click **OK**. To add the new condition, leave the **Logical operator** field at the default **And (&)**, click  **New** for a new condition, select **Operator Less than**, and enter **Value 95**.

**Edit Condition**

---

Count  ☐ Time Delta  ☐

Attribute  CPU\_Usage\_Current\_Average 

Operator  Greater than 

Value  75

**Edit Condition**

---

Count  ☐ Time Delta  ☐

Attribute  CPU\_Usage\_Current\_Average 

Operator  Less than 

Value  95

Home > Threshold Manager > Threshold Editor

## Tutorial: Defining a threshold to run a command on the managed resource

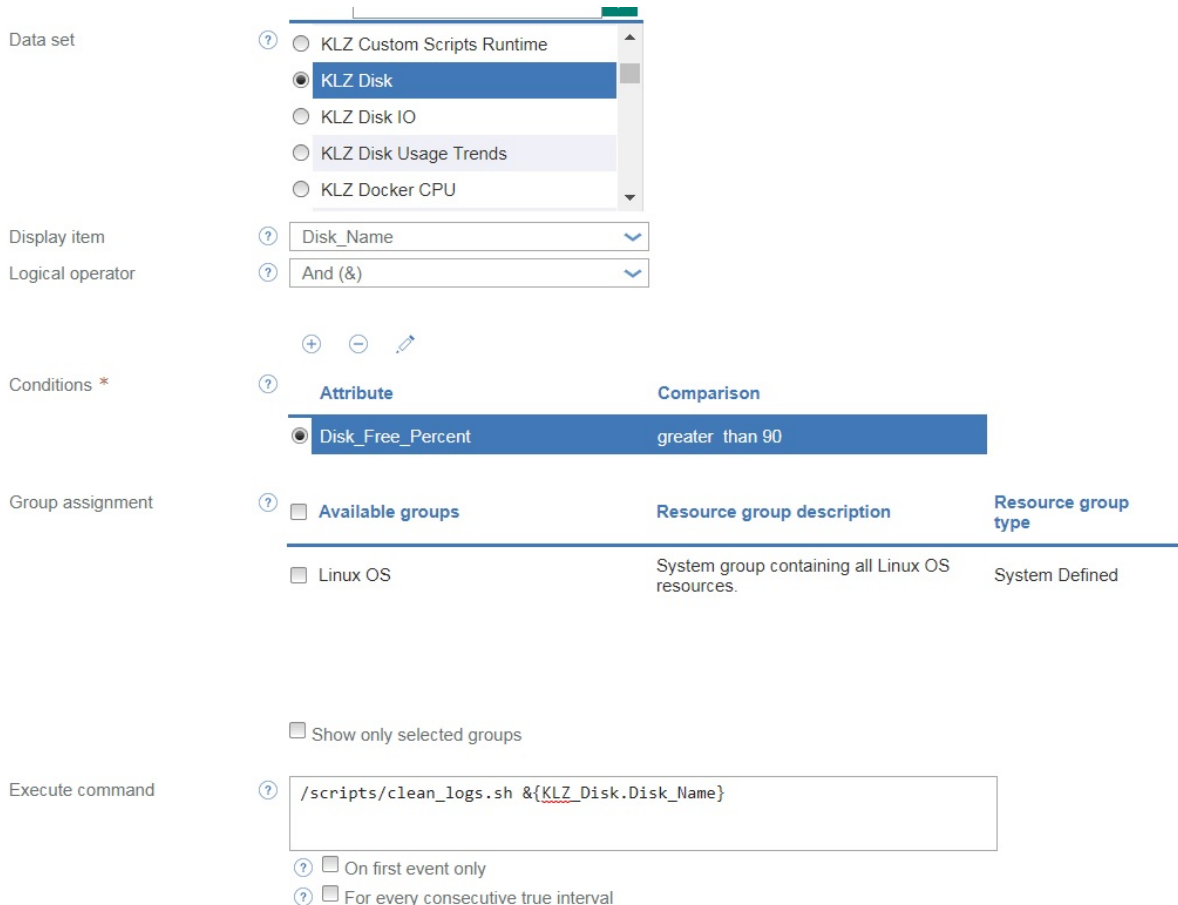

You can use the **Threshold Editor** to pass certain parameters to agents. You can specify commands or a script of commands to run automatically when an event is triggered.

### About this task

This tutorial shows you how to use the **Execute Command** field to pass a parameter to your IBM Cloud Application Performance Management agent.

### Procedure

1. Open the **Threshold Manager** by selecting  **System Configuration > Threshold Manager**.
2. Select *Linux OS* from the **Data Source Type** field.  
The thresholds that were defined for the Linux OS agent are displayed in the table.
3. Click  **New** to open the **Threshold Editor** for defining the threshold.
4. Define the threshold and conditions by specifying values for the various parameters, such as **Name**, **Severity**, and **Conditions**.
5. Select *KLZ Disk* from the **Data set** field.

The screenshot shows the Threshold Editor interface with the following configuration:

- Data set:** A dropdown menu with options: KLZ Custom Scripts Runtime, **KLZ Disk** (selected), KLZ Disk IO, KLZ Disk Usage Trends, and KLZ Docker CPU.
- Display item:** A dropdown menu with the option: **Disk\_Name**.
- Logical operator:** A dropdown menu with the option: **And (&)**.
- Conditions:** A table with two columns: **Attribute** and **Comparison**.
 

| Attribute                | Comparison             |
|--------------------------|------------------------|
| <b>Disk_Free_Percent</b> | <b>greater than 90</b> |
- Group assignment:** A table with three columns: **Available groups**, **Resource group description**, and **Resource group type**.
 

| Available groups                  | Resource group description                      | Resource group type |
|-----------------------------------|---|---------------------|
| <input type="checkbox"/> Linux OS | System group containing all Linux OS resources. | System Defined      |
- Execute command:** A text input field containing the command: `/scripts/clean_logs.sh &{KLZ_Disk.Disk_Name}`.
- Execution options:** Two checkboxes: ☐ On first event only and ☐ For every consecutive true interval.

6. Enter the following command in the **Execute Command** field:

```
/scripts/clean_logs.sh &{KLZ_Disk.Disk_Name}
```

You must replace the space in the *KLZ Disk* data set name with an underscore.

**Note:** The data set name referenced in the **Execute Command** field must be the same data set that is selected in step 5.

The *KLZ\_Disk.Disk\_Name* is passed into the command script.

## Results

Your script or command is set up to automatically run for your defined threshold. You must ensure the script or programs executed by the command are installed on the agent system since Cloud APM does not provide a mechanism to distribute scripts or programs. The command or script is run on the system of the monitoring agent that is monitoring the threshold condition. The user who starts the monitoring agent must have permission to execute the script or command.

### Related reference

[“Threshold Manager” on page 1119](#)

## Threshold Manager

Use the **Threshold Manager** to review the predefined thresholds for a monitoring agent and to create and edit thresholds. Thresholds are used to compare the sampled value of an attribute with the value set in the threshold. If the sampled value satisfies the comparison, an event is opened. The event closes automatically when the threshold comparison is no longer true.

After you click  **System Configuration** > **Threshold Manager**, the page is displayed with a table of the thresholds that were defined for the selected data source type.

The data types that display when you click the **Data Source Type** list box are for the types of monitoring agents and data collectors that are installed in your managed environment. Select the data type for which you want to create or view thresholds.

The table lists all the thresholds that were created for the selected data type, and has tools for managing thresholds:

-  **New** opens the **Threshold Editor** for defining a threshold for the selected data type.
- Select a threshold and click  **Edit** to open the **Threshold Editor** for editing the definition.
- Select a threshold that you no longer want and click  **Delete**. After you confirm that you want to delete the threshold, it is removed from the list and from any resource groups that it was assigned to. Any open events for the threshold are closed.
- For a long list, you can click inside the filter text box  and type the beginning of the value to filter by. As you type, the rows that do not fit the criteria are filtered out. To clear the filter, click the  in the filter box  or press the Backspace key.

For more information about the predefined thresholds and custom thresholds that are displayed in the table and the significance of the resource group assignment (or lack thereof), see [“Background information” on page 1110](#). For a quick hands-on lesson, see [“Tutorial: Defining a threshold” on page 1116](#).

## Threshold Editor

After you click  **New** or select a threshold and click  **Edit**, the Threshold Editor is displayed with the following fields:

### Name

Enter a unique name for the threshold. The name must begin with a letter and can be up to 31 letters, numbers, and underscores, such as "Average\_Processor\_Speed\_Warning". The threshold name is displayed in the Application Performance Dashboard **Events** tab and in certain dashboard tables.

## Description

Optional. A description is useful for recording the purpose of the threshold that users can see in the **Threshold Manager**.

## Severity

Select the appropriate event severity from the list:  Fatal,  Critical,  Minor,  Warning, or  Unknown.

The severities are consolidated for display in the Application Performance Dashboard: Fatal and Critical events show as ; Minor and Warning events show as ; and Unknown events show as  (see “Event Status” on page 1280).

## Forward EIF Event?

If you configured event forwarding in the  **System Configuration > Advanced Configuration** page (“Event Manager” on page 1240), open events are forwarded by default to the event destinations that you configured, for example, EIF event targets, or to Cloud Event Management. Change the setting to **No** if you do not want to forward events for this threshold to any event destinations. But if you configured event forwarding to a SMTP server, all events are sent to the SMTP server even if Forward EIF Event is set to **No**.

If you configured event forwarding in the  **System Configuration > Advanced Configuration** page (Event Manager), open events are forwarded to an EIF receiver by default. Change the setting to **No** if you do not want to forward events for this threshold to an EIF receiver.

To customize how thresholds are mapped to forwarded events, thus overriding the default mapping between thresholds and events forwarded to the event server, click **EIF Slot Customization**. For more information, see “Customizing an event to forward to an EIF receiver” on page 1124.

## Interval

Enter or select the time to wait between taking data samples in *HHMMSS* format, such as 00 15 00 for 15 minutes. For sampled-event thresholds, the minimum interval is 000030 (30 seconds) and the maximum is 235959 (23 hours, 59 minutes, and 59 seconds).

A value of 000000 (six zeros) indicates a *pure event* threshold. Pure events are unsolicited notifications. Thresholds for pure events have no sampling interval, thus they have no constant metric that can be monitored for current values. Pure events are closed after 24 hours or as set in the **Advanced Configuration** page **Pure Event Close Time** field in category “Event Manager” on page 1240.

## Required consecutive samples

Specify how many consecutive threshold samples must evaluate to true before an event is generated: For any threshold with a setting of 1 and a sample that evaluates to true, an event is generated immediately; a setting of 2 means that two consecutive threshold samples must evaluate to true before an event is opened.

## Data set

Select the data set (attribute group) for the type of data to be sampled. The attributes that are available for inclusion in the condition are from the chosen data set. If the threshold has multiple conditions, they must all be from the same data set.

To get a short description of a data set, hover the mouse over the name. You can get the complete description of the data set and attributes by clicking the “Learn more” link in the hover help. You can also click  **Help > Help Contents** or  **Help > Documentation** in the navigation bar, and open the help or download the reference for the monitoring agent.

Some agents are categorized as multi-node agents, which have subnodes for monitoring multiple agent resources. A multi-node agent might have data sets that can be used in a threshold but any events opened for the threshold do not display in the Application Performance Dashboard. A message notifies you of the limitation. Such events can be forwarded to the IBM Netcool/OMNIbus event manager.

## Display item

Optional. For multiple row data sets only. After a row evaluation causes an event to open, no more events can be opened for this threshold on the monitored system until the event is closed. By

selecting a display item, you enable the threshold to continue evaluating the other rows in the data sampling and open more events if other rows qualify. As well, the display item is shown in the **Events** tab of the Application Performance Dashboard so that you can easily distinguish among the rows for which events were opened. The list contains only the attributes that you can designate as display items.

### Logical Operator

Ignore this field if your threshold has only one condition. If you are measuring multiple conditions, select one of the following operators before you click **New** to add a second or third (or more) condition:

**And (&)** if the previous condition and the next condition must be met for the threshold to be breached

**Or (|)** if either of them can be met for the threshold to be breached

A mix of logical operators is not supported; use either all And operators or all Or operators. The threshold can have up to nine conditions when the Or operator is used; up to 10 conditions when the And operator is used.

If you are using the Missing function (described later in the **Operator** section), you can use only the And operator in the formula.

### Conditions

The threshold definition can logically include multiple simultaneous thresholds or conditions.

Click **New** to add a condition. Select a condition and click **Edit** to modify the expression, or click **Delete** to remove the expression.

After you click **New** or **Edit**, complete the fields in the **Add Condition** or **Edit Condition** dialog box that opens:

#### Count ☐

For data sets that return multiple rows for each data sample, you can have each row that meets the criteria of the condition counted. An event is opened after the count **Value** is reached and any other conditions in the formula are met. For example, if the number of "zombie" processes exceeds 10, issue an alert.

In the following example, the condition is true when more than 10 rows are counted: **Attribute** Timestamp, **Operator** Greater Than, **Value** 10.

Select the **Count** check box, the **Attribute** to be counted, the relational **Operator**, and count **Value**.

If the formula has multiple conditions, each condition must use the **And** Boolean operator. **Count** and **Time Delta** are mutually exclusive: If you select the check box for one function, the other function is disabled. The attribute cannot be a system identifier, such as Server Name or ORIGINNODE, be specified as the **Display Item**, or be from a data set for which the threshold opens pure events.

#### Time Delta ☐

Use the **Time Delta** function in a condition to compare the sampled time stamp (such as recording time) with the specified time difference.

After you select the **Time Delta** check box, the Time Delta field is displayed for you to combine + (plus) or - (minus) with the number of Days, Hours, Minutes, or Seconds. Select **Sampled Time** or **Specific Time** as the Value to use in the comparison.

In the following Event Log example, the formula compares the time that the event was logged with the time stamp from the data sampling. If the event occurred seven days earlier, the comparison is true. If the relational operator was changed to Less Than or Equal, the comparison would be true after 8 days, 9 days, and so on:

**Attribute** Timestamp  
**Time Delta** -7 Days  
**Operator** Equal

## Value Entry Time

### Attribute

Select the attribute that you want to compare in this condition. To see a short description of the attribute, hover the mouse over the name in the list.

### Operator

Select the relational operator for the type of comparison:

- Equal
- Not Equal
- Greater than
- Greater than or Equal
- Less than
- Less than or equal
- Regular expression contains
- Regular expression does not contain

Regular expression contains and Regular expression does not contain look for a pattern match to the expression. The easier it is to match a string with the expression, the more efficient the workload at the agent. The expression does not need to match the entire line; only the substring in the expression. For example, in `See him run`, you want to know if the string contains `him`. You could compose the regular expression using `him`, but you could also use `.*him.*`. Or if you are looking for `See`, you could enter `See`, or you could enter `^See` to confirm that it's at the beginning of the line. Entering `.*` wildcards is a less efficient search and raises the workload. For more information about regular expressions, see the [developerWorks® technical library](#) topic or search `regex` in your browser.

You can also select the Missing function, which compares the value of the specified metric with a list of values that you supply. The condition is true when the value does not match any in the list. This function is useful when you want notification that something is not present in your system. Requirements and restrictions:

1. The selected metric must be a text attribute: time and numeric attributes cannot be used.
2. Separate each value with a comma (,), for example, `fred,mary,jean`.
3. You can have only one Missing condition in a threshold.
4. Missing must be the last condition in the formula. If other conditions are required, enter them before you add the Missing function and use only the **And (&)** operator in the formula. Otherwise, all subsequent rows are disabled.

### Value

Enter the value to compare by using the format that is allowed for the metric, such as 20 for 20% or 120 for 2 minutes.

### Group assignment

Assign a resource group to distribute the threshold to the managed systems of the same type within the resource group. The resource groups that are available are the user defined groups that you have Modify permission for and the system groups (for the agent type) that you have View permission for. The available system groups are also limited to those that are suitable for the chosen data set.

A threshold with no group assigned is distributed to no monitored systems and remains stopped until it is distributed to a resource group.

A system group, such as `Linux OS` or `HTTP Server`, distributes the threshold to all managed systems where that agent is installed. By default, every predefined threshold is assigned to the system group for that agent. (You can disable all predefined thresholds in the **Advanced Configuration** page, as described in [“Thresholds Enablement”](#) on page 1243.)

The exception is managed systems from the IBM Tivoli Monitoring domain: Managed systems from the Tivoli Monitoring domain must be monitored with situations that were distributed in your Tivoli Monitoring environment.

To assign groups to the threshold, select the check box of one or more resource groups. If the list of assigned groups is long, you can select ☐ **Show only selected groups**.

If you do not see a resource group that you want to assign the threshold to, you can save the threshold definition, and click **OK** when prompted to confirm that you want to save the threshold without assigning it to a group. You can then create a new group in the **Resource Group Manager**, and assign a threshold to the new group in the **Resource Group Editor**. For more information, see [“Resource Group Manager” on page 1114](#).

### Execute command

After an event is opened for a threshold that evaluates to true, you can have a command or script of commands run automatically. For example, you might want to log information, trigger an audible beep, or stop a job that is overusing resources when an event is opened. The command or script is run on the system of the monitoring agent that opened the event.

The command uses the following syntax:

```
&{data_set.attribute}
```

where *data\_set* is the data set name and *attribute* is the attribute name as shown in the Threshold Editor. If the data set or attribute name contains a space, replace with an underscore. The *data\_set* must be the same data set that you select in the Data set selection field.

The following example shows how you can pass the disk name parameter to your managed resource:

```
/scripts/clean_logs.sh &{KLZ_Disk.Disk_Name}
```

You can pass in one or more attributes from the data set. If specified, multiple attributes are passed into the command in order (\$1, \$2, and so on).

You must ensure the script or programs executed by the command are installed on the agent system since Cloud APM does not provide a mechanism to distribute scripts or programs. The command runs from the command line with the same user account that the agent was started with. Ensure the user that starts the agent has permission to execute the command. For example, if the agent is running as root, then root runs the command on the managed system.

The following options control how often the command is run:

Select ☐ **On first event only** if the data set returns multiple rows and you want to run the command for only the first event occurrence in the data sample. Clear the check box to run the command for every row that causes an event.

Select ☐ **For every consecutive true interval** to run the command every time the threshold evaluates to true. Clear the check box to run the command when the threshold is true, but not again until the threshold evaluates to false, followed by another true evaluation in a subsequent interval.

After you click **Save**, the threshold is applied to all monitored systems of the same data type within the assigned resource groups.

**Tip:** You can control event behavior and event forwarding through the **Event Manager** options in the **Advanced Configuration** page. See [“Advanced Configuration” on page 1239](#).

**Note:** To see a list of the attributes that are suitable for inclusion in the threshold definition, create a table with the data set that you plan to use. .

## Customizing an event to forward to an EIF receiver

You can customize the threshold events that are sent to an Event Integration Facility (EIF) receiver, such as Netcool/OMNIBus ObjectServer, to Cloud Event Management, or to a SMTP server. Use the **EIF Slot Customization** window to customize the event content that is forwarded to the event destinations, thus overriding the default mapping. You can create map definitions for threshold events that sent to the Event Integration Facility receiver. Use the **EIF Slot Customization** window to customize how events are mapped to forwarded EIF events, thus overriding the default mapping. By customizing the message template, you can add information about the problem that was identified by the event and specific data from the event. By customizing the message template, you can add information about the problem that was identified by the event and include specific data from the event.

### About this task

You can customize the EIF base slot, which is a predefined **msg** slot that sends the threshold formula to an event destination. You can also add one or more EIF custom slots to the event. If you are using the Netcool/OMNIBus ObjectServer, you must update the EIF probe rules file and the ObjectServer triggers if you want to see the custom slots in the Netcool/OMNIBus UI.

You can customize the EIF base slot, which is a predefined **msg** slot that sends the threshold formula to the EIF receiver. You can also add one or more EIF custom slots, which requires an update to the EIF receiver and the probe rules file.

### Procedure

Complete these steps to customize how events for the current threshold are mapped to forwarded events:

1. If the **Threshold Manager** is not open, click  **System Configuration > Threshold Manager**.
2. Click the **Data Source Type** list box and select the data type that you want to work with.
3. If this is a new threshold, click  **New**; otherwise, select a threshold and click  **Edit**.
4. To customize how events for this threshold are mapped to forwarded events, ensure that **EIF Forwarder** is set to Yes, click **EIF Slot Customization**, and take one of the following steps:
  - **EIF Base Slots:** To customize the base slot, select the radio button for **msg** and click  **Edit**.
  - **EIF Custom Slots:** To add a custom slot, click  **Add**; to edit a custom slot, select the radio button for the slot and click  **Edit**.

The **Edit Slot** or **Add Slot** window opens.

5. Complete the fields to customize the slot values:

| Field            | Description   | Restriction  |
|------------------|---|--|
| <b>Slot name</b> | The name of the EIF custom slot, which must begin with a character. | The EIF base slot is <b>msg</b> and cannot be changed. |

| Field                   | Description   | Restriction  |
|-------------------------|---|--|
| <b>Slot type</b>        | The type of EIF custom slot: <b>String Type</b> or <b>Number Type</b> .   | The EIF base slot is <b>String Type</b> and cannot be changed.   |
| <b>Subtype</b>          | <p>The value that is assigned to the slot, which corresponds to the slot type:</p> <ul style="list-style-type: none"> <li>• <b>Mapped Attribute</b> enables the <b>Mapped attribute</b> field for adding the value of the selected attribute at the time the event occurred</li> <li>• <b>Literal Value</b> enables the <b>Literal value</b> field for adding text to the message template</li> <li>• <b>Literal Value + Mapped Attribute</b> enables the <b>Literal value</b> and <b>Mapped attribute</b> fields for adding text and attribute values to the message template, and enables the <b>Add</b> button for adding multiple text or attribute values (or both). A space is added after each literal value or attribute.</li> </ul> <p>Typical usage for the EIF base slot <b>msg</b>, is to specify a <b>Literal Value + Mapped Attribute</b> for the message template.</p> | A <b>Number Type</b> slot can use only <b>Mapped Attribute</b> .   |
| <b>Add</b>              | <p>If you want to send multiple literal values or attribute values in the forwarded message, click <b>Add</b> to add another set of <b>Literal value</b> and <b>Mapped attribute</b> fields. Each time you select <b>Add</b>, these fields are added to the panel.</p> <p>To remove a set of <b>Literal value</b> and <b>Mapped attribute</b> fields, clear both fields before clicking <b>OK</b>.</p> <p>See <a href="#">Example</a>.</p>  | <p>Enabled only when <b>Subtype</b> is <b>Literal Value + Mapped Attribute</b>.</p> <p>Maximum of 6 sets of <b>Literal value</b> and <b>Mapped attribute</b> fields. If you're not able to see the fields you added, use the browser zoom out feature (Ctrl -) to shrink the layout to fit the dialog box.</p> |
| <b>Literal value</b>    | <p>The text to include in the message template. For example, a literal value of Memory utilization is high at with the mapped attribute <b>%Memory Utilization</b>, is shown in the <b>Event Manager</b> user interface as Memory Utilization is high at 97.3%.</p> <p>The message template consists of fixed message text and variable substitution references, or symbols. The symbol refers to common or event slot data or a special reference to the threshold formula. Common slots are those slots that are included in all forwarded events, such as <i>threshold_name</i>; event slots are those slots that are specific to the threshold msg.</p>   | Disabled when <b>Subtype</b> is <b>Mapped Attribute</b> .  |
| <b>Mapped attribute</b> | The attribute whose value you want to add to the message template. The attributes available are from the data set that was selected for the threshold. For example, for a threshold that monitors for high processor time, you might want to map the user time percentage attribute.  | <p>Maximum of 6 <b>Mapped attribute</b> fields.</p> <p>Disabled when <b>Subtype</b> is <b>Literal Value</b>.</p>   |

| Field             | Description  | Restriction  |
|-------------------|--|--|
|                   |  | When the <b>Slot type</b> is <b>Number Type</b> , only numeric attributes are available. |
| <b>Multiplier</b> | The multiplier is the value that is defined after you customize the original mapped attribute number value by a multiplier: slot value = <i>attribute1</i> * <i>n</i> . For example, if you want to convert minutes to seconds in the EIF event, you would specify a multiplier of 60. The multiplier value can be a fraction, expressed as a decimal, such as 0.5 or 5.4. | Enabled only for numeric attributes ( <b>Slot type</b> is <b>Number Type</b> ).          |

After you click **OK** to close the window, the **EIF Slot Customization** window lists the slot name and whether it is customized.

6. After you are finished editing the EIF base slot or adding, deleting, or editing EIF custom slots for the threshold, click **OK**.

7. After you are finished editing the threshold, click **Save**.

For more information, see [“Threshold Manager” on page 1119](#).

### Example

The `Linux_BP_ProcHighCpu_Critical` threshold tests for CPU consumption of 95% or higher. To add the Busy CPU percentage, the process command name, and the process ID to the summary message (contained in the msg slot), the msg slot was customized with three sets of **Literal value** and **Mapped attribute** fields:

**Edit Slot - msg**

Slot name \*

Slot type

Subtype

Add

Literal value

Mapped attribute

Literal value

Mapped attribute

Literal value

Mapped attribute

Multiplier

The message template looks like this:

CPU percentage is *Busy\_CPU\_Pct* for process *Process\_Command\_Name* and PID *Process\_ID*

And the resulting message viewed in the Event Manager might look like this:

CPU percentage is 97 for process *large.exe* and PID 9876

You can also add the **Literal value** and **Mapped attribute** fields and leave one field empty. For example, to append "for review" to the message template, click **Add** and enter `for review` for **Literal value**.

The message template now looks like this:

CPU percentage is *Busy\_CPU\_Pct* for process *Process\_Command\_Name* and PID *Process\_ID* for review

And the resulting message viewed in the **Event Manager** might look like this:

CPU percentage is 96 for process *big.exe* and PID 5432 for review

## What to do next

If you created new EIF custom slots, you must identify the new slots in the `alerts.status` table on your Netcool/OMNIbus ObjectServer, then update the `itm_apm_event.rules` configuration file that was installed during Netcool/OMNIbus integration with Cloud APM.

## Adding EIF custom slots to the Netcool/OMNIbus ObjectServer database

When you add new EIF custom slots for thresholds, you must identify them in your EIF receiver before you can view forwarded events that use the custom slots. If you have Netcool/OMNIbus integrated with Cloud APM, update the `alerts.status` table to define the new slots.

## About this task

When you configured Netcool/OMNIbus integration with Cloud APM, step “3” on page 1072 had you load `itm_apm_db_update.sql`. The following procedure has you use the SQL interactive interface to update the `alerts.status` table in the `itm_apm_db_update.sql` database.

## Procedure

Complete these steps on the Netcool/OMNIbus ObjectServer to define the new EIF custom slots that you created in the **Threshold Editor**:

1. Start the SQL interactive interface for editing the database:

### Linux

```
$OMNIHOME/bin/nco_sql -user user_name -password password
-server server_name > itm_apm_db_update.sql
```

Example:

```
$OMNIHOME/bin/nco_sql -user smadmin -password passw0rd -server NCOMS >
/tmp/apm/itm_apm_db_update.sql
```

### Windows

```
itm_apm_db_update.sql | %OMNIHOME%\..\bin\isql -U user_name
-P password -S server_name
```

Example:

```
\temp\apm\itm_apm_db_update.sql | %OMNIHOME%\..\bin\isql -U smadmin
-P passw0rd -S NCOMS
```

2. For each EIF custom slot, type the **ALTER TABLE** SQL command with the custom slot name and slot type in the following format, press Enter, then type go and press Enter:

- For a string slot type,

```
alter table alerts.status add CustomSlotName varchar(512);
```

- For a number slot type,

```
alter table alerts.status add CustomSlotName integer;
```

where *CustomSlotName* is the name of the EIF custom slot exactly as it was entered in the **slotName** field of the **Add Slot** window in the **Threshold Editor**.

### Example

The example shows the **alter table** commands to add **BusinessApplication** and **GenericMetric** custom slots.

```
alter table alerts.status add BusinessApplication varchar(512);
```

```
alter table alerts.status add GenericMetric integer;
```

### What to do next

Update the `itm_apm_event.rules` configuration file that was installed as part of Netcool/OMNIBus integration with Cloud APM. For more information, see [“Adding EIF custom slots to the EIF receiver event rules”](#) on page 1128.

## Adding EIF custom slots to the EIF receiver event rules

If you defined new EIF custom slots for thresholds, you must update the rules file to identify the new slots to the EIF receiver.

### About this task

These steps have you update the `itm_apm_event.rules` file on the Netcool/OMNIBus Probe for Tivoli EIF to identify each new EIF custom slot. If you are using another EIF receiver, update the rules files as required by the receiver.

### Procedure

1. On the system where the Probe for Tivoli EIF is installed, change to the installation directory.

```
Linux cd install_dir/tivoli/netcool/omnibus/probes/linux2x86
```

```
Windows cd install_dir\Tivoli\Netcool\omnibus\probes\win32
```

where *install\_dir* is the default `/opt/IBM/` or `C:\IBM\` or the directory that you specified when the probe was installed.

2. Make a backup copy of the `itm_apm_event.rules` file.
3. Open the Probe for Tivoli EIF `itm_apm_event.rules` file in a text editor.  
The file has three parts to it that you are editing to add the custom EIF custom slot (or slots) that you created.
4. Append the **if** statements with a new statement for each EIF custom slot that uses the following format:

```
if(exists($CustomSlotName))
{
    if(regmatch($CustomSlotName, "^.*'$"))
    {
        $SourceType = extract($CustomSlotName, "^'(.*)'$")
    }
}
```

where *CustomSlotName* is the name of the EIF custom slot exactly as it was entered in the **slotName** field of the **Add Slot** window.

- Append the list of @ entries with a new row for each EIF custom slot that uses the following format:

```
@CustomSlotName=$CustomSlotName
```

where *CustomSlotName* is the name of the EIF custom slot.

- Append the list of \$tmpEventData entries with a new row for each EIF custom slot that uses the following format:

```
$tmpEventData = nvp_remove( $tmpEventData, "CustomSlotName")
```

where *CustomSlotName* is the name of the EIF custom slot.

- Save and close the itm\_apm\_event.rules file.
- Restart the Probe for Tivoli EIF to implement your updates.

## Results

The rules file is updated and the Probe for Tivoli EIF can now process threshold events that use the new EIF custom slots and forward the event details to the Netcool/OMNIbus ObjectServer.

## Example

Here is an excerpt from the itm\_apm\_event.rules after it was edited to add these EIF custom slots: **BusinessApplication** and **GenericMetric** (shown in *italic*).

```
# -----
if(exists($SourceID))
{
    if(regmatch($SourceID, "^'.*'$"))
    {
        $SourceID = extract($SourceID, "^'(.*)'$")
    }
}
...
...
if(exists($ManagedSystemGroups))
{
    if(regmatch($ManagedSystemGroups, "^'.*'$"))
    {
        $SourceType = extract($ManagedSystemGroups, "^'(.*)'$")
    }
}
if(exists($BusinessApplication))
{
    if(regmatch($BusinessApplication, "^'.*'$"))
    {
        $SourceType = extract($BusinessApplication, "^'(.*)'$")
    }
}
    if(exists($GenericMetric))
    {
        if(regmatch($GenericMetric, "^'.*'$"))
        {
            $SourceType = extract($GenericMetric, "^'(.*)'$")
        }
    }
}

@SourceID=$SourceID
@URL=$ManagementURL
@Service=$Service
@SourceType=$SourceType
@SubscriberID=$TenantID
@APMHostname=$apm_hostname
@ManagedSystemGroups=$ManagedSystemGroups
@BusinessApplication=$BusinessApplication
@GenericMetric=$GenericMetric

# -----
# -   RTC 66157
# -----
```

```

if ( exists ( $appl_label ) )
{
    if ( match($appl_label, "PI:A:S"))
    {
        @Class = 87723
    }
}
# -----
# - RTC 48775 - APM FP5 agents do not populate data in email of EMaaS Basic
# -----
if (match( $situation_eventdata, "~" ) )
{
    # Dump all fields into the ITMEEventData field
    $tmpEventData = nvp_add($*)
    # Remove the duplicated fields
    $tmpEventData = nvp_remove( $tmpEventData, "appl_label")
    $tmpEventData = nvp_remove( $tmpEventData, "control")
    ...
    ...
    ...
    $tmpEventData = nvp_remove( $tmpEventData, "ManagedSystemGroups")
    $tmpEventData = nvp_remove( $tmpEventData, "EventSeqNo")
    $tmpEventData = nvp_remove( $tmpEventData, "BusinessApplication")
    $tmpEventData = nvp_remove( $tmpEventData, "GenericMetric")
    @ITMEEventData = $tmpEventData
}

```

## Using the Resource Group Management Service API

Use the Resource Group Management Service API to manage the lifecycle of groups of managed systems from the command line.

### About this task

Complete resource group tasks such as creating, viewing, updating, and deleting groups of managed systems. Add and remove individual systems from custom groups. View a list of systems that you added to a specific custom resource group, and view a list of systems that are automatically added to the built-in groups such as the system resource group.

You can create scripts for automating such tasks as defining resource groups and assigning agents to these resource groups. The resource groups can be targets of threshold distributions and or access control policies.

In this task you can use either access tokens or basic authorisation in the curl command:

#### Access tokens

Use the OpenID Connect (OIDC) protocol to get an access token from the OIDC server on the Cloud APM server. The access token gives you authorised access to the API for running operations until the token expires after 30 minutes.

#### Basic authorisation

Use a base64 tool to encode your Cloud APM console user ID and password into a single base64 string. The input string format is *userId:password*, such as *apmadmin:apmpass*. The output is a string such as: *YXBtYWRTaW46YXBtcGFzcw==*

Use *base64\_encoded\_string* in the authorisation header of every request as shown in the curl command examples.

Note the Cloud APM console user ID must be added to a role with appropriate permissions.

The following operations are described in API Explorer and in the Example at the end of this topic.

- Return all resource groups, agents, or a specific resource group or agent.
- Create a custom resource group or update the definition of an existing group
- Delete a specified custom resource group
- Add agents to a custom resource group
- Remove agents from a custom resource group

Disabling OIDC authentication, which is required before you can enable single sign-on (SSO) between Cloud APM and other IBM products such as Tivoli Common Reporting that require LTPA for single sign-on, does not affect the API. The RESTful API continues to use the Cloud APM internal OIDC server, even if OIDC is disabled for single sign-on between the Cloud APM console and other product user interfaces.

Resource Group Management Service API requests can be issued by using https to the port 8091 of the Cloud APM server or using http to the port 8090 of the Cloud APM server.

## Procedure

Complete these steps to define and change custom resource groups with the Resource Group Management Service API. System resource groups and agents cannot be modified.

1. On the system where the Cloud APM server is installed, open the following file and copy the values of the *client.secret.apmui* and *client.id.apmui* variables:

```
install_dir/wlp/usr/shared/config/clientSecrets.xml
```

The following example shows what the file contains:

```
<server>
  <variable name="client.secret.apmui" value="{xor}BiY3KQgIa2gRCms3Cxxr
MhUYL2YRJSwvCjUnJxYb" />
  <variable name="client.id.apmui" value="rpapmui" />
</server>
```

2. Optional: If you plan to use an access token in your **curl** command, use an XOR decoder to decode the value of the *client.secret.apmui* variable to get the actual secret value.  
For example, when you use an XOR decoder to decode  
BiY3KQgIa2gRCms3CxxrMhUYL2YRJSwvCjUnJxYb, you get the following value:  
YyhvWW47NU4hTC4mJGp9NzspUjxxID
3. Optional: If you plan to use an access token in your curl command, complete this step. To get an access token, contact the token endpoint of the Cloud APM OIDC server with the four required items: **username**, **password**, **client\_id**, and **client\_secret**, as in the following command:

```
curl --tlsv1.2 -v -k -d "grant_type=password
&client_id=rpapmui&client_secret=YyhvWW47NU4hTC4mJGp9NzspUjxxID
&username=apmadmin&password=apmpass&scope=openid"
https://example.mycompany.com:8099/oidc/endpoint/OP/token
```

Where:

- username is the username of the Cloud APM console user
- password is the password of a Cloud APM console user
- clientid is the value of the *client.id.apmui* variable from step 1.
- client\_secret is the value created by the XOR decoder in step 2.

Output:

```
{"access_token": "jnz4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8",
"token_type": "Bearer", "expires_in": 1800, "scope": "openid",
"refresh_token": "VsCWUhPHBRpidD2F1PVyZ2LNGMuQPTN837t30oqZj71FcBfsGE"}
```

**Note:** If the *client\_secret*, *username*, or *password* values contain characters other than digits (0-9), ASCII letters (A-Z, a-z), and a few special characters ("-", ".", "\_", "~"), you must URL encode the other characters. For example, if the decoded client secret is  
TEVINjROVT8iPF9r=1dNNW8+SGFgJ0, replace the = character with %3D, replace the + character with %2B, and enter *client\_secret=TEVINjROVT8iPF9r%3D1dNNW8%2BSGFgJ0* instead of  
*client\_secret=TEVINjROVT8iPF9r01dNNW8+SGFgJ0*.

4. Optional: If you plan to use an access token in your curl command, extract the **access\_token** value. Looking at the output in the previous example, the value is  
jnz4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8.

5. Enter requests to the Resource Group Management Service API using either an access token or basic authorization.

Access token example

```
curl --tlsv1.2 -v -k --request GET --url 'https://myAPMServer.mycompany-domain.com:8091/1.0/topology/mgmt_artifacts?_field=keyIndexName' --header 'authorization: Bearer jnz4Ad0zpeCpYcUlUf7o4A40tz5trnIW9GutICG8' --header 'content-type: application/json'
```

Basic authorization example:

```
curl --tlsv1.2 -v -k --request GET --url 'https://myAPMServer.mycompany-domain.com:8091/1.0/topology/mgmt_artifacts?_field=keyIndexName' --header 'authorization: Basic YXBtYWRTaW46YXBtcGFzcw==' --header 'content-type: application/json'
```

6. For more details about API operations, see API documentation in API Explorer. For instructions about accessing API Explorer, see [Exploring the APIs](#).

**Note:** Part of the URL and some of the headers that are shown in the examples are required for Cloud APM only. For example: `https://api.ibm.com/perfmgmt/run`, `x-ibm-service-location`, `X-IBM-Client-Id`, `X-IBM-Client-Secret`. See step “5” on page 1132 for request examples.

7. You must include a referer header in all POST, PUT, and DELETE requests. The value for the referer header is:

```
-H 'Referer: https://apm_server:8091'
```

where *apm\_server* is the IP address or the fully qualified host name of your Cloud APM server.

## Results

The changes that you make to custom resource groups in the API are effective immediately and displayed in the **Resource Group Manager** (see “[Resource Group Manager](#)” on page 1114).

## Example

This command returns the names, unique identifiers, status, hostname, version, and agent type for all agents:

```
GET /1.0/topology/mgmt_artifacts?_filter=entityTypes=Agent&_field=keyIndexName&_field=online&_field=hostname&_field=version&_field=productCode&_field=description
```

This command returns a list of all Linux OS agents:

```
GET /1.0/topology/mgmt_artifacts?_filter=entityTypes=Agent&_filter=description="Linux OS"&_field=keyIndexName
```

This command returns a list of system and custom groups:

```
GET /1.0/topology/mgmt_artifacts?_filter=entityTypes:AgentGroup,AgentSystemGroup&_field=keyIndexName&_field=displayLabel
```

This command returns the list of agents that are assigned to a group that has the unique identifier {id}:

```
GET /1.0/topology/mgmt_artifacts/{id}/references/to/contains
```

The following example uses the curl command to create a custom group.

```
POST /1.0/topology/mgmt_artifacts
```

**Note:** The body of the POST request must contain a JSON object that defines the group as shown by the **-d** parameter.

```
curl -X POST \
  https://apm_server:8091/1.0/topology/mgmt_artifacts \
  -H 'Referer: https://apm_server:8091' \
  -H 'authorization: Bearer Your_Access_Token' \
  -H 'content-type: application/json' \
  -d '{
```

```

    "keyIndexName": "customGroup",
    "description": "Custom group description",
    "displayLabel": "customGroupLabel",
    "entityTypes": [
      "AgentGroup"
    ],
    "arbitraryStringProperty": "Your custom property value"
  },
}
```

This command adds an agent with unique identifier {otherid} to a custom group that has unique identifier {id}:

```
POST /1.0/topology/mgmt_artifacts/{id}/references/to/contains/{otherid}
```

This command removes an agent with unique identifier {otherid} from a custom group that has unique identifier {id}:

```
DELETE /1.0/topology/mgmt_artifacts/{id}/references/to/contains/{otherid}
```

## Using the Threshold Management Service API

Use the Threshold Management Service API to manage the lifecycle of monitoring thresholds from the command line.

### About this task

Complete threshold manager tasks such as creating, viewing, updating, and deleting thresholds. Assign resource groups to these thresholds. View a list of all thresholds and resources assignments. View a list of all thresholds that are assigned to a specific resource group.

You can create scripts for automating such tasks as defining thresholds and assigning these thresholds to resource groups.

In this task you can use either access tokens or basic authorisation in the curl command:

#### Access tokens

Use the OpenID Connect (OIDC) protocol to get an access token from the OIDC server on the Cloud APM server. The access token gives you authorised access to the API for running operations until the token expires after 30 minutes.

#### Basic authorisation

Use a base64 tool to encode your Cloud APM console user ID and password into a single base64 string. The input string format is *userId:password*, such as *apmadmin:apmpass*. The output is a string such as: *YXBtYWRTaW46YXBtcGFzcw==*

Use *base64\_encoded\_string* in the authorisation header of every request as shown in the curl command examples.

Note the Cloud APM console user ID must be added to a role with appropriate permissions.

The following operations are described in API Explorer and in the Example at the end of this topic.

- Return all thresholds or get a specific threshold. You can filter the request with these attributes: **label**, which corresponds to the threshold name; **\_appliesToAgentType**, which corresponds to the 2-character product code, and **\_uiThresholdType**, which corresponds to the threshold type that is shown in the Threshold Manager and Resource Group editor pages of the Cloud APM console. You can use **\_offset** or **\_limit** when getting thresholds
- Create a threshold or update the definition of an existing threshold. You must include the X-HTTP-Method-Override header and set to PATCH for update request
- Delete a specified threshold
- Return all resource assignments or a specific resource assignment, which shows the thresholds that are assigned to each resource group. You can filter the request with these attributes: **resource.\_id** and **threshold.\_id**; and use these supported operators are = (equal) and != (not equal)

- Create a resource assignment, which assigns a single threshold to a single resource group
- Delete a resource assignment, which removes a single threshold from a single resource group

Disabling OIDC authentication, which is required before you can enable single sign-on (SSO) between Cloud APM and other IBM products such as Tivoli Common Reporting that require LTPA for single sign-on, does not affect the API. The RESTful API continues to use the Cloud APM internal OIDC server, even if OIDC is disabled for single sign-on between the Cloud APM console and other product user interfaces.

Threshold Management Service API requests should be issued by using https to the port 8091 of the Cloud APM server. If you issue a Threshold Management API http request to the port 8090 of the Cloud APM server, then the request is redirected to https and the port 8091.

## Procedure

1. On the system where the Cloud APM server is installed, open the following file and copy the values of the *client.secret.apmui* and *client.id.apmui* variables:

```
install_dir/wlp/usr/shared/config/clientSecrets.xml
```

The following example shows what the file contains:

```
<server>
  <variable name="client.secret.apmui" value="{xor}BiY3KQgIa2gRCms3Cxxr
MhUYL2YRJSwvCjUnJxYb" />
  <variable name="client.id.apmui" value="rpapmui" />
</server>
```

2. Optional: If you plan to use an access token in your **curl** command, use an XOR decoder to decode the value of the *client.secret.apmui* variable to get the actual secret value.  
For example, when you use an XOR decoder to decode *BiY3KQgIa2gRCms3CxxrMhUYL2YRJSwvCjUnJxYb*, you get the following value:  
*YyhvWW47NU4hTC4mJGp9NzspUjxxID*
3. Optional: If you plan to use an access token in your curl command, complete this step. To get an access token, contact the token endpoint of the Cloud APM OIDC server with the four required items: **username**, **password**, **client\_id**, and **client\_secret**, as in the following command:

```
curl --tlsv1.2 -v -k -d "grant_type=password
&client_id=rpapmui&client_secret=YyhvWW47NU4hTC4mJGp9NzspUjxxID
&username=apmadmin&password=apmpass&scope=openid"
https://example.mycompany.com:8099/oidc/endpoint/OP/token
```

Where:

- **username** is the username of the Cloud APM console user
- **password** is the password of a Cloud APM console user
- **clientid** is the value of the *client.id.apmui* variable from step 1.
- **client\_secret** is the value created by the XOR decoder in step 2.

Output:

```
{"access_token": "jnZ4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8",
"token_type": "Bearer", "expires_in": 1800, "scope": "openid",
"refresh_token": "VsCWUhpHBRpidD2F1PVyZ2LNGMuQPTN837t30oqZj71FcBfsGE"}
```

**Note:** If the **client\_secret**, **username**, or **password** values contain characters other than digits (0-9), ASCII letters (A-Z, a-z), and a few special characters ("-", ".", "\_", "~"), you must URL encode the other characters. For example, if the decoded client secret is *TEVINjROVT8iPF9r=1dNNW8+SGFgJ0*, replace the **=** character with **%3D**, replace the **+** character with **%2B**, and enter **client\_secret=TEVINjROVT8iPF9r%3D1dNNW8%2BSGFgJ0** instead of **client\_secret=TEVINjROVT8iPF9r01dNNW8+SGFgJ0**.

4. Optional: If you plan to use an access token in your curl command, extract the **access\_token** value.

Looking at the output in the previous example, the value is  
jnz4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8.

5. Enter requests to the Threshold Management Service API using either an access token or basic authorization.

Access token example

```
curl --tlsv1.2 -v -k --request GET
--url 'https://myAPMServer.mycompany-domain.com:8091/1.0/thresholdmgmt/
threshold_types/itm_private_situation/thresholds'
--header 'authorization: Bearer jnz4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8'
--header 'content-type: application/json'
```

Basic authorization example

```
curl --tlsv1.2 -v -k --request GET
--url 'https://myAPMServer.mycompany-domain.com:8091/1.0/thresholdmgmt/
threshold_types/itm_private_situation/thresholds'
--header 'authorization: Basic YXBtYWRTaW46YXBtcGFzcw==' --header
'content-type: application/json'
```

6. For more details about API operations, see API documentation in API Explorer. For instructions about accessing API Explorer, see [Exploring the APIs](#).

**Note:** Part of the URL and some of the headers shown in the examples are required for Cloud APM only. For example: <https://api.ibm.com/perfmgmt/run>, `x-ibm-service-location`, `X-IBM-Client-Id`, `X-IBM-Client-Secret`. See step “5” on page 1135 for request examples.

## Example

This command returns all the thresholds that are registered with the server:

```
GET /threshold_types/itm_private_situation/thresholds
```

This command returns the information for the threshold with the label (name) `My_threshold`.

```
GET /threshold_types/itm_private_situation/thresholds?_filter=label%3DMy_threshold
```

This command returns all the thresholds for agent type `LZ`, which is the component code for the Linux OS agent.

```
GET /threshold_types/itm_private_situation/thresholds?_filter=_appliesToAgentType%3DLZ
```

This command has the same output as the previous command but the agent name as it appears in the Cloud APM console is given.

```
GET /threshold_types/itm_private_situation/thresholds?_filter=_uiThresholdType%3DLinux OS
```

This command returns all the resource groups that threshold 123 is assigned to:

```
GET /resource_assignments?_filter=threshold._id=123
```

The following example uses the `curl` command to create a new threshold.

```
POST /1.0/thresholdmgmt/threshold_types/itm_private_situation/thresholds
```

**Remember:** The body of the POST request must contain a JSON object that defines the threshold as shown by the `-d` parameter. Example:

```
curl -X POST\
https://apm_server:8091/1.0/thresholdmgmt/threshold_types/itm_private_situation/thresholds \
-H 'authorization: Bearer Your_Access-Token' \
-H 'content-type: application/json' \
-d '{
  "label": "Your_Linux_Threshold_Name",
  "description": "Your Linux Threshold Definition",
  "configuration": {
```

```

"type": "json",
"payload": {
  "formulaElements": [
    {
      "function": "*MKTIME",
      "metricName": "KLZ_CPU.Timestamp",
      "operator": "*EQ",
      "threshold": "1455767100000",
      "timeDelta": {
        "operator": "+",
        "delta": "3",
        "unit": "Hours"
      }
    }
  ],
  "period": "011500",
  "periods": "3",
  "severity": "Fatal",
  "matchBy": "KLZCPU.CPUID",
  "operator": "*OR",
  "actions": [
    {
      "name": "command",
      "command": "ps -ef",
      "commandFrequency": "Y",
      "commandWhen": "Y",
      "commandWhere": "N"
    }
  ]
}
}
}

```

## Managing user access

Use the Role Based Access Control feature in IBM Cloud Application Performance Management to grant users the access privileges they require for their role.

Security in Cloud APM is based on roles. A role is a group of permissions that control the actions you can perform in Cloud APM. You can create customized roles in Cloud APM. You can assign permissions to customized roles, or you can assign more permissions to existing default roles. You can assign users and user groups to existing default roles or to customized roles. You can assign users and user groups to multiple roles. Permissions are cumulative, a user or user group is assigned all the permissions for all the roles they are assigned to.

If you are not a member of a role and you attempt to log in to Cloud APM, you receive a **Not Authorized** message.

Cloud APM uses the WebSphere Application Server Liberty profile basic registry as the default method for user authentication. Alternatively, you can use an LDAP registry for user authentication.

The default user is apmadmin. The apmadmin user is by default a member of the Role Administrator role. The apmadmin user is added to the basic registry during installation, and you can add more users. For more information, see [“Managing user access” on page 1136](#).

**Note:** Because the basic registry does not perform user account lockout or enable you to control user password expiration, it is good for test and demonstration environments only. An LDAP server provides additional security controls. For production environments, you should configure Cloud APM to use an LDAP server for authentication instead of the basic registry. For more information, see [“Integrating with LDAP” on page 1097](#).

### User authentication with WebSphere Application Server Liberty profile basic registry

Complete the following steps if you are using WebSphere Application Server Liberty profile basic registry for user authentication:

1. Create users and user groups in the basic user registry. The basicRegistry.xml file is available in the /opt/ibm/wlp/usr/shared/config directory. The basicRegistry.xml file has an id attribute and a name attribute for each user entry. Cloud APM only uses the value of the name

attribute. It is recommended that you set both attributes to the same value to avoid confusion. For more information on configuring basic user registry with Liberty profile, see the [Using BasicRegistry and role mapping on Liberty](#) example in the WebSphere Application Server Knowledge Center

2. In Cloud APM, use the Role Based Access Control page to assign users and user groups to default and customized roles. For more information on working with roles, see [“Roles and permissions”](#) on page 1137.

## User authentication with LDAP registry

1. Configure Cloud APM to integrate with your LDAP repository. For more information, see [“Integrating with LDAP”](#) on page 1097.
2. Create users and user groups in your LDAP repository if they do not already exist.
3. Change the default user to an LDAP user. For more information, see [“Updating the primary role administrator”](#) on page 1104.
4. In Cloud APM, use the Role Based Access Control page to assign users and user groups to default and customized roles. For more information on working with roles, see [“Roles and permissions”](#) on page 1137.

If you are not a member of a role and you attempt to log in to Cloud APM, you receive a **Not Authorized** message.

## Roles and permissions

A *role* is a group of permissions that control the actions you can perform in Cloud APM. Use the Role Based Access Control page to manage users and roles or alternatively use the Authorization API to complete role-based access control tasks from the command line. For more information, see [“Exploring the APIs”](#) on page 1237.

Cloud APM has four default roles:

### Role Administrator

This role is intended for users whose primary job function is to create access control policies for Cloud APM. This role has all permissions. If you change the default user, the new default user is automatically a member of the Role Administrator role. This role cannot be edited. Role Administrators are prevented from removing themselves from the Role Administrator role. This restriction removes the risk of accidentally removing all users from the Role Administrator role.

### Monitoring Administrator

This role is intended for users whose primary job function is to use Cloud APM to monitor systems. Monitoring Administrators perform tasks such as adding monitoring applications, creating thresholds, adding groups of resources, and distributing the thresholds to these resource groups. This role can be edited.

### System Administrator

This role is intended for users whose primary job function is to perform administration tasks for the Cloud APM system. System Administrators perform tasks such as configuring the Event Manager, or configuring the Hybrid Gateway. This role can be edited.

### Monitoring User

This role is intended for users whose primary job function is to configure and maintain the health and state of systems that are monitored by Cloud APM. This role can be edited.

The following table describes the permissions that you can assign to roles, and the four available default roles and associated permissions:

Table 265. Roles and permissions

|   | Role Administrator  |        | Monitoring Administrator |        | System Administrator |        | Monitoring User |        |
|---|---|--------|--------------------------|--------|----------------------|--------|-----------------|--------|
|   | View  | Modify | View                     | Modify | View                 | Modify | View            | Modify |
| <b>System configuration permissions</b> |   |        |                          |        |                      |        |                 |        |
| Advanced Configuration                  | ✓   | N/A    | —                        | N/A    | ✓                    | N/A    | —               | N/A    |
| Agent Configuration                     | ✓   | N/A    | ✓                        | N/A    | —                    | N/A    | —               | N/A    |
| Informational Pages                     | ✓   | N/A    | ✓                        | N/A    | ✓                    | N/A    | ✓               | N/A    |
| Search Provider                         | ✓   | N/A    | ✓                        | N/A    | —                    | N/A    | —               | N/A    |
| Usage Statistics                        | ✓   | N/A    | ✓                        | N/A    | —                    | N/A    | —               | N/A    |
| <b>Resource permissions</b>             |   |        |                          |        |                      |        |                 |        |
| Application Performance Dashboard       | ✓   | ✓      | ✓                        | ✓      | ✓                    | —      | ✓               | —      |
| Applications                            | ✓   | ✓      | ✓                        | ✓      | —                    | —      | ✓               | —      |
| Individual Application                  | <a href="#">“Application and resource group permissions” on page 1141</a> |        |                          |        |                      |        |                 |        |
| Diagnostics Dashboard                   | ✓   | N/A    | —                        | N/A    | —                    | N/A    | —               | N/A    |
| Resource Group Manager                  | ✓   | N/A    | ✓                        | N/A    | —                    | N/A    | —               | N/A    |
| Individual Resource group               | <a href="#">“Application and resource group permissions” on page 1141</a> |        |                          |        |                      |        |                 |        |
| Resource Groups                         | ✓   | ✓      | ✓                        | ✓      | —                    | —      | —               | —      |
| Synthetic Script Manager                | ✓   | N/A    | —                        | N/A    | —                    | N/A    | —               | N/A    |
| Threshold Manager                       | ✓   | N/A    | ✓                        | N/A    | —                    | N/A    | —               | N/A    |

**Where**

- ✓ indicates that members of this role have this permission
- indicates that members of this role do not have this permission
- N/A indicates that this permission does not exist

**Note:** Although **Usage Statistics** is displayed in the list of **System configuration permissions**, it is no longer applicable to Cloud APM.

The following table describes the actions that are associated with each permission:

| Table 266. Permissions |   |
|------------------------|---|
| Permission             | Description   |
| Advanced Configuration | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>View  <b>System Configuration &gt; Advanced Configuration</b> in the menu bar.</li> <li>Make and save changes in the <b>Advanced Configuration</b> window.</li> <li>View  <b>System Configuration &gt; Hybrid Gateway Manager</b> in the menu bar.</li> <li>Make and save changes in the <b>Hybrid Gateway Manager</b> window.</li> </ul> |

Table 266. Permissions (continued)

| Permission                        | Description  |
|-----------------------------------|--|
| Agent Configuration               | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View  <b>System Configuration</b> &gt; <b>Agent Configuration</b> in the menu bar.</li> <li>• Make and save changes in the <b>Agent Configuration</b> window.</li> </ul>  |
| Informational Pages               | <p>If you have view permission, you can perform the following task:</p> <ul style="list-style-type: none"> <li>• View  <b>Getting Started</b> and  <b>Help</b> in the menu bar.</li> </ul> <p><b>Note:</b> When the <b>Getting Started</b> page opens, if you clear <b>Show this page at startup</b>, for subsequent logins, you see a permission denied error. However, you are still able to navigate to the <b>Getting Started</b> page and any other areas that you have permission to.</p>  |
| Search Provider                   | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View  <b>System Configuration</b> &gt; <b>Configure Search Providers</b> in the menu bar.</li> <li>• Make and save changes in the <b>Configure Search Providers</b> page.</li> </ul>  |
| Application Performance Dashboard | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View  <b>Performance</b> &gt; <b>Application Performance Dashboard</b> in the menu bar.</li> <li>• View the Application Performance Dashboard and the <b>My Components</b> and <b>My Transactions</b> predefined applications.</li> </ul> <p><b>Note:</b> To determine what permissions are required to see systems in the My Components application, see <a href="#">“Application and resource group permissions”</a> on page 1141.</p> <p><b>Note:</b> All Synthetic transactions are displayed in the My Transactions application.</p> <ul style="list-style-type: none"> <li>• Open custom dashboard pages in the Custom Views tab.</li> <li>• Create views in the Attribute Details tab and save them for your own use.</li> </ul> <p>If you have modify permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View  <b>Performance</b> &gt; <b>Application Performance Dashboard</b> in the menu bar.</li> <li>• View the Application Performance Dashboard and the <b>My Components</b> and <b>My Transactions</b> predefined applications.</li> </ul> <p><b>Note:</b> To determine what permissions are required to see systems in the My Components application, see <a href="#">“Application and resource group permissions”</a> on page 1141.</p> <p><b>Note:</b> All Synthetic transactions are displayed in the My Transactions application.</p> <ul style="list-style-type: none"> <li>• Create and save custom dashboard pages in the Custom Views tab.</li> <li>• Create views in the Attribute Details tab and share them with others.</li> <li>• View the <b>Actions</b>&gt;<b>Edit</b> option in component pages, this option enables you to edit the threshold values and other settings of the group widgets that display in the Components dashboard.</li> </ul> |

Table 266. Permissions (continued)

| Permission                       | Description  |
|----------------------------------|--|
| Applications                     | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View applications in the Application Dashboard.</li> </ul> <p>If you have modify permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View applications in the Application Dashboard</li> <li>• Create, modify, and delete applications with the    tools in the Application Dashboard.</li> </ul>   |
| <i>Individual Application</i>    | See <a href="#">“Application and resource group permissions” on page 1141.</a>   |
| Resource Group Manager           | <p>If you have view permission, you can perform the following task:</p> <ul style="list-style-type: none"> <li>• View  <b>System Configuration</b> &gt; <b>Resource Group Manager</b> in the menu bar.</li> </ul>   |
| Resource Groups                  | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View resource groups and the systems in them in the Resource Group Manager if you also have the Resource Group Manager view permission.</li> <li>• View the systems in the My Components predefined application if you also have the Application Performance Management view permission or modify permission</li> <li>• View the systems in the <b>Add Application</b> window if you also have permission to modify applications.</li> </ul> <p>If you have modify permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View resource groups and their contents in the Resource Group Manager if you also have Resource Group Manager view permission.</li> <li>• View the systems in the My Components predefined application if you also have Application Performance Management view or modify permission.</li> <li>• View the systems in the <b>Add Application</b> window if you also have permission to modify applications.</li> <li>• Create, modify, and delete resource groups in the Resource Group Manager if you also have Resource Group Manager view permission. To assign thresholds to a resource group, you also need to be a member of a role that has view permission for Threshold Manager.</li> </ul> <p><b>Note:</b> The Resource Group Manager is used to organize monitored systems into groups, so that thresholds can be assigned to these groups. If you do not have view permission to the Threshold Manager, you are not able to see the thresholds that are assigned to Resource Groups. If you assign the modify Resource Groups permission to a role, you also need to assign the view Threshold Manager permission to the role.</p> |
| <i>Individual Resource Group</i> | See <a href="#">“Application and resource group permissions” on page 1141.</a>   |

| Table 266. Permissions (continued) |  |
|------------------------------------|--|
| Permission                         | Description  |
| Threshold Manager                  | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View  <b>System Configuration</b> &gt; <b>Threshold Manager</b> in the menu bar.</li> <li>• Create, modify, and delete thresholds in the Threshold Manager.</li> <li>• View and edit resource group assignment for thresholds in the Threshold Manager if you have appropriate permissions for the resource group (or groups).</li> <li>• Alternatively, view and edit thresholds assignment for resource groups in the Resource Group Manager if you have appropriate permissions for the Resource Group Manager and resource group (or groups), and view permission for the Threshold Manager.</li> </ul> |
| Synthetic Script Manager           | <p>If you have view permission, you can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• Create, modify, and delete synthetic transactions in the Synthetic Transaction Manager.</li> </ul> <p><b>Note:</b> To work with synthetic transactions in the Synthetic Transaction Manager, you also need to be a member of a role that has view permission for <b>Agent Configuration</b>.</p>   |
| Diagnostics Dashboard              | <p>If you have view permission, the <b>Diagnose</b> button is enabled on the diagnostic dashboards for the WebSphere Applications agent, Node.js agent, Ruby agent, and Microsoft .NET agent. Click the <b>Diagnose</b> button to drill-down to diagnostics dashboards.</p>  |

## Application and resource group permissions

Permissions can be assigned to individual applications and resource groups.

### Application permissions

In Cloud APM, an application is a group of components and the instances within those components. Use the **Add Application** window to define an application. For more information on how to define an application, see [Managing Applications](#).

To select **Performance** > **Application Performance Dashboard** in the Cloud APM console, you must be assigned the view or modify permission for the Application Performance Dashboard. This permission also allows you to see the **My Components** and **My Transactions** predefined applications. To see other custom applications, you must have view permission or modify permission for either all applications or for an individual application.

**Note:** If an application is renamed, permissions are not retained; you must reassign view and modify permissions.

#### View

View permission for an application is dominant over any other permissions. To view an application, you do not need to be a member of a role that has view permission for each component and component instance within the application. The following table describes the actions that you can perform if you have view permission for an application:

| Table 267. View permission for an application               |   |
|---|---|
| Action  | Permission available  |
| View all the supporting components within that application. |  |

| Table 267. View permission for an application (continued)                       |                      |
|---|----------------------|
| Action  | Permission available |
| View the application and its components in the navigation tree.                 | ✓                    |
| View the application components in My Components.                               | ✓                    |
| View customized dashboard pages that are associated with the application.       | ✓                    |
| Add or remove components from the application.                                  | —                    |
| Assign thresholds to the components of the applications.                        | —                    |
| View the supporting components of an application in the Resource Group Manager. | —                    |

### Modify

If you are a member of a role that has modify permission for an individual application, you can

- Delete the application.
- Create customized dashboard pages in the Custom Views tab. See [“Custom views”](#) on page 1283.
- Add or remove components and component instances by using the **Edit Application** window. The components and component instances that are available to you in the **Edit Application** window are filtered based on your role permissions. The following components will be available:
  - Components that you directly have permission to access in system resource groups and custom resource group
  - Components that you indirectly inherited permissions from, based on other applications that you have modify permission to

### Resource Group permissions

Use Resource groups to group components together by their type or purpose. For more information on how to create resource groups, see [“Resource Group Manager”](#) on page 1114.

To select **System Configuration > Resource Group Manager**, you must be assigned the Resource Group Manager view permission. To view resource groups in the **Resource Group Manager** or to view resource group members in the **My Components** application, you also must be assigned view or modify permission for all resource groups or for individual resource groups.

There are two different types of resource groups: custom resource groups and system resource groups.

#### Custom defined resource groups

Create custom resource groups in the Resource Group Manager. Use custom resource groups to group resources together based on their purpose.

The following table describes the actions that you can take if you have the view permission for a custom resource group:

| Table 268. View permission for a custom resource group  |                      |
|---|----------------------|
| Action  | Permission available |
| View the custom resource group and the resources in it in Resource Group Manager.   | ✓                    |
| View resources that are part of the custom resource group in the <b>Add Application</b> window if you also have modify permission for applications. | ✓                    |

| Table 268. View permission for a custom resource group (continued)  |                      |
|---|----------------------|
| Action  | Permission available |
| View resources that are part of the custom resource group in the <b>My Components</b> predefined application if you also have one of the Application Performance Dashboard permissions. | ✓                    |
| Add resources to the custom resource group.   | —                    |
| Delete resources from the custom resource group.  | —                    |

The following table describes the actions that you can take if you have the modify permission for a custom resource group:

| Table 269. Modify permission for a custom resource group  |                      |
|---|----------------------|
| Action  | Permission available |
| Assign thresholds to the custom resource group in Threshold Editor.<br><b>Note:</b> To assign thresholds, you also need to be a member of a role that has view permission for Threshold Editor. | ✓                    |
| Add resources to the custom resource group.   | ✓                    |
| Delete resources from the custom resource group.  | ✓                    |

## System resource groups

System resource groups are automatically defined as part of your Cloud APM environment setup. System resource groups cannot be created manually, deleted, or customized. Only the view permission is available for system resource groups, the modify permission is not available.

System resource groups are defined for each resource type at the time that the resource becomes known to the Cloud APM server. A system resource group exists for each resource type that is connected to the Cloud APM server.

Cloud APM agents are an example of a resource. For example, the first time you download, install, and start a Db2 agent, a system resource group called Db2 is created. This group contains all Db2 agents that are subsequently added to the Performance Management environment.

The system resource group for each resource type contains all the resources of that type including IBM Tivoli Monitoring resources. If your environment has both IBM Tivoli Monitoring and IBM Cloud Application Performance Management, you can install the IBM Cloud Application Performance Management Hybrid Gateway to provide a view of agents from both domains. System defined resource groups contain agents from both domains. For more information, see [“Integrating with IBM Tivoli Monitoring V6.3”](#) on page 1039.

Some system resource groups are based on subnode agents. While you can assign thresholds to system resource groups that are based on subnode agents, events are not displayed in the Application Performance Dashboard. Thresholds are assigned to system resource groups based on subnode agents for event forwarding. System resource groups based on subnode agents have the following description in the Resource Group Manager: 'members of this group cannot be added to an application and do not have events displayed in the Performance Management console'. For more information, see [“Resource Group Manager”](#) on page 1114.

The following table describes the actions you can take if you have view permission for a system resource group:

| Table 270. View permission for a system resource group  |                      |
|---|----------------------|
| Action  | Permission available |
| View the system resource group in Resource Group Manager.   | ✓                    |
| View resources that are part of the system resource group in the <b>Add Application</b> window if you also have modify permission for applications.                                     | ✓                    |
| View resources that are part of the system resource group in the <b>My Components</b> predefined application if you also have one of the Application Performance Dashboard permissions. | ✓                    |
| Assign thresholds to the system resource group in Threshold Editor.   | ✓                    |
| Add resources to the system resource group.   | —                    |
| Delete resources from the system resource group.  | —                    |

## Working with roles, users, and permissions

Use the Role Based Access Control page to work with roles, users, and permissions.

### Procedure

- To filter the list of roles, users, or user groups showing in the Role Based Access Control page, complete the following steps:
  - Select  **System Configuration > Role Based Access Control**.
  - Click inside the   **Filter** text box and type the partial or full text to filter by.  
As you type, any rows that do not contain what you typed in the filter box are removed from the table.
  - To remove the quick filter, delete the value or click the "x".
  - To apply the filter, click .
- To create a new customized role, complete the following steps:
  - Select  **System Configuration > Role Based Access Control**.
  - In the **Roles** tab, click . The **Role Editor** page is displayed.
  - In the **Assign Users to Roles** tab, select the **User Groups** tab, or the **Individual Users** tab and select the users and user groups you want to add to the role.
  - In the **Assign Permissions to Roles** tab, select the **System Configuration Permissions** or the **Resource Permissions** tab, and select the permissions that you want to assign to the role.
  - Click **Save**.
- To edit an existing default or customized role, complete the following steps:
  - Select  **System Configuration > Role Based Access Control**.
  - In the **Roles** tab, click . The **Role Editor** page is displayed.
  - In the **Assign Users to Roles** tab, click the **User Groups** tab, or the **Individual Users** tab and select the users or user groups you want to add to the role.

- d) In the **Assign Permissions to Roles** tab, select the **System Configuration Permissions** or the **Resource Permissions** tab, and select the permissions that you want to assign to the role.
- e) Click **Save**.
- To delete a role, complete the following steps:
  - a) Select  **System Configuration > Role Based Access Control**.
  - b) In the **Roles** tab, select the role that you want to delete and click . A confirmation message is displayed, click **OK**.

**Note:** When you delete a role, the users that are members of that role are not deleted. They are still available in the **Individual Users** tab, and can be assigned to another role by a Role Administrator.
- To view the permissions for a user group, complete the following steps:
  - a) Select  **System Configuration > Role Based Access Control**.
  - b) Select the **User Groups** tab. The list of roles that are assigned to each user group is displayed.

**Note:** All users in the user group are assigned the roles for the user group.
- To view the permissions for an individual user, complete the following steps:
  - a) Select  **System Configuration > Role Based Access Control**.
  - b) Select the **Individual Users** tab. The list of roles that are assigned to each user is displayed.

**Note:** Only the roles that are assigned directly to a user are displayed. If a user is a member of a user group and roles are assigned to the user group, then the user group's roles are not displayed in the list of roles for the individual user on the **Individual Users** tab. However, when the user logs in to the Cloud APM console, they have the permissions that are assigned directly to them and the permissions of any user groups that they are a member of.
- To edit the permissions for an individual user or user group, complete the following steps:
  - a) Select  **System Configuration > Role Based Access Control**.
  - b) In the **Individual User** or **User Groups** tab, select the user or user group you want to edit, and click . The **Individual User Editor** page or **User Group Editor** page is opened.
  - c) Select the role or roles that you want to assign to the user or user group.
  - d) Click **Save**.
- To create a csv file that summarizes the permissions for a user or user group, complete the following steps:
  - a) In the **Individual User** or **User Groups** tab, select the required user or user group, and click . The **Individual User Editor** or **User Group Editor** page is opened.
  - b) Click **Export Summary**.
  - c) Select **Save File**, click **OK**.

A csv file that summarizes the permission for the user or user group is saved to the specified location.

## Results

Role and permission assignment takes effect immediately when you click **Save**.

## Configuring audit logging for role based access control activity

The audit logging feature in Cloud APM logs significant events relating to role-based access control activity. The output of the audit logging feature helps you to determine the following information:

- Who (user, service, or process) initiated the action?
- What activity occurred and what was the result?
- When did the activity occur?
- Where was the activity observed?

- What resource did the activity target?
- Where did the activity get initiated?
- Where was the target of the activity?

**Note:** The audit logging feature does not capture events relating to user authentication, for example, it does not capture if a user is created or deleted, but it does capture if a user is added to a role, or deleted from a role. All activity on the Role Based Access Control page conducted by a role administrator is captured.

Each audit log event is written as a single line in the audit log file. A single audit log event has the following general structure:

```
<AuditEvent ...>
<Who ... />
<What .../>
<When .../>
<OnWhat .../>
<Where .../>
<WhereFrom .../>
<WhereTo .../>
</AuditEvent>
<AuditEvent ...>
```

The PD Collector tool is the Problem Determination Collector tool. You use the PD Collector tool to gather required logs and other problem determination information. The output of the PD Collector tool is requested by IBM Support if you open a support ticket. The audit log and trace log files are collected when you run the PD collector tool. For more information, see the [Chapter 13, “Troubleshooting and support,”](#) on page 1357.

## Configuring audit logging

The location of the audit log files, the number of log files that are maintained, and the maximum size of log files are controlled in the `w7auditconfig.properties` file that is located in the `install_dir/wlp/usr/servers/server1/cscs/conf` directory.

### Procedure

1. Open the `w7auditconfig.properties` file that is located in the `install_dir/wlp/usr/servers/server1/cscs/conf` directory.

Where

`install_dir` is the directory where the Cloud APM server is installed

2. Specify the maximum size in bytes for a single audit log file by editing the following property:

```
AUDIT_LIMIT_BYTES=2097152
```

The default is 2097152.

The audit logging feature supports a generational log file approach. New audit log files are created when an audit log file reaches the maximum size as specified in the `AUDIT_LIMIT_BYTES` property.

3. Specify the maximum number of unique audit log files that are created before wrapping occurs by editing the following property:

```
AUDIT_COUNT=10
```

The default is 10.

4. Specify the directory where audit log files are saved by editing the following property:

```
AUDIT_PATH=install_dir/wlp/usr/servers/server1/logs
```

Where  
*install\_dir* is the directory where the Cloud  
APM server is installed

The audit log files have the following naming convention:

```
hostname_timestamp.w7_audit.log
```

Where  
*hostname* is the short host name of the machine where the audit logging is occurring  
*timestamp* is the time stamp when the audit log file is created

## Configuring trace logging for audit logging

If more detailed audit logging is required, enable additional tracing for the server1 service.

### Procedure

1. Open *install\_dir*/wlp/usr/servers/server1/server.xml file.  
where *install\_dir* is the directory where the Cloud APM server is installed.
2. Copy the **<logging... traceSpecification="..." />** xml element from server.xml to user-exit.xml.

**Note:** The user-exit.xml file is an override file for server.xml. The user-exit.xml file is backed up by the Cloud APM server backup.sh so that it can be restored if you perform disaster recovery. Changes to the server.xml file are not backed up.

3. Edit user-exit.xml and modify the **traceSpecification** value to add this string:

```
com.ibm.smai.cscs.service=finest:com.ibm.apm.cscs.audit.impl=finest:com.ibm.tivoli.audit.w7.*  
=finest
```

Ensure that each option is delimited by a colon. For example, if the **<logging ... traceSpecification="..." />** element looks like (default value) this:

```
<logging maxFiles="100" maxFileSize="10" consoleLogLevel="OFF"  
traceSpecification="*=INFO:com.ibm.  
tivoli.monitoring.provider.sql.SQLLUWStep=DETAIL:com.ibm.tivoli.monitoring.provider.sql.SQLRe  
port  
Collection=DETAIL"/>
```

then change it to look like this:

```
<logging maxFiles="100" maxFileSize="10" consoleLogLevel="OFF"  
traceSpecification="*=INFO:com.ibm.  
tivoli.monitoring.provider.sql.SQLLUWStep=DETAIL:com.ibm.tivoli.monitoring.provider.sql.SQLRe  
port  
Collection=DETAIL:com.ibm.smai.cscs.service=finest:com.ibm.apm.cscs.audit.impl=finest:com.ibm  
.tivoli.  
audit.w7.*=finest"/>
```

4. Remove the **<logging ... traceSpecification="..." />** xml element from the server.xml file.

### Results

The trace statements are written to the *install\_dir*/wlp/usr/servers/server1/logs/  
trace\*.log file where *install\_dir* is the directory where the Cloud APM server is installed.

### What to do next

If you are asked to modify the server1 service tracing by the Cloud APM server support team, you must edit the **<logging traceSpecification="..." />** element in the server1 user-exit.xml file and not in the server.xml file.

## Configuring certificates for the Cloud APM console

Configure custom certificates by using a private root certificate authority or a third-party root certificate authority for communication between Cloud APM console users and the Cloud APM server.

The default certificates for the Cloud APM console are self-signed certificates that are created when the Cloud APM server is installed. The certificates expire 3 years after the server is installed. Because the certificates are not signed by a trusted certificate authority, Cloud APM console users see certificate errors in their browsers when they access the console. You have two options for eliminating the certificate error messages or to create new certificates before the current certificates expire:

- Use the Cloud APM server to create a private root certificate authority certificate and use it to sign the certificates that are used by the Cloud APM server processes. Then, provide the private root certificate authority file to the Cloud APM console users so that they can import it into the trusted root certificate authorities list in their browsers.
- Use a third-party root certificate authority (such as GeoTrust or a certificate authority in your company) to sign the certificates that are used by the Cloud APM server processes. If the third-party root certificate authority is not already trusted by Cloud APM console users' browsers, then they must import the root certificate authority file into the trusted root authorities certificate list in their browsers.

### Configuring certificates by using a private root certificate authority

You can use the Cloud APM server to create a private root certificate authority (CA) file and use it to sign the certificates that are used by the server processes. Your Cloud APM console users must then import the private root CA certificate into the trusted root certificate authorities list in their browsers so that the Cloud APM certificates are trusted by their browsers.

#### About this task

- Use the default `/opt/ibm` as the directory where you installed the Cloud APM server or use the path that you specified for installation.
- Replace `apm_server_hostname` with the host name of the Cloud APM server. Use the fully qualified host name (such as `myapmserver.ibm.com`) unless Cloud APM console users are able to use the short host name (such as `myapmserver`). For example, replace `Signer_CA_on_apm_server_hostname` in the following steps with `Signer_CA_on_myapmserver.ibm.com`.
- Replace `password` in the following steps with either `ROOTCAPASS`, which is the root certificate authority password or `APMPASS`, which is the password of the Cloud APM server UI keystore.
- Replace `my company name` with your company name, for example `IBM`.
- You have two choices for the key algorithm: RSA or Elliptic Curve (EC). The algorithm that is used by the CA for signing its root and intermediate certificates must match the algorithm that is specified by the `-keyalg` parameter. The procedure assumes that the RSA algorithm is used. If the root CA certificate was signed using the Elliptic Curve algorithm, replace `-keyalg RSA` with `-keyalg EC` in every step of this procedure where a key algorithm is specified. The use of Elliptic Curve is encouraged because it supports forward secrecy and does not rely on static keys.
- The new certificates expire 10 years after they are created.
- If you are copying commands directly from the text and pasting into the command line, copy from the HTML version of this topic in the IBM Knowledge Center. The PDF version has line breaks inserted to accommodate the page width limitations that should not be read necessarily as a new command.

#### Procedure

1. Create the private root certificate authority certificate:

```
export ROOTCAPASS="password"
```

```
/opt/ibm/ccm/create_security_artifacts.sh -genrootca -workdir "/opt/ibm/ccm  
/uikeyfiles" -keyalg RSA -hostname Root_CA_on_apm_server_hostname -dname
```

```
"O=my company name" -label "Root_CA_for_APM_UI"
```

2. Generate the certificate signing request (CSR) for the signer certificate authority:

```
export APMPASS="password"
```

```
/opt/ibm/ccm/create_security_artifacts.sh -gencsr  
-workdir /opt/ibm/ccm/uikeyfiles -keyalg RSA -hostname Signer_CA_on_apm_server_hostname  
-dname "O=my company name" -label "Signer_CA_for_APM_UI"
```

3. Import the root CA certificate into the signer CA key database:

```
/opt/ibm/ccm/create_security_artifacts.sh -addkeytodb  
-destkdb /opt/ibm/ccm/uikeyfiles/Signer_CA_on_apm_server_hostname/keyfiles/keyfile.kdb -  
importfile /opt/ibm/ccm/uikeyfiles/apmCA/exports/apmCA.cer  
-label "Root_CA_for_APM_UI"
```

4. Sign the signer CA certificate:

```
/opt/ibm/ccm/create_security_artifacts.sh -signcsr -keyalg RSA  
-rootcakdb /opt/ibm/ccm/uikeyfiles/apmCA/keyfiles/keyfile.kdb  
-rootcalabel "Root_CA_for_APM_UI" -csrfile /opt/ibm/ccm/uikeyfiles  
/Signer_CA_on_apm_server_hostname/exports/Signer_CA_on_apm_server_hostname.aim  
-ca true
```

5. Generate the certificate signing request (CSR) for the Cloud APM server certificate:

```
/opt/ibm/ccm/create_security_artifacts.sh -gencsr -workdir /opt/ibm/  
ccm/uikeyfiles -keyalg RSA -hostname apm_server_hostname  
-dname "O=my company name" -san_name  
apm_server_hostname -label "defaultKeyStore"
```

You must specify defaultKeyStore as the label so that you do not have to edit the keystore alias in the `server.xml` file for the `apmui`, `server1`, `uviews`, and `oidc` processes.

6. Add the root CA certificate into the key database for the Cloud APM server certificate:

```
/opt/ibm/ccm/create_security_artifacts.sh -addkeytodb  
-destkdb /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb  
-importfile /opt/ibm/ccm/uikeyfiles/apmCA/exports/apmCA.cer  
-label "Root_CA_for_APM_UI"
```

7. Add the signer CA certificate into the key database for the Cloud APM server certificate:

```
/opt/ibm/ccm/create_security_artifacts.sh -addkeytodb  
-destkdb /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb  
-importfile /opt/ibm/ccm/uikeyfiles/Signer_CA_on_apm_server_hostname/exports/  
Signer_CA_on_apm_server_hostname.cer -label "Signer_CA_for_APM_UI"
```

8. Sign the Cloud APM server certificate using the signer CA:

```
/opt/ibm/ccm/create_security_artifacts.sh -signcsr -keyalg RSA  
-rootcakdb /opt/ibm/ccm/uikeyfiles/Signer_CA_on_apm_server_hostname/keyfiles/keyfile.kdb -  
rootcalabel "Signer_CA_for_APM_UI" -csrfile /opt/ibm/ccm  
/uikeyfiles/apm_server_hostname/exports/apm_server_hostname.aim
```

9. Convert the Cloud APM server signed certificate to the JKS format:

```
/opt/ibm/ccm/create_security_artifacts.sh -kdb2jks -sourcekdb /opt/ibm  
/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb
```

10. To remove the passwords from the command line environment, enter these commands:

```
export -n APMPASS
```

```
export -n ROOTCAPASS
```

11. Copy the Cloud APM server signed certificate to the shared location for the `apmui`, `server1`, `uviews`, and `oidc` processes:

```
cp /opt/ibm/wlp/usr/shared/resources/security/key.jks /opt/ibm/wlp/usr/shared/resources/security/key.jks.sav
```

```
cp /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.jks /opt/ibm/wlp/usr/shared/resources/security/key.jks
```

12. Encode the APMPASS password value from step 3 by using the Liberty securityUtility tool and AES cipher:

```
/opt/ibm/wlp/bin/securityUtility encode --encoding=aes password
```

13. Update the keystore password in the /opt/ibm/wlp/usr/shared/config/serverVariables.xml file:

- Search for the line that contains **key.store.password**.
- Replace the value with the output from the previous step (step “12” on page 1150).

14. Update the oidc entry in the shared truststore with the new Cloud APM server signed certificate:

```
cp /opt/ibm/wlp/usr/shared/resources/security/trust.jks /opt/ibm/wlp/usr/shared/resources/security/trust.jks.sav
```

```
/opt/ibm/java/jre/bin/keytool -delete -alias oidc -keystore /opt/ibm/wlp/usr/shared/resources/security/trust.jks -storepass 'ccmR0cKs!'
```

```
/opt/ibm/java/jre/bin/keytool -importcert -alias oidc -file /opt/ibm/ccm/uikeyfiles/apm_server_hostname/exports/apm_server_hostname.cer -noprompt -keystore /opt/ibm/wlp/usr/shared/resources/security/trust.jks -storepass 'ccmR0cKs!'
```

where *ccmR0cKs!* is the default truststore password. If you want to use a different password, follow the procedure in “[Changing the password for the shared truststore](#)” on page 1155 and use the new password in this step.

15. If you want to limit which cipher suites are negotiated by your Cloud APM console users and the Cloud APM server, perform these steps:

- Copy the **<ssl>** element and all of its attributes from the /opt/ibm/wlp/usr/servers/apmui/server.xml file to the apmui/user-exit.xml file, and then delete the **<ssl>** element and its attributes from the apmui/server.xml file.  
For example, copy all of these lines from apmui/server.xml to apmui/user-exit.xml, and then delete the lines from apmui/server.xml:

```
<ssl
  id="defaultSSLConfig"
  sslProtocol="TLSv1.2"
  keyStoreRef="defaultKeyStore"
  trustStoreRef="sharedTrustStore"
  enabledCiphers=""
  serverKeyAlias="" />
```

- In the apmui/user-exit.xml file, change the value of the enabledCiphers attribute to the following value if you specified -keyalg RSA in step 1.c.

```
enabledCiphers="TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256"
```

Otherwise, change the value of the enabledCiphers attribute to the following if you specified -keyalg EC in step 1.c.

```
enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256"
```

**Note:** If these cipher suite combinations are too restrictive for your Cloud APM console users, you can choose other cipher suite combinations that are compatible with the signature algorithm (RSA or EC) that you chose in step 1.c. The Cloud APM server installs IBM Java 8, and IBM Java determines the cipher suites that can be used for Cloud APM. For the list of IBM Java 8 supported

cipher suites, see [Cipher suites](#). Choose ones that can be used for TLS 1.2 and that are compatible with your signature algorithm.

c) Repeat steps “15.a” on page 1150 and “15.b” on page 1150 for these files:

```
/opt/ibm/wlp/usr/servers/oidc/server.xml and oidc/user-exit.xml
/opt/ibm/wlp/usr/servers/server1/server.xml and server1/user-exit.xml
/opt/ibm/wlp/usr/servers/uviews/server.xml and uviews/user-exit.xml
```

**Note:** The content of the **<ssl>** element in the `apmui/server.xml`, `oidc/server.xml`, `server1/server.xml`, and `uviews/server.xml` files is slightly different. Copy the content of the **<ssl>** element in each `server.xml` file to the corresponding `user-exit.xml` file, and then update the `enabledCiphers` attribute as described.

16. Add the root CA certificate to the Java truststore:

a) Enter the following command:

```
/opt/ibm/java/bin/keytool -importcert
-file /opt/ibm/ccm/uikeyfiles/apmCA/exports/apmCA.cer
-keystore /opt/ibm/java/jre/lib/security/cacerts -alias Root_CA_for_APM_UI
```

b) After you are prompted, enter the keystore password:

```
changeit
```

c) After you are prompted to trust this certificate, enter yes.

17. Restart the Cloud APM server processes:

```
apm restart_all
```

18. Send the `/opt/ibm/ccm/uikeyfiles/apmCA/exports/apmCA.cer` and `/opt/ibm/ccm/uikeyfiles/Signer_CA_on_apm_server_hostname/exports/Signer_CA_on_apm_server_hostname.cer` files to your Cloud APM console users.

- Users must import the `apmCA.cer` file into the trusted root certificate list in their browsers and indicate that the browser should trust this certificate to identify websites.
- They must also import the `Signer_CA_on_apm_server_hostname.cer` file into the intermediate certificate authorities list if it exists and indicate that the browser should trust this certificate to identify websites. If the browser does not have an intermediate certificate authorities list, then users should import the certificate into the trusted root certificate list.
- The steps to import the root certificate authority depend on the browser and browser version. For more information, see your web browser documentation.

## Results

After Cloud APM console users import the private root certificate and signer certificate, they no longer see certificate errors that indicate the Cloud APM server certificates are not signed by a trusted root certificate authority.

## Configuring certificates by using a Third-Party Root Certificate Authority

You can create a custom certificate that is not signed by you but is generated by a third-party root certificate authority (CA).

### About this task

- Use the default `/opt/ibm` as the directory where you installed the Cloud APM server or use the path that you specified for installation.
- Replace `apm_server_hostname` with the host name of the Cloud APM server. Use the fully qualified host name (such as `myapmserver.ibm.com`) unless Cloud APM console users are able to use the short host name (such as `myapmserver`). For example, replace `Signer_CA_on_apm_server_hostname` in the following steps with `Signer_CA_on_myapmserver.ibm.com`.

- Replace *password* in the following steps with either ROOTCAPASS, which is the root certificate authority password or APMPASS, which is the password of the Cloud APM server UI keystore.
- Replace *my company name* with your company name, for example IBM.
- You have two choices for the key algorithm: RSA or Elliptic Curve (EC). The algorithm that is used by the CA for signing its root and intermediate certificates must match the algorithm that is specified by the **-keyalg** parameter. The procedure assumes that the RSA algorithm is used. If the root CA certificate was signed using the Elliptic Curve algorithm, replace **-keyalg RSA** with **-keyalg EC** in every step of this procedure where a key algorithm is specified. The use of Elliptic Curve is encouraged because it supports forward secrecy and does not rely on static keys.
- The new certificates expire 10 years after they are created.
- If you are copying commands directly from the text and pasting into the command line, copy from the HTML version of this topic in the IBM Knowledge Center. The PDF version has line breaks inserted to accommodate the page width limitations that should not be read necessarily as a new command.

## Procedure

### 1. Create the Certificate Signing Request (CSR):

#### a) Add your keystore password to the environment:

```
export APMPASS="password"
```

where *password* is the administrator password for the Cloud APM server.

#### b) Create a uikeyfiles directory to hold the files that are associated with your CSR, under /opt/ibm/ccm:

```
mkdir /opt/ibm/ccm/uikeyfiles
```

These files are included during the Cloud APM server backup and restore procedures.

#### c) Run the following script:

```
./create_security_artifacts.sh -gencsr -workdir /opt/ibm/ccm/uikeyfiles  
-keyalg RSA -hostname apm_server_hostname -dname OU=ou,O=o,L=l,ST=st,C=c  
-label defaultKeyStore
```

You must specify defaultKeyStore as the label so that you do not have to edit the keystore alias in the `server.xml` file for the `apmui`, `server1`, `uviews`, and `oidc` processes.

A CSR is created in `/opt/ibm/ccm/uikeyfiles/apm_server_hostname/exports/apm_server_hostname.arm` that you send to have signed by your CA. Your CA returns your new certificate, the issuing certificate, and any other certificates in the issuer certificate chain of trust. It also creates a set of files in `/opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles` that need to be updated when you get your certificates back from the third-party CA and import them into `opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb`. These files are important to keep and are reused in the steps that follow.

Some of the more recent versions of Chrome require imported certificates to specify a Subject Alternate DNS name. If your CA does not add the Subject Alternate Name automatically, you can add it to the CSR with the **-san\_name** parameter. If you need to specify multiple hostnames, separate each hostname with a comma. If your certificate is generated without a Subject Alternate DNS Name, Chrome users need to override the warning message when they start the Cloud APM console.

The **-gencsr** parameter creates a private key that is, for now, in the `keyfile.rdb` file. It is moved to the `keyfile.kdb` later when you run the import.

### 2. After your certificates are returned, add the root, any intermediates, and the issuing certificate into the keyfile.kdb that was created with the **-gencsr** parameter:

#### a) Add your CA's root certificate:

```
/opt/ibm/ccm/create_security_artifacts.sh -addkeytodb -destkdb /opt/ibm/ccm/uikeyfiles  
/apm_server_hostname/keyfiles/keyfile.kdb -importfile your_CA's_root_cert_path
```

```
-label your_CA's_root_label
```

Where *your\_CA's\_root\_cert\_path* is the path to the location of the root certificate file that you obtained from the third party CA and copied to the Cloud APM server, for example, `/opt/ibm/mycert-files/root.crt` or `/opt/ibm/mycert-files/root.cer` and *your\_CA's\_root\_label* is a unique label to identify the CA root certificate in the Cloud APM keystore. Enter a unique string for the label, for example, `Root_CA_for_APM_UI`.

- b) Add your CA's intermediate certificate (if needed):

```
/opt/ibm/ccm/create_security_artifacts.sh -addkeytodb -destkdb /opt/ibm/ccm  
/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb -importfile  
your_CA's_intermediate_cert_path -label your_CA's_intermediate_label
```

Where *your\_CA's\_intermediate\_cert\_path* is the path to the location of the intermediate certificate files that you obtained from the third party CA and copied to the Cloud APM server, for example, `/opt/ibm/mycert-files/intermediate.crt` or `/opt/ibm/mycert-files/intermediate.cer` and *your\_CA's\_intermediate\_label* is a unique label to identify an intermediate certificate in the Cloud APM keystore (if you have intermediate certificates). Enter a unique string for the label, for example, `Intermediate_Cert_for_APM_UI`.

All of the other key files must also be in that directory because they are used by the next steps, even though you specify only the path to the `keyfile.kdb` file. Thus, you first add the certificates to build the chain of trust.

3. Import your new certificate and the signing certificate.

```
/opt/ibm/ccm/create_security_artifacts.sh -importcert  
-rootcacert path_to_CA_issuer_cert -rootcalabel issuer_cert_label  
-destkdb /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb  
-importfile path_to_new_signed_certificate
```

This command is unusual because it uses "rootcalabel" and "rootcacert" for the parameter names that correspond to the signer certificate.

Where *issuer\_cert\_label* is a unique label to identify the signer certificate in the Cloud APM keystore. Enter a unique string for the label, for example, `Issuer_for_APM_UI` and *path\_to\_new\_signed\_certificate* is the path to the location of the signed certificate that you obtained from the third party CA and which should be used for the Cloud APM server. For example, `/opt/ibm/mycert-files/my-apm-server-cert.crt` or `/opt/ibm/mycert-files/my-apm-server-cert.cer`.

The keystore files in `/opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles` are now modified and the `keyfile.kdb` file can now be converted to jks format.

4. Convert the `keyfile.kdb` file to jks format:

```
/opt/ibm/ccm/create_security_artifacts.sh -kdb2jks -sourcekdb /opt/ibm/ccm/  
uikeyfiles/apm_server_hostname/keyfiles/keyfile.kdb
```

Two files are created: `/opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.jks` and `/opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.p12`. The p12 file is not used for Cloud APM but openssl supports this keystore format and it can be validated by using `openssl pkcs12 -in /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.p12`.

5. To remove the password from the command line environment, enter the following command:

```
export -n APMPASS
```

6. Copy the new keystore to the shared location for the apmui, server1, uviews, and oidc servers:

- a) Back up the original keystore:

```
cp /opt/ibm/wlp/usr/shared/resources/security/key.jks /opt/ibm/wlp/usr/shared/resources  
/security/key.jks.sav
```

- b) Copy the new keystore:

```
cp /opt/ibm/ccm/uikeyfiles/apm_server_hostname/keyfiles/keyfile.jks /opt/ibm/wlp/usr/
shared
/resources/security/key.jks
```

7. Run the Liberty securityUtility tool with the AES option to encode your keystore password that you added to the environment in APMPASS. Respond to the Enter text: prompt with your password.

```
/opt/ibm/wlp/bin/securityUtility encode --encoding=aes
Enter text:
Re-enter text:
{aes}your_encoded_password
```

8. Update the keystore password in the /opt/ibm/wlp/usr/shared/config/serverVariables.xml file by searching for the line that contains **key.store.password** and replace the value with the output of the previous step (step “7” on page 1154).

Be sure to include {aes} before your encoded password in the XML file.

9. Update the oidc entry in the shared truststore with your certificate:

- a) Back up the original:

```
cp /opt/ibm/wlp/usr/shared/resources/security/trust.jks /opt/ibm/wlp/usr/shared/resources
/security/trust.jks.orig
```

- b) Remove the oidc entry:

```
/opt/ibm/java/bin/keytool -delete -alias oidc -keystore /opt/ibm/wlp/usr/shared/resources
/security/trust.jks -storepass 'ccmR0cKs!'
```

where *ccmR0cKs!* is the default truststore password. If you want to use a different password, follow the procedure in [“Changing the password for the shared truststore” on page 1155](#) and use the new password in this step.

- c) Add the new certificate as the oidc entry:

```
/opt/ibm/java/bin/keytool -importcert -alias oidc -file path_to_new_signed_cert
-noprompt -keystore /opt/ibm/wlp/usr/shared/resources/security/trust.jks -storepass
'ccmR0cKs!'
```

where *ccmR0cKs!* is the default truststore password. If you want to use a different password, follow the procedure in [“Changing the password for the shared truststore” on page 1155](#) and use the new password in this step.

10. If your third-party Root CA is not well known, add that certificate to the Java truststore:

- a) Enter the following command:

```
/opt/ibm/java/bin/keytool -importcert -file path_to_Root_CA_certificate
-keystore /opt/ibm/java/jre/lib/security/cacerts
-alias Root_CA_certificate
```

- b) After you are prompted, enter the following password:

```
changeit
```

- c) After you are prompted to trust this certificate, enter yes.

11. If you want to limit which cipher suites are negotiated by your Cloud APM console users and the Cloud APM server, perform these steps:

- a) Copy the **<ssl>** element and all of its attributes from the /opt/ibm/wlp/usr/servers/apmui/server.xml file to the apmui/user-exit.xml file, and then delete the **<ssl>** element and its attributes from the apmui/server.xml file.

For example, copy all of these lines from apmui/server.xml to apmui/user-exit.xml, and then delete the lines from apmui/server.xml:

```
<ssl
  id="defaultSSLConfig"
  sslProtocol="TLSv1.2"
  keyStoreRef="defaultKeyStore"
```

```
trustStoreRef="sharedTrustStore"
enabledCiphers=""
serverKeyAlias="" />
```

- b) In the `apmui/user-exit.xml` file, change the value of the `enabledCiphers` attribute to the following value if you specified `-keyalg RSA` in step 1.c.

```
enabledCiphers="TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256"
```

Otherwise, change the value of the `enabledCiphers` attribute to the following if you specified `-keyalg EC` in step 1.c.

```
enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256"
```

**Note:** If these cipher suite combinations are too restrictive for your Cloud APM console users, you can choose other cipher suite combinations that are compatible with the signature algorithm (RSA or EC) that you chose in step 1.c. The Cloud APM server installs IBM Java 8, and IBM Java determines the cipher suites that can be used for Cloud APM. For the list of IBM Java 8 supported cipher suites, see [Cipher suites](#). Choose ones that can be used for TLS 1.2 and that are compatible with your signature algorithm.

- c) Repeat steps “11.a” on page 1154 and “11.b” on page 1155 for these files:

```
/opt/ibm/wlp/usr/servers/oidc/server.xml and oidc/user-exit.xml
/opt/ibm/wlp/usr/servers/server1/server.xml and server1/user-exit.xml
/opt/ibm/wlp/usr/servers/uviews/server.xml and uviews/user-exit.xml
```

**Note:** The content of the `<ssl>` element in the `apmui/server.xml`, `oidc/server.xml`, `server1/server.xml`, and `uviews/server.xml` files is slightly different. Copy the content of the `<ssl>` element in each `server.xml` file to the corresponding `user-exit.xml` file, and then update the `enabledCiphers` attribute as described.

12. Restart the Cloud APM server processes:

```
apm restart_all
```

13. Send the root certificate file to your Cloud APM console users.

- Users must import the root certificate into the trusted root certificate list in their browsers and indicate that the browser should trust this certificate to identify websites.
- Some browsers also require the intermediate certificates to be imported. If the browser requires it, users must import the intermediate certificate file into the intermediate certificate authorities list and indicate that the browser should trust this certificate to identify websites.
- The steps to import the root certificate authority depend on the browser and browser version. For more information, see your web browser documentation.

## Changing the password for the shared truststore

The shared truststore is used by selected Liberty servers to verify credentials. If required, you can change the password.

### Before you begin

Replace `/opt/ibm` with the installation path you specified during the Cloud APM server installation.

### Procedure

1. Verify that you know the current password for the shared truststore. Run the following command:

```
cd /opt/ibm/wlp/usr/shared/resources/security/
keytool -list -v -keystore trust.jks
```

When prompted, enter the password. The default password is:

```
ccmR0cKs!
```

The command should print the aliases of all entries in the keystore.

2. Stop the Cloud APM server:

```
apm stop_all
```

3. Change the password for the truststore:

```
cd /opt/ibm/wlp/usr/shared/resources/security/  
cp trust.jks trust.jks.sav  
keytool -storepasswd -keystore trust.jks
```

4. Encode the password by using the Liberty securityUtility tool and AES cipher:

```
/opt/ibm/wlp/bin/securityUtility encode --encoding=aes
```

5. Update the Cloud APM server configuration:

```
cd /opt/ibm/wlp/usr/shared/config/  
cp serverVariables.xml serverVariables.xml.sav
```

Update the value of the `trust.store.password` variable in the `serverVariables.xml` file. Use the value determined in “4” on [page 1156](#), for example:

```
<variable name="trust.store.password" value="{aes}AKPjaLK2Ng7Epa+PX41P0yWfbfyu98/  
g0FhhGDx/  
wpK/" />
```

6. Start the Cloud APM server:

```
apm start_all
```

## Accessing and using the Role-Based Access Control Service API

Use the Role-Based Access Control Service API to manage the lifecycle of role-based access control policies from the command line.

### About this task

Complete role-based access tasks such as creating, viewing, updating, and deleting roles. Add and delete a set of users or user groups from a specific role. Grant permissions to a specific role. View a list of roles, users, user groups, and permissions that are defined in the system.

You can create scripts for automating such tasks as defining new roles and assigning users, user groups, and permissions to these roles.

In this task you can use either access tokens or basic authorisation in the curl command:

#### Access tokens

Use the OpenID Connect (OIDC) protocol to get an access token from the OIDC server on the Cloud APM server. The access token gives you authorised access to the API for running operations until the token expires after 30 minutes.

#### Basic authorisation

Use a base64 tool to encode your Cloud APM console user ID and password into a single base64 string. The input string format is `userId:password`, such as `apmadmin:apmpass`. The output is a string such as: `YXBtYWRTaW46YXBtcGFzcw==`

Use `base64_encoded_string` in the authorisation header of every request as shown in the curl command examples.

Note the Cloud APM console user ID must be added to a role with appropriate permissions.

Disabling OIDC authentication, which is required before you can enable single sign-on (SSO) between Cloud APM and other IBM products such as Tivoli Common Reporting that require LTPA for single sign-on, does not affect the API. The RESTful API continues to use the Cloud APM internal OIDC server, even if OIDC is disabled for single sign-on between the Cloud APM console and other product user interfaces.

Role-Based Access Control Service API requests must be issued by using https to the port 9443 of the Cloud APM server.

## Procedure

1. On the system where the Cloud APM server is installed, open the following file and copy the values of the *client.secret.apmui* and *client.id.apmui* variables:

```
install_dir/wlp/usr/shared/config/clientSecrets.xml
```

The following example shows what the file contains:

```
<server>
  <variable name="client.secret.apmui" value="{xor}BiY3KQgIa2gRCms3Cxxr
MhUYL2YRJSwvCjUnJxYb" />
  <variable name="client.id.apmui" value="rpapmui" />
</server>
```

2. Optional: If you plan to use an access token in your **curl** command, use an XOR decoder to decode the value of the *client.secret.apmui* variable to get the actual secret value.  
For example, when you use an XOR decoder to decode  
BiY3KQgIa2gRCms3CxxrMhUYL2YRJSwvCjUnJxYb, you get the following value:  
YyhvWW47NU4hTC4mJGp9NzspUjxxID
3. Optional: If you plan to use an access token in your curl command, complete this step. To get an access token, contact the token endpoint of the Cloud APM OIDC server with the four required items: **username**, **password**, **client\_id**, and **client\_secret**, as in the following command:

```
curl --tlsv1.2 -v -k -d "grant_type=password
&client_id=rpapmui&client_secret=YyhvWW47NU4hTC4mJGp9NzspUjxxID
&username=apmadmin&password=apmpass&scope=openid"
https://example.mycompany.com:8099/oidc/endpoint/OP/token
```

Where:

- username is the username of the Cloud APM console user
- password is the password of a Cloud APM console user
- clientid is the value of the *client.id.apmui* variable from step 1.
- client\_secret is the value created by the XOR decoder in step 2.

Output:

```
{"access_token": "jnZ4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8",
"token_type": "Bearer", "expires_in": 1800, "scope": "openid",
"refresh_token": "VsCWUhPHBRpidD2F1PVyZ2LNGMuQPTN837t30oqZj71FcBfsGE"}
```

**Note:** If the *client\_secret*, *username*, or *password* values contain characters other than digits (0-9), ASCII letters (A-Z, a-z), and a few special characters ("-", ".", "\_", "~"), you must URL encode the other characters. For example, if the decoded client secret is TEV1NjROVT8iPF9r=1dNNW8+SGFgJ0, replace the = character with %3D, replace the + character with %2B, and enter *client\_secret=TEV1NjROVT8iPF9r%3D1dNNW8%2BSGFgJ0* instead of *client\_secret=TEV1NjROVT8iPF9r01dNNW8+SGFgJ0*.

4. Optional: If you plan to use an access token in your curl command, extract the **access\_token** value. Looking at the output in the previous example, the value is  
jnZ4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8.

5. Enter requests to the Role-Based Access Control Service API using either an access token or basic authorisation.

Access token example:

```
curl --tlsv1.2 -v -k --request GET
--url 'https://myAPMServer.mycompany-domain.com:9443/1.0/authzn/users'
--header 'authorization: Bearer jnz4Ad0zpeCpYcU1Uf7o4A40tz5trnIW9GutICG8'
--header 'content-type: application/json'
```

Basic authorisation example:

```
curl --tlsv1.2 -v -k --request GET
--url 'https://myAPMServer.mycompany-domain.com:9443/1.0/authzn/users'
--header 'authorization: Basic YXBtYWRTaW46YXBtcGFzcw=='
--header 'content-type: application/json'
```

6. For more details about API operations, see API documentation in API Explorer. For instructions about accessing API Explorer, see [Exploring the APIs](#).

**Note:** Part of the URL and some of the headers that are shown in the examples are required for Cloud APM only. For example: `https://api.ibm.com/perfmgmt/run`, `x-ibm-service-location`, `X-IBM-Client-Id`, `X-IBM-Client-Secret`. See step “5” on page 1158 for request examples.

7. You must include a referer header in all POST, PUT, and DELETE requests. The value for the referer header is:

```
-H 'Referer: https://apm_server:9443'
```

where *apm\_server* is the IP address or the fully qualified host name of your Cloud APM server.

## Example

The following example uses the curl command to create a new role.

```
POST /1.0/authzn/roles
```

**Note:** The body of the POST request must contain a JSON object that defines the role as shown by the **-d** parameter.

```
curl -X POST \
https://apm_server:9443/1.0/authzn/roles \
-H 'Referer: https://apm_server:9443' \
-H 'authorization: Bearer Your_Access-Token' \
-H 'content-type: application/json' \
-d '{
  "description": "Your Role Description",
  "id": "/authzn/roles/Your_Role_Id",
  "label": "Your Role Name"
}'
```

## Administering your agents

Your IBM Cloud Application Performance Management installation has tools for managing your monitoring agents.

Some of these tools are also used during initial configuration of your managed systems: [“Using agent commands” on page 236](#), [“Agent Configuration page” on page 242](#), and [“Using the IBM Cloud Application Performance Management window on Windows systems” on page 242](#).

## Starting agents as a non-root user

If you want to start agents as different users, create a common group on the system and make each user a member of this group.

### Before you begin

If you installed and configured your agent as the same non-root user and you want to start the agent as the same user, no special action is required. If you installed and configured your agent as a selected user and want to start the agent as a different user, create a common group on the system. Make all agent management users members of this common group. Transfer ownership of all agent files and directories to this group.

### About this task

An autostart script is generated by an installation, upgrade, or configuration. This script (named ITMAgentsN or rc.itmN, depending on the UNIX operating system) contains an entry for each application in a particular installation. By default all agents are started with root user access. To update system startup scripts and start agents as a non-root user, you must edit the `install_dir/config/kcirunas.cfg` file, which contains a superset of the XML syntax. Each **productCode** section in the `kcirunas.cfg` file is disabled by default. Activate a **productCode** section for your agent by removing the comment indicator from **!productCode**. Commented or deactivated sections are ignored. Uncommented or activated sections for applications that are not installed are ignored.

### Procedure

1. Install your monitoring agents on Linux or UNIX as described in [“Installing agents” on page 189 on AIX systems](#) or [“Installing agents” on page 199 on Linux systems](#).
2. Optional: Configure your monitoring agents on Linux or UNIX as necessary, see [Chapter 8, “Configuring your environment,” on page 223](#).
3. Run the `./secure.sh` script with the group name of the non-root user to secure the files and set the file group ownership to the files.  
For example: `./secure.sh -g db2iadm1`
4. To update the system startup scripts, complete the following steps:
  - a) Update the `install_dir/config/kcirunas.cfg` file. Activate **productCode** sections for your agents. For agents that do not require an instance value, specify the `product_code`, instance, and user, where the `product_code` value is the two-letter code that is specified in [Table 27 on page 236](#). For agents that do require an instance value, such as the Db2 monitoring agent (product code: ud), specify the `product_code`, instance, user, and name.  
For example:

```
<productCode>ud</productCode>
<instance>
<name>db2inst1</name>
<user>db2inst1</user>
</instance>
<instance>
<name>db2inst2</name>
<user>root</user>
</instance>
```

- b) Run the following script with root user or sudo user access: `install_dir/bin/UpdateAutoRun.sh`

### What to do next

For more information about the `./secure.sh` script, see [Securing the agent installation files](#).

Use the same user ID for agent installation and upgrades.

## Managing historical data retention values

You can change the number of days that resource monitoring data samples are retained in the Cloud APM server database from the default eight days to the best practices values that were established by the agent and data collector developers. The best practices values retain up to 32 days of data for a subset of the data sets. You can also configure custom retention periods of up to 32 days for data sets. The retention period for transaction tracking data from the Response Time Monitoring Agent or middleware agents and Synthetic transaction data cannot be modified.

### About this task

After you change the max data retention period to more than 8 days for resource monitoring data, you can see data up to the max retention period on these tabs in the Cloud APM console:

- For dashboard line charts that plot a time range such as the last 4 hours on the Status Overview tab, you can compare the values from the time range today with the same time range from another day up to the max retention period. For example, compare the last 4 hours today with the last 4 hours on another day up to 32 days ago. See [“Adjusting and comparing metrics over time”](#) on page 1263 for more information.
- For custom views, you can display data from a time range for any day within the max retention period, for example, you can display a 4 hour time range for any day within the past 32 days. See [“Viewing custom pages”](#) on page 1290 for more information.

#### Note:

- You cannot display data from more than a week ago in the **Attribute Details** tab even if you change the max retention period to more than 8 days.
- After changing the max retention period, in the **Status Overview** tab, and **Custom Views** tab, you can select a day in the past up to the max retention period you configured. For example, if you configure the best practices, the Cloud APM console allows you to select a day up to 32 days ago. However, the best practices do not retain 32 days of data for all datasets. So line charts or custom views for datasets that still have a retention period of 8 days will only display data if you select a day within the past week.
- After you change the retention period, the Cloud APM server starts retaining data for the configured number of days and older data is not available right away. For example, if you enable the best practices retention today, data from 32 days ago cannot be displayed in the Cloud APM console until at least 3 weeks from today.
- Historical data for synthetic transactions and transaction tracking is saved in the DATAMART database. The data retention settings cannot be modified for data in the DATAMART database. To view historical data for synthetic transactions or Response Time Monitoring agent transaction data, you must install Tivoli Common Reporting and the Cloud APM reports. For more information, see [“Integrating with Tivoli Common Reporting”](#) on page 1083 and [“Reports”](#) on page 1294.

The Cloud APM server Db2 historical database, WAREHOUS, typically stores 8 days of data samples from the IBM Cloud APM agents and data collectors. The exact number for each data set is published in the agent or data collector attribute help and in the reference PDF (see [Chapter 2, “PDF documentation,”](#) on page 49).

The Cloud APM server has a `get_metrics_retention.sh` script that you can run to see the number of days that data samples are retained for the data sets in every monitoring agent and data collector, and a `set_metrics_retention.sh` script for adjusting those values to adopt the best practices settings or the changes you specify. For complete descriptions of the parameters supported by the historical data retention scripts, see [“Historical data retention scripts”](#) on page 1162.

The procedure has steps for 3 typical scenarios: Set the data retention to the best practices values, reset the retention values to their default 8 days, and apply customized data retention settings after generating a file with the current historical data retention settings and editing the values.

The scripts require the password for the Db2\_server\_instance\_user *db2apm*, such as `db2Usrpasswd@08` (see [Default users and passwords](#)).

## Procedure

On the system where the Cloud APM server is installed, change to the `/opt/ibm/ccm` directory or to the directory that you specified during server installation and complete any of the following steps:

- Change the data retention settings to the best practices values:

```
./set_metrics_retention.sh -pw db2_instance_user -retention BEST_PRACTICES
```

After you enter `y` in response to the prompt, `Do you want to continue ? (y/n)`, the data retention settings are changed to the best practice values on the Db2 historical database.

- Return the data retention settings to their default values:

```
./set_metrics_retention.sh -pw db2_instance_user -retention 8DAYS
```

After you enter `y` in response to the prompt, `Do you want to continue ? (y/n)`, the data retention settings are reset to the default 8 days on the Db2 historical database.

- Customize the data retention values of specific data sets:

- a) Enter the following command to generate the historical configuration file:

```
./get_metrics_retention.sh -pw db2_instance_user -retention CURRENT
```

After you enter `y` in response to the prompt, `Do you want to continue ? (y/n)`, the data retention values of all Cloud APM agents and data collectors are read from the Db2 historical database and output to `tmp/history_file.cfg`.

- b) Change the data retention settings of specific data sets by editing `/tmp/history_file.cfg` from 2 to 32 days.

For example, this is the Linux OS agent Disk IO data set after changing the retention value to 22 days: `KLZ,KLZ_Disk_IO,KLZDSKIO,Detailed,22,D`.

- c) After saving your changes to the `history_file.cfg`, enter the following command:

```
./set_metrics_retention.sh -pw db2_instance_user -history tmp/history_file.cfg
```

After you enter `y` in response to the prompt, `Do you want to continue ? (y/n)`, any changes to the data retention values are applied to the Db2 historical database.

## Example

This is the Windows OS agent section of the `history_file.cfg` after the best practices values were set:

```
***** PRODUCT CODE: KNT *****  
  
KNT,Knt_LFAPProfiles,KNTLFAPFLS,Detailed,32,D  
KNT,Knt_Log_File_Status,KNTLOGFST,Detailed,8,D  
KNT,Knt_LogfileProfileEvents,KNTLOGPEVT,Detailed,8,D  
KNT,NT_Computer_Information,NTCOMPINFO,Detailed,8,D  
KNT,NT_IP_Address,NTIPADDR,Detailed,8,D  
KNT,NT_Monitored_Logs_Report,NTLOGINFO,Detailed,32,D  
KNT,NT_Memory_64,NTMEMORY,Detailed,32,D  
KNT,NT_Network_Interface,NTNETWRKIN,Detailed,32,D  
KNT,NT_Paging_File,NTPAGEFILE,Detailed,32,D  
KNT,NT_Process_64,NTPROCESS,Detailed,32,D  
KNT,NT_Processor,NTPROCSSR,Detailed,32,D  
KNT,NT_Logical_Disk,WTLOGCLDSK,Detailed,32,D  
KNT,NT_Objects,WTOBJECTS,Detailed,32,D  
KNT,NT_Physical_Disk,WTPHYSDSK,Detailed,14,D  
KNT,NT_System,WTSYSTEM,Detailed,32,D
```

## What to do next

If you change the max retention period, you must logout of the Cloud APM console and log back in. You will then be able to select a day up to the new max retention period in the **Status Overview** tab or **Custom Views** tab.

## Historical data retention scripts

Review the parameters that you can specify when running the historical data retention scripts to make changes such as the history configuration file path or the remote Db2 server name.

### **get\_metrics\_retention.sh**

The `get_metrics_retention.sh` script creates a historical configuration file that you can use to review the current data retention settings or the settings that you plan to apply. The historical configuration file is required if you plan to customize the data retention values of individual data sets for agents or data collectors.

#### **-db\_inst database\_instance**

If you used a Db2 database instance name that is different from the default `db2apm`, use this parameter to specify the name.

#### **-db\_name database\_name**

Specify an alternative name of the Db2 historical database.

#### **-db\_port database\_port**

Specify the Db2 port when it is different from the default 50000.

#### **-h installdir**

Specify a different directory from the `/opt/ibm` default Cloud APM server installation directory.

#### **-help**

Display the `get_metrics_retention.sh` parameters.

#### **-history history\_config\_file**

Specify a different path and name for the history configuration file from the default `tmp/history_file.cfg`, such as `/root/myfile.cfg`.

#### **-logName log\_name**

Specify a different log file name from the default `get_metrics_retention.sh_YYYYMMDDHHMM.log`.

#### **-logPath log\_path**

Specify a different directory for storing the log file from the default `/tmp`.

#### **-pw instance\_pw**

This is the password for the `db2apm` instance user, such as `db2Usrpasswd@08`. If you are using the **-db\_inst** parameter to specify a different instance from `db2apm`, use the password for that instance. For the `get_metrics_retention.sh` script, the Db2 instance user password is required only when you specify `-retention CURRENT`.

#### **-quiet Y|N**

The default setting is `N`. To turn off the `Do you want to continue ? (y/n)` prompt, use `-quiet Y`. If you are invoking this script from another script or through automation, you might want to turn off the interactive prompt. You can see the output in the `get_metrics_retention.sh_YYYYMMDDHHMM.log`.

#### **-retention BEST\_PRACTICES|8DAYS|2DAYS|CURRENT**

Generates the history configuration file with the best practices, 8 days, 2 days, or current settings.

#### **-server database\_server\_hostname**

When your Cloud APM server connects to a remote Db2 server rather than the default local Db2 server, specify the IP address or fully qualified host name of the Db2 server.

Examples:

This command enters the `db2apm` default user password and creates a `hist/history_file.cfg` file with the current settings:

```
./get_metrics_retention.sh -pw db2Usrpasswd@08 -h /opt/ibm/ccm/hist  
-retention CURRENT
```

This command creates a `/root/my_config_file.txt` history configuration file with the best practices settings:

```
./get_metrics_retention.sh -history /root/my_config_file.txt  
-retention BEST_PRACTICES
```

## set\_metrics\_retention.sh

The `set_metrics_retention.sh` script creates a historical configuration file that you can use to change the data retention of agent and data collector data sets to adopt the best practices settings, the changes you specify, or to return to the default 8 days data retention values.

### -db\_inst database\_instance

If you used a Db2 database instance name that is different from the default `db2apm`, use this parameter to specify the name.

### -db\_name database\_name

Specify an alternative name of the Db2 historical database.

### -db\_port database\_port

Specify the Db2 port when it is different from the default 5000.

### -h installdir

Specify a different directory from the `/opt/ibm` default Cloud APM server installation directory.

### -help

Display the `set_metrics_retention.sh` parameters.

### -history history\_config\_file

Specify the name of the history configuration file that you customized and apply to the Db2 historical database (WAREHOUS).

### -ksy ksy\_home\_path

Specify the home path of the Summarization and Pruning Agent for maintaining database partitions and pruning monitoring data in the Db2 server. The default path is `installdir/sy`.

### -logName log\_name

Specify a different log file name from the default `set_metrics_retention.sh_YYYYMMDDHHMM.log`.

### -logPath log\_path

Specify a different directory for storing the log file from the default `tmp`.

### -override ON|OFF|RESET

By default, `-override` is set to **ON**, which means the settings that you apply with the `set_metrics_retention.sh` script to the Db2 historical database are not changed by Cloud APM updates during upgrades. Unless you include the `-override OFF` parameter when you run the `set_metrics_retention.sh` script, or included it when you ran the script previously, the updated historical settings are saved in a `WAREHOUSESUMPRUNE_OVERRIDE` table to indicate that those values will prevail over any future upgrades.

Setting `-override OFF` means that the values are valid only until the next Cloud APM upgrade; they will be overwritten by the default Db2 historical database (WAREHOUS) values.

Setting `-override RESET` remove the entries in the `WAREHOUSESUMPRUNE_OVERRIDE` table.

### -pw instance\_pw

This is the password for the `db2apm` instance user, such as `db2Usrpasswd@08`. If you are using the `-db_inst` parameter to specify a different instance from `db2apm`, use the password for that instance.

### -quiet Y|N

The default setting is `N`. To turn off the `Do you want to continue ? (y/n)` prompt, use `-quiet Y`. If you are invoking this script from another script or through automation, you might want to turn off the interactive prompt. You can see the output in the `get_metrics_retention.sh_YYYYMMDDHHMM.log`.

### **-retention *BEST\_PRACTICES|8DAYS|2DAYS|CURRENT***

Apply the best practices, 8-day, or 2-day data retention values to the historical database. This parameter is not used if you are specifying the **-history** parameter.

### **-server database\_server\_hostname**

When your Cloud APM server connects to a remote Db2 server rather than the default local Db2 server, specify the IP address or fully qualified host name of the Db2 server.

## **Event thresholds for Transaction Monitoring**

You can use event thresholds to immediately monitor your environment. You can also create customized event thresholds that test for certain conditions and raise an event when key performance indicators exceed the threshold.

### **Response Time Monitoring events**

Response Time events are created when web transactions exceed a **Response Time** threshold.

After you click  **System Configuration > Threshold Manager**, select **Response Time** as the **Data Source Type**. All event thresholds for the Response Time Monitoring environment are applied to all managed systems of the same type.

The following predefined thresholds are available for the Response Time Monitoring Agent.

| Table 271. Response Time Monitoring thresholds |   |   |
|--|---|---|
| Threshold                                      | Description   | Formula   |
| Response_Time_Availability_Crit                | A high percentage of the web transactions failed.     | If WRT Transaction Status.Percent_Failed is greater than 10 and WRT Transaction Status.Transaction_Definition_Name is not equal to 'Ignore Resources' then Response_Time_Availability_Crit is true  |
| Response_Time_Availability_Warn                | A moderate percentage of the web transactions failed. | If WRT Transaction Status.Percent_Failed is greater than 0 and WRT Transaction Status.Percent_Failed is less than 10 and WRT Transaction Status.Transaction_Definition_Name is not equal to 'Ignore Resources' then Response_Time_Availability_Warn is true |

| Table 271. Response Time Monitoring thresholds (continued) |   |   |
|--|---|---|
| Threshold  | Description   | Formula   |
| Response_Time_Critical                                     | The percentage of the web transactions with a slow response time is high.     | If WRT Transaction Status.Percent_Slow is greater than 5 and WRT Transaction Status.Percent_Available is equal to 100 and WRT Transaction Status.Transaction_Definition_Name is not equal to 'Ignore Resources' then Response_Time_Critical is true   |
| Response_Time_Warning                                      | The percentage of the web transactions with a slow response time is moderate. | If WRT Transaction Status.Percent_Slow is greater than 1 and WRT Transaction Status.Percent_Slow is less than 5 and WRT Transaction Status.Percent_Available is equal to 100 and WRT Transaction Status.Transaction_Definition_Name is not equal to 'Ignore Resources' then Response_Time_Warning is true |

*Good requests* have a response time less than 10 seconds. *Slow requests* have a response time greater than 10 seconds. The 10 second value used to determine good vs slow response time is not configurable.

## Transaction Tracking events

Transaction Tracking events are created when middleware transactions exceed a Transaction Tracking threshold.

To view the default Transaction Tracking thresholds, click  **System Configuration > Threshold Manager**, and select **Transaction Tracking** as the **Data Source Type**.

**Tip:** You can create your own Transaction Tracking thresholds if required.

The following predefined thresholds are available for middleware transactions.

| Table 272. Transaction Tracking thresholds |  |  |
|--|--|--|
| Threshold                                  | Description  | Formula  |
| Interaction_Avail_Critical                 | A high percentage of the middleware interactions failed.     | If KTE INTERACTION AGGREGATE DATA.PERCENTAGE_FAILED is greater than 10, then Interaction_Avail_Critical is true  |
| Interaction_Avail_Warning                  | A moderate percentage of the middleware interactions failed. | If KTE INTERACTION AGGREGATE DATA.PERCENTAGE_FAILED is greater than 0 and KTE INTERACTION AGGREGATE DATA.PERCENTAGE_FAILED is less than or equal to 10, then Interaction_Avail_Warning is true |

Table 272. Transaction Tracking thresholds (continued)

| Threshold                  | Description   | Formula  |
|----------------------------|---|--|
| Interaction_Time_Critical  | The percentage of the middleware interactions with a slow total time is high.     | If KTE INTERACTION AGGREGATE DATA.PERCENTAGE_SLOW is greater than or equal to 5 and KTE INTERACTION AGGREGATE DATA.PERCENTAGE_FAILED is equal to 0, then Interaction_Time_Critical is true   |
| Interaction_Time_Warning   | The percentage of the middleware interactions with a slow total time is moderate. | If KTE INTERACTION AGGREGATE DATA.PERCENTAGE_SLOW is greater than 1 and KTE INTERACTION AGGREGATE DATA.PERCENTAGE_SLOW is less than 5 and KTE INTERACTION AGGREGATE DATA.PERCENTAGE_FAILED is equal to 0 then Interaction_Time_Warning is true |
| Transaction_Avail_Critical | A high percentage of the middleware transactions failed.                          | If KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_FAILED is greater than 10, then Transaction_Avail_Critical is true  |
| Transaction_Avail_Warning  | A moderate percentage of the middleware transactions failed.                      | If KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_FAILED is greater than 0 and KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_FAILED is less than or equal to 10, then Transaction_Avail_Warning is true   |
| Transaction_Time_Critical  | The percentage of the middleware transactions with a slow total time is high.     | If KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_SLOW is greater than or equal to 5 and KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_FAILED is equal to 0, then Transaction_Time_Critical is true   |
| Transaction_Time_Warning   | The percentage of the middleware transactions with a slow total time is moderate. | If KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_SLOW is greater than 1 and KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_SLOW is less than 5 and KTE TRANSACTION AGGREGATE DATA.PERCENTAGE_FAILED is equal to 0 then Transaction_Time_Warning is true |

*Good requests* have a response time less than 10 seconds. *Slow requests* have a response time greater than 10 seconds. The 10 second value used to determine good vs slow response time is not configurable.

## Creating thresholds to generate events for transaction monitoring

Use the Threshold Manager to create thresholds for transactions. Thresholds are used to compare the sampled value of an attribute with the value set in the threshold. If the sampled value satisfies the comparison, a transaction event is generated.

### About this task

You can monitor when applications report specific conditions using thresholds. For more information about the default thresholds for Transaction Monitoring, see [“Event thresholds for Transaction Monitoring”](#) on page 1164.

You can create extra thresholds to monitor other aspects of a transaction. For example, you can create a threshold to monitor if the middleware transaction event rate falls. Then, if the transaction event rate falls below that specified by your threshold, an event is generated.

### Procedure

To create a threshold and associate it with one or more transactions, complete the following tasks:

1. On the Navigation Bar, click  **System Configuration > Threshold Manager**. Set the **Data Source type** as **Transaction Tracking**.
2. Click  **Add** to create a new threshold.
3. Set a severity for the event that exceeds this threshold.
4. To associate the threshold with a transaction, set the following values:
  - Data set - KTE TRANSACTION AGGREGATE DATA
  - Display item - Resource\_Value
  - Logical operator - And (&)
5. Alternatively, to associate the threshold with an interaction, set the following values:
  - Data set - KTE INTERACTION AGGREGATE DATA
  - Display item - Source\_Resource\_Value
  - Logical operator - And (&)
6. Click  **Add** to add a condition. In the **Add Condition** box, select an attribute and an operator, then enter a threshold value.

For example, to add a threshold condition that generates a transaction event when the number of transactions per minute falls below 100, set the following values and click **OK**:

  - Attribute - Transaction\_Rate
  - Operator - Less than
  - Value - 100

Repeat this step to add more conditions to your threshold if required.
7. In the Group assignment section, select Transaction Tracking to assign your threshold to that resource group.
8. Click **Save**.

### Results

You created a threshold and associated it with a transaction or interaction. When the threshold conditions are met, an event is generated. You can monitor events in the Events tab of the Application Performance Dashboard.

## Example

To create thresholds for the Response Time Monitoring agent to monitor other aspects of a web transaction in addition to the defaults:

1. In the Threshold Manager, set the **Data Source type** as **Response Time**.
2. When you add the threshold, use the following settings:
  - Data set - WRT Transaction Status
  - Display item - Application
  - Logical operator - And (&)
  - Group assignment - Web Response Time

## Managing OS agent events

You can configure the OS agent to manage events.

### Event filtering and summarization

Use the event filtering and summarization options that you set in the configuration (.conf) file to control how duplicate events are handled by the OS agent.

When a log is monitored, an event can display multiple times quickly. For example, this repeated logging can occur when the application that produces the log encounters an error and it logs this error continuously until the threshold is resolved. When this type of logging occurs, an excessive number of events are sent to the Performance Management infrastructure. The volume of events has a negative impact on performance.

**Note:** The event detection and summarization procedures are supported only on events that are sent to Performance Management. You cannot complete these procedures on events that are sent to OMNIbus by EIF.

### Detecting and filtering duplicate events

You can configure the OS agent to handle duplicate events.

To alleviate the problem of multiple duplicate events, you define what constitutes a duplicate event by using the DupDetectionKeyAttributes tag in the .conf file. In a comma-separated list, you include one or more defined Performance Management attributes that you want to use to determine whether an event is considered a duplicate. In the following example, events with the same message and the same CustomSlot1 are to be considered duplicates:

```
DupDetectionKeyAttributes=msg,CustomSlot1
```

Duplicate events are detected from Performance Management attributes. Therefore, if you want detection of duplicates to be based on particular slots that you defined, complete the following steps:

1. Map the slot value to a Performance Management attribute.
2. Map that Performance Management attribute to the DupDetectionKeyAttributes tag in the .conf file.

Using the following example, where the important slots, eventclass and eventid, are mapped to *CustomSlot1* and *CustomSlot2*:

```
REGEX BaseAuditEvent
^([A-Z][a-z]{2} [0-9]{1,2} [0-9]{1,2}:[0-9]{2}:[0-9]{2}
[0-9]{4}) [0-9] (\S+) (\S+) \
Microsoft-Windows-Security-Auditing (\S+) ([0-9]+) (.*)
timestamp $1
severity $2
eventclass $3 CustomSlot1
eventkeywords $4
eventid $5 CustomSlot2
```

```
msg $6
END
```

if you want to specify certain events as duplicate events, in the `.conf` file, map the Performance Management attributes to the `DupDetectionKeyAttributes` tag as shown here:

```
DupDetectionKeyAttributes=CustomSlot1,CustomSlot2
```

**Note:**

1. The `CustomSlot` attribute names are case-sensitive and so you must enter the names exactly as shown in the preceding example.
2. If you do not provide a list of attributes, the values are defaulted to `Class` and `Logname`.

The events where these attributes match are considered to be duplicate events by the agent.

Since the duplicate detection is global, it is good practice to pick a set of custom slots to use as keys and use them this way in all format statements. For example, use slots 1 - 3 for keys. If a format needs only one key but also needs more slots, use slot one to contain the name value and slots four to *n* to contain the other data.

## Summary interval

The duplication detection procedure operates over a time period that is known as the Summary Interval.

Duplicate events are counted during this interval and then reset when the interval expires. The counter starts the count again beginning at 0 at the start of each new summary interval.

The agent sends a summary event for each event set that it monitors during the interval. The summary event contains the attribute values of the first event that matched. The summary event also contains a count that indicates how many duplicates of that event occurred during the summary interval.

The summary interval is set in the configuration (`.conf`) file as shown in the following example:

```
EventSummaryInterval=300
```

The value that is assigned to the summary interval is in seconds, so in this example, the summary interval is 5 minutes.

## Filtering events

If event filtering is running, the `EventFloodThreshold` setting in the (`.conf`) file informs the agent when to send an event.

The following table shows the `EventFloodThreshold` values.

| Table 273. EventFloodThreshold values |   |
|---------------------------------------|---|
| EventFloodThreshold values            | Description   |
| send_all                              | The <i>send_all</i> value is the default value. All events are sent even if these events are duplicate events.  |
| send_none                             | The <i>send_none</i> value means that no individual events are sent. Only the summary events are sent.  |
| send_first                            | Use the <i>send_first</i> value to send the first event as soon as it is encountered. If duplicates of that first event occur within a specified time, then subsequent duplicates of this first event are not sent. For more information, see <a href="#">“Summary interval” on page 1169</a> . |

| Table 273. <i>EventFloodThreshold</i> values (continued) |  |
|--|--|
| EventFloodThreshold values                               | Description  |
| <i>n</i> integer   | Use the <i>n</i> integer value to send only every <i>n</i> occurrence of an event (for example every fifth duplicate) during a specific time. For more information, see “Summary interval” on page 1169. |

## Summarization attributes

The Event Type and Occurrence Count attributes are used to help summarize events.

When event summarization is enabled, the Event Type and Occurrence Count attributes become meaningful. The Event Type attribute indicates the type of the event, being either an *Event* or a *Summary Event*. General events that correspond to records found in the log on a one-to-one basis are tagged as *Event*. Summary events that are sent at the end of the Summary Interval, are tagged as *Summary Event*.

The Occurrence Count attribute indicates the total amount of duplicate records found in the log for the event. Summary events include this count because it shows the number of events received that matched the summary event during the previous summary interval.

## Thresholds and Summary Events

Regardless of the filter value as described in “Filtering events” on page 1169, you always get the summary events at the end of each summary interval, for any event that occurred at least once during that interval. If you are not expecting the summary events, your thresholds can be accidentally triggered. To avoid this accidental triggering of a threshold, include a clause in the threshold for *Event Type*==*Event* or *Event Type*!=*Summary Event*.

## Windows Event Log

The OS agent uses the .conf file to monitor events from the Windows Event Log.

The OS agent continues to use the WINEVENTLOGS configuration ( . conf) file option to monitor events from the Windows Event Log. The agent monitors a comma-separated list of event logs as shown in the following example:

```
WINEVENTLOGS=System,Security,Application
```

The OS agent also continues to use the WINEVENTLOGS=All setting. The All setting refers to the following standard event logs: Security, Application, System, Directory, Domain Name System (DNS), and File Replication Service (FRS) that come with Windows versions earlier than 2008. However, all the event logs on the system are not checked.

The UseNewEventLogAPI configuration file tag allows the event log (Windows Event Log 2008 or later) to access any new logs added by Microsoft, and any Windows event logs created by other applications or the user. The new logs are listed by the WINEVENTLOGS keyword.

In the following example, the UseNewEventLogAPI tag is set to y.

```
UseNewEventLogAPI=y
WINEVENTLOGS=Microsoft-Windows-Hyper-V-Worker-Admin
```

In this example, the Microsoft-Windows-Hyper-V/Admin is monitored on a Windows system that has the Hyper-V role.

In the Windows Event Log, each event has the following fields in this order:

- Date in the following format: month, day, time, and year
- Event category as an integer

- Event Level
- Windows security ID. Any spaces in the Windows security ID are replaced by an underscore if SpaceReplacement=TRUE in the configuration (.conf) file.  
**Note:** SpaceReplacement=TRUE is the default if you set UseNewEventLogAPI to y in the (.conf) file (designated that you are using the event log).
- Windows source. Any spaces in the Windows source are replaced by an underscore if SpaceReplacement=TRUE in the configuration (.conf) file.
- Windows event log keywords. Any spaces in the Windows event log keywords are replaced by an underscore if SpaceReplacement=TRUE in the configuration (.conf) file.  
**Note:** The keyword field that is described here is new to the Windows 2008 version of Event Log. It did not exist in the previous Event Log, and so its presence prevents you from reusing your old Event Log format statements directly. They must be modified to account for this additional field.
- Windows event identifier
- Message text

For example, when an administrative user logs on to a Windows 2008 system, an event is generated in the Security log indicating the privileges that are assigned to the new user session:

```
Mar 22 13:58:35 2011 1 Information N/A Microsoft-Windows-
Security-Auditing Audit Success 4672 Special privileges assigned to new logon.
S-1-5-21-586564200-1406810015-1408784414-500 Account Name:
Administrator Account Domain: MOLDOVA Logon ID:
0xc39cb8e Privileges: SeSecurityPrivilege
SeBackupPrivilege SeRestorePrivilege
SeTakeOwnershipPrivilege SeDebugPrivilege
SeSystemEnvironmentPrivilege SeLoadDriverPrivilege
SeImpersonatePrivilege
```

To capture all events that were created by the Microsoft-Windows-Security-Auditing event source, you write a format statement as shown here:

```
REGEX BaseAuditEvent
^([A-Z][a-z]{2} [0-9]{1,2} [0-9]{1,2}:[0-9]{2}:[0-9]{2} [0-9]
{4}) [0-9] (\S+) (\S+) Microsoft-Windows-Security-Auditing (\S+)
([0-9]+) (.*?)
timestamp $1
severity $2
login $3
eventsources "Microsoft-Windows-Security-Auditing"
eventkeywords $4
eventid $5
msg $6
END
```

For the previous example event, the following example indicates the values that are assigned to slots:

```
timestamp=Mar 22 13:58:35 2011
severity=Information
login=N/A
eventsources=Microsoft-Windows-Security-Auditing
eventid=4672
msg="Special privileges assigned to new logon.
S-1-5-21-586564200-1406810015-1408784414-500 Account Name:
Administrator Account Domain: MOLDOVA Logon ID:
0xc39cb8e Privileges: SeSecurityPrivilege
SeBackupPrivilege SeRestorePrivilege
SeTakeOwnershipPrivilege SeDebugPrivilege
SeSystemEnvironmentPrivilege SeLoadDriverPrivilege
SeImpersonatePrivilege
```

Because it is difficult to anticipate exactly what these events look like, a useful approach to writing your regular expressions is to capture the actual events in a file. Then, you can examine the file, choose the events that you want the agent to capture, and write regular expressions to match these events. To capture all events from your Windows Event Log, use the following steps:

1. Create a format file that contains only one pattern that does not match anything, as shown in the following example:

```
REGEX NoMatch
This doesn't match anything
END
```

2. Add the following setting to the configuration (.conf) file:

```
UnmatchLog=C:/temp/evlog.unmatch
```

3. Run the agent and capture some sample events.

## Event mapping

The Tivoli Event Integration Facility (EIF) interface is used to forward situation events to Tivoli Netcool/OMNIBus, Tivoli Enterprise Console, or Operations Analytics - Log Analysis.

EIF events specify an event class, and the event data is specified as name-value pairs that identify the name of an event slot and the value for the slot. An event class can have subclasses. Performance Management provides the base event class definitions and a set of base slots that are included in all monitoring events. Agents extend the base event classes to define subclasses that include agent-specific slots. For OS agent log file events, the event classes correspond to the agent attribute groups, and the agent-specific slots correspond to the attributes in the attribute group.

For events that are generated by thresholds in the LFAProfiles attribute group, events are sent by using the ITM\_KLO\_LFAPROFILES event class. This event class contains the following slots:

- node: STRING
- timestamp: STRING
- subnode\_msn: STRING
- subnode\_affinity: STRING
- subnode\_type: STRING
- subnode\_resource\_name: STRING
- subnode\_version: STRING
- subnode\_config\_file: STRING
- subnode\_description: STRING
- subnode\_description\_enum: STRING

For events that are generated by thresholds in the Log File RegEx Statistics attribute group, events are sent by using the ITM\_KLO\_LOG\_FILE\_REGEX\_STATISTICS event class. This event class contains the following slots:

- node: STRING
- timestamp: STRING
- table\_name: STRING
- attrib\_name: STRING
- filter\_number: INTEGER
- average\_processor\_time: REAL
- average\_processor\_time\_enum: STRING
- total\_processor\_time: REAL
- total\_processor\_time\_enum: STRING
- max\_processor\_time: REAL

- max\_processor\_time\_enum: STRING
- min\_processor\_time: REAL
- min\_processor\_time\_enum: STRING
- filter\_count: REAL
- filter\_count\_matched: REAL
- filter\_count\_unmatched: REAL
- regex\_pattern: STRING
- last\_matched\_time: STRING
- last\_matched\_time\_enum: STRING
- last\_unmatched\_time: STRING
- last\_unmatched\_time\_enum: STRING
- result\_type: INTEGER
- result\_type\_enum: STRING

For events that are generated by thresholds in the Log File Status attribute group, events are sent by using the ITM\_KLO\_LOG\_FILE\_STATUS event class. This event class contains the following slots:

- node: STRING
- timestamp: STRING
- table\_name: STRING
- file\_name: STRING
- regex\_pattern: STRING
- file\_type: INTEGER
- file\_type\_enum: STRING
- file\_status: INTEGER
- file\_status\_enum: STRING
- num\_records\_matched: INTEGER
- num\_records\_not\_matched: INTEGER
- num\_records\_not\_matched\_enum: STRING
- num\_records\_processed: INTEGER
- current\_file\_position: REAL
- current\_file\_position\_enum: STRING
- current\_file\_size: REAL
- current\_file\_size\_enum: STRING
- last\_modification\_time: STRING
- last\_modification\_time\_enum: STRING
- codepage: STRING

For events that are generated by thresholds in the LogfileEvents attribute group, events are sent by using the ITM\_KLO\_LOGFILEEVENTS event class. This event class contains the following slots:

- node: STRING
- timestamp: STRING

- klo\_class: STRING
- logname: STRING
- eifevent: STRING
- klo\_msg: STRING
- customslot1: STRING
- customslot2: STRING
- customslot3: STRING
- customslot4: STRING
- customslot5: STRING
- customslot6: STRING
- customslot7: STRING
- customslot8: STRING
- customslot9: STRING
- customslot10: STRING
- occurrence\_count: INTEGER
- occurrence\_count\_enum: STRING
- event\_type: INTEGER
- event\_type\_enum: STRING
- custominteger1: REAL
- custominteger1\_enum: STRING
- custominteger2: REAL
- custominteger2\_enum: STRING
- custominteger3: REAL
- custominteger3\_enum: STRING
- remotehost: STRING

For events that are generated by thresholds in the LogfileProfileEvents attribute group, events are sent by using the ITM\_KLO\_LOGFILEPROFILEEVENTS event class. This event class contains the following slots:

- node: STRING
- timestamp: STRING
- klo\_class: STRING
- logname: STRING
- eifevent: STRING
- klo\_msg: STRING
- customslot1: STRING
- customslot2: STRING
- customslot3: STRING
- customslot4: STRING
- customslot5: STRING
- customslot6: STRING

- customslot7: STRING
- customslot8: STRING
- customslot9: STRING
- customslot10: STRING
- occurrence\_count: INTEGER
- occurrence\_count\_enum: STRING
- event\_type: INTEGER
- event\_type\_enum: STRING

## Managing synthetic transactions and events

Create synthetic transactions that monitor the performance and availability of internal applications and external applications.

Create a *synthetic transaction* in the Synthetic Script Manager. Generate simple scripts in the Synthetic Script Manager to test the availability of an application, or use Selenium IDE to record synthetic scripts that replicate different user actions with an application. Then, configure a synthetic transaction to playback your script at specific intervals and playback locations.

Your available playback locations are the locations where you installed the Monitoring Agent for Synthetic Playback.

Create thresholds and resource groups to raise events and notify stakeholders when your applications are slow or unavailable. View performance data and generate historical reports in the Application Performance Dashboard.

If you monitor end-user response time for an application with the Response Time agent, you can view KPIs for both end-user and synthetic transactions in the Application Performance Dashboard. Add synthetic transactions as components to the application that you are monitoring with the Response Time agent.

**Note:** To work in Synthetics Script Manager, you must be a member of a role that has view permission for Synthetic Script Manager and Agent Configuration. For more information, see [“Roles and permissions” on page 1137](#).

## Recording synthetic scripts

Record a synthetic script by using the Firefox web browser and the Selenium IDE add-on. With Selenium IDE, you can record user actions on a web page, such as loading a page, clicking a link, or selecting an object. When Selenium IDE is recording, it generates a command for each user action in a script. Then, using Synthetic Script Manager, you can configure scripts to simulate user behavior at your website, at set intervals and at different locations.

## Before you begin

### You must use the Firefox web browser when recording scripts

Selenium IDE is available only as a Firefox add-on. If Selenium IDE is not installed or running, complete the following steps:

1. Ensure that you are running a version of Firefox 60 or later that supports Selenium IDE 3.2.X or 3.3.X. If you have a later version of Selenium IDE, it is not supported; you must uninstall it and install version 3.2.X or 3.3.X.

**Note:** By default, Selenium IDE is automatically updated after you install version 3.2.X or 3.3.X. Turn off automatic updates for Selenium IDE to prevent version upgrades.

2. Download and install Selenium IDE 3.2.X or 3.3.X from the **Selenium** home page (<https://addons.mozilla.org/firefox/addon/selenium-ide/versions/>). Allow Selenium IDE to install all plug-ins.
3. After Selenium IDE is installed, restart Firefox.
4. Navigate to the web page that you want to test and close any other tabs. To open Selenium IDE, click **Tools > Selenium IDE**. In the **Selenium IDE** window, ensure that the **Base URL** field contains the URL of the displayed web page. Selenium IDE starts recording all user actions on the displayed web page.

### Selenium .side script format

Scripts created with newer versions of Selenium use the `.side` format. With Selenium IDE 3.2.X or 3.3.X, you can import older scripts that were created with the `.html` format and save to the `.side` format. For more information, see [“Updating scripts from earlier Selenium IDE versions” on page 1181](#).

If you will be using Selenium `.side` scripts, you must first install these updates:

- IBM Cloud Application Performance Management V8.1.4.0 Synthetic Playback agent Interim Fix 5 or later on the systems where you installed the Synthetic Playback agent. You can also get the Synthetic Playback agent updates from the IBM Cloud APM V8.1.4.0.7 (or later) agent packaging release.
- IBM Cloud APM V8.1.4.0 Server Interim Fix 8 or later. Update the Synthetic Playback agents with the agent interim fix before you apply the Cloud APM server interim fix.

Interim fixes for Cloud APM V8.1.4.0 are available to download from [IBM Support > Fix Central > IBM APM 8.1.4.0](#).

## About this task

In this task, you perform user actions on a web page and use Selenium IDE to record these actions as commands in a simple script. You can use scripts to monitor the performance and availability of your web application in the Application Performance Dashboard.

## Procedure

Complete the following steps to record a script of user actions on a web page:

1. Click **Record** to start recording a script. Perform user actions on your web page, such as clicking a link. For every user action on a web page, Selenium IDE records a command and adds it to a script.

For example, complete the following actions to record when a user loads the [IBM Marketplace](#) web page and navigates to a free trial of Cloud APM, in a script:

| Table 274. Recorded user actions and Selenium IDE commands   |                          |
|--|--------------------------|
| User action  | Commands added to script |
| To record when the Cloud APM web page on the IBM Marketplace website opens, open the IBM Marketplace web page. Right-click anywhere on the displayed web page and select <b>open</b> .   | open                     |
| To ensure that the script checks that the web page loads, right-click the title text of the web page (IBM Cloud Application Performance Management) and click <b>Show All Available Commands &gt; verifyTitle IBM Cloud Application Performance Management</b> . | verifyTitle              |
| To record when the user clicks a link to view details about Cloud APM, click the <b>Details</b> link. The <b>Details</b> page loads.   | clickAndWait             |
| To ensure that the script checks that the <b>Details</b> page has loaded, right-click on the "Feature spotlights" heading and select <b>Show All Available Commands &gt; verifyText css=h2.heading--TERTIARY</b> .   | verifyText               |
| To record when the user clicks a link to view details about how to purchase Cloud APM, click the <b>Purchase</b> link. The <b>Purchase</b> page loads.   | clickAndWait             |
| To record when the user clicks a button to register for a free trial of Cloud APM, click the <b>Try Free</b> button.   | click                    |

2. In the Selenium IDE window, click **Record** to stop the recording. Click the **Save Project** tool, give your script a meaningful name, and save as a .side file (such as open\_webpage.side).
3. In the Selenium IDE window, review your recorded script. Click the **Table** tab to display the script in a table format. In the Selenium IDE window, click **Play Current Test Case** to test the playback of the script that you recorded.

In this example, Selenium IDE displays the script of user actions on the IBM Marketplace website, as described in step 1.

| Table 275. Example of a Selenium IDE script recording of user actions on the IBM Marketplace website |  |                    |
|--|--|--------------------|
| Command  | Target                                       | Value              |
| open   | /  |                    |
| verifyTitle  | IBM Cloud Application Performance Management |                    |
| clickAndWait   | css=ul > #details > a                        |                    |
| verifyText   | css=h2.heading--TERTIARY                     | Feature spotlights |
| clickAndWait   | css=ul > #purchase > a                       |                    |
| click  | link=Try Free                                |                    |

## Results

You recorded a script that you can use to monitor the performance and availability of a web application.

## What to do next

If you recorded a complex script, you can organize your script into simpler scripts, where each script represents a specific business process or user action on your web application.

Use the Synthetic Script Manager to upload your script file to a new or existing synthetic transaction.

## Structuring complex scripts

Organize a complex script into multiple scripts; then, save scripts together in a collection of scripts called a *test suite*.

### About this task

If you create a complex script, you can organize that script into simple scripts that represent different business or user processes on your web application. Save the scripts together as a test suite. You can then use these scripts to monitor the performance and availability of your web application in response to specific user actions in the Application Performance Dashboard.

There should be only one test suite and all tests should be added into it.

**Important:** It is good practice to organize complex scripts into separate scripts, where each script represents a typical user or business process that you want to monitor. For example, create separate scripts that record when a user logs in to a website, or searches for an item. If you organize your scripts according to user or business processes, you can then monitor the response of your web application to these specific processes in the Application Performance Dashboard.

### Procedure

To organize your complex script into separate scripts, and save your scripts as a test suite, complete the following steps:

1. To create a separate script for each user process that is recorded in your script, click **Tests > +** in Selenium IDE. Give each script a meaningful name that describes the user process and save each script as a *.side* file, such as `load_homepage.side`.

For more information, see [“Recording synthetic scripts”](#) on page 1177.

**Important:** The name that you give to your script in Selenium IDE is the name that identifies the recorded business or user process that you monitor in the Application Performance Dashboard.

2. In Selenium IDE, open a complex script that you recorded previously. Organize your script commands into separate scripts, according to different user actions. **Cut** commands from the original complex script in the **Test Case** window and **Paste** commands into the different **Test Case** window.

For example, the complex script example in [Recording synthetic scripts](#) contains Selenium IDE commands for three different user processes.

- Open the Cloud APM home page on the IBM Marketplace website.
- Open the **Details** page on IBM Marketplace.
- Open the **Pricing** page and record when the user opens the registration page for a free trial.

The user actions are then organized into three different scripts.

| Table 276. Sample script for opening the IBM Marketplace page ( <i>load_homepage.side</i> ) |  |       |
|---|--|-------|
| Command   | Target                                       | Value |
| open  | /  |       |
| verifyTitle   | IBM Cloud Application Performance Management |       |

| Table 277. Sample script for opening the <b>Details</b> page on IBM Marketplace ( <i>load_products.side</i> ) |                          |                    |
|---|--------------------------|--------------------|
| Command   | Target                   | Value              |
| clickAndWait  | css=ul > #details > a    |                    |
| verifyText  | css=h2.heading--TERTIARY | Feature spotlights |

Table 278. Sample script for opening the **Purchase** and trial registration pages on IBM Marketplace (Load\_APM.side)

| Command      | Target                 | Value |
|--------------|------------------------|-------|
| clickAndWait | css=ul > #purchase > a |       |
| click        | link=Try Free          |       |

- To put individual test cases into a test suite, change to the **Test suite** window and add tests to the test suite according to the business logic sequence. Finally, click the **Save Project** tool to save the test suite and all tests in the test suite to a .side file.

As an example, consider the logical sequence Load\_URL, Select Manage inventory, Select IBM Machine Type. When we add these test cases to the test suite, we first check Load\_URL, followed by Select Manage inventory, then Select IBM Machine Type

## Results

You recorded a set of scripts that you can use to monitor the performance and availability of your web applications. Use the Synthetic Script Manager to upload your .side test suite of scripts to a new or existing synthetic transaction.

## Updating scripts from earlier Selenium IDE versions

The supported Selenium IDE versions 2.2.X and 3.2.X use the .side format for recording synthetic scripts rather than the .html format used by older versions of Selenium IDE. If you have existing .html scripts, you can still use them. Scripts that were created with older versions of Selenium IDE might not work fully with the latest Firefox and Selenium drivers used by IBM Cloud Availability Monitoring. In some instances, you might want to edit the .html scripts, re-record them in the new .side format, or import the .html script and save to the .side format.

## Procedure

- Exception: If you want to interact with the Select2 element, do not use the **select** command (see <https://github.com/SeleniumHQ/selenium-ide>).

The old script is

```
<td>select</td>
<td>id=country</td>
<td>label=United States</td>
```

It should be changed to

```
<tr>
  <td>runScript</td>
  <td>window.scrollTo(0,810)</td>
  <td></td>
</tr>
<tr>
  <td>click</td>
  <td>id=select2-country-container</td>
  <td></td>
</tr>
<tr>
  <td>click</td>
  <td>xpath=("//ul[@id='select2-country-results']/li[text() = 'United States'])</td>
  <td></td>
</tr>
```

- Limitation: .side scripts recorded with Selenium IDE 3.2.X or 3.3.X are supported; the **linkText** locator is not supported.

## Managing synthetic transactions

Use the Synthetic Script Manager to create, configure, and delete synthetic transactions.

To display the Synthetic Script Manager, click the **System Configuration** icon  and select **Synthetic Script Manager**. To work in Synthetics Script Manager, you must be a member of a role that has view permission for **Synthetic Script Manager** and **Agent Configuration**. For more information, see [“Roles and permissions” on page 1137](#).

You can perform the following tasks with the Synthetic Script Manager:

- Create and edit a synthetic transaction.
- Configure synthetic transaction variables.
- Delete a synthetic transaction.

### ***Creating and editing a synthetic transaction***

To view data about the performance and availability of a web application, you must first create a synthetic transaction in the Synthetic Script Manager.

#### **About this task**

Use the Synthetic Script Manager to create, edit, and configure a synthetic transaction. Enter the URL of a web application in the Synthetic Script Editor to generate a simple script for your synthetic transaction. To simulate complex user processes, upload a synthetic script to a synthetic transaction in the Synthetic Script Editor. Then, configure your synthetic transaction to run at regular intervals and at different locations.

#### **Procedure**

To create a transaction, or to edit an existing transaction, complete the following steps:

1. Optional: If the Synthetic Script Manager is not displayed, click the **System Configuration** icon  and select **Synthetic Script Manager**.
2. To create a new transaction, click the **New** icon . To edit an existing transaction, click the **Edit** icon .
3. In the **Synthetic Script Editor**, click the **Upload a Script** tab and enter a transaction name in the **Transaction Name** text box. Enter a description of your transaction in the **Description** text box.
4. To generate a simple script to test a web application, select **Enter the URL of web page to test** and enter a URL. The Synthetic Script Manager generates a simple synthetic script based on that URL.
5. To assign a previously created script file to your transaction, select **Upload script file**. Click **Upload Script** to browse for scripts on your system. Choose a script and click **Open**.

**Important:** The synthetic script file must be one of the following file types:

- .html
- .zip

Save simple individual scripts (test cases) as .html files. Compress test cases and test suites together in a .zip file.

6. To configure simultaneous or staggered playback of a synthetic transaction, click the **Schedule a Script** tab. Select **Simultaneous** to execute the transaction from all locations simultaneously, or select **Staggered** to execute the transaction from a different location at each interval.
7. To choose how often a script runs, click the **Schedule a Script** tab. Click the **Interval** text box and enter a number, based on how often you want to monitor your web application. Choose an interval length between 1 and 60 minutes.

**Note:** Large or complex scripts can take longer to run. Choose a longer interval length for large or complex scripts.

8. To choose the playback locations for your script, click the **Schedule a Script** tab and then select the agent installation locations where you want your script to run.
9. To set response time thresholds for synthetic transactions and subtransactions, click the **Advanced Settings** tab; then, click and expand a synthetic transaction to reveal all subtransactions. Double-click the response time threshold value and enter a value. Choose a value between 0 and 3600 seconds. If you do not want to set a threshold, enter 0. The default response time threshold value is 10 seconds.

**Note:** Some commands can take longer than others. Choose a response time threshold that is suitable for the command that you want to test. If your transaction tests how long a web page takes to open, choose a longer response time.

10. To finish creating or editing your transaction, click **Save**.

## Results

You configured a synthetic transaction. The synthetic transaction is listed in the Synthetic Script Manager.

## What to do next

You can view metrics and KPIs recorded by a synthetic transaction in the Application Performance Dashboard. You can also add transactions as components to an application, and view all synthetic transactions that are associated with that application.

**Important:** When you first add a synthetic transaction, a blank space might appear in the **Availability Over Time** group widget in the Application Performance Dashboard. The blank space disappears quickly, when the server receives the first playback results of the transaction.

## Configuring synthetic transaction variables

Use the Synthetic Script Manager to update variable values, such as user names and passwords that are stored in synthetic scripts, without the need to edit the script files. The values of your variables can be unique for each playback location. Configure variables for your synthetic scripts when your web applications require different variable values at different locations. For example, if your web application does not allow the same login details at different locations, use the Synthetic Script Manager to provide different login details at each location. You can create variables in synthetic scripts by using the `store` command in the Selenium-IDE plug-in.

## About this task

In this task, use the Synthetic Script Manager to configure variables that are stored in your synthetic script.

## Procedure

To configure the variables of a synthetic transaction, complete the following steps:

1. If the Synthetic Script Manager is not displayed, click the **System Configuration** icon  and select **Synthetic Script Manager**. Select a synthetic transaction from the list and click the **Edit** icon .
2. Select the playback locations for your synthetic transaction.
3. Click the **Advanced Settings** tab. If the synthetic script contains variables, you can edit these variables in the **Configure Variable Substitutions for Different Locations** window. To edit a variable, double-click the value. To finish, click **Save**.

For example, the following script contains the variables `username` and `password`. The values of these variables, `user1` and `pass`, are saved by using the `store` command in Selenium-IDE. The variables have the same value at two locations, Dallas and San Jose.

| Table 279. Example of a script with variables |               |              |
|---|---------------|--------------|
| Command                                       | Target        | Value        |
| store   | user1         | username     |
| store   | pass          | password     |
| type  | id=j_username | \${username} |
| type  | id=j_password | \${password} |

The values of the script variables are displayed in the **Configure Variable Substitutions for Different Locations** window. Change the value of *username* at the location Dallas from *user1* to *admin1* so that the synthetic transaction uses different login details at different locations.

| Table 280. Script variable values at different locations |          |          |
|--|----------|----------|
| Location   | username | password |
| San Jose   | user1    | pass     |
| Dallas   | admin1   | pass     |

## Results

You configured the variables of a synthetic transaction. You can now use this synthetic transaction to test the performance and availability of a web application at different locations.

## What to do next

You can view metrics and KPIs recorded by a synthetic transaction in the Application Performance Dashboard. You can also add transactions as components to an application, and view all synthetic transactions that are associated with that application.

### *Hiding passwords in the Synthetic Script Manager*

Store passwords as variables in your synthetic scripts to hide password values in the Synthetic Script Manager.

## Before you begin

This procedure requires you to edit a synthetic script. Record a synthetic script by using Selenium IDE. For more information, see [“Recording synthetic scripts” on page 1177](#).

## About this task

Manually modify your synthetic scripts in the Selenium IDE to store your password as a variable. You can then create synthetic transactions with hidden passwords in the Synthetic Script Manager. Hidden passwords are displayed as asterisks in the Synthetic Script Manager.

**Important:** It is recommended that you store your passwords in synthetic scripts so that the password values are not displayed in the Synthetic Script Manager. Hidden passwords make your web applications more secure by preventing others from viewing passwords.

## Procedure

1. Open the script that you want to modify in Selenium IDE. Use the `store` command to assign a password to the variable *password*, following the example that is described in this step; then, save the script.

**Important:** You must store the password as the variable name *password* so that the password is not displayed in the Synthetic Script Manager.

For example, the following synthetic script contains a user name *test@example.com* and a password value *ibm4value*.

```
<tr>
  <td>type</td>
  <td>id=username</td>
  <td>test@example.com</td>
</tr>
<tr>
  <td>type</td>
  <td>id=password</td>
  <td>ibm4value</td>
</tr>
```

The following script shows how to assign the password value *ibm4value* to the variable *password* by using the `store` command.

```
<tr>
  <td>store</td>
  <td>ibm4value</td>
  <td>password</td>
</tr>
<tr>
  <td>type</td>
  <td>id=username</td>
  <td>test@example.com</td>
</tr>
<tr>
  <td>type</td>
  <td>id=password</td>
  <td>$(password)</td>
</tr>
```

2. Optional: To hide the password at script level, assign a blank value to the variable *password* by using the `store` command; then, save the script.

You can set the password later in the Synthetic Script Manager.

For example, the following script shows how to assign a blank value to the variable *password* by using the `store` command.

```
<tr>
  <td>store</td>
  <td></td>
  <td>password</td>
</tr>
<tr>
  <td>type</td>
  <td>id=username</td>
  <td>test@example.com</td>
</tr>
<tr>
  <td>type</td>
  <td>id=password</td>
  <td>$(password)</td>
</tr>
```

3. Log in to the Cloud APM console and open the **Synthetic Script Manager**. Create a transaction and upload your script to that transaction. Click the **Advanced Settings** tab.

The password for each location is hidden. You can change the password for each location. For more information, see [“Managing synthetic transactions”](#) on page 1181.

## Deleting a synthetic transaction

Use the Synthetic Script Manager to delete synthetic transactions.

## Procedure

To delete a synthetic transaction, complete the following steps:

1. If a synthetic transaction is assigned to an application, you must first remove the transaction from that application. On the Application Performance Dashboard, click and expand **All My Applications** and then click the application that is associated with the synthetic transaction that you want to delete.

Click the **Edit** icon . In the **Edit Application** window, remove the synthetic transaction component from the application. For more information, see [Managing Applications](#).

The synthetic transaction can now be deleted.

2. On the navigation bar, click the **System Configuration** icon  and select **Synthetic Script Manager**. Select a synthetic transaction and then click the **Delete** icon . To confirm that you want to delete this synthetic transaction, click **OK**.

## Results

The synthetic transaction is deleted.

## Viewing synthetic transaction data in the Application Performance Dashboard

View synthetic transaction data in the Application Performance Dashboard. Associate synthetic transactions with a new or existing application, and view all associated synthetic transactions together in the Application Performance Dashboard.

### About this task

You can view synthetic transaction data in the **My Transactions** window in the Application Performance Dashboard.

You can also create groups of synthetic transactions by associating your transactions with an application. Use the **Add Application** or **Edit Application** tool in the Application Performance Dashboard to add synthetic transactions as components to a new or existing web application. You can then view data for all synthetic transactions that are associated with that application together in the Application Performance Dashboard.

If you are already using the Response Time agent to monitor user response time for an application, you can add a synthetic transaction to that application. You can then view more metrics and KPIs for that application in the Application Performance Dashboard.

## Procedure

- To view synthetic transactions, complete the following step:
  - a) Click the **Performance** icon  and select **Application Performance Dashboard**. In the **Applications** window, expand **All My Applications** and select **My Transactions**. In the **Groups** window, expand **Transactions** and select **Synthetic Transactions**.
  - b) Click a synthetic transaction to view availability and performance data for that transaction, along with a graph of response times for transaction instances over a defined period.
- To associate synthetic transactions with an application, complete the following steps:
  - a) Click the **Performance** icon  and select **Application Performance Dashboard**. Select and edit an existing application or create a new application. For more information, see [Managing applications](#).
  - b) In the **Add Application** window, click the **Add Components** icon  and select **Synthetic Transactions** from the list of components. In the **Component Editor** window, select a synthetic transaction and click **Add** to associate the synthetic transaction with the application.
  - c) Click **Back**. Click **Close** to close the **Component Editor** window. Click **Save**. To add another synthetic transaction as a component, repeat steps 1 - 3.

## Results

You associated a synthetic transaction with an application. You can now view the application and its associated synthetic transactions in the Application Performance Dashboard. For more information, see [Managing applications](#).

**Note:** When you associate a synthetic transaction with an application, the initial availability of that application is unknown. The status can take several minutes to update.

## Managing synthetic events

Use the Threshold Manager and the Resource Group manager to configure thresholds and assign them to synthetic transactions. Synthetic events are generated when the value of a transaction attribute matches the condition that is defined in the threshold. You can monitor synthetic events in the Application Performance Dashboard.

### *Creating a threshold for synthetic transactions*

Use the Threshold Manager to create thresholds for synthetic transactions. Thresholds are used to compare attribute values with the values set in the threshold. If the sampled value satisfies the comparison, an event is generated.

### About this task

Thresholds allow users to monitor when applications report specific conditions. For example, you can create a threshold to monitor the time that a website takes to respond to a particular user command. If the website takes longer than the time specified by your threshold, a synthetic event is generated.

### Procedure

To create a threshold and associate it with one or more synthetic transactions, complete the following steps:

1. On the navigation bar, click the **System Configuration** icon  and select **Threshold Manager**. Set the **Data Source** type as **Synthetic Transaction**.
2. Create a threshold. For more information, see [“Threshold Manager”](#) on page 1119.
3. To associate the threshold with a transaction, select **KSO TRANSACTION** as the **Data Set** and then select **TRANSACTION** as **Display Item**. For the **Logical operator**, select **And (&)**.

**Note:** You must select **TRANSACTION** as the **Display Item**. If you do not select **TRANSACTION**, you cannot view synthetic events on the Application Performance Dashboard.

4. To add a condition, click the **New Condition** icon . In the New Condition box, select an **Attribute** and an **Operator**. Then, enter a threshold value for **Value**. To add this condition to the threshold, click **OK**.

For example, to add a threshold condition that generates a synthetic event when over 50% of transactions are slow, select **PSLOW** as **Attribute** and then select **Greater than** as **Operator**. To set the percentage of slow transactions to generate an event, enter 50 as the **Value**.

5. To define more threshold attributes, add more conditions to your threshold.
6. When you are finished, click **Save**. If you do not want to assign the threshold to a resource group, click **OK**.

### Results

You created a threshold and associated it with a synthetic transaction. When the threshold conditions are met, an event is generated. You can monitor events in the Application Performance Dashboard, in the **Events** tab.

### What to do next

You can group your synthetic transactions into resource groups.

## ***Creating a resource group for synthetic transactions***

Organize your synthetic transactions into a resource group and apply thresholds to all transactions in that resource group.

### **Before you begin**

Create a threshold to apply to all synthetic transactions in your resource group.

### **About this task**

You can organize your synthetic transactions into resource groups, and apply thresholds to every synthetic transaction in that resource group. Use the Resource Group manager to create a resource group and assign a threshold to that resource group. Then, assign one or more synthetic transactions subnodes to that resource group. The threshold that is associated with the resource group now applies to all associated synthetic transactions.

### **Procedure**

To create a resource group for synthetic transactions, complete the following steps:

1. Click the **System Configuration** icon  and select **Resource Group Manager**. Create a resource group, or edit an existing resource group. For more information, see [“Resource Group Manager” on page 1114](#).

To create a resource group for synthetic transactions, complete the following steps:

2. Give your resource group a name and description. Assign a threshold to your resource group in the **Threshold Assignment** table and click **Save**. In the Resource Group Manager, select your resource group again and click the **Edit** icon .
3. Associate your resource group with synthetic transaction subnodes from the **Resource Assignment** table, and click **Save**.

The format of synthetic transaction subnodes is `S0:TransactionName`. For example, if you have a transaction `open_webpage`, the available subnode is called `S0:open_webpage`.

### **Results**

You organized your synthetic transactions into a resource group, and you applied a threshold to every transaction in that resource group.

## ***Creating critical thresholds for simultaneous and staggered synthetic transactions***

Use the Threshold Manager to create critical thresholds for simultaneous and staggered synthetic transactions.

### **About this task**

Create thresholds that notify stakeholders when consecutive staggered transactions fail, or when simultaneous transactions fail at all playback locations. For more information, see [“Creating and editing a synthetic transaction” on page 1182](#).

### **Procedure**

To create a critical threshold that creates an event when staggered transaction playback instances fail, complete the following steps:

1. Create a threshold for synthetic transactions in the Threshold Manager. For more information, see [“Creating a threshold for synthetic transactions” on page 1187](#).
2. In the Threshold Manager, select **Critical** as the **Severity** and enter 1 minute as the threshold **Interval (HHMMSS)**. Use the following formula to determine the **Required consecutive samples**:

Required consecutive samples = (playback interval \* expected consecutive failures) - 1

For example, if the playback interval of the synthetic transaction you want to monitor is 5 minutes, and you want to detect 8 consecutive playback failures, you must set **Required consecutive samples** as  $(5 * 8) - 1 = 39$ .

3. Add a condition. In the New Condition box, select **LOCATION** as **Attribute**, select **Equals** as **Operator**, and enter None as the **Value**. Add a second condition, and set **PFAILED** = 100. Save the threshold.
4. On the navigation bar, open the **Resource Group Manager**. Create a resource group. Assign one or more staggered synthetic transactions to your resource group, then assign the threshold that you created in steps 1-3 to your resource group. Save the resource group. For more information, see [“Creating a resource group for synthetic transactions” on page 1188](#).

To create a critical threshold that creates an event when simultaneous transaction playback instances fail at several locations, complete the following steps:

5. Create a threshold for synthetic transactions in the Threshold Manager. For more information, see [“Creating a threshold for synthetic transactions” on page 1187](#).
6. In the Threshold Manager, select **Critical** as the **Severity** and enter 1 minute as the **Interval (HHMMSS)**. Set the **Required consecutive samples** as the same value as the playback interval of the transaction that you want to monitor.

For example, if the playback interval of the synthetic transaction that you want to monitor is 5 minutes, set **Required consecutive samples** as 5.

7. Add a condition. In the New Condition box, select **LOCATION** as **Attribute**, select **Equals** as **Operator**, and enter None as the **Value**. Add a second condition, and set **PFAILED** = 100. Save the threshold.
8. Create a resource group. Assign one or more synthetic transactions and the new critical threshold to your resource group. For more information, see [“Creating a resource group for synthetic transactions” on page 1188](#).

## Results

You created a critical threshold for a staggered or simultaneous synthetic transaction. When the threshold conditions are met, an event is generated. You can monitor events in the Application Performance Dashboard, in the **Events** tab.

## Guidelines to maximize agent and server performance for log file monitoring

To ensure that you get maximum performance from the OS agents and the Performance Management server, you must define the regular expressions in the format (.fmt) file and also limit the number of log file monitoring events that are reported to the Cloud APM console.

### Guidelines to define regular expressions in the .fmt file

The .fmt file uses regular expressions that require a large amount of CPU processing. To improve agent and server performance, minimize the time spent checking records in the monitoring source log against regular expression in the .fmt file by using the following guidelines:

#### Minimize the use of multi-line patterns.

Multi-line patterns are expensive because the agent must determine what the records are and whether they match. When you use a multi-line pattern that is a regular expression that contains the "\n" character, or a TEC-style format that contains the '%n' token, the agent must break the monitored file into records of various sizes first. Then, the agent must check the records against the expressions in the format file. This procedure requires checking the regular expressions twice, so processing is slow. If you use the single-line pattern, it is assumed that each line of the file is a record and processing is much faster.

In some cases, it might be possible to ignore some of the lines and achieve better performance. For example, a single record from a RAS1 trace log is shown here:

```
(4D66DACB.0001-1:RAS1,400,"CTBLD")
```

```
+4D66DACB.0001 Component: ira
```

```
+4D66DACB.0001 Driver: agent_fac:15/4114877.7
```

```
+4D66DACB.0001 Timestamp: Feb 24 2011 13:18:54
```

```
+4D66DACB.0001 Target: sos510amd64-d
```

In the example, if you are only interested in processing this line:

```
+4D66DACB.0001 Driver: agent_fac:15/4114877.7
```

you can write the following single-line pattern:

```
^\+.*Driver: agent_fac:([0-9\.\/]+)$
```

This single-line pattern processes the important value that you need without requiring the multi-line format. The other four lines of the logical record are treated as single-line records that do not match anything and are discarded.

### **Sort the expressions in the format file by frequency of occurrence in the monitoring log.**

The agent checks each record that it reads from the log against the expressions in the format file until it finds a match. It starts with the final expression in the file, and searches upwards. When it finds a match, it stops searching. If the most commonly logged expression is listed last, then when that expression is logged, it is the only expression that is checked.

If you have 100 expressions in the format file, every time a log record matches the first one that is listed in the format file, the agent must check the other 99 expressions first, which slows down the processing. When a record that is read from the log does not match any of the patterns in the format file, the agent must check it against all of the patterns before it knows that it does not match. This process is slow and costly.

### **Include as much constant data as possible in the regular expressions.**

For example, if the following error is returned in the log:

```
Disk error on device: /dev/sda1 Disk error on device: /dev/sdb2 yyy
```

you can write this expression:

```
^Disk.*: .*$
```

This expression causes a match, but it forces the regex engine to consider more possibilities on other lines that might be similar but ultimately do not match, for example, if the colon is missing.

The following expression is more useful because it is more precise and it causes the regular expression engine to stop processing errors that do not match:

```
^Disk error on device: /dev/sd[a-b][0-9]$
```

### **Do not use subexpressions that you do not need.**

Subexpressions that are shown in parentheses in the example that follows are used to inform the regex engine that you want to use a value that is returned in the matched data. These subexpressions cause extra processing and are not necessary if you do not use the value that is returned. For example, when the following error is returned in the log:

```
write failure in writing to client 9.27.135.191. Error Broken pipe
```

if you include the following regular expression in the format file, the error message is captured at the end; but, if you do not use the returned value, performance is affected negatively:

```
REGEX  
WriteFailure
```

```
^write failure in writing to client (.*)\. Error  
(.*)$
```

```
ClientAddr $1
CustomSlot1

END
```

### Use parentheses in expressions for grouping purposes.

You can use the `?` operator to inform the regex engine not to capture the value that is returned. Therefore, you can use the `?` operator to group only values that are returned. This grouping has a positive impact on performance. For example, if the following log data is returned:

```
Login succeeded on the first attempt for user Bob.
Login succeeded on the third attempt for user Joe.
```

To match both of the values that are returned, you must consider the first or third login attempt. If you do not care which specific login attempt succeeded or which specific user succeeded, you can include this expression to group the returned values:

```
REGEX
LoginSucceeded

^login succeeded on the (?:[a-z]+) attempt for user ([A-Z][a-z]*)\.$

UserName $1
CustomSlot1
END
```

### If possible, do not use the OR ( | ) operator in expressions.

The `|` operator is expensive to process. The `|` operator causes the regex engine to complete a backup and to try to match values that did not match initially. This procedure is much more inefficient than having two separate expressions. For example, if you have the following expression:

```
REGEX DiskError
^.*disk error.*4|^.*disk failure.*4
END
```

it is much more efficient to use these two expressions:

```
REGEX DiskError
^.*disk error.*4
END

REGEX DiskError
^.*disk failure.*4
END
```

These expressions return the same results.

**Important:** These expressions violate the guideline to use as much constant data as is possible and demonstrate only the issues with the `|` operator.

### Do not use ambiguous expressions.

Ambiguous expressions force the regex engine to back up and look for different ways to match an expression. For more information, see [Performance Tips](#).

Ambiguous expressions might occur as a result of an expression that is included to break up a long record into many subexpressions. In this degenerate version of this problem, the expression has a space between the two `(.*)`:

```
(.*) (.*)
```

In this example of the degenerate version, the regex engine looks for two strings of any expressions that are separated by a space. However, `*` also matches a space so the regex engine might assign the first space that it comes to initially to the first `(.*)`. If it reaches the end of the input record without finding another space, it must back up and try again by using the space as the literal space called for in the expression.

To improve performance, use specific expressions only. You can use the [Regex Pal](#) tool to check whether the format file that you define matches the monitoring log. For more information, see [Regex Pal](#).

## Guidelines to limit the log file events that are reported.

The following guidelines limit the log file events that might cause the OS agents or the Cloud APM server to perform poorly:

### Write specific formats in the `.fmt` file.

Write formats in the `.fmt` file that are specific and return relevant records. For example, you can generate an event for a specific error, such as the lines that begin with `Error:` and ignore the lines that begin with `Warning:`

```
Error: disk failure
Error: out of memory
WARNING: incorrect login
```

### Do not turn on the `Unmatchlog` setting in the `.conf` file.

Ensure that you do not turn on the `Unmatchlog` setting in the `.conf` file because this setting logs all the unmatched files and overloads your file system.

### Specify the `*DISCARD*` event class in the `.fmt` file.

Try to limit the CPU usage of the agent by specifying the predefined `*DISCARD*` event class in the `.fmt` file to discard data intentionally. When you use the `*DISCARD*` event class, events are not created for log records that match the pattern in the `.fmt` file. For example:

```
REGEX *DISCARD*
```

### Turn on duplicate event detection over a longer time period.

You can turn on duplicate event detection by using the following keys in the `.conf` file:

- `DupDetectionKeyAttributes`
- `EventSummaryInterval`
- `EventFloodThreshold`

In this example, the duplicated lines are recognized by the `msg` and `CustomSlot1` values:

```
DupDetectionKeyAttributes=msg,CustomSlot1
EventSummaryInterval=300
EventFloodThreshold=send_first
```

If you have numerous duplicate events, apply the `send_first` or `send_none` threshold values to the events. For more information, see [“Detecting and filtering duplicate events” on page 1168](#).

### Write specific threshold conditions.

Write specific threshold conditions that limit the set of rows that match the threshold. For example, the following threshold formula causes the threshold to fire only when an event of the `FileSystemUsage` event class has a value greater than or equal to 95 in `CustomInteger1`:

```
( Class == 'FileSystemUsage' AND CustomInteger1 >= 95)
```

### Provide the correct set of `.conf` and `.fmt` files for the agent.

Ensure that you provide the correct set of `.conf` and `.fmt` files for the agent. For example, if you are configuring log file monitoring for the Windows OS agent, ensure that you configure the `.conf` and `.fmt` files that you created specifically for the Windows OS agent.

### Query the MongoDB alarms database to determine the number of open events or event rate.

- Complete the following steps to query the MongoDB alarms database to determine the number of open events or event rate:
  1. Create an event-query.js file with a MongoDB query for the alarms database, for example:
    - This query counts all open and closed events with the following threshold name:

```
UDB_DB_Pool_Hit_Rat_Pct_Crit_2 db.alarms.count
```

```
({ "threshold_name" : "UDB_DB_Pool_Hit_Rat_Pct_Crit_2" })
```

- This query counts open and closed events in the MongoDB:

```
db.alarms.count()
```

2. Run this command to get the results to the query in the `event-query.js` file: **`/opt/ibm/mongodb/bin/mongo 127.0.0.1:27000/alarm -u user -p mongoUsrpasswd@08 <event-count.js.`**

- Limit the amount of CPU that you specify for log monitoring. For more information, see [“Log file monitoring environment variables”](#) on page 731.

## Administering server components

The Cloud APM server requires some ongoing maintenance such as changing passwords and backing up the components. Use the available functions for server administration tasks. You must complete these tasks as the root user.

### Enabling virtual hosts for the server1 service

The Cloud APM server `server1` process is susceptible to the External service interaction (DNS) vulnerability. An artificially modified HTTP HOST header value might cause the Cloud APM server to perform a DNS lookup of another host if the HTTP HOST header does not specify the host name of the Cloud APM server. You can mitigate this vulnerability by creating a virtual host definition for the `server1` process.

#### Procedure

Complete these steps to add a virtual host definition for the `server1` process to the `user-exit.xml` file:

1. Upgrade one of your OS agents to the version in the Cloud APM V8.1.4.0.7 or later agent refresh release.

See [Agent and data collector version in Cloud APM, Private releases](#) in the APM Developer Center for more details on the OS agent versions included in the V8.1.4.0 agent refreshes. The OS agent upgrade updates the OS agent application support on the Cloud APM server and provides a fix that is required for using the OS agent log file monitoring configuration UI when a virtual host is defined for the `server1` process.

2. Apply Cloud APM V8.1.4.0 server interim fix 8 or later.

Interim fixes for the Cloud APM server V8.1.4.0 are available from [IBM Fix Central](#).

3. Open the `install_dir/wlp/usr/servers/server1/user-exit.xml` file in a text editor.

4. Add the following virtual `<hostAlias>` definitions:

```
<virtualHost id="default_host" >
  <hostAlias>${hostname.long.apmui}:8090</hostAlias>
  <hostAlias>${hostname.long.apmui}:8091</hostAlias>
  <hostAlias>${hostname.short.apmui}:8090</hostAlias>
  <hostAlias>${hostname.short.apmui}:8091</hostAlias>
  <hostAlias>${hostname.ip.apmui}:8090</hostAlias>
  <hostAlias>${hostname.ip.apmui}:8091</hostAlias>
  <hostAlias>localhost:8090</hostAlias>
  <hostAlias>localhost:8091</hostAlias>
  <hostAlias>127.0.0.1:8090</hostAlias>
  <hostAlias>127.0.0.1:8091</hostAlias>
</virtualHost>
```

The host aliases define the specific HTTP HOST headers that can be used in HTTP requests to the `server1` process, for example, in Threshold Manager API requests. If one of these aliases is not

specified in a HTTP HOST header, an HTTP 404 response code is returned and no DNS lookup is performed.

**Note:** Cloud APM V8.1.4.0 server interim fix 8 or later automatically creates virtual host aliases for the apmui, oidc, and uviews services. If you want to protect the Cloud APM server min process from a similar vulnerability, perform the steps in [“Enabling virtual hosts for agent traffic” on page 240](#).

## Passwords and user IDs for components

Various components require user IDs and passwords for access.

### Default users and passwords

Default user IDs and passwords are available for accessing some components.

The following table contains a list of default user IDs, the purpose of each ID, the default password for each user ID, and the script that can be used to change the default password after the installation:

| Table 281. Default users and passwords |   |                   |  |
|--|---|-------------------|--|
| Default user ID                        | Purpose   | Default password  | Directory and script that can be used to change the default password after the installation  |
| apmadmin                               | Used to log in to the Cloud APM console. The default user for Cloud APM is apmadmin. For information on changing the default user, see <a href="#">“Updating the primary role administrator” on page 1104</a> . | apmpass           | /opt/ibm/ccm/apmpasswd.sh  |
| smadmin                                | Used to authenticate with server1 Liberty process   | apmpass           | /opt/ibm/ccm/tools/smapasswd.sh  |
| itmuser                                | Used to access the Prefetch data store and SCR and DATAMART databases   | db2Usrpasswd@08   | /opt/ibm/ccm/db2_users_passwd.sh<br>user_name<br>Where user_name is <b>itmuser</b>   |
| db2apm<br>db2fenc1<br>dasusr1          | Db2 instance users  | db2Usrpasswd@08   | /opt/ibm/ccm/db2_users_passwd.sh<br>user_name<br>Where user_name is <b>db2apm</b> , <b>db2fenc1</b> , or <b>dasusr1</b>                      |
| admin<br>user                          | Used to access the MongoDB, which stores Transaction Tracking data. MongoDB admin is used for managing MongoDB user accounts and MongoDB user has no special privileges.  | mongoUsrpasswd@08 | /opt/ibm/ccm/mongopasswd.sh<br>to change the password for both users simultaneously. You are prompted for the old password and new password. |

## Changing a password

You can run a script to change the password for the following users: apmadmin, smadmin, itmuser, db2apm, db2fenc1, and dasusr1.

### About this task

The Cloud APM server creates an smadmin user ID with a default password of apmpass for communication between the Performance Management components. You might need to change the password, for example, to comply with your organization's security requirements, or if you changed the password but forgot it when IBM Support requested that you to run the data collection tool.

In Cloud APM, the default user is apmadmin. The apmadmin user is by default a member of the Role Administrator role.

If you change the default password for the apmadmin user during the Cloud APM server installation, the password for the smadmin user is also changed to use the same password. Use this procedure if you want the smadmin user to use a different password from the apmadmin user password or if you want to change its password after the server installation.

If the Cloud APM server databases are using a remote Db2 server on an external system, you can change the password for the associated user ID on that system. See [“Changing passwords on a remote Db2 server”](#) on page 1196.

### Procedure

Complete the procedure on the system where the Cloud APM server is installed to change the password for one of the default user IDs.

1. Open the directory where the script is located and run the script for the password you want to change:

| Table 282. Scripts for default user passwords |                   |   |
|---|-------------------|---|
| Default user ID                               | Default password  | Directory and script for password you want to change  |
| apmadmin                                      | apmpass           | /opt/ibm/ccm/apmpasswd.sh   |
| smadmin                                       | apmpass           | /opt/ibm/ccm/tools/smapasswd.sh   |
| itmuser<br>db2apm<br>db2fenc1<br>dasusr1      | db2Usrpasswd@08   | /opt/ibm/ccm/db2_users_passwd.sh<br><i>user_name</i><br>Where <i>user_name</i> is itmuser, db2apm, db2fenc1, or dasusr1.                  |
| admin user                                    | mongoUsrpasswd@08 | /opt/ibm/ccm/mongopasswd.sh to change the password for both users simultaneously. You are prompted for the old password and new password. |

If you use the db2\_users\_passwd.sh script when the Db2 server is on the same system as the Cloud APM server, the script uses the **passwd** command to change the password of the specified Db2 user and updates the Cloud APM server configuration with the modified password.

When you use the db2\_users\_passwd.sh script when Cloud APM is configured to use a remote Db2 server, you use the script in the following ways:

- Change the password of the itmuser on the Cloud APM server to match the itmuser password that has been set on the remote Db2 server.
- Change the password of the db2apm user on the system where the Cloud APM server is installed.

The Cloud APM server configuration is also updated with the modified passwords.

You do not use the `db2_users_passwd.sh` script to modify the Db2 instance user's password or other database user passwords for the remote Db2 server.

To change the password of the `itmuser` and Db2 instance user when your configuration uses a remote Db2 server, see [“Changing passwords on a remote Db2 server” on page 1196](#).

The Cloud APM server is restarted if you change the password for `itmuser` but not if you change the password for the other database users.

2. After you are prompted to provide a new password, type the password, press Enter, and retype the new password as prompted.
3. If you are changing the `smadmin` user's password, you are also prompted for the Performance Management UI administrator account user name and password:
  - If the Cloud APM server is not configured to use an LDAP server, enter the `apmadmin` user and its password.
  - If the Cloud APM server is configured to use an LDAP server, specify the LDAP user that is configured as the `systemUser` value in the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file and the LDAP user's password. When you specify the LDAP user name, follow the same format that you use for logging into the Cloud APM console.

The Performance Management UI administrator account user name and password are required for updating the server connection with the new `smadmin` password.

## Results

The Cloud APM server is recycled and the new password for the user is recorded.

## Related tasks

[“Updating the primary role administrator” on page 1104](#)

The default user for Cloud APM is `apmadmin`, and the default realm is `customRealm`. By default `apmadmin` is also the primary role administrator. When you configure LDAP to authenticate Cloud APM console users, you must change the primary role administrator from `apmadmin` to a LDAP user.

## Changing passwords on a remote Db2 server

If your Cloud APM server uses a remote Db2 server on an external system, you must complete this procedure to change the Db2 user passwords on the Db2 server and configure the Cloud APM server with the updated `itmuser` password. These steps differ slightly to the steps for changing Db2 user passwords on the Cloud APM server that is connected to the default local Db2 server.

## About this task

During this procedure, the Cloud APM server components are stopped. The components are recycled after you complete these steps.

## Procedure

Complete the following steps as the root user:

1. Stop all the Cloud APM server components by entering the following command:

```
apm stop_all
```

2. On the system where you installed the Db2 server, enter the `passwd` command followed by the user name of the Db2 user whose password you want to change.
  - For the `external_db2_instance` user, enter `passwd external_db2_instance`  
where `external_db2_instance` is the remote Db2 server instance user name that you created when you set up the remote Db2 server.
  - For the `itmuser`, enter `passwd itmuser`

3. On the system where you installed the Cloud APM server, run the `db2_users_passwd.sh` script to change the `itmuser` password to match the password you configured for that user on the remote Db2 server:

```
install_dir/ccm/db2_users_passwd.sh itmuser
```

where `install_dir` refers to the directory where the Cloud APM server is installed. The default installation directory is `/opt/ibm`.

The `db2_users_passwd.sh` script changes the password of `itmuser` on the system where the Cloud APM server is installed, updates the Cloud APM server configuration with the modified password, and restarts the Cloud APM server. The script does not verify that the password can be used to connect to the remote Db2 server. Therefore, you must ensure the password matches the password of `itmuser` on the remote Db2 server.

4. The `db2apm` user exists on the system where you installed the Cloud APM server and is used with the Db2 client on that system. Its password is independent of the Db2 instance user password on the remote Db2 server. If you need to change the password of the `db2apm` user on the Cloud APM server, run the `db2_users_passwd.sh` script:

```
install_dir/ccm/db2_users_passwd.sh db2apm
```

The `db2_users_passwd.sh` script changes the password of the `db2apm` user and updates the Cloud APM server with the modified password. The Cloud APM server is not restarted when you change the `db2apm` password.

## Changing your Db2 server version, location, or database names after Cloud APM server installation

After you install the Cloud APM server, you can upgrade your local or remote Db2 server version. You can also change the names of the Cloud APM server Db2 databases on the remote Db2 server, change the remote Db2 server port number, host name or IP address, or you can move the Cloud APM server Db2 databases to a different computer system or to a different Db2 instance user.

Table 283. Changing Db2 details

| What Db2 task do you want to complete?   | Follow these steps  |
|--|---|
| <p>If you want to switch from using a local Db2 server to a remote Db2 server, or you want to move the Cloud APM server Db2 databases to a different remote Db2 server, or to a different Db2 instance user, complete the steps in the adjacent topics.</p> <p><b>Note:</b> The adjacent steps also handle changing the Cloud APM database names or changing the itmuser password as part of moving the databases.</p> | <p>Complete the steps in these topics:</p> <ol style="list-style-type: none"> <li>1. <a href="#">“Moving Db2 databases to a different Db2 server or Db2 instance” on page 1199.</a></li> </ol> <p><b>Note:</b> When you move the Cloud APM server Db2 databases to a different Db2 server, the new Db2 server can be running a later Db2 version. For example, you can switch from using a local Db2 server, which is running Db2 Advanced Enterprise Server Edition version 10.5 to a remote Db2 server that running a supported fix pack of Db2 Advanced Enterprise Server Edition version 11.1.x or Db2 Advanced Workgroup Server Edition V11.1.</p> <ol style="list-style-type: none"> <li>2. <a href="#">Cataloging Db2 databases after changing the Db2 server</a></li> <li>3. <a href="#">“Updating the Cloud APM server configuration for Db2 server changes” on page 1206</a></li> <li>4. If you moved the databases to a Db2 server that is running a later Db2 version, complete steps 1, 4, 5, and 6 in the <a href="#">“Upgrading the Db2 server to Db2 version 11.1.x” on page 1208</a> procedure.</li> </ol> |

## Moving Db2 databases to a different Db2 server or Db2 instance

After you install the Cloud APM server, you can move your Cloud APM server Db2 databases from the local to a remote Db2 server or if you are already connected to a remote Db2 server, you can move the databases to a different remote Db2 server or a different Db2 instance user.

### About this task

Use this procedure to back up and move the Db2 databases from one Db2 server either local or remote to a different remote Db2 server or to a different Db2 instance user. You can use the same database names or change the database names during the move. The following procedure uses the Db2 **RESTORE REDIRECT** command to move the databases to the new remote Db2 server. Complete the following main tasks to move the databases:

- Stop the Cloud APM server and the connections to the current Db2 databases. See [Step 1 - Stop the Cloud APM server and Db2 database connections](#).
- Back up the databases. See [Step 2 - Back up the databases](#).
- Move (restore) the Db2 to the new Db2 server. See [Step 3 - Move \(restore\) the databases](#).
- Check the grant requests. See [Step 4 - Check the grant requests](#).
- Set up TBSMDB for SCR UDF functions. See [Step 5 - Set up TBSMDB for SCR UDF functions](#) and [Step 6 - Set up the SCR UDF functions](#).
- Verify the databases. See [Step 7 - Verify the databases](#).

When you are completing the steps in the following procedure, keep the following items in mind:

- It is an example procedure that describes how to move your existing Db2 databases to a new Db2 server. If your organizations Db2 administrator completes their own processes and procedures for moving databases, use your organizations Db2 procedures instead of completing the steps in this procedure. Each step in this procedure is either marked Cloud APM or Db2 so that you are aware of the Cloud APM specific steps and the Db2 steps.
- It includes the steps to change the Db2 database names, port number, instance name, password, and database file system location. If you want to change a straight forward item such as the Db2 port number only, you might want to refer to the standard Db2 procedures and run the **db2 update dbm cfg using svcename** command and update /etc/services instead of completing the following specific port number steps.
- The following steps are using an offline backup to create the backup files. After the files are created, they are copied to the new Db2 server. On the new Db2 server, a **RESTORE REDIRECT** is used to create a specific restore script. This script can then be used to move and restore the databases to the new Db2 server. Before the script is run, it is edited to allow the user to specify items such as the directory where the new databases are being stored. The script runs the restore process twice, the first time to complete the initial restore, and the second time with the CONTINUE option to process storage group storage paths and DMS table space containers.

- The Cloud APM server does not support moving from the db2apm instance user for a local Db2 server to a different Db2 instance user for the local Db2 server. When the Db2 server is installed, db2apm must be the instance user name.

## Procedure

Complete the following steps to move your Cloud APM Db2 databases to a new Db2 server and optionally change the default names of the databases, change the port number, and change the instance ID.

1. **Cloud APM** Stop the Cloud APM server and the connections to the current Db2 databases by completing the following steps:

- a. As user root, stop the Cloud APM server by issuing the following command

```
apm stop_all
```

- b. On the current Db2 server, issue **su** to the Db2 instance user ID. For example, for the db2apm instance user ID, issue the following command:

```
su - db2apm
```

- c. Start the current Db2 server by issuing the following command:

```
db2start
```

- d. Verify that no connections to the Cloud APM Db2 database that you are moving exist. Issue the following command to check the connections:

```
db2 list applications
```

If you have more than one Cloud APM server that use this Db2 instance, you can specify the database name. For example:

```
db2 list applications for db WAREHOUS
```

- e. If connections still exist, investigate them and kill them if necessary by issuing the following command:

```
db2 "force application (31441, 54612)"
```

where 31441 and 54612 are handles to the applications. You can use the **db2 force applications all** command if no other applications are using the Db2 instance.

- f. Verify again that no connections to each of the databases exist. For example for the WAREHOUS database, issue the following command:

```
db2 list applications for db WAREHOUS
```

where WARESHOUS is the database that you are checking for connections. Output similar to the following output is displayed if no connections to this database exist:

```
SQL1611W No data was returned by Database System Monitor
```

- g. Repeat steps [“2.d” on page 1200](#), [“2.e” on page 1200](#), and [“2.f” on page 1200](#) for each of the databases.

At the end of this step, the Db2 server is started with no connections to the three Cloud APM server Db2 databases that are being moved. The offline backups require a writable directory that your Db2 instance user ID (which is either the default user ID db2apm or another user ID) either owns or has write access to the directory.

2. **Db2** Back up the databases by completing the following steps.

- a. As user root on the current Db2 server, create a directory for Db2 backups. For example:

```
mkdir /db2; mkdir /db2/backups; chown db2apm:db2iadm1 -R /db2
```

- b. As the Db2 instance user ID on the current DB2 server, complete an offline backup for all three Cloud APM server Db2 databases. Use the default names WAREHOUS, DATAMART, and SCR32 unless your databases already have different names. Issue the following commands:

```
db2 backup db WAREHOUS to /db2/backups/  
db2 backup db DATAMART to /db2/backups/  
db2 backup db SCR32 to /db2/backups/
```

After each backup command is run, a backup file is created with a name similar to this name: /db2/backups/WAREHOUS.0.db2apmc.DBPART000.20180427141206.001 and a message similar to the following message is displayed:

```
Backup successful. The timestamp for this backup image is : 20180727141206
```

The backup file name and output message has a different time stamp to the one in this example.

3. Move (restore) the databases to the new Db2 server by completing the following steps:

- a. **Cloud APM** On the new Db2 server, you should have previously installed a supported version of Db2 and followed [step 1](#) and [steps 2.a to 2.k](#) in the [“Connecting to a remote Db2 server”](#) on page 146 topic to copy the Cloud APM server files to the Db2 server and create the Db2 instance user ID.
- b. **Cloud APM** If you want to run with Db2 authentication set to `server_encrypt`, complete the [step 1](#) and [step 2](#) in [“Changing Db2 authentication from server to server\\_encrypt”](#) on page 154.
- c. **Db2** Complete the following steps for the three databases: Copy the Db2 backup to the new Db2 server, grant Db2 requests, create the `.clp` files, and restore the Db2 databases to the new Db2 server:
- Use a command such as **scp** to copy the Db2 backups that are taken in [step 2.b.](#) to the new Db2 server.
  - As the Db2 instance user ID on the new remote Db2 server, issue the following command:

```
db2set DB2_RESTORE_GRANT_ADMIN_AUTHORITIES=ON
```

**Note:** If your Db2 server is running Db2 Advanced Enterprise Server Edition version 10.5, you must also restart the Db2 server by running the `db2stop` command followed by the **db2start** to activate the **db2set update**.

As another option, you can log on as the previous Db2 instance user ID and grant access to the new instance user ID after each database is restored.

- As the Db2 instance user ID on the new Db2 server, run the following commands to create the `.clp` files, which are used later in this procedure.
- As the Db2 instance user ID on the new Db2 server, issue the **db2 restore** command for all three databases.

For example:

```
db2set DB2_RESTORE_GRANT_ADMIN_AUTHORITIES=ON  
db2 restore db WAREHOUS from /db2/backups taken at 20180427141206 into WHOUSG  
redirect generate script WHOUSG_db.clp  
db2 restore db DATAMART from /db2/backups taken at 20180427141101 into DMARTG  
redirect generate script DMARTG_db.clp  
db2 restore db SCR32 from /db2/backups taken at 20180427141501 into SCRG  
redirect generate script SCRG_db.clp
```

- WAREHOUS, DATAMART, and SCR32 are the default original Db2 database names.
- /db2/backups is the directory where the backups were copied to on the new Db2 server.
- 20180727141206 is the time stamp.

- WHOUSG, DMARTG, and SCRG are the new database names.
- WHOUSG\_db.clp, DMARTG\_db.clp, and SCRG\_db.clp are the output .clp file names.

The contents of the .clp files are similar to the following.

```
-- *****
-- ** automatically created redirect restore script
-- *****
UPDATE COMMAND OPTIONS USING S ON Z ON DATAMART_NODE0000.out V ON;
SET CLIENT ATTACH_MEMBER 0;
SET CLIENT CONNECT_MEMBER 0;
-- *****
-- ** automatically created redirect restore script
-- *****
RESTORE DATABASE DATAMART
-- USER <username>
-- USING '<password>'
FROM '/db2/backups'
TAKEN AT 20180427141101
-- ON '/db2/DATAMART_data'
-- DBPATH ON '<target-directory>'
INTO DMARTG
-- NEWLOGPATH '/db2/DATAMART_data/db2apmc/NODE0000/SQL00001/LOGSTREAM0000/'
-- WITH <num-buff> BUFFERS
-- BUFFER <buffer-size>
-- REPLACE HISTORY FILE
-- REPLACE EXISTING
REDIRECT
-- PARALLELISM <n>
WITHOUT ROLLING FORWARD
-- WITHOUT PROMPTING
```

- d. **Db2** Edit the .clp files for the three databases. The following information includes guidance to help you update these files.

- The lines beginning with -- are comments.
- Uncomment the line --ON and specify the location where you want the database to be stored on the new Db2 server. In the previous example, the ON line was the only line updated like this:

```
ON '/db2/db2apmc/WHOUSG_data'
```

- You can also uncomment the line beginning with --NEWLOGPATH to specify the location where you want the logs to be stored.
- The --USER line does not need to be updated if you are running the restore as the db2apm user instance ID or as your own custom Db2 user instance ID.
- You can leave the lines for buffers commented out. When you complete a restore operation, the Db2 database products automatically choose an optimal value for the number of **BUFFER**, **buffer size**, and the **PARALLELISM** settings.

- e. **Db2** For each .clp file for the three databases, as the Db2 instance user ID on the new Db2 server, create the directory that is specified in the **ON** parameter in the database .clp file. Go to the directory where the .clp file was saved for the particular database, and run the .clp file. Here is an example for the DMARTG (originally the DATAMART) database.

```
mkdir /db2/db2apmc/DMARTG_data
cd /db2/backups
db2 -tvf DMARTG_db.clp
```

The following code is sample output after the DMARTG .clp file is run. It runs a redirect restore followed by a normal **RESTORE DATABASE DATAMART CONTINUE**. It automatically runs the second restore to handle the SQL1277W warning message that was generated during the redirect restore. If the second restore is successful, the warning message can be ignored.

```
$ db2 -tvf DMARTG_db.clp
UPDATE COMMAND OPTIONS USING S ON Z ON DATAMART_NODE0000.out V ON
DB20000I The UPDATE COMMAND OPTIONS command completed successfully.
```

```

SET CLIENT ATTACH_MEMBER 0
DB20000I The SET CLIENT command completed successfully.

SET CLIENT CONNECT_MEMBER 0
DB20000I The SET CLIENT command completed successfully.

RESTORE DATABASE DATAMART FROM '/db2/backups' TAKEN AT 20180427141101
ON '/db2/db2apmc/DMARTG_data' INTO DMARTG NEWLOGPATH
'/db2/db2apmc/DMARTG_data/db2apmg/NODE0000/SQL00001/LOGSTREAM0000/'
REDIRECT WITHOUT ROLLING FORWARD
SQL1277W A redirected restore operation is being performed.
During a table space restore,
only table spaces being restored can have their paths reconfigured.
During a database restore,
storage group storage paths and DMS table space containers can be reconfigured.
DB20000I The RESTORE DATABASE command completed successfully.

RESTORE DATABASE DATAMART CONTINUE
DB20000I The RESTORE DATABASE command completed successfully.

```

- f. **Db2** If you complete an offline backup, you should not need to run a **db2 rollforward** command. However, if you have log records that are pending then you might need to run the following commands as the Db2 user instance ID on the new Db2 server before you can connect to the databases.

```

db2 rollforward db WAREHOUSE complete
db2 rollforward db DATAMART complete
db2 rollforward db SCR32 complete

```

where WAREHOUSE, DATAMART, and SCR32 are the original database names.

4. **Cloud APM** Check the grant requests. If you changed the Db2 instance user ID when you moved the databases, the original Db2 instance user ID can still access the databases. Run the following command to review the existing grants on the databases. If the original Db2 instance user ID has grants on the databases, these grants should be revoked.

```

db2 connect to db_name
db2 "SELECT DISTINCT GRANTEETYPE, GRANTEE, SECURITYADMAUTH from SYSCAT.DBAUTH"
db2 "SELECT DISTINCT GRANTEETYPE, GRANTEE, DBADMAUTH from SYSCAT.DBAUTH"
db2 connect reset

```

where *db\_name* is the name of one of the three databases. The Db2 instance user ID should have dbadmin and secadm authority. The itmuser user ID should have dbadmin authority. Public should have authority=N. If other IDs are displayed and they have authority, you might want to revoke their authority. An example of the command to revoke authority is:

```

db2 connect to WHOUSG
db2 REVOKE DBADM ON DATABASE FROM USER db2apm BY ALL
db2 REVOKE SECADM ON DATABASE FROM USER db2apm BY ALL

```

db2apm in the previous commands is the default Db2 instance user ID. The user ID might be different if you changed it. Complete this step on all three databases for authorities that you want to revoke.

5. **Cloud APM** Set up TBSMDB for SCR UDF functions. Complete [step 2.n](#) in the “Connecting to a remote Db2 server” on [page 146](#) topic. When you are completing [step 2.n](#), for the question: Should the installer create the schema for this database, enter 2 for No instead of 1 for yes as indicated in [step 2.n](#).
6. **Cloud APM** Set up SCR UDF functions. Install the jars and create the UDF functions. Complete this step once for each Db2 instance. The *\*\_JAR.jar* files are installed in the *Db2 instance home directory/sqlllib/function/jar/TBSMUDF* directory. Issue the following commands as the Db2 instance user ID on the new Db2 server.

```

cd $home
cd tbsmdb/sql
db2 connect to db_name

```

```
db2 -v -f ./tbsmudf_cleanupudf.db2.sql -t
db2 -v -f ./tbsmudf_removeudf.db2.sql -t
db2 -v -f ./tbsmudf_installudf.db2.sql -t
db2 -v -f ./tbsmudf_setupudf.db2.sql -t
db2 connect reset
```

where *db\_name* is the name of one of the three databases. If this is the first database added to the Db2 instance, you might see error messages when running the **cleanupudf** and **removeudf** SQL commands. Ignore the messages and run the remaining **installudf** and **setupudf** SQL commands.

7. Verify the databases. As the Db2 instance user ID on the new remote Db2 server connect to your SCR database and run the select statement. For example:

```
db2 connect to scr32;
db2 "select ROUTINE_CATALOG, ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE from sysibm.routines
"
| grep -i TBSMUDF |wc -l
```

The line count should be about 32 functions.

## Results

The three databases are moved to the new Db2 server, the Db2 instance user ID that the databases are using is changed, and the Cloud APM functions are added to the SCR database.

## What to do next

[“Cataloging Db2 databases after changing the Db2 server” on page 1204.](#)

## Cataloging Db2 databases after changing the Db2 server

If you change the Db2 database names, Db2 server node, or Db2 port number, you must update the catalogs.

## About this task

When you catalog a database, you can set the *authentication* to either *server* or *server\_encrypt* depending on the authentication configuration on the Db2 server. For more information, see [“Changing Db2 authentication from server to server\\_encrypt” on page 154](#). The following example shows how to set authentication to *server\_encrypt* for the APMG Db2 server node while you are cataloging the DMARTG database.

```
db2 catalog database DMARTG as DATAMART at node APMG authentication server encrypt
```

**Note:** If you are changing the Db2 server node or Db2 port number only when you are moving the Db2 databases from one Db2 server to another Db2 server, then you need to recatalog the Db2 server node only. Issue the following commands:

1. To uncatalog the node. Issue the following command:

```
db2 uncatalog node Db2_server_node
```

where *Db2\_server\_node* is the existing Db2 server node.

2. Catalog the new Db2 server. Issue the following command:

```
db2 catalog tcpip node current_Db2_server_node remote
new_Db2_server server new_db2port
```

where:

- *current\_Db2\_server\_node* is the current Db2 server node.
- *new\_Db2\_server* is the new Db2 server host name or IP address.
- *db2port* is the new Db2 port number.

You can optionally set the authentication type when you are issuing the **db2 catalog** command. You should uncatalog and recatalog the APM\_NODE that was created by the initial Cloud APM server installation and uncatalog and recatalog any additional nodes that you created.

For more information about the **db2 catalog tcpip node** commands, see [CATALOG TCPIP/TCPIP4/TCPIP6 NODE command](#). For more information about the **db2 catalog db** command, see [CATALOG DATABASE command](#).

## Procedure

Complete the following steps to catalog the databases, Db2 server nodes and Db2 port number:

**Note:** This is an example procedure. The catalog commands that you use when you are completing your cataloging will be the same but the database names, Db2 server node, Db2 server host name, port number, and itmuser password will be different.

1. On the Cloud APM server, issue **su** to the Db2 instance user ID. For example, for the db2apm instance user ID, issue the following command:

```
su - db2apm
```

2. Run the following **catalog** commands to catalog the databases, Db2 server node, and Db2 port number.

- a. Save a copy of your current catalog information. For example:

```
db2 list db directory >> /tmp/db.directory  
db2 list node directory >> /tmp/node.directory
```

- b. Uncatalog the existing Db2 server node. Issue the following command:

```
db2 uncatalog node Db2_server_node
```

- c. Catalog to the new Db2 server node. Issue the following command:

```
db2 CATALOG TCPIP NODE new_node REMOTE db2server SERVER db2port
```

where *new\_node* is APMG, *db2server* is db21056.rtp.raleigh.ibm.com, and *db2port* is 50005.

- d. Uncatalog the default original databases. Issue the following commands:

```
db2 uncatalog db WAREHOUS  
db2 uncatalog db DATAMART  
db2 uncatalog db SCR32
```

- e. Catalog your new databases as the new default database names. Issue the following commands.

```
db2 catalog db new_warehous at node new_node  
db2 catalog db new_datamart at node new_node  
db2 catalog db new_scr32 at node new_node
```

where *new\_warehous* is WHOUSG, *new\_datamart* is DMARTG, *new\_scr32* is SCR32, and *new\_node* is APMG. Never use APM\_NODE as the node name because the Cloud APM server uses the APM\_NODE node name.

The following type of output is displayed when the catalog commands are successful.

```
DB2XXXX The CATALOG X command completed successfully.
```

- f. Catalog the default alias names for the new databases. Issue the following commands.

```
db2 catalog db new_warehous as WAREHOUS at node new_node  
db2 catalog db new_datamart as DATAMART at node new_datamart
```

```
db2 catalog db new_scr32 as SCR32 at node new_node
db2 terminate
```

g. Test the connections to the new databases. Issue the following commands.

```
db2 connect to new_warehous user itmuser using itmpw
db2 connect to new_datamart user itmuser using itmpw
db2 connect to new_scr32 user itmuser using itmpw
db2 connect to WAREHOUS user itmuser using itmpw
db2 connect to DATAMART user itmuser using itmpw
db2 connect to SCR32 user itmuser using itmpw
db2 terminate
```

Based on the variables, *itmpw* in the previous commands is xxxyyy. Output similar to the following is displayed if the connections are successful. This output is for the new DMARTG database.

```
$ db2 connect to new_datamart user itmuser using itmpw
Database Connection Information

Database server          = DB2/LINUX8664 10.5.6
SQL authorization ID     = ITMUSER
Local database alias     = DMARTG
```

## Results

The new databases, the Db2 server node, and port number are cataloged.

## What to do next

[“Updating the Cloud APM server configuration for Db2 server changes” on page 1206](#)

## Updating the Cloud APM server configuration for Db2 server changes

If you move to a different Db2 server, move to a different Db2 instance user, change the Db2 server host name, IP address, or port number, or change the Db2 database names, then you must reconfigure the Cloud APM server to pick up the Db2 server changes.

## Before you begin

Before you update the Cloud APM server configuration for the Db2 server changes, you must recatalog the Db2 databases on your Cloud APM server for the Db2 instance user ID that you are using. If this task is not completed, see [“Cataloging Db2 databases after changing the Db2 server” on page 1204](#) for instructions before you proceed with this procedure.

## About this task

If you move the Db2 databases from one Db2 server to another, or change the database names, Db2 instance user ID, or port number, you must reconfigure the Cloud APM server to pick up the database changes by using the `update_db_config.sh` script.

To access the `update_db_config.sh` script, you must install the IBM Cloud Application Performance Management Private, V8.1.4.0 interim fix 6 (8.1.4.0-IBM-APM-SERVER-IF0006) or later after you complete the Cloud APM server installation. Interim fixes for the Cloud APM server version 8.1.4 are available to download from IBM Fix Central. After you install the interim fix, the `update_db_config.sh` script is located under the `install_dir/ccm/` directory. `install_dir` is the directory where you installed your Cloud APM server.

The steps in this procedure are using the default `/opt/ibm` directory as the directory where you installed the Cloud APM server. If you specified a different directory when you installed the server, use that directory instead of `/opt/ibm` in the following steps.

The password for the itmuser user on the Cloud APM server is changed to match the itmuser password on your new remote database during this procedure. The Cloud APM server is restarted when the `update_db_config.sh` script is run.

## Procedure

Complete the following steps to reconfigure the Cloud APM server to match the new database changes.

1. As the Db2 instance user ID, log in to the new Db2 server and start Db2 if it is not already running.

Issue the following command:

```
db2start
```

2. As user root, log in to the Cloud APM server and start the Cloud APM services that might be stopped.

Issue the following command:

```
apm start_all
```

3. As user root, run the `/opt/ibm/ccm/update_db_config.sh` script with the configuration parameters and corresponding values that match your new Db2 server. Ensure that you enter the values for all the configuration parameters correctly because the `update_db_config.sh` script updates the configuration files for all three databases even if you are changing the configuration for one of the databases only. These are the configuration parameters:

- **-h `installdir`** is the directory where the Cloud APM server is installed. The default installation directory is `/opt/ibm`.
- **-server `hostname_or_ipaddress`** is the directory location and host name or IP address of the new Db2 server.
- **-db2\_port** is the new Db2 port number.
- **-whous\_db** is the database name of your WAREHOUS database. The default name is WAREHOUS. If you are using a new name instead of the default name, enter the new name.
- **-scr\_db** is the database name of your SCR32 database. The default name is SCR32. If you are using a new name instead of the default name, enter the new name.
- **-dm\_db** is the database name of your DATAMART database. The default name is DATAMART. If you are using a new name instead of the default name, enter the new name.
- **-db2\_inst** is the new Db2 user instance ID. The default user ID is db2apm.
- **db\_pw** is the itmuser password on the system where the Db2 server is installed.

An example of how to run the `update_db_config.sh` is:

```
./update_db_config.sh -h /opt/ibm -server db21056.rtp.raleigh.ibm.com -db2_port 50005  
-scr_db SCR32 -dm_db DMARTG -whous_db WHOUSG -db2_inst db2apmg -db_pw xxxyyy
```

If you do not enter the itmuser password on the command line with the other configuration parameters, you are prompted for it.

4. Start Cloud APM. Issue the following command:

```
apm restart_all
```

5. Complete a Cloud APM server backup. For more information, see [“Backing up components” on page 1227](#).

## Results

The Cloud APM server is reconfigured to use the new database connection information.

## What to do next

If other products use these databases, update the configuration for these products. For example; if you change the host name, IP address, or database names of the Cloud APM Db2 server and you have previously integrated with other products such as Tivoli Common Reporting, complete the following steps:

1. Uncatalog the original Db2 server node and databases on the Tivoli Common Reporting server. Issue the following commands:

```
db2 list node directory >> db2_server_node_directory
db2 uncatalog node original_db2_server_node
db2 list db directory >> db2_directory
db2 uncatalog db original_db_name
```

where:

- *db2\_server\_node\_directory* is the original Db2 server node directory.
  - *original\_db2\_server\_node* is the original Db2 server node.
  - *db2\_directory* is the original Db2 directory.
  - *original\_db\_name* is the original database name.
2. Recatalog the new Db2 server databases on the Tivoli Common Reporting server by completing the steps in the [“Configuring an ODBC connection” on page 1084](#) topic.
  3. Reconfigure and reinstall the reports to update the Tivoli Data Warehouse and APPMART connection by completing the steps in the [“Configuring the reports installation image” on page 1085](#) topic.

Log in to the Cloud APM console and verify that your agents can connect to the Cloud APM server.

## Upgrading the Db2 server to Db2 version 11.1.x

After the Cloud APM server is installed, you can upgrade your local or remote Db2 server from Db2 Advanced Enterprise Server Edition version 10.5 to version 11.1.x or Db2 Advanced Workgroup Server Edition version 11.1.x.

For the list of supported Db2 fix packs, open the Software Product Compatibility Report for your offering and click the **Prerequisites** tab to view the database requirements:

[IBM Cloud Application Performance Management, Base Private V8.1.4](#)

[IBM Cloud Application Performance Management, Advanced Private V8.1.4](#)

## Before you begin

Make sure that the IBM Cloud Application Performance Management, Private V8.1.4.0 interim fix 4 or a later interim fix is applied to the Cloud APM server. Interim fixes for the Cloud APM server V8.1.4 are available to download from [IBM Fix Central](#).

## About this task

To upgrade the Db2 server 10.5 to Db2 11.1.x, follow the Db2 server upgrade instructions in the [IBM® Db2 Version 11.1 Knowledge Center](#). Then complete additional steps to update the Db2 server to use Cloud APM server jars and to upgrade the Db2 client on the Cloud APM server.

## Procedure

Complete the procedure on the Cloud APM server and on remote Db2 server if the Db2 server is remote.

1. On the system where the Cloud APM server is installed, stop all server components by running the following command in the `/usr/bin` directory:

```
apm stop_all
```

2. On the system where the Db2 server 10.5 is installed, upgrade the Db2 server by following the upgrade instructions in the [IBM® Db2 Version 11.1 Knowledge Center](#).

3. On the system where the Db2 server is installed, configure the new version of Db2 to use the Cloud APM server jars by completing the following steps:

- a) Enter the following Db2 command from a Db2 command window

```
db2 connect to scr-db user db2-instance-user using db2-instance-password
```

where:

- *scr-db* is the SCR database name. The default is SCR32.
- *db2-instance-user* is the Db2 instance user. The default is db2apm.
- *db2-instance-password* is the Db2 instance user's password. The default is db2Usrpasswd@08.

- b) Change to one of the following directories:

- Local Db2 server:

```
cd install_dir/db2/tbsmdb/sql
```

- Remote Db2 server:

```
cd path-specified-during-setup-db-config/sql
```

where, *path-specified-during-setup-db-config* is the path that you specified for the Db2 instance when you ran the Cloud APM **setup-dbconfig** program. The default path is /opt/IBM/tivoli/tbsmdb.

- c) Execute the following .sql files:

```
db2 -vf ./tbsmudf_cleanupudf.db2.sql -t
db2 -vf ./tbsmudf_removeudf.db2.sql -t
db2 -vf ./tbsmudf_installudf.db2.sql -t
db2 -vf ./tbsmudf_setupudf.db2.sql -t
```

- d) Run the following command:

```
db2 connect reset
```

4. On the system where the Cloud APM server is installed, upgrade the IBM Data Server Client component from the Db2 installation package to match the version of the Db2 server.

Follow the instructions in the [IBM® Db2 Version 11.1 Knowledge Center](#).

5. On the system where the Cloud APM server is installed, ensure that the *KQZ\_JDBC\_JAR\_PATHS* variable is set to the path where the upgraded Db2 client JDBC driver is located. To update the *KQZ\_JDBC\_JAR\_PATHS* variable, complete the following steps:

- a) Go to the *install\_dir*/serveragents/config directory.

- b) Back up the *hostname\_te.cfg* file, where *hostname* is the Cloud APM server host name.

- c) Open the *hostname\_te.cfg* file and locate the following line that starts with *KQZ\_JDBC\_JAR\_PATHS*=.

- d) Set the *KQZ\_JDBC\_JAR\_PATHS* value to the path where your Db2 11.1 JDBC driver jars are located.

For example, if you are using Db2 V11.1, and your IBM Data Server Client is installed in the default /opt/ibm directory, the *KQZ\_JDBC\_JAR\_PATHS* path looks like:  
*KQZ\_JDBC\_JAR\_PATHS*=/opt/ibm/db2/V11.1/java.

- e) Save and close the file.

6. Start all server components by running the following command in the /usr/bin directory:

```
apm start_all
```

## Results

Your Db2 server that the Cloud APM server is connected to is upgraded.

**Remember:** If you complete a backup and restore for a disaster recovery, remember to upgrade the Db2 server to match the version used by the source server before completing the restore into the target server.

## Starting, stopping, and checking the status of server components

Use the commands for checking the status or for starting, stopping, and recycling the Cloud APM server components when necessary for maintenance and troubleshooting tasks.

### About this task

As the root user, run any of the **apm** commands in the `/usr/bin/` directory on the system where the Cloud APM server is installed. For each command, a short version is available and shown as "Short command".

### Procedure

As the root user, complete any of these steps:

- To list the available commands and see the syntax, enter the following command:

```
apm --help
```

- To start all, stop all, or recycle all server components, enter one of the following commands:

```
apm start_all
```

```
apm stop_all
```

```
apm restart_all
```

Short commands: **sta**, **spa**, and **rta**

- To check whether all Cloud APM components or a particular component is running or stopped, enter one of the following commands:

```
apm status
```

for all components.

```
apm status component_name
```

where *component\_name* is one of the following components.

| Option         | Description   |
|----------------|---|
| <b>apmui</b>   | Cloud APM console component that handles incoming user interface requests.  |
| <b>biagent</b> | Component for Cloud APM data collectors, which is enabled by default.   |
| <b>db2</b>     | Db2 server that is used to persist monitoring data and applications that are displayed in the Performance Management console. This component is only used if you install a local Db2 server when you install the Cloud APM server.  |
| <b>dqe</b>     | Component for Cloud APM data collectors, which is enabled by default.   |
| <b>kafka</b>   | Message bus component for internal communication between components.  |
| <b>ksy</b>     | Summarization and Pruning Agent for maintaining database partitions and pruning monitoring data in the Db2 server.  |
| <b>min</b>     | Monitoring Infrastructure Node component that maintains the list of connected agents, advanced configuration data, and threshold events. The min component is also the agent interface component that includes the agent REST interface and central configuration services HTTP server. The REST interface is used by agents to send monitoring data that is persisted in the Db2 server and threshold events. The central configuration service HTTP |

| Option         | Description   |
|----------------|---|
|                | server handles requests from agents for their configuration files, for example, threshold definitions.  |
| <b>mongodb</b> | (Not available with Cloud APM, Base Private) MongoDB NoSQL open-source database that stores data for threshold events and for the transaction tracking functionality. This component is only used if you install a local MongoDB database when you install the Cloud APM server.  |
| <b>oidc</b>    | OpenID Connect (OIDC) is a simple identity protocol over OAuth 2.0. The OIDC provider in Liberty Profile is implemented as an OAuth 2.0 extension.  |
| <b>oslc</b>    | Open Services for Lifecycle Collaboration service provider that registers the computer system, software server, and application resources that are monitored by agents in the service component registry.   |
| <b>scr</b>     | Service Component Registry that persists application definitions and their relationships to agent resources in the Db2 server.  |
| <b>server1</b> | Cloud APM console backend component that retrieves monitoring data and applications from the Db2 server and persists threshold definitions, resource group definitions, and role-based access control definitions.<br>Be aware that if you restart server1, you must also restart the apmui component after restarting the server1 component. |
| <b>soagent</b> | (Not available with Cloud APM, Base Private) Agent that aggregates transaction data from multiple playback agents and generates events according to threshold definitions.<br>Be aware that if you stop this component, the agent cannot generate events.   |
| <b>spark</b>   | (Not available with Cloud APM, Base Private) Component that controls the spark infrastructure and the applications such as the AAR Aggregator and Instance Analyzer that run on it. If you stop this service, you will lose functionality.  |
| <b>txagent</b> | (Not available with Cloud APM, Base Private) Transactions Event agent, which sets the thresholds that are used to classify middleware transactions. If you stop this component, you will lose functionality.  |
| <b>uview</b>   | Universal View service for defining dashboard pages in the <b>Custom Views</b> tab of the Application Performance Dashboard.  |

Short command: **ss**

- If you were directed by IBM Support or an IBM Knowledge Center topic to start, stop, or restart a particular component, enter the command using the following syntax:

```
apm command component_name
```

where *command* is one of the following **apm** commands:

| Option         | Description   |
|----------------|---|
| <b>start</b>   | Start the specified <i>component_name</i> .<br>Short command: <b>st</b> .   |
| <b>stop</b>    | Stop the specified <i>component_name</i> . To do a force stop, insert <b>-f</b> or <b>--force</b> between <b>apm</b> and <b>stop</b> . For example, <code>apm -f stop apmui</code> , stops the Cloud APM console immediately.<br>Short command: <b>sp</b> |
| <b>restart</b> | Restart the running <i>component_name</i> .<br>Be aware that after restarting the server1 component, you must also restart the apmui component.<br>Short command: <b>rt</b>   |

and *component\_name* is one of the components that are listed in the previous step (apmui, biagent, db2, dqe, kafka, ksy, min, mongodb, oidc, oslc, scr, server1, soagent, spark, or txagent).

**Note:** If the following message is displayed after you are start or stop a component:

```
This process currently executes start/stop operations of component
component_name: process_ID. Wait for it to complete then retry the
operation.
```

It means that the specific service is already being started or stopped by the **apm** command that is running under the process ID displayed. To check the status of this service, run the

```
apm status service_name
```

command. If the service is still running from the other **apm** command, wait a few minutes for it to complete, and retry the operation again.

**Note:** If a service does not stop when you use the `apm stop service_name`, `apm stop_all`, or `apm restart_all` commands, do not use the Linux **kill** command to stop the process. Instead, use the **-f** or **--force** option with the `apm stop service_name` command to stop the process. The **-f** or **--force** option must be used only when you cannot stop the process without forcing it to stop.

## Managing the maximum Java heap size and Db2 bufferpool

Manage the maximum Java heap size and Db2 bufferpool size using the **server\_size.sh** command.

### Procedure

1. To view the server size, run the **server\_size.sh** command from the `/opt/ibm/ccm/` directory.  
The output describes the number of CPUs, memory size, and free disk space in the server. Based on this output, a recommended server size is given, for example:

```
Number of CPUs: 6
Memory size: 16.00 GB
Recommended server size: small
Current server size: medium
```

2. To change the server size and Db2 bufferpool, run the **server\_size.sh** command again followed by the recommended size, for example, **server\_size.sh small**.

Note, this command stops and restarts the four Liberty servers. The maximum Java heap size is adjusted according to the values in the following table:

| Table 284. Maximum Java heap size setting |  |         |         |
|---|--|---------|---------|
| Cloud APM server components               | Small  | Medium  | Large   |
| Server1 application server                | 1526 MB or 1536 MB   | 2048 MB | 3072 MB |
| APMUI service                             | 1526 MB or 1536 MB   | 3072 MB | 4096 MB |
| Uviews (Liberty server instance)          | 1024 MB  | 1024 MB | 1024 MB |
| MIN (Liberty server instance)             | 512 MB if you have Cloud APM server V8.1.4.0 with no interim fix or interim fix 6 or earlier; 768 MB if you have Cloud APM server V8.1.4.0 with interim fix 6 or later | 1536 MB | 2048 MB |

| Table 284. Maximum Java heap size setting (continued) |   |         |         |
|---|---|---------|---------|
| Cloud APM server components                           | Small   | Medium  | Large   |
| OIDC  | 128 MB  | 128 MB  | 256 MB  |
| Kafka   | 256 MB  | 512 MB  | 512 MB  |
| Zookeeper   | 256 MB  | 256 MB  | 256 MB  |
| MongoDB Cache   | 1024 MB for all Cloud APM, Base Private install | 2048 MB | 4096 MB |

The buffer pool is adjusted according to the values in the following table:

| Table 285. Db2 Bufferpool |              |        |        |        |
|---------------------------|--------------|--------|--------|--------|
| Database                  | Bufferpool   | Large  | Medium | Small  |
| DATAMART                  | IBMDEFAULTBP | 300000 | 200000 | 100000 |
| WAREHOUS                  | IBMDEFAULTBP | 200000 | 100000 | 50000  |
| SCR32                     | TBSMSCR16KBP | 100000 | 50000  | 30000  |
| SCR32                     | TBSMCFG16KBP | 10000  | 5000   | 1000   |

Example output is included here:

```
/opt/ibm/ccm/server_size.sh small

Setting heap size to 256 MB for service kafka.
Setting heap size to 256 MB for service zookeeper.
Setting heap size to 1024 MB for service apmui.
Setting heap size to 512 MB for service min.
Setting heap size to 128 MB for service oidc.
Setting heap size to 1526 MB for service server1.
Setting ENABLE_MY_COMPONENTS to true for service apmui.
Setting cache size (GB) to 1 for service mongodb.
Setting prefetch pause to 100000 for service min.
Setting prefetch resume to 75000 for service min.
Setting datamart_ibm_default_buf_pool value to 100.

Database Connection Information

Database server      = DB2/LINUX8664 10.5.6
SQL authorization ID = DB2APM
Local database alias = DATAMART

DB20000I The SQL command completed successfully.
Setting scr_ibm_default_buf_pool value to 5000.

Database Connection Information

Database server      = DB2/LINUX8664 10.5.6
SQL authorization ID = DB2APM
Local database alias = SCR32

DB20000I The SQL command completed successfully.
Setting scr_tbsm_cfg_16k_buf_pool value to 1000.

Database Connection Information

Database server      = DB2/LINUX8664 10.5.6
SQL authorization ID = DB2APM
Local database alias = SCR32

DB20000I The SQL command completed successfully.
Setting scr_tbsm_4k_buf_pool value to 1000.

Service min is started (PID 12376).
Starting service apmui
.....
Service apmui is started (PID 16226).

```

3. If you are using a remote Db2 server for the Cloud APM server databases then you must update the buffer pool sizes and transaction logs on the Db2 server. Enter the following command as the external\_db2\_instance user for each database to adjust the buffer pool and transaction log.

```

db2 connect to WAREHOUS
db2 UPDATE DATABASE CONFIGURATION FOR WAREHOUS USING LOGSECOND WAREHOUS_LOGSECOND
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size WAREHOUS_PAGE_COUNT
db2 disconnect WAREHOUS
db2 connect to DATAMART
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size DATAMART_PAGE_COUNT

```

```
db2 disconnect DATAMART
db2 connect to SCR32
db2 UPDATE DATABASE CONFIGURATION FOR SCR32 USING LOGSECOND SCR_LOGSECOND
db2 alter bufferpool TBSMCFG16KBP IMMEDIATE size SCR_CFG_PAGE_COUNT
db2 alter bufferpool TBSMSCR16KBP IMMEDIATE size SCR_PAGE_COUNT
db2 disconnect SCR32
```

where:

#### **WAREHOUS\_LOGSECOND**

The number of secondary transaction logs: 25 for a small environment; 50 for a medium environment; or 100 for a large environment.

#### **WAREHOUS\_PAGE\_COUNT**

The buffer pool page count (8-KB page sizes): 50000 for a small environment; 100000 for a medium environment; or 200000 for a large environment.

#### **DATAMART\_PAGE\_COUNT**

The buffer pool page count (8-KB page sizes): 100000 for a small environment; 200000 for a medium environment; or 300000 for a large environment.

#### **SCR\_LOGSECOND**

The number of secondary transaction logs: 25 for a small environment; 50 for a medium environment; or 100 for a large environment.

#### **SCR\_CFG\_PAGE\_COUNT**

The buffer pool page count (16-KB page sizes): 1000 for a small environment; 5000 for a medium environment; or 10000 for a large environment.

#### **SCR\_PAGE\_COUNT**

The buffer pool page count (16-KB page sizes): 30000 for a small environment, 50000 for a medium environment, and 100000 for a large environment.

**Note:** If you are not using the default database names, then replace the WAREHOUS, DATAMART, and SCR32 names with your custom database names.

## Changing the server IP address and host name

You can change the IP address and host name of the Cloud APM server at any time. If you change the IP address and host name of the server, you must also change the IP address and host name that all of the agents use to connect to the Cloud APM server.

### Before you begin

If you change the IP address and host name of the Cloud APM server and you plan to install new agents, create new configuration packages for the agent images (see step 2 in [“Configuring the downloaded images”](#) on page 182). Otherwise, the agents will not connect to the server or show in the Cloud APM console.

### Procedure

Complete the following steps as the root user on the Cloud APM server:

1. Stop all of the server components by entering the following command in the `/usr/bin` directory:

```
apm stop_all
```

2. Start the `kafka` and `server1` components by entering the following commands:

```
apm start kafka
apm start server1
```

3. Change the IP address and host name of the server that is used to start the Cloud APM console. This is the address that users enter to start the console from their web browsers. Change to the `install_dir/ccm` directory and run the following command:

```
configure_server_address.sh
```

You are prompted for the following values:

- Fully qualified domain name, for example: `myserver.example.com`.
- Short host name
- IP address

**Tip:** The fully qualified domain name and short host name are resolved using DNS. If your system does not have good DNS resolution, enter the IP for all three values.

4. Update the server agent file names. The server agents include the Synthetic Events agent, the Transaction Events agent, and optionally, the Bluemix Integration agent. Change to the `install_dir/serveragents/bin` directory and run the following command:

```
update_config_files.sh
```

5. Change the Cloud APM server references on the local Db2 server to the new IP address and host name:

- a) Update the `DB2SYSTEM` registry variable for the local Db2 server to match the new host name of the Cloud APM server:

```
source /home/db2apm/sqlllib/db2profile
db2set -g DB2SYSTEM=host_name
```

where `host_name` is the new host name of the server.

- b) On your local Db2 server, modify the host name on the Cloud APM server by editing the `/home/db2apm/sqlllib/db2nodes.cfg` file and replacing the old server host name with the new server host name.
- c) On your local Db2 server, update the Db2 administrator's configuration file by entering the following commands:

```
su - db2apm -c 'db2 update admin cfg using DB2SYSTEM host_name'
su - db2apm -c 'db2 update admin cfg using SMTP_SERVER host_name'
```

where `host_name` is the new host name of the server.

6. Verify that the server agents that were installed with the Cloud APM server are configured to use `localhost` to communicate with the server.

Open the `install_dir/serveragents/config/global.environment` file and locate the `IRA_ASF_SERVER_URL` and `IRA_API_DATA_BROKER_URL` properties. Complete one of the following steps:

- If the properties specify `localhost` in the URL string, no change is required.
- If the properties contain the IP address of the Cloud APM server, which is likely if you configured the agents to communicate using HTTPS, change the IP addresses to `localhost`.

7. Restart the server components by entering the following command in the `/usr/bin` directory:

```
apm restart_all
```

8. Override the host name of the Cloud APM server in the Central Configuration Services component.

- a) If you are not already logged in to the Cloud APM console, log in now.

(See [“Starting the Cloud APM console”](#) on page 1109.)

- b) Click  **System Configuration** > **Advanced Configuration** and click **Agent Central Configuration**.

- c) In the **Host Name Override** field, enter the new IP address or fully qualified host name of the Cloud APM server.

- After you click **Save**, the new host name is updated in the Central Configuration Services component.
9. On the systems where your agents are installed, connect the agents to the new server IP address and host name.  
See [“Configuring agents to connect to a different server or to use HTTPS communication”](#) on page 255.
  10. If you have reports packages for the Response Time Monitoring Agent and the WebSphere Applications agent installed, you must reinstall the reports packages for both agents.  
For more information, see [“Installing reports”](#) on page 1086. Restart the Tivoli Common Reporting server, complete the steps in the sub topics under [Restarting Jazz for Service Management application servers](#).

## Results

The IP address and host name of the server is changed.

## Configuring the communications protocol for server agents

Either the HTTP or HTTPS protocol is used to communicate between the Cloud APM server and the server agents. The Cloud APM server allows connections from server agents that authenticate themselves with a valid certificate. If you change the communication protocol that is used by the server to communicate with monitoring agents, you must change the protocol used by the server agents.

### About this task

Server agents are components of the Cloud APM server. The server agents provide the following functions:

- The Transactions Event agent provides services for transaction tracking.
- The Synthetic Events agent provides services for synthetic transactions.
- The Bluemix Integration agent integrates the Cloud APM server with your IBM Cloud environment.

The server agents are installed and started automatically when you install the Cloud APM, Advanced offering. If you have the Cloud APM, Base offering, no server agents are used and you do not need to configure communications protocols for server agents.

Default certificates are generated during the Cloud APM server installation. The server agents might use the default certificates or they might use self-signed or custom certificates to connect to the Cloud APM server.

Complete the following steps to configure the communication protocol between the server agents and the Cloud APM server:

### Procedure

- If you want to change from HTTPS communication to HTTP communication between the Cloud APM server and server agents, complete the following steps:

- a) On the Cloud APM server, open a command window and change to the *install\_dir/serveragents/bin* directory.

For example:

```
cd /opt/ibm/apm/serveragents/bin
```

- b) Run the following commands to stop the server agents.

```
apm stop biagent
apm stop soagent
apm stop txagent
```

- c) Run the following command to configure HTTP communication between the Cloud APM server and the server agents:

```
./agent2server.sh -p HTTP
```

d) Restart the server agents by running the following commands:

```
apm start biagent
apm start soagent
apm start txagent
```

- If you want to use HTTPS communication and default certificates between the Cloud APM server and server agents, complete the following steps:

a) On the Cloud APM server, open a command window and change to the *install\_dir*/serveragents/bin directory.  
For example:

```
cd /opt/ibm/apm/serveragents/bin
```

b) Run the following commands to stop the server agents.

```
apm stop biagent
apm stop soagent
apm stop txagent
```

c) Run the following command to configure HTTPS communication between the Cloud APM server and the server agents:

```
./agent2server.sh -p HTTPS
```

d) Restart the server agents by running the following commands:

```
apm start biagent
apm start soagent
apm start txagent
```

- If you want to use HTTPS and either self-signed certificates or certificates that are signed by a third-party certificate authority for communication between the Cloud APM server and server agents, complete the following steps:

a) On the Cloud APM server, open a command window and stop the server agents by entering the following commands:

```
apm stop biagent
apm stop soagent
apm stop txagent
```

b) Copy the contents of the *install\_dir*/ccm/keyfiles/*serverhostname*.agent/keyfiles directory to the *install\_dir*/serveragents/keyfiles directory, where *install\_dir* is the installation directory of the Cloud APM server and *serverhostname* is the Cloud APM server hostname.

**Note:** If you are using the default certificates that are created by the Cloud APM server installation, specify *default.agent* in place of *serverhostname.agent*.

c) Modify the *install\_dir*/serveragents/config/global.environment file to specify which certificate is used by the server agents. Add or edit the following variable:

```
KDEBE_KEY_LABEL="APM_Agent_Certificate"
```

**Important:** If you used a label other than "APM\_Agent\_Certificate" when you created the certificates, you must specify that label instead of "APM\_Agent\_Certificate".

d) If your third-party CA provides only an RSA signature, change the *KDEBE\_FIPS\_MODE\_ENABLED=SuiteB-128* variable to *KDEBE\_FIPS\_MODE\_ENABLED=NO* in the *install\_dir*/serveragents/config/global.environment file.

e) Change to the *install\_dir*/serveragents/bin directory.  
For example:

```
cd /opt/ibm/apm/serveragents/bin
```

- f) Run the following command to configure HTTPS communication between the Cloud APM server and the server agents:

```
./agent2server.sh -p HTTPS
```

- g) Restart the server agents by running the following commands:

```
apm start biagent  
apm start soagent  
apm start txagent
```

## Results

The communication protocol that is used to connect the server agents to the Cloud APM server is changed.

## Switching to a local MongoDB

If your Cloud APM server is connected to a MongoDB on a remote server, you can switch to use the local MongoDB at any time.

### Procedure

Complete the following steps as the root user on the system where you installed the Cloud APM server:

1. Go to the `install_dir/mongodb/bin` directory.

For example:

```
cd install_dir/mongodb/bin
```

2. Delete the `/mongodb/mongodb-remote` file.
3. Run the **activate-mongodb.sh** command to apply the change.
4. Configure communications between the local MongoDB and the Cloud APM server:
  - a) If you are not already logged in to the Cloud APM console, log in now.  
(See [“Starting the Cloud APM console”](#) on page 1109.)
  - b) Click  **System Configuration** > **Advanced Configuration** and click **Mongo Configuration**.
  - c) In the **Host Name** field, enter `localhost`.
  - d) Click **Save** to save the configuration.

After you click **Save**, the transaction tracking components begin communicating with the local MongoDB.

5. If the remote MongoDB was using a custom password rather than the default `mongoUsrpasswd@08` password, run the `install_dir/ccm/mongopasswd.sh` script to configure the local MongoDB and Cloud APM server to use your password.

## Results

The Cloud APM server is connected to the local MongoDB.

After you switch to the local version of MongoDB, *new* threshold events and *new* transaction tracking data are transferred between the Cloud APM server and the local MongoDB.

Existing open events and existing transaction tracking data are not migrated to MongoDB on the local system. Use the Linux **touch** command to modify the date and time of all of the `private_situation.xml` files in the subdirectories under the `install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/data_source` directory to view existing open events in the Cloud APM console.

## Related tasks

[“Installing a remote MongoDB” on page 169](#)

## Retaining middleware transactions

If you want to see middleware transaction instance details from more than the last 4 hours on the Instance Analysis dashboard for middleware agents, you must change the retention period in the MongoDB database.

### About this task

You can retain middleware transaction data for transaction tracking enabled agents such as WebSphere MQ agent, or DataPower agent in the MongoDB database for more than 4 hours. For the full list of transaction tracking enabled agents, see [“Transaction tracking” on page 80](#) or [“Capabilities” on page 60](#).

To change the retention period for middleware transaction tracking data, complete the following steps

### Procedure

1. Use the load projections spreadsheet to confirm that you have sufficient disk space to save more data in the MongoDB database: [IBM Cloud App Management Load Projections Spreadsheet](#) . The storage requirements for the MongoDB database are entered on the MongoDB and DatamartDB tab of the spreadsheet.
2. Edit the `install_dir/mongodb/scripts/cron/mongodb.cfg` file and change the default value for the `IIDOCRETSECS` and `MIDDOCRETSECS` properties from the default value of 18000 seconds to 82800 seconds to retain data in the MongoDB middleware collections for the last 23 hours. The 24th collection will be used to save data from the current hour of the day. You should not increase the values of the other retention properties in the `mongodb.cfg` file since they will not affect the data that you see in the transaction dashboards.

## Configuring the server to return the Strict Transport Security header

IBM Cloud Application Performance Management is vulnerable to the HTTP Strict Transport Security (HSTS) Policy Not Enabled issue by default. To prevent this vulnerability, you can configure the Cloud APM server to include the Strict Transport Security header in responses for HTTPS ports 9443, 8099, 8091, 8093, and 443.

### Before you begin

- If you are using the default self-signed certificates for the Cloud APM console on the Firefox browser, console users might not be able to accept the exception for the Cloud APM console self-signed certificates when Cloud APM returns the Strict Transport Security header. (The Firefox behavior might be different depending on whether your users are running Firefox on Windows or Firefox on macOS.) If you have this scenario, you need to create custom certificates using one of the approaches described in this topic before configuring Cloud APM to return the Strict Transport Security header: [“Configuring certificates for the Cloud APM console” on page 1148](#).
- The Cloud APM server does not return the Strict Transport Security header when an HTTP 404 response code (Not found) is returned.

### Procedure

Complete these steps on the Cloud APM server to return the Strict Transport Security header.

**Note:** These steps include editing the `webContainer` XML element for multiple Cloud APM services. The `webContainer` element might be different for each service. Therefore, ensure that you update the existing `webContainer` element for each service or add the `webContainer` element if it is not already defined rather than copying the same `webContainer` definition from one service to another service.

1. Configure the apmui service to return the Strict Transport Security header for HTTPS requests to port 9443:
  - a) If the `install_dir/wlp/usr/servers/apmui/server.xml` file contains a `webContainer` XML element, copy the element and its attributes to the `apmui/user-exit.xml` file, and then delete the `webContainer` element and its attributes from the `apmui/server.xml` file. For example, copy this line from `apmui/server.xml` to `apmui/user-exit.xml`, and then delete the line from `apmui/server.xml`: `<webContainer deferServletLoad="false" com.ibm.ws.webcontainer.disableServletContainerInitializerOnPrev8apps="true" />`
  - Note:** Your `webContainer` element might be different from the one in the example. Copy the version in your `server.xml` file to the `user-exit.xml` file rather than the example.
  - b) Edit the `apmui/user-exit.xml` file and add `addstricttransportsecurityheader="max-age=31536000;includeSubDomains"` to the `webContainer` element.  
Example:

```
<webContainer deferServletLoad="false"
com.ibm.ws.webcontainer.disableServletContainerInitializerOnPrev8apps="true"
addstricttransportsecurityheader="max-age=31536000;includeSubDomains"/>
```
2. Configure the oidc service to return the Strict Transport Security header for HTTPS requests to port 8099:
  - a) If the `install_dir/wlp/usr/servers/oidc/server.xml` file contains a `webContainer` XML element, copy the element and its attributes to the `oidc/user-exit.xml` file, and then delete the `webContainer` element and its attributes from the `oidc/server.xml` file.
  - b) Edit the `oidc/user-exit.xml` file:  
If you copied a `webContainer` element from the `oidc/server.xml` file to the `oidc/user-exit.xml` file, add `addstricttransportsecurityheader="max-age=31536000;includeSubDomains"` to the `webContainer` element that you copied. Otherwise, add the following `webContainer` element:

```
<webContainer addstricttransportsecurityheader="max-age=31536000;includeSubDomains"/>
```
3. Configure the server1 service to return the Strict Transport Security header for HTTPS requests to port 8091:
  - a) If the `install_dir/wlp/usr/servers/server1/server.xml` file contains a `webContainer` XML element, copy the element and its attributes to the `server1/user-exit.xml` file, and then delete the `webContainer` element and its attributes from the `server1/server.xml` file.  
The `webContainer` element might span multiple lines. Copy everything starting with `<webContainer` until you get to the `/>` closing characters for the XML element.
  - b) Edit the `server1/user-exit.xml` file and add `addstricttransportsecurityheader="max-age=31536000;includeSubDomains"` to the `webContainer` element.
4. Configure the uviews service to return the Strict Transport Security header for HTTPS requests to port 8093:
  - a) If the `install_dir/wlp/usr/servers/uviews/server.xml` file contains a `webContainer` XML element, copy the element and its attributes to the `uviews/user-exit.xml` file, and then delete the `webContainer` element and its attributes from the `uviews/server.xml` file.
  - b) Edit the `uviews/user-exit.xml` file and add `addstricttransportsecurityheader="max-age=31536000;includeSubDomains"` to the `webContainer` element.
5. Configure the min service to return the Strict Transport Security header for HTTPS requests to port 443:

- a) If the `install_dir/wlp/usr/servers/min/server.xml` file contains a `webContainer` XML element, then copy the element and all of its attributes to the `min/user-exit.xml` file, and then delete the `webContainer` element and its attributes from the `min/server.xml` file.  
The `webContainer` element might span multiple lines. Copy everything starting with `<webContainer` until you get to the `/>` closing characters for the XML element.
  - b) Edit the `min/user-exit.xml` file and add `addstricttransportsecurityheader="max-age=31536000;includeSubDomains"` to the `webContainer` element.
6. Restart the Cloud APM components by running the following command:

```
apm restart_all
```

**Note:** If you cannot log in to the Cloud APM console after making these updates or you do not see agent data in the dashboards, there might be an XML syntax error in one of the files that you updated.

## Backing up and restoring components

Backup and recovery of data files and databases is an essential operation for any business system, particularly for data and applications that are running in production environments. Create and follow a plan for backing up and recovering the data for all components of your Cloud APM infrastructure.

For disaster recovery planning, consider backing up the data on your Cloud APM server regularly and saving the backup file to a mounted drive or copying it to another server. If your Cloud APM server uses a remote Db2 server, you should also complete backups on the Db2 server. For more information, see [“Backing up components” on page 1227](#).

The Cloud APM server stores configuration data in local files and also in local internal Derby databases. The Cloud APM server Db2 databases contain the following data:

- DATAMART and prefetch (WAREHOUS) databases contain transaction tracking and resource monitoring metric data. If you changed the historical data retention values, the WAREHOUS database also contains configuration data.
- The SCR32 database contains resource group and application definitions.

It is important to keep the Cloud APM server local configuration data synchronized with the configuration data in the Db2 databases when the Db2 server is remote.

If you have a very recent backup file for the Cloud APM server and you need to recover the local configuration data on the Cloud APM server only, then you can complete a recovery procedure that just restores data on the Cloud APM server and not on a remote Db2 server. Otherwise, follow one of the following recovery scenarios that restore configuration data on the Cloud APM server and on the remote Db2 server.

The Cloud APM server where the backup is complete is called the source server. The Cloud APM server where the recovery is completed is called the target server. If there is a hardware issue with the source server, the target server can be on a different computer system from the source server. Otherwise, the source and target server can be the same computer system. The target server must be at the same release and interim fix level as the source Cloud APM server, and use the same type of database (local or remote), and database version.

If a remote Db2 server is configured for the source server, the target server can either use the same Db2 server, instance, and databases or different ones depending on whether the Cloud APM Db2 databases require recovery.

Recovery is a disruptive action. The Cloud APM server components are stopped and started multiple times throughout the process. Choose one of the following recovery methods to restore the configuration data from a backup file.

Table 286. Recovery scenarios, approaches, and procedures to follow.

**Note:** You should install IBM Cloud Application Performance Management Private, V8.1.4.0 interim fix 6 or later so that you have the fixes that are required to complete disaster recovery if the Cloud APM server is operational and to run the `restore.sh` script on the remote Db2 server when you are logged in as the Db2 instance user.

**Note:** A Cloud APM server is operational if you can use the Cloud APM console to log in and view monitoring data, custom views, events, thresholds, resource groups, synthetic scripts, and role based access control policies.

| Recovery scenario   | Recovery approach  | Recovery procedures to complete  |
|---|--|--|
| The Cloud APM server is configured to use a local Db2 server and the Cloud APM server is operational.     | If the Cloud APM server is operational and you want to restore a previous version of the configuration data, run the <code>restore.sh</code> script on the Cloud APM server. The restore script restores the Cloud APM server configuration data and the data in the local Db2 databases.  | See <a href="#">Restoring components for disaster recovery</a> .   |
| The Cloud APM server is configured to use a local Db2 server and the Cloud APM server is not operational. | <p>If the Cloud APM server is not operational and requires complete recovery, you must reinstall the Cloud APM server, and then run the restore script to restore the configuration data and Db2 databases.</p> <p>If there is no hardware issue, you can either reinstall the Cloud APM server on the source server or you can install the Cloud APM server on another computer system.</p> <p>If you must install the Cloud APM server on another computer system, then you should configure the target Cloud APM server to use the same host name and IP address as the source Cloud APM server. Otherwise, Cloud APM is not fully functional after the disaster recovery completes until you reconfigure your managed systems to point to a different Cloud APM server and inform your Cloud APM console users to log in with a different URL.</p> | <p>Complete these procedures in the following order:</p> <ol style="list-style-type: none"> <li>1. See <a href="#">“Installing the Cloud APM server for disaster recovery” on page 1236</a>.</li> <li>2. See <a href="#">Restoring components for disaster recovery</a>.</li> <li>3. If the target server is not the same system as the source server, and you cannot change the host name and IP address of the target server, then see <a href="#">“Changing the server IP address and host name” on page 1215</a>.</li> </ol> |

Table 286. Recovery scenarios, approaches, and procedures to follow.

**Note:** You should install IBM Cloud Application Performance Management Private, V8.1.4.0 interim fix 6 or later so that you have the fixes that are required to complete disaster recovery if the Cloud APM server is operational and to run the `restore.sh` script on the remote Db2 server when you are logged in as the Db2 instance user.

**Note:** A Cloud APM server is operational if you can use the Cloud APM console to log in and view monitoring data, custom views, events, thresholds, resource groups, synthetic scripts, and role based access control policies.

(continued)

(continued)

| Recovery scenario   | Recovery approach  | Recovery procedures to complete   |
|---|--|---|
| The Cloud APM server is configured to use a remote Db2 server, the Cloud APM server is not operational, and the remote Db2 databases also require recovery. | <p>For this scenario, you can either use the same remote Db2 server and databases that are configured for the source server or use a different Db2 server or databases. If you can use the same Db2 server and databases, you must drop the existing remote Db2 databases.</p> <p>If there is no hardware issue, you can either reinstall the Cloud APM server on the source server or you can install the Cloud APM server on another computer system. Before installing the Cloud APM server, you must create the databases on the remote Db2 server. After the installation is complete, run the <code>restore.sh</code> script on the remote Db2 server and on the Cloud APM server.</p> <p>If you must install the Cloud APM server on another computer system, then you should configure the target Cloud APM server to use the same host name and IP address as the source Cloud APM server. Otherwise, Cloud APM is not fully functional after the disaster recovery completes until you reconfigure your managed systems to point to a different server and inform your Cloud APM console users to log in with a different URL.</p> | <p>Complete these procedures in the following order:</p> <ol style="list-style-type: none"> <li>1. See <a href="#">“Installing the Cloud APM server for disaster recovery” on page 1236</a>, which also refers you to <a href="#">“Connecting to a remote Db2 server” on page 146</a>.</li> <li>2. See <a href="#">Restoring components for disaster recovery</a>.</li> <li>3. If the target server is not the same as the source server and you cannot change the host name and IP address of the target server, see <a href="#">“Changing the server IP address and host name” on page 1215</a>.</li> </ol> |

A high availability solution that uses backup and restore is also available for your Cloud APM server. For more information, see the `APM_High_Availability_V<version>.pdf` document in the IBM-cloud-apm-samples github repository, where `<version>` is the latest version published, only the latest version is available in the github repository.

For information about backing up and restoring when you are upgrading your Cloud APM server, see [“Upgrading your server” on page 1307](#).

## Configuring role administrator password

When you use LDAP to authenticate Cloud APM console users, the `backup.sh` and `restore.sh` scripts need the password of the primary role administrator. You can provide the user's password on the command line by using the `backup.sh` and `restore.sh -p` option. You can also run the `roleadmin_password.sh` script to save the primary role administrator's password in an internal keystore.

### About this task

If you run the `roleadmin_password.sh` script, then specify the `-P` option for the `backup.sh` and `restore.sh` scripts, the scripts will retrieve the password from the internal keystore so that you are not required to provide the password on the command line.

The primary role administrator is the user that is specified for the **systemUser** attribute in the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file. The `server-oauth2-tai.xml` contains the user's LDAP distinguished name, which is different from the username that is entered on the Cloud APM server login page.

If you change the user who is specified in the `server-oauth2-tai.xml` file or if the user's password changes, you need to run the `roleadmin_password.sh` script again to specify the new password.

**Note:** To run the `roleadmin_password.sh` script, you must apply Cloud APM Version 8.1.4.0 Server Interim Fix 11(8.1.4.0-IBM-APM-SERVER-IF0011) or a later server interim fix. Interim fixes for the Cloud APM server version 8.1.4 are available to download from [IBM Fix Central](#).

### Procedure

On your Cloud APM server, do these steps to configure the role administrator's password:

1. Change to the `install_dir/ccm` directory.
2. Run the `roleadmin_password.sh` script.
3. After you are prompted to provide a new password, type the password, press Enter, and retype the new password as prompted.

### What to do next

When you run the `backup.sh` and `restore.sh` scripts, specify the `-P` option so that the primary role administrator's password is retrieved from the internal keystore and you do not have to specify the password on the command line.

## Backing up components

The Cloud APM server configuration and metric data is backed up using the `backup.sh` script.

### Before you begin

Before you back up the Cloud APM server or the Db2 databases on a remote Db2 server, ensure that you create a location on your file system such as a mounted NFS drive to store the output of the backup command. The backup file with the Db2 database data can be large.

When you are backing up the Cloud APM server Db2 databases, you can either complete an offline backup or an online backup. By default, Db2 is configured for offline backups. For an offline database backup, the Cloud APM `backup.sh` script quiesces database activity at the database level by default. However, database backups might fail if connections to the database still exist when the offline backup runs. If a failure occurs, retry the backup. If the failure persists, the `backup.sh` script provides the `-q inst` option that allows you to quiesce all database activity at the database instance level. Quiescing at the instance level can be more efficient for stopping all database connections but it prevents all users from

connecting to the Db2 database instance and can prevent connections to other databases under the Db2 database instance. For more information about the Db2 **QUIESCE** command, see the [QUIESCE command](#).

Alternatively, you can enable an online backup of the Db2 databases which runs in the background. While the online backup is running, applications can continue to access the database so no downtime occurs. Online database backups are recommended for production environments.

If you want to complete an online database backup, enable online backups by following the procedure in [“Enabling online backup of the Db2 databases”](#) on page 1230. Once you enable online backups, the Cloud APM server backup . sh script completes an online database backup by default.

When you have LDAP configured, if you do not want to enter the primary role administrator's password on the command line, you can run the `roleadmin_password.sh` script. The primary role administrator's password is stored in an internal keystore and you can specify the `-P` option for the `backup.sh` and `restore.sh` scripts. Then the scripts will retrieve the password from the internal keystore so that you are not required to provide the password on the command line. For more information, see [configuring role administrator password](#).

## About this task

Complete regular backups on your Cloud APM server and on your Db2 server if it is on a remote computer system. Save the backup file to another server or mounted drive so you can complete recovery if your Cloud APM server becomes corrupted and must be restored later.

If your Cloud APM server is using a local Db2 server, run the `backup.sh` script on the Cloud APM server to backup the local configuration data and Db2 databases. If your Cloud APM server is connected to a remote Db2 server, run the `backup.sh` script on the Cloud APM server to backup local configuration data and also run the `backup.sh` script on the remote Db2 server to backup the Db2 databases.

## Procedure

Back up the Cloud APM server configuration data and the Db2 databases by completing the following steps:

1. Log on as the root user to your Cloud APM server.
2. The `TMOUT` environment variable should not be set when the Cloud APM server `backup.sh` script is executed because it may cause the backup process to exit before the backup has completed. To confirm that the variable is not set, perform these steps:
  - a) Enter the following command and confirm that the `TMOUT` environment variable is not set:

```
env | grep TMOUT
```

- b) If the variable is set then enter this command to unset it:

```
unset TMOUT
```

- c) If the `unset` command fails then your OS administrator may have defined the `TMOUT` variable as read-only so work with your administrator to unset it before you backup the Cloud APM server. You can set the `TMOUT` environment variable back to its original value after the Cloud APM server backup completes.
3. As the root user, run the `install_dir/ccm/backup.sh` script on the Cloud APM server to generate the backup tar file. Specify the following options:

```
backup.sh -f backup_file -u roleadmin_user -p roleadmin_password  
-j warehous_db_name -k scr_db_name -l datamart_db_name  
-q inst -t tmp_dir
```

where:

- `-f backup_file` is the name and file path of the backup TAR file. By default, the script creates a backup TAR file in the `install_dir/backups` directory.

- `-u roleadmin_user` is the primary role administrator user ID. If you are using the basic registry to authenticate Cloud APM console users, specify `apmadmin`. If you are using LDAP to authenticate Cloud APM console users, specify the LDAP user that is configured as the `systemUser` value in the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file. When you are specifying the LDAP user name, specify it in the same format that you use when logging into the Cloud APM console. The default name is `apmadmin`.
- `-p apmadmin_password` is the password of the user specified by the `-u` option. The default password is `apmpass`. If you are using the basic registry, you can omit the `-p` option and the `apmadmin` user's password is retrieved from an internal keystore.

**Note:** If you provide a custom password that has non-alphanumeric characters, you must surround the password with single quotation marks. For example, `-p 'Z!@12ws*'`

- `-P` this option can be used instead of the `-p` option if you use the `roleadmin_password.sh` script to save the primary role administrator's password. When you use this option, the primary role administrator's password is retrieved from the internal key store and you do not have to specify it on the command line.
- `-j warehous_db_name` is the name of the Warehouse database. The default name is `WAREHOUS`.
- `-k scr_db_name` is the name of the SCR database. The default name is `SCR32`.
- `-l datamart_db_name` is the name of the Datamart database. The default name is `DATAMART`.
- `-q inst` This is an optional parameter that can be specified if you are performing an offline Db2 backup and need to quiesce all database activity during the backup. By default, database activity is quiesced at the database level but database backups might fail if the Cloud APM server or other applications are accessing the Cloud APM databases during the backup. You can specify this option to quiesce all database activity so that the backup succeeds. However, if you are using the Cloud APM Monitoring Agent for Db2, the Monitoring Agent for Db2 can still access the database even if this option is specified and may cause the database backup to fail. If that occurs either stop the Monitoring Agent for Db2 or retry the backup. If you decide to specify this option, enter `-q inst` as shown in the command example. Do not replace `inst` with the Db2 instance user.

**Note:** This option prevents all users from connecting to the Db2 database instance and can prevent connections to other databases under the Db2 database instance. For more information about the Db2 **QUIESCE** command, see the **QUIESCE** command.

- `-t tmp_dir` is the directory that you are using for the temporary files. The default directory is `/tmp`.
4. If your Cloud APM server is configured to use a remote Db2 server, complete the following additional steps:
    - a. Copy the `install_dir/ccm/backup.sh` and `restore.sh` scripts from the system where the Cloud APM server is installed to the system where Db2 is installed if the file is not previously copied. Ensure that the scripts have permissions so that they can be run by the Db2 database instance user. If you installed a Cloud APM server interim fix recently, copy the latest `backup.sh` and `restore.sh` scripts to the Db2 server.
    - b. Log in as the Db2 instance user on the system where Db2 is installed.
    - c. Run the `backup.sh` script with the following options to backup the Cloud APM Db2 databases.

```
backup.sh -f backup_file -j warehous_db_name
-k scr_db_name -l datamart_db_name -q inst -z custom_Db2_instance_name -t tmp_dir
```

where:

- `-f backup_file` is the name and file path of the backup TAR file. By default, the script creates a backup TAR file in the `install_dir/backups` directory.
- `-j warehous_db_name` is the name of the Warehouse database. The default name is `WAREHOUS`.
- `-k scr_db_name` is the name of the SCR database. The default name is `SCR32`.
- `-l datamart_db_name` is the name of the Datamart database. The default name is `DATAMART`.
- `-q inst` Enter the `-q inst` as shown in the previous command. Do not replace `inst` with the Db2 instance. If you are completing an offline database backup, use this option to quiesce

database activity at the Db2 instance level instead of at the database level. By default, activity is quiesced at the database level but database backups might fail if applications that are accessing the database during the backup so you might need to specify this option to quiesce all database activity.

**Note:** This option prevents all users from connecting to the Db2 database instance and can prevent connections to other databases under the Db2 database instance. For more information about the Db2 **QUIESCE** command, see the [QUIESCE](#) command.

- `-z custom_Db2_instance_name` is the Db2 instance user ID. The default user ID is db2apm.
- `-t tmp_dir` is the that you are using for the temporary files. The default directory is `/tmp`.

## Results

The Cloud APM server backup is complete and the data is stored in a TAR file that can be used to recover your Cloud APM server and its Db2 databases.

## What to do next

When your Cloud APM server requires recovery, restore the backed up data by following the steps in [“Restoring components for disaster recovery”](#) on page 1232

### ***Enabling online backup of the Db2 databases***

By default, the Cloud APM Db2 databases are configured for offline backup, which means database activity must be stopped before you run a backup. You can enable an online backup of the Db2 databases to run in the background. While the online backup is running, applications can continue to access the database so no downtime occurs.

## About this task

Several backup options are available for Cloud APM Db2 databases, so the solution that is included in this task might require modification for specific environments.

To enable online backup, modify the database configuration. This example specifies a configuration for full backup. Full backup requires substantial disk space and takes more time because the entire database is being backed up each time. Db2 provides a means for incremental backup that has several options.

- For more information about configuring incremental backup, see [Incremental backup and recovery](#) and [Restoring from incremental backup images](#).
- For descriptions of the Db2 configuration parameters that are used in this task, see [Db2 database configuration parameters](#).
- If you need to access any other Db2 documentation, see [IBM Db2 10.5 for Linux, Unix and Windows topic collection](#) on IBM Knowledge Center.

You can use the following Db2 configuration parameters for online backup configuration. All these parameters are optional except the **LOGARCHMETH1** parameter, which is mandatory.

### **LOGARCHMETH1**

This mandatory parameter specifies the media type. Change the drive that is specified on this property to an appropriate directory.

### **AUTO\_DEL\_REC\_OBJ**

This optional parameter specifies whether database log files, backup images, and load copy images must be deleted when their associated recovery history file entry is pruned.

### **REC\_HIS\_RETENTN**

This optional parameter specifies the number of days that historical information about backups is retained.

### **NUM\_DB\_BACKUPS**

This optional parameter specifies the number of full database backups to retain for a database.

## LOGARCHCOMPR1

This optional parameter specifies whether the log files that are written to the primary archive destination for logs are compressed.

**Tip:** The following procedure enables log files to be archived on the disk permanently. You can prune the history and log files with some Db2 commands. For more information, see [PRUNE HISTORY/LOGFILE](#).

## Procedure

1. To configure the SCR32 database for online backup, run the following command as the db2apm user.  
The directory path in the following command is for example purposes only. The Db2 administrator can choose the directory to contain the database logs.

```
mkdir -p /db2_dir/logs/SCR32/archive
```

where *db2\_dir* is the directory that contains all the database log files.

Start the Db2 command line processor (command **db2**) and run the following Db2 commands:

```
CONNECT TO SCR32;  
UPDATE DB CFG FOR SCR32 USING LOGARCHMETH1 'DISK: /<db2_dir>/logs/SCR32/archive';  
UPDATE DB CFG FOR SCR32 USING AUTO_DEL_REC_OBJ ON;  
UPDATE DB CFG FOR SCR32 USING REC_HIS_RETENTN 10;  
UPDATE DB CFG FOR SCR32 USING NUM_DB_BACKUPS 10;  
UPDATE DB CFG FOR SCR32 USING LOGARCHCOMPR1 OFF;  
DISCONNECT CURRENT;
```

2. To configure the WAREHOUS database for online backup, run the following Db2 command as the db2apm user.

The directory path in the following command is for example purposes only. The Db2 administrator can choose the directory to contain the database logs.

```
mkdir -p /db2_dir/logs/WAREHOUS/archive
```

Start the Db2 command line processor (command **db2**) and run the following commands:

```
CONNECT TO WAREHOUS;  
UPDATE DB CFG FOR WAREHOUS USING LOGARCHMETH1 'DISK: /<db2_dir>/logs/WAREHOUS/archive';  
UPDATE DB CFG FOR WAREHOUS USING AUTO_DEL_REC_OBJ ON;  
UPDATE DB CFG FOR WAREHOUS USING REC_HIS_RETENTN 10;  
UPDATE DB CFG FOR WAREHOUS USING NUM_DB_BACKUPS 10;  
UPDATE DB CFG FOR WAREHOUS USING LOGARCHCOMPR1 OFF;  
DISCONNECT CURRENT;
```

3. To configure the DATAMART database for online backup, run the following Db2 command as the db2apm user:

The directory path in the following command is for example purposes only. The Db2 administrator can choose the directory to contain the database logs.

```
mkdir -p /db2_dir/logs/DATAMART/archive
```

Start the Db2 command line processor (command **db2**) and run the following commands:

```
CONNECT TO DATAMART;  
UPDATE DB CFG FOR DATAMART USING LOGARCHMETH1 'DISK: /<db2_dir>/logs/DATAMART/archive';  
UPDATE DB CFG FOR DATAMART USING AUTO_DEL_REC_OBJ ON;  
UPDATE DB CFG FOR DATAMART USING REC_HIS_RETENTN 10;  
UPDATE DB CFG FOR DATAMART USING NUM_DB_BACKUPS 10;  
UPDATE DB CFG FOR DATAMART USING LOGARCHCOMPR1 OFF;  
DISCONNECT CURRENT;
```

4. Run an initial offline database backup after you configure the database for online backup. Stop the processes that use the databases. To run the initial offline backup, run the following commands:
  - a) As the root user, run the following commands:

```
apm stop_all  
apm start db2
```

b) As the db2apm user, run the following commands:

```
db2 backup db SCR32 to /dev/null
```

```
db2 backup db WAREHOUS to /dev/null
```

```
db2 backup db DATAMART to /dev/null
```

c) As the root user, run the following command:

```
apm start_all
```

## Results

The databases are now ready for online backup. When you run the `Cloud APM backup . sh` script, an online database backup is completed.

## Restoring components for disaster recovery

If disaster recovery is required for your Cloud APM server configuration data, run the `restore . sh` script to restore the server components and their databases to the configuration data in a recent back up file.

### Before you begin

To complete the recovery, you must have a recent backup file. If your Cloud APM server is using a remote Db2 server, you need a backup file for your Cloud APM server and optionally a backup file for your remote Db2 server. You should complete regular backups so that you have backup files ready if recovery is required. For more information about how to create backup files, see [“Backing up components” on page 1227](#).

In this topic, the source server indicates the Cloud APM server where the backup file was created and the target server indicates the Cloud APM server where the recovery is completed. The source and target servers can be the same computer system or different computer systems.

For the recovery scenarios and to help you decide which approach to use, see “Backing up and restoring components” on page 1222. If you choose an approach that requires reinstalling the Cloud APM server on same computer system or installing the Cloud APM server on another system, you must complete the Cloud APM server installation before running the `restore . sh` script. For instructions, see [“Installing the Cloud APM server for disaster recovery” on page 1236](#).

If your Cloud APM server is using a remote Db2 server, and you must complete recovery for the databases, then you must run the `restore . sh` script on the remote Db2 server, and then on the Cloud APM server.

When you have LDAP configured, if you do not want to enter the primary role administrator's password on the command line, you can run the `roleadmin_password . sh` script. The primary role administrator's password is stored in an internal keystore and you can specify the `-P` option for the `backup . sh` and `restore . sh` scripts. Then the scripts will retrieve the password from the internal keystore so that you are not required to provide the password on the command line. For more information, see [configuring role administrator password](#).

Recovery is a disruptive action. The Cloud APM server components are stopped and started multiple times throughout the process

### Procedure

Complete the following steps. For the steps that you must complete on the Cloud APM server, you must be the root user.

1. The *TMOUT* environment variable should not be set when the Cloud APM server `restore.sh` script is executed because it may cause the restore process to exit before the process has completed. To confirm that the variable is not set, perform these steps:

- a) Enter the following command and confirm that the *TMOUT* environment variable is not set:

```
env | grep TMOUT
```

- b) If the variable is set then enter this command to unset it:

```
unset TMOUT
```

- c) If the `unset` command fails then your OS administrator may have defined the *TMOUT* variable as read-only so work with your administrator to unset it before you restore the Cloud APM server. You can set the *TMOUT* environment variable back to its original value after the Cloud APM server restore completes.

2. On the target Cloud APM server, stop all the server components by issuing the following command.

```
apm stop_all
```

3. If the target Cloud APM server is on a different computer system than the source Cloud APM server, complete the following steps:

- a. If the source Cloud APM server is still operational, stop all of the server components by issuing the following command on the source server.

```
apm stop all
```

Shutdown the computer system.

- b. Configure the target Cloud APM server to use the same host name and IP address as the source Cloud APM server. If you cannot change the hostname and IP address of the target server then you must reconfigure all of your agents and data collectors to connect to the target Cloud APM server hostname or IP address after the restore is complete. See the [first bullet point](#) in the What to do next section for more details.

4. If your target Cloud APM server is configured to use a remote Db2 server and you must recover your Cloud APM Db2 databases, then complete the following steps on the remote Db2 server as the Db2 instance user ID.

- a. Copy the backup file for your Cloud APM Db2 databases to the Db2 server or ensure it can be accessed from a mounted drive. The Db2 instance user ID must have read access to the file.
- b. Copy the `install_dir/ccm/restore.sh` script from your target Cloud APM server to the Db2 server and ensure the Db2 instance user has permission to execute the script.
- c. Run the `restore.sh` script with the following options:

```
restore.sh -f backup_file -j warehouse_db_name  
-k scr_db_name -l datamart_db_name -q inst  
-z custom_Db2_instance_name -1 warehouse_db_log_path -2 scr-db_log_path -3  
datamart_db_log_path
```

where:

- `-f backup_file` is the file name and path to the backup TAR file. This option is mandatory.
- `-j warehouse_db_name` is the name of the Warehouse database. The default name is WAREHOUS.
- `-k scr_db_name` is the name of the SCR database. The default name is SCR32.
- `-l datamart_db_name` is the name of the Datamart database. The default name is DATAMART.
- `-q inst` Enter the `-q inst` as shown in the previous command. Do not replace `inst` with the Db2 instance. Use this option to quiesce database activity at the Db2 instance level instead of at the database level. By default, activity is quiesced at the database level but database restores might fail if applications that are accessing the database during the restore so you might need to specify this option to quiesce all database activity.

**Note:** This option prevents all users from connecting to the Db2 database instance and can prevent connections to other databases under the Db2 database instance. For more information about the Db2 **QUIESCE** command, see the [QUIESCE command](#).

- `-z custom_Db2_instance_name` is the Db2 instance user ID. The default user ID is `db2apm`.
- `-1 warehouse_db_log_path` is the path to the log files for the database specified using the `-j` option or the WAREHOUS database if the `-j` option is not specified. The default path is the log file path that was used when the database backup was taken.
- `-2 scr-db_log_path` is the path to the log files for the database specified using the `-k` option or the SCR32 database if the `-k` option is not specified. The default path is the log file path that was used when the database backup was taken.
- `-3 datamart_db_log_path` is the path to the log files for the database specified using the `-l` option or the DATAMART database if the `-l` option is not specified. The default path is the log file path that was used when the database backup was taken.

**Note:** The database restore uses the same database storage path that was used on the Db2 server where the backup file was created.

5. On your target Cloud APM server, complete the following steps:

- a. Copy the backup file from your Cloud APM server to the computer system where you are completing the recovery or ensure it can be accessed from a mounted drive. The root user must have read access to the backup file.
- b. Run the `restore.sh` script with the following options:

```
restore.sh -f backup_file -u roleadmin_user -p roleadmin_password  
-j warehous_db_name -k scr_db_name -l datamart_db_name -q inst
```

where:

- `-f backup_file` file name and path to the backup TAR file for the Cloud APM server. This option is mandatory.
- `-u roleadmin_user` is the primary role administrator user ID. If you are using the basic registry to authenticate Cloud APM console users, specify `apmadmin`. If you are using LDAP to authenticate Cloud APM console users, specify the LDAP user that is configured as the `systemUser` value in the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file. When you are specifying the LDAP user name, specify it in the same format that you use when logging into the Cloud APM console. The default name is `apmadmin`.
- `-p apmadmin_password` is the password of the user specified by the `-u` option. The default password is `apmpass`. If you are using the basic registry, you can omit the `-p` option and the `apmadmin` user's password is retrieved from an internal keystore.

**Note:** If you provide a custom password that has non-alphanumeric characters, you must surround the password with single quotation marks. For example, `-p 'Z!@12ws*'`

- `-P` this option can be used instead of the `-p` option if you use the `roleadmin_password.sh` script to save the primary role administrator's password. When you use this option, the primary role administrator's password is retrieved from the internal key store and you do not have to specify it on the command line.
- `-j warehous_db_name` is the name of the Warehouse database. The default name is WAREHOUS.
- `-k scr_db_name` is the name of the SCR database. The default name is SCR32.
- `-l datamart_db_name` is the name of the Datamart database. The default name is DATAMART.
- `-q inst` Enter the `-q inst` as shown in the previous command. Do not replace `inst` with the Db2 instance. If your Db2 server is local, use this option to quiesce database activity at the Db2 instance level instead of at the database level. By default, activity is quiesced at the database level but database restores might fail if applications that are accessing the database during the restore so you might need to specify this option to quiesce all database activity.

**Note:** This option prevents all users from connecting to the Db2 database instance and can prevent connections to other databases under the Db2 database instance. For more information about the Db2 **QUIESCE** command, see the [QUIESCE command](#).

6. If you configured your target Cloud APM server to use different remote Db2 databases than the source Cloud APM server, then some of the target Cloud APM server components are configured to use the source server databases after the restore finishes. Complete the steps in [“Updating the Cloud APM server configuration for Db2 server changes”](#) on page 1206 to reconfigure the target Cloud APM server to use its databases.
7. If you completed the restore using a database backup file that was created more than two days ago then there may not be active partitions in the WAREHOUS database after the restore completes. As a result, you won't see any resource monitoring data in the Cloud APM console dashboard pages. To force the ksy service to create new partitions now (instead of waiting until 2 am), complete the following steps as the root user on the Cloud APM server.
  - a. Issue the `apm stop ksy` command.
  - b. Edit the `install_dir/sy/config/sy.ini` file and uncomment `KSY_ON_DEMAND=Y` by removing the `#` tag at the beginning of the line with this environment variable.
  - c. Go to the `install_dir/sy/bin` directory by issuing the following command:

```
cd install_dir/sy/bin
```

- d. Issue the `itmcmd agent start sy` command.
- e. Check the latest `*sy_java*` log file in the `install_dir/sy/logs` directory. If you see the following messages at the end of the log file, you can confirm that the partitions are created successfully. It can take some time to create the partitions for the multiple agents.

```
== 4750 t=Thread-5 Summarization and pruning agent successfully ended  
== 2017-12-03 03.03.02.264 +0800 : Trace paused
```

- f. Issue the `itmcmd agent stop sy` command.
- g. Edit the `install_dir/sy/config/sy.ini` file and comment out the `KSY_ON_DEMAND=Y` line by adding the `#` tag at the beginning of the line with this environment variable.
- h. Issue the `apm start ksy` command.

## Results

The Cloud APM server recovery is complete. You can now access data for your agents and other components from your Cloud APM server.

## What to do next

- If you could not complete [step 2.b](#), then complete the steps in [“Changing the server IP address and host name”](#) on page 1215 to update the IP address and host name that are used by the target Cloud APM server components and by your agents and data collectors. Also, if a different URL is needed to log in, notify your Cloud APM console users.
- During the restore process, the Cloud APM server key files are changed, which does not affect existing agents and data collectors. However, the key files in the agent and data collector images are not updated if you installed or reinstalled the Cloud APM server for the recovery. If you intend to install new agents and data collectors with secure HTTPS communications between the Cloud APM server and agents by using the newly configured agent or data collector images that were generated during the Cloud APM server installation, you must reconfigure the agents and data collector images to pick up the restored key files. When you run the `make_configuration_packages.sh` script to create the configuration packages, ensure that you select the HTTPS protocol. For more information, see [“Configuring the downloaded images”](#) on page 182.

- If your Cloud APM server is configured to use HTTPS communication for agent to server communication, update the communication protocol and certificates that are used by the Cloud APM server agents. For more information, see [“Configuring the communications protocol for server agents”](#) on page 1217.

### ***Installing the Cloud APM server for disaster recovery***

If you are installing a new Cloud APM server or reinstalling an existing Cloud APM server for disaster recovery, you must ensure the Cloud APM server has the same version, interim fix, passwords, and database version as the Cloud APM server where the backup was completed.

### **About this task**

When you complete disaster recovery, you restore the Cloud APM server configuration from a backup file. In this procedure, the source server indicates the Cloud APM server where the backup file was created and target server indicates the Cloud APM server where the restore is completed. The source and target servers can be the same computer system or different systems. For more information, see [“Backing up and restoring components”](#) on page 1222.

When you install the Cloud APM server on the target server, you must meet the following requirements:

- Install the same version and offering of the Cloud APM server on the target server as the source server. If a Cloud APM server interim fix is installed on the source server, you must install the same Cloud APM server interim fix on the target server. To download the required interim fix, go to [IBM Fix Central](#).
- Configure the same type of Db2 database (either local or remote) on the target server as the source server. If you installed a Db2 fix pack on the Db2 server that is used by the Cloud APM source server, then you must apply the same Db2 fix pack on the database server that is used by the Cloud APM target server before you complete the restore so that the source and target servers are using the same version of Db2. For more information about Db2 fix packs, see the Db2 IBM Knowledge Center for the Db2 version that you are running. For example, for Db2 version 11.1, see the [IBM® Db2 Version 11.1 Knowledge Center](#).
- Use the same installation path on the target server as the source server.
- Use the same passwords for the following user IDs on the target server as the source server:
  - apmadmin
  - smadmin
  - MongoDB user IDs
  - itmuser
  - db2apm user when the Cloud APM server database is local.

For more information, see [“Default users and passwords”](#) on page 1194.

### **Procedure**

1. If the target Cloud APM server is the same as the source server, uninstall the Cloud APM server. For instructions, see [“Uninstalling the server”](#) on page 165.

**Note:** You must complete the following tasks before you attempt to reinstall the local Db2 server.

- Uninstall the Db2 server or client if it is already installed.
  - Delete all Cloud APM Db2 users such as db2apm, itmuser, dasusr1, and db2fenc1 from the Cloud APM server.
  - Delete all user groups such as db2iadm1, db2fadm1, and dasadm1 from the Cloud APM server.
  - Delete all home directories from the Cloud APM server.
2. If the source Cloud APM server is configured to use a remote Db2 server, you have three options:
    - a. If the target Cloud APM server is being installed so that it is ready for a future disaster recovery and you plan to continue using the source Cloud APM server until recovery is required, or you need the target Cloud APM server to use a different remote Db2 server, instance or databases, then the

target Cloud APM server must be installed and configured to use different Db2 databases than the source Cloud APM server. Create the new databases by following the steps in [“Connecting to a remote Db2 server”](#) on page 146.

- b. Or if you are ready to complete recovery and the Cloud APM server databases require recovery, then the target Cloud APM server can use the same Db2 server, Db2 instance user, and database names as the source Cloud APM server. For this scenario, complete the following steps:
    - i) If the source Cloud APM server components are still running, stop all the server components by issuing the **apm stop\_all** command on the source server.
    - ii) Work with your database administrator to drop the three Cloud APM server databases.
    - iii) Re-create the databases by following the steps in [“Connecting to a remote Db2 server”](#) on page 146.
  - c. Or if you are ready to complete recovery and you plan to complete recovery on the Cloud APM server only and not on the Db2 server, then the target Cloud APM server is configured to use the local database server during installation and is reconfigured to use the same databases as the source Cloud APM server after installation completes.
3. Complete the server installation on the target Cloud APM server.

First review these topics to determine if any of them apply:

[“Setting HTTP or HTTPS communications”](#) on page 145

[“Installing on a system using an external directory service”](#) on page 156

[“Creating Db2 users before you connect to a local Db2 server”](#) on page 158

**Note:** If your Db2 users for the source server had custom passwords then you must perform the steps in this topic:

[“Creating Db2 users before you connect to a local Db2 server”](#) on page 158

Then install the Cloud APM server. For instructions, see:

[“Downloading and installing the server”](#) on page 159

**Note:** If the source Cloud APM server is configured to use a remote Db2 server and you are following option 2.c., then you must install the target Cloud APM server to use a local Db2 server so that the installation process does not change the existing databases. After the Cloud APM server installation is complete, then reconfigure the target Cloud APM server to use the same databases as the source Cloud APM server by completing the steps in the following topics:

- a. [“Cataloging Db2 databases after changing the Db2 server”](#) on page 1204
- b. [“Updating the Cloud APM server configuration for Db2 server changes”](#) on page 1206. Remember to set the itmuser password to the itmuser password on the remote Db2 server when you are completing this procedure.
- c. See [“Changing a password”](#) on page 1195 to set the password for the db2apm instance user to match the Db2 instance password on your remote Db2 server so that the `restore.sh` script can determine the remote Db2 instance password when you complete a disaster recovery.

## Results

The target Cloud APM server installation is complete and the server is ready to be used for recovery.

## What to do next

Complete recovery by using a recent backup file. For instructions, see [“Restoring components for disaster recovery”](#) on page 1232.

## Exploring the APIs

---

Use the IBM Cloud Application Performance Management APIs to create scripts for automating the onboarding of your IBM Cloud Application Performance Management, Private environment. From the Cloud APM API-managed service offering in API Explorer on IBM developerWorks, you can access and explore the available Resource Group Management Service API, Threshold Management Service API, and Role-Based access control Service API.

## Procedure

1. Open the API Explorer in your browser: <https://developer.ibm.com/api>.
2. Select the IBM Cloud Application Performance Management API tile.
3. Click **Documentation** on the left side of the API Explorer window.
4. Select the specific API.
5. Select the sub section to expand the list of API operations.
6. Select an API operation for more details.
7. Select one of the languages (such as shell or curl) at the top of the [API Explorer page](#) to view a request example.

## What to do next

For more information about how to get your access token and run API operations, see the following topics:

[“Accessing and using the Role-Based Access Control Service API” on page 1156](#)

[“Using the Resource Group Management Service API” on page 1130](#)

[“Using the Threshold Management Service API” on page 1133](#)

## Adjusting the console timeout value

---

When you start the Cloud APM console, an LTPA (Lightweight Third-Party Authentication) token and an OIDC (OpenID Connect) ID token are granted during the logon process. The LTPA token has a default expiration timeout of 200 minutes after which you are automatically logged off. You can adjust the timeout value to accommodate your work requirements.

### Before you begin

The OIDC ID token has an expiration of 120 minutes after which you are presented with the login page. The expiration time of the LTPA token is configurable but the expiration time of the OIDC ID token is not configurable, which has the following implications:

- If OIDC is enabled for Cloud APM, which is the default behavior, setting the LTPA token expiration to a value greater than 120 minutes has no effect since that is when the OIDC ID token expires and console users are presented with the login page. Thus, when OIDC is enabled, you can configure the console to time out before the OIDC ID token expires by setting the LTPA token expiration to a value below 120 minutes.
- You can disable OIDC so that you can extend the console timeout. Complete the steps in [“Disabling OpenID Connect authentication for the Cloud APM console” on page 1088](#) followed by step “9” on [page 1090](#) (specify the domain name of the Cloud APM server for the **ssoDomainNames** attribute) through step “13” on [page 1091](#) of [“Enabling single sign-on between Cloud APM and Tivoli Common Reporting” on page 1089](#). You can perform these steps even if you are not integrating with another product such as Tivoli Common Reporting or Dashboard Application Services Hub.

**Note:** You must install the Cloud APM server V8.1.4.0 interim fix 9 or later if you perform this procedure so that the timeout value in the `user-exit.xml` files is used. (The `user-exit.xml` file is an override file for `server.xml`.) You can either install the interim fix before or after performing the procedure. You can download the interim fix for Cloud APM server V8.1.4 from [IBM Fix Central](#).

## Procedure

Complete these steps on the system where the Cloud APM server is installed to change the LTPA token expiration and `httpSession` values in the `user-exit.xml` files:

1. Open the `install_dir/wlp/usr/servers/apmui/user-exit.xml` file in a text editor.
2. If the `<ltpa expiration>` xml element does not exist in the `user-exit.xml` file, copy this element from `server.xml` to `user-exit.xml`.

3. Edit the `<ltpa expiration="200m" />` parameter and change the LTPA expiration value to a positive integer followed by a unit of time, which can be hours (h) or minutes (m).  
For example, "8h" specifies 8 hours.  
The maximum value supported for the timeout is 35,791 minutes (m) or 596 hours (h), which is about 24 days. Use lower case "h" or "m". If you use a capital letter (such as "H") or a different letter (such as "d"), your connection will be dropped by the Liberty component of the Cloud APM server without warning.
4. Remove the `<ltpa>` xml element from the `install_dir/wlp/usr/servers/apmui/server.xml` file.
5. Open the `install_dir/wlp/usr/servers/uview/user-exit.xml` file in a text editor.
  - a) Add the `<ltpa expiration>` xml element if it does not exist, and set the value to match the expiration value in the `install_dir/wlp/usr/servers/apmui/user-exit.xml` file (step "3" on page 1239).
  - b) Add the `<authCache>` xml element below if it does not exist and set the timeout attribute to the same value as the LTPA expiration time from step 5a. For example:
 

```
<authCache timeout="300m"/>
```
  - c) Add the `<httpSession>` xml element below if it does not exist, and set the `invalidationTimeout` attribute to the same value as the LTPA expiration time from step 5a.  
For example: `<httpSession  
 invalidateOnUnauthorizedSessionRequestException="true" cookieSecure="true"  
 invalidationTimeout="300m" />`
6. Remove the `<ltpa>`, `<authCache>`, and `<httpSession>` xml elements from the `install_dir/wlp/usr/servers/uview/server.xml` file.
7. Save and close both `user-exit.xml` files.

## Results

The next time users log in to the Cloud APM server, they are logged out after the timeout period is passed.

# Advanced Configuration

---

Use the **Advanced Configuration** page to control communications settings and advanced features such as event forwarding.

After you click  **System Configuration** > **Advanced Configuration**, the following configuration categories are displayed in the Advanced Configuration page.

## UI Integration

For products that integrate with the Cloud APM console, you can add or edit the URL for launching the integrated application. The fields are populated with any URLs that were set during the integration configuration procedure.

- **Cognos Reporting URL** is used to launch the IBM Cognos Viewer for viewing the Cloud APM reports through  **Reporting** > **Work with Reports** and **Actions** > **Launch to Reports**.

The **Cognos Reporting URL** must adhere to the following format:

`https://reporting-server-hostname:port/tarf/servlet/dispatch/secured`

If you want to view reports using Tivoli Common Reporting 3.1.1 or higher, the **Cognos Reporting URL** must adhere to the following format:

`https://reporting-server-hostname:port/tarf/servlet/reporting/secured`

For more information, see [“Reports”](#) on page 1294.

- **Cognos Reporting Requires XSS Validation** is used to reformat the URL for the Cognos report to pass XSS validation. Set this field to True if your configuration enables the Cognos Application Firewall (CAF) and third party XSS checking. Default: False. For more information, see [“Integrating with Tivoli Common Reporting”](#) on page 1083.
- **Log Analysis URL** is used to launch IBM Operations Analytics - Log Analysis for searching through application logs from the Application Performance Dashboard. For more information, see [“Searching log files”](#) on page 1253.
- **Enable Subnode Events**, for agents with subnodes, controls whether subnodes are shown in the Events tab. When subnode events are enabled, the node and subnode for which an event was opened are displayed. Specifically, if you want to display log file monitoring situations in the Events tab, you must ensure that Subnode events are enabled. Default: False.
- **Dashboard Refresh Rate** controls the frequency of the Application Performance Dashboard automatic refresh. You can adjust the setting to any value from 1 to 60 minutes. The setting affects resource status that is displayed in the navigator and Status Overview tab. It has no effect on the Events tab entries. Default: 1 minute.
- **DASH Console Integration Enabled** controls whether the Cloud APM console can send data to the Dashboard Application Services Hub console when integration has been configured and your Cloud APM server has the IBM Cloud Application Performance Management V8.1.4.0 interim fix 9 (or a later server interim fix). Set this field to True to enable the integration. Default: False.

## Event Manager

The Event Manager controls the flow (through forwarding to Simple Mail Transfer Protocol) and storage of received events, and email notification setup. If you enter a value for Target Email Addresses, Sending Email Account, Sending Email Account Password, and SMTP Server Address, an email will be sent for each open, close, and stop event.

If you configure the SMTP forwarder to use SSL, you must add the SMTP Server's signing CA certificate to the Cloud APM server keystore. Add the CA certificate to the default keystore using the JVM keytool command:

```
install_dir/java/jre/bin/keytool -importcert \
-noprompt \
-alias your_CA_cert_alias \
-file path_to_your_CA_cert_file (*.cer)
-keystore /install_dir/wlp/usr/servers/min/resources/security/key.jks \
-storepass ccmR0cKs! \
-storetype jks \
-trustcacerts
```

To view a sample email, see [“Event email”](#) on page 1243.

- **Event Cache Time** determines the number of minutes that closed events are retained in the MongoDB database, as few as 10 minutes or up to 480 minutes (8 hours). If the event list is long, consider reducing the number of minutes that closed events are persisted. Default: 60 minutes.
- **Pure Event Close Time** determines how long to leave a pure event open before closing it. Default: 24 hours.
- **Master Reset Event** controls whether to send a master reset event to clear previously received sampled events after the monitoring agent is restarted. If you have email notifications configured, you also receive an email (see sample at [“Master reset event after agent restart”](#) on page 1245). Default: True.
- **EIF Port** specifies the port number to use to receive Event Integration Facility events from Operations Analytics - Predictive Insights. If you do not specify a port number for an EIF target in the **EIF Event Target(s)** field, the value of the **EIF Port** field is also used as the port number when forwarding events to that EIF target. Default: 9998.
- **EIF Event Target(s)** specifies the list of host names or IP addresses and port numbers to which all received Event Integration Facility events are forwarded. For example, if you are forwarding events

to the Netcool/OMNIbus Probe for Tivoli EIF, enter the fully qualified host name or IP address of the computer where the probe is installed, followed by the receiver port number. Separate the host name and port number with a colon (:), and separate each host name with a comma (,), such as 9.87.65.111:8989,localhost:9090,myhostname.en.ibm.com. If you do not include a port number with the EIF event receiver host name, the value of the **EIF Port** field is used. IPv6 addresses are not supported for EIF transmission.

- **Target Email Addresses** specifies the email addresses that events are forwarded to. Separate each address with a comma (,), such as annette@ibm.com,jim@ibm.com,owen@ibm.com.
- **Sending Email Account** is the email address for sending an SMTP event email and shows as the sender of the email. When **Use SSL** is set to **True**, the email account name and password are authenticated by the SMTP server. When **Use SSL** is set to **False**, no authentication is performed for the sending email account but you must specify a value for this field since it is used as the sending email address for the event emails.
- **Sending Email Account Password** is the password that is associated with the sending email account when **Use SSL** is set to **True**. When **Use SSL** is set to **False**, the value of this field is not used and you can leave it blank.
- **SMTP Server Address** is the fully qualified host name of the SMTP server that is used for sending events as emails, such as smtp.gmail.com.
- **Use SSL** determines whether to use TLS (Transport Layer Security) as the SMTP (Simple Mail Transfer Protocol) transport mechanism. If you set the field to **True**, enter a valid email account name and password in the **Sending Email Account** and **Sending Email Account Password** fields, which are required for authentication. Default: **False**.
- **SMTP Port** is the port number to use for sending SMTP email. Default: 25.
- **SSL SMTP Port** is the port number to use for sending SMTP email using the TLS (Transport Layer Security) protocol. Default: 465.
- **Cloud Event Management Webhook** is the Webhook url that is generated in Cloud Event Management when you configure the integration between IBM Cloud Application Performance Management and Cloud Event Management. You must paste the generated Webhook url here so that events are forwarded from Cloud APM.

If you are forwarding events to an EIF (Event Integration Facility) receiver, you can customize the EIF slots such as to add an attribute to the EIF event. For more information, see [“Customizing an event to forward to an EIF receiver” on page 1124](#). For information about forwarding your events to the IBM Netcool/OMNIbus event manager, see [“Integrating with Netcool/OMNIbus” on page 1071](#).

## MongoDB Configuration

Configure the MongoDB database.

- **Host Name** is the host name of the system where MongoDB is running. Default: localhost.
- **Port Number** is the port number for the Mongo database. Default: 27000.
- **Batch Size** is the number of AAR documents that are processed and inserted by the MongoDB ETL into the MongoDB document in a single batch insert. Default: 100.
- **Batch Wait** is the time since the last message was processed that the MongoDB ETL waits before an incomplete batch of AAR documents is inserted into the MongoDB document. Default: 10 seconds.

## Agent Central Configuration

The settings here are required information that is used by the Cloud APM server to configure the Central Configuration Services. The Central Configuration Services are used to distribute events and thresholds, and historical data settings to the monitoring agents. Each agent of the same type is given the same thresholds and settings.

- **Host Name Override** is an optional override for the host name or IP address of Central Configuration Services if the value of the server is not correct. By default, the IP address or host name that you provided when you configured the agent packages is used.
- **Change Check Interval** controls the frequency, in minutes, that the monitoring agents use to query configuration details from the server. Default: 5 minutes.

- **Protocol** establishes whether HTTP or HTTPS is the protocol to communicate with the monitoring agent. If the `APM_SECURE_COMMUNICATION` variable was set to Y before server installation, this field is set to HTTPS for a secure connection. For more information, see [“Setting HTTP or HTTPS communications”](#) on page 145. Default: HTTP.
- **HTTP Port** determines the port to use for HTTP communications. Default: 80.
- **HTTPS Port** determines the port to use for secure HTTPS communications. Default: 443.

### Data Mart

These settings can be adjusted to improve performance:

- **Batch size** is the number of rows to include in a single database transaction. Default: 100 rows.
- **Batch Interval** is the interval between sending data to the database to allow it to be inserted. Default: 10 seconds.

Configure an external database for the data mart.

- **JDBC Optional** can be used to set extra properties, such as encryption. The format is `key=value`, one entry per line.

### Kafka Configuration

The Kafka message broker has predefined configuration settings. Leave these settings at their defaults unless instructed to change them by IBM Support.

- **Producer Batch Size** is the number of messages batched at the producer before dispatch to the event handler. Default: 200 messages.
- **Producer Batch Wait** is the producer wait time. Default: 5 seconds.
- **Consumer Batch Size** is the consumer batch size is the number of records to include in a single database transaction. Default: 100 records.
- **Consumer Batch Wait** is the wait time between sending data batches to the database to allow for batch insertions. If the **Consumer Batch size** is not reached in this interval the data is flushed. Default: 10 seconds.
- **Consumer Thread Count** is the consumer thread count. Default: 2 threads.

### Tracking Analytics Service

The settings that are used for the Tracking Analytics Service. The settings apply only to the Cloud APM, Advanced Private offering and if you are configuring transactions tracking in your environment.

- **Connection Pool Size** is the number of concurrent Db2 connections that the Tracking Analytics Service holds in the connection pool for the "Top N" query. Increase this value if you are experiencing slow query times due to a large number of concurrent Cloud APM console users. Default: 10.
- **Pseudo Nodes** enable the visualization of services that are not instrumented. Default: `True`.
- **Query Timeout in Seconds** is the number of seconds before each "Top N" (where N is a number, as in "Top 5" or "Top 10") query take before timing out. The timeout value can be increased if needed for applications that have a higher workload and have larger expected query times. Default: 120 seconds.
- **DB2 Query Re-optimization Enabled** should not normally need to be changed. The parameter affects the Db2 query optimizer. In some environments, turning off the optimizer might improve performance for some sets of transactions. Default: `False`.

### Agent Subscription Facility

The Agent Subscription Facility includes the agent REST (Representative State Transfer) interface and Central Configuration Services HTTP server. The REST interface is used by agents and data collectors to send monitoring data that is persisted in the Db2 server and threshold events. The Central Configuration Services HTTP server handles requests from agents for their configuration files, such as threshold definitions. Use these parameters for configuring the communications between the Agent Subscription Facility and the Cloud APM server.

- **Missed Poll Limit (Fast Heart Beat)** is the maximum number of times that a monitoring agent with a 60-second or lower heartbeat interval fails to connect before it is marked offline. Default: 30 intervals.
- **Missed Poll Limit (Slow Heart Beat)** is the maximum number of times that a monitoring agent with a heartbeat interval that is greater than 60 seconds fails to connect before it is marked offline. Default: 3 intervals.
- **Transaction Time Out** is the amount of time, in seconds, that the server waits for a response to a request. Default: 120 seconds.
- **Pacing Count** is the number of times that the server makes a request to the monitoring agent to call back after a short delay before allowing it to close the connection. Default: 5.
- **Pacing Delay** is the amount of time, in milliseconds, that a monitoring agent waits before making a request to the server for more work. Default: 600000 milliseconds (10 minutes).
- **Remove Offline System Delay** determines the number of minutes to wait before removing the display of a managed system that is offline. In the Application Performance Dashboard, offline managed systems are indicated by the  unknown status indicator. The managed system continues to display, even if you uninstall the agent, until the delay time has passed. For more information, see [“Viewing and removing offline agents” on page 1275](#). Default: 5760 minutes (4 days).

### Thresholds Enablement

Your monitoring agents each come with a set of predefined thresholds that are enabled and started with the agent. These predefined thresholds are assigned to the default system resource group for the agent.

- **Choose action to define policy for predefined best practice thresholds** controls whether the predefined thresholds for your managed resources are enabled or disabled by default. Set the field to **Disable All** if you do not want to run the predefined thresholds. The **Disable All** setting removes the assignment of the system group from all predefined thresholds. A threshold with no group assigned is distributed to no monitored systems and remains stopped until it is distributed to a resource group. If you decide later that you want to turn on the predefined thresholds, set the field to **Enable All**.

For more information about the predefined thresholds and custom thresholds, see [“Background information” on page 1110](#) and [“Examples of disabled thresholds” on page 1112](#).

## Event email

Use the Event Manager fields on the Advanced Configuration page to set up event notification by email to a list of addressees.

### Email for open event

When a threshold condition becomes true, an event is opened and the email message sent by the Cloud APM server contains the base attributes that apply to all agent events + attributes from the first row of the dataset that matched the threshold condition. The `situation_status` attribute has a value of Y for open events.

### Email for close events

When the threshold condition is no longer true, a close event is generated. The email message for close events only contains the base attributes that apply to all agent events and the `situation_status` value is N. The agent's attributes are not included in these email messages because the threshold condition is not met.

### Email for stop event

When a threshold is stopped, a stop event is generated. The email message for stop events only contains the base attributes that apply to all agent events and the `situation_status` value is P. The agent's attributes are not included in these email messages because the threshold condition is not met.

A threshold is stopped for an agent if you delete the threshold definition or you make a change to any of the threshold definitions that are distributed to the agent.

The following samples shows an email for an open event:

## Enabling advanced pruning of the Datamart database

---

You can enable advanced pruning of the Datamart database to control the size of the database.

### About this task

Transaction tracking data is stored in multiple tables in the Datamart database. Pruning automatically occurs for the transaction instance data in the database table names that start with **F\_** and for aggregated transaction data in the table names that start with **AGG\_**. However, pruning does not automatically occur for the static data stored in the table names that start with **D\_**. In some environments, the data in a subset of the **D\_xxx** tables is dynamic and causes the size of the Datamart database to continually grow. You can run a script to enable advanced pruning which deletes unreferenced rows in the **D\_xxxx** to control the size of the Datamart database.

### Before you begin

The `enable_dmart_pruning.sh` script can be run at any time to enable pruning of the unreferenced rows in the **D\_xxx** tables in the Datamart database. The pruning occurs nightly when the Datamart daily cron job runs between 3 am and 4 am based on the time zone of the Cloud APM server.

**Note:** Before you run the `enable_dmart_pruning.sh` script, you need to install IBM Cloud Application Performance Management V8.1.4.0 interim fix 10 or a later server interim fix. You can download the interim fixes for IBM Cloud Application Performance Management V 8.1.4 from [IBM Fix Central](#).

If there is not a large amount of data in the Datamart database tables, the `enable_dmart_pruning.sh` script automatically enables pruning of the **D\_xxx** tables and no further action is required on your part. However, if there is a large amount of transaction tracking data in the Datamart database, then the `enable_dmart_pruning.sh` does not enable pruning and instead displays a message indicating that you should plan a maintenance window to execute the initial pruning to prevent a performance impact to your Cloud APM server and database server.

The `enable_dmart_pruning.sh` script indicates the Datamart database contains a large amount of data if the **D\_xxxx** tables contain over 100 million rows, or the **D\_xxxx** tables contain over 10 million rows and the **F\_xxxx** tables contain over 100 million rows. The script displays the number of rows in each **D\_xxxx** table and also writes the information to the latest `/opt/ibm/dtl/datalayer/logs/enable_dmart_pruning.sh-*.log` file.

During the pruning of the **D\_xxx** tables, the **D\_xxx** table and the **F\_xxx** tables that reference the **D\_xxx** table are locked which prevents these tables from being updated with new data until the pruning is complete. By default, the pruning deletes up to 1 million rows in the **D\_xxxx** tables to prevent the tables from being locked too long. Pruning 1 million rows might take 30 to 60 minutes. If there are more than 1 million rows in the **D\_xxx** tables to prune, the next 1 million rows are pruned when the cron job runs the next day or if you manually run the Datamart daily cron job. The following procedure describes how you can configure the max number of rows that are deleted per pruning job if you want to adjust the number of rows that are pruned at one time. Also for the initial pruning of a large Datamart database, the steps in the procedure describe how to configure the pruning job to prune one large **D\_xxxx** table at a time.

When the `enable_dmart_pruning.sh` script indicates there is a large amount of transaction tracking data in the Datamart database, the initial pruning of the **D\_xxxx** tables might also require you to increase the Datamart database transaction log size or increase the Db2 LOCKTIMEOUT value for the initial pruning of the **D\_xxx** tables. The steps in the procedure indicate what Db2 error messages are displayed for those scenarios and how to increase the Db2 transaction log size or LOCKTIMEOUT value.

Complete the following steps as the root user on the Cloud APM server:

## Procedure

1. Change to the `/opt/ibm/dtl/datalayer/cron` directory and run the following command:

```
./enable_dmart_pruning.sh
```

**Note:** `/opt/ibm/` is the default Cloud APM server install directory. If you installed Cloud APM into a different directory, use your install directory instead of `/opt/ibm/`.

2. If your DATAMART database does not contain a large amount of data, the script automatically enables advanced pruning of the **D\_xxx** tables and displays messages similar to the following ones. No further action is required. The pruning will run daily as part of the existing Datamart daily cron job.

```
The DATAMART database has low usage for transaction tracking data.
Editing /opt/ibm/dtl/datalayer/cron/delete_unreferenced_rows.cfg to enable datamart pruning.
Changing _CHECK_FOR_UNREFERENCED_ROWS_ENABLED to Yes.
DATAMART database pruning is already enabled for D_REQUEST.
DATAMART database pruning is already enabled for D_TRANSACTION.
DATAMART database pruning is already enabled for D_URL_DETAILS.
DATAMART database pruning is already enabled for D_SOURCE_IP_ADDRESS.
DATAMART database pruning is already enabled for D_USER.
DB20000I The TERMINATE command completed successfully.
.... Done
```

3. If your DATAMART database contains a large amount of transaction tracking data, the script does not enable advanced pruning and displays messages similar to the following ones:

```
"The DATAMART database has high usage for transaction tracking data.
The D_xxx tables contain 12345678 rows for database DATAMART.
The F_xxx tables contain 87654321 rows for database DATAMART."
"We recommend that you cleanup the unreferenced rows in the DATAMART D_xxx tables.
Edit the /opt/ibm/dtl/datalayer/cron/delete_unreferenced_rows.cfg file.
For detailed instructions refer to the topic "Enable advanced pruning of the Datamart
database" in the Knowledge Center at URL:
https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/welcome.html.
```

If you see the messages, plan a maintenance window to perform the initial pruning of the **D\_xxx** tables.

4. During the maintenance window, perform these steps to perform pruning:
  - a) Confirm you configured the recommended number of Datamart buffer pools for a large Cloud APM server environment. You can display the current number of buffer pools by running these commands on the Cloud APM server if a local Db2 server is being used or on the remote Db2 server:

- Logon as the Db2 instance user

```
su - db2apm
```

Where `db2apm` is the default instance user.

- `db2 connect to DATAMART`

**Note:** You must connect as the instance ID. Connecting as `ITMUSER` will not have the authority to update bufferpools.

- `db2 "select * from syscat.bufferpools where BPNAME = 'IBMDEFAULTBP' "`

**Note:** If this command fails when you cut and paste it, try typing it manually.

If the number of buffer pools is less than 300000, you should set it to the recommended value by running these commands:

```
db2 alter bufferpool IBMDEFAULTBP immediate size 300000
db2 connect reset; db2 terminate
```

- b) On the Cloud APM server, logon as root and change to the `/opt/ibm/dtl/datalayer/cron` directory and run the following command to get the latest count of the number of rows in the **D\_xxxx** tables.

```
./enable_dmart_pruning.sh
```

The script displays the number of rows in each **D\_XXXX** table that can be pruned.

- c) Only prune one **D\_** table with over 1 million rows at a time during the maintenance window to minimize the impact on Db2 resources. The `/opt/ibm/dtl/datalayer/cron/delete_unreferenced_rows.cfg` file has a line for each **D\_XXXX** table that can be pruned.

- If the number of rows for a **D\_XXXX** table is less than 1 million, set the value for that table to **YES** in the `delete_unreferenced_rows.cfg` file.
- Choose one **D\_XXXX** table with more than 1 million rows to prune and set the value for the other large **D\_XXXX** tables to **NO**. We recommend waiting to enable pruning for the largest **D\_XXXX** table until the other **D\_XXXX** tables have been pruned.

For example, if the `enable_dmart_pruning.sh` displays these messages for the number of rows in the **D\_XXX** tables:

```
1200000 rows exist in table D_REQUEST for DB DATAMART
1500000 rows exist in table D_TRANSACTION for DB DATAMART
1400000 rows exist in table D_URL_DETAILS for DB DATAMART
10000 rows exist in table D_SOURCE_IP_ADDRESS for DB DATAMART
5000 rows exist in table D_USER for DB DATAMART
```

Then edit `opt/ibm/dtl/datalayer/cron/delete_unreferenced_rows.cfg`. Ensure `_DATAMART_clean_D_SOURCE_IP_ADDRESS` and `_DATAMART_clean_D_USER` are set to **YES** because they have less than 1 million rows and set `_DATAMART_clean_D_REQUEST` to **YES** as the first large **D\_XXX** table to prune because it is not the table with the most rows. Then set `_DATAMART_clean_D_TRANSACTION` and `_DATAMART_clean_D_URL_DETAILS` to **NO** as the following:

```
_DATAMART_clean_D_REQUEST=YES
_DATAMART_clean_D_TRANSACTION=NO
_DATAMART_clean_D_URL_DETAILS=NO
_DATAMART_clean_D_SOURCE_IP_ADDRESS=YES
_DATAMART_clean_D_USER=YES
```

Also if you want to change the max number of rows to prune at a time then change the value of the `_MAX_NUM_ROWS_TO_DELETE` config property in the `delete_unreferenced_rows.cfg` file.

- d) Run the following command to run the Datamart daily cron job to perform the pruning:

```
/etc/cron.daily/datamart.daily
```

The cron job prunes up to 1 million unreferenced rows from the **D\_XXX** tables that are enabled for pruning. The cron job might take 30 to 60 minutes to perform the pruning when there are more than 1 million unreferenced rows to delete.

- e) In a separate console window, run the following command to view the latest log file for the cron job:

```
ls -ltr /opt/ibm/dtl/datalayer/logs/partition-maintenance.sh-*.log | tail -1
```

- f) Locate the following line and check for any error messages that occur after that line:

```
***** Running Delete Unreferenced Rows *****
```

- If you see the following message, it means Db2 timed out before the pruning could be completed.

```
DB21034E The command was processed as an SQL statement because it was not a valid
Command Line Processor command.
During SQL processing it returned:
SQL0911N The current transaction has been rolled back because of a deadlock or
timeout.
Reason code "2".  SQLSTATE=40001"
```

You should increase the value for the Db2 LOCKTIMEOUT setting by performing these steps:

- i) If the Db2 server is local, enter the following command:

```
su - db2apm
```

- ii) If the Db2 server is remote, logon to the remote Db2 server as the Db2 instance user.

```
db2 connect to DATAMART
db2 get db cfg for DATAMART | grep LOCKTIMEOUT
```

- iii) Enter this command to update the LOCKTIME value so that Db2 does not timeout locks:

```
db2 update db cfg for DATAMART using LOCKTIMEOUT -1
db2 connect reset; db2 terminate
```

- If you see the following message, the Db2 transaction log size should be increased.

```
DB21034E The command was processed as an SQL statement because it was not a valid
Command Line Processor command.
During SQL processing it returned:
SQL0964C The transaction log for the database is full.  SQLSTATE=57011
```

You should increase the values for the Db2 LOGPRIMARY and LOGSECOND configuration values. Db2 does not provide an algorithm for determining the value that should be set. You should double the LOGSECOND value (which is for temporary space). If you still run out of transaction log space, double the value for the LOGPRIMARY config value.

Perform the following steps to change the Db2 transaction log size:

- If the Db2 server is local, enter the following command:

```
su - db2apm
```

- If the Db2 server is remote, logon to the remote Db2 server as the Db2 instance user and record the current values.

```
db2 connect to DATAMART
db2 get db cfg for DATAMART | egrep "LOGFILESIZ|LOGPRIMARY|LOGSECOND"
```

- To update the LOGSECOND config value, enter this command:

```
db2 update db cfg for DATAMART using LOGSECOND 50
```

Where you should replace 50 with 2 times the LOGSECOND value displayed by the db2 get db cfg command.

- To update LOGPRIMARY, run:

```
db2 update db cfg for DATAMART using LOGPRIMARY 20
```

Where you should replace 20 with 2 times the LOGPRIMARY value displayed by the db2 get db cfg command.

- The LOGFILESIZ config value is normally between 4K and 25K. There is no requirement to change it unless it is less than 4K. To update LOGFILESIZ, enter this command:

```
db2 update db cfg for DATAMART using LOGFILESIZE 16000
```

Where 16000 is larger than the current value.

- After you have completed the Db2 configuration updates, enter this command:

```
db2 connect reset; db2 terminate
```

- Ignore the following Db2 messages in the /opt/ibm/dtl/datalayer/logs/partition-maintenance.sh-\*.log file:

- sqlEscalateLocks: DB2 locks several 100 thousand rows at a time. When it reaches a high number of rows being locked for a given table, it escalates to the point where it locks the entire table. This is normal.

- SQL0598W: Existing index *ITMUSER.D\_SRCIP\_SRCIPADDID\_IDX* is used as the index for the primary key or a unique key. SQLSTATE=01550. This is normal.
  - SQL0598W: Existing index *ITMUSER.D\_USER\_USERID\_IDX* is used as the index for the primary key or a unique key. SQLSTATE=01550. This is normal.
  - SQL fails when attempting to add the primary key or foreign key constraint. This happens because the tables are large and there is not enough Db2 memory to add the constraint. The constraints are dropped to improve performance when deleting rows. It takes very little memory to disable a constraint, but it takes a lot of memory to enable it. When the tables become smaller, the constraints are restored.
- g) If you saw error messages in the log file and performed Db2 config updates then perform steps 4d through 4f again to re-run the Datamart daily cron job as root on the Cloud APM server.
- h) If the log file shows that pruning is successfully deleting rows then the Datamart daily cron job should automatically reduce the number of unreferenced rows by up to 1 million rows each night until there are no more unreferenced rows for the tables that you enabled for pruning in step 4c . You can also manually run `"/etc/cron.daily/datamart.daily"` multiple times per day to reduce the number of rows.
- i) If you have additional *D\_XXXX* tables to enable for pruning, repeat steps 4b through 4h to enable the next large *D\_XXXX* table for pruning. You can either enable the next *D\_XXXX* table for pruning in the current maintenance window or schedule another maintenance window to enable pruning for the other large *D\_XXXX* tables. The Datamart daily cron job will continue to prune the tables that have already been enabled for pruning in the `/opt/ibm/dtl/datalayer/cron/delete_unreferenced_rows.cfg` file.
- j) If you have issues enabling the advanced pruning then contact IBM Cloud APM support for assistance.

## What to do next

There are two additional setting in the `delete_unreferenced_rows.cfg` file that you can tune:

- `_MAX_NUM_ROWS_TO_DELETE=1000000`: This setting controls the time the Datamart database tables are locked. It takes about 30 minutes for Db2 to delete 1 million rows. Check the timestamps in the latest `/opt/ibm/dtl/datalayer/logs/partition-maintenance.sh-*.log` file to determine when the deletes start and when they finish. If the nightly deletes are finishing up before your work day begins, you can increase this setting. A run time of 30-60 minutes is normal for large customers until the pruning stabilizes.
- `_SKIP_SMALL_TABLES=5000000`: This setting prevents the scanning for unreferenced rows in the **D\_XXXX** tables from being run every night. After the unreferenced rows in the *D\_* tables have been cleaned up, you might not want to run the Datamart daily cron job to scan for new unreferenced rows until you have a large number of rows to delete again. When there are no more unreferenced rows to be deleted, the latest `opt/ibm/dtl/datalayer/logs/partition-maintenance.sh-*.log` file indicates a low number (less than 1 million) of rows have been deleted. At this point you can adjust the value of this config property to be 2 million higher than the number of rows in your largest *D\_* table. Then the Datamart daily cron jobs skips the step to scan for unreferenced rows until there are at least 2 million new rows to be scanned.

## Chapter 11. Using the dashboards

Select  **Performance** > **Application Performance Dashboard** to get a comprehensive status overview of your applications. You can drill down from the highest level overview to in-depth metrics in the same display.

Use the tools that are available on the dashboards to investigate critical and warning conditions in your environment, create additional metric views, and to perform actions such as searching trace logs and comparing metrics over time.

### All My Applications - Application Performance Dashboard

The Application Performance Dashboard presents the summary status for your monitored domains in **All My Applications**. A *summary box* is displayed for each user defined application, such as "Inventory Management", and for the predefined applications, "My Components" or "My Transactions" if your environment includes them. From the summary boxes or the navigator, drill down to each application and its constituents to see detailed metrics.

As you select items, the path is shown and you can click one of the path links to return to that view. From any Cloud APM console page, you can click  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard. View areas of interest either by selecting from the navigator or by clicking in a summary box to drill down to the next level.

#### Summary boxes

**All My Applications** has a summary box for each defined application. Indicators show the highest status severity for the application in the title bar and for each group in the summary box. The following predefined groups are available, depending on which monitoring products are included in the defined application:

 **Components** has a subgroup for each monitoring agent type that supports your application

 **Transactions** can include **End User Transactions** and **Synthetic Transactions** subgroups

In addition, each summary box includes  **Events**, which shows the severity of the highest severity event that is open for the application. You can click the Events link to investigate any open events (see [“Event Status” on page 1280](#)).

Click a summary box title bar to open the Status Overview tab for the application. Or click one of the summary box icons to open the Status Overview tab for the Components group or Users or Transactions subgroup, or to open the Events tab for the application group or subgroup.

You can collapse the summary boxes and filter them by selecting or clearing check boxes:

- To show only the summary box title bars for easy scrolling through your defined applications, clear the **Show Details** check box.
- To filter the summary boxes for the severity status that you want to hide, clear the check box for a counter, such as ☐  12 . The check box for a severity with no events is disabled. For example, in this graphic, the filters for Critical and Normal are enabled; Warning and Unknown are disabled because they have a 0 count: ☒  2 ☒  0 ☒  1 ☐  0 .

#### Search

Use the Search field to find log entries from the past hour that contain the entered text. You can click  to show results from a different time range. The Search text is compared to the log entries that are associated with the navigator selection and any matches are shown in a new browser tab or window. For instructions, see [“Searching log files” on page 1253](#). The search capability is provided by IBM Operations Analytics - Log Analysis.

## Actions

The **Actions** menu has options for copying the URL, opening the dashboard log, and setting a trace for troubleshooting. For more information, see [“Copying the dashboard URL” on page 1292](#) and [“Setting a trace” on page 1293](#).

Use the **Dashboard Log** option to review the list of agent dashboards that were updated since the last server restart.

When the **All My Applications** home dashboard or one of the applications is selected, the Actions menu includes **Launch to Reports** to help you analyze usage and performance trends if Cognos based reports are available and your environment includes Tivoli Common Reporting. For more information, see [“Reports” on page 1294](#).

When the **Components** group is selected, from either the navigator **Groups** section or from a summary box, the **Actions** menu includes an **Edit** option for editing the Component status overview dashboard. The **Edit** option is only available if the logged in user has the modify permission for Performance Management Dashboard and the create permission for Applications. For more information, see [“Editing the Components dashboard group widgets” on page 1262](#).

## Help

Open the pop-up help to get a short description of the current dashboard, with the following links:

**Learn More** opens the full dashboard topic in the local Cloud APM help system; and **Take a Dashboard Tour** starts the IBM Cloud APM Dashboard tour, which presents a brief description of the dashboard elements as it guides you through the features.

## Navigator

The navigator displays a hierarchy of defined applications and their users, transactions, and components that reflects how they are organized. The navigator has a section for each level of the application hierarchy. At every level of the navigator, the dashboard metrics change to show data from the component. Select an item to switch the dashboard context to the selection. The scope of what you can see is determined by your user permissions.

Each navigator item has a  critical,  warning,  normal, or  unknown status indicator, which indicates that the agent is unavailable. Each navigator section presents a count of events for each severity that is associated with the selected navigator item. For a mapping of status to threshold events, see [“Event Status” on page 1280](#).

To make more room for other sections, click a title bar to collapse the section, and click again to restore the section. You can also hide the navigator entirely by clicking  on the navigator border; and restore it by clicking , or adjust the width by dragging the  border.

The navigator has three sections:

- The **Applications** section lists all the defined applications in your domains or that are allowed for your user role.
  - After you select an application, the dashboard changes to a high-level status summary in the **Status Overview** tab, and an indicator of the highest severity status is displayed in the **Events** tab. For more information, see [“Application - Application Performance Dashboard” on page 1254](#).
  - If your Cloud APM server is sized as small or medium, a predefined application named *My Components* is created. The application contains any resource monitoring components in your domain that have been discovered by the monitoring infrastructure and that you are authorized to view. For more information on authorization, see [“Roles and permissions” on page 1137](#). *My Components* cannot be edited or deleted. The event status of the *My Components* application and its components is based on the status of all components discovered by the monitoring infrastructure and not just the components and component instances that you are authorized to view. For example, if some Linux OS agents have Critical status but all of the Linux OS agents that you are authorized to view have Normal status, then the Linux OS status is Critical for the *My Components* application even though the status is Normal for all Linux OS agent instances that you see.

**Note:** For performance reasons, the My Components application is not available for Cloud APM servers that are sized as large. See [“Cloud APM server hardware requirements”](#) on page 111.

- If you are using Cloud APM Synthetic Playback agents, you can view synthetic data in the predefined *My Transactions* application, which cannot be edited or deleted. My Transactions displays all synthetic transactions, and you cannot restrict which transactions are displayed in the application. For more information on working with synthetic transaction data, see [“Managing synthetic transactions and events”](#) on page 1177.
- If you have administrator role privileges, the **Applications** toolbar includes    tools for managing applications. For instructions, see [“Managing applications”](#) on page 1269.
- After you select an application, the **Groups** section shows the groups that support the application. For more information, see [“Group and Instance - Application Performance Dashboard”](#) on page 1259.
- After you select a subgroup, the **Instances** section is renamed for the subgroup title and populated with the individual managed system names. The **Status Overview** changes to show KPIs for the selected subgroup. After you select a managed system, detailed group widgets are displayed with KPIs from the managed system. For component instances, you also have an **Attribute Details** tab for viewing a table of KPIs from the data set attributes of your choosing. For more information, see [“Viewing and managing custom charts and tables”](#) on page 1264.

If you get a **Network Error** pop-up message in the navigator, the status indicators might change to  normal until after the connection is restored. At that time, any open events are reprocessed and the status might appear normal until processing is completed.

## Searching log files

To find the root cause of a problem that is experienced by users, such as slowness or a failure, you can search through log data that is associated with your applications. IBM Operations Analytics - Log Analysis provides the search capability. Application log data and performance data are brought together to help you find the root cause of a problem that is experienced by your applications and expedite problem resolution.

### Procedure

Take the following steps to locate log entries that might correlate to a problem you are investigating, such as high CPU usage.

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu.
2. If you want to search within an application, select one of the applications in the "All My Applications" dashboard.  
For example, click "My Components" to search the logs of all component resources.
3. Enter the log file text to find in the  search box.  
For example, enter `rolled back` to look for WebSphere Applications agent resources that were rolled back to the previous level.
4. If you want to find data from a time range other than **Last hour**, click  and select a different period.
5. Click .

### Results

All log entries that contain the search text in the context of the current navigator level are displayed in a new browser tab or window. The browser window is named for the context, such as the "Credit Card Processing" application.

### What to do next

Review the search results. You can select another application to change the search results for the context. Use the search field to further refine the results. For example, if the search field shows `db2 AND (datasourceHostName:Pear* OR datasourceHostname:Persimmon* OR`

`datasourceHostname:Pomegranate*)`, you can delete data sources to narrow the results: `db2 AND (datasourceHostname:Persimmon*)`.

For more information, see the [IBMOperations Analytics Log Analysis](#) topic collection on IBM Knowledge Center or go to the [IBM Operations Analytics - Developers Community](#).

## Application - Application Performance Dashboard

---

After you select an application from the navigator or from a summary box in the **All My Applications** dashboard, a tabbed dashboard presents different facets of your application. The **Status Overview** tab presents a high-level status summary of your application. The chart thresholds and status indicators give overall health and performance feedback. Select the **Events** tab to see which event thresholds are contributing to application health.

For a description of the navigator and banner elements, see [“Navigator” on page 1252](#), [“Search” on page 1251](#), [“Actions” on page 1252](#), and [“ Help” on page 1252](#).

### Status Overview

- Depending on the composition of the selected application, the **Status Overview** tab presents one or more perspectives for evaluating application status at a high level:

#### Availability Over Time

The **Availability Over Time** bar chart is displayed if the application includes the Synthetic Playback agent (in the **Transactions** navigator group and in the predefined application, **My Transactions**).

Each plot point is a transaction sample with a color indicator for a status of  **Healthy**,  **Slow** or  **Unavailable**.

Click anywhere on the bar time line to open a pop-up window with **Transaction List** and **Location List** tables.

#### Requests and Response Time

The **Requests and Response Time** stacked bar chart is displayed if the application includes the Response Time Monitoring Agent (**End User Transactions** in the **Transactions** navigator group).

Use this chart to look for trending patterns in performance. Each stacked bar plots the percentage of requests that completed with good response time, slow response time, or that failed to complete. The line chart overlay plots the average response time during the 5-minute period. Use the time selector to change the time range displayed, described in [“Adjusting and comparing metrics over time” on page 1263](#).

#### Aggregate Transaction Topology

The **Aggregate Transaction Topology** is displayed when transaction tracking is enabled and the application includes any of the following agents or data collectors:

- DataPower agent
- HTTP Server agent
- IBM Integration Bus agent
- J2SE data collector
- JBoss agent
- Liberty data collector
- Microsoft .NET agent
- Microsoft SQL Server agent
- Node.js data collector
- Response Time Monitoring agent
- SAP NetWeaver Java Stack agent
- Tomcat agent

- WebLogic agent (Linux and Windows only)
- WebSphere Applications agent
- WebSphere MQ agent

You must enable transaction tracking manually for all agents except the Response Time Monitoring agent. Transaction tracking is enabled automatically for data collectors. For more information, see [“Agent Configuration page” on page 242](#).

The **Aggregate Transaction Topology** presents the resources that are associated with the application and their relationships. The footer shows a count of the selected nodes, resources, relationships, and any filters in the topology, as well as the time when the data was last refreshed.

If an application component is added to a business application, and the component carries traffic for multiple applications, the application topology that is displayed for those business applications includes paths to nodes for all applications.

For the IBM Java application stack where JavaScript is automatically injected, the highest level node represents the browser and the most granular node is the database. For other applications, the highest level node represents the application and the most granular node is the managed system instance.

Each node has a status indicator and background highlighting to show the highest status severity at that level of aggregation. If you collapse the navigator to make more space, you can still see the same status in the **Aggregate Transaction Topology**. The node's source environment shows as  **Cloud** (IBM Cloud Application Performance Management),  **ITM** (IBM Tivoli Monitoring),  **On Premises** (IBM Cloud Application Performance Management, Private) ,  **Private Cloud** (IBM Cloud Private), or  **Public Cloud** (IBM Cloud). No icon is shown for **Other** (managed resource is from another environment).

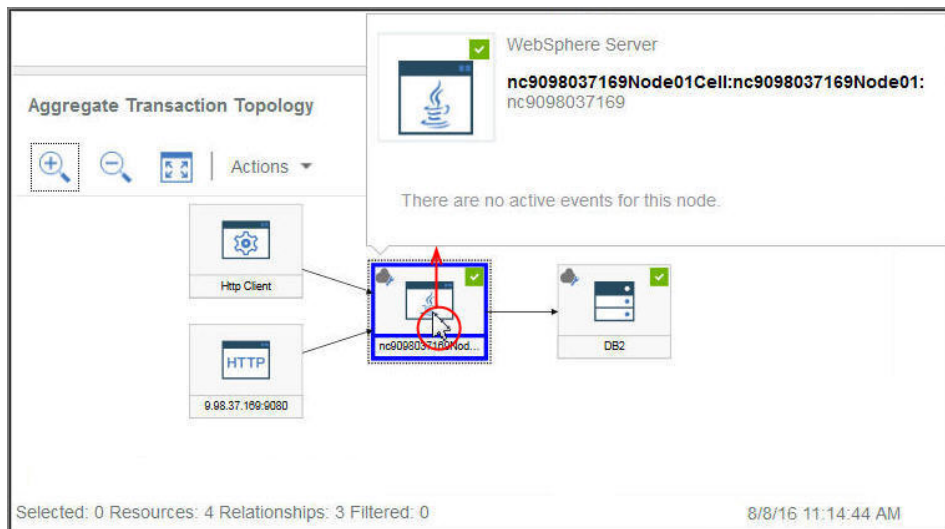

Hover the mouse over a node, open the shortcut menu, and select nodes to get more information about the status and help you identify the root cause of a problem:

- As you hover the mouse over a node, a pop-up message provides a list of the  critical and  warning events.
- Double-click a link URL in a node to open the corresponding dashboard with component or transaction details.
- Right-click a node and select one of the dashboard drill down options: **Go to Transactions Summary page** of the selected subgroup node; **Go to Component Instance page** of the instance node; or **Properties** to see the resource name, status, managed system name, and provider domain (such as "Cloud").

Use the toolbar icons to adjust the display and take actions as described in [“Manipulating the Aggregate Transaction Topology widget” on page 1257](#).

Click the  tool to toggle between this view and the **Current Components Status**, described next.

Any monitoring agents with no topology information do not show in the Aggregate Transaction Topology widget.

### Current Components Status

The **Current Component Status** stacked bar chart shows the percentage and a count of critical, warning, normal, and unknown status for each component type in the application. Consider, for example, that 5 Linux systems are supporting the selected application. A stacked bar showing 40% critical and 60% normal indicates that 2 systems have critical status and 3 systems have normal status.

Hover the mouse over a bar segment to read the status in a pop-up window: the percentage and count of the component instances with that status. The domain or domains where the instances reside is also shown with a status count for each domain: IBM Cloud, Cloud, On Premises, ITM and Other. For example, 2 of your 5 Linux systems are in the ITM domain and 3 are in the Cloud domain. If one of the Critical systems is in the ITM domain and the other is in the Cloud domain, when you hover the mouse over the Critical 40% bar segment, the status pop-up window shows 1 system in the ITM domain and 1 in the Cloud domain.

You can click a bar to open the status summary dashboard for the component type, with a group widget for each monitored system.

Click the  tool to toggle between this view and the **Aggregate Transaction Topology**, described earlier.

### Synthetic Transactions

The Synthetic Playback agent has a predefined application called *My Transactions*, which opens to the Synthetic Transactions subgroup dashboard page. From here you can drill down to the transaction instance level. For more information, see [Synthetic Playback monitoring](#).

- After you select a subgroup from the **Groups** section, the **Instances** section is renamed for the subgroup title and populated with the individual instance names. For information about the dashboards at the group, subgroup, and instance level of the navigator, and about the **Attribute Details** tab that opens after you select a managed system, see [“Group and Instance - Application Performance Dashboard”](#) on page 1259 and [“Viewing and managing custom charts and tables”](#) on page 1264.
- Some of the dashboard widgets show metrics that are based on a time range, and other widgets show the most recent metrics. If a time selector bar is displayed, you can adjust the time range for the dashboard that affects any charts or tables whose values are derived from historical data samples. For more information, see [“Adjusting and comparing metrics over time”](#) on page 1263. While viewing charts, you can click a plot point to open a tool tip with the plot point value and other pertinent information. After viewing a line chart in the Internet Explorer Version 11 browser, you might continue to see the tool tip appear as you move the cursor around the window. If you experience this behavior, you can close the tool tip by clicking a few times in the chart.
- Data is auto-refreshed every minute in the console. This activity is essential and cannot be paused, stopped, or hidden.
- If no data is available for a chart or status summary box, an information message is displayed.

## Events

- The status indicators that are displayed next to the **Events** tab title, such as  **14**  **3**, show a count of the highest event severities for the selected navigator item: application, group, subgroup, or instance. Threshold severities are consolidated, as shown in the following table. For example, **Events**  means that the highest severity event is minor or warning.

| Events tab   | Threshold Severity |
|--|--------------------|
|  Critical | Fatal and Critical |
|  Warning  | Minor and Warning  |
|  Normal   | Unknown            |

When your managed environment includes IBM Operations Analytics - Predictive Insights and an anomaly is detected, an event is opened. A diamond-shaped icon overlays the status indicator, such as , to notify you that at least one anomaly has been detected by Operations Analytics - Predictive Insights. For example, **Events**  , indicates that the highest status event is  Warning and that at least one anomaly event is open.

- Click the **Events** tab to see a summary of the total event count, a count of each severity type, and a percentage gauge for the severities. For more information, see [“Event Status” on page 1280](#).

## Custom Views

The pages that you create and save are associated with the selected application. For example, the Inventory Management application in the Cloud APM [Guided Demo](#) has the following monitoring agents: Linux OS, MySQL, Node.js, Hadoop, and Ruby. You can create and save a custom page at any level of the navigator from application to instance and then open it at the same level where it was created. A page that is created at a particular level can be opened only at the same level. The metrics available for the widgets can be from any of the resources in the application. Using the Inventory Management example, you can create a page with a table from the Ruby agent, a chart from Linux OS agent, and so on.

- The **Custom Views** tab is available at any level of the navigator when you select an application from **All My Applications**.
- After you open the **Custom Views** tab, the **Select a Template for your Custom Page** window is displayed or the default page is displayed if it is already set.
  - In the **Select a Template for your Custom Page** window, you can select a template to create a page.
  - On the default page, you can click  to create a new page.
- On the default page, Click  in the page list and select one of the saved pages from the list.
- The options that you see in the Custom Views tab vary based on whether a page is being edited or viewed. For information about editing a page, see [“Creating and managing custom pages” on page 1284](#). For information about viewing a page, see [“Viewing custom pages” on page 1290](#).

## Manipulating the Aggregate Transaction Topology widget

Use the **Aggregate Transaction Topology** widget to see the hierarchy of resources in the selected application. You can adjust and move around the display to see the status of each component and its relationship to other components, and open a node's corresponding dashboard.

### Before you begin

After you select an application in the Application Performance Dashboard, the **Status Overview** tab is displayed with one or more charts, depending on the monitored resources that are included in the application.

The **Aggregate Transaction Topology** is displayed for the following agents that support transaction tracking:

- DataPower agent
- HTTP Server agent
- IBM Integration Bus agent
- J2SE data collector
- JBoss agent
- Liberty data collector
- Microsoft .NET agent
- Microsoft SQL Server agent
- Node.js data collector
- Response Time Monitoring agent
- SAP NetWeaver Java Stack agent
- Tomcat agent
- WebLogic agent (Linux and Windows only)
- WebSphere Applications agent
- WebSphere MQ agent

The **Aggregate Transaction Topology** shows a node object for every monitored resource that supports the topology feature.

## Procedure

Take any of the following steps to manipulate the **Aggregate Transaction Topology** widget and open dashboards that are associated with the nodes:

- To open a linked dashboard, double-click the topology node. You can also right-click a node and select one of the dashboard drill-down options, **Go to Transactions Summary page** or **Go to Component Instance page**, or select **Properties** to see information about the managed system.
- To enlarge the topology display size, click  **Zoom In**. You can also click **Actions > Zoom In** if no node is selected.
- To reduce the topology display size, click  **Zoom Out**. You can also click **Actions > Zoom Out** if no node is selected.
- To adjust topology display size to fit within the current widget space, click  **Fit Contents**. You can also click **Actions > Fit Contents** if no node is selected.
- To filter the topology nodes, select one of the indicators in the filter bar. You can toggle the filters on and off, and select multiple filters. Any node with a property that does not match the filter is dimmed, and the nodes that match the filter remain visible.
  -  Normal,  Warning,  Critical, or  Unknown to filter by node status.
  - To filter by environment, select  **Cloud** (IBM Cloud Application Performance Management),  **ITM** (IBM Tivoli Monitoring),  **On Premises** (IBM Cloud Application Performance Management, Private),  **Private Cloud** (IBM Cloud Private), or  **Public Cloud** (IBM Cloud).
  -  Filter to add a custom filter.
- To make more room for the topology widget, click  **Collapse Section** on the navigator or surrounding chart widgets, or  drag a widget border.

## Group and Instance - Application Performance Dashboard

Use the dashboard for the selected application group, subgroup, or instance to get a high level status of your managed systems. You can drill down to detailed dashboards with metrics for the selected instance and create custom charts and tables.

After you select an application under **All My Applications** in the Application Performance Dashboard, the **Status Overview** and **Events** tabs are displayed.

The navigator **Groups** section lists one or more of several possible groups, depending on the constituents of the defined application.

For a description of the navigator and banner elements, see [“Navigator” on page 1252](#), [“Search” on page 1251](#), [“Actions” on page 1252](#), and [“Help” on page 1252](#).

### Status Overview

#### Groups and subgroups

- Select a group or  expand a group and select a subgroup to see a summary group widget for each managed system in the application. After you select a subgroup, the summary group widgets in the **Status Overview** tab are specific to that subgroup.
- The following predefined groups are available, depending on which monitoring products are installed:

#### Components

This group is displayed for all applications, with the exception of the Response Time Monitoring Agent, the Synthetic Playback agent, and Availability Monitoring.

The **Components** has a subgroup for each monitored software component that supports the selected application.

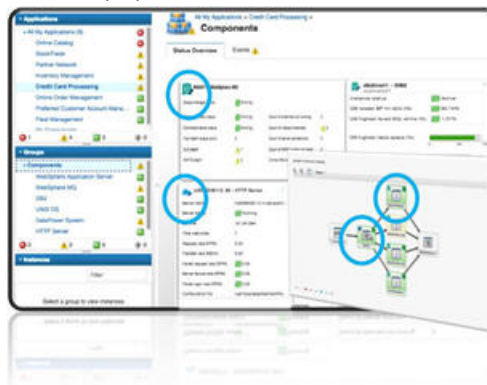

#### Transactions

This group includes **End User Transactions** and **Synthetic Transactions** subgroups. For more information, see the help for Transaction Monitoring and the Synthetic Playback agent or their reference PDFs on the IBM Knowledge Center for [Monitoring Agent Reference Guides](#).

**Note:** The Transactions group is not available for the My Components application.

- After you select **Components** or a subgroup from the **Groups** section, the **Status Overview** tab changes to show a summary dashboard with a group widget for each managed resource. The source environment shows as  **Cloud** (IBM Cloud Application Performance Management),  **ITM** (IBM Tivoli Monitoring),  **On Premises** (IBM Cloud Application Performance Management, Private),  **Private Cloud** (IBM Cloud Private), or  **Public Cloud** (IBM Cloud). The **Instances** section is renamed for the subgroup title and is populated with the individual instance names.

If the application has many managed system instances, many group widgets are displayed. You can scroll through the list to see them all. You can also select a managed system type from the list of

component subgroups, such as Windows OS, to confine the display to the same managed system types. You can also filter the managed system instances.

Firefox browser only: Depending on the number of agents and bandwidth, as you scroll down the Components page, you might see a pop-up message that the script to load the resource page takes a long time to complete. Select the option, "Don't ask me again" to disable the message and continue opening the widgets. Alternatively, you can enter `about:config` in the address box, search for `dom.max_script_run_time` and increase the time out value (in seconds). A value of 0 (zero) disables time out.

## Instances

- Click inside a group widget or select the instance name from the navigator to open a detailed dashboard for the managed resource.
- If many instances are displayed in the navigator, use the search field  in the Instances toolbar. As you type, any instances that do not match are removed from the display.
- To pause the Application Performance Dashboard automatic refresh, click **Pause** in the Instances toolbar; to resume automatic refresh, click **Resume**.
- The widgets and KPIs shown for any managed system might depend on the agent version. If an agent installed on the managed system is at an earlier version, it might be unable to provide as much information as the current version of the agent. A message is displayed instead of one or more KPIs in a chart or table when no data is available. The reason could be as simple as no data was reported for the time span. Or it could be related to a back-leveled agent that doesn't support the data set or an attribute included in the chart or table.

To see a list of agent dashboards that were updated since the last Cloud APM server restart, select **Actions > Dashboard Log**.

- Some of the dashboard widgets show metrics that are based on a time range, and other widgets show the most recent metrics. If a time selector bar is displayed, you can adjust the time range for the dashboard that affects any charts or tables whose values are derived from historical data samples. For more information, see [“Adjusting and comparing metrics over time”](#) on page 1263. While viewing charts, you can click a plot point to open a tool tip with the plot point value and other pertinent information. After viewing a line chart in the Internet Explorer Version 11 browser, you might continue to see the tool tip appear as you move the cursor around the window. If you experience this behavior, you can close the tool tip by clicking a few times in the chart.
- If you're viewing a chart with bars missing, it means that the value is 0 (zero) for that data point.

- IBM Cloud Application Performance Management, Advanced Private users have additional diagnostics dashboards that are accessed by clicking the **Diagnose** link from a group widget in the details dashboard.

**Restriction:** The managed system for which you are opening the diagnostics dashboards must reside in the IBM Cloud APM domain. If the managed system resides in the IBM Cloud or IBM Tivoli Monitoring source domain, the diagnostics dashboards are not available. See also [“Cloud APM agent and Tivoli Monitoring agent coexistence”](#) on page 1040.

- If your environment includes the Synthetic Playback agent, you can launch Cloud APM reports for the agent instance from the **Actions** menu.

## Events

- The status indicators that are displayed next to the **Events** tab title, such as **14** **3**, show a count of the highest event severities for the selected navigator item: application, group, subgroup, or instance.

Threshold severities are consolidated, as shown in the following table. For example, **Events** ⚠️ means that the highest severity event is minor or warning.

| Events tab | Threshold Severity |
|------------|--------------------|
| ❌ Critical | Fatal and Critical |
| ⚠️ Warning | Minor and Warning  |
| ✅ Normal   | Unknown            |

When your managed environment includes IBM Operations Analytics - Predictive Insights and an anomaly is detected, an event is opened. A diamond-shaped icon overlays the status indicator, such as ❌, to notify you that at least one anomaly has been detected by Operations Analytics - Predictive Insights. For example, **Events** ⚠️, indicates that the highest status event is ⚠️ Warning and that at least one anomaly event is open.

- Click the **Events** tab to see a summary of the total event count, a count of each severity type, and a percentage gauge for the severities. For more information, see [“Event Status” on page 1280](#).

## Custom Views

The pages that you create and save are associated with the selected application. For example, the Inventory Management application in the Cloud APM Guided Demo has the following monitoring agents: Linux OS, MySQL, Node.js, Hadoop, and Ruby. You can create and save a custom page at any level of the navigator from application to instance and then open it at the same level where it was created. A page that is created at a particular level can be opened only at the same level. The metrics available for the widgets can be from any of the resources in the application. Using the Inventory Management example, you can create a page with a table from the Ruby agent, a chart from Linux OS agent, and so on.

- The **Custom Views** tab is available at any level of the navigator when you select an application from **All My Applications**.
- After you open the **Custom Views** tab, the **Select a Template for your Custom Page** window is displayed or the default page is displayed if it is already set.
  - In the **Select a Template for your Custom Page** window, you can select a template to create a page.
  - On the default page, you can click  to create a new page.
- On the default page, Click  in the page list and select one of the saved pages from the list.
- The options that you see in the Custom Views tab vary based on whether a page is being edited or viewed. For information about editing a page, see [“Creating and managing custom pages” on page 1284](#). For information about viewing a page, see [“Viewing custom pages” on page 1290](#).

## Attribute Details

- The **Attribute Details** tab is displayed after you select a component instance from the navigator **Instances** section (renamed to the selected subgroup name) or by clicking inside a summary group widget.
- If chart or table pages have been saved for the agent, the most recently opened page is displayed with metrics from the selected component instance. Click the title  to select a different saved page from **My Pages**  or **Shared Pages** .
- You can edit the chart or table and click **Preview Results** to render the chart or table with the selected attributes. For more options, see [“Creating a custom chart or table page” on page 1264](#).

## Editing the Components dashboard group widgets

You can edit the threshold values of the group widgets that display in the **Components** dashboard (selected from the navigator **Groups** section). You can also control which group widgets are displayed and their position, and decide whether a widget threshold should be included in determining the component status.

### About this task

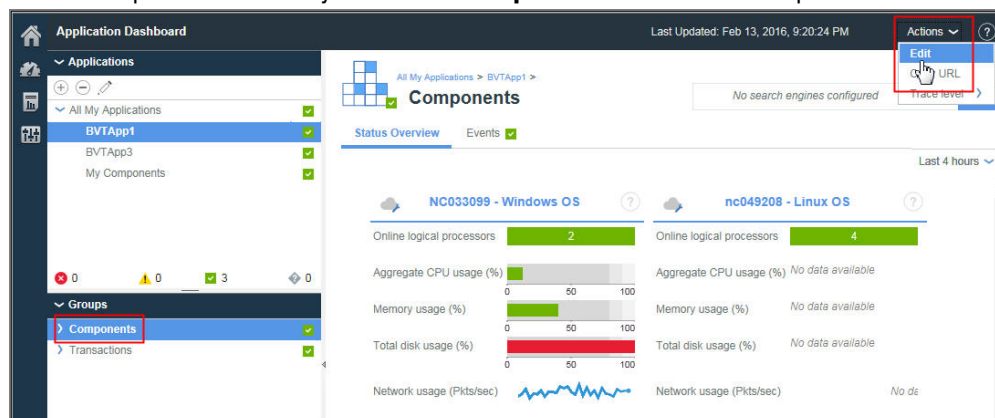

This task involves editing the Components group dashboard and its constituent summary group widget for a defined application. The Components group editor is not available for the **My Components** predefined application. For more information about defined applications, see [“Managing applications”](#) on page 1269.

Your user ID must also have the modify permission for Application Performance Dashboard and the create permission for Applications. For more information, see [“Roles and permissions”](#) on page 1137.

### Procedure

1. After you open the Application Performance Dashboard from the  **Performance** menu, select the application whose summary group widgets you want to edit from the **All My Applications** dashboard.
2. In the navigator **Groups** section, click **Components** to open a dashboard showing group widgets for all the components in the application.
3. Click **Actions** > **Edit** to open the editor for the group widgets in the **Components** group.

The **Edit** option shows only when the **Components** dashboard is open.

4. Make any of the following changes to the group widgets:
  - To remove a group widget from view, click .
  - To modify the summary thresholds for a widget, click  **Settings**, select the **Thresholds** tab, and change the threshold values for the critical, warning, or normal severity. After editing the thresholds for the group widget, click **Done**.
  - To add a widget, click , click applications icons until the one that you want is displayed, click inside the group widget to select it, and click **Add**.
  - To resize a widget, drag the handle icon . Resizing a widget does not change the size of the text or the height of the widget.
  - To move a widget, drag it to a new position.
5. To save your changes and close the editor, click **Save**; or to discard your changes, click **Cancel**.

### Results

The **Components** dashboard of the selected application is displayed with the new settings.

## What to do next

For more information about the dashboard when a group or subgroup is selected in the navigator, see [“Group and Instance - Application Performance Dashboard”](#) on page 1259; for more information about the monitored component dashboard, click the  button in the **Application Dashboard** banner.

## Adjusting and comparing metrics over time

Some of the dashboard charts show metrics that are based on a time range and other charts show only the most recent metrics. When a time selector is displayed in the **Status Overview** tab of a managed system instance, you can adjust the time range for the charts whose values are derived from historical data samples. For attributes that have data collected for multiple days and presented in a line chart, you can compare today's values with a previous day.

### Before you begin

If you are comparing with a time range from a previous day, how far back you can go depends on the number of days that the Cloud APM server has saved and the type of data displayed on the page. For most resource monitoring data sets, data samples are stored for 8 days. The exact number is published in the agent or data collector attribute help and reference PDF (see [Chapter 2, “PDF documentation,”](#) on page 49). Transaction tracking data from the Response Time Monitoring Agent or middleware agents can only be displayed from the last 24 hours (or for the last 4 hours in some cases) and its retention period cannot be changed.

You can configure your Cloud APM server to store up to 32 days of resource monitoring data for some data sets. For more information, see [Managing historical retention values](#).

### Procedure

Take these steps to adjust the time range that is displayed in the line chart for a managed resource instance or to compare the values with the same time range from a previous day.

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu.
2. Navigate to the dashboard page for an instance that shows historical line charts and click the **Last 4 Hours** time selector.
3. Select one or more of the following options:
  - To change the time range displayed, select **Last 4 hours**, **Last 12 hours**, or **Last 1 day**.
  - To compare the time range displayed in a line chart with the metrics from a different day, select **Compare to** and select an earlier day up to the number of days shown in the pop-up calendar as available (a line is drawn through unavailable dates).
  - To have the time range applied to the dashboards of all defined applications in your monitored environment, select **All Applications**. Otherwise, leave the setting at **Only This Application** to apply the time range to only the current application (such as "My Components"). The **Compare to** selection is effective only for the current page.

### Results

- If you are viewing historical data without comparison, all dashboards in the current application (or all applications) are affected by the change.
- If you are viewing a comparison, only line charts in the current page are affected. A line is drawn for each KPI to show the metrics from the chosen day. Some line charts are unavailable for comparison, as indicated by a watermark on the chart: "No Comparison Available". This can happen with newer managed resources that have not yet collected data for the date specified. Try selecting a more recent date for the comparison.
- Any widgets for which no historical data is collected continue to display the most recent values.
- Data points are distributed along the full length of the chart for the selected time range. Time stamps are displayed on the axis label, starting with the earliest time stamp and ending with the most recent

time stamp. Check the oldest data sample to confirm whether a partial range or the full range of historical data is displayed.

- Data sent to the charts and tables is normalized to GMT (Greenwich Mean Time). The **Timestamp** axis prints time stamps based on the time zone of your browser. If your time zone uses Standard Time and Daylight Saving Time, the time stamp displayed during the transition hour is displaced by one hour. Consider, for example, that you are viewing a line chart in Spain and the time changes from 2:00 AM Standard Time to 3:00 AM Daylight Saving Time. The discrepancy between the GMT of the data and the local time of the time stamp results in the time stamps having a gap of one hour from 2:00 AM to 3:00 AM. If you are viewing the same chart in New Zealand during the switch from 3:00 AM Daylight Saving Time to 2:00 AM Standard Time, the time stamps from 2:00 AM to 3:00 AM are repeated.

## Viewing and managing custom charts and tables

The Application Performance Dashboard provides predefined dashboards of your managed system key performance indicators. While you are viewing the dashboard for a component instance, use the **Attribute Details** tab to view saved chart or table pages and to create and manage other pages.

For example, you observe a critical indicator in the summary dashboard and drill down to the instance where the condition is occurring. From here, you add a chart that plots the busy CPU rate to see what is happening over time. You can view details about any available attributes of the selected component instance and save the custom chart or table with the agent for display whenever you open a managed system instance.

A subset of the agent's data sets and attributes is available for use in custom charts and tables. These attributes are the most useful for displaying in dashboards. The full set of attributes is available for use in custom thresholds (see [“Threshold Manager” on page 1119](#)).

To improve performance and reduce redundancy, agents restrict the number of rows that show for certain data sets in the Attribute Details. The data set descriptions in the agent help and reference PDF indicate whether the default data sample limits the number of rows that are sent to the Cloud APM server.

For visually impaired users, the ability to create historical tables provides an alternative to line charts, which assistive technologies such as screen-reader software cannot interpret. For this reason, the **Attribute Details** tab is available for Response Time Monitoring agent and Synthetic Playback agent transaction instances for creating historical tables. For more information, see [“Example of creating a custom table with keyboard controls” on page 1267](#).

## Creating a custom chart or table page

While you are viewing the Application Performance Dashboard for a component instance, you can select the **Attribute Details** tab to view saved chart or table pages and to create and manage other pages.

### About this task

After you drill down from the Application Performance Dashboard home page to an instance of your managed resource, the **Attribute Detailstab** is added to the **Status Overview** and **Events** tabs on the dashboard page.

These instructions are for creating custom charts and tables for component instances. You can follow the steps for Response Time Monitoring agent and Synthetic Playback agent transaction instances, with the following limitations: historical tables only (no charts); you cannot filter the **Data Set** or **Attributes** list; all attributes are selected (you cannot select or deselect individual attributes); you cannot save the page; and the time selector **Previous** option is unavailable for the Synthetic Playback agent.

## Procedure

Complete the following steps to construct a chart or table from any of the data sets that are available for the selected component instance:

1. After you open the Application Performance Dashboard from the  **Performance** menu, drill down to an instance of the managed resource.

The selected system is highlighted in the navigator **Instances** section, which is named for the component type, such as **Ruby App**.

- Click the **Attribute Details** tab.

If no chart or table pages were saved for this monitoring agent type, the **Real time**  **Table** is selected. Real time is appropriate for data sets that return multiple rows and is available only for tables.

- If a saved chart or table page is displayed, click  **New**.

- Enter a name for the chart or table page in the title field.

Do not use any of the following characters in the title: ! " % & ' \* ? < > } { \.

- If you prefer to see data samples over time, change the type to **Historical**.

The **Chart** option is enabled.

- If you selected ☒ **Historical** and prefer a chart rendering rather than a table, click  **Chart**.

- From the **Data Set** list, select the radio button for the attribute type that you want to see. If the list is long, use the  filter box to reduce the list by entering the text that must be included in the data set name.

For example, "config" for the Linux OS agent, filters the data sets to show only the **Linux\_CPU\_Config** and **Linux\_OS\_Config** data sets.

- To include an attribute in the chart or table, select the check box next to the name in the **Attributes** list; to include all attributes, select the check box at the beginning of the list. Enter text in the

 filter box to locate specific attributes, such as "percent".

For example, "percent" on the KLZ\_VM\_Stats data set, filters the list to show **Free Virtual Storage (Percent)** and 5 more "Percent" attributes.

Charts can plot only numeric values; any text or time attributes are disabled.

- Click **Preview Results** to generate the page with the chosen data set, one table column or chart line grouping for each attribute, and one row or plot point for each data sample.

You also get a row or plotted line for the aggregate of all the values.

- To hide chart lines or table rows, take one of the following steps:

| Option       | Description  |
|--------------|--|
| <b>Chart</b> | Hide a metric (a line in the chart) by clearing the check box next to the name in the legend. Select a check box to display a metric.  |
| <b>Table</b> | Reduce the number of rows that are displayed by entering the value to filter by in the  filter box. You can also create an advanced filter, as described in <a href="#">“Defining a table filter”</a> on page 1268. |

- To adjust the time range, use the time selector:

| Option           | Description  |
|------------------|--|
| <b>Real Time</b> | For tables only, refreshes and shows only the latest data sampling.  |
| <b>2 Hours</b>   | Plots a point or adds a row for each data sample that was taken in the past two hours, at intervals.   |
| <b>4 Hours</b>   | Plots a point or adds a row for each data sample that was taken in the past four hours, at intervals.  |
| <b>12 Hours</b>  | Plots a point or adds a row for each data sample that was taken in the past 12 hours, at intervals.  |
| <b>24 Hours</b>  | Plots a point or adds a row for each data sample that was taken in the past 24 hours, at intervals.  |
| <b>Previous</b>  | Submenu of options to include data from the same time period <b>Yesterday</b> , <b>2 days ago</b> , or from any day up to <b>1 week ago</b> . For example, it's 2:10 PM on August 22 and you set the chart or table to show the past 4 hours. By selecting <b>Previous &gt; 1 week ago</b> , you |

| Option | Description   |
|--------|---|
|        | see data points from 10:10 AM - 2:10 PM today and from 10:10 AM - 2:10 PM on August 15.<br>After you select a previous day, the time selector shows an asterisk (*) such as <b>Last 4 hours*</b> and the selected day's data is table is regenerated: |

- It is only possible to view data from today and up to one week ago (even if you have increased the maximum historical data retention period to more than 8 days).
- Historical charts are plotted from the oldest data sample to the most recent for the time range selected, for example, last 4 hours. When a previous day is selected, you see the data from the selected time range on the previous day and the time range for today. Any days that are between the earlier date and today show a plot point with a time stamp and no data samples.
- Historical tables are plotted in descending chronological order. When a previous day is selected for the Response Time Monitoring agent, each column is replicated for the previous day with "Previous" in the column heading.
- Regardless of the time range selected, a maximum of 11,000 rows can be displayed. For example, if you chose to display 12 hours from a data set that sends 7,000 rows in 2 hours, fewer than 3 hours of historical data is returned and the oldest data samples are displayed.

12. To save or make other changes to the chart or table, select one of the following options:

| Option   | Description  |
|--|--|
|  <b>Edit</b>            | Returns you to the editor for making any of the following changes: <ul style="list-style-type: none"> <li>• Edit the title</li> <li>• Change to <b>Real time</b> or <b>Historical</b> data samples</li> <li>• Change to  <b>Chart</b> or  <b>Table</b></li> <li>• Select a different <b>Data Set</b> or <b>Attributes</b> or both</li> </ul> |
|  <b>New</b>           | Discards any unsaved changes to the current view and returns you to the selection page for creating a new chart or table.  |
|  <b>Cancel</b>        | Cancels the editing session for the current chart or table page.   |
|  <b>Delete</b>        | Deletes the page.  <b>Delete</b> is available only after a page is saved and any current editing is canceled.   |
|  <b>Save for Me</b>   | Saves the chart or table page for viewing by your user ID only. No other users can see the saved page.   |
|  <b>Save to Share</b> | Saves the chart or table page for viewing by any user ID that is logged in to the Cloud APM console  |

Views that you save have an opened lock  next to the title. Views that another user saved that you do not have the authority to edit have a closed lock icon.

## Results

After you save the custom chart or table, it is added to the list of saved pages. The next time that you select an instance of the same data source type, such as WebSphere Applications, and select the **Attribute Details** tab, the most recently opened saved page is displayed. Click the title  to select a different saved page from **My Pages**  or **Shared Pages** .

## What to do next

Repeat this procedure to create and manage other chart or table pages.

For guidance on creating a table by using keyboard controls instead of mouse clicks, see [“Example of creating a custom table with keyboard controls”](#) on page 1267.

## Example of creating a custom table with keyboard controls

Visually impaired users can use the **Attribute Details** dashboard tab to create historical tables as an accessible alternative to historical line charts, which cannot be interpreted by assistive technologies such as screen-reader software.

### About this task

The following example illustrates the use of keyboard controls to create a historical table for transactions that are reported by the Synthetic Playback agent. For more information about the agent, see [“Managing synthetic transactions and events”](#) on page 1177.

As you press the Tab key, the focus moves to the next field or next section of the application window, from left to right and top to bottom. You can use these steps to generate a transactions table for the Response Time Monitoring Agent by substituting **My Transactions** with an application that includes the agent, or to generate a table for a component instance by substituting **My Transactions** with another application and selecting the **Components** group.

### Procedure

Follow these steps to create a table of transactions from the Synthetic Playback agent in the **Attribute Details** tab using the keyboard shortcuts:

1. Log in to IBM Cloud Application Performance Management.  
The focus is on the navigation bar.
2. To open the Application Performance Dashboard, press down-arrow to move the focus to the **Performance** menu, press Enter to select it, press down-arrow to the **Application Performance Dashboard** option, and press Enter again.
3. To open the **Synthetics Transactions** dashboard page, press Tab repeatedly (about 7 times) until the focus moves to the navigator, press down-arrow to focus on the **My Transactions** predefined application, and press Enter.
4. To open the **Transactions Details** dashboard page, press Tab (about 10 times) until the focus moves to the navigator **Instances** section on a **Synthetics Transactions** transaction instance, and press Enter.  
The **Attribute Details** tab is displayed on the dashboard.
5. To open the **Attribute Details** tab, press Tab (about 6 times) until the focus is on the **Status Overview** tab, and press right-arrow until the focus is on the **Attribute Details** tab.  
The **Historical**  **Table** and all attributes of the **Transaction Availability Over Time** data set are selected.
6. To generate the table, press Tab (about 18 times) until the focus is on the **Preview Results** button, and press Enter.

### Results

The **Transaction Availability Over Time** attributes are displayed in a table, with column for each attribute and one row for each data sample over the past 4 hours.

### What to do next

- To reduce the number of rows that are displayed, you can press Tab to focus on the  **Filter** text box, and enter a partial or entire text or timestamp value to filter by.
- To change the time range, move the focus to the Time Selector **Last 4 hours**  drop-down menu and select another option. For more information, see step [“11”](#) on page 1265 in [“Creating a custom chart or table page”](#) on page 1264.

- To generate a table with the **Transaction Response Time** data set, press Tab (about 2 times) to move the focus to the  **New** tool, and press Enter. The selection panel is displayed. Select the **Transaction Response Time** data set and the **Preview Results** button.

## Defining a table filter

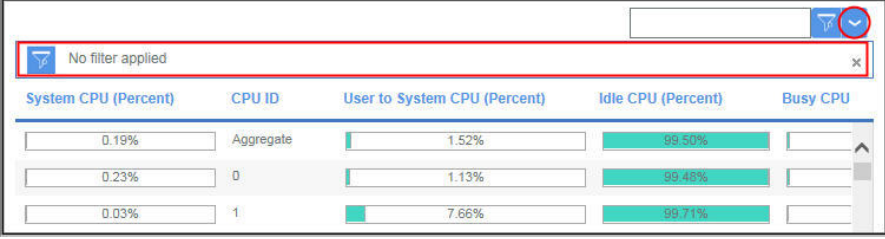

You can limit the rows in a table that you are viewing in the dashboard **Attribute Details** tab to show only rows of a certain type, or that have specific by text or timestamp attribute values. Although numeric values are not available for filtering, such as percentages, some numeric attribute values are converted to a display value for the table and treated as text. You can apply a quick filter or open an editor to compose an advanced filter.

## Procedure

Complete these steps to filter a custom table by text or timestamp attribute values. Although numeric values are not available for filtering, such as percentages, some numeric attribute values are converted to a display value for the table and treated as text.

1. After you open the Application Performance Dashboard from the  **Performance** menu, drill down to an instance of the managed resource.
2. Click the **Attribute Details** tab.  
The most recently saved page is displayed or, if no pages have been saved, the **Data Set** and **Attributes** selection lists are displayed.
3. If a saved table page is displayed, continue to step “5” on page 1268, select another saved table page from the drop-down menu , or click  **Add** to create a new table.
4. If you are creating a new table or editing a saved table, select the **Data Set** and **Attributes** to use, and click **Preview Results**.
5. For a quick filter, click in the  **Filter** text box and type the partial or full text to filter by.  
As you type, any rows that do not contain what you typed are removed from the table. To remove the quick filter, delete the value or click the "x".
6. For an advanced filter, click the  drop-down menu and select **Build Filter** or click anywhere in the filter bar.

The **Build Filter** window opens with any rules that were defined.

The screenshot shows a 'Build Filter' window with a table of CPU metrics. The table has five columns: System CPU (Percent), CPU ID, User to System CPU (Percent), Idle CPU (Percent), and Busy CPU. The first row is labeled 'Aggregate' and shows values: 0.19%, 1.52%, 99.50%, and an empty Busy CPU cell. The second row is labeled '0' and shows values: 0.23%, 1.13%, 99.48%, and an empty Busy CPU cell. The third row is labeled '1' and shows values: 0.03%, 7.66%, 99.71%, and an empty Busy CPU cell. A filter bar at the top shows 'No filter applied' with a clear button (x).

| System CPU (Percent) | CPU ID    | User to System CPU (Percent) | Idle CPU (Percent) | Busy CPU |
|----------------------|-----------|------------------------------|--------------------|----------|
| 0.19%                | Aggregate | 1.52%                        | 99.50%             |          |
| 0.23%                | 0         | 1.13%                        | 99.48%             |          |
| 0.03%                | 1         | 7.66%                        | 99.71%             |          |

7. To define a rule, complete the fields:
  - a) Leave the column setting at "Any Column" or select the attribute to filter by from the list.
  - b) Leave the condition at "contains" or select another operator from the list and enter the text or timestamp value to filter by in the text box:

| Condition      | Row is included in the table when...                                      |
|----------------|---|
| contains       | the filter value is found somewhere in the cell.                          |
| equals         | the cell value matches the filter value exactly, including letter casing. |
| starts with    | the cell value begins with the same characters as the filter value.       |
| ends with      | the cell value has the same characters at the end as the filter value.    |
| does not equal | the cell value is not an exact match of the filter value.                 |

| Condition           | Row is included in the table when...   |
|---------------------|--|
| does not contain    | the cell value does not include the same text or number as the filter value. |
| does not start with | the cell value does not begin with the same characters as the filter value.  |
| does not end with   | the cell value does not end with the same characters as the filter value.    |
| is empty            | the cell shows no data.  |

c) After you complete the rule, click **Filter** to see the results, click  **Add Filter Rule** to add another rule, or go to the next step.

8. If the filter has multiple rules, take any of these steps:

- **Match** is initially set to **All rules**, which means that a row is displayed only if the data in the row follows all the rules in the filter. The row is excluded if no text or timestamp values follow any one rule. If you have multiple rules and you want a row included if it follows any of the rules, change the setting to **Any rule**.
- To edit a rule, change any of the field values.
- To delete a rule, select it and click  **Remove Rule**.

9. When you are finished defining a rule (or rules), click **Filter** to close the dialog box and apply the filter.

## Results

The groups that do not meet the filter criteria are removed from the display and the filter bar reports the number of items, for example, "480 of 1200 items shown".

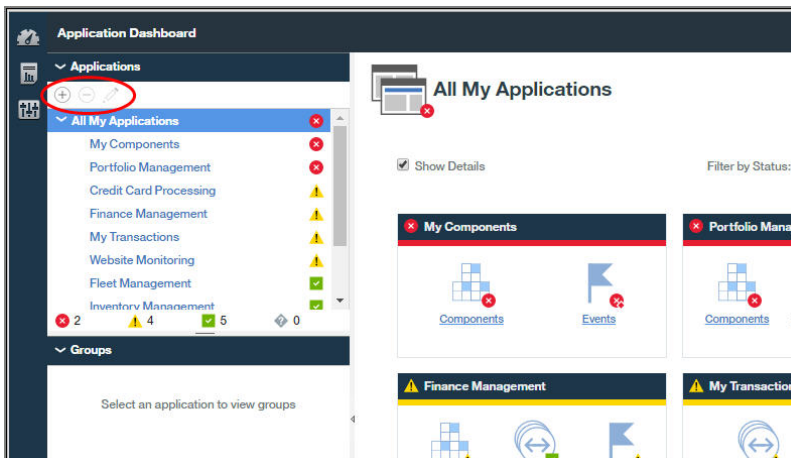

## What to do next

- Hover the mouse pointer over the filter bar to open a pop-up window with the filter criteria. You can delete a rule (click ) or click inside the window to edit the filter criteria.
- Click **Clear filter** in the filter bar or **Clear** in the **Build Filter** window to remove the filter and display all rows.

## Managing applications

Use the tools that are available in the Application Performance Dashboard to organize your managed resources into applications.

The navigator **Applications** tools open the Applications editor for creating or editing applications and applying the managed resources that are available.

The *My Components* application is a predefined application that includes the managed systems that were discovered by the Cloud APM server. **My Components** cannot be edited or deleted.

The *My Transactions* application is a predefined application that includes synthetic transaction data. My Transactions cannot be edited or deleted.

For a video demonstration about adding an application, watch [Application Performance Management - Define Application](#).

For a scenario about creating an application for monitoring the IBM Java application stack, see [“Adding web applications to the Application Performance Dashboard ” on page 118](#) and [“Associating the IBM Java application stack with the web application ” on page 119](#).

**Restriction:** You must have modify permission for Applications to use the Add application tool. You must have modify permission for Applications or the specific application to use the Remove and Edit tools. For more information, see [“Working with roles, users, and permissions” on page 1144](#).

## Adding an application

Use the Applications editor to create a new application and apply the managed resources that are available, or select one from any discovered applications.

### Before you begin

You must have modify permission for Applications to use the Add application tool. For more information, see [“Working with roles, users, and permissions” on page 1144](#).

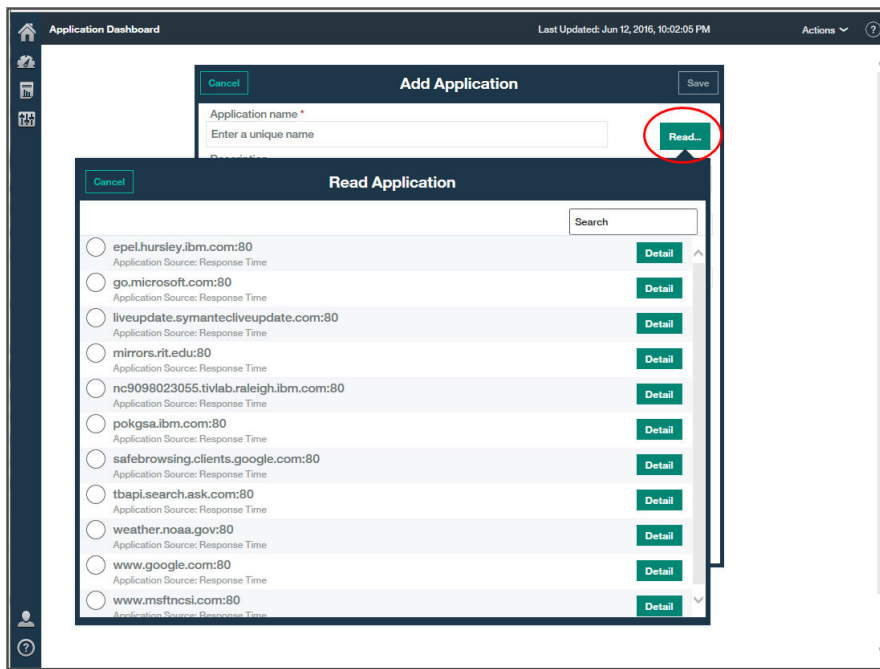

### Procedure

Complete the following steps in the Cloud APM console to add an application to the Application Performance Dashboard.

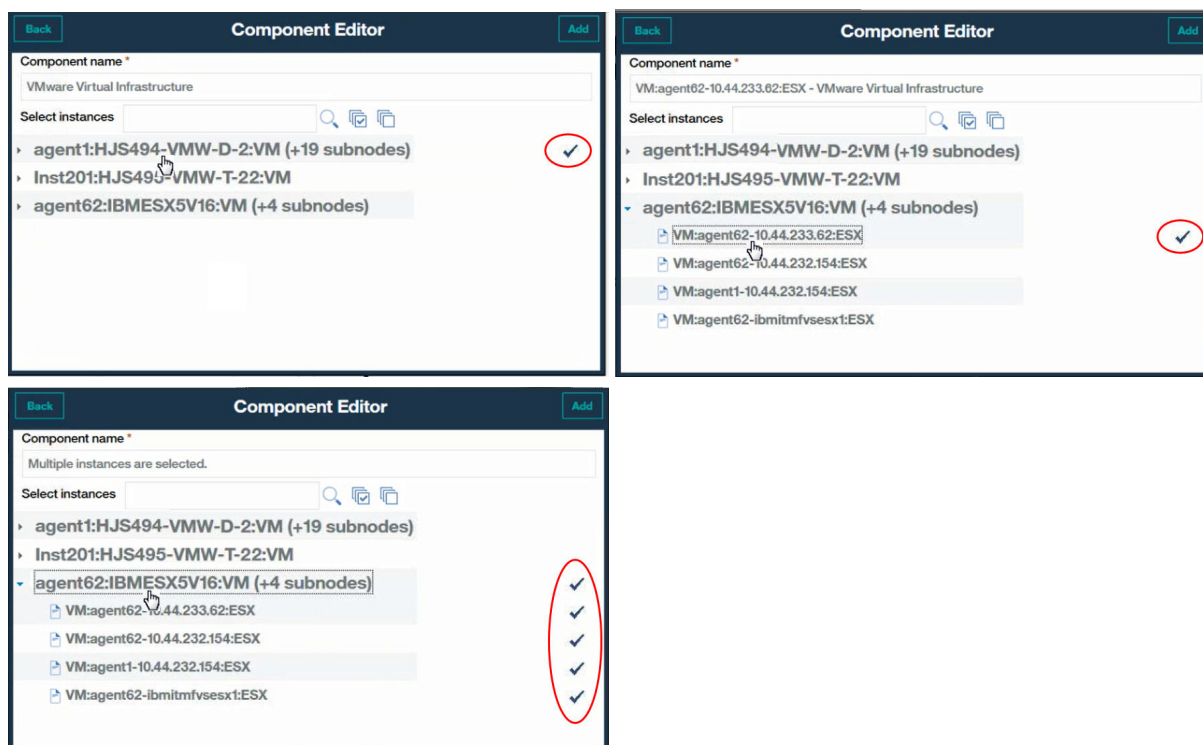

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu or, if you are on another console page, click the **Home** link.
2. In the **Applications** section of the navigator, click . The **Add Application** window is displayed.

3. Enter a name for your application in the **Application name** field and, optionally, a description in the **Description** field.  
Do not use the ! " % & ' \* ? < > } { \ symbols in the name or description.  
You can see some examples of application names, such as "Finance Management" and "Credit Card Processing" in the [Guided Demo](#).
4. Click **Read** to open the **Read Application** window with a list of any discovered applications, and take one or more of the following steps:
  - Click **Detail** to see the components of an application.
  - Select the application that you want to use, and click **Save**. The **Read Application** window closes, the source repository is displayed in the **Application read from** field, and the components are listed in **Application components**.
  - Click **Cancel** to close the window without making a choice.

5. In the **Template** field, keep the **Custom Application** template or select a different template with the  button, and click **Save**.  
Any associated component types and instances are shown in the **Application components** list.
6. Click  **Add components** and, in the **Select Component** window that opens, select a component from the list.  
The **Component Editor** is displayed.
7. To find and select agent node or subnode instances (or both) for the application, take one or more of the following steps:
  - Click an instance to select it.
  - For agent nodes that have subnodes, select the node alone by clicking the name while the tree is collapsed, select the node and all subnodes by expanding the node tree (click ) and clicking the node, or select individual subnodes by expanding the node tree and clicking the instance.
  - Use the    toolbar to search for instances that contain the text in the search text box, to select all instances, or to clear all instances.
  - If you want to change the display name in the navigator, edit the component name.

**V6-V7** If you are adding a Tivoli Monitoring agent instance and don't see it in the list of available instances, check that the Tivoli Enterprise Portal Server that is associated with the Hybrid Gateway is at a supported version (see [Hybrid Gateway supported agents \(APM Developer Center\)](#)).

8. Click **Add** to add the selected agent nodes and subnodes to the application, and click **Back**.  
The Application components list is updated with the new component names.
9. Select another component to add instances to and repeat “6” on page 1271, “7” on page 1271, and “8” on page 1272 or click **Close**.
10. If other instances are related to the components in the **Application components** list, a button that shows the number of related instances is displayed and you can take the following steps:
  - a) Click the **i** button to see the related instances in the **Updated Details** window.  
A bar is shown for each type of update, including the instance name. For example, if one of the components was removed, it shows beneath the **Deleted** components bar.
  - b) Select one or more instances and click **Save** to update the Application resources list.
11. When you are finished defining the application, close the application editor by clicking **Save** to save your changes or click **Cancel** to undo the changes.

## Results

Your application updates are completed by the Cloud APM server after you save your changes. It might take a few minutes before your changes appear in the dashboard. (Try clearing the browser cache if it takes a long time for your changes to display.) The new application is displayed in the Application Performance Dashboard and the navigator **Applications** section. When the application is selected, the components are displayed in the **Groups** section.

## Editing an application

Use the Applications editor to modify a defined application to add or remove managed resources as components of the application.

### Before you begin

You must have Modify permission for Applications or the specific application to use the Edit tool. For more information, see [“Roles and permissions” on page 1137](#).

### Procedure

Complete the following steps in the Cloud APM console to edit an application.

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu or, if you are on another console page, click the **Home** link.
2. Select the application that you want to edit from the **All My Applications** list in the navigator and click .

The **Edit Application** window is displayed.

3. Optional: Edit the **Application name** or **Description**.

Do not use the ! " % & ' \* ? < > } { \ symbols in the name or description.

If your Applications View or Modify permissions are for individual applications and not all applications, you might not be able to see the application in the dashboard or modify the application after it is renamed. This limitation is because the renamed application is treated as a new application. Your role administrator or monitoring administrator must give you View or Modify permission for the renamed application.

4. To add components and instances to the application, take the following steps.

- a) Click  and, select a component from the list in the window that opens.

The **Component Editor** is displayed.

- b) Select agent node or subnode instances (or both) for the application:

- Click an instance to select it.
- For nodes that have subnodes, select the node by clicking the name while the tree is collapsed, select the node and all subnodes by expanding the node tree (click ) and clicking the node, or select individual subnodes by expanding the node tree and clicking the instance.
- Use the    toolbar to search for instances that contain the text in the search text box, to select all instances, or to clear all instances.
- If you want to change the display name in the navigator, edit the component name.

- c) Click **Add** to add the instance or instances, and click **Back**.

The Application components list is updated with the new component names.

- d) You can select another component to add instances to, or click **Close**.

The Application components list is updated with the new component names. A number in parentheses after the name indicates how many instances are associated with the component.

5. To edit a component name or change the instance that is associated with it, select the component from the **Application components** list and click .

- a) To associate a different instance with the component, search for and select the instance that you want.

- b) To change the component name that is used as the display name in the navigator for this application, edit the **Component name** field.
  - c) Click **Save**.
- The Application components list is updated with the changes that you made.
- 6. To remove a component or instance from the application, select it and click . Click **OK** to confirm that you want to remove it.
  - 7. If other instances are related to the components in the **Application components** list, a button that shows the number of related instances is displayed and you can take the following steps:
    - a) Click the  button to see the related instances in the **Updated Details** window.  
A bar is shown for each type of update, including the instance name. For example, if one of the components was removed, it shows beneath the **Deleted** components bar.
    - b) Select one or more instances and click **Save** to update the Application resources list.
  - 8. After you are finished editing the application, close the application editor by clicking **Save** to save your changes, or **Cancel** to undo the changes.

## Results

Your application updates are completed by the Cloud APM server after you save your changes. It might take a few minutes before your changes appear in the dashboard.

### Related reference

[“Roles and permissions” on page 1137](#)

## Deleting an application

When you no longer need an application that you have defined for display in the Application Performance Dashboard, you can delete it. Deleting an application does not uninstall the supporting components; only the application that they are contained in. The same components are available for adding to other applications and are not removed from other applications that they belong to.

### Before you begin

You must have modify permission for Applications or the specific application to use the Remove tool. For more information, see [“Working with roles, users, and permissions” on page 1144](#).

### Procedure

Complete the following steps to remove an application from the Application Performance Dashboard.

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu or, if you are on another console page, click the **Home** link.

2. In the **Applications** section of the navigator, select the application that you want to delete from the **All My Applications** list and click .
- A message asks you to confirm.
3. Click **Yes** to confirm that you want to delete the application; or **No** if you are not sure.

## Results

After you click **Yes**, the application is deleted from the Application Performance Dashboard.

## What to do next

Repeat this step for any other applications that you want to delete.

## Viewing and removing offline agents

After an agent has been offline for four days, it is removed from the Cloud APM console. Review how offline agents are indicated and the effect on resource groups, topology views, and other features. Use the application editor to remove a managed system from the dashboard before the four days have passed. You can also adjust the timing for removing offline managed systems..

### About this task

After agents are installed on the systems that you want to manage, they connect to the Cloud APM server and send data samples to the Application Performance Dashboard for presentation and threshold evaluation. If the agent is offline, the  status indicator is displayed in the navigator and in the dashboard. The server waits for a specific number of intervals to pass with no response from the agent before showing that the agent is unavailable. See [“Examples of offline agents” on page 1276](#).

After four days, the offline agent is removed from the user interface with the following exception: If the agent is one that supports transaction tracking, the offline agent continues to show in the Aggregate Transaction Topology and Transaction Instance Topology views.

You can remove the offline agent from any defined applications, which removes it from the Cloud APM console before the four-day waiting period is complete. For future occurrences of offline agents, you can also adjust the wait time before the offline agent is removed from view. See "What to do next" at the end of this topic.

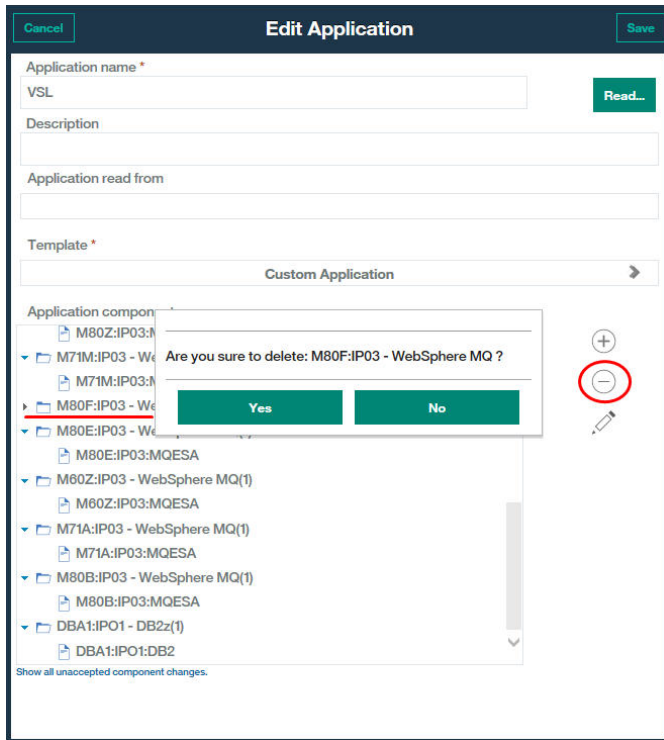

## Procedure

Take these steps to remove an offline agent from a defined application:

1. If the Application Performance Dashboard is not displayed, select it from the  **Performance** menu or, if you are on another console page, click the **Home** link.
2. In the **Applications** section of the navigator, select the application that the offline agent is a component of and click  **Edit Application**.

3. Select the agent or agent subnode in the Application Components list and click .  
For agents that have subnodes, select the agent alone by clicking the name while the tree is collapsed, select the node and all subnodes by expanding the node tree (click ) and clicking the node, or select individual subnodes by expanding the node tree and clicking the instance.

4. After you are finished editing the application to remove the offline agent or subnode, click **Save**.

## Results

Your application updates are completed by the Cloud APM server after you save your changes. It might take a few minutes before the offline agent is removed from the Application Performance Dashboard.

## What to do next

You can adjust the **Remove Offline System Delay** setting in the **Advanced Configuration** page to increase or decrease the wait time before the offline agent is removed from view. For more information, see [“Agent Subscription Facility” on page 1242](#).

## Examples of offline agents

Review the examples of how offline agents are displayed in the Cloud APM console. You can remove the display for any offline agents that you no longer want to monitor. If the agent comes back online later, monitoring resumes.

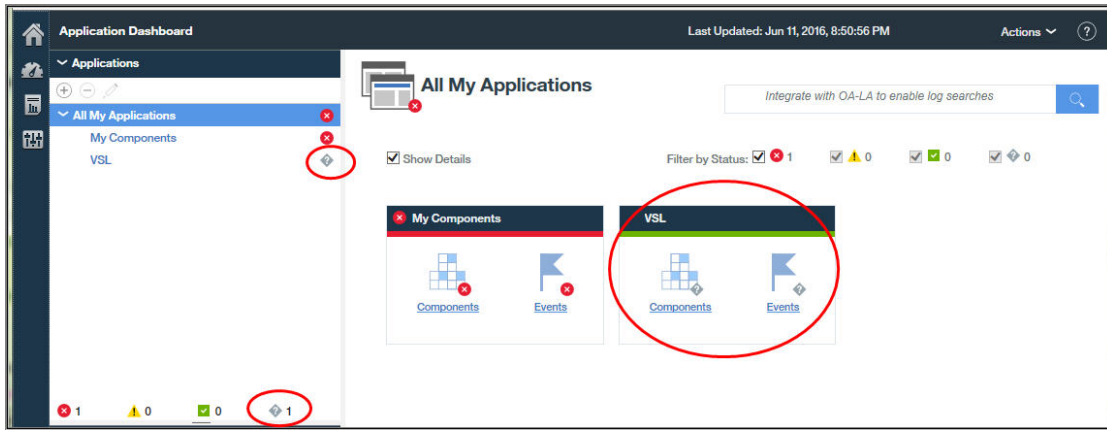

When an agent is offline, no data is sent to the Cloud APM console and the Application Performance Dashboard displays a  status indicator for the agent and the applications it belongs to. The agent is unavailable for adding to a defined application in the Application editor or to a custom group in the Resource Group Manager, or for creating tables and historical line charts in the Attribute Details tab.

### Application Performance Dashboard - All My Applications

The home dashboard page, **All My Applications**, gives the first indication of offline status. The counter in the navigator Applications section shows the number of applications with unavailable resources.

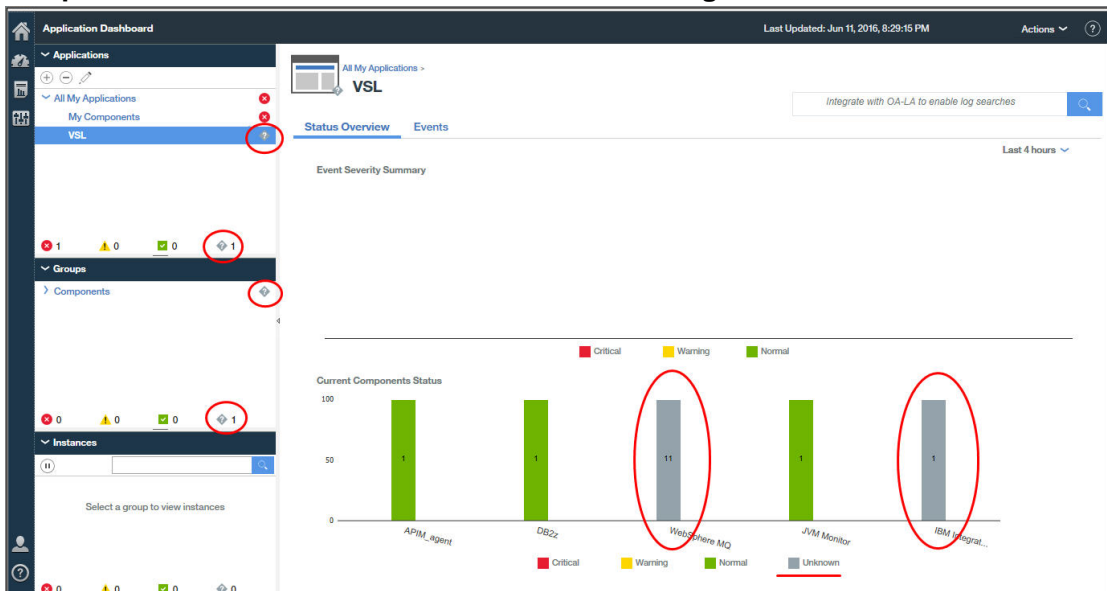

The summary box shows Normal event status because no events are open for any of the application's managed resources.

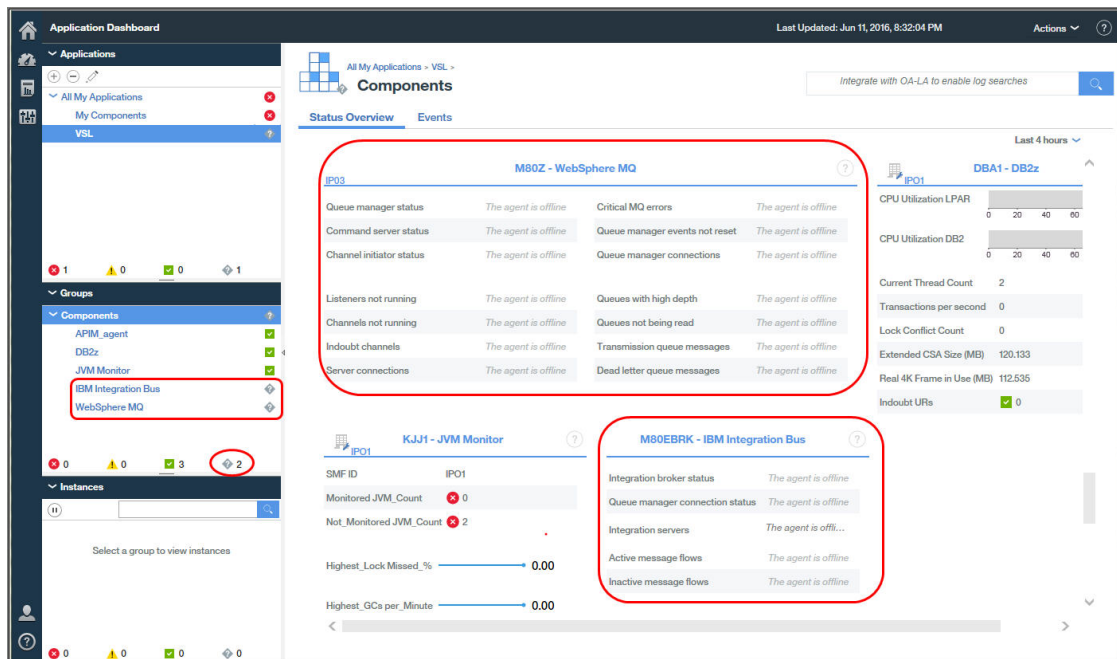

### Application Performance Dashboard - Application

After the user clicks the summary box title bar or selects the application from the navigator, the **Status Overview** tab is displayed with an empty **Event Severity Summary** chart. The **Current Component Status** bar chart shows the status for offline agents as "Unknown".

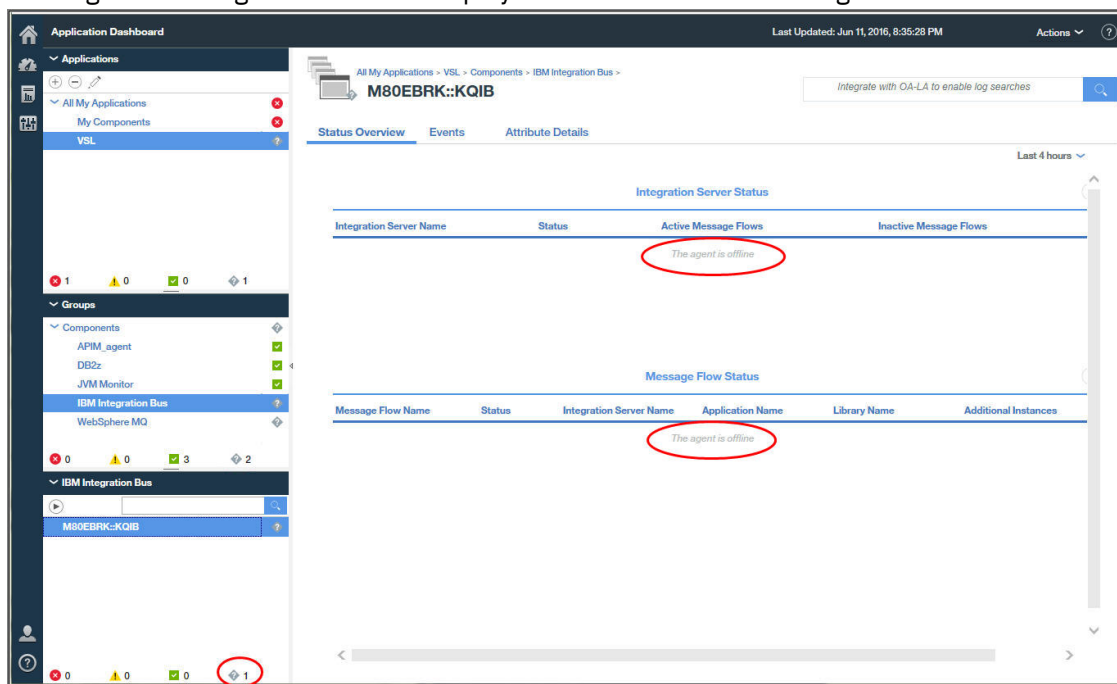

### Application Performance Dashboard - Group

After the user clicks inside the **Current Component Status** chart or the navigator **Components** group, the **Status Overview** tab changes to show a summary group widget for each managed resource. The group widgets for the unavailable agents display a message that the agent is offline instead of KPIs.

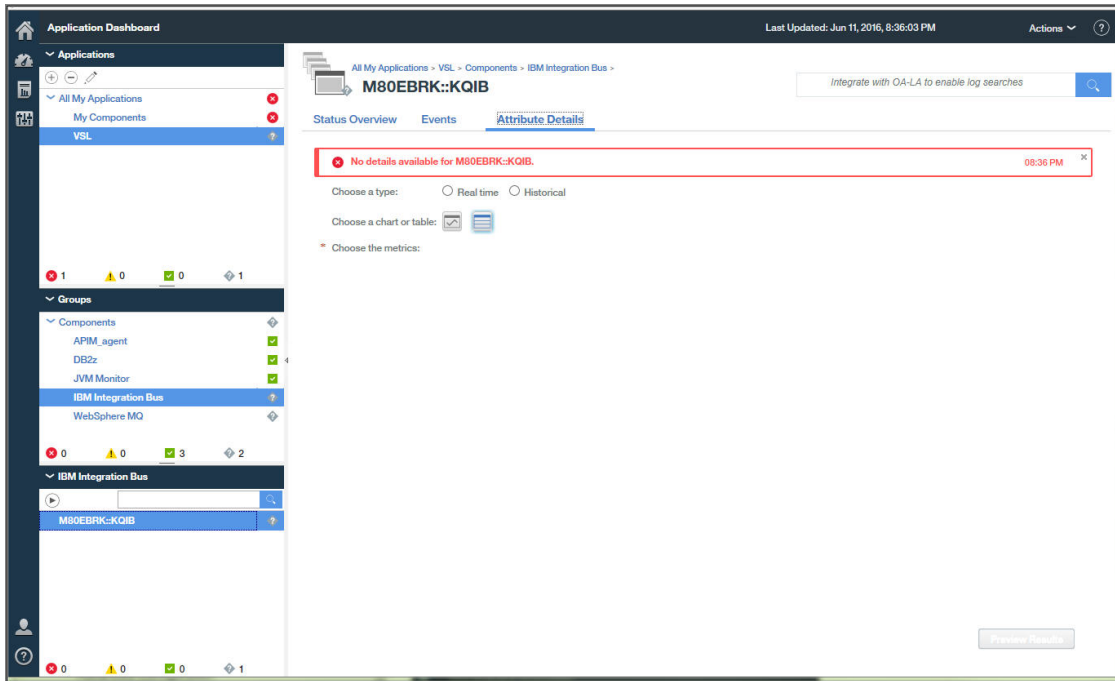

### Application Performance Dashboard - Instance

After the user clicks inside one of the offline agent summary group widgets, the **Status Overview** tab shows chart and table widgets for the selected agent. But, as for the summary group widget, only a message that the agent is offline is displayed instead of KPIs for the agent instance.

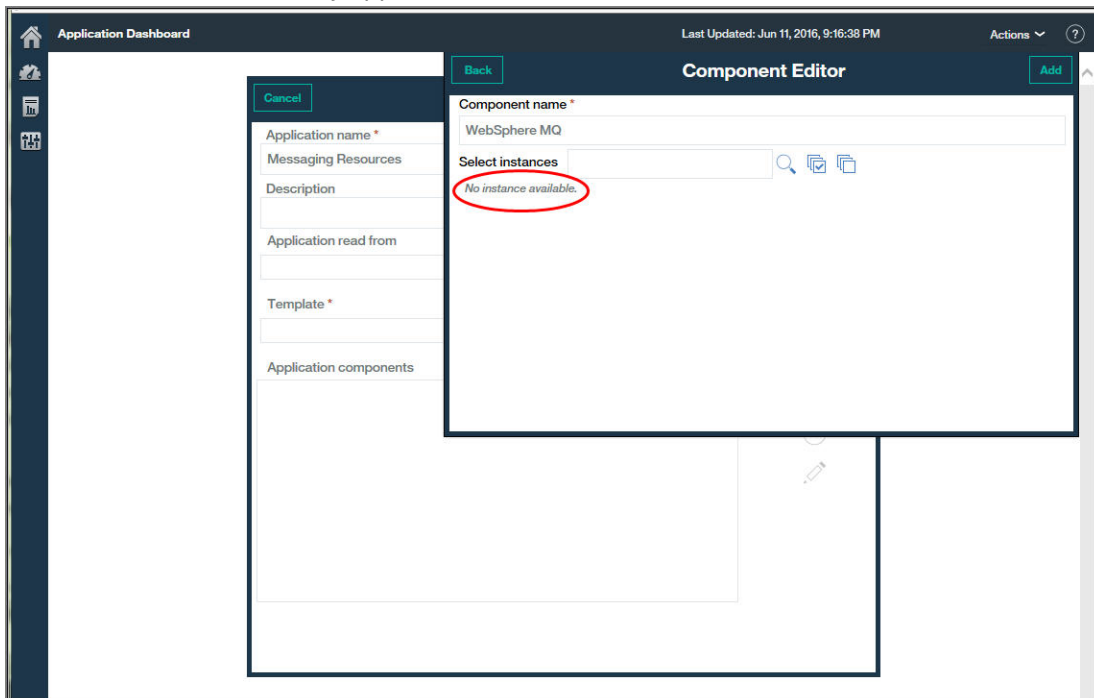

After the user clicks the **Attribute Details** tab, a message says that no details are available for the agent instance. It's not possible to create a custom chart or table for the offline agent instance.

### Application editor

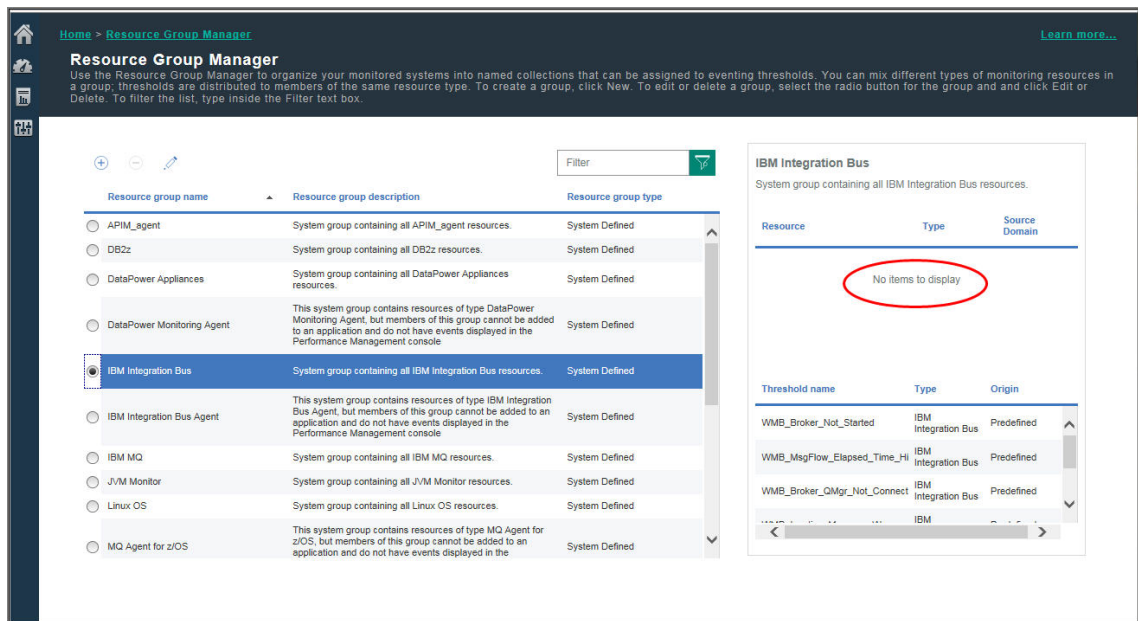

In the Application Performance Dashboard, after the user clicks the navigator Applications **Add Application** or **Edit Application** tool, the Application editor window pops up.

After the user clicks **Add components** and selects an agent type, if no agents of that type are installed or are offline, a message informs you that no agent instances are available. If other agent instances are available, they appear in the list.

### Resource Group Manager

After the user selects **System Configuration > Resource Group Manager**, the page opens with a table of resource groups. As you select a group, its constituent agent instances are listed along with the assigned thresholds. If all agents instances are offline, a message says that no instances are available.

## Related concepts

[“Managing applications” on page 1269](#)

Use the tools that are available in the Application Performance Dashboard to organize your managed resources into applications.

[“Using the dashboards” on page 1251](#)

## Related reference

[“Resource Group Manager” on page 1114](#)

Your monitored environment might have multiple managed systems that can be categorized by their purpose. Such systems often have the same threshold requirements. Use the **Resource Group Manager** to organize managed systems into groups that you can assign thresholds to. You can also create resource groups that correlate with your role-based access control (RBAC) policies.

## Event Status

Use the **Event Status** to get a summary overview of open events for the selected navigator item and to respond to events with a critical or warning status by drilling down to detailed dashboards.

The status indicators are for events from the thresholds that are running on your managed systems. If you have Hybrid Gateways configured, the events can also be from situations that are running on the managed systems in your IBM Tivoli Monitoring environment. If your configuration includes IBM Operations Analytics - Predictive Insights, any detected anomalies are also displayed.

Events for some thresholds do not display in the Application Performance Dashboard. The thresholds use attributes for resources that are not published, which can occur in agents that support subnodes. (For a description of subnodes, see the Agent Builder topic, ).

### Critical, Warning, Normal

- The status indicators consolidate the event severities from the thresholds:

- Critical status indicates all events with a Fatal or Critical severity
- Warning status indicates all events with a Minor or Warning severity
- Normal status indicates all events with an Unknown severity

- Unknown status indicates that the managed system is offline. After 4 days offline, the managed system is removed from any applications and no longer is displayed in the dashboards. To check the status, stop, or start an agent, see [“Using agent commands” on page 236](#). To change the time to wait before an offline managed system is removed, see the **Remove Offline System Delay** option in [“Agent Subscription Facility” on page 1242](#)

- **V6-V7** When one or more Hybrid Gateways are configured, the status indicators for events from Tivoli Monitoring situations are the same as for thresholds except that Normal status indicates events with Harmless, Informational, or Unknown severity.
- When your managed environment includes IBM Operations Analytics - Predictive Insights, any detected anomalies are indicated by a diamond-shaped icon over the status indicator, such as . For more information, see [“Investigating anomalies with Operations Analytics - Predictive Insights”](#) on page 1282.

### Event Severity Summary percentage gauge

- The Event Severity Summary gauge shows the Critical, Warning, and Normal event status percentages. For example, shows that 50% of events are from thresholds with a Minor or Warning severity and 50% are from thresholds with a Fatal or Critical severity.
- Also reported is the total number of events and how many for each status level.
- The event count includes any anomalies from Operations Analytics - Predictive Insights. For example, a total of "8 including 1 anomaly" means that there are 7 threshold events and 1 anomaly event.

### Events table

- The table of open events and status is defined by the selected navigator item: application, group, subgroup, or instance.
- Events are sorted by the **Severity** column, with the highest severity shown first. Click a column heading to change the sort order.
- Each row provides the following information about the event:

#### Threshold Name

The name that was given to the threshold.

**V6-V7** The name that was given to the situation.

#### Status

The status of the event, such as **Open**.

#### Severity

The severity value of the event: Critical (applies to Fatal and Critical threshold severities), Warning (applies to Minor and Warning threshold severities), or Normal (applies to Unknown threshold severities; for Tivoli Monitoring events, applies to Harmless, Informational, and Unknown severities).

Unknown status indicates that the managed system is offline. After 4 days offline, the managed system is removed from any applications and no longer is displayed in the dashboards. (To check status, stop, and start an agent, see [“Using agent commands”](#) on page 236.)

When your managed environment includes IBM Operations Analytics - Predictive Insights, analytics applied to the historical data might detect an anomaly and open an event. An event opened for a detected anomaly is indicated by an icon overlaying the status indicator, such as . Click the **View anomaly analysis** link to open the Predictive Insights **Service Diagnosis** view in a new browser tab or window. Use the **Service Diagnosis** view to review the anomalous behavior in the components that support the application.

#### Display Item

Applies to multiple-row data sets only. The display item is a key attribute that was selected for the threshold to distinguish multiple events from one another that were opened for the same managed system.

#### Source

The system host name or other name that is derived from the monitoring agent that identifies the source of the event.

**Timestamp**

The date and time when the event occurred or the condition was observed by the originating agent, expressed in the time zone of the Cloud APM console user.

If an agent is restarted or threshold definitions are modified for an agent, then the agent's sampled events are closed and reopened if the threshold condition is still true. In these scenarios, the Timestamp value is updated to the time when the originating agent reopened the event.

For pure events, a new event is opened by the agent and replaces the previous event instance each time the originating agent determines that the threshold condition is true. A pure event remains open for 24 hours (or a configurable number of hours) after the last time the threshold condition evaluated to true. Only the latest instance of a pure event is displayed on the Cloud APM console.

**Description**

The description, if any, that was written for the threshold.

- Click a row to expand the details about the event:

**Node**

The managed system name of the node instance.

For agents with subnodes, the **Enable Subnode Events** option controls whether subnodes are shown. For more information, see [“UI Integration” on page 1239](#).

**Threshold ID**

The threshold identifier.

**Global Timestamp**

The date and time when the event was received from the originating agent by the Cloud APM server, expressed in the time zone of the Cloud APM console user.

**Type**

Whether the event is pure or sampled. Pure events are unsolicited notifications. Thresholds for pure events have no sampling interval or constant metric that can be monitored for current values.

**Description**

The description, if any, that was written for the threshold.

**Formula**

The formula as it is written in the Threshold Editor. For example, `Percent Failed > 10.000 AND Transaction Definition Name != 'Ignore_Resources'`.

IBM Cloud Application Performance Management 8.1.4.0 Interim Fix 3 Server Patch or later (on Fix Central): If the EIF Slot Customization function was used to customize the value of the **msg** base slot, the customized **msg** slot value is displayed instead of the threshold formula. For more information, see [“Forward EIF Event?” on page 1120](#) in the Threshold Manager topic and [“Customizing an event to forward to an EIF receiver” on page 1124](#).

You can select and expand other rows, or click again to collapse a row. While a row is expanded, you can drill down to the dashboards for the managed system that you can use to help determine the cause of the event.

## Investigating anomalies with Operations Analytics - Predictive Insights

IBM Cloud Application Performance Management only: When your managed environment includes IBM Operations Analytics - Predictive Insights, analytics applied to the historical data can detect anomalies and open events. Use the Application Performance Dashboard to locate and view anomalies that were detected by Operations Analytics - Predictive Insights.

## Before you begin

Operations Analytics - Predictive Insights must be integrated with your Cloud APM environment for you to be alerted of anomalies in the Application Performance Dashboard. For more information, see [“Integrating with Operations Analytics - Predictive Insights” on page 1077](#).

## About this task

The Application Performance Dashboard shows the status summary of the applications in your domains and their component managed systems. Event status indicators in the **All My Applications** dashboard summary boxes show  Critical,  Warning, and  Unknown severities. If the events include anomalies that are detected by Operations Analytics - Predictive Insights, the status indicator includes an anomaly icon: , , or . The same indicator for critical and warning anomalies appears next to the **Events** tab title as you drill down to application, group, and instance dashboard pages: **Events**  <sup>2</sup>. For a hands-on demonstration, start the IBM Cloud Application Performance Management [Guided Demo](#), scroll down the Tasks list, and select *Identify & Diagnose Predictive Insights Anomalies*.

## Procedure

Complete these steps to identify anomalies and view them in the Operations Analytics - Predictive Insights **Service Diagnosis** view:

1. Click  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard.
2. If a summary box has an  **Events** status indicator that shows the anomaly icon, click the **Events** link. The application dashboard opens to the **Events** tab. The **Event Severity Summary** reports the total number of events including the number of anomalies.
3. Click a table row of an anomaly event, which is indicated in the **Severity** column by , , or . The row expands to show the event details.
4. Click **View anomaly analysis**  to open the Operations Analytics - Predictive Insights **Service Diagnosis** view in a new browser tab or window.

## What to do next

- Use the **Service Diagnosis** view to review the anomalous behavior in the components that support the application. Click  to open the online help for the **Service Diagnosis** view.
- Return to the application dashboard and look for any other events on the managed system that might indicate a related issue. Click the **Status Overview** tab, and drill down to the managed system instance on which the event occurred to investigate further. Use the information to determine what actions need to be taken to avoid the issues identified by Predictive Insights.
- If you expect to see anomalies but none is displayed, the Operations Analytics - Predictive Insights training time might not be sufficient to produce anomalies. Two weeks is the typical training time. It is also possible that additional configuration is required.

## Custom views

Use the IBM Cloud Application Business Insights Universal View to enhance the value that the predefined Application Performance Dashboard pages already provide by customizing your own pages.

The Universal View can be used to display resource monitoring data. It cannot be used to display synthetic transaction data, transaction tracking data, response time agent data, and deep-dive diagnostic data. By using the Universal View, you can quickly build monitoring pages for an application and save them for viewing. While viewing a saved custom dashboard page, you can view the dashboard in auto refresh mode or export the dashboard to Raw data file or edit the dashboard, or delete the dashboard.

The four default roles in Cloud APM: Role Administrator, Monitoring Administrator, System Administrator, and Monitoring User have different permissions to view and modify dashboard pages. For more information, see [Table 1. Roles and permissions](#).

The options that are available in the **Custom Views** tab depend on whether the page is being edited or viewed.

## Creating and managing custom pages

Use the Custom Views tab to create or edit dashboard pages for selected application or group or instance by adding or updating widgets that are populated with the resource metrics of your choice.

### About this task

The pages that you create and save are associated with the selected application. For example, the Inventory Management application in the Cloud APM [Guided Demo](#) has the following monitoring agents: Linux OS, MySQL, Node.js, Hadoop, and Ruby. You can create and save a custom page at any level of the navigator from application to instance and then open it at the same level where it was created. A page that is created at a particular level can be opened only at the same level. The metrics available for the widgets can be from any of the resources in the application. Using the Inventory Management example, you can create a page with a table from the Ruby agent, a chart from Linux OS agent, and so on.

### Procedure

The pages that you create and save are associated with the selected application. Complete the following steps to create and customize a dashboard page:

1. After you open the Application Performance Dashboard from the  **Performance** menu, select an application.  
The **Custom Views** tab is displayed after **Status Overview** and **Events** tabs. You can also drill down to the group, subgroup, or instance level of the navigator.
2. Click the **Custom Views** tab.  
The tab shows the **Select a Template for your Custom page** window or the default page if a default page is already set.
  - If the **Select a Template for your Custom Page** window opens, go to [step 4](#).
  - If the default page is displayed, go to [step 3](#).
3. Click  **Add** to create a new page.
4. Click a template from the following default template options:
  - 1x1 Template
  - 1x2 Template
  - 2x2 Template
  - 2x3 Template
  - 3x3 Template
  - 3x2 Template
  - 2x1 Template
  - 1x3 Template
  - 3x1 Template

If you click **Back**, the page that is marked as favorite or the first page from the list opens. If no page exists, then the **Select a Template for your Custom Page** window opens.
5. Customize the template. For details, see [Customizing templates](#).
6. Create a widget. For details, see [“Defining widget properties” on page 1287](#).
7. Click  **Set Default Timeframe for the page** and set the default data retention period for the page to 1, 2, 4, 12, or 24 hours.
8. When you are ready to save the page, complete these steps:

a) In the **Page Name** field, enter name for the page.

**Important:** Space, underscore (\_), and dash (-) are allowed in the **Page name** field. However, dash followed by underscore (-\_) is not allowed. For example, System-\_Overview is not allowed.

b) Click **Save**.

The following changes may occur on the dashboard or message may be displayed:

- The Dashboard saved message is displayed.
- If \* is selected in the **Set Conditions**, then the following message is displayed:

You selected \* in Resource Instance or in Set Conditions, which will result in a large number of data series (such as lines on a graph). The large number of data series can make the page readability or performance unusable. The advisable limit for this chart is 50 data series. Adding specific values helps to narrow the data within recommended limits and results in a better user experience.

- A red indicator is displayed on the  to indicate that chart type is not selected and you need to select it.
- A red indicator is displayed on the  to indicate that Select Metric is not selected and you need to select it, and then the following message is displayed:

A metric must be saved to save a chart.

9. Select any of the following options in the page title bar:

| Option  | Description   |
|---|---|
|  <b>Retrieve latest resource Metric Types</b> | <p>Click to refresh metric types. If there is change in the metric type or metric when any agent patch is applied, you need to refresh the metric types.</p> <p>The interval between two refreshes is restricted to 15 minutes. If you click  <b>Retrieve latest resource Metric Types</b> within 15 minutes of previous refresh, then following message is displayed:</p> <p>Metadata cache was refreshed recently.<br/>Please wait for <i>time_remaining</i> minute(s) to reload it.</p> <p>When the metadata is loading a loading image is displayed.</p> <p>When the metadata is loaded, the following message is displayed:<br/>Metadata Cache reloaded successfully.</p> <p>If the metadata refresh takes more than 30 seconds, then the following message is displayed:<br/>Reloading of Metadata cache might take some more time.<br/>Do you want to wait until it is done?</p> <p>You can click <b>Ok</b> or <b>Cancel</b>.</p> |
|  <b>View Dashboard</b>                       | <p>Click to view the data in the dashboard.</p> <p><b>Important:</b> The limit for the number of rows that are returned per data definition is 11,000 rows. By default, latest data is displayed when the limit is crossed. For high volume of data, entire data for selected time interval is not displayed. For example, if you select to view last 24 hours of data for high volume data source, then only last 6 hours of data might be displayed if the 11000 rows limit is reached.</p> <p>If in a chart data series exceed 50, then the following message displayed in the widget:</p>   |

## Option

## Description

This chart cannot be loaded because the number of data series (such as lines on a graph) exceeds 50. The number of data series is currently *current\_data\_series*. You can reduce the number by selecting fewer metrics or resources instances, or by refining the Conditions per Metric. For more information, see Defining widget properties: for Cloud APM - <http://ibm.biz/widgetprops> and for Cloud APM Private - <http://ibm.biz/widgetprops-private>

If a chart is taking more than 30 seconds to load, then the following message is displayed in the widget:

This chart took too long to load because of a large amount of data, long network latency, or connectivity issue. Reduce the number of Resource Instances or refine the Conditions per Metric to narrow down the data. For more information, see Defining widget properties: for Cloud APM - <http://ibm.biz/widgetprops> and for Cloud APM Private - <http://ibm.biz/widgetprops-private>

## Save As

Click the arrow next to **Save**, and click **Save As** and specify a different name in the **Page Name** field to save the page with a different name.

**Important:** If you specify a page name same as an existing page, then the existing page is overwritten.

## Delete

Click to delete the current page.

Back

## Back

Click to go back to the previous page or favorite page.

## What to do next

View the custom pages as described in [“Viewing custom pages” on page 1290](#).

## Customizing templates

You can customize the template by resizing, moving, or adding widget placeholders according to your requirement.

## About this task

**Remember:** You can customize an existing template and use it. But the customized template cannot be saved for future use to create new dashboards.

## Procedure

1. In the Custom Views tab, click  **Edit Template**.
2. Select a widget placeholder.

You can resize a widget placeholder from all the sides and drag it to a different location. If the widgets overlap each other while you are resizing or dragging them, the Invalid resize operation or Invalid move operation message is displayed.
3. To add a widget placeholder to existing template, complete the following steps:
  - a) Click **Set page height** in menu options and specify a higher value for row count and click anywhere outside the menu to increase the height of the page.

- b) Specify a widget placeholder according to your requirement in the blank area on the page by placing the pointer and dragging it to create a box.
4. Use the following menu options to complete different operations on the template:

| Option                     | Description   |
|----------------------------|---|
| <b>Undo</b>                | To undo the last action.  |
| <b>Redo</b>                | To redo the last action.  |
| <b>Delete selected box</b> | To delete a widget, select the widget and click <b>Delete selected box</b> icon.  |
| <b>Reset</b>               | To create a blank template.<br><br>To specify a widget placeholder on the blank template, place the pointer in the Draw Templates Here area and drag it to create a box. You can create widget placeholders of different sizes in the Draw Templates Here area. The placeholders can be moved or resized but cannot overlap each other. |
| <b>Set page height</b>     | To set the height of the page. You can specify the row count as 20 through 120 rows.  |

5. Click  **Edit Template** to use the template that is created.

## What to do next

Create the widget. Go to [step 6](#) in the Creating and managing custom pages topic.

## Defining widget properties

Define different properties for the widgets such as metrics and charts to view real-time data in the widgets.

## Procedure

To define the properties for a widget, complete these steps:

1. In a widget, click  to select a chart type to display data.
  - Line
  - Area
  - Bar
  - Grid

**Important:** For line, area, bar charts, if there are more than nine legends then the color of graph repeats after ninth legend. The color of the graph is same for 1st and 10th legend, 2nd and 11th legend, and so on.

A green indicator is displayed on the  to indicate that chart type is selected.

2. Specify the following chart properties for line, area, and bar charts:
  - X Axis Label
  - Y Axis Label
  - Show Legend
  - Show Interpolation: The data that is collected to be plotted on the chart, it might include some Null values. Therefore, when the chart is plotted, the chart line is disconnected where it encounters a Null value and multiple disconnected lines appear in the chart. If you select interpolation, the line on the chart does not look disconnected where it encounters a Null value, instead it connects to the

next available valid value. Therefore, you get a single connected chart line when you select interpolation.

**Note:** For APM V8.1.4.0 IF0005 and later versions, the line and area charts no longer display disconnected lines for null values. Therefore, Show Interpolation feature is not required anymore and hence, it is not supported.

**Important:** Grid has no properties.

3. Click  to select the metric content.

| Option                                | Description  |
|---------------------------------------|--|
| <b>Resource Type</b>                  | <p>From the <b>Resource Type</b> list, select a resource. The available resources are associated with the application.</p> <p>If a resource that is a part of the application is not available in the list, its resource definition was not found. Either the resource definition was not published or the managed system is not connected to the Cloud APM server.</p>  |
| <b>Metric Type</b>                    | <p>From the <b>Metric Type</b> list, select a data set that you want to include in the widget.</p>   |
| <b>Metric</b>                         | <p>From the <b>Metric</b> list, select an attribute to include in the view. The available attributes are from the selected data set.</p> <p>To select metrics, complete the following steps:</p> <ol style="list-style-type: none"><li>Click the <b>Metric</b> list.</li></ol> <p>A pop-up window opens where the metrics are listed alphabetically sorted in ascending order.</p> <ol style="list-style-type: none"><li>Click the attributes that are listed under Metrics (select one or more) or click <b>Select All</b>.</li></ol> <p><b>Note:</b> When you click <b>Select All</b>, all the metrics in the list get selected.</p> <ol style="list-style-type: none"><li>Click  to add the metrics under <b>Selected Metrics</b> list.</li><li>If you want to delete a metric under <b>Selected Metrics</b>, click .</li><li>Click the <b>Resource Instance</b> list to close the pop-up window.</li></ol> <p><b>Important:</b> For line, bar, and area charts, metric containing numeric value needs to be selected. Metrics containing string values cannot be displayed in these charts.</p> <p><b>Tip:</b> For grid, limit your selection on metrics according to the output that suits your visibility on the UI.</p> |
| <b>Resource Instance</b>              | <p>Initially, the selection is *, which retrieves metrics from all the instances in the list. Retain the default selection or select the instance from the list.</p> <p><b>Important:</b> If you select an instance, then this widget cannot be used to display data for any other agent or instance. But it is good to specify the instance to avoid processing of huge data.</p>   |
| <b>Set Condition for Metric Group</b> | <p>If the selected <b>Metric Type</b> has multiple elements, such as CPUs or disks, then <b>Set Condition for Metric Group</b> displays other elements for you to select from the <b>WHERE</b> field.</p> <p><b>Important:</b> Specify values for elements in the <b>WHERE</b> field. Avoid specifying * to reduce processing of huge data.</p>  |

| Option   | Description  |
|--|--|
|  | By default WHERE condition displays last 4 hours of data. This time interval can be changed between 1 to 24 hours by the system administrator, see <a href="#">“Changing time interval for WHERE condition data” on page 1289</a> .  |
| <b>Actions</b>   | <p>Click  <b>Save</b> to save a metric.</p> <p>Click  <b>Edit</b> to edit a metric.</p> <p>Click  <b>Delete</b> to delete a metric.</p> |
| 4. To add another metric, click <b>+ Add Another Metric</b> .  |  |
| <b>Important:</b> Not applicable for grid.   |  |
| 5. Close the <b>Select Metrics</b> window after all the metrics are added.   |  |
| All the metrics are saved automatically after you close the <b>Select Metrics</b> window.  |  |
| The following changes may occur on the dashboard or message may be displayed:  |  |
| <ul style="list-style-type: none"> <li>If <b>*</b> is selected in the <b>Resource Instance</b> list in any of the metrics, then the following message is displayed:<br/> You selected * in Resource Instance or in Set Conditions, which will result in a large number of data series (such as lines on a graph). The large number of data series can make the page readability or performance unusable. The advisable limit for this chart is 50 data series. Adding specific values helps to narrow the data within recommended limits and results in a better user experience.</li> <li>A green indicator is displayed on the  to indicate that metrics are selected correctly to narrow the data within recommended limits.</li> <li>A orange indicator is displayed on the  to indicate that metrics are not selected correctly to narrow the data within recommended limits. Either <b>*</b> is selected in <b>Resource Instance</b> or in <b>Set Conditions</b>.</li> </ul> |  |
| 6. Click  to enter the widget title.  |  |
| If widget title is not added, then the first metric name is assigned as the widget title automatically.  |  |

## What to do next

Similarly, add charts, metrics, and titles to all the widgets and then go to [step 7](#) in the Creating and managing custom pages topic.

## Changing time interval for WHERE condition data

The time interval can be changed between 1 to 24 hours by the system administrator.

### Procedure

To change the time interval, system administrator can complete the following steps:

1. Log in to the APM server where the build is deployed.
2. On the command line, run the following commands:

```
export CLASSPATH=$CLASSPATH:/install_dir/gaian/lib/derbytools.jar:
```

```
export CLASSPATH=$CLASSPATH:/install_dir/gaian/lib/derbyclient.jar:
export CLASSPATH=$CLASSPATH:/install_dir/gaian/lib/derby.jar:
java org.apache.derby.tools.ij
connect 'jdbc:derby://localhost:port/
gaiandb;user=gaiandb;password=gaian_db_password';
```

In these commands, *install\_dir* refers to the directory where APM was deployed, by default it is /opt/ibm. In the **connect** command, *port* refers to the value of port on which the database is configured and *gaian\_db\_password* is the Gaian database password. Contact IBM support for this password.

3. After the database is connected, run the following query to modify values for time range:

```
UPDATE "OED_TOOL"."PREFERENCETABLE" SET PREFERENCES=' -24H' WHERE
FIELD='TIMEINTERVAL';
```

```
Commit;
```

```
Exit;
```

Here the value of the time range is given in the SET PREFERENCES=' -24H'. It can be set from 1H to 24H.

## Viewing custom pages

After you create and save dashboard pages for an application, group, subgroup, or instance in the **Custom Views** tab, you can view them at any time. Some of the options that you can select include refreshing the page, selecting different time interval, editing the page to retrieve data from different resources, and exporting the dashboard as Raw Data file.

### Procedure

Complete these steps to view a saved page in the **Custom Views** tab of the dashboard.

1. After you open the Application Performance Dashboard from the  **Performance** menu, select an application.

The **Custom Views** tab is displayed after **Status Overview** and **Events** tabs. You can also drill down to the group, subgroup, or instance level of the navigator.

2. Select the **Custom Views** tab.

The tab shows the **Select a Template for your Custom page** window or the default page if a default page is already set.

3. Click  in the page list and select one of the saved pages from the list.

The pages available were saved by you or were shared by another user.

After you select a saved page, the current and historical data samples are reported in the page.

4. Select any of the viewing options in the page title bar:

| Option  | Description   |
|---|---|
|  <b>Refresh</b>              | Indicates that auto refresh is off. Click to turn auto refresh on.  |
|  <b>Refresh</b>              | Indicates that auto refresh is on. Click to turn auto refresh off.<br><b>Important:</b> Default refresh time is 1 min.  |
|  <b>Export &gt; Raw Data</b> | Click to export the page as DAT format. Since multiple DAT files are exported, they are downloaded to your computer in ZIP format.<br><b>Remember:</b> If the downloaded file does not have any extension, then add zip as the extension to it. |

## Option

## Description

**Important:** If the file is not downloaded to your computer, then check if software to block pop-up ad windows is enabled. You can add this site to your exception list.

Extract the downloaded ZIP file. The extracted files are plain text files. The file contains of page name, duration, filters, date, time, interval, chart title, and data. The data delimiter is pipe.

You can open the DAT files by using appropriate editor or import the files to excel by specifying appropriate value separators.

**Export > PDF**

Click to export the page as PDF format.

The file contains page name, time interval, widgets, created by, and report created on.

**Edit**

Click to edit the current page.

You can change the charts and metrics in the widgets, or add new widgets, change the default time frame, or edit the name for the page.

**Delete**

Click to delete the current page.

**Add**

Click to create a new page. To customize the page and save it, see [“Creating and managing custom pages”](#) on page 1284.

5. Select any of the following viewing options in the widget:

## Option

## Description

**Chart Type**

Click the **Chart Type** icon and select an appropriate option from the list to change the existing chart type.

- For line and area charts, **Lines** and **Areas** options are available.
- For bar chart, **Clustered Bars** and **Clustered Columns** options are available.

**Important:** For grid, there are no chart type options.

For data displayed in a grid, you can filter the data as follows:

a. Click **Define filter**. The **Filter** window opens.

b. Specify values for **Column**, **Condition**, and **Value** to add a filter rule.

**Note:** You can filter numeric values and text values by selecting appropriate conditions.

c. Click **Add Filter Rule** to add another filter rule. You can add multiple filter rules.

d. In the **Match** field, select **All rules** or **Any rule** to filter the data.

You can select **Match case** if you want to search as per the case of text that you provide in the **Value** field.

e. Click **Filter** to filter the data that is displayed in the grid.

f. Click **Clear filter** to clear the filter results.

g. Click **Cancel** to close the **Filter** window.

| Option  | Description   |
|---|---|
|  <b>Collapse</b> | Click to collapse the widget.   |
|  <b>Expand</b>   | Click to expand the widget.   |
|  <b>Maximize</b> | Click to maximize the widget to the size of the page.   |
|  <b>Restore</b>  | Click to restore the widget to its original size.   |
| <b>Legends</b>  | The widget contains check boxes for each metric. Select or clear the check boxes for each metric to view data of a particular metric or multiple metrics. |

6. You can filter the data on the page by using the **Date**, **Time**, and **Interval** lists. You can also define a Custom filter for the page to display data for selected date and time intervals. To use Custom filter, from the **Interval** list, select **Custom**, and then in the **Time Period Selection** window, select the required date and time intervals.

**Note:**

- The custom filter option is available from APM V8.1.4.0 IF0005 onwards. Pages that are created by using earlier versions of Cloud APM do not display the Custom filter option.
- Use Custom filter to filter data for a minimum time interval of 1 minute and maximum time interval of 24 hours.
- When you are applying a custom filter, in the **Time Period Selection** window, if you click **Cancel**, then on the dashboard page, the **Interval** list does not display the interval that you applied earlier.
- If you apply Custom filter to a page, then the data on the page is not auto refreshed.

7. To set a default page, click  in the page list and click  **Favorite** next to the page name that you want to set as the default page.

## Dashboard utilities

Use the available options to manage the appearance and behavior of the **Application Performance Dashboard** pages.

### Copying the dashboard URL

After you navigate to a place in your application hierarchy, the URL in the browser address box does not change for the new view. You can copy the URL of the Application Performance Dashboard page that you are displaying. Paste the URL into a new browser window to open the dashboard page or use the URL to access the dashboard later or to share with other.

#### Procedure

1. Navigate to the Application Performance Dashboard page that you want to remember.
2. Click **Actions** > **Copy URL**.
3. Right-click the **Link to the current page** hypertext link and select the option to copy the URL.

#### What to do next

Keep a copy of the URL or share with other users in your managed environment. After you paste the URL into your browser's address box, the target dashboard page is opened in the Cloud APM console.

If you are not logged on to the Cloud APM server, you are prompted to enter your user ID and password before the target dashboard page can be displayed. If the **Getting started** page is opened instead of the

dashboard page, press F5 or click the browser's refresh toolbar button. You can turn off the **Getting started** page for future work sessions by clearing the "Show this **Getting started** page at startup" check box.

## Setting a trace

Adjust the trace settings to help your administrator or IBM Support to diagnose the cause of problems with the Application Performance Dashboard. Several levels of tracing are available while you work with the navigator and the **Status Overview** tab. You can start a detailed level of tracing exactly at the point in the user interface where you are having a problem, then return tracing to a reduced level after capturing the necessary log data. For example, if a particular dashboard is behaving unexpectedly, you can raise the trace level before opening the dashboard to log the activity and then return trace logging to the normal level.

### About this task

Take the following steps to set the trace level when you want to increase or reduce the amount of trace logging.

### Procedure

1. If the Application Performance Dashboard is not open, select it from the **Performance** option in the navigation bar.
2. Select All My Applications or an application from the navigator or Status Overview tab.
3. Click **Actions** > **Trace level** and select one of the following levels:
  - **Verbose** to have all activity logged. Verbose trace level includes Moderate, Light, and Minimal trace logging.
  - **Moderate** to have variable changes logged, such as what parameters were passed in and what calculations were made. Moderate trace level includes Light and Minimal trace logging.
  - **Light** to log error and variable activity. You might want to set the trace to this level if you have a problem such as no data being returned but the dashboard continues to function. Light trace level includes Minimal trace logging.
  - **Minimal** is the default setting and records only unrecoverable errors. You can set the trace level back to minimal after collecting a specific activity sequence. Even if a different trace level was set before logout, the trace is always reset to the lowest level the next time you log in.
4. If you want to send performance records to a common logging file, select **Enable Log Performance Statistics**.

The performance information from the console is written to the server where it can be combined with performance statistics from the server to provide end to end transaction response time. The required performance information includes the time that a function was started and the time that it ended.

### Results

The trace is adjusted to the level chosen. The next time you log in, the trace is to **Minimal** until you change it again.

To keep communications traffic to a minimum, the log messages are transferred in batches. A final transfer is made after you log out, whether manually or after a timeout period. (If the browser fails, no final logging is sent.) The log is saved on the server computer and named `itp.log`. A new `itp.log` is created each time the server is restarted.

If you set **Enable Log Performance Statistics**, records similar to those in the following example are saved to `install_dir/usr/servers/apmui/logs/itp.log`:

```
<record>
  <date>2013-10-02T10:52:46</date>
  <millis>1380736366788</millis>
  <sequence>28008</sequence>
  <level>INF0</level>
```

```

<class>StatusItemList</class>
<method>tracing</method>
<thread>96</thread>
<message>BeginTrace:onSelectApp:272wt877d05</message>
</record>
<record>
  <date>2013-10-02T10:52:46</date>
  <millis>1380736366809</millis>
  <sequence>28009</sequence>
  <level>INFO</level>
  <class>StatusItemList</class>
  <method>tracing</method>
  <thread>96</thread>
  <message>EndTrace:onSelectApp:272wt877d05</message>
</record>

```

## Locking the Cloud APM console

You can temporarily lock your work session without having to log out of the Cloud APM console. The session lock feature is not available on the Apple iPad.

### Procedure

1. While you are logged in to the Cloud APM console, click  **apmadmin** > **Lock Session** where *apmadmin* is the name that you used to log in.  
The log in screen is displayed and your session is locked.
2. To unlock your session, enter the password for your user ID.  
Your work session resumes.

### Related tasks

[“Adjusting the console timeout value” on page 1238](#)

## Reports

Historical reports are available in Cloud APM console for data that are collected by the Response Time Monitoring Agent, the WebSphere Applications agent, and the Synthetic Playback agent.

You can run reports from the **All My Applications** dashboard. From any Cloud APM console page, click  **Performance** > **Application Performance Dashboard** to open the **All My Applications** dashboard.

**Note:** You cannot run the reports from the **All My Applications** dashboard if you are using IBM Cognos Analytics version 11.x. When using Cognos 11.x, you must run the Cloud APM reports from the Cognos Analytics user interface.

**Note:** The first time that you run a report, you must log in to Tivoli Common Reporting as a user who has permission to run Cloud APM reports. IBM Cognos Viewer is the default report output viewer.

### Response Time Monitoring Agent reports

To view the **Application Performance and Usage** or **Compare Application Performance over Two Time Periods** reports, select an application that includes Response Time Monitoring agent managed systems, and select **Actions** > **Launch To Reports**.

To view the **All My Applications** or **Compare Performance of Multiple Applications** report, select **All My Applications**, and select **Actions** > **Launch To Reports**.

### WebSphere Applications agent reports

To view any WebSphere Applications agent reports, select an application that includes WebSphere Applications agent managed systems, and select **Actions** > **Launch To Reports**.

### Synthetic Playback agent

To view any Synthetic Playback agent reports, select an application that includes synthetic transactions, and select **Actions** > **Launch To Reports**.

**Note:** If the option **Launch To Reports** is missing from the **Actions** menu, check that Cloud APM reports are installed correctly. For more information, see [“Integrating with Tivoli Common Reporting”](#) on page 1083.

**Important:** If your reports do not display the correct times for transaction instances, you might need to reset the user time zone in Cognos Connection. For more information, see the technote [How to convert time into local time depending on time zone setting](#).

For information on the supported browsers for viewing Synthetic Playback agent, Response Time Monitoring agent, and WebSphere Applications agent reports, see the [Software Product Compatibility Reports for Cognos 10.2.1.7](#).

## Response Time Monitoring Agent reports

Historical reports are available for data that is collected by the Response Time Monitoring agent. Response Time Monitoring Agent reports are not available in Cloud APM, Base. They are only available in Cloud APM, Advanced.

**Note:** If you configured the Response Time Monitoring agent to use the IBM HTTP Server for Response Time module then, Transaction Data Volume is not available in the reports for any applications monitored by the agent. Transaction Count data is present.

There are two types of reports available for data that is collected by the Response Time Monitoring agent: active and simple.

### Active reports

Active reports are viewed in a browser in MHTML format. Internet Explorer supports MHTML by default. For other browsers, an MHTML support plug-in can be installed. Active reports are also referred to as offline interactive reports.

### Simple reports

Simple reports are viewed in IBM Cognos Viewer. IBM Cognos Viewer is the default report output viewer.

The following historical predefined reports are available for data that is collected by the Response Time Monitoring agent:

| Table 287. Predefined historical reports                              |        |
|---|--------|
| Report  | Type   |
| <a href="#">All My Applications</a>                                   | Active |
| <a href="#">Application Performance and Usage</a>                     | Active |
| <a href="#">Compare Application Performance over Two Time Periods</a> | Simple |
| <a href="#">Compare Performance of Multiple Application</a>           | Simple |

The data for the reports is stored in the DATAMART Db2 database. The reports display summarized daily, weekly, and monthly data which is retained for 26 weeks, 12 months, and 3 years respectively. Cloud APM does not provide scripts or instructions to change these retention periods.

For more information about the mapping between the Response Time Monitoring agent and Performance Management reports, see [Response Time Monitoring agent attributes mapping](#).

## All My Applications report

Use the All My Applications report to view information about user devices, data volume, response time, and error counts.

In this report, you view information for all your applications. Specify the report time period as **Last day** (default), **Last Week**, or **Last Month**. View the following information by selected time period by application:

- Stacked column chart of transaction count
- Column chart of transaction data volume
- Column chart of average transaction response time
- Stacked column chart of error counts

## Application Performance and Usage report

Use this report to view performance, availability, and user device information for single applications.

In the **Select an Application** window, select an application. Click **Next**. In the **Select Key Transactions for Application**, select the transaction/s you want to filter the report by. Click **OK**. This report has three tabs - Performance, Availability, and Devices. The default time interval is week.

On the Performance tab, view the following information by selected time interval for the application you are currently viewing in the Application Performance Dashboard:

- Line chart of average response time by (key) transactions
- Line chart of average transaction response time by success, server error, and client error
- Bar and line chart of transaction data volume, the bars show transaction data volume, and the line shows transaction data volume average
- Bar and line chart of transaction count, the bars show transaction count, and the line shows polynomial values and moving average

On the Availability tab, view the following information by selected time interval for the application you are currently viewing in the Application Performance Dashboard:

- Stacked bar chart of successful versus failed transaction percentage, the failures are broken down into server error and client error
- Stacked bar chart of successful versus failed transaction count by device types, the failures are broken down into server error and client error
- Pie chart of most frequently occurring error codes

On the Devices tab, view the following information by selected time interval for the application you are currently viewing in the Application Performance Dashboard:

- Bar chart of transactions by device type
- Bar chart of transactions by device operating system
- Bar chart of transaction by device browser
- Table showing transaction performance by dimensions, you can filter this table based on device type, device operating system, device brand, and device browser

## Compare Application Performance over Two Time Periods report

Use this report to examine application performance for a selected application.

In the **Select Application and Time Frequency** window, specify an application, and time frequency (weekly, daily, monthly). In the **Select Time Periods** window, choose time periods appropriate to the time interval and click **OK**.

The report displays the following charts for the selected application, for the selected time periods by the selected time interval:

- Line chart of transaction count for device type
- Line chart of transaction volume
- Line chart of average response time
- Line chart of error count

## Compare Performance of Multiple Applications report

Use this report to compare the performance of multiple applications for the same time period.

In the **Select Applications and Time Frequency**, specify an application, and time frequency ( weekly, daily, monthly). Click **Next** . Choose a time period appropriate to the time interval.

The report displays the following charts for the selected applications, for the selected time period by the selected time frequency:

- Line chart of transaction count
- Line chart of transaction data volume
- Line chart of average response time
- Line chart of error count

## Response Time Monitoring Agent attributes mapping

Some Cloud APM reports are based on data that is collected by the Response Time Monitoring Agent. The data in these reports maps to Response Time Monitoring agent attributes.

The following table provides mapping of data items in Response Time Monitoring agent reports to the agent attributes:

| <i>Table 288. Response Time Monitoring agent attribute mapping</i> |   |                           |                        |
|--|---|---------------------------|------------------------|
| <b>Report data item</b>  | <b>Description</b>  | <b>ODI Attribute name</b> | <b>ODI file Column</b> |
| Application Name   | The name of the monitored application reported to the Cloud APM console   | Application Name          | T5TXCS.APPLICATIN      |
| Transaction Count  | The total number of request and response sequences that are observed by the monitoring agent during the current aggregate interval. | Total Requests            | T5TXINS.TOTREQ         |
| Client Errors  | The number of HTTP requests with a status code 400 - 499.   | Client Errors             | T5TXCS.NUM4XX          |
| Server Errors  | The number of HTTP requests with a status code 500 - 599.   | Server Errors             | T5TXCS.NUM5XX          |
| Transaction Name   | The transaction name reported to the Application Management Console.  | Transaction Name          | T5TXCS.TRANSACTION     |
| Transaction Status   | The response code that is associated with the transaction   | Status Code               | T5TXCS.STATUSCODE      |

*Table 288. Response Time Monitoring agent attribute mapping (continued)*

| <b>Report data item</b> | <b>Description</b>  | <b>ODI Attribute name</b> | <b>ODI file Column</b> |
|-------------------------|---|---------------------------|------------------------|
| Code Reply Kilobytes    | The total number of kilobytes in each reply of the request during the data interval.  | Reply Bytes               | T5TXCS.REPLYBYT        |
| Request Kilobytes       | The total number of kilobytes in the request during the data interval.  | Request kBytes            | T5TXCS.REQBYTES        |
| Total Kilobytes         | The total number of kilobytes transferred for all request during the time period.   | Total Bytes               | T5TXCS.TOTBYTES        |
| Total Object Count      | The total number of objects that are embedded in a web page for the time period   | Total Object Count        | T5TXCS.OBJCNT          |
| Total Object Size       | The total size of all objects that are embedded in the web page for the time period.  | Total Object Size         | T5TXCS.OBJSIZE         |
| Response Time (seconds) | The total number of seconds required for the overall server transaction to complete.  | Response Time             | T5TXCS.RESPTIME        |
| Render Time             | The elapsed time, in seconds, to fully render the web page on the web browser using embedded JavaScript tags.                   | Render Time               | T5TXCS.RENDERTIME      |
| Client Time             | The average elapsed time, in seconds, that the transaction spends running on the client during the current monitoring interval. | Average Client Time       | T5TXCS.CLIENTTIME      |
| Load Time               | The average elapsed time, in seconds, from the time the user requests a download to the completion of the web object download.  | Average Load Time         | T5TXCS.LOADTIME        |
| Browser                 | A description of the web browser on which the web page is displayed.  | Browser Description       | T5TXCS.BROWSEDESC      |

| Table 288. Response Time Monitoring agent attribute mapping (continued) |  |                    |                   |
|---|--|--------------------|-------------------|
| Report data item  | Description  | ODI Attribute name | ODI file Column   |
| Server  | The name or IP address of the server for the TCP Transaction.  | Server Description | T5TXCS.SERVERDESC |
| URL Hostname  | The TCP/IP hostname of the URL.  | URL Hostname       | T5TXCS.URLHOST    |
| URL Method  | The method that is used for performing HTTP requests (GET, POST, HEAD, PUT, OPTIONS, DELETE, TRACE, or CONNECT). | Method             | T5TXCS.METHOD     |
| URL Details   | The URL path to the file on the server hosting the web page.   | URL Path           | T5TXCS.URLPATH    |

For more information on the Response Time Monitoring agent, see the [Transaction Monitoring Reference](#).

## Generating Synthetic Playback agent reports

Run reports for applications that are associated with synthetic transactions.

### About this task

Select an application and an associated synthetic transaction in the Application Performance Dashboard and then generate reports based on your selection. The data for the reports is stored in the DATAMART Db2 database. The reports display summarized hourly, weekly, and monthly data which is retained for 371 days, 53 weeks, and 12 months respectively. Cloud APM does not provide scripts or instructions to change these retention periods.

Five multi-page reports are available:

#### Transactions Overall

This two page report displays the response times and availability ratios of the selected synthetic transaction over a set date range.

Page one displays the following data:

- A line chart of the response times of the selected synthetic transactions at set intervals over a set date range
- A table of the average response times in seconds of each synthetic transaction over the set date range

Page two displays the following data:

- A line chart of the availability ratios of the selected synthetic transactions at set intervals over a set date range
- A table of the average availability ratio of each synthetic transaction over the set date range

You can access two extra reports from the **Transactions Overall** report, **Timely Analysis by Transactions** and **HTTP Metrics by Transactions**.

**Timely Analysis by Transaction** displays HTTP metrics of the selected synthetic transaction at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected synthetic transaction at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected synthetic transaction over the set date range

**HTTP Metrics by Transaction** displays HTTP metrics of the selected synthetic transaction at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected synthetic transaction at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected synthetic transaction over the set date range

### Transaction Detail By Locations

This two page report displays the response times and availability ratios by location of the selected synthetic transactions and subtransactions over a set date range.

Page one displays the following data:

- Line charts of the response times by location of the selected synthetic transactions and subtransactions at set intervals over a set date range
- Tables of the average response times in seconds of all synthetic subtransactions over a set date range at each location

Page two displays the following data:

- Line charts of the availability ratios by location of the selected synthetic transactions and subtransactions at set intervals over a set date range
- Tables of the average availability ratios of all synthetic subtransactions over a set date range at each location

You can access four extra reports from the **Transaction Detail by Locations** report, **Timely Analysis by Locations of Transaction**, **HTTP Metrics by Locations of Transaction**, **Timely Analysis by Locations of Subtransaction**, and **HTTP Metrics by Locations of Subtransaction**.

**Timely Analysis by Locations of Transaction** displays HTTP metrics of a synthetic transaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected synthetic transaction by locations at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected synthetic transaction by locations over the set date range

**HTTP Metrics by Locations of Transaction** displays HTTP metrics of a synthetic transaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected synthetic transaction by locations at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected synthetic transaction by locations over the set date range

**Timely Analysis by Locations of Subtransaction** displays HTTP metrics of a subtransaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected subtransaction by locations at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected subtransaction by locations over the set date range

**HTTP Metrics by Locations of Subtransaction** displays HTTP metrics of a synthetic subtransaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected subtransaction by locations at set intervals over the set date range
- A table of the HTTP metrics in milliseconds of the selected subtransaction by locations over the set date range

### **Transaction Detail By Subtransactions**

This two page report displays the response times and availability ratios of synthetic subtransactions at set intervals over a set date range.

Page one displays the following data:

- A line chart of the response times of the selected synthetic subtransactions at set intervals over a set date range
- A table of the average response times in seconds of each synthetic subtransaction over the set date range

Page two displays the following data:

- A line chart of the availability ratios of the selected synthetic subtransactions at set intervals over a set date range
- A table of the availability ratios of each synthetic subtransaction over the set date range

You can access two extra reports from the **Transaction Detail by Subtransactions** report, **Timely Analysis by Subtransactions** and **HTTP Metrics by Subtransactions**.

**Timely Analysis by Locations of Subtransaction** displays HTTP metrics of a subtransaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected subtransaction at set intervals over a set date range
- A table of the HTTP metrics in milliseconds of the selected subtransaction over the set date range

**HTTP Metrics by Locations of Subtransaction** displays HTTP metrics of a synthetic subtransaction by locations at set intervals over a set date range. The report includes the following items:

- A column chart of the HTTP metrics of the selected subtransaction at set intervals over a set date range
- A table of the HTTP metrics in milliseconds of the selected subtransaction over the set date range

### **Trend Of Transactions**

This four page report displays a trend analysis of response times, availability ratios, and HTTP metrics over the previous week and over the previous five weeks.

Page one displays trend data on the response times and availability ratios of a synthetic transaction:

- A combined line chart of the average response times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the availability ratio of a selected synthetic transaction that compares the availability ratio for the previous week with the baseline availability ratio over the previous 5 weeks
- A table of the average response time and availability ratio of a synthetic transaction over the previous week and over the previous 5 weeks date range
- A combined line chart of the average response times of a selected synthetic transaction over the previous week and over the previous 5 weeks, by location
- A combined line chart of the availability ratio of a selected synthetic transaction that compares the availability ratio for the previous week with the baseline availability ratio over the previous 5 weeks, by location
- A table of the average response times and availability ratios of a selected synthetic transaction over the previous week and over the previous 5 weeks, by location
- A combined line chart of the average response times of the subtransactions of a selected synthetic transaction over previous last week and over the previous 5 weeks

- A combined line chart of the average availability ratios of the subtransactions of a selected synthetic transaction that compares the availability ratio for the previous week with the baseline availability ratio over the previous 5 weeks
- A table of the average response times and availability ratios of the subtransactions of a selected synthetic transaction over the previous week and over the previous 5 weeks

Page two displays trend data on the HTTP metrics of a synthetic transaction:

- A combined line chart of the average blocking times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average DNS times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average SSL times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average connect times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average sending times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average receiving times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A combined line chart of the average rendering times of a selected synthetic transaction over the previous week and over the previous 5 weeks
- A table of average HTTP metrics of a synthetic transaction over the previous week and over the previous 5 weeks

Page three displays trend data on HTTP metrics in milliseconds of a synthetic transaction by location. The charts and table compare HTTP metric averages over the previous week with the baseline metric average over the previous 5 weeks:

- Seven combined line charts that compare different average HTTP metrics of a selected synthetic transaction for the previous week with the baseline metric over the previous 5 weeks by location
- A table of average HTTP metrics of a selected synthetic transaction over the previous week and over the previous 5 weeks by location

Page four displays trend data on HTTP metrics in milliseconds for subtransactions. The charts and table compare HTTP metric averages over the previous week with the baseline metric averages over the previous 5 weeks:

- Seven combined line charts that compare average values of different HTTP metrics of a selected synthetic transaction for the previous week with the baseline metric over the previous 5 weeks by subtransaction
- A table of average values of HTTP metrics of a selected synthetic transaction over the previous week and over the previous 5 weeks by subtransaction

### **Trend Of Subtransactions**

This two page report displays a trend analysis of the response times, availability ratios, and HTTP metrics for subtransactions over the last week and over the previous five weeks.

Page one displays trend data on the response times and availability ratios of subtransactions for the previous Sunday, the previous week, and the previous five weeks:

- A table that compares subtransaction response times and availability ratios from the previous Sunday, the previous week, and the previous 5 weeks
- A combined line chart that compares the average response times of subtransactions for the previous week with the baseline response time for the previous 5 weeks
- A combined line chart that compares the average availability ratio of subtransactions for the previous week with the baseline availability ratio for the previous 5 weeks
- A table of average response times and availability ratios of subtransactions for the previous week.

- A table of average response times and availability ratios of subtransactions for the previous 5 weeks.

Page two displays trend data on HTTP metrics in milliseconds for subtransactions. The charts and tables display HTTP metric averages of subtransactions over the previous week with the baseline metric averages over the previous five weeks:

- Seven tables of average values of HTTP metrics of the selected transaction for the previous Sunday, the previous week, and over the previous 5 weeks by subtransactions
- Seven combined line charts that compare different average HTTP metrics in milliseconds of the selected transaction for the previous week with the baseline availability ratio over the previous 5 weeks by subtransactions
- A table of average values of HTTP metrics of subtransactions for the previous week.
- A table of average values of HTTP metrics of subtransactions for the previous 5 weeks.

## Procedure

To generate reports, complete the following steps:

1. Click the **Performance** icon  and select **Application Performance Dashboard**. To choose an application, expand **All My Applications** and select an application. To display all synthetic transactions that are associated with the selected application, click **Groups > Transactions > Synthetic Transactions**.
2. Select a synthetic transaction from the Transaction List table. To run a report, click **Actions > Launch to Reports** and select one of the following reports:

- **Transactions Overall**
- **Transaction Detail By Locations**
- **Transaction Detail By Subtransactions**
- **Trend of Transactions**
- **Trend of Subtransactions**

A configuration page opens in a new tab in your web browser.

3. To set the date range for your report, select a predefined date range, or enter a custom date range.
4. To set the time interval for your report, select an interval from **Time Type**. Set your report to display data from your synthetic transactions and subtransactions at **Hourly**, **Daily**, or **Weekly** intervals, over the set date range. To generate your report, click **Finish**.
5. To view reports on HTTP metrics for transactions, subtransactions, or locations, you must select a transaction, subtransaction, or location in the **Transactions Overall**, **Transaction Detail By Locations**, or **Transaction Detail By Subtransactions** reports.
  - To view **Timely Analysis by Transactions**, right-click on a transaction name in the **Transactions Overall** report and select **Go To > Http Metrics Analysis by Time**.
  - To view **HTTP Metrics by Transactions**, right-click on a transaction name in the **Transactions Overall** report and select **Go To > Http Metrics Aggregation**.
  - To view **Timely Analysis by Locations of Transaction**, right-click on a transaction name in the **Transaction Detail By Locations** report and select **Go To > Http Metrics Analysis by Time**.
  - To view **HTTP Metrics by Locations of Transaction**, right-click on a transaction name in the **Transaction Detail By Locations** report and select **Go To > Http Metrics Aggregation**.
  - To view **Timely Analysis by Locations of Subtransaction**, right-click on a subtransaction name in the **Transaction Detail By Locations** report and select **Go To > Http Metrics Analysis by Time**.
  - To view **HTTP Metrics by Locations of Subtransaction**, right-click on a subtransaction name in the **Transaction Detail By Locations** report and select **Go To > Http Metrics Aggregation**.
  - To view **Timely Analysis by Subtransactions**, right-click on a subtransaction name in the **Trend of Subtransactions** report and select **Go To > Http Metrics Analysis by Time**.

- To view **HTTP Metrics by Subtransactions**, right-click on a subtransaction name in the **Trend of Subtransactions** report and select **Go To > Http Metrics Aggregation**.

## WebSphere Applications agent reports

Predefined reports are available for data that is collected by the WebSphere Applications agent.

Scope of the WebSphere Applications agent report:

### Supported subnodes

- WebSphere Application Server (KYNS)
- WebSphere Portal Server (KYNR)

### Unsupported subnodes

- WebSphere Process Server (KYNP)

The data for the reports is stored in the WAREHOUS Db2 database. The reports display hourly, daily, weekly, and monthly data which is retained for 1 month, 3 months, 1 year , and 1 year respectively. Cloud APM does not provide scripts or instructions to change these retention periods. The following reports are available for data that is collected by the WebSphere Applications agent:

## Application Request Performance

### Description

This report analyzes how applications perform at an aggregated level across an application server. The pie-chart shows the aggregate level requests for applications. The bar chart shows the average response time for applications at an aggregate level. The two time series line charts show the average response time and total request count trend for all of the applications. To drill down into the individual requests for an application, click a pie slice or a bar.

### Parameters

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type and Application Server Type

### Tables Used

Request\_Analysis\_\*V

## DB Connection Pools

### Description

This report analyzes database connection pools in an application server. The table shows the key statistics for all the connection pools at an aggregate level. When you select a specific data source, two trend charts show the trend of the key statistics.

### Parameters

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Application Server Name

### Tables Used

DB\_Connection\_Pools\_\*V

## EJB Performance

### Description

This report analyzes how EJBs deployed in the application server perform. The pie chart shows the aggregate level method count for the EJBs. The bar chart shows the average Method Response Time across EJBs at an aggregate level. The Two Time series charts show the Method Invocation Count trend and Average Method Response Time trend for all EJBs. The trend lines can be filtered per EJB by clicking a row from the list.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Application Server Name

**Tables Used**

Enterprise\_Java\_Beans\_ \*V

**GC Usage of Application Server****Description**

This report analyzes garbage collection. Use this report to determine whether garbage collection is creating problems or if the heap is not sized properly. The first graph shows the average heap percent that is used and the average real-time percent garbage collection over time. The second graph shows the average real-time percent garbage collection runs and the average garbage collection rate.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Application Server Type

**Tables Used**

Garbage\_Collection\_Analysis\_ \*V

**JVM Usage for Application Server****Description**

This report analyzes how the JVM of an application server performs. The stacked bar chart shows how the JVM Memory is used and is freed up. The dual line chart shows the JVM CPU consumption vis-a-vis JVM Memory usage.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Application Server Type

**Tables Used**

Application\_Server\_ \*V

**Threadpools****Description**

This report analyzes thread pools in an application server. The table shows the key statistics for all thread pools at an aggregate level. Once you select a thread pool from the list, the trend chart shows the trending of the key statistics for the selected Thread Pool. If no thread pool is selected, the trends show summary of all the thread pools.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar

Required parameters: Summarization Type, Application Server Type

**Tables Used**

Thread\_Pools\_ \*V

**Web Application Performance****Description**

This report analyzes how the applications perform in the web container of an application server (PMI Data). The pie charts show the aggregate level requests for the applications. The bar chart shows the average response time for applications at an aggregate level. The two time series line charts show the

Average Response time and Total Request count trend for all the applications. Click a pie slice or a bar or a line to drill down into the individual servlet/jsps for that application.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Application Server Type

**Tables Used**

Thread\_Pools\_\*V

## Application Request Performance for Clusters

**Description**

This report analyzes how servers in a cluster are performing. The first chart shows the number of requests that are completed by each of the cluster members during the selected time interval. The second chart provides information about the average response time trend for each of the cluster members. There is a separate line in this chart for each server in the cluster. Click a line to drill down into the individual server data. The Application Request Performance report for this server opens

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Cluster Name

**Tables Used**

Request\_Analysis\_\*V

## JVM and GC Usage for Clusters

**Description**

This report analyzes JVM and garbage collection usage trends by each of the cluster members. The first chart shows the average real-time percent garbage collection runs. The second chart shows average heap percent used. The last charts show CPU and JVM memory usage. All of these charts show data for each cluster member as a separate line.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Cluster Name

**Tables Used**

Garbage\_Collection\_Analysis\_\*V, Application\_server\_\*V

## Top applications with slowest response times across servers

**Description**

This report analyzes how the applications perform at an aggregated level across all application servers. A bar chart shows the average response time for applications at an aggregate level.

**Parameters**

Date Range: select one of the predefined reporting periods or select exact start and end times from the calendar.

Required parameters: Summarization Type, Number of Applications

---

## Chapter 12. Upgrading

Upgrade your Cloud APM server, agents, and data collectors to get the latest features and functionality that are available in the current release.

### Upgrading your server

---

You can upgrade your Cloud APM server from V8.1.3 to V8.1.4 to access the latest functions and to improve performance. If your server is running V8.1.2, upgrade to V8.1.3 first.

When you are upgrading from V8.1.3 to V8.1.4, remember V8.1.4 supports two offerings instead of the previous four offerings in V8.1.3. The V8.1.4 Cloud APM, Base offering now includes the V8.1.3 IBM Monitoring offering capability. The Cloud APM, Advanced offering now includes the capability of the other three V8.1.3 offerings. You must use the V8.1.4 offering file that matches the offering that was installed on the V8.1.3 Cloud APM server for the upgrade. The mapping of V8.1.3 or earlier offerings to V8.1.4 offerings is described in more detail in the product rebranding and simplification section in the [Chapter 1, “What’s new,”](#) on page 1 topic.

You can use two different methods to complete the server upgrade solution. The method that you choose depends on the size of your monitored environment. One method uses two separate systems where the upgrade steps are completed *side-by-side* on these systems. The other method is completed on a single system that runs V8.1.3 of the Cloud APM server. You then upgrade that same system to V8.1.4 of the Cloud APM server.

For either method, you must apply the Cloud APM V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later patch to the Cloud APM server before you complete the upgrade.

If your Cloud APM server is connected to a remote MongoDB, you must install MongoDB Version 3.2.12 before you upgrade the Cloud APM server.

After you determine which method to use for the upgrade, use these guidelines to determine which procedures to follow:

- If you are completing a side-by-side upgrade of the Cloud APM server, follow these procedures:
  1. When your Cloud APM server is connected to a remote MongoDB, install MongoDB V3.2.12 on your remote system. For instructions, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.
  2. Depending on the location of your Db2 server, follow one of these procedures:
    - If your Cloud APM server is using a local Db2 server, complete the steps in [“Upgrading the server side-by-side”](#) on page 1321.
    - If your Cloud APM server is connected to a remote Db2 server, complete the steps in [“Upgrading your server when connected to a remote Db2 server”](#) on page 1332. This procedure references the steps in the [“Upgrading the server side-by-side”](#) on page 1321 topic.
- If you are upgrading the Cloud APM server on the same system, follow these procedures:
  1. When your Cloud APM server is connected to a remote MongoDB, install MongoDB V3.2.12 on your remote system. For instructions, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.
  2. Complete the steps in [“Upgrading the server on the same system”](#) on page 1311. Use this procedure when your Cloud APM server is connected to either a local or a remote Db2 server.

**Note:** If you upgrade your Cloud APM server, you must also upgrade your data collectors. For more information, see [Upgrading your data collectors](#).

## Installing MongoDB V3.2.12 on your remote system

If your V8.1.3 Cloud APM server is connected to a remote MongoDB, you must install MongoDB V3.2.12 before you upgrade the Cloud APM server.

You can uninstall MongoDB V3.x and reinstall V3.2.12 on the remote system, but this procedure requires you to stop the Cloud APM server. Alternatively, to avoid stopping the Cloud APM server, you can install MongoDB V3.2.12 on another remote system and update the backup file that is used to upgrade the Cloud APM server to include the MongoDB V3.2.12 connection parameters.

## Reinstalling MongoDB V3.2.12 on the existing remote system

To install MongoDB V3.2.12 on the existing remote system, uninstall MongoDB V3.x and reinstall V3.2.12 on the same remote system. This procedure requires you to stop the Cloud APM server.

### Procedure

Complete the following steps as a root user:

1. Complete one set of the following steps depending on the type of server upgrade that you are completing:
  - If you are planning to upgrade the server side-by-side, see steps [1](#) to [“4”](#) on page [1323](#) in *Upgrading the server side-by-side*.
  - If you are planning to upgrade the server on a single system, see steps [1](#) to [“4”](#) on page [1313](#) in *Upgrading the server on the same system*.
2. Run the `backup.sh` script without parameters from the `tools` directory on the system where the V8.1.3 Cloud APM server is installed. The script outputs the name of the backup file.

For example:

```
[root]# /root/min/tools/backup.sh
The server is configured with a remote DB2.
This script must additionally be run on the DB2 machine to backup the database.
The log file was created at "/opt/ibm/ccm/logs/backup_20160424_005922.log".
Starting components of the IBM Performance Management server
and verifying the passwords...
Performing a backup...
Processing the "install" component...
Processing the "oslc" component...
Processing the "ccs" component...
Processing the "apmui" component...
Processing the "spark" component...

Processing the "scr" component...
Processing the "mongodb" component...
Processing the "itmcdp" component...
Processing the "supports" component...
Processing the "biagent" component...
Backup operation completed.
Starting the components...
Creating the backup file...
All tasks finished successfully. Your backup is available in the following file:
/opt/ibm/backups/backup_20160424_005922.tar
```

For more information about running the backup script when a non-default user name is configured for the Cloud APM UI administrator user name, see step [6](#) of *Upgrading the server on the same system*.

3. Stop the Cloud APM server.

From the command line, enter:

```
apm stop_all
```

4. Copy the backup file to the system where you plan to install the V8.1.4 Cloud APM server.
5. Uninstall MongoDB V3.x from the remote system.

From the command line, enter:

```
opt/ibm/mongodb/bin/uninstall-mongodb.sh
```

6. Install MongoDB V3.2.12 on the same system where the previous version of the MongoDB was installed.

For instructions, see steps [1](#) to [2](#) in *Installing a remote MongoDB*.

## Results

The MongoDB on the remote system is running V3.2.12.

## What to do next

Upgrade the Cloud APM server:

- If you are upgrading the Cloud APM server on a single system, start from step 5 of [“Upgrading the server on the same system” on page 1311](#).
- If you are performing a side-by-side upgrade of the Cloud APM server with a local Db2 server, start from step 5 of [“Upgrading the server side-by-side” on page 1321](#).
- If you are performing a side-by-side upgrade of the Cloud APM server with a remote Db2 server, start from step 2 of [“Upgrading your server when connected to a remote Db2 server” on page 1332](#).

## Installing MongoDB V3.2.12 on a separate remote system

You can install MongoDB V3.2.12 on a separate remote system. Update the backup script that you plan to use for the Cloud APM server upgrade to include the host name or IP address of the new version of MongoDB. This procedure does not require you to stop the Cloud APM server.

## About this task

The system where you install MongoDB cannot be any of the following systems:

- The system where the V8.1.3 Cloud APM server is installed.
- The remote system that is running MongoDB V3.x.
- The system where you plan to install the V8.1.4 Cloud APM server.

## Procedure

Complete the following steps as a root user:

1. Install MongoDB V3.2.12 on a remote system.  
Follow the steps in [“Installing a remote MongoDB” on page 169](#).
2. Complete one set of the following steps depending on the type of server upgrade that you are completing:
  - If you are planning to upgrade the server side-by-side, see steps [1](#) to [“4” on page 1323](#) in *Upgrading the server side-by-side*.
  - If you are planning to upgrade the server on a single system, see steps [1](#) to [“4” on page 1313](#) in *Upgrading the server on the same system*.
3. Run the backup.sh script without parameters from the tools directory on the system where the V8.1.3 Cloud APM server is installed. The script outputs the name of the backup file.  
For example:

```
[root]# /root/min/tools/backup.sh
The server is configured with a remote DB2.
This script must additionally be run on the DB2 machine to backup the database.
The log file was created at "/opt/ibm/ccm/logs/backup_20160424_005922.log".
Starting components of the IBM Performance Management server
and verifying the passwords...
Performing a backup...
Processing the "install" component...
```

```

Processing the "oslc" component...
Processing the "ccs" component...
Processing the "apmui" component...
Processing the "spark" component...
Processing the "min" component...
Processing the "min_config" component...
Processing the "cscs" component...
Processing the "oidc" component...
Processing the "oauth2" component...
Processing the "scr" component...
Processing the "mongodb" component...
Processing the "itmcdp" component...
Processing the "supports" component...
Processing the "biagent" component...
Backup operation completed.
Starting the components...
Creating the backup file...
All tasks finished successfully. Your backup is available in the following file:
/opt/ibm/backups/backup_20160424_005922.tar

```

For more information about running the backup script when a non-default user name is configured for the Cloud APM UI administrator user name, see [step 6 of Upgrading the server on the same system](#).

4. Copy the backup file to the system where you plan to install the V8.1.4 Cloud APM server.
5. Update the backup file to use the MongoDB V3.2.12 host name or IP address during the upgrade procedure.
  - a. Go to the directory where your backup file is stored.

```
cd directory_with_your_backup_file
```

- b. Create a directory, backup.extracted.

```
mkdir backup.extracted
```

- c. Go to your new directory.

```
cd backup.extracted
```

- d. Extract the backup tar file.

```
tar -xf ../backup_timestamp.tar
```

- e. Open the `./min_config/ibm_min_config_backup.json` file.

- f. In the JSON file, find the line that contains the host name or IP address of your V3.x MongoDB.

```

\"service\\\": \"com.ibm.tivoli.ccm.mongo\\\", \"name\\\": \"hostname\\\", \"value\\\": \"
Remote_MongoDB_v3.x_IP_address_or_hostname\"

```

**Tip:** Search for the text `com.ibm.tivoli.ccm.mongo` and move your cursor forward character by character until you locate the IP address or host name of your V3.x MongoDB.

- g. Update the host name or IP address with the value for your V3.2.12 MongoDB. For example:

```

\"service\\\": \"com.ibm.tivoli.ccm.mongo\\\",
\"name\\\": \"hostname\\\", \"value\\\": \"mongodb3.example.net\"

```

- h. Edit the `./mongodb/mongo.properties` file. Change the property

```
mongo.hostname=Remote_MongoDB_v3.x_IP_address_or_hostname
```

to

```
mongo.hostname=Remote_MongoDB_v3.2.12_IP_address_or_hostname
```

For example:

```
mongo.hostname=mongodb3.example.net
```

- i. Create a backup file in the backup.extracted directory.

```
tar -cf ../backup_timestamp.updated.tar *
```

## Results

MongoDB V3.2.12 is running on another remote system and the backup file includes the IP address or host name of the new version of MongoDB.

## What to do next

Upgrade the Cloud APM server:

- If you are upgrading the Cloud APM server on a single system, start from step 5 of [“Upgrading the server on the same system”](#) on page 1311.
- If you are performing a side-by-side upgrade of the Cloud APM server with a local Db2 server, start from step 5 of [“Upgrading the server side-by-side”](#) on page 1321.
- If you are performing a side-by-side upgrade of the Cloud APM server with a remote Db2 server, start from step 2 of [“Upgrading your server when connected to a remote Db2 server”](#) on page 1332.

When the upgrade of the Cloud APM server is complete, you can uninstall the 3.x version of MongoDB from the remote system. To uninstall, from the command line, enter:

```
opt/ibm/mongodb/bin/uninstall-mongodb.sh
```

## Upgrading the server on the same system

You can upgrade your Cloud APM server from V8.1.3 to V8.1.4 on the same system. The advantage with this method is that a second system is not required for the upgrade. Customers with small to medium environments usually choose this method.

### Before you begin

- When you perform the Cloud APM server upgrade, the Db2 server for the Cloud APM server V8.1.4.0 must be at the same version as the Db2 server used by the Cloud APM server V8.1.3. Check the Db2 version that is in use by the Cloud APM server V8.1.3:
  - If Db2 is installed on the same system as the Cloud APM server, enter the following command to check the Db2 version:

```
install_dir/db2/V10.5/bin/db2level
```

where *install\_dir* is the directory where Db2 is installed.

- If Db2 is installed on a remote system, ask the Db2 administrator to check the Db2 server version.

### Important:

The Db2 server for your V8.1.4 Cloud APM server must be at the same version as your V8.1.3 Cloud APM server during the Cloud APM server upgrade.

If the Db2 version for your V8.1.3 Cloud APM server is Db2 Advanced Enterprise Server Edition V10.5 fix pack 9 (or later), complete the steps in this technote [Upgrading your Cloud APM server from V8.1.3 to V8.1.4 when your Db2 server is running V10.5 fix pack 9 or a later fix pack](#) now to continue your Cloud APM server upgrade from V8.1.3 to V8.1.4.

If you want to use Db2 V11.1 for your V8.1.4 Cloud APM server, you can upgrade your Db2 server to a supported version of Db2 V11.1 after the Cloud APM server upgrade completes. Follow the procedure in [“Upgrading the Db2 server to Db2 version 11.1.x”](#) on page 1208.

- If your Cloud APM server is connected to a remote Db2 server, Db2 Advanced Workgroup Server Edition V11.1 is supported when you are upgrading your Cloud APM server from V8.1.3 to V8.1.4.

- If your V8.1.3 Cloud APM server is connected to a remote MongoDB, install MongoDB V3.2.12. For instructions, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.
- If LDAP is enabled on your V8.1.3 Cloud APM server to authenticate Cloud APM console users, complete the following steps on your V8.1.3 Cloud APM server before you back up your V8.1.3 data:
  1. Retrieve the value of the *realm* attribute from the `install_dir/wlp/usr/shared/config/ldapRegistry.xml` file.
  2. Check the value of the *oauthRealm* attribute in the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file. If the value of *oauthRealm* attribute does not match the value of the *realm* attribute in the `ldapRegistry.xml` file, update the value of the *oauthRealm* attribute to match the value of the *realm* attribute.
  3. Complete the following steps to update the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to add the user from the `install_dir/wlp/usr/servers/server1/cscs/conf/cscsRoleAdmin.conf` file:
    - a. Find the properties line **<properties>**, and identify the **systemUser** parameter, if it does not exist you will need to add it in the next step. Identify the closing tag **/>** for the properties line.
    - b. Add a new line or edit the existing line before the **/>** closing tag as follows:
 

```
systemUser="testuser LDAP distinguished name"
```

where *testuser* matches the user string from the `cscsRoleAdmin.conf` file, for example:

```
systemUser="CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
```
    - c. Confirm that the **/>** closing tag was not deleted, then save and close the file.
- If you modified the trust store password for your Cloud APM server V8.1.3, change the password back to the default password before performing the server upgrade. After the upgrade completes, you can change the password back to your custom trust store password. For details, [Changing the password for the shared truststore](#).
- If a custom password is configured for MongoDB on your V8.1.3 Cloud APM server, you must set the MongoDB password back to the default value before running `backup.sh`. After the upgrade to version 8.1.4.0 is complete, you can set the MongoDB password back to a custom password. For more information, see [“Default users and passwords”](#) on page 1194.

## About this task

The procedure for upgrading the Cloud APM server from V8.1.3 to V8.1.4 on the same system involves these general steps:

- Install the Cloud APM V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later on your V8.1.3 Cloud APM server.
- Back up your V8.1.3 interim fix 16 or later server data and configuration files with the backup script that is part of the V8.1.3 interim fix 16 server installation.
- Uninstall your V8.1.3 Cloud APM server. After the uninstall is finished, delete any `install_dir/wlp-backup*` directories; for example: `wlp-backup-02`.
- If your Cloud APM server is connected to a remote Db2 server, back up the DATAMART, WAREHOUS, and SCR32 databases if these databases were not backed up recently. The `backup.sh` script can be used to complete this backup. Then, run commands to update the SCR database on the remote Db2 server.
- Install the V8.1.4 Cloud APM server and indicate that you are upgrading. The installation script restores the server data and configuration files from the V8.1.3 Cloud APM server backup file.

## Procedure

While logged in as the root user on the system where your V8.1.3 Cloud APM server is installed, complete these steps to upgrade your server to V8.1.4 on the same system:

Download and extract the V8.1.4 Cloud APM server installation image

1. Download the V8.1.4 Cloud APM server installation image from the download site to a staging location of your choosing.

See “[Downloading from Passport Advantage](#)” on page 134.

2. If you plan to configure the agent images, the Hybrid Gateway image, or both during the server upgrade, download the images.

For more information, see “[Download instructions](#)” on page 131.

3. Extract the server installation files for your offering.

In V8.1.4, two offerings are supported instead of four offerings that were supported in the V8.1.3 release. These offerings are:

**IBM Cloud Application Performance Management, Advanced Private**  
advanced\_8.1.4.0.tar

**IBM Cloud Application Performance Management, Base Private**  
base\_8.1.4.0.tar

The IBM Cloud Application Performance Management, Base Private offering now includes the V8.1.3 IBM Monitoring offering capability and the IBM Cloud Application Performance Management, Advanced Private offering now includes the capability of the other three V8.1.3 offerings. You must use the V8.1.4 offering file that matches the offering that was installed on the V8.1.3 Cloud APM server for the upgrade.

For example, if IBM Monitoring was installed in the V8.1.3 Cloud APM server, you must use the V8.1.4 IBM Cloud Application Performance Management, Base Private offering file to complete the upgrade.

Download and install the V8.1.3 patch on your V8.1.3 Cloud APM server

4. Install the V8.1.3 patch on your V8.1.3 Cloud APM server:

- a) Download the V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later patch from [IBM Fix Central](#) on the IBM support site.

- b) Copy the 8.1.3.0-IBM-IPM-SERVER-IF0016.tar file to your V8.1.3 Cloud APM server and complete these steps on the V8.1.3 Cloud APM server.

- i) Extract the patch package:

```
tar xvf 8.1.3.0-IBM-IPM-SERVER-IF0016.tar
```

- ii) Run the following script to apply the patch:

```
apmpatch.sh
```

5. Verify that the default permissions are set correctly. Open a command prompt and enter umask.

A value of 0022 is returned if the permissions are set correctly. If any other value is returned, set the permissions by entering the following command:

```
umask 0022
```

Back up your V8.1.3 Cloud APM server and then uninstall the server

6. Run the following command as user root to back up your V8.1.3 interim fix 16 or later Cloud APM server installation.

```
install_dir/ccm/backup.sh [-f ~/backup813.tar]
```

where *install\_dir* is the directory where you installed the V8.1.3 interim fix 16 Cloud APM server. Include the **-f** option when you want to specify the path and file name for the server backup. For example, ~/backup813.tar saves to /root/backup813.tar. The default path is /opt/ibm/

backups/backup\_yyyymmdd\_hhmmss.tar, such as /opt/ibm/backups/  
backup\_20160826\_155605.tar.

**Important:**

- If your MongoDB was installed on a remote system, use the backup file that you created when you upgraded MongoDB instead. For more information, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.

If your existing V8.1.3 server is configured with a non-default user name for the Cloud APM user interface administrator account, you must run the following **backup.sh** script as user root:

```
install_dir/ccm/backup.sh [-f ~/backup813.tar]  
-u uiadmin_username -p uiadmin_password
```

For example, if the Cloud APM UI administrator user name is uiadmin and the non-default password for this user is uiadminpwd, enter the following command:

```
install_dir/ccm/backup.sh -u uiadmin -p uiadminpwd
```

**Note:**

- If you do not want the password to be visible by other users, you can use environment variables to provide the password and the user name by entering the following commands:

```
export APMADMIN_USERNAME=uiadmin
```

```
export APMADMIN_PASSWORD=uiadminpwd
```

Then, run the backup.sh script as user root by entering the following command:

```
install_dir/ccm/backup.sh [-f ~/backup813.tar]
```

The Cloud APM UI administrator's user name and password is read from the backup during the restore phase.

- If your Cloud APM server is connected to a remote Db2 server, you can ignore the warning to run the backup script on the remote Db2 server.

Output messages inform you of the backup progress, backup path, and file name upon completion.

7. Uninstall your V8.1.3 Cloud APM server:

- a) Run the following command in the /opt/ibm/ccm directory (or /custom\_path/ccm if you installed the server in a different path):

```
./uninstall.sh
```

- b) Review the list of installed Cloud APM offerings and enter the number that uninstalls all the offerings (the whole product) or enter q (quit) to cancel the uninstall operation.

If your Cloud APM server connects to a remote Db2 server, back up databases and update the SCR database

8. If your Cloud APM server is connected to a remote Db2 server, complete these steps as root user:

- a) As Db2 instance user db2apm on the system where Db2 is installed, back up the DATAMART, WAREHOUS, and SCR32 databases.

If the database administrator who is managing the remote Db2 server does not have procedures for backing up the database, run the Cloud APM server backup script:

- i) Copy /tools/backup.sh from the V8.1.4 Cloud APM server installation image to the remote Db2 server.

- ii) As user root and Db2 instance user db2apm, enter the following commands on the remote Db2 server:

```
chmod 755 backup.sh
```

```
./backup.sh [-f ~/backup814.tar]
```

**AIX** If your Db2 server is running on AIX, you must run the backup.sh script in the bash shell. If the bash shell is not installed on your Db2 server, download the rpm for bash from the [AIX Toolbox for Linux Applications](#).

- b) Copy the setup-dbconfig-*platform\_64*.bin script from the packages/SCR directory of the V8.1.4 Cloud APM server installation image to the remote Db2 server system.
- c) If you are not already logged in as db2apm, enter:

```
su - db2apm
```

- d) Run the setup\_dbconfig-*platform\_64*.bin script to set up the SCR32 database where *platform* is either AIX or Linux.
- Run the script as the same Db2 instance user db2apm who ran the script during the creation of the V8.1.3. SCR database. Do not run the script as user root.

```
/path/setup-dbconfig-linux_64.bin -i console
```

Follow the console prompts:

- i) When you are prompted to choose a locale, enter 2 to select English.
  - ii) Enter 1 to accept the license agreement.
  - iii) Enter the absolute path to the installation folder or press Enter to accept the default path. The default path is the setup-dbconfig installation path for V8.1.3. Do not change this path, unless the path is incorrect. In this procedure, this path is referred to as /opt/ibm/db2/tbsmdb.
- The Cloud APM SCR database configuration tools installed by the setup\_dbconfig-*platform\_64*.bin script should not be installed into the same directory as the Tivoli Business Service Manager database configuration tools if the databases for both products reside on the same remote Db2 server.
- iv) Enter 1 to select IBM Cloud Application Performance Management (APM) as the product that uses the database.
  - v) Enter 1 to select Simple as the type of installation to run.
  - vi) Enter 2 to instruct the installer not to create the database schema, including the tables, table spaces, and views.
  - vii) Enter the following database configuration details when you are prompted:
    - Database Name (maximum 8 characters) (DEFAULT: SCR32): SCR32
    - Database host name or IP address (DEFAULT): *hostname\_or\_IP\_address*
    - Database Port (DEFAULT: 50000): *port*
    - Database Path (Default: <default>): *default\_path*
  - viii) Create an encrypted database (only applicable on Db2 for Cloud V10.5 fix pack 3 or later). Press **Enter** and accept the default selection that is displayed.
- e) Upgrade the database schema and Java UDF routines in the Db2 SCR database.

Enter:

```
cd install_path/tbsmdb/tools/XMLtoolkit/bin
./scr_restore.sh -U db2apm -P passw0rd -n
```

where *install\_path* is the path that you entered when you set up `setup-dbconfig`.

If you do not want the password visible on the command line, you can omit the `-P` flag and the script prompts for the password. For example:

```
./scr_restore.sh -n  
Enter the database password:
```

- f) Enter the following command as the `db2apm` user for each database to adjust the buffer pool after you determine the size of your environment.

```
db2 connect to WAREHOUS  
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size WAREHOUS_PAGE_COUNT  
db2 disconnect WAREHOUS  
db2 connect to DATAMART  
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size DATAMART_PAGE_COUNT  
db2 disconnect DATAMART  
db2 connect to SCR32  
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size 5000  
db2 alter bufferpool TBSMCFG16KBP IMMEDIATE size 1000  
db2 alter bufferpool TBSM4KBP IMMEDIATE size 1000  
db2 alter bufferpool TBSM32KBP IMMEDIATE size 1000  
db2 alter bufferpool TBSMSCR16KBP IMMEDIATE size SCR32_PAGE_COUNT  
db2 disconnect SCR32
```

where:

*WAREHOUS\_PAGE\_COUNT* is the page count (8 K page size) for the WAREHOUS database  
IBMDEFAULTBP bufferpool: 50000 for small; 100000 for medium; or 200000 for large

*DATAMART\_PAGE\_COUNT* is the page count (8 K page size) for the DATAMART database  
IBMDEFAULTBP bufferpool: 100000 for small; 200000 for medium; or 300000 for large

*SCR32\_PAGE\_COUNT* is the page count (16 K page size) for the SCR32 database  
TBSMSCR16KBP bufferpool: 30000 for small; 50000 for large; or 100000 for large

Estimate the size of your environment (small, medium, or large) from the server requirements table in [“Cloud APM server hardware requirements” on page 111](#).

Install the V8.1.4 Cloud APM server

9. Install the new version of the Cloud APM server and restore the data and configuration from the backup. Complete these sub-steps as the root user.

- a) If the computer system or virtual machine where you are installing the Cloud APM server with a local Db2 server is using LDAP to authenticate the root user or Db2 users for your Cloud APM server, you must create local Db2 users before installing the V8.1.4. Cloud APM server. Complete steps [1 to 7](#) in [“Installing on a system using an external directory service” on page 156](#).
- b) If your V8.1.3 Cloud APM server has a local Db2 server with custom passwords set for Db2 users `itmuser` and `db2apm`, you must change the values of the database passwords in Cloud APM 8.1.4.0 `install.properties` before running `install.sh`:

```
db2apm.password=my_custom_password  
itmuser.password=my_custom_password
```

- c) When you are upgrading your Cloud APM server from V8.1.3 to V8.1.4, you must install V8.1.4 in the same directory where the V8.1.3 server was previously installed. This installation path was either the default `/opt/ibm` directory or a directory that you chose. Run the `./install.sh` command to start the installation script.
- d) When you are asked if you want to upgrade from an existing installation of the Cloud APM server, enter 1 (Yes).
- e) When you are asked if you want to migrate the server data and configuration automatically or manually, enter 2 for manual migration.
- f) When you are asked for the backup file location, enter the path and file name that you created in Step [“6” on page 1313](#) (such as `/opt/ibm/backups/backup_20160826_155605.tar`).
- g) When you are asked whether you accept the license agreement, enter 1 to accept the agreement and continue, or enter 2 to decline.

- h) After you are asked whether you want to configure your agent installation images and Hybrid Gateway installation image (if used) to connect to the server, enter either 1 (yes) to configure the images now or 2 (no) to defer configuration of the agent and Hybrid Gateway images.

If you entered 1 (yes), you are prompted to confirm the following information:

- The path to the directory on the server where the agent images and Hybrid Gateway (if used) are stored.  
The agent images and Hybrid Gateway images can be mounted on an NFS partition but must be accessible using the file system.
- Enter the path to the directory for the configured agent installation images or accept the default *install\_dir/ccm/depot* directory.
- If you accepted the default directory for storing the configured agent and Hybrid Gateway images, the installer creates the directory *install\_dir/ccm/depot* for storing the configured agent and Hybrid Gateway images. However, if you chose to change the directory, or if the installer fails to create the directory, or the directory is not writable, you are prompted to specify the output directory.

If you entered 2 (no), this step is skipped.

- i) When you are prompted to enter the host name and IP address of the server that will be used in a web browser to log into the Cloud APM console, accept the default values or enter your own values.

This is the address that users enter to start the Cloud APM console from their web browsers, for example: <https://myserver:9443> or <http://myserver:8080>. You can change the IP address and host name later. See [“Changing the server IP address and host name”](#) on page 1215.

- j) If your Cloud APM server is connected to a remote Db2 server, respond to the prompts to connect to the remote Db2 database:

```
Enter configuration parameters to establish connection
to the existing DB2 database.
Enter the hostname/IP address to the DB2 host
or accept the default [10.46.40.100]:
Enter the port number of the DB2 instance
or accept the default [50000]:
Enter the password for the user "itmuser":
Enter the remote DB2 instance name or accept the default [db2apm]:
Enter the password for the instance user "db2apm":
```

If you get a message that the Db2 database names must match, accept the default values to use the V8.1.3 names:

```
Enter the name of Metric Cache database or accept the default [WAREHOUS]:
Enter the name of Topology database or accept the default [SCR32]:
Enter the name of Datamart database or accept the default [DATAMART]:
```

**Note:** After this step is completed, do not restore the remote Db2 server.

If the installer detects any agent configuration packages in *install\_dir/ccm/depot* from a previous installation of the Cloud APM server, it warns you that it renamed the old packages and created new agent packages. The old packages are named *install\_dir/ccm/depot.old*.

If the installer detects a *keyfiles* directory in *install\_dir* from a previous installation of the Cloud APM server, it warns you that it renamed the old *keyfiles* directory and created a new directory. The old *keyfiles* directory is named *install\_dir/keyfiles.old*.

A prerequisite scan of your environment starts and takes a few moments to complete. If any requirements are missing, a message directs you to a log file with the reason for the failure, such as insufficient disk space. You must address the failure and start the installation again. A "soft" prerequisite such as low available memory does not stop the installation but you must enter 1 to continue installing or 2 to stop.

If the Hybrid Gateway is installed, migrate your configuration

#### 10. Migrate your Hybrid Gateway configuration:

- To migrate the Hybrid Gateway immediately after a restore, run these commands on the Cloud APM server as the root user:

- a. Copy the restored `config.properties` file to the `ccm` directory:

```
cp install_dir/ccm/properties/config.properties.restored install_dir/ccm/properties/
config.properties
```

- b. Update the date and time of the `config.properties` file so that any Hybrid Gateways already running will reload their configuration:

```
touch config.properties
```

- c. Copy the updated `config.properties` file to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/
dropins/
CentralConfigurationServer.war/common/config.properties
```

- If any configurations were done on the upgraded system after the restore, complete these steps:

- a. Copy these two lines from the `install_dir/ccm/properties/config.properties.restored` file:

```
com.ibm.tivoli.ccm.encryption\key=
com.ibm.tivoli.ccm.gaian.connect\gaianReq=
```

- b. Replace the same lines in `install_dir/ccm/properties/config.properties` with the lines that you just copied.

- c. Copy `config.properties` to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/
dropins/
CentralConfigurationServer.war/common/config.properties
```

To verify that the `config.properties` file in `install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/common/` was replaced, check that the modified date and time are current.

## Results

The installer upgrades to the new version of the Cloud APM server and restores the data and configuration from the server backup. This upgrade procedure can take up to 1 hour or longer depending on the size of your backup.

## What to do next

- If you are using the default out of the box certificates for accessing the Cloud APM console, you must complete the steps in this technote [V8.1.4 Application Performance Management UI certificates are expiring in upgraded environments](#) to update the default certificates to prevent them from expiring in April 2019.
- Before you use the Cloud APM console that you upgraded, clear your web browser cache and restart your browser. Clearing the cache avoids display issues that new capabilities in this update introduced to some of the user interfaces.
- Hybrid Gateway users: During the upgrade, the server restore script adds the V8.1.4 encryption key and `gaian`db credential to the restored `config.properties` file. The Hybrid Gateway then downloads the `config.properties` file and attempts to use the new encryption key to decrypt the ITM password. Since this key was not used to encrypt the password, the decryption attempt fails and the connection with the Tivoli Enterprise Portal Server fails. The workaround for this problem follows:
  1. After a restore, the `install_dir/ccm/properties` directory contains `config.properties` and `config.properties.restored`.

2. To recover the Hybrid Gateway immediately after a restore, run these commands on the Cloud APM server as the root user:

```
cp install_dir/ccm/properties/config.properties.restored install_dir/ccm/properties/config.properties
```

Update the date and time of the `config.properties` file so that any Hybrid Gateways already running will reload their configuration:

```
# touch config.properties
```

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/common/config.properties
```

- If you want to use the old agent configuration packages from a previous installation for agent installations, complete these steps:
  1. Go to the *install\_dir*/ccm directory.
  2. Delete the `agentconfig` file.
  3. Change the name of the `agentconfig.old` file to `agentconfig`.
- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server, you must change `clientAuthentication` to `true`. Copy the `<ssl>` xml element that contains the `enabledCiphers` attribute from the *install\_dir*/wlp/usr/servers/min/server.xml file to the *install\_dir*/wlp/usr/servers/min/user-exit.xml file if it does not already exist in the user-exit.xml file. Then add this `clientAuthentication="true"` line after the `enabledCiphers` line in the user-exit.xml file. Remove the `<ssl>` xml element from the server.xml file. The following code example shows you where to add the `clientAuthentication="true"` line in the user-exit.xml.

```
<ssl
id="defaultSSLConfig"
sslProtocol="TLSv1.2"
enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256"
clientAuthentication="true"
serverKeyAlias="server_key"
clientKeyAlias="IBM_Tivoli_Monitoring_Certificate"
keyStoreRef="defaultKeyStore"/>
```

- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and used the default certificates, change the communication protocol that the Cloud APM server agents use to HTTPS. For instructions, see [Configuring the communications protocol for server agents](#).
- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and did not use the default certificates, complete these steps:
  1. Encode the (xor) server keystore password that you used when you created certificates for the V8.1.3 Cloud APM server:

```
/opt/ibm/wlp/bin/securityUtility encode
```

2. Copy the `<keyStore>` xml element from the *install\_dir*/ibm/wlp/usr/servers/min/server.xml to the *install\_dir*/wlp/usr/servers/min/user-exit.xml file if it does not already exist in the user-exit.xml file. Then in the user-exit.xml file, replace the value of the `password` attribute with the newly encoded password from the step “1” on page 1319. Remove the `<keyStore>` xml element from the server.xml file.
3. Go to the *install\_dir* directory.
4. Delete the `keyfiles` directory.
5. Change the name of the `keyfiles.old` directory to `keyfiles`.
6. Update the certificates that are used by the monitoring agents to connect to the Cloud APM server to use the new keystore. For instructions, see [“Configuring certificates between the server and agents for HTTPS communication”](#) on page 244.

7. Update the communication protocol and certificates that are used by the Cloud APM server agents.  
For instructions, see [Configuring the communications protocol for server agents](#).
- If the system where you installed the Cloud APM server is using LDAP to authenticate the root user or Db2 users, and you updated the passwords for the `itmuser` and the Db2 instances users when following the procedure referenced in step 9.a, then complete step “9” on page 158 in the *Installing on a system using an external directory service* topic.
- Reconfigure and reinstall the reports by completing the steps in “[Configuring the reports installation image](#)” on page 1085 and “[Installing reports](#)” on page 1086.
- If you change the host name or IP address of the Cloud APM server and Db2 is installed locally and previously integrated with other products (such as Tivoli Common Reporting), complete these steps:
  1. Complete steps “6” on page 1090, “7” on page 1090, and “8” on page 1090 in “[Enabling single sign-on between Cloud APM and Tivoli Common Reporting](#)” on page 1089.
  2. Uncatalog the old server node and databases for Tivoli Common Reporting:

```
db2 list db|node directory
```

```
(db2 list db2 directory or db2 list node directory)
```

```
db2 uncatalog node node_alias
```

```
db2 uncatalog db db_alias
```

3. Recatalog the server node and databases for Tivoli Common Reporting by completing the steps in “[Configuring an ODBC connection](#)” on page 1084.
- Review the WAREHOUS database settings that were applied by the restore process.

```
update database config for warehous using DFT_DEGREE any
update database config for warehous using LOGBUFSZ 1024
update database config for warehous using LOCKLIST AUTOMATIC
update database config for warehous using SORTHEAP AUTOMATIC
update database config for warehous using SHEAPTHRES_SHR AUTOMATIC
update database config for warehous using NUM_IOCLEANERS AUTOMATIC
update database config for warehous using NUM_IOSERVERS AUTOMATIC
update database config for warehous using LOGFILSIZ 4096
update database config for warehous using LOGPRIMARY 10
update database config for warehous using DBHEAP AUTOMATIC
update database config for warehous using LOGSECOND 40
update database config for warehous using AVG_APPLS AUTOMATIC
update database config for warehous using logarchmeth1 OFF
update database config for warehous using logarchmeth2 OFF
update database config for warehous using DATABASE_MEMORY 250000 AUTOMATIC
```

Because Cloud APM does not support pruning of database logs, the `logarchmeth1` and `logarchmeth2` settings are set to OFF. If you back up your Warehouse database and you support log pruning in your environment, modify these settings.

- Most V8.1.3 Cloud APM agents are compatible with the V8.1.4 Cloud APM server. However, you must upgrade the following agents after you upgrade the Cloud APM server to version 8.1.4.0:
  - If you are using the Synthetic Playback agent, you must upgrade the agent by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#). Then, you must apply the latest Cloud APM 8.1.4.0 server interim fix that is available from Fix Central.
  - The Monitoring Agent for WebSphere Applications must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).
  - The Monitoring Agent for MongoDB must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).
-

## Upgrading the server side-by-side

The *side-by-side* upgrade task is completed by using two separate systems; one system runs version 8.1.3 of the Cloud APM server and the other system will run version 8.1.4 of the server after this upgrade procedure is completed. With this method, minimal downtime occurs because V8.1.3 of the Cloud APM server is running continuously while the new V8.1.4 server is being installed.

The V8.1.3 server is shut down only during the switch to the new V8.1.4 server; hence, the user experiences minimal disruption. Another advantage of this method is that if upgrade issues or failure occur, you can continue to use the previous Cloud APM server version before the upgrade, which is V8.1.3. Customers with large monitoring environments usually choose this method.

### Before you begin

- Before you can complete this upgrade procedure, ensure that two systems are available, a system that is running V8.1.3 of the Cloud APM server and a separate system to upgrade to V8.1.4 of the server.
- When you perform the Cloud APM server upgrade, the Db2 server for the Cloud APM server V8.1.4.0 must be at the same version as the Db2 server used by the Cloud APM server V8.1.3. Check the Db2 version that is in use by the Cloud APM server V8.1.3:
  - If Db2 is installed on the same system as the Cloud APM server, enter the following command to check the Db2 version:

```
install_dir/db2/V10.5/bin/db2level
```

where *install\_dir* is the directory where Db2 is installed.

- If Db2 is installed on a remote system, ask the Db2 administrator to check the Db2 server version.

#### Important:

The Db2 server for your V8.1.4 Cloud APM server must be at the same version as your V8.1.3 Cloud APM server during the Cloud APM server upgrade.

If the Db2 version for your V8.1.3 Cloud APM server is Db2 Advanced Enterprise Server Edition V10.5 fix pack 9 (or later), complete the steps in this technote [Upgrading your Cloud APM server from V8.1.3 to V8.1.4 when your Db2 server is running V10.5 fix pack 9 or a later fix pack](#) now to continue your Cloud APM server upgrade from V8.1.3 to V8.1.4.

If you want to use Db2 V11.1 for your V8.1.4 Cloud APM server, you can upgrade your Db2 server to a supported version of Db2 V11.1 after the Cloud APM server upgrade completes. Follow the procedure in [“Upgrading the Db2 server to Db2 version 11.1.x” on page 1208](#).

- If LDAP is enabled on your V8.1.3 Cloud APM server to authenticate Cloud APM console users, complete the following steps on your V8.1.3 Cloud APM server before you back up your V8.1.3 data:
  1. Retrieve the value of the *realm* attribute from the `install_dir/wlp/usr/shared/config/ldapRegistry.xml` file.
  2. Check the value of the *oauthRealm* attribute in the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file. If the value of *oauthRealm* attribute does not match the value of the *realm* attribute in the `ldapRegistry.xml` file, update the value of the *oauthRealm* attribute to match the value of the *realm* attribute.
  3. Complete the following steps to update the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to add the user from the `install_dir/wlp/usr/servers/server1/cscs/conf/cscsRoleAdmin.conf` file:
    - a. Find the properties line **<properties>**, and identify the **systemUser** parameter, if it does not exist you will need to add it in the next step. Identify the closing tag **/>** for the properties line.
    - b. Add a new line or edit the existing line before the **/>** closing tag as follows:

```
systemUser="testuser LDAP distinguished name"
```

where *testuser* matches the user string from the `cscsRoleAdmin.conf` file, for example:

```
systemUser="CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
```

**Note:** Do not include the user:prefix or realm name that was specified in `cscsRoleAdmin.conf`.

c. Confirm that the `/>` closing tag was not deleted, then save and close the file.

- If your V8.1.3 Cloud APM server is connected to a remote MongoDB, install MongoDB V3.2.12. For instructions, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.
- If you modified the trust store password for your Cloud APM server V8.1.3, change the password back to the default password before performing the server upgrade. After the upgrade completes, you can change the password back to your custom trust store password. For details, [Changing the password for the shared truststore](#).
- If a custom password is configured for MongoDB on your V8.1.3 Cloud APM server, you must set the MongoDB password back to the default value before running `backup.sh`. After the upgrade to version 8.1.4.0 is complete, you can set the MongoDB password back to a custom password. For more information, see [“Default users and passwords”](#) on page 1194.

## About this task

These steps assume that the system that is running V8.1.3 of the Cloud APM server is using the local Db2 server that is installed by default with the Cloud APM server. If the V8.1.3 Cloud APM server system that you are using is connected to a remote Db2 server, you must complete the steps in the [“Upgrading your server when connected to a remote Db2 server”](#) on page 1332 topic and complete the steps in this topic. Start with the steps in [“Upgrading your server when connected to a remote Db2 server”](#) on page 1332. You are referred to the steps in this topic.

The procedure for upgrading the Cloud APM server from V8.1.3 to V8.1.4 on the two systems involves these general steps:

1. Install the Cloud APM V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later on your V8.1.3 Cloud APM server.
2. Back up your V8.1.3 interim fix 16 or later server data and configuration files with the backup script that is part of the V8.1.3 interim fix 16 server installation.
3. Install your V8.1.4 Cloud APM server and either restore the V8.1.3 Cloud APM server data from step 2 or complete an automatic backup and restore of your V8.1.3 server data.
4. Shut down your V8.1.3 Cloud APM server.
5. Reassign the V8.1.3 Cloud APM server IP address or both the IP address and host name to the V8.1.4 Cloud APM server.

If you are using a remote Db2 server, the procedure involves these general steps:

1. Install the Cloud APM V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later on your V8.1.3 Cloud APM server.
2. Back up your V8.1.3 Db2 databases.
3. Set up the new V8.1.4 SCR database.
4. Restore the V8.1.3 Db2 database data to the new V8.1.4 databases.
5. Back up your V8.1.3 Cloud APM server data and configuration files with the backup script that is part of the V8.1.3 server installation if you are completing a manual backup.
6. Install your V8.1.4 Cloud APM server and either restore the V8.1.3 Cloud APM server data from step 5 or complete an automatic backup and restore of your V8.1.3 server data.
7. Stop your V8.1.3 Cloud APM server.
8. Optionally, rename your new V8.1.4 databases to use the same database names that were used for V8.1.3.
9. Reassign the V8.1.3 Cloud APM server IP address or both the IP address and host name to the V8.1.4 server.

## Procedure

Complete the following steps as a root user:

1. Download the V8.1.4 Cloud APM server installation image from the download site to a staging location of your choosing.

See [“Downloading from Passport Advantage” on page 134](#).

2. If you plan to configure the agent images, the Hybrid Gateway image, or both during the server upgrade, download the images.

For more information, see [“Download instructions” on page 131](#).

3. Extract the server installation files for your offering.

4. Install the V8.1.3 patch on your V8.1.3 Cloud APM server:

- a) Download the V8.1.3 interim fix 16 (8.1.3.0-IBM-IPM-SERVER-IF0016) or later patch from [IBM Fix Central](#) on the IBM support site.

- b) Copy the 8.1.3.0-IBM-IPM-SERVER-IF0016.tar file to your V8.1.3 Cloud APM server and complete these steps on the V8.1.3 Cloud APM server.

- i) Extract the patch package:

```
tar xvf 8.1.3.0-IBM-IPM-SERVER-IF0016.tar
```

- ii) Run the following script to apply the patch:

```
apmpatch.sh
```

5. If the computer system or virtual machine where you are installing the Cloud APM server with a local Db2 server is using LDAP to authenticate the root user or Db2 users for your Cloud APM server, you must create local Db2 users before installing the V8.1.4. Cloud APM server. Complete steps [1](#) to [7](#) in [“Installing on a system using an external directory service” on page 156](#).

6. Verify that the default permissions are set correctly. Open a command prompt and enter umask.

A value of 0022 is returned if the permissions are set correctly. If any other value is returned, set the permissions by entering the following command:

```
umask 0022
```

7. From the directory where you extracted the installation files, install V8.1.4 of the Cloud APM server on the virtual machine or computer system that you are using for the upgrade.

- a) Take note of the installation location of the V8.1.3 server on the existing system because you must install V8.1.4 in the same directory on the upgrade system.

The installation path was either the default /opt/ibm directory or a directory that you chose.

- b) If your V8.1.3 Cloud APM server has a local Db2 server with custom passwords set for Db2 users itmuser and db2apm, you must change the values of the database passwords in Cloud APM 8.1.4.0 install.properties before running install.sh:

```
db2apm.password=my_custom_password  
itmuser.password=my_custom_password
```

- c) Start the installation script:

```
./install.sh
```

8. After you start the installation, when you are asked if you are upgrading from an existing installation of the Cloud APM server, enter 1 (yes) to continue with the upgrade.

9. When you are asked if you want to move the data and configuration automatically or manually from the existing system, enter 1 (yes) to accept the default and automatically move the data or 2 (no) to complete a manual migration.

- a) If you entered 2 [manually] to move your data from the existing V8.1.3 server, you must run the backup as user root on this existing server. The backup.sh script is in the ccm directory of the V8.1.3 Cloud APM server installation directory.

**Important:**

- If your MongoDB was installed on a remote system, use the backup file that you created when you upgraded MongoDB instead. For more information, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.

If your existing V8.1.3 server is configured with a non-default user name for the Cloud APM user interface administrator account, you must run the following **backup.sh** script as user root:

```
install_dir/ccm/backup.sh [-f ~/backup813.tar]
-u uiadmin_username -p uiadmin_password
```

For example, if the Cloud APM UI administrator user name is uiadmin and the non-default password for this user is uiadminpwd, enter the following command:

```
install_dir/ccm/backup.sh -u uiadmin -p uiadminpwd
```

**Note:**

- If you do not want the password to be visible by other users, you can use environment variables to provide the password and the user name by entering the following commands:

```
export APMADMIN_USERNAME=uiadmin
```

```
export APMADMIN_PASSWORD=uiadminpwd
```

Then, run the backup.sh script as user root by entering the following command:

```
install_dir/ccm/backup.sh [-f ~/backup813.tar]
```

The Cloud APM UI administrator's user name and password is read from the backup during the restore phase.

- If your Cloud APM server is connected to a remote Db2 server, you can ignore the warning to run the backup script on the remote Db2 server.

- b) If you entered 1 [automatically] to move your data from the existing V8.1.3 server, you are prompted to provide or accept default values to set up the SSH connection to the existing V8.1.3 server.

i) name for the Performance Management UI administrator account or accept the default [apmadmin]

ii) password for the Performance Management UI administrator account

iii) hostname/IP address of the remote server

After you respond to the prompts, a connection is established and a backup of the existing server data and configuration is created. The time that it takes to create the backup depends on the size of the backup.

10. After the backup is finished, you must enter the root password of the V8.1.4 Cloud APM server so you can copy the backup file to this server.
11. If you are manually migrating your data, copy the backup tar image from [step 9](#) to the server where you are installing the Cloud APM server and enter the path and file name that you created (such as /opt/ibm/backups/backup\_20160826\_155605.tar) when you are prompted.
12. After you are asked whether you want to configure your agent installation images and Hybrid Gateway installation image (if used) to connect to the server, enter either 1 (yes) to configure the images now or 2 (no) to defer configuration of the agent and Hybrid Gateway images.

If you entered 1 (yes), you are prompted to confirm the following information:

- The path to the directory on the server where the agent images and Hybrid Gateway (if used) are stored.  
The agent images and Hybrid Gateway images can be mounted on an NFS partition but must be accessible using the file system.
- Enter the path to the directory for the configured agent installation images or accept the default *install\_dir/ccm/depot* directory.
- If you accepted the default directory for storing the configured agent and Hybrid Gateway images, the installer creates the directory *install\_dir/ccm/depot* for storing the configured agent and Hybrid Gateway images. However, if you chose to change the directory, or if the installer fails to create the directory, or the directory is not writable, you are prompted to specify the output directory.

If you entered 2 (no), this step is skipped.

13. When you are prompted to enter the host name and IP address of the server that will be used in a web browser to log into the Cloud APM console, accept the default values or enter your own values.

This is the address that users enter to start the Cloud APM console from their web browsers, for example: `https://myserver:9443` or `http://myserver:8080`. You can change the IP address and host name later. See [“Changing the server IP address and host name”](#) on page 1215.

**Important:** These steps assume that the Cloud APM server system that you are upgrading from is using the local Db2 server that is installed by default when the server was installed. If this version of the server is connected to a remote Db2 server, during the V8.1.4 installation, you are prompted to complete the steps in [“Upgrading your server when connected to a remote Db2 server”](#) on page 1332 to back up the databases separately to avoid any issues between the V8.1.3 server and the new V8.1.4 server.

The V8.1.4 Cloud APM server installation is started.

If the installer detects any agent configuration packages in *install\_dir/ccm/depot* from a previous installation of the Cloud APM server, it warns you that it renamed the old packages and created new agent packages. The old packages are named *install\_dir/ccm/depot.old*.

If the installer detects a *keyfiles* directory in *install\_dir* from a previous installation of the Cloud APM server, it warns you that it renamed the old *keyfiles* directory and created a new directory. The old *keyfiles* directory is named *install\_dir/keyfiles.old*.

A prerequisite scan of your environment starts and takes a few moments to complete. If any requirements are missing, a message directs you to a log file with the reason for the failure, such as insufficient disk space. You must address the failure and start the installation again. A "soft" prerequisite such as low available memory does not stop the installation but you must enter 1 to continue installing or 2 to stop.

14. When the installation is complete, you can verify that the V8.1.4 upgrade is a success by completing the following steps:
  - a) Issue the **apm status** command from the `/usr/bin/` directory on the upgraded V8.1.4 server to view the list of running components. If all the components are running, the upgrade is a success.
  - b) If you log in to the Application Performance Dashboard using the same credentials that you used for V8.1.3 and check your applications, groups, and instances for V8.1.4, they are the same as they were for V8.1.3.

15. Shut down the V8.1.3 Cloud APM server system if it is running by entering the following command from any directory:

```
shutdown -P now
```

16. Reassign the V8.1.3 Cloud APM server IP address or both the IP address and host name to the V8.1.4 server. Whether you reassign the IP address only or both the IP address and host name depends on your configuration.
  - If you use the Cloud APM server IP address to connect your agents to your server, complete the steps in [Reassigning the server IP address to another server](#).

- If you use the Cloud APM server host name to connect your agents to your server, complete the steps in [Reassigning the server IP address and host name to another server](#).

#### 17. Migrate your Hybrid Gateway configuration:

- To migrate the Hybrid Gateway immediately after a restore, run these commands on the Cloud APM server as the root user:

- a. Copy the restored `config.properties` file to the `ccm` directory:

```
cp install_dir/ccm/properties/config.properties.restored install_dir/ccm/properties/
config.properties
```

- b. Update the date and time of the `config.properties` file so that any Hybrid Gateways already running will reload their configuration:

```
touch config.properties
```

- c. Copy the updated `config.properties` file to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/
dropins/
CentralConfigurationServer.war/common/config.properties
```

- If any configurations were done on the upgraded system after the restore, complete these steps:

- a. Copy these two lines from the `install_dir/ccm/properties/config.properties.restored` file:

```
com.ibm.tivoli.ccm.encrypted:key=
com.ibm.tivoli.ccm.gaian.connect:gaianReq=
```

- b. Replace the same lines in `install_dir/ccm/properties/config.properties` with the lines that you just copied.

- c. Copy `config.properties` to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/
dropins/
CentralConfigurationServer.war/common/config.properties
```

To verify that the `config.properties` file in `install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/common/` was replaced, check that the modified date and time are current.

## Results

The Cloud APM server upgrade to V8.1.4 is complete. You can now access the latest functions for your agents and other components.

## What to do next

- If you are using the default out of the box certificates for accessing the Cloud APM console, you must complete the steps in this technote [V8.1.4 Application Performance Management UI certificates are expiring in upgraded environments](#) to update the default certificates to prevent them from expiring in April 2019.
- Before you use the Cloud APM console that you upgraded, clear your web browser cache and restart your browser. Clearing the cache avoids display issues that new capabilities in this update introduced to some of the user interfaces.
- If you want to use the old agent configuration packages from a previous installation for agent installations, complete these steps:
  1. Go to the `install_dir/ccm` directory.
  2. Delete the `agentconfig` file.
  3. Change the name of the `agentconfig.old` file to `agentconfig`.

- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server, you must change `clientAuthentication` to `true`. Copy the `<ssl>` xml element that contains the `enabledCiphers` attribute from the `install_dir/wlp/usr/servers/min/server.xml` file to the `install_dir/wlp/usr/servers/min/user-exit.xml` file if it does not already exist in the `user-exit.xml` file. Then add this `clientAuthentication="true"` line after the `enabledCiphers` line in the `user-exit.xml` file. Remove the `<ssl>` xml element from the `server.xml` file. The following code example shows you where to add the `clientAuthentication="true"` line in the `user-exit.xml`.

```
<ssl
id="defaultSSLConfig"
sslProtocol="TLSv1.2"
enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256"
clientAuthentication="true"
serverKeyAlias="server_key"
clientKeyAlias="IBM_Tivoli_Monitoring_Certificate"
keyStoreRef="defaultKeyStore"/>
```

- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and used the default certificates, change the communication protocol that the Cloud APM server agents use to HTTPS. For instructions, see [Configuring the communications protocol for server agents](#).
- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and did not use the default certificates, complete these steps:
  1. Encode the (xor) server keystore password that you used when you created certificates for the V8.1.3 Cloud APM server:
 

```
/opt/ibm/wlp/bin/securityUtility encode
```
  2. Copy the `<keyStore>` xml element from the `install_dir/ibm/wlp/usr/servers/min/server.xml` to the `install_dir/wlp/usr/servers/min/user-exit.xml` file if it does not already exist in the `user-exit.xml` file. Then in the `user-exit.xml` file, replace the value of the `password` attribute with the newly encoded password from the step “1” on page 1327. Remove the `<keyStore>` xml element from the `server.xml` file.
  3. Go to the `install_dir` directory.
  4. Delete the `keyfiles` directory.
  5. Change the name of the `keyfiles.old` directory to `keyfiles`.
  6. Update the certificates that are used by the monitoring agents to connect to the Cloud APM server to use the new keystore. For instructions, see “[Configuring certificates between the server and agents for HTTPS communication](#)” on page 244.
  7. Update the communication protocol and certificates that are used by the Cloud APM server agents. For instructions, see [Configuring the communications protocol for server agents](#).
- If the system where you installed the Cloud APM server is using LDAP to authenticate the root user or Db2 users, and you updated the passwords for the `itmuser` and the Db2 instances users when following the procedure referenced in step “5” on page 1323, then complete step “9” on page 158 in the *Installing on a system using an external directory service* topic.
- Reconfigure and reinstall the reports by completing the steps in “[Configuring the reports installation image](#)” on page 1085 and “[Installing reports](#)” on page 1086.
- If you change the host name or IP address of the Cloud APM server and Db2 is installed locally and previously integrated with other products (such as Tivoli Common Reporting), complete these steps:
  1. Complete steps “6” on page 1090, “7” on page 1090, and “8” on page 1090 in “[Enabling single sign-on between Cloud APM and Tivoli Common Reporting](#)” on page 1089.
  2. Uncatalog the old server node and databases for Tivoli Common Reporting:

```
db2 list db|node directory
```

```
(db2 list db2 directory or db2 list node directory)
```

```
db2 uncatalog node node_alias
```

```
db2 uncatalog db db_alias
```

3. Recatalog the server node and databases for Tivoli Common Reporting by completing the steps in “Configuring an ODBC connection” on page 1084.
- Most V8.1.3 Cloud APM agents are compatible with the V8.1.4 Cloud APM server. However, you must upgrade the following agents after you upgrade the Cloud APM server to version 8.1.4.0:
  - If you are using the Synthetic Playback agent, you must upgrade the agent by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#). Then, you must apply the latest Cloud APM 8.1.4.0 server interim fix that is available from Fix Central.
  - The Monitoring Agent for WebSphere Applications must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).
  - The Monitoring Agent for MongoDB must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).

## Reassigning the server IP address and host name to another server

If you are using the server host name to connect your agents to the Cloud APM server, after the server upgrade is finished, you must reassign the IP address and host name of the V8.1.3 Cloud APM server to the upgraded V8.1.4 server. As part of this reassignment, you are also changing the host name setting in the Db2 configuration on the V8.1.4 Cloud APM server.

### Before you begin

If you plan to install new agents after you reassign the IP address and host name of the server, create new configuration packages for the agent images (see step 2 in “Configuring the downloaded images” on page 182). Otherwise, the agents will not connect to the Cloud APM server or show in the Cloud APM console.

### Procedure

Complete the following steps as the root user on the V8.1.4 upgraded Cloud APM server:

1. Stop all of the server components by entering the following command in the /usr/bin directory:

```
apm stop_all
```

2. Reassign the IP address from the V8.1.3 Cloud APM server to the V8.1.4 server:
  - a) To determine the IP address and the number of network adapters on the 8.1.3 server, run the following command from this server:

```
ip addr
```

- b) To determine the IP address and the number of network adapters on the new upgraded V8.1.4 server, run the following command from this server:

```
ip addr
```

- c) If there is only one network adapter on the V8.1.3 server, enter the following command to shut down this server system and free up the IP address for reuse:

```
shutdown -P now
```

If there are multiple network adapters on the V8.1.3 server, enter the following command to shut down the network adapter that is configured with the IP address on the server and free up the IP address for reuse:

```
ip link set dev ADAPTER down
```

where *ADAPTER* is the adapter name from sub step “2.a” on page 1328.

- d) Enter the following commands on the V8.1.4 server to reassign the V8.1.3 IP address to the V8.1.4 server. This V8.1.3 IP address becomes the IP address for the V8.1.4 server:

```
TEMP=/tmp/adapter.$$  
sed 's/IPADDR=.*$/IPADDR="'IP"'/'  
/etc/sysconfig/network-scripts/ifcfg-ADAPTER >$TEMP
```

where *IP* is the V8.1.3 server IP address, and *ADAPTER* is the adapter name from the sub step “2.b” on page 1328.

Enter the following command to complete the reassignment:

```
cp $TEMP /etc/sysconfig/network-scripts/ifcfg-ADAPTER
```

Enter this command to restart the network adapter:

```
/etc/init.d/network restart
```

The V8.1.4 network adapter is now using the V8.1.3 IP address as its IP address.

3. Change the IP address and host name of the server that is used to start the Cloud APM console. This is the address that users enter to start the console from their web browsers, for example: `https://myserver:9443` or `http://myserver:8080`. Change to the *install\_dir/ccm* directory and run the following command:

```
configure_server_address.sh
```

When prompted, enter the new server host name and IP address.

4. Update the server agent file names. The server agents include the Synthetic Events agent, the Transaction Events agent, and optionally, the Bluemix Integration agent. Change to the *install\_dir/serveragents/bin* directory and run the following command:

```
update_config_files.sh
```

5. Change the Cloud APM server references on the Db2 server to the new IP address and host name:
  - a) On the V8.1.4 Cloud APM server, update the *DB2SYSTEM* registry variable to match the V8.1.3 Cloud APM server host name:

```
source /home/db2apm/sqlllib/db2profile  
db2set -g DB2SYSTEM=host_name
```

where *host\_name* is the host name of the V8.1.3 server.

- b) If your Db2 database is on a local system, modify the host name on the V8.1.4 Cloud APM server by editing the */home/db2apm/sqlllib/db2nodes.cfg* file and replacing the V8.1.4 host name with the V8.1.3 server host name.
- c) If your Db2 database is on a local system, update the Db2 administrator's configuration file by entering the following commands:

```
su - db2apm -c 'db2 update admin cfg using DB2SYSTEM host_name'  
su - db2apm -c 'db2 update admin cfg using SMTP_SERVER host_name'
```

where *host\_name* is the host name of the V8.1.3 server.

6. Restart the server components by entering the following command in the */usr/bin* directory:

```
apm start_all
```

7. Override the host name of the Cloud APM server in the Central Configuration Services component.
  - a) If you are not already logged in to the Cloud APM console, log in now.  
(See [“Starting the Cloud APM console”](#) on page 1109.)
  - b) Click  **System Configuration** > **Advanced Configuration** and click **Agent Central Configuration**.
  - c) In the **Host Name Override** field, enter the new IP address or fully qualified host name of the Cloud APM server.  
After you click **Save**, the new host name is updated in the Central Configuration Services component.
8. On the systems where your agents are installed, connect the agents to the new server IP address and host name.  
See [“Configuring agents to connect to a different server or to use HTTPS communication”](#) on page 255.
9. If you have reports packages for the Response Time Monitoring Agent and the WebSphere Applications agent installed, you must reinstall the reports packages for both agents.  
For more information, see [“Installing reports”](#) on page 1086. Restart the Tivoli Common Reporting server, complete the steps in the sub topics under [Restarting Jazz for Service Management application servers](#).

## Results

The V8.1.4 Cloud APM server becomes the new active server.

## Reassigning the server IP address to another server

If you are using the server IP address to connect your agents to the Cloud APM server, after the server upgrade is finished, you must reassign the IP address of the V8.1.3 Cloud APM server to the upgraded V8.1.4 server and point the V8.1.3 IP address to the host name of the V8.1.4 server.

**Important:** This procedure describes one method of reassigning the IP address. There are other ways to complete this task. For more information, see the network configuration using the command line interface information in the Networking Guide in [Red Hat documentation](#).

## Before you begin

If you plan to install new agents after you reassign the IP address of the server, create new configuration packages for the agent images (see step 2 in [“Configuring the downloaded images”](#) on page 182). Otherwise, the agents will not connect to the Cloud APM server or show in the Cloud APM console.

## Procedure

Complete the following steps as the root user:

1. Change the IP address and host name of the server that is used to start the Cloud APM console. This is the address that users enter to start the console from their web browsers, for example: `https://myserver:9443` or `http://myserver:8080`. Change to the `install_dir/ccm` directory and run the following command:

```
configure_server_address.sh
```

When prompted, enter the new server host name and IP address.

2. Update the server agent file names. The server agents include the Synthetic Events agent, the Transaction Events agent, and optionally, the Bluemix Integration agent. Change to the `install_dir/serveragents/bin` directory and run the following command:

```
update_config_files.sh
```

3. Reassign the IP address from the V8.1.3 Cloud APM server to the V8.1.4 server:

- a) To determine the IP address and the number of network adapters on the 8.1.3 server, run the following command from this server:

```
ip addr
```

- b) To determine the IP address and the number of network adapters on the new upgraded V8.1.4 server, run the following command from this server:

```
ip addr
```

- c) If there is only one network adapter on the V8.1.3 server, enter the following command to shut down this server system and free up the IP address for reuse:

```
shutdown -P now
```

If there are multiple network adapters on the V8.1.3 server, enter the following command to shut down the network adapter that is configured with the IP address on the server and free up the IP address for reuse:

```
ip link set dev ADAPTER down
```

where *ADAPTER* is the adapter name from sub step “3.a” on page 1331.

- d) Enter the following commands on the V8.1.4 server to reassign the V8.1.3 IP address to the V8.1.4 server. This V8.1.3 IP address becomes the IP address for the V8.1.4 server:

```
TEMP=/tmp/adapter.$$  
sed 's/IPADDR=.*$/IPADDR="'IP"'/'  
/etc/sysconfig/network-scripts/ifcfg-ADAPTER >$TEMP
```

where *IP* is the V8.1.3 server IP address, and *ADAPTER* is the adapter name from the sub step “3.b” on page 1331.

Enter the following command to complete the reassignment:

```
cp $TEMP /etc/sysconfig/network-scripts/ifcfg-ADAPTER
```

Enter this command to restart the network adapter:

```
/etc/init.d/network restart
```

The V8.1.4 network adapter is now using the V8.1.3 IP address as its IP address.

4. On the V8.1.4 server, open the `/etc/hosts` file in a text editor of your choice and replace the IP address opposite the V8.1.4 host name with the IP address of the V8.1.3 server.

**Note:** If you reassigned the V8.1.3 IP address to the V8.1.4 server, you do not have to change the network DNS configuration.

5. Override the host name of the Cloud APM server in the Central Configuration Services component.
- a) If you are not already logged in to the Cloud APM console, log in now.  
(See “Starting the Cloud APM console” on page 1109.)
- b) Click  **System Configuration > Advanced Configuration** and click **Agent Central Configuration**.
- c) In the **Host Name Override** field, enter the new IP address or fully qualified host name of the Cloud APM server.

After you click **Save**, the new host name is updated in the Central Configuration Services component.

6. If you have reports packages for the Response Time Monitoring Agent and the WebSphere Applications agent installed, you must reinstall the reports packages for both agents.

For more information, see “Installing reports” on page 1086. Restart the Tivoli Common Reporting server, complete the steps in the sub topics under [Restarting Jazz for Service Management application servers](#).

7. Optional: If at any time you need to restore the original IP addresses to the existing V8.1.3 and upgraded V8.1.4 servers, complete the following steps:

- a) To return the IP address on the V8.1.4 server to its original IP address, enter the following commands:

```
TEMP=/tmp/adapter.$$  
sed 's/IPADDR=.*$/IPADDR="'IP"'/'  
/etc/sysconfig/network-scripts/ifcfg-ADAPTER >$TEMP
```

Replace *IP* in the previous command with the original V8.1.4 server IP address that is being restored and replace *ADAPTER* with the adapter name from the previous step 3. b.

Enter the following command to complete the reassignment:

```
cp $TEMP /etc/sysconfig/network-scripts/ifcfg-ADAPTER
```

Issue this command to restart the V8.1.4 network adapter:

```
/etc/init.d/network restart
```

- b) If there is only one network adapter on the V8.1.3 server system and the system was shut down, you must restart the system. If you are using a virtual system, you must use the virtual administration software to restart the system. If you are using a physical system, you must locate the system and power it back up.

If there are multiple network adapters on the V8.1.3 server, enter the following command to start the specific network adapter that is configured with the IP address that you are restoring to this server:

```
ip link set dev ADAPTER up
```

Replace *ADAPTER* in the previous command with the adapter name from the previous step 3.a to restore the original V8.1.3 IP address to the V8.1.3 server.

The original IP address on the V8.1.4 network adapter is now restored. The V8.1.3 network adapter also has its original IP address restored.

## Results

The V8.1.4 Cloud APM server becomes the new active server.

## Upgrading your server when connected to a remote Db2 server

If you are completing a side-by-side upgrade, and the V8.1.3 Cloud APM server that you are upgrading from is connected to an existing remote Db2 server instead of the default local Db2 server, you must back up the databases separately to avoid any issues between the existing V8.1.3 server and the new V8.1.4 server that use these databases.

### Before you begin

- When you perform the Cloud APM server upgrade, the Db2 server for the Cloud APM server V8.1.4.0 must be at the same version as the Db2 server used by the Cloud APM server V8.1.3. Check the Db2 version that is in use by the Cloud APM server V8.1.3:
  - If Db2 is installed on the same system as the Cloud APM server, enter the following command to check the Db2 version:

```
install_dir/db2/V10.5/bin/db2level
```

where *install\_dir* is the directory where Db2 is installed.

- If Db2 is installed on a remote system, ask the Db2 administrator to check the Db2 server version.

### Important:

The Db2 server for your V8.1.4 Cloud APM server must be at the same version as your V8.1.3 Cloud APM server during the Cloud APM server upgrade.

If the Db2 version for your V8.1.3 Cloud APM server is Db2 Advanced Enterprise Server Edition V10.5 fix pack 9 (or later), complete the steps in this technote [Upgrading your Cloud APM server from V8.1.3 to V8.1.4](#) when your Db2 server is running V10.5 fix pack 9 or a later fix pack now to continue your Cloud APM server upgrade from V8.1.3 to V8.1.4.

If you want to use Db2 V11.1 for your V8.1.4 Cloud APM server, you can upgrade your Db2 server to a supported version of Db2 V11.1 after the Cloud APM server upgrade completes. Follow the procedure in [“Upgrading the Db2 server to Db2 version 11.1.x”](#) on page 1208.

- If your Cloud APM server is connected to a remote Db2 server, Db2 Advanced Workgroup Server Edition V11.1 is supported when you are upgrading your Cloud APM server from V8.1.3 to V8.1.4.
- If you are upgrading the Cloud APM server on the same system and you have a remote Db2 server, follow the instructions in [Upgrading the server on the same system](#).
- If your V8.1.3 Cloud APM server is connected to a remote MongoDB, install MongoDB V3.2.12. For more information, see [“Installing MongoDB V3.2.12 on your remote system”](#) on page 1308.
- **AIX** The backup.sh script is not supported on AIX. Use the Db2 utilities to back up your databases. For more information, see [Backup overview](#) and [BACKUP DATABASE command](#) in the Db2 V10.5.0 topic collection on IBM Knowledge Center.
- **AIX** The restore.sh script is not supported on AIX. Use the Db2 utilities to restore your databases. For more information, see [RESTORE DATABASE command](#).
- If LDAP is enabled on your V8.1.3 Cloud APM server to authenticate Cloud APM console users, complete the following steps on your V8.1.3 Cloud APM server before you back up your V8.1.3 data:
  1. Retrieve the value of the *realm* attribute from the `install_dir/wlp/usr/shared/config/ldapRegistry.xml` file.
  2. Check the value of the *oauthRealm* attribute in the `install_dir/wlp/usr/shared/config/oauthVariables-onprem.xml` file. If the value of *oauthRealm* attribute does not match the value of the *realm* attribute in the `ldapRegistry.xml` file, update the value of the *oauthRealm* attribute to match the value of the *realm* attribute.
  3. Complete the following steps to update the `install_dir/wlp/usr/servers/apmui/server-oauth2-tai.xml` file to add the user from the `install_dir/wlp/usr/servers/server1/cscs/conf/cscsRoleAdmin.conf` file:
    - a. Find the properties line **<properties>**, and identify the **systemUser** parameter, if it does not exist you will need to add it in the next step. Identify the closing tag **</>** for the properties line.
    - b. Add a new line or edit the existing line before the **</>** closing tag as follows:

```
systemUser="testuser LDAP distinguished name"
```

where *testuser* matches the user string from the `cscsRoleAdmin.conf` file, for example:

```
systemUser="CN=testuser,CN=users,dc=adtest,dc=mycity,dc=mycompany,dc=com"
```

**Note:** Do not include the user:prefix or realm name that was specified in `cscsRoleAdmin.conf`.

- c. Confirm that the **</>** closing tag was not deleted, then save and close the file.
- If you modified the trust store password for your Cloud APM server V8.1.3, change the password back to the default password before performing the server upgrade. After the upgrade completes, you can change the password back to your custom trust store password. For details, [Changing the password for the shared truststore](#).
  - If a custom password is configured for MongoDB on your V8.1.3 Cloud APM server, you must set the MongoDB password back to the default value before running `backup.sh`. After the upgrade to version 8.1.4.0 is complete, you can set the MongoDB password back to a custom password. For more information, see [“Default users and passwords”](#) on page 1194.

## About this task

- The Cloud APM server stores data in the WAREHOUS, SCR32, and DATAMART databases on the Db2 server. Before you install V8.1.4 of the Cloud APM server on the system that you are using for the upgrade, you must create copies of these three databases with names different from the names that were used for the V8.1.3 server.
- In this procedure, the names of the three Db2 databases are referenced as follows:

| Table 289. Db2 database names |                      |                          |
|-------------------------------|----------------------|--------------------------|
|                               | V8.1.3 Database Name | New V8.1.4 Database Name |
| Warehouse                     | WAREHOUS             | W1                       |
| Datamart                      | DATAMART             | D1                       |
| SCR                           | SCR32                | S1                       |

Different names can be used for the V8.1.4 databases by substituting the desired name for the name that is listed in [Table 289 on page 1334](#) in the following procedure.

- In the V8.1.4 release, if your Cloud APM server is connected to a remote Db2 server that is also running on a V8.1.4 Cloud APM server, you can create a custom name for the Db2 instance user or you can accept the default db2apm name. In previous Cloud APM releases, the db2apm instance user name only was supported. For the V8.1.4 release, because the steps in this procedure refer to an existing remote Db2 server, which is a pre-V8.1.4 remote Db2 server, you must complete these steps as the db2apm user.
- Most steps are run as a root user. Some steps are run as the Db2 instance user db2apm and include an **su** to the Db2 instance user and a subsequent **exit** to return to the root user.

## Procedure

Complete the following steps as a root user to clone the WAREHOUS, SCR32, and DATAMART databases before the upgrade and to back up these databases separately.

1. Download the Cloud APM server installation image. Extract the server installation files for your offering. Complete steps [“1” on page 1323](#) to [“4” on page 1323](#) in [“Upgrading the server side-by-side” on page 1321](#).
2. Copy the backup.sh, rename.sh, and restore.sh scripts from the tools directory and the setup-dbconfig-linux\_64.bin script from the packages/SCR directory on the V8.1.4 Cloud APM server installation image to the remote Db2 server system. You can connect to the existing Db2 server that was configured for Cloud APM V8.1.3.
3. Run the backup.sh script on the remote Db2 server system. If you are using the default Cloud APM administrator user IDs and passwords, run the backup.sh without parameters.

For example:

```
[root]# /root/min/tools/backup.sh
Performing a backup...
Processing the "install" component...
Processing the "db2" component...Backup operation completed.
Creating the backup file...All tasks finished successfully.
Your backup is available in the following file:
/tmp/backups/backup_20160824_061708.tar
```

If you are using non-default user IDs and passwords, run the script with these parameters. For example,

```
[root]# /root/min/tools/backup.sh -u username -p password
-z external_db2_instance
```

where:

### **username**

The non-default Cloud APM administrator user ID.

**password**

The non-default Cloud APM administrator password

**external\_db2\_instance**

The remote Db2 server instance user name.

The script outputs the name of the backup file.

4. Run the script `setup_dbconfig-linux_64.bin` on the remote Db2 server system to set up the V8.1.4 SCR database. Run the script as the same Db2 instance user `db2apm` who ran the script during the creation of the V8.1.3. SCR database. Do not run the script as user root.

```
su - db2apm
/path/setup-dbconfig-linux_64.bin -i console
exit
```

Follow the console prompts:

- a. When you are prompted to choose a locale, enter 2 to select English.
- b. Enter 1 to accept the license agreement.
- c. Enter the absolute path to the installation folder or press Enter to accept the default path. The default path is the `setup-dbconfig` installation path for V8.1.3. Do not change this path, unless the path is incorrect. In this procedure, the path is referred to as `/opt/ibm/db2/tbsmdb`.

The Cloud APM SCR database configuration tools installed by the `setup_dbconfig-platform_64.bin` script should not be installed into the same directory as the Tivoli Business Service Manager database configuration tools if the databases for both products reside on the same remote Db2 server.

- d. Enter 1 to select IBM Cloud Application Performance Management (APM) as the product that uses the database.
- e. Enter 1 to select Simple as the type of installation to run.
- f. Enter 2 to instruct the installer not to create the database schema, including the tables, table spaces, and views.
- g. Enter the following database configuration details when you are prompted:

```
Database Name (maximum 8 characters) (DEFAULT: SCR32): S1
Database host name or IP address (DEFAULT): host_name_or_IP_address
Database Port (DEFAULT: 50000): port
Database Path (DEFAULT): default_path
```

where:

**port**

The port number that was specified when the SCR database was created. If you don't know the value, see the port number that is specified for the `db2c_db2apm` service in the `/etc/services` file.

**default\_path**

The file system where the database was created. The default path is the home directory of the `db2apm` user. If a different file system was specified when the database was created, that file system should be specified instead.

- h. Enter 2 to specify not to encrypt the database.
5. As user root, run the `restore.sh` script on the remote Db2 server system to restore the backup that you created in step “3” on page 1334. This backup file is restored with the new V8.1.4 database names W1, S1, and D1.  
Run the `restore.sh` with the following options and values:

```
[root]# min/tools/restore.sh -f backup_file
-j metric_db_name -k scr_db_name -l
datamart_db_name -z external_db2_instance
```

For example:

```
[root]# min/tools/restore.sh -f /tmp/backups/backup_20150824_061708.tar
-j W1 -k S1 -l D1 -z db2apm
Restoring the data...Processing the "db2" component...
Restore operation completed.
All tasks finished successfully.
```

where:

**backup\_file**

The backup file name that you created in step “3” on page 1334.

**metric\_db\_name**

The optional new name for the metric database.

**scr\_db\_name**

The optional new name for the topology database.

**datamart\_db\_name**

The optional new name for the DATAMART database.

**external\_db2\_instance**

The remote Db2 server instance user name.

- Upgrade the database schema and Java UDF routines in the restored Db2 SCR database.

Enter:

```
cd install_path/tbsmdb/tools/XMLtoolkit/bin
./scr_restore.sh -U db2apm -P passwd -n
```

where *install\_path* is the path that you entered when you set up setup-dbconfig.

If you do not want the password visible on the command line, you can omit the -P flag and the script prompts for the password. For example:

```
./scr_restore.sh -n
Enter the database password:
```

- Enter the following command as the db2apm user for each database to adjust the buffer pool and transaction log after you determine the size of your environment.

```
su - db2apm
db2 connect to W1
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size
W1_PAGE_COUNT
db2 disconnect W1
db2 connect to D1
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size D1_PAGE_COUNT
db2 disconnect to D1
db2 connect to S1
db2 UPDATE DATABASE CONFIGURATION FOR S1 USING LOGSECOND 25
db2 alter bufferpool IBMDEFAULTBP IMMEDIATE size 5000
db2 alter bufferpool TBSMCFG16KBP IMMEDIATE size 1000
db2 alter bufferpool TBSM4KBP IMMEDIATE size 1000
db2 alter bufferpool TBSM32KBP IMMEDIATE size 1000
db2 alter bufferpool TBSMSCR16KBP IMMEDIATE size
S1_PAGE_COUNT
db2 disconnect to S1
exit
```

where:

**W1\_PAGE\_COUNT**

The buffer pool page count (8 K page sizes): 50000 for small; 100000 for medium; or 200000 for large.

**D1\_PAGE\_COUNT**

The buffer pool page count (8 K page sizes): 100000 for small; 200000 for medium; or 300000 for large.

## **S1\_PAGE\_COUNT**

The buffer pool page count (16 K page sizes): 30000 for small; 50000 for medium; 100000 for large.

Estimate the size of your environment (small, medium, or large) from the server requirements table in “Cloud APM server hardware requirements” on page 111.

8. Install the IBM Data Server Client on the virtual machine or computer system that you are using for the upgrade to Cloud APM server V8.1.4 by completing [step 3](#) in “Connecting to a remote Db2 server” on page 146.
9. Install the 8.1.4 version of the Cloud APM server. Complete steps [5](#) to [13](#) in “Upgrading the server side-by-side” on page 1321.

Use the information in steps [10](#) and [11](#) in this procedure to guide your responses.

10. After the installation script detects that the backup of the V8.1.3 Cloud APM server information is configured with an existing remote Db2 server, respond to the prompts to provide or accept default values for the following configuration parameters to establish a connection with the remote Db2 database:
  - a. hostname/IP address to the DB host or accept the default [localhost]:
  - b. port number of the DB2 instance or accept the default [50000]:
  - c. password for the user "itmuser":
  - d. remote DB2 instance name or accept the default [db2apm]:
  - e. password for the instance user "db2apm":
11. When you are prompted to enter the names of the new V8.1.4 databases (W1, S1, and D1) that you created when you specified the **restore.sh** command previously, accept the default values or enter the new values depending on your requirements.

If you plan to use the V8.1.3 server, enter the names of the new databases (W1, S1, and D1) that you created when you ran the **restore.sh** command in step 5. Otherwise, if you accept the default values, you corrupt the databases that continue to be used by V8.1.3 of the Cloud APM server.

**Important:** If you are entering the new database names, these names must match the names that are used with the **restore.sh** script in [step 5](#) on the remote Db2 server:

```
name of Metric database or accept the default [WAREHOUS]: W1
name of Topology database or accept the default [SCR32]: S1
name of Metric database or accept the default [DATAMART]: D1
```

The V8.1.4 Cloud APM server installation continues.

If the installer detects any agent configuration packages in *install\_dir/ccm/depot* from a previous installation of the Cloud APM server, it warns you that it renamed the old packages and created new agent packages. The old packages are named *install\_dir/ccm/depot.old*.

If the installer detects a *keyfiles* directory in *install\_dir* from a previous installation of the Cloud APM server, it warns you that it renamed the old *keyfiles* directory and created a new directory. The old *keyfiles* directory is named *install\_dir/keyfiles.old*.

A prerequisite scan of your environment starts and takes a few moments to complete. When the installation finishes, V8.1.4 of the Cloud APM server is configured with the existing remote Db2 server, which is the same instance as V8.1.3 but it is using different databases. It is using the databases that were created in [step 5](#).

12. If you are not continuing to use the V8.1.3 Cloud APM server, you can use the V8.1.3 default database names with your V8.1.4 system by completing the following steps:
  - a) When the V8.1.4 installation is complete, shut down the V8.1.3 and V8.1.4 Cloud APM server systems by entering the following command from any directory on both systems:

```
apm stop_all
```

- b) On the remote Db2 server system, run the `rename.sh` script. Include the database names that you created in [step 5](#) as arguments.

For example, the following command renames the V8.1.4 databases from W1 to WAREHOUSE, S1 to SCR32, and D1 to DATAMART:

```
./rename.sh W1 S1 D1
```

- c) On the V8.1.4 Cloud APM server system, start the kafka and server1 components by entering the following commands:

```
apm start kafka
apm start server1
```

- d) On the V8.1.4 upgraded system, enter the following command:

```
install_dir/ccm/db_common.sh restore_original_db_names
```

where *install\_dir* is the Cloud APM server installation directory.

The V8.1.4 Cloud APM server is reconfigured to use the original databases: WAREHOUSE, SCR32, and DATAMART.

13. Shut down the V8.1.3 Cloud APM server system if it is running by entering the following command from any directory:

```
shutdown -P now
```

14. Reassign the V8.1.3 Cloud APM server IP address or both the IP address and host name to the V8.1.4 server. Whether you reassign the IP address only or both the IP address and host name depends on your configuration.

- If you use the Cloud APM server IP address to connect your agents to your server, complete the steps in [Reassigning the server IP address to another server](#).
- If you use the Cloud APM server host name to connect your agents to your server, complete the steps in [Reassigning the server IP address and host name to another server](#).

15. Migrate your Hybrid Gateway configuration:

- To migrate the Hybrid Gateway immediately after a restore, run these commands on the Cloud APM server as the root user:

- a. Copy the restored `config.properties` file to the `ccm` directory:

```
cp install_dir/ccm/properties/config.properties.restored install_dir/ccm/properties/
config.properties
```

- b. Update the date and time of the `config.properties` file so that any Hybrid Gateways already running will reload their configuration:

```
touch config.properties
```

- c. Copy the updated `config.properties` file to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/
dropins/
CentralConfigurationServer.war/common/config.properties
```

- If any configurations were done on the upgraded system after the restore, complete these steps:
  - a. Copy these two lines from the `install_dir/ccm/properties/config.properties.restored` file:

```
com.ibm.tivoli.ccm.encrypted\key=
com.ibm.tivoli.ccm.gaian.connect\gaianReq=
```

- b. Replace the same lines in *install\_dir*/ccm/properties/config.properties with the lines that you just copied.
- c. Copy config.properties to the Central Configuration Services component:

```
cp install_dir/ccm/properties/config.properties install_dir/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/common/config.properties
```

To verify that the config.properties file in *install\_dir*/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/common/ was replaced, check that the modified date and time are current.

## Results

The Cloud APM server upgrade to V8.1.4 is complete and connected to the existing remote Db2 server that you were using with V8.1.3.

## What to do next

- If you are using the default out of the box certificates for accessing the Cloud APM console, you must complete the steps in this technote [V8.1.4 Application Performance Management UI certificates are expiring in upgraded environments](#) to update the default certificates to prevent them from expiring in April 2019.
- Before you use the Cloud APM console that you upgraded, clear your web browser cache and restart your browser. Clearing the cache avoids display issues that new capabilities in this update introduced to some of the user interfaces.
- If you want to use the old agent configuration packages from a previous installation for agent installations, complete these steps:
  1. Go to the *install\_dir*/ccm directory.
  2. Delete the agentconfig file.
  3. Change the name of the agentconfig.old file to agentconfig.
- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server, you must change clientAuthentication to true. Copy the <ssl> xml element that contains the enabledCiphers attribute from the *install\_dir*/wlp/usr/servers/min/server.xml file to the *install\_dir*/wlp/usr/servers/min/user-exit.xml file if it does not already exist in the user-exit.xml file. Then add this clientAuthentication="true" line after the enabledCiphers line in the user-exit.xml file. Remove the <ssl> xml element from the server.xml file. The following code example shows you where to add the clientAuthentication="true" line in the user-exit.xml.

```
<ssl
id="defaultSSLConfig"
sslProtocol="TLSv1.2"
enabledCiphers="TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256"
clientAuthentication="true"
serverKeyAlias="server_key"
clientKeyAlias="IBM_Tivoli_Monitoring_Certificate"
keyStoreRef="defaultKeyStore"/>
```

- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and used the default certificates, change the communication protocol that the Cloud APM server agents use to HTTPS. For instructions, see [Configuring the communications protocol for server agents](#).
- If you configured HTTPS communication between the Cloud APM server and agents in your V8.1.3 Cloud APM server and did not use the default certificates, complete these steps:

1. Encode the (xor) server keystore password that you used when you created certificates for the V8.1.3 Cloud APM server:

```
/opt/ibm/wlp/bin/securityUtility encode
```

2. Copy the <keyStore> xml element from the *install\_dir*/ibm/wlp/usr/servers/min/server.xml to the *install\_dir*/wlp/usr/servers/min/user-exit.xml file if it does not already exist in the user-exit.xml file. Then in the user-exit.xml file, replace the value of the password attribute with the newly encoded password from the step “1” on page 1340. Remove the <keyStore> xml element from the server.xml file.
  3. Go to the *install\_dir* directory.
  4. Delete the keyfiles directory.
  5. Change the name of the keyfiles.old directory to keyfiles.
  6. Update the certificates that are used by the monitoring agents to connect to the Cloud APM server to use the new keystore. For instructions, see “Configuring certificates between the server and agents for HTTPS communication” on page 244.
  7. Update the communication protocol and certificates that are used by the Cloud APM server agents. For instructions, see [Configuring the communications protocol for server agents](#).
- If the system where you installed the Cloud APM server is using LDAP to authenticate the root user or Db2 users, and you updated the passwords for the itmuser and the Db2 instances users when following the procedure referenced in step 9.a, then complete step “9” on page 158 in the *Installing on a system using an external directory service* topic.
  - Review the WAREHOUS database settings that were applied by the restore process.

```
update database config for warehouse using DFT_DEGREE any
update database config for warehouse using LOGBUFSZ 1024
update database config for warehouse using LOCKLIST AUTOMATIC
update database config for warehouse using SORTHEAP AUTOMATIC
update database config for warehouse using SHEAPTHRES_SHR AUTOMATIC
update database config for warehouse using NUM_IOCLEANERS AUTOMATIC
update database config for warehouse using NUM_IOSERVERS AUTOMATIC
update database config for warehouse using LOGFILSIZ 4096
update database config for warehouse using LOGPRIMARY 10
update database config for warehouse using DBHEAP AUTOMATIC
update database config for warehouse using LOGSECOND 40
update database config for warehouse using AVG_APPLS AUTOMATIC
update database config for warehouse using logarchmeth1 OFF
update database config for warehouse using logarchmeth2 OFF
update database config for warehouse using DATABASE_MEMORY 250000 AUTOMATIC
```

Cloud APM does not support pruning of database logs, as a result, the logarchmeth1 and logarchmeth2 settings are set to OFF. If you back up your Warehouse database and you support log pruning in your environment, modify these settings.

- Most V8.1.3 Cloud APM agents are compatible with the V8.1.4 Cloud APM server. However, you must upgrade the following agents after you upgrade the Cloud APM server to version 8.1.4.0:
  - If you are using the Synthetic Playback agent, you must upgrade the agent by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#). Then, you must apply the latest Cloud APM 8.1.4.0 server interim fix that is available from Fix Central.
  - The Monitoring Agent for WebSphere Applications must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).
  - The Monitoring Agent for MongoDB must be upgraded by using the latest agent package on Passport Advantage. To view the Passport Advantage part numbers for the agent packages, see: [Part numbers](#).

## Upgrading your agents

Periodically, new archive files that contain upgraded monitoring agents are available for download. Archive files are available from [IBM Passport Advantage](#).

## Before you begin

For the following agents, an agent-specific task must be completed before you complete the upgrade procedure:

- For the agents on AIX, if you are running as a non-root user, you must clear one of the libraries from memory before you start the installation procedure to upgrade the agent. Follow the instructions in [“Agents on AIX: Stopping the agent and running slibclean before you upgrade”](#) on page 1344.
- For the HMC Base agent on AIX, if you are upgrading the agent as a non-root user, you must first stop the HMC Base agent and clear dependent libraries from cache. Follow the instructions in [“HMC Base agent on AIX: Stopping the agent as a non-root user and running slibclean before you upgrade”](#) on page 1344.
- For the Microsoft .NET agent, you must remove the data collector from your .NET applications before you upgrade the agent. Follow the instructions in [“Microsoft .NET agent: Removing the .NET data collector before you upgrade”](#) on page 1347.
- For the Node.js agent, you must remove the data collector plug-ins from your Node.js applications before you upgrade the agent. Follow the instructions in [“Node.js agent: Removing the data collector plug-ins before you upgrade”](#) on page 1345.
- For the Ruby agent, you must remove the data collector from your Ruby applications before you upgrade the agent. Follow the instructions in [“Ruby agent: Removing the data collector plug-ins before you upgrade”](#) on page 1348.
- For the HTTP Server agent, you must stop the HTTP server before you upgrade the agent.
- For the WebSphere MQ agent, if you enabled transaction tracking for the agent in the previous release, you must stop the agent instance before you upgrade the agent.
- For the SAP NetWeaver Java Stack agent, if you are upgrading from V8.1.3.2 to V8.1.4 then stop all the SAP NetWeaver Java Stack instances that are configured with the data collector before you upgrade the agent.
- For the Skype for Business Server agent, if you are upgrading from the older version to V8.1.4.0.2 then at the agent side, the agent name changes to Skype for Business Server. Also, after the support upgrade through SDA, you need to restart the APMUI service to reflect the new agent name (Skype for Business Server) at the MIN Server side or else you will see the old agent name (MS Lync Server) on the MIN Server dashboard.
- For Tomcat agent, if you want to upgrade TEMA core framework on Windows, you must stop both agent and server. Follow the instructions in [Tomcat agent: Upgrading the TEMA Core Framework on Windows](#)

## About this task

If a new version of the agent is available, running the installation script automatically upgrades the agent. If the agent does not have a newer version available, a message is displayed explaining that the agent is already installed; your installed agent is not affected.

To install an upgraded agent, use the following procedures:

## Procedure

- [“Installing agents on UNIX systems”](#) on page 185
- [“Installing agents on Linux systems”](#) on page 191
- [“Installing agents on Windows systems”](#) on page 201

## Results

The agent is upgraded to the latest version. If a newer version of the monitoring agent is not available, a message is displayed explaining that the agent is already installed; your installed agent is not affected.

## What to do next

After an upgrade of a Windows agent, you must restart any agent that is not both automatically configured and started by the Windows Installer. Run the following command to check the agent status:

```
./name-agent.bat status
```

Use one of the following methods to start the agent:

- Click **Start > All Programs > IBM Monitoring agents > IBM Performance Management**. Right-click on an agent and click **Start**.
- Run the following command:

```
./name-agent.bat start
```

For information about the monitoring agent commands, including the name to use, how to check agent status, and more, see [“Using agent commands”](#) on page 236. For information about which agents are started automatically and manually, see [Chapter 6, “Agent and data collector deployment,”](#) on page 173

- For the Hadoop agent, complete the following steps after you upgrade from the socket - based agent (8.1.2, Fix Pack 2, or earlier) to the REST API - based agent (8.1.3, or later):
  1. To prevent generation of unnecessary logs, remove the 17-line code from the `hadoop-metrics2.properties` files of all Hadoop nodes.
  2. Stop the Hadoop services.
  3. Delete the `Plugin.jar` file that was copied from the agent installer from all nodes in the Hadoop cluster.
  4. Start the Hadoop services.

For information about the 17-line code and the `Plugin.jar` file, see [Configuring Hadoop nodes](#).

- For the HMC Base agent, after you upgrade the agent from version 6.2.2.6 to 6.2.2.7, you must configure the agent again and restart the agent. For instructions, see [“Configuring HMC Base monitoring”](#) on page 338.
- For the HTTP Server agent, if you upgrade the agent from a version that is earlier than 1.0.0.4 to 1.0.0.4 or later, you must also update the `.conf` file, which is used by the HTTP Server, to replace the previous data collector configuration file with the newly generated file. You must also add the new agent instance to the console. For instructions, see [“Configuring HTTP Server monitoring”](#) on page 344.
- For the Microsoft .NET agent, after you upgrade the agent, configure the data collector. For instructions, see [“Registering the data collector”](#) on page 618.

If you installed the agent into a new directory, you must change the Profiler service bin path by using the service controller (sc) command. For example,

```
sc \\localhost config DotNetProfilerService binPath=
"${install_dir}\qe\bin\DotNetProfilerService.exe
```

where `install_dir` is the new installation directory.

- For the Node.js agent, after you upgrade the agent, configure the agent data collectors. For instructions, see [“Configuring the Node.js agent”](#) on page 684.
- For the OpenStack agent, to further configure the agent to use OpenStack identity API v3, reconfigure all agent instances and update the agent data collector configuration file. For instructions, see [“OpenStack agent: Reconfiguring agent instances to use OpenStack identity API v3”](#) on page 1347.
- For the Ruby agent, after you upgrade the agent, configure the data collector. For instructions, see [“Configuring the diagnostics data collector”](#) on page 813.
- For the WebSphere Applications agent, after you upgrade the agent, migrate the data collector by running the command `dc_home/bin/migrate.sh/bat` from the installation directory of the new version of the agent and restart the application server instance. For instructions, see [“WebSphere Applications agent: Migrating the data collector”](#) on page 1349.

- **Linux** If you want to upgrade an older version of the agent that is installed in the `/opt/ibm/ccm/agent` directory you must complete these steps on the Linux system:
  1. If you confirm that you want to migrate the agent configuration from the old installation directory `/opt/ibm/ccm/agent` to the new installation directory, for example, `/opt/ibm/apm/agent`, you must start the agent in the new installation location.
 

**Restriction:** The older version of the agent is stopped automatically in the old installation location but it is not started automatically in the new installation location.
  2. After you verify that the agent works in the new installation directory, you must uninstall the older version of the agent from the `/opt/ibm/ccm/agent` directory. If you want to remove all agents, run the `/opt/ibm/ccm/agent/bin/smai-agent.sh uninstall_all` command.

## Preserving agent configuration changes

Advanced users can apply override values to component customization. Applying override values ensures that values are retained during an upgrade. Test the changes in your environment first before you apply them globally.

### About this task

- These instructions are for Linux and AIX agents. For a list of the agent product codes and the commands for stopping and starting the agents, see [“Using agent commands”](#) on page 236.
- The Windows agent process preserves configuration changes by design: Updated variables in the `kpccma.ini` file, where `pc` is the product code, are kept in the Override Local Settings section. These variables are used during each configuration to update the Windows registry entries that the agents use at run time.
- The customized settings in the `.pc.environment` file and `global.environment` file are lost after agent upgrade. To preserve your settings, make customization changes in the `pc.environment` and `global.environment` files. The settings in these files are not overwritten by agent upgrade.

### Procedure

Take the following steps to save the configuration changes that were made to the environment file and preserve them after agent upgrade:

1. Create or update any of the following files as needed, where `install_dir` is the agent installation directory (such as the Linux default `/opt/ibm/apm/agent` or AIX default `/opt/ibm/ccm/agent`):

| File name   | Description  |
|---|--|
| <code>install_dir/config/<br/>pc.environment</code>     | The <code>pc</code> in the file name is the agent product code, such as <code>mq</code> or <code>tz</code> . |
| <code>install_dir/config/<br/>global.environment</code> | Update the global environment file for changes that you want to affect all agent types.                      |

For example, `as.environment` is the persistent WebSphere Applications agent environment file. The `.as.environment` is overwritten when the agent is upgraded to a new version.

Define variables in the `key=value` format where `key` is the environment variable name and `value` is the value or setting (such as `KDC_FAMILIES=${KDC_FAMILIES}HTTP:10001`).

2. After you are finished updating the variable settings, save and close the environment file and restart the affected agents.

### Results

The updates are applied to all agents of the same type or, if you updated the global environment file, to all agents that report to the Cloud APM server. The changes are persisted with agent version upgrades.

## Agents on AIX: Stopping the agent and running **slibclean** before you upgrade

If you are upgrading an agent as a non-root user on AIX systems, you must complete this task. Before you run the agent installer, you must stop the agent and run **slibclean** to clear the `libkududp.a` library.

### Procedure

1. Stop the agent by running one of the following commands, depending on whether the agent supports multiple instances:

- `./name-agent.sh stop`
- `./name-agent.sh stop instance_name`

See [“Using agent commands”](#) on page 236.

2. Run the following command with root user privileges.

```
slibclean
```

See [slibclean Command](#) in the IBM Knowledge Center.

### Results

The agent is stopped and the `libkududp.a` library is cleared.

### What to do next

Run the agent installer to upgrade the agent to the release that you have downloaded. See Chapter 7, [“Installing your agents,”](#) on page 181. If the upgrade fails, reboot the server and repeat the procedure.

## HMC Base agent on AIX: Stopping the agent as a non-root user and running **slibclean** before you upgrade

Before you upgrade the HMC Base agent as a non-root user on AIX, you must stop the HMC Base agent and run **slibclean** to clear dependent libraries from cache.

### About this task

### Procedure

1. Run the following command as the non-root user to stop the agent.

```
hmc_base-agent.sh stop
```

2. Run the following command with root user privileges.

```
slibclean
```

See [slibclean Command](#) in the IBM Knowledge Center.

### Results

The HMC Base agent is stopped and the dependent libraries are cleared.

### What to do next

Run the agent installer to upgrade the HMC Base agent.

# Node.js agent: Removing the data collector plug-ins before you upgrade

Before you upgrade the Node.js agent, you must remove the monitoring plug-ins from your Node.js application.

## About this task

Based on your Node.js agent version, you need to complete different procedure to remove the monitoring plug-ins from your Node.js application. To find out the agent version, see [Agent Version Command](#).

## Procedure

1. Remove data collector plug-ins from the beginning of the Node.js application file.

- If you upgrade the Node.js agent from V01.00.12.00 to V01.00.13.00, complete the following procedure:
  - If you enabled resource data collection, remove the following line from the beginning of the Node.js application file:

```
require('KNJ_NPM_LIB_LOCATION/node_modules/ibm-apm/knj_index.js');
```

where *KNJ\_NPM\_LIB\_LOCATION* is the directory to the *lib* folder of your npm package global installation directory. The default directory is */usr/local/lib*.

- If you enabled resource data collection and deep-dive diagnostics data collection, remove the following line from the beginning of the Node.js application file:

```
require('KNJ_NPM_LIB_LOCATION/node_modules/ibm-apm/knj_deepdive.js');
```

- If you enabled resource data collection, deep-dive diagnostics data collection, and method traces collection, remove the following line from the beginning of the Node.js application file:

```
require('KNJ_NPM_LIB_LOCATION/node_modules/ibm-apm/knj_methodtrace.js');
```

- If you upgrade the Node.js agent from V01.00.10.00 to V01.00.13.00, complete the following procedure:
  - If you enabled resource data collection, remove the following line from the beginning of the Node.js application file.

```
require('install_dir/1x8266/nj/bin/plugin/knj_index.js');
```

, where *install\_dir* is the installation directory of Node.js agent.

- If you enabled resource data collection and deep-dive diagnostics data collection, remove the following line from the beginning of the Node.js application file.

```
require('install_dir/1x8266/nj/bin/plugin/knj_deepdive.js');
```

- If you enabled resource data collection, deep-dive diagnostics data collection, and method traces collection, remove the following line from the beginning of the Node.js application file.

```
require('install_dir/1x8266/nj/bin/plugin/knj_methodtrace.js');
```

2. Restart your Node.js application to disable the data collector plug-ins.

- If the version of your current Node.js agent is V01.00.10.00, till now the data collector plug-ins are successfully removed.
- If the version of your current Node.js agent is V01.00.12.00, continue to the following step.

3. Run the `./uninstall.sh` command from the *install\_dir/1x8266/nj/bin* directory to remove your previous agent settings.

## What to do next

Upgrade the Node.js agent. See [“Upgrading your agents”](#) on page 1340.

## Response Time Monitoring agent: upgrading IBM HTTP Server Response Time module

If you were previously monitoring IBM HTTP Server using IBM HTTP Server Response Time module or HTTP Server agent, upgrade your installation.

### About this task

The following table shows some installation scenarios that might be similar to the way you are monitoring IBM HTTP Server.

| Response Time Monitoring agent                                    | Using IBM HTTP Server Response Time module? | Using Packet Analyzer? | HTTP Server agent installed? |
|---|---|------------------------|------------------------------|
| AIX and xLinux: 08.11.00 and later<br>Windows: 08.14.02 and later | ✓   | —                      | ✓                            |
| AIX and xLinux: 08.10.00  | ✓   | —                      | —                            |
| AIX and xLinux: 08.10.00  | ✓   | —                      | ✓                            |
| 7.40.07 or earlier  | —   | ✓                      | —                            |
| 7.40.07 or earlier  | —   | ✓                      | ✓                            |

For all of these scenarios, the installation process is similar.

### Procedure

1. Install the HTTP Server agent from release V8.1.1 or later on AIX or Linux; from release V8.1.4.02 or later on Windows.

The IBM HTTP Server Response Time module is automatically installed with the agent.

2. Configure the HTTP Server agent.

**Note:** If you were previously using IBM HTTP Server Response Time module, update the web server configuration file (`httpd.conf`) with the location of the new IBM HTTP Server Response Time module and remove the old load module configuration file (`mod_wrt.so`).

**Note:** Response Time Monitoring agent V8.1.1 and later does not work with the load module file (`mod_wrt.so`) from previous releases. If you attempt to use an old version of this file, error log messages are created. Transactions might still be tracked, but transaction instance data will not be displayed.

For more information, see the HTTP Server agent reference PDF, which you can download from <http://ibm.biz/agent-httpserver>.

3. Ensure that the IBM HTTP Server and HTTP Server agent are running. If the Response Time Monitoring installer detects the HTTP Server agent, the Response Time Monitoring agent enables the IBM HTTP Server Response Time module rather than the Packet Analyzer.
4. Install the Response Time Monitoring agent to the same location `AGENT_HOME` as the HTTP Server agent.

- **Linux** **UNIX** Install V8.1.1 or later as **root**. AGENT\_HOME example /opt/ibm/apm/agent/
  - **Windows** Install V8.1.4.0.2 or later with administrator permissions. AGENT\_HOME example C:\IBM\APM\.
5. If you used the Packet Analyzer in earlier releases, you might need to disable the Packet Analyzer to start monitoring IBM HTTP Server with IBM HTTP Server Response Time module.
  6. Restart IBM HTTP Server.

## Microsoft .NET agent: Removing the .NET data collector before you upgrade

Before you upgrade the Microsoft .NET agent, you must remove the .NET data collector from your .NET applications.

### Procedure

1. Unregister all modules of the data collector.

As an administrator, enter:

```
cd install_dir\qe\bin configdc unregisterdc all
```

Where *install\_dir* is the installation directory of the Microsoft .NET agent.

2. Restart the .NET applications.

### What to do next

Upgrade the Microsoft .NET agent. See [“Upgrading your agents” on page 1340](#).

## OpenStack agent: Reconfiguring agent instances to use OpenStack identity API v3

To upgrade the OpenStack agent to use OpenStack identity API v3, after you install the latest version of the agent, you must reconfigure all agent instances and update the data collector configuration file.

### About this task

This task is mandatory only when you upgrade the agent to use OpenStack identity API v3.

### Procedure

1. Reconfigure all existing agent instances. For detailed instructions, see [“Configuring the OpenStack agent” on page 706](#).
2. Find the *ksg\_dc\_instance\_name.cfg* agent data collector configuration file, where *instance\_name* is the name you specified for your agent instance.

If the file does not exist, copy *install\_dir/1x8266/sg/bin/ksg\_dc.cfg* to the *install\_dir/config* directory and change the file name to *ksg\_dc\_instance\_name.cfg*.

For example, if the instance name is OS1, change the name to *ksg\_dc\_OS1.cfg*.

3. Add the following section to the *ksg\_dc\_instance\_name.cfg* file:

```
#OpenStack authentication information
[OS_authentication_info]
OS_project_domain_name=Default
OS_user_domain_name=Default
OS_cert_path=
```

4. Restart the agent instance by running the following commands:

```
install_dir/bin/openstack-agent.sh stop instance_name
install_dir/bin/openstack-agent.sh start instance_name
```

where *instance\_name* is the name of the agent instance to be configured.

## Ruby agent: Removing the data collector plug-ins before you upgrade

Before you upgrade the Ruby agent, you must remove the monitoring plug-ins from your Ruby application.

### Procedure

1. Remove the old version data collector by running the following command.

```
gem uninstall stacktracer
```

2. Navigate to the home directory of your application, open its Gemfile, and remove the following line:  
`gem 'stacktracer', 'version'`  
Where *version* is the version number of the Ruby agent.
3. In the home directory of your application, enter: `bundle install`

### What to do next

Upgrade the Ruby agent. See [“Upgrading your agents”](#) on page 1340.

## SAP agent upgrade on Windows platforms: Creating backup of configuration file

### Before you begin

Create a backup of the configuration file before you upgrade the SAP agent on Windows platform.

### About this task

This task helps to create backup of the agent configuration file before you upgrade SAP agent on Windows platform.

### Procedure

Perform the following steps to save the configuration changes that are made to the environment file (KSAENV):

1. Create a backup copy of the KSAENV file containing the modified changes and store it locally in another folder. KSAENV file can be found in `<install_dir>\tmaitm6_x64` directory, where *<install\_dir>* is the agent installation directory such as `C:\IBM\APM` on Windows OS.
2. Perform the agent upgrade.
3. The KSAENV file is overwritten when the agent is upgraded to a new version, however the instance specific file, `KSAENV_XXX` remains intact after upgrade, where *XXX* is the instance name.
4. Set the required SAP Agent configuration parameters in the new KSAENV file by referring to the backup copy of KSAENV before agent upgrade. Then save and close the file.
5. For all existing agent instances, re-configure the agent instances and restart the agent instances to reflect the change.
6. If new agent instances are configured, start the agent instances.

### Results

The updates in the KSAENV file are applied to all agent instances after the agent upgrade.

# SAP agent upgrade on non-Windows platforms: Creating backup of configuration file

## Before you begin

Create a backup of the configuration file before you upgrade the SAP agent on non-Windows platform.

## About this task

This task helps to create backup of the agent configuration file before you upgrade SAP agent on non-Windows platform.

## Procedure

Perform the following steps to save the configuration changes made to the environment file `.sa.environment` and preserve them after agent upgrade:

1. Create a backup copy of the `.sa.environment` file containing the modified changes and store it locally in another folder. The `.sa.environment` file can be found in `<install_dir>/config` directory, where `<install_dir>` is the agent installation directory such as `/opt/IBM/APM` on Non-Windows OS.
2. Perform the agent upgrade.
3. The `.sa.environment` file is overwritten after the agent is upgraded to a new version, however the instance specific `sa_XXX.environment` file remains intact after the upgrade, where XXX is the instance name .
4. Update the SAP agent configuration parameters in the new `.sa.environment` file by referring the backup copy of `.sa.environment` before the agent upgrade. Then save and close the file.
5. For all existing agent instances, re-configure the agent instances and restart the agent instances to reflect the change.
6. If new agent instances are configured, start the agent instances.

## Results

The updates in the `.sa.environment` file are applied to all agent instances after the agent upgrade.

## WebSphere Applications agent: Migrating the data collector

After you update the agent, you must migrate the data collector either interactively or in silent mode.

### Migrating the data collector interactively

You can migrate an earlier maintenance level of the data collector interactively using the migration utility.

## Before you begin

**Linux** **UNIX** If you installed the WebSphere Application Server or WebSphere Portal Server using a non-root user account, before you run the configuration utilities, verify that the non-root user has read and write privileges to the following agent directories in `install_dir/yndchome/7.3.0.14.08` where `install_dir` is the installation directory of the WebSphere Applications agent:

- `data`
- `bin`
- `runtime`
- `logs`

Provide read and write permissions using the `chmod 777` command, if required. Also, log in as the user that was used to install the application server.

## About this task

You can migrate an earlier maintenance level of the data collector interactively using the migration utility. If you want to migrate many application server instances, it might be more convenient to use the migration utility in silent mode.

### Important:

- You can only migrate previous maintenance levels of 7.3 version of a data collector. The version of the data collector is indicated in the data collector home directory path.
- You cannot migrate from the data collector version 7.3 to 7.3 fix pack 1. Instead, unconfigure the data collector and uninstall the agent version 7.3. Then install the agent version 7.3 fix pack 1 and configure the data collector again.

## Procedure

1. **Linux** **UNIX** Log in as the user that was used to install the application server.
2. Start the migration utility from the installation directory of the latest version of the agent.

**Linux** **UNIX** Run the command `dc_home/bin/migrate.sh`

**Windows** Run the command `dc_home\bin\migrate.bat`

3. The utility displays the IP addresses of all network cards that are found on the local computer system.  
Enter the number that corresponds to the IP address to use.
4. The utility discovers all servers configured by older maintenance levels of the data collector and lists them. The data collectors are grouped by maintenance level.  
Select one or more application server instances from the list.

The list might include both traditional WebSphere server instances and Liberty servers. Traditional WebSphere server instances might be under different profiles.

### Tip:

- If several instances under one profile are monitored, you must select them all for migrating at the same time.
- Migrate all servers under the liberty profile at the same time. Partially migrating configured servers might cause instability.

### Remember:

- For a stand-alone environment, application server instances must be running.
  - For a Network Deployment environment, the node agent and deployment manager must be running.
  - Liberty servers are not required to be running during the migration.
5. Enter the number that corresponds to the application server instance whose data collector is to be migrated or enter an asterisk (\*) to migrate the data collector of all application server instances.  
To specify a subset of servers, enter the numbers, separated by commas, that represents the servers. For example: 1, 2, 3.  
The migration utility automatically integrates each data collector with the monitoring agent. The monitoring agent host and port values are retrieved from the existing configuration files.
  6. Enter an alias for each of the selected servers.  
The default value is the existing server alias.
  7. For the Liberty server instance, enter the JVM home directory when prompted. For example, `/opt/IBM/java`.
  8. The utility determines whether WebSphere global security is enabled for each of the profiles where data collection is being migrated.

If WebSphere Global Security is enabled for one or more profiles, specify whether to retrieve security settings from a client properties file:

The data collector communicates with the WebSphere Administrative Services using the RMI or the SOAP protocol. If global security is enabled for a profile, you must specify the user ID and password of a user who is authorized to log in to the IBM WebSphere Application Server administrative console for the profile.

Alternatively, you can encrypt the user name and password and store them in the application server client properties files before configuring the data collector. You must use the `sas.client.props` file for an RMI connection, or the `soap.client.props` file for an SOA connection.

9. Enter 1 to allow the utility to retrieve the user name and password from the appropriate client properties file and skip to step “11” on page 1351. Otherwise, enter 2 to enter the user name and password.

**Important:** It may take some time to log in to the WebSphere Application Server administrative console.

10. Enter the user name and password for each profile whether WebSphere Global Security is enabled.
11. The utility migrates data collection for each selected application server instance. It displays a status message that indicates whether the migration of each server completed successfully.
12. Restart the instances as directed by the utility. The data collector configuration takes effect when the application server instances are restarted.

## Results

The data collector is migrated to the latest maintenance level installed.

## What to do next

The migration utility preserves the settings that were configured in the older version of the data collector. To modify these settings, you can run either the configuration or reconfiguration utility in interactive or silent mode from the `dc_home\bin` directory of the new data collector. For more information, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940 .

## Migrating the data collector in silent mode

You can migrate an earlier maintenance level of the data collector using the migration utility in silent mode.

## Before you begin

**Linux** **UNIX** If you installed the WebSphere Application Server or WebSphere Portal Server using a non-root user account, before you run the configuration utilities, verify that the non-root user has read and write privileges to the following agent directories in `install_dir/yndchome/7.3.0.14.08` where `install_dir` is the installation directory of the WebSphere Applications agent:

- data
- bin
- runtime
- logs

Provide read and write permissions using the `chmod 777` command, if required. Also, log in as the user that was used to install the application server.

## About this task

A sample silent properties file, `sample_silent_migrate.txt`, is packaged with the migration utility. The file is available in the `install_dir/yndchome/7.3.0.14.08/bin` directory.

When you create your silent properties file, keep in mind these considerations:

- A line in the file that starts with a number sign (#) is treated as a comment, and is not processed. If the number sign is used elsewhere in the line, it is not considered to be the start of a comment. This means that you can use the number sign in passwords or for other uses.
- Each property is described on a separate line, in the following format: property = value.

**property**

This is the name of property. The list of valid properties that you can configure is shown in Table 290 on page 1352. Do not modify or remove properties in the sample file that are not listed in the table.

**value**

This is the value of the property. Default values for some properties are already provided. You can delete default values to leave property values blank, or empty. An empty value is treated as if the property is not specified, as opposed to using the default value. If you want to use default values, you can comment out the property in the file.

- Passwords are in plain text.
- Properties and their values are case-sensitive.

Table 290 on page 1352 describes the properties that are available when migrating the data collector in silent mode.

| Table 290. Available properties for running the migration utility in silent mode |  |
|--|--|
| Property   | Comment  |
| migrate.type   | Must be AD.  |
| default.hostip   | If the computer system uses multiple IP addresses, specify the IP address for the data collector to use.   |
| itcam.migrate.home   | Specifies the data collector home directory of the older maintenance version of the data collector. The directory is not deleted as part of the migration.   |
| was.wsadmin.connection.host  | Specifies the name of the host to which the wsadmin tool is connecting. In a Network Deployment environment, specify the wsadmin connection to the Deployment Manager. In a stand-alone environment, specify the wsadmin connection to the server. |
| was.wsadmin.username   | Specifies the user ID of a user who is authorized to log on to the IBM WebSphere Application Server administrative console. This user must have the agent role on the application server.  |
| was.wsadmin.password   | Specifies the password that corresponds to the user specified in the was.wsadmin.username property.  |
| was.appserver.profile.name   | Specifies the name of the application server profile you want to configure.<br><br><b>Remember:</b> The property is not required for a Liberty profile.  |
| was.appserver.home   | Specifies the WebSphere Application Server home directory.   |

Table 290. Available properties for running the migration utility in silent mode (continued)

| Property                  | Comment   |
|---------------------------|---|
| was.appserver.cell.name   | Specifies the WebSphere Application Server cell name.<br><b>Remember:</b> The property is not required for a Liberty profile.   |
| was.appserver.node.name   | Specifies the WebSphere Application Server node name.<br><b>Remember:</b> The property is not required for a Liberty profile.   |
| was.appserver.server.name | Specifies the application server instance within the application server profile to migrate to the new version of the data collector. The silent properties file can have multiple instances of this property. |

#### Important:

- You can only migrate previous maintenance levels of 7.3 version of a data collector. The version of the data collector is indicated in the data collector home directory path.
- You cannot migrate from the data collector version 7.3 to 7.3 fix pack 1. Instead, unconfigure the data collector and uninstall the agent version 7.3. Then install the agent version 7.3 fix pack 1 and configure the data collector again.

#### Procedure

1. Specify configuration options in the silent migration properties file.
2. Run the command to start the migration utility in silent mode from the installation directory of the latest version of the agent.
  - **Linux** **UNIX** `dc_home/bin/migrate.sh -silent sample_silent_migration_filename`
  - **Windows** `dc_home\bin\migrate.bat -silent sample_silent_migration_filename`

#### Results

The data collector is migrated to the latest maintenance level installed.

#### What to do next

The migration utility preserves the settings that were configured in the older version of the data collector. To modify these settings, you can run either the configuration or reconfiguration utility in interactive or silent mode from the `dc_home\bin` directory of the new data collector. For more information, see [“Configuring or reconfiguring the data collector with full configuration utilities”](#) on page 940.

## Tomcat agent: Upgrading the TEMA Core Framework on Windows

To upgrade TEMA core framework on windows for Tomcat agent, you must stop both the agent and server to upgrade the TEMA framework successfully.

#### Procedure

1. Prepare the Tomcat server setup.
2. Install and configure the Tomcat agent.

3. Log in to the IBM Cloud Application Performance Management dashboard, goto **Agent configuration** > **Tomcat**, select an instance of Tomcat agent, and click **Enable TT/DD**.
4. Restart the Tomcat Server.
5. To apply IBM APM CORE FRAMEWORK, stop both Tomcat Agent and Server.
6. Goto TEMA/<IBM APM CORE FRAMEWORK\_HOME>. Run the command **apmpatch.bat <Tomcat Agent InstallationDir>**.  
The framework is upgraded.
7. Check the upgraded IBM APM CORE FRAMEWORK version by executing the following instructions.  
Goto <TOMCAT\_Agent\_Install\_Dir>\InstallITM  
Run: KinCInfo.exe -i.
8. Start both Tomcat server and agent.

## Upgrading your data collectors

---

Periodically, new archive files that contain upgraded data collectors are available for download. Archive files are available from [IBM Passport Advantage](#).

### Before you begin

If you upgrade your Cloud APM server, you must also upgrade your data collectors.

### About this task

To upgrade a data collector, complete the following steps:

### Procedure

- Unconfigure the data collector from your local and/or IBM Cloud applications:
  - For the J2SE data collector, unconfiguration steps are not required.
  - For the Liberty data collector, follow the instructions in [“Unconfiguring the data collector for IBM Cloud applications”](#) on page 567 and/or [“Unconfiguring the data collector for on-premises applications”](#) on page 561.
  - For theNode.js data collector, follow the instructions in [“Unconfiguring the stand-alone Node.js data collector for IBM Cloud applications”](#) on page 695 and/or [“Unconfiguring the stand-alone Node.js data collector for on-premises applications”](#) on page 700.
  - For thePython data collector, follow the instructions in [“Unconfiguring the Python data collector for IBM Cloud applications”](#) on page 769 and/or [“Unconfiguring the Python data collector for on-premises applications”](#) on page 774.
  - For theRuby data collector, follow the instructions in [“Unconfiguring the Ruby data collector for IBM Cloud applications”](#) on page 820.
- Download the data collector package.
- Reconfigure the data collector to monitor your local and/or IBM Cloud applications:
  - For the Node.js data collector, after you upgrade the data collector, reconfigure the data collector. For instructions, see [“Configuring the stand-alone Node.js data collector for IBM Cloud\(formerly Bluemix\) applications”](#) on page 690 and/or [“Configuring the stand-alone Node.js data collector for on-premises applications”](#) on page 695.
  - For the Python data collector, after you upgrade the data collector, reconfigure the data collector. For instructions, see [“Configuring the Python data collector for IBM Cloud applications”](#) on page 765 and/or [“Configuring the Python data collector for on-premises applications”](#) on page 770.
  - For the Liberty data collector, after you upgrade the data collector, reconfigure the data collector. For instructions, see [“Configuring the Liberty data collector in IBM Cloud environment \(Liberty V18.\\* and older versions\)”](#) on page 562 and/or [“Configuring the Liberty data collector in on-premises environments \(Liberty V18.\\* and older versions\)”](#) on page 558.

- For the J2SE data collector, after you upgrade the data collector, reconfigure the data collector. For instructions, see [“Configuring J2SE monitoring”](#) on page 525.
- For the Ruby data collector, after you upgrade the data collector, reconfigure the data collector. For instructions, see [“Configuring the Ruby data collector for IBM Cloud applications”](#) on page 817.

## Results

The data collector is upgraded to the latest version.

---

## Chapter 13. Troubleshooting and support

Review the troubleshooting entries for problems that you might experience with installing, configuring, or using IBM Cloud Application Performance Management.

Troubleshooting content is available in this Knowledge Center. Previously, troubleshooting content was available in the Cloud Application Performance Management forum on IBM developerWorks. Going forward, the IBM developerWorks platform where this forum resides is not available. The troubleshooting content from the forum is now ported into this [IBM Cloud Application Performance Management Troubleshooting Guide](#).

For IBM Cloud Application Performance Management Hybrid Gateway troubleshooting, see [“Managing the Hybrid Gateway”](#) on page 1054.

---

### Troubleshooting agents

Troubleshoot IBM Cloud Application Performance Management agent installation and configuration issues.

We are migrating our troubleshooting content from the [Cloud Application Performance Management Forum](#) in developerWorks to this Knowledge Center. Previously, troubleshooting content was available in the [Cloud Application Performance Management Forum](#) on developerWorks. You can continue to search for older entries in this forum. Search for entries that start with "Troubleshooting".

### Db2 Monitoring

You may find here more details about Db2 Monitoring known issues.

#### **Incorrect value shown for fullyQualifiedName property in related resources widget**

##### **Problem**

Incorrect value is showed for fullyQualifiedName property in the related resources widget.

##### **Symptom**

Incorrect value is displayed for FQDN, IP address is truncated.

##### **Cause**

Invalid or missing hostname details in /etc/hosts file

##### **Solution**

User needs to add the correct hostname entry in /etc/hosts file.

On Linux system:

1. Logon as root user.
2. Edit the /etc/hosts file by using a text editor and add the correct entry for hostname.
3. Check **fullyQualifiedName** property in related resources widget to ensure it shows the correct value.

## Incorrect value for Db2 server name attribute in KUD\_DB2\_IPADDR\_TABLE

### Problem

Incorrect value shown for Db2 server name attribute in KUD\_DB2\_IPADDR\_TABLE attribute group for Db2 agent remote monitoring.

### Symptom

Incorrect value is displayed for Db2 server name, IP address is truncated.

### Cause

Invalid or missing hostname details in /etc/hosts file.

### Solution

User needs to add correct hostname entry in /etc/hosts file.

On Linux system

1. Log in as root user.
2. Edit the /etc/hosts file by using a text editor and add the correct entry for hostname.
3. Verify the Db2 server name attribute value property in KUD\_DB2\_IPADDR\_TABLE attribute group.

## Internet Service Monitoring

You may find here more details about Internet Service Monitoring known issues.

### Profile will not be created after create profile page is kept open for more than 10 minutes and another profile with same name will not be created

#### Problem

Profile will not be created after **create profile page** is kept open for more than 10 minutes and another profile with same name will not be created.

#### Symptom

While creating a profile if the user keeps **create profile page** idle (open without any activity) for more than 10 minutes, and then tries to create the profile, it will not get created. After that, if user tries to create the profile again with the same name, profile will not get created.

#### Cause

A lock file gets created at the MIN side at the time of profile creation which locks the profile creation activity for the same profile for other users. The lock file gets deleted after profile creation is done. But if the create window is idle for more than 10 minutes, the create event gets locked, and user is not able to create the profile.

#### Solution

- User should not keep the window idle for more than 10 minutes while creating a profile.
- Administrator can delete the lock file of the profile that was created from MIN side at /opt/ibm/wlp/usr/servers/min/dropins/CentralConfigurationServer.war/data\_source/is.

For example, if the profile name is ABC, a lock file \$\$ABC\$\$1UjQ9wy1boIHTAQeWSj1IU.lock gets created.

## **Data is displayed for deactivated (Active field is false) monitor elements on APM UI on windows platform**

### **Problem**

Data is displayed for deactivated (Active field is false) monitor elements on APM UI on windows platform.

### **Symptom**

While adding monitor elements if active field is kept as false and the monitor elements is deployed on agent machine, data for that element is getting collected initially and is shown on the dashboard. This data from the dashboard is then automatically vanishing after some time as the active field is false. This issue is occurring only on windows platform.

### **Cause**

In the monitor code active fields value is randomly becoming true even if it is set as false in monitor xml. Hence, monitor is collecting the data.

### **Solution**

Data will go automatically from the dashboard after some time. User doesn't need to do anything.

## **custom.properties file is getting empty when agent is offline for more than 10 minutes and no profile is deployed after the agent is upgraded to 8.1.4.0.11**

### **Problem**

When agent is upgraded to 814011 version from older versions, contents of the file custom.properties are not getting stored to CCS DB automatically. Hence, custom.properties file is getting empty when agent is offline for more than 10 minutes and no profile is deployed after the agent is upgraded to 8.1.4.0.11.

### **Symptom**

Due to the custom.properties file getting empty when agent is offline for more than 10 minutes and no profile is deployed after the agent is upgraded to 8.1.4.0.11, data will not be shown in the dashboard unless user redeploy the profiles.

### **Cause**

CCS DB is updated only when user deploys or renames profiles. CCS DB will not be updated unless user deploys or renames the profile after upgrade.

### **Solution**

Deploy at least one profile after upgrade so that CCS DB will be updated with latest configuration from custom.properties file.

## Discrepancy in data in the monitor XML

### Problem

Discrepancy in data in the monitor XML that is present at ISMHOME/profiles/active of agent. It occurs when \$ is used or entered in any field while configuration of profiles for all the monitors.

### Solution

Refrain from using or entering \$ in any field while configuration of profiles for all the monitors to avoid this issue.

***303 status code default data validation condition is not visible under the DVC tab in old profiles for http and https monitor elements after agent upgrade.***

### Problem

303 status code default data validation condition is not visible under the DVC tab in old profiles for http and https monitor elements after agent upgrade.

### Symptom

HTTP and HTTPS URL responses are not evaluated for 303 status codes.

### Cause

The page is already loaded for the old profiles, hence after upgrading the agent, when the profile is opened in edit mode, the old data gets fetched. Hence 303 status condition does not get added after agent upgrade.

### Solution

Add the 303 status code condition under the DVC tab manually for old profiles containing http and https monitor elements as follows:

| Metric | Operator | Operand | Status |
|--------|----------|---------|--------|
| status | !=       | 303     | FAILED |

## Bad data for SNMP monitor

### Problem

Bad data is shown for SNMP monitor when the MIB name used in Data Validation conditions(DVC's) of SNMP elements is modified under particular OID group, from OID tab in APM config panel.

### Symptom

Bad data for SNMP monitor is shown on portal.

### Cause

DVC with old MIB name still exists under the DVC tab though the MIB name is modified in OID tab.

## **Solution**

Edit the DVC of SNMP element in a profile having old MIB name with the latest MIB name and redeploy the profile.

## **Microsoft Active Directory Monitoring**

You may find here more details about Microsoft Active Directory monitoring known issues.

### **Microsoft Active Directory agent does not show updated Online help content**

#### **Problem**

Online help pages are not updated with the latest content for Microsoft Active Directory agent.

#### **Symptom**

On the APM dashboard Eclipse help for Microsoft Active Directory agent, the help content is missing for Data collection interval and retention period of the following newly added attribute groups:

- Directory Services
- Kerberos Consistency Checker
- Kerberos Key Distribution Center
- Name Service Provider
- Exchange Directory Service

#### **Cause**

The problem occurs due to constraint in the build server.

#### **Solution**

User may find the help content in the respective attribute groups contextual help on the APM dashboard.

**Note:** The issue appears in APM V8.1.4.10 release.

## **Microsoft Cluster**

You may find here more details about Microsoft Cluster known issues.

### **High memory consumption with IBM Application Performance Management 8.1.4.0 Interim Fix 20 server patch**

#### **Problem**

MS Cluster agent v8.1.4.0.15 observes high memory consumption with IBM Application Performance Management 8.1.4.0 Interim Fix 20 server patch.

#### **Symptom**

Memory consumption is high for MS Cluster agent if using Interim Fix 20 server patch.

#### **Cause**

8.1.4.0 Interim Fix 20 Server patch causes high memory consumption in Kq5agent.exe.

## Solution

Install IBM Application Performance Management 8.1.4.0 Interim Fix 21 patch on APM server to minimize the memory consumption.

## Microsoft IIS monitoring

You may find here more details about Microsoft Internet Information Services known issues.

### Online help pages are not updated with latest content for Microsoft IIS APM agent

#### Problem

Online help pages are not updated with latest content for Microsoft IIS APM agent

#### Symptom

Newly added attribute groups are missing in the Online help content:

- WPROCESS
- MEMIISUS
- ASP Garbage Collection
- IISSVRINFO

#### Cause

This problem is occurring due to build server issues.

#### Workaround

Not Available. However, you can see the help contents of particular attribute group on APM dashboard.

### When user installs IIS agent, prerequisite checker scanner fails to install and displays an error message

#### Problem

When user installs IIS agent, prerequisite checker scanner fails to install and displays below error message: "Scenario: Prerequisite Scan KQ7 – KQ7 [version 08200300]:

| Table 291.              |        |             |                                     |
|-------------------------|--------|-------------|-------------------------------------|
| Property                | Result | Found       | Expected                            |
| zDotNetFrameworkVersion | FAIL   | [Not found] | 4.6 Onwards (Release DWORD: 393295) |

Overall Result: FAIL"

#### Solution

Refer the steps to resolve this issue

1. After downloading and extracting the installation files, bypass the prerequisite scan.
2. To bypass the prerequisite scan run the following command in CLI while IIS agent installation export SET SKIP\_PRECHECK=Y

## Microsoft .NET Monitoring

You may find here more details about Microsoft .NET monitoring known issues.

### Microsoft .NET agent does not show updated Online help content

#### Problem

Online help pages are not updated with the latest content for Microsoft .NET agent.

#### Symptom

On the APM dashboard Eclipse help for Microsoft .NET agent, the Request Name attribute help content is missing under the Database Call Details attribute group.

#### Cause

The problem occurs due to constraint in the build server.

#### Solution

User may find the help content in the Database Call Details attribute group widget contextual help on the APM dashboard.

**Note:** The issue appears in APM V8.1.4.10 release.

### No items are displayed in Attribute Details tab of attribute group KQE\_SERVICEDetails

#### Problem

There are no items displayed in the **Attribute Details** tab of attribute group **KQE\_SERVICEDetails**.

#### Symptom

In the **Attribute Details** tab of attribute group **KQE\_SERVICEDetails**, the message No items to display is showed.

#### Cause

This attribute group is implemented for **Monitoring** of **IBM Cloud Pak for Multicloud Management**.

#### Solution

Not applicable.

### Common issues related to .NET Core Applications monitoring

#### Extra random garbage value

##### Problem

There may be extra random garbage value for instance name in ASP.NET Applications widget and Attribute Details tab for ASP.NET\_Apps\_Filter / KQE\_ASP.NET\_APPS\_ERROR\_FILTER for a short duration.

##### Solution

The symptom can be safely ignored as there is no data loss. You can restart the IIS service if you wish to remove the extra random garbage value immediately.

## Additional application issues

1. If the .NET Core Application that needs to be monitored does not work through IIS, you could check the handler mappings in IIS and ensure the ASP .NET Core is enabled and mapped to `AspNetCoreModuleV2`.
2. If you are unable to access the handler mappings or modules in IIS, you could repair the Microsoft .NET Core 3.1.2 Windows server hosting from Programs and Features by performing the following steps:
  - a. Launch **Control Panel**.
  - b. Navigate to **Uninstall a program**.
  - c. Right click **Microsoft .NET Core 3.1.2 Windows server hosting** and select **Change Options**.
  - d. Click **Repair**.
3. If you encounter the errors for your application like HTTP Error 500.31- ANCM Failed to Find Native dependencies, ensure that the application is published in self-contained mode; Or if the application is published in framework dependent mode, ensure the supported .NET Core Runtime version is installed on agent machine.
4. Create a new environment variable **ASPNETCORE\_ENVIRONMENT** under the tag `<aspNetCore>` and set its value to **Development** in the file `web.config` of .NET Core Application. It would provide more detail description for your applications to resolve the issues.

**Note:** The file `web.config` is located in the published folder of the application.

```
<aspNetCore processPath="dotnet" arguments=".\AspDotNetCoreApp.dll" stdoutLogEnabled="false"
stdoutLogFile=".\logs\stdout" hostingModel="inprocess">
  <environmentVariables>
    <environmentVariable name="ASPNETCORE_ENVIRONMENT" value="Development" />
  </environmentVariables>
</aspNetCore>
```

5. If all above attempts do not resolve the issue, perform the following steps:
  - a. Stop the agent services from **IBM Performance Management** window
  - b. Launch a command prompt from the path `APM_HOME\qe\bin` in administrator mode and stop **DotNetProfilerService** by running the following command:

```
net stop DotNetProfilerService
```

Where `APM_HOME` is the agent installation directory.

- c. Run the following command to stop the IIS:

```
iisreset /stop
```

- d. Revert all the .NET Core Applications to the original state. Refer to [“Disabling Modules for .NET Core Applications”](#) on page 628.
- e. Run the following commands to unregister the components:

```
configdc unregisterdc all
configdc unregisterdc rtmodule
```

- f. Run the following command to start IIS:

```
iisreset /start
```

- g. Run the following command to stop the IIS:

```
iisreset /stop
```

h. Run the following commands to register the components:

```
configdc registerdc all  
configdc registerdc rtmodule
```

i. Start the DotNetProfilerService and agent services.

j. Enable support for .NET Core Applications. Refer to [“Enabling Support for .NET Core Applications Monitoring”](#) on page 627.

k. Restart the .NET Core Application and ensure the application works successfully in IIS.

## Microsoft Office365 Server Monitoring

You can find here more details about Microsoft Office365 Server monitoring known issues.

### No Data available message observed for group widgets

User observes “No Data available” message under “Inactive Exchange Users (Top 50)” and “Inactive OneDrive Users (Top 50)” group widgets.

#### Problem

User observes “No Data available” message under “Inactive Exchange Users (Top 50)” and “Inactive OneDrive Users (Top 50)” group widgets.

#### Symptom

No symptoms.

#### Cause

The widgets are not supported due to data inconsistency.

#### Solution

You may observe " No data available " message under “Inactive Exchange Users (Top 50)” and “Inactive OneDrive Users (Top 50)” group widgets, which can be ignored for 8.1.4.0.14 release version because the problem occurs due to inconsistent data.

## Microsoft Skype for Business Server Monitoring

You can find here more details about Microsoft Skype for Business Server monitoring known issues.

### The Skype topology widget does not display data after the agent upgrade

When you upgrade the Skype for Business Server agent from v8.1.4.0.11 to v8.1.4.0.12, the Skype Topology group widget does not display data on the APM UI.

#### Problem

The Skype topology widget does not display data after the agent upgrade.

#### Symptom

On the Overview page, the Skype Topology group widget does not display data.

#### Cause

After the agent upgrade, the KQL\_LyncTop\_Enable variable value is not updated from false to true.

## Solution

To display the Skype Topology group widget data after the agent upgrade, follow these steps:

1. Navigate to <CANDLE\_HOME>\TMAITM6\_x64 or right click on **Monitoring Agent for Skype for Business Server -> Advanced -> Edit ENV File**. The KQLENV file opens.
2. Change the variable *KQL\_LyncTop\_Enable* value from false to true.
3. Restart the agent.

**Note:** The issue appears in APM V8.1.4.12 release.

## Microsoft SharePoint Server Monitoring

You can find here more details about Microsoft SharePoint Server monitoring known issues.

### Microsoft SharePoint Server agent does not show updated Online help content

#### Problem

Online help pages are not updated with the latest content for Microsoft SharePoint Server agent.

#### Symptom

On the APM dashboard Eclipse help for Microsoft SharePoint Server agent, the help content is missing for the newly added group widgets called Last 1 Hour Trace Log Count and Trace Log Details.

#### Cause

The problem occurs due to constraint in the build server.

#### Solution

User may find the help content in the respective group widgets contextual help on the APM dashboard.

**Note:** The issue appears in APM V8.1.4.10 release.

### SharePoint Agent Configuration window does not appear while configuration if it coexists with V6 agent

#### Problem

If ITCAM for Microsoft Applications: Microsoft SharePoint Server Agent and Monitoring Agent for Microsoft SharePoint Server (V8) are installed on same system and if you try to reconfigure APM agent (V8) then agent configuration window does not appear and a message The agent configuration process did not complete. is shown.

#### Symptom

Agent configuration window does not open while configuring Monitoring Agent for Microsoft SharePoint Server.

#### Cause

While opening agent Configuration window, factory creates a temporary file temp.ini and writes JAVA\_HOME variable in it as: JAVA\_HOME=Candle\_Home\java\java80\_x64\jre

But if ITCAM for Microsoft Applications: Microsoft SharePoint Server Agent is already installed on the same system then factory cannot write *JAVA\_HOME* variable intermittently in *temp.ini* file. Hence, configuration window fails to open.

## Workaround

Configure Monitoring Agent for Microsoft SharePoint Server silently using agent configuration response file.

## Microsoft SQL Server monitoring

You may find here more details about Microsoft SQL Server known issues.

### Memory leak for Collector process

#### Problem

Memory is leaked for collector process when the *perfmon* counters for one or more databases is not available under the “SQLServer:Databases” *perfmon* object.

**Note:** This issue is fixed in the APM 8.1.4.0.13 release.

#### Symptom

The memory for collector process keeps on increasing and the memory is not released.

#### Cause

The SQL agent uses *perfmon* counter as source for data collection. When database is not under the “SQLServer:Databases” object in Performance Monitor(*perfmon.exe*), the counter value retrieval operation fails for the database. During this failure, *perfmon* counter handles are not released properly in the Collector process, resulting in a memory leak.

One of the possible causes for the why the database instance is not present under the “SQLServer:Databases” object is that the database is not in ONLINE state.

#### Solution

You may apply any of the following solutions to resolve the problem:

- **Configure MS SQL Agent to collect data only for databases having valid counters:**

Refer the following guide for setting up parameter “*Database*” and disable the collection for databases which do not have database instance under SQLServer:Databases object in Performance Monitor.

[https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/install/sql\\_config\\_agent\\_parameters\\_database\\_server\\_properties.html](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/install/sql_config_agent_parameters_database_server_properties.html)

- **Troubleshoot performance counter issues for the database which do not have instance under the SQLServer:Databases object in Performance Monitor:**

- If the database instance is not present under SQLServer:Databases object and database is not in ONLINE state, making database state ONLINE might resolve the problem.
- Unloading and loading the counter for MS SQL Server might help. Please refer “*Resolving The Problem*” section in the following link:

<https://www.ibm.com/support/pages/mssql-agents-oq-not-collecting-data-koqcollexe-exits>

- **Disable collection for Database Detail attribute group:**

Refer following guide for setting up parameter “*Extended Params*” to disable Database Detail Attribute Group (KOQDBD), [https://www.ibm.com/support/knowledgecenter/SSHLNR\\_8.1.4/com.ibm.pm.doc/install/sql\\_config\\_agent\\_parameters\\_database\\_server\\_properties.html](https://www.ibm.com/support/knowledgecenter/SSHLNR_8.1.4/com.ibm.pm.doc/install/sql_config_agent_parameters_database_server_properties.html)

**Note:** SQLServer:Databases is the name of performance object for default instance of SQL Server. For named instance the object name is MSSQL\$<instance\_name>:Databases

## Services are ‘Disabled’ after removal of multiple configured instances

### Problem

Services are ‘Disabled’ after removal of multiple configured instances.

### Cause

The cause is unknown.

### Symptom

When you have multiple instances configured and you revert the configuration for more than one instances from ‘IBM Performance Management’ (IPM) window, the agent services are not removed from the service manager and remain disabled. This may prevent you from configuring the same instance again. If you configure the same instance again and try to start the same instance, the following error is displayed: “The service cannot be started, either because it is disabled or because it has no enabled devices associated with it.”

### Solution

If you revert the configuration for multiple instances, close the IPM window and ensure that services corresponding to reverted configuration instances are removed from the Service Manager (services.msc). After confirming, you can re-open the IPM window and configure the removed instance again. Also, if the services for the newly configured instances are in disabled state, then close the IPM window. The services which are in disabled state will be deleted. Open the IPM window and double click the instance row to create a new agent service, and start the agent.

## MongoDB Monitoring

You may find here more details about MongoDB monitoring known issues.

### MongoDB agent log file shows some invalid character errors

#### Problem

When MongoDB agent is installed to monitor MongoDB version 4.x, the agent log file shows invalid character errors.

#### Symptom

When MongoDB agent is installed to monitor MongoDB version 4.x, its agent log file shows the following errors:

```
(5F16E2E0.0003-34:utilities.cpp,242,"parseNumericString") Invalid characters undefined found for metric Total_Size_of_Namespace getting numeric value from undefined, returning 0.000000
(5F16E303.0001-34:utilities.cpp,242,"parseNumericString") Invalid characters undefined found for metric Open_Cursor getting numeric value from undefined, returning 0.000000
(5F16E2E0.0000-34:utilities.cpp,242,"parseNumericString") Invalid characters undefined found for metric Total_Size_of_Database getting numeric value from undefined, returning 0.000000
```

## Solution

The following metrics (**Total\_Size\_of\_Namespace**, **Open\_Cursor**, **Total\_Size\_of\_Database**) are deprecated / removed from MongoDB version 4.0 and later. These attributes are applicable and available in MongoDB database versions 2.x, 3.x only.

User can ignore these errors for MongoDB agent that is installed to monitor MongoDB version 4.x, since it does not impact any functionalities.

## MySQL Monitoring

You may find here more details about MySQL Monitoring known issues.

### MySQL agent fails to collect data when it is configured with JDBC version 8.0.19 and later on non-Windows platform

#### Problem

MySQL agent is not able to collect data if agent is configured with JDBC version 8.0.19 or later on non-Windows platform. The following exception is displayed in the logs: *CANDLE\_HOME*/logs/kse\_instance\_name\_trace0.log.

```
- SEVERE - bodkatamari - Thread-1 - agent.client.connection.JDBCConnection.createJDBCConnection  
- com.mysql.cj.jdbc.exceptions.CommunicationsException: Communications link failure
```

Or

```
- SEVERE - localhost - Thread-1 - agent.client.Utility.logSQLException - Cause:  
javax.net.ssl.SSLHandshakeException: No appropriate protocol (protocol is disabled or cipher  
suites are inappropriate)
```

Where:

- *instance\_name* is the agent instance name.
- *CANDLE\_HOME* is the agent installation directory.

#### Symptom

No data is displayed on dashboard for MySQL agent.

#### Cause

MySQL agent is configured with JDBC version 8.0.19 or later on non-Windows platform.

#### Solution

Use stable JDBC version 8.0.11 to configure MySQL agent. For example: `mysql-connector-java-8.0.11.jar`.

Or

Upgrade MySQL agent to the latest version, such as 08.21.03.00, install JAVA 8 and provide *JAVA\_HOME* path during agent configuration.

### MySQL agent fails to collect data when server time zone value is unrecognized or represents more than one time zone values

#### Problem

MySQL agent is not able to collect data when server time zone value is unrecognized or represents more than one time zones.

The following exception is displayed in logs: *CANDLE\_HOME*/logs/kse\_instance\_name\_trace0.log:

```
The server time zone value 'CDT' is unrecognized or represents more than one time zone. You must configure either the server or JDBC driver (via the serverTimezone configuration property) to use a more specific time zone value if you want to utilize time zone support.
```

Where:

- *instance\_name* is the agent instance name.
- *CANDLE\_HOME* is the agent installation directory.

## Symptom

No data is displayed on dashboard for MySQL agent.

## Cause

The server time zone value is unrecognized or represents more than one time zones.

## Solution

Upgrade MySQL agent to the latest version such as 08.21.03.00.

## MySQL server status shows incorrect data when time zone property is set in JDBC config file

## Problem

MySQL server status shows incorrect data when the time zone property is set in JDBC config file. The following exception is displayed in logs: *CANDLE\_HOME*/logs/kse\_instance\_name\_trace0.log:

```
agent.client.attributeGroups.Application_Availability.collectData - Server is down and Server FQDN: bodkatamari.PrivateCloud.cloud - The server time zone value 'CDT' is unrecognized or represents more than one time zone. You must configure either the server or JDBC driver (via the serverTimezone configuration property) to use a more specific time zone value if you want to utilize time zone support.
```

Where:

- *instance\_name* is the agent instance name.
- *CANDLE\_HOME* is the agent installation directory.

## Symptom

MySQL server status is showed as inactive.

## Cause

The server time zone value is unrecognized or represents more than one time zone.

## Solution

Upgrade MySQL agent to the latest version such as 08.21.03.00.

# PostgreSQL Monitoring

You may find here more details about PostgreSQL Monitoring known issues.

## No data is displayed in all of the widgets for PostgreSQL Instance resource and Database resource.

### Problem

No data is displayed in all of the widgets for PostgreSQL Instance resource and Database resource.

### Symptom 1

Following exception occurs in logs:

```
<CANDLE HOME>/logs/kpn_JDBC_<instance_name>_trace.log java.io.IOException: Connection to 10.46.44.18:5432 refused. Check that the hostname and port are correct and that the postmaster is accepting TCP/IP connections.
```

### Cause

Agent is not able to connect to remote PostgreSQL database.

### Solution

Refer the steps given to resolve this issue:

1. Open `postgresql.conf` file located at `/var/lib/pgsql/12/data`
2. Update the **listen\_addresses** parameter to accept the connection from remote host. For example  
**listen\_addresses = '\*'**
3. Restart the PostgreSQL database server
4. Restart the PostgreSQL agent

### Symptom 2

Following exception occurs in logs:

```
<CANDLE HOME>/logs/kpn_JDBC_<instance_name>_trace.log java.io.IOException: FATAL: no pg_hba.conf entry for host "<TEMA IP>", user "postgres", database "ibmdb", SSL off
```

### Cause

SSL is off and agent is not able to connect to remote PostgreSQL database; OR  
SSL is on and agent is not able to collect data from PostgreSQL database.

### Solution

1. Stop the PostgreSQL agent.
2. Locate the `postgresql.conf` file at `/var/lib/pgsql/<server_version>/data`, where `<server_version>` is the PostgreSQL server version.  
Note the configuration of SSL. It can be set to ON or OFF.
3. Locate the `pg_hba.conf` file at `/var/lib/pgsql/<server_version>/data`, where `<server_version>` is the PostgreSQL server version.
4. Ensure the IPv6 local connection section in `pg_hba.conf` file is configured to accept connection from remote host. For example:

If SSL is OFF, configure the following:

```
host all all 0.0.0.0/0 md5
```

If SSL is ON, configure the following:

```
hostssl all all 0.0.0.0/0 md5
```

5. Ensure the PostgreSQL agent is configured with the latest JDBC jar.  
If the agent is not configured with the latest JDBC jar, reconfigure the PostgreSQL agent with the latest JDBC jar.
6. Restart the PostgreSQL database server if any change is made to pg\_hba.conf file.
7. Start PostgreSQL agent.

## No data displayed for Worst SQL execution time and SQL Statement Execution Time

### Problem

No data displayed for Worst SQL execution time and SQL Statement Execution Time - Slowest 5 and Average Response Time by Operation(ms) - Top 10 widgets.

The following exception is displayed in logs: *CANDLE\_HOME/logs/kpn\_JDBC\_instance\_name\_trace.log*.

```
JdbcConnection.executeFromList-new - org.postgresql.util.PSQLException: ERROR: column  
"total_time" does not exist
```

### Symptom

No data is displayed for the worst SQL execution time and the response time on UI for PostgreSQL agent.

### Cause

The PostgreSQL agent is trying to monitor the latest PostgreSQL Server version, such as PostgreSQL 13.x.

### Solution

Option 1: Configure the agent to monitor PostgreSQL Server version 12.x or earlier.

Option 2: Upgrade PostgreSQL agent to the latest agent version 08.21.03.00.

## Status, Worst SQL execution time and response time data are not showed if JAVA\_HOME path has spaces on Windows platform

### Problem

Status, worst SQL execution time and response time are not showed on UI for PostgreSQL agent installed on Windows platform if environment variable *JAVA\_HOME* contains spaces and is not quoted accordingly. For example:

```
JAVA_HOME= C:\Program Files\Java\jre1.8.0_241
```

### Symptom

Status, Worst SQL execution time and response time are not showed on UI for PostgreSQL agent.

### Cause

Agent could not collect data if the value of environment variable *JAVA\_HOME* contains spaces.

### Solution

Option 1: Set the path value of *JAVA\_HOME* without spaces.

Option 2: If the path value of *JAVA\_HOME* contain spaces, enclose the path value in double quotes.

```
JAVA_HOME="C:\Program Files\Java\jre1.8.0_241"
```

## SAP Monitoring

You may find here more details about SAP Monitoring known issues.

### When Name attribute is used as a display item in threshold for R/3\_Buffer\_Performance and R/3\_Buffer\_Performance\_64 attribute groups, value of Name field may get truncated for multi-byte characters

#### Problem

When Name attribute is used as a display item in threshold for R/3\_Buffer\_Performance and R/3\_Buffer\_Performance\_64 attribute groups, value of Name field may get truncated for multi-byte characters

#### Cause

Length of Name attribute is insufficient to support multi-byte characters.

#### Solution

Newly added attribute Name\_U can be used as a display item in order to avoid truncation.

### Incorrect Node name displayed for SAP systems with - symbol in hostname

#### Problem

Incorrect Node names will be displayed under **All My Applications > My Components > Overview page** for SAP Systems that have – symbol in the hostname.

#### Solution

Create a custom application under **All My Applications** by adding the required components where node name truncation is observed. Refer [“Adding an application” on page 1270](#) to create a new custom application.

### Incorrect Node name displayed after agent upgrade for SAP systems with - symbol in hostname

#### Problem

Incorrect Node names will be displayed after agent upgrade under **All My Applications > My Components > Overview page** for SAP Systems that have – symbol in the hostname.

## Solution

Perform following steps:

1. Upgrade the SAP Agent to version 8.1.4.0.14.
2. Restart **apmui** service on server side.
3. Create a custom application for following scenarios:
  - If custom application is already created before agent upgrade then new node names will not be reflected in same custom application after agent upgrade. Create a new custom application where node name truncation is observed.
  - If custom application is not created before agent upgrade then create a custom application under **All My Applications** by adding the required components where node name truncation is observed.

To create a custom application, refer [“Adding an application” on page 1270](#)

## WebSphere Applications monitoring

You can find more details about WebSphere Applications monitoring known issues.

### Failed to install WebSphere Applications agent on Linux for IBM Z if libstdc++.so.5 is missing

Installation of WebSphere Applications agent on Linux for IBM Z fails if `libstdc++.so.5` is not installed on your system.

### Symptoms

When installing the WebSphere Applications agent, you might have the following errors:

- Run the pre-check tool (SKIP\_PRECHECK=0) when installing WebSphere Applications agent v07.3.0.14.10, an error message is displayed like the following example:

```
KYN - WAS Monitoring Agent [version 07301410]:
PropertyResultFoundExpected
=====
os.lib.libstdc++_64FAILUnavailableregex{libstdc++.so.5}
```

- Skip the pre-check tool (SKIP\_PRECHECK=1) when installing WebSphere Applications agent, configure the data collector for the WebSphere Applications server, and then restart the server. You can find the following error in the server log:

```
J9VMD11Main failed
JVMJ9VM135W /proc/sys/kernel/core_pattern setting "|/usr/lib/systemd/systemd-coredump %P %u
%g %s %t %c %e" specifies that core dumps are to be piped to an external program. The JVM may
be unable to locate core dumps and rename them.

JVMJ9TI001E Agent library am_ibm_16 could not be opened (libstdc++.so.5: cannot open shared
object file: No such file or directory)

JVMJ9VM015W Initialization error for library j9jvmti29(-3): JVMJ9VM009E J9VMD11Main failed
```

### Cause

`libstdc++.so.5` is required when installing the WebSphere Applications agent on Linux for IBM Z. On SUSE Linux Enterprise 12 and 15 for IBM Z, `libstdc++.so.5` is not installed by default. The errors are caused by the missing of `libstdc++.so.5` or being not correctly linked by `am_ibm_16.so`.

## Solution

1. Install `libstdc++.so.5` and check if the dependency is correctly set up in `am_ibm_16.so`.
2. Verify whether `libstdc++.so.5` is successfully installed:

```
/usr/lib64 # ls | grep libstdc
libstdc++.so.5
libstdc++.so.5.0.7
```

3. Check `am_ibm_16.so` if `libstdc++.so.5` can be found:

```
/opt/ibm/apm/agent/yndchome/7.3.0.14.10/toolkit/lib/ls3266 # ldd libam_ibm_16.so
libstdc++.so.5 => not found
librt.so.1 => /lib64/librt.so.1 (0x000003ff7e680000)
libcclog_64.so => not found
libmsg23_64.so => not found
libcfdc_64.so => not found
libc.so.6 => /lib64/libc.so.6 (0x000003ff7e480000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x000003ff7e400000)
/lib/ld64.so.1 (0x000003ff7e900000)
```

4. If `libstdc++.so.5` is not found, add the following lines into `/etc/ld.so.conf` file:

```
/usr/lib
/usr/lib64
```

5. Reboot the server.
6. Verify that `libstdc++.so.5` is correctly linked.

```
/opt/ibm/apm/agent/yndchome/7.3.0.14.10/toolkit/lib/ls3266 # ldd libam_ibm_16.so
libstdc++.so.5 => /usr/lib64/libstdc++.so.5 (0x000003ff8cd80000)
librt.so.1 => /lib64/librt.so.1 (0x000003ff8cd00000)
libcclog_64.so => not found
libmsg23_64.so => not found
libcfdc_64.so => not found
libc.so.6 => /lib64/libc.so.6 (0x000003ff8cb00000)
libgcc_s.so.1 => /lib64/libgcc_s.so.1 (0x000003ff8ca80000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x000003ff8ca00000)
/lib/ld64.so.1 (0x000003ff8d100000)
```

Now the errors will be resolved and you can successfully install and start the WebSphere Applications agent.

## WebSphere Applications monitoring

You can find more details about WebSphere Applications monitoring known issues.

### Failed to install WebSphere Applications agent on Linux for IBM Z if `libstdc++.so.5` is missing

Installation of WebSphere Applications agent on Linux for IBM Z fails if `libstdc++.so.5` is not installed on your system.

#### Symptoms

When installing the WebSphere Applications agent, you might have the following errors:

- Run the pre-check tool (`SKIP_PRECHECK=0`) when installing WebSphere Applications agent v07.3.0.14.10, an error message is displayed like the following example:

```
KYN - WAS Monitoring Agent [version 07301410]:
PropertyResultFoundExpected
=====
os.lib.libstdc++_64FAILUnavailableregex{libstdc++.so.5}
```

- Skip the pre-check tool (`SKIP_PRECHECK=1`) when installing WebSphere Applications agent, configure the data collector for the WebSphere Applications server, and then restart the server. You can find the following error in the server log:

```
J9VMDllMain failed
JVMJ9VM135W /proc/sys/kernel/core_pattern setting "|/usr/lib/systemd/systemd-coredump %P %u
%g %s %t %c %e" specifies that core dumps are to be piped to an external program. The JVM may
be unable to locate core dumps and rename them.
```

```
JVMJ9TI001E Agent library am_ibm_16 could not be opened (libstdc++.so.5: cannot open shared object file: No such file or directory)
```

```
JVMJ9VM015W Initialization error for library j9jvmti29(-3): JVMJ9VM009E J9VMDllMain failed
```

## Cause

libstdc++.so.5 is required when installing the WebSphere Applications agent on Linux for IBM Z. On SUSE Linux Enterprise 12 and 15 for IBM Z, libstdc++.so.5 is not installed by default. The errors are caused by the missing of libstdc++.so.5 or being not correctly linked by am\_ibm\_16.so.

## Solution

1. Install libstdc++.so.5 and check if the dependency is correctly set up in am\_ibm\_16.so.
2. Verify whether libstdc++.so.5 is successfully installed:

```
/usr/lib64 # ls | grep libstdc
libstdc++.so.5
libstdc++.so.5.0.7
```

3. Check am\_ibm\_16.so if libstdc++.so.5 can be found:

```
/opt/ibm/apm/agent/yndchome/7.3.0.14.10/toolkit/lib/ls3266 # ldd libam_ibm_16.so
libstdc++.so.5 => not found
librt.so.1 => /lib64/librt.so.1 (0x000003ff7e680000)
libcclog_64.so => not found
libmsg23_64.so => not found
libcffdc_64.so => not found
libc.so.6 => /lib64/libc.so.6 (0x000003ff7e480000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x000003ff7e400000)
/lib/ld64.so.1 (0x000003ff7e900000)
```

4. If libstdc++.so.5 is not found, add the following lines into /etc/ld.so.conf file:

```
/usr/lib
/usr/lib64
```

5. Reboot the server.
6. Verify that libstdc++.so.5 is correctly linked.

```
/opt/ibm/apm/agent/yndchome/7.3.0.14.10/toolkit/lib/ls3266 # ldd libam_ibm_16.so
libstdc++.so.5 => /usr/lib64/libstdc++.so.5 (0x000003ff8cd80000)
librt.so.1 => /lib64/librt.so.1 (0x000003ff8cd00000)
libcclog_64.so => not found
libmsg23_64.so => not found
libcffdc_64.so => not found
libc.so.6 => /lib64/libc.so.6 (0x000003ff8cb00000)
libgcc_s.so.1 => /lib64/libgcc_s.so.1 (0x000003ff8ca80000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x000003ff8ca00000)
/lib/ld64.so.1 (0x000003ff8d100000)
```

Now the errors will be resolved and you can successfully install and start the WebSphere Applications agent.

## JBoss monitoring

You can find more details about JBoss monitoring known issues.

### No JBoss agent transaction tracking and diagnostics data in the Application Performance Dashboard

After you configure transaction tracking or diagnostics data collector of the JBoss agent, restart JBoss server, and trigger several requests, you might see no JBoss agent transaction tracking data in the Application Performance Dashboard, and the default 5457 port is not listening.

#### Cause

If the JBoss agent is re-configured after JBoss agent transaction tracking or diagnostics data collector was configured, the APIs that are related with the transaction tracking environment variables will be overwritten by the JBoss agent reconfiguration.

#### Solution

You need to re-configure the JBoss agent transaction tracking or diagnostics data collector to take effect. For more information, see [Setup the JBoss agent transaction tracking or diagnostics data collector](#).

## WebLogic monitoring

You can find more details about WebLogic monitoring known issues.

### No WebLogic agent transaction tracking and diagnostics data in the Application Performance Dashboard

After you configure transaction tracking or diagnostics data collector of the WebLogic agent, restart WebLogic server, and trigger several requests, you might see no transaction tracking data in the Application Performance Dashboard, and the default 5457 port is not listening.

#### Cause

If the WebLogic agent is re-configured after WebLogic agent transaction tracking or diagnostics data collector was configured, the APIs that are related with the transaction tracking environment variables will be overwritten by the WebLogic agent reconfiguration.

#### Solution

You need to re-configure the WebLogic agent transaction tracking or diagnostics data collector to take effect. For more information, see [Configuring transaction tracking for the WebLogic agent](#).

## Agent installation and configuration failed on RHEL 8 and CentOS 8

---

### Problem

Agent installation failed on RHEL8.

OR

Agent configuration failed on CentOS 8.

### Symptom

1. Agent installation failed on RHEL 8 due to unavailability of libnsl.so.1.

Example: Agent installation failed on RHEL 8.

```
KAX - KAK=Azure Compute AgentKAL=Amazon ELBIBM Tivoli Monitoring Shared Libraries [version
06400015]:
Property                                Result      Found
Expected                                =====
=====
os.lib.libnsl_64                        FAIL        Unavailable
regex{libnsl.so.1}
```

2. Agent configuration failed on CentOS 8 due to error while loading shared libraries: libnsl.so.1.

Example: Agent configuration failed on CentOS 8.

```
/opt/ibm/tmaitm6/lx8266/bin/xc_silent: error while loading shared libraries: libnsl.so.1:
cannot open shared object file: No such file or directory
```

## Cause

The shared library libnsl is not installed in the system.

## Solution

1. Download libnsl RPM package for RHEL 8 or CentOS 8 accordingly.
2. Install the RPM package:

```
rpm -ivh <libnsl rpm>
```

## Collecting Cloud APM server logs for IBM Support

Gather the log files from the Cloud APM server and supporting components when requested by IBM Support to help diagnose issues.

### Before you begin

Root permission is required to collect system information from the Cloud APM server.

**Important:** Cloud APM server log files start wrapping when the configured number and size of the log files is reached. The Cloud APM server disk space requirements account for the number and size of the log files that are configured by default. It is recommended that you use an OS agent to monitor disk space usage on the Cloud APM server.

### Procedure

To run the log collection command, complete the following steps:

1. On the command line, change to the Cloud APM server `/opt/ibm/ccm/` directory or to the directory that you specified when you installed the server.
2. Run the following command:

```
./collectLogs.sh
```

A `tar.gz` file with a time stamp in the file name is generated in the `/tmp` directory, such as `/tmp/SCMAI_Logs_min_hostname_20150207_105132.tar.gz`.

You might receive a message that the system cannot find the path specified. You can ignore this message.

3. Send the output file to your IBM Support representative.

### Results

The script gathers the following component logs. The log directory paths in the following table start with the default `/opt/ibm` installation directory. If you specified a different installation directory when you installed the server, your log directory paths include this installation directory.

Table 292. Log files that are collected by the collectLogs.sh script

| Component                              | Log directory                     | Log file name   | Description   |
|--|-----------------------------------|---|---|
| Cloud APM server                       | /opt/ibm/wlp/usr/servers/min/logs | messages.log  | The main Cloud APM server log file.   |
|  |                                   | Agent interface<br>main:server.xml,<br>jvm.options,<br>bootstrap.properties         | Agent interface JVM and configuration information.  |
|  |                                   | Agent interface logs:<br>messages.log,<br>console.log,trace.log                     | Agent interface standard messages and traces.   |
|  |                                   | Agent interface FFDC:<br>ffdc_date_time.N.log,<br>exception_summary_date_time.N.log | Agent interface standard messages and traces.   |
|  |                                   | console.log   | Startup, session, transaction, and shutdown information.  |
| System Information of Cloud APM server | /opt/ibm/ccm/systemInfoLogs       | cpuinfo.log   | CPU configuration information.  |
|  |                                   | df.log  | Disk configuration information.   |
|  |                                   | filelist.log  | The list of files in the usr/servers/apmui, usr/servers/min, and usr/servers/server1 directories. |
|  |                                   | hosts.log   | Copy of etc/hosts   |
|  |                                   | meminfo.log   | Memory configuration information.   |
|  |                                   | opt-ibm-files.log   | The list of files in the product installation directory.  |
|  |                                   | ps.log  | The task list at the time of collection.  |
|  |                                   | rpm.log   | The software packages installed at the time of collection.  |
|  |                                   | sfdisk.log  | Information about mounted volumes.  |
|  |                                   | ss.log  | Open network sockets at the time of the collection  |
|  |                                   | timestamp.log   | Date and time of collection.  |
|  |                                   | ulimit.log  | Setting of ulimit at the time of the collection.  |
|  |                                   | version.log   | Linux version information.  |

Table 292. Log files that are collected by the collectLogs.sh script (continued)

| Component                       | Log directory                                       | Log file name            | Description  |
|---------------------------------|---|--------------------------|--|
| OSLC Service Provider           | /opt/ibm/ccm/oslc_pm/logs                           | candle_installation.log  | Include installation environment information that is collected at each restart.      |
|                                 |   | UpdateAutoRun.log        | Sets up automation environment.  |
|                                 |   | hostname_as.inv          | Index of log files.  |
|                                 |   | hostname_as_NNNNNN.log   | Trace file for OSLC Performance Monitoring service.                                  |
| Service Component Registry      | /opt/ibm/ccm/SCR/XMLToolKit/log                     | msgGTM_CI.log.N          |  |
|                                 |   | msgGTM_XT.log.N          |  |
|                                 |   | msgGTM_XT.log.N.lck      |  |
|                                 |   | traceGTM_CI.log.N        |  |
|                                 |   | traceGTM_XT.log.N        |  |
|                                 |   | traceGTM_XT.log.N.lck    |  |
|                                 | /opt/ibm/ccm/SCR/XMLToolkit/bin                     | xmltoolkitsvc.properties | XML Toolkit configuration information.   |
|                                 | /opt/ibm/ccm/SCR/XMLToolkit/log/install/maintenance |                          | DB maintenance scripts and SQL information.  |
| MongoDB                         | /opt/ibm/mongodb/logs                               | mongodb.log              | The main MongoDB log. MongoDB stores threshold events and transaction tracking data. |
| Kafka Message Broker            | /opt/ibm/kafka/logs                                 | controller.log           | Log of "controller" subsystem in Kafka.  |
|                                 |   | kafka-request.log        | Log of "request" subsystem in Kafka.   |
|                                 |   | server.log               | The main Kafka log.  |
|                                 |   | state-change.log         | Log of "state-change" subsystem in Kafka.  |
|                                 |   | kafka-server.err         | Standard error stream of Kafka process.  |
|                                 |   | zookeeper-server.err     | Standard error stream of Zookeeper process.  |
| Cloud APM server Derby database | /opt/ibm/gaian                                      | gaiandb.log              | Node startup and performance information.  |
|                                 |   | derby.log                | Derby database startup information.  |
|                                 |   | *.properties             | Database configuration information.  |

Table 292. Log files that are collected by the collectLogs.sh script (continued)

| Component                                     | Log directory                      | Log file name  | Description   |
|---|------------------------------------|--|---|
| Db2 database used by the Cloud APM server     | /opt/ibm/db2/tbsmdb/logs           |  | Log files showing the Db2 operations that were completed during the product installation. |
| Cloud APM server data layer                   | /opt/ibm/dtl/datalayer/logs        |  | Log files showing the Db2 performance statistics for the DATAMART database.               |
| Performance Management infrastructure install | /opt/ibm/ccm/logs                  | smai_oslc_pm-rpm_inst_trace.log<br>IA_SCR_Install6.1.2-00.log<br>deploymentResults.log<br>apm-server-install_20150217_110258.log<br>smai-apmui-configuration_trace.log<br>smai-oslc-prestart.log<br>configureMIN.log<br>itmcdp.log<br>db2setup_wse.log   | Installation log files.   |
| ksy agent                                     | /opt/ibm/sy/logs                   |  | ksy agent log files   |
| Db2 server                                    | /home/db2apm/sqllib/db2dump        |  | Db2 server log files  |
| Agent install (Windows only)                  | install1_dir\logs                  | APMADV_Agents_install.1og,<br>IAPM_Agents_install.log,<br>APD_Agents_install.log,<br>APM_Agents_install.log  | Agent installation log files.   |
| OpenID Connect Provider                       | /opt/ibm/wlp/usr/servers/oidc/logs | messages.log   | OpenID Connect Provider standard messages.  |
| Server agents                                 | /opt/ibm/serveragents/logs         | The directory contains multiple log files. To find log files for a specific agent, use one of the following strings in your search: <ul style="list-style-type: none"> <li>• For the Monitoring Agent for Bluemix Integration (biagent), search for *bi*.</li> <li>• For the Monitoring Agent for Synthetic Events (soagent), search for *so*.</li> <li>• For the Monitoring Agent for Transactions Event (txagent), search for *tx*.</li> </ul> | Server agents log files.  |
| Diagnostic Query Service                      | /opt/ibm/wlp/usr/servers/dqe/logs  | message.log, trace.log   | Diagnostic Query Service (dqe) log files.   |

Table 292. Log files that are collected by the collectLogs.sh script (continued)

| Component  | Log directory                              | Log file name                                 | Description   |
|--|--|---|---|
| Performance Management console backend (server1) |  |   |   |
| Server1 Main                                     | /opt/ibm/wlp/usr/servers/server1           | server.xml, jvm.options, bootstrap.properties | Server1 server JVM and configuration information.   |
| Server1 Logs                                     | /opt/ibm/wlp/usr/servers/server1/logs      | messages.log                                  | Server1 standard messages.  |
|  |  | trace.log                                     | Server1 trace logs.   |
|  |  | kd8collectdate_time.tar.gz                    | Archive that contains Data Provider debug information.  |
|  |  | console.log                                   | Server1 standard output containing startup, session, transaction, and shutdown information.   |
|  |  | w7_audit.log                                  | Role Based Access Control audit log of changes to RBAC-related artifacts, such as creating permissions and roles, assigning permissions to roles, and assigning users and user groups to roles. |
|  |  | scrderby.log                                  | Service Component Repository Derby startup information.   |
|  |  | scrserver.log                                 | SCR Server process logs.  |
| Server1 FFDC                                     | /opt/ibm/wlp/usr/servers/server1/logs/ffdc | scrserver-errors.log                          | SCR Server process error messages.  |
|  |  | ffdc_date_time.N.log                          | First failure data capture logs.  |
|  |  | exception_summary_date_time.N.log             | Exception summaries from FFDC processing.   |
|  |  |   |   |
| Performance Management console (APM UI)          |  |   |   |
| APM UI Server Main                               | /opt/ibm/wlp/usr/servers/apmui             | server.xml, jvm.options, bootstrap.properties | Cloud APM console (APM UI) server JVM and configuration information.  |
| APM UI Server Logs                               | /opt/ibm/wlp/usr/servers/apmui/logs        | messages.log                                  | APM UI server standard error messages.  |
|  |  | trace.log                                     | APM UI server trace log.  |
|  |  | console.log                                   | APM UI server standard output containing startup, session, transaction, and shutdown information.   |
|  |  | APM_UI.log                                    | APM UI process log.   |
|  |  | derby.log                                     | APM UI Derby log.   |
|  |  | itp.log                                       | IT Portal log containing client and server information.   |

| Table 292. Log files that are collected by the collectLogs.sh script (continued) |  |                                   |   |
|--|--|-----------------------------------|---|
| Component  | Log directory                            | Log file name                     | Description                               |
| APM UI FFDC  | /opt/ibm/wlp/usr/servers/apmui/logs/ffdc | ffdc_date_time.N.log              | First failure data capture logs.          |
|  |  | exception_summary_date_time.N.log | Exception summaries from FFDC processing. |

## Collecting monitoring agent logs for IBM Support

Use the problem determination collection tool, *pdcollect*, to gather required logs and other problem determination information that is requested by IBM Support for monitoring agents. The PD collector tool is installed with each monitoring agent.

### Before you begin

Root or administrator permission is required for the PD collector tool to collect system information from the monitoring agents. You can review the agent logs individually in the following folders:

- **Windows** [64-bit] `install_dir\TMAITM6_x64\logs`
- **Windows** [32-bit] `install_dir\TMAITM6\logs`
- **Linux** | **UNIX** `install_dir/logs`

**Restriction:** It is only possible to run one instance of the *pdcollect* script.

### About this task

The default location of *install\_dir* is:

- **Windows** `C:\IBM\APM`
- **Linux** `/opt/ibm/apm/agent`
- **AIX** `/opt/ibm/apm/agent`

To run the PD collector tool, complete the following steps:

### Procedure

1. On the command line, change to the agent directory:

- **Linux** | **UNIX** `install_dir/bin`
- **Windows** `install_dir\BIN`

2. Run the following command:

- **Linux** | **UNIX** `./pdcollect`
- **Windows** `pdcollect`

A file with a time stamp in the file name is generated in the `tmp` directory, such as `/tmp/pdcollect-nc049021.tar.Z`.

3. Send the output files to your IBM Support representative.

## Chapter 14. Agent Builder

The IBM Agent Builder tool provides a graphical user interface to help you create, modify, debug, and package agents for monitoring data sources in IBM Cloud Application Performance Management.

### Overview of Agent Builder

You can use IBM Agent Builder to create and modify custom agents that extend the monitoring capabilities of an IBM Tivoli Monitoring, IBM Cloud Application Performance Management, IBM Cloud Pak for Multicloud Management environment. A custom agent uses either of these environments to monitor any type of in-house or customized software.

Agent Builder is based on Eclipse, an open source integrated development environment.

Agent Builder includes the following features for the Tivoli Monitoring and Cloud APM environments:

#### Define and modify agents

You can create and modify agents. The agents collect and analyze data about the state and performance of different resources, such as disks, memory, processor, or applications, and provide this data to the monitoring environment.

#### Test and prepare agents for deployment

You can test an agent within Agent Builder, collecting data on the host where Agent Builder runs (in some cases you can collect information from a different host too). You can package the agent for easy distribution and deployment.

The following additional features are available for Tivoli Monitoring:

#### Custom workspaces, situations and Take Action commands

You can use Agent Builder to package additional workspaces, situations and Take Action commands as application support extensions with a new or existing agent running in the Tivoli Monitoring environment

#### Report data models

You can use Agent Builder to generate a Cognos data model which you can use to build Tivoli Common Reporting reports. These reports can be packaged as part of your agent image.

## Common Agent Builder procedures

The following table lists the main procedures that you can complete with Agent Builder.

You can use Agent Builder to create agents for the IBM Tivoli Monitoring and IBM Cloud Application Performance Management environments. You can also use it to create application support extensions for the Tivoli Monitoring environment. Application support extensions are created by creating workspaces and situations to enhance one or more existing agents.

Before you use Agent Builder, you must install it. For instructions, see [“Installing and starting Agent Builder” on page 1390](#).

To create, test, and use an agent, complete the procedures in the following table in the order that they are listed.

| Table 293. Quick-reference information for creating agents  |   |
|---|---|
| Goal  | Refer to  |
| Create an agent by using the <b>Agent</b> wizard.   | <ul style="list-style-type: none"><li>• <a href="#">“Creating an agent” on page 1395</a></li></ul>  |
| Create data sources and attributes for your agent.<br><b>Important:</b> For a Cloud APM environment, a summary dashboard can display up to approximately five attributes; one of the attributes must denote overall agent or subnode status.  | <ul style="list-style-type: none"><li>• <a href="#">“Editing data source and attribute properties” on page 1415</a></li></ul>   |
| For the Tivoli Monitoring environment, create workspaces and situations for your agent. <ul style="list-style-type: none"><li>• Running at least Tivoli Monitoring Version 6.1 Fix Pack 1</li><li>• Setting the Tivoli Universal Agent solution version back to "00"</li><li>• Setting the value for "AppTag"</li></ul> | <ul style="list-style-type: none"><li>• <a href="#">“Creating workspaces, Take Action commands, and situations” on page 1585</a></li><li>• <a href="#">“Importing application support files” on page 1621</a></li></ul>   |
| For the Cloud APM environment, create resource definitions and dashboards for your agent.   | <ul style="list-style-type: none"><li>• <a href="#">“Preparing the agent for Cloud APM” on page 1590</a></li></ul>  |
| For the Tivoli Monitoring environment, create Cognos data models for reports for your agent.  | <ul style="list-style-type: none"><li>• <a href="#">“Cognos data model generation” on page 1690</a></li></ul>   |
| Test and debug your created agent, ensuring the availability of monitoring information.   | <ul style="list-style-type: none"><li>• <a href="#">“Testing your agent in Agent Builder” on page 1595</a></li><li>• <a href="#">“Command-line options” on page 1630</a></li><li>• <a href="#">“Using the Agent Editor to modify the agent” on page 1398</a>.</li></ul> |
| Generate an installation package and install the agent on the monitored host.   | <ul style="list-style-type: none"><li>• <a href="#">“Installing an agent” on page 1604</a></li></ul>  |
| Remove an agent that you created with the Agent Builder.  | <ul style="list-style-type: none"><li>• <a href="#">“Uninstalling an agent” on page 1619</a></li></ul>  |

You can also use Agent Builder for packaging custom workspaces, situations, and Take Action commands as application support extensions for existing agents. These functions are available only for the Tivoli Monitoring environment:

| Table 294. Quick-reference information for other functions      |  |
|---|--|
| Goal  | Refer to   |
| Create custom workspaces, situations, and Take Action commands. | <ul style="list-style-type: none"> <li>• <a href="#">“Creating workspaces, Take Action commands, and situations” on page 1585</a></li> </ul>   |
| Package your application support extension.                     | <ul style="list-style-type: none"> <li>• <a href="#">“Creating application support extensions for existing agents” on page 1688</a></li> </ul> |
| Build custom bundles.   | <ul style="list-style-type: none"> <li>• <a href="#">“Creating Non-agent file bundles” on page 1710</a></li> </ul>                             |

## Data sources and data sets

An agent can monitor information from one or several data sources. It presents the information to the monitoring infrastructure as attributes, which are organized into data sets.

When you create an agent, you must define a *data source* for it. You can add more data sources. The data source defines how the agent gathers the monitoring information.

You can use Agent Builder to create agents that use data sources monitoring information from the following *data providers*:

- Process and service availability
- Network system availability (using ICMP ping)
- Command return codes
- Script output
- The Windows Event Log
- Windows Management Instrumentation (WMI)
- Windows Performance Monitor (Perfmon)
- Simple Network Management Protocol (SNMP)
- SNMP Events
- Hypertext Transfer Protocol (HTTP) availability and response time
- SOAP or other HTTP data source
- Java Database Connectivity (JDBC)
- Java application programming interface (API)
- Java Management Extensions (JMX)
- Common Information Model (CIM)
- Log files
- AIX binary logs
- Socket

You can also use other development tools to create custom monitoring applications that pass information to the agent through log, script output, and Java API data sources.

When you add a data source, Agent Builder adds the corresponding *data set* to the agent. The data set organizes the information that is presented to the monitoring environment. In IBM Tivoli Monitoring, a data set is known as an *attribute group*.

A data set can consist of several *attributes*, which are values that the data source provides. Each time the monitoring environment queries the agent, it fetches values from data sources and returns them as attributes in data sets.

Some data sources can return several *rows* of attribute values in the same query, for example, if the data source monitors several services at once.

Most data sources present information as one data set. SNMP and JMX data sources can, depending on the configuration, provide diverse sets of information. When you add an SNMP or JMX data source, Agent Builder creates multiple data sets to accommodate this information.

You can edit the data sets to filter the data and to create additional *derived* attributes, that is, attributes that are calculated from existing attributes using a formula. You can also join data sets, creating a new data set with information from two or more data sets. In this way, users can view combined information from different data sources.

In IBM Tivoli Monitoring, you can view all attribute content. You can also create workspaces that present information from all agent data sets in a customized view. You can use IBM Tivoli Monitoring to create situations that are triggered when any attribute reaches a certain value. A situation can issue an alert and to call a system command.

In IBM Cloud Application Performance Management, you must define a *summary* dashboard for the agent, selecting up to five attributes that are visible in the dashboard. You can also define a *detail* dashboard that displays information from any data sets as tables. You can create thresholds that are triggered when any attribute reaches a certain value; you are not required to add this attribute to the dashboard. A threshold can issue alerts.

In IBM Cloud Pak for Multicloud Management you define resources for the agent, select attributes to be displayed, and identify important metrics to chart.

## Monitoring multiple servers or instances of a server

An agent can monitor multiple servers, including multiple instances of the same server. There are two ways of creating such agents: multiple instances of an agent and subnodes within an agent.

Multiple instances are a standard way to monitor application servers that can have a number of similar instances on the same host. Many standard agents in IBM Tivoli Monitoring and IBM Cloud Application Performance Management support multiple instances.

With *multiple instances*, you install an agent on a monitored hosts and then configure one or several instances, setting a name for every instance. Configure an instance of the agent for each instance of the server that you want to monitor. Each instance is a separate identical copy of the agent, and it can be started and stopped separately.

You can also define one or several types of *subnode* within an agent. Each type must correspond to a different type of resource that an agent can monitor. A subnode type contains data sources and data sets; you can also define data sources and data sets at agent level, outside any subnode. When you install the agent on a host, you can configure the required number of subnodes of each type; for every subnode type, you can set the number of subnodes independently. For IBM Cloud Application Performance Management, you can create a dashboard for the agent and a separate dashboard for each subnode.

Subnodes require different configuration steps on the monitored host. Also, to reconfigure, add or remove a subnode, you must stop and restart the entire agent; an instance can be reconfigured, added, or removed without affecting other instances. However, subnodes have a number of advantages:

- With subnodes, you can monitor a large amount of server instances while consuming less resources. As a guideline, the number of agent instances of a specific type supported on a single system is 10. But an agent can monitor up to 100 local or remote servers using subnodes.
- One agent can include subnode types for a few different kinds of servers. On the monitored system, you can configure any number of subnodes of each type. You can use this feature to conserve resources further.
- An agent with subnodes can supply system-wide data on the agent level.

You can define both multiple instances and subnodes for the same agent. In this case, each instance can include a number of subnodes. You can stop and restart each instance independently of other instances; all subnodes in an instance are stopped and restarted together.

## Testing, installing, and configuring an agent

You can create an installation package for an agent and then install it on any number of monitored hosts. For some data sources, you need to set configuration values for collecting data.

After defining data sources and attributes for an agent, you can test it by running it within Agent Builder. You can test a single data set (attribute group) or the full agent.

To test the agent more extensively and to use it, you can create an installation image. This image provides scripts for installing and configuring the agent on any monitored host.

**Tip:** Before installing the agent, ensure that the operating system agent for your monitoring environment (IBM Tivoli Monitoring, IBM Cloud Application Performance Management, or IBM Cloud Pak for Multicloud Management) is installed on the host.

After installing the agent, you might need to configure it. If the agent supports multiple instances, you must configure the agent to create at least one instance.

Some data sources require additional configuration values; for example, for the SNMP data source, you must configure the IP address of the host that you monitor using the SNMP protocol. Use the configuration script, which is deployed by the installation package, to set these values.

Alternatively, you can set these values in Agent Builder before creating the installation image. In this case, you do not have to set them again on the monitored hosts.

**Tip:** The help files for your custom agent might not display in Help Contents after the Cloud APM server is upgraded. To display the help files, complete these steps:

1. Download the latest version of IBM Agent Builder.
2. Re-create your custom agent. Make sure to assign a higher version number, fix pack, or patch level in the Agent Information page.
3. Install your custom agent on the monitored host.
4. From the Cloud APM console, click **Help > Help Contents** from the navigation bar. Your custom agent help is displayed.

## Operating system requirements

Agents that are created by Agent Builder are supported on various operating systems, depending on the monitoring environment and on the settings you select when creating the agent.

In a Tivoli Monitoring environment, agents that are created by Agent Builder can support the following operating systems:

- AIX
- HP-UX
- Linux
- Solaris
- Windows

The agents support the same operating system versions as the OS agents. For details, access the [Software Product Compatibility Reports](#) website. Search for the Tivoli Monitoring product name and select the OS Agents & TEMA (Tivoli Enterprise Monitoring Agent) component check box.

In an IBM Cloud Application Performance Management environment, agents that are created by Agent Builder can support the following operating systems:

- AIX
- Linux
- Windows

The agents support the same versions as the OS agents. For details, use the links in the Component reports section of [System requirements \(APM Developer Center\)](#).

To run your monitoring agent in an Tivoli Monitoring environment, install the appropriate operating system agent on every monitored system where your agent runs.

To run your monitoring agent in an IBM Cloud Application Performance Management environment, install any of the agents shipped with IBM Cloud Application Performance Management on every monitored system where your agent runs.

**Note:** Agent Builder browsers operate on the data sources and information accessible from the system on which the Agent Builder is run. Ensure that you run Agent Builder on either of the following types of systems:

- A system that runs on the same level as the operating system and monitored applications for which you are developing the agent
- A system that connects to another system that runs on the same level as the operating system and monitored applications for which you are developing the agent

## Features specific to IBM Tivoli Monitoring

Agent Builder provides several features that apply only to IBM Tivoli Monitoring.

You can use navigator groups to organize the data that the agent displays in the IBM Tivoli Monitoring navigator views and workspaces. A navigator group combines the data from several attribute groups (data sets) into a single view, while hiding the original separate data sets from the user.

You can use Tivoli Enterprise Portal to create workspaces, situations, and Take Action commands for your agent. You can then use Agent Builder to save the workspaces, situations, and Take Action commands as application support files and bundle them with the agent. Moreover, Agent Builder can also import workspaces, situations, and Take Action commands for other agents and create custom application support files for them.

Agent Builder can generate a Cognos data model for the agent. Use the data model to import agent information into the Cognos Framework Manager, a part of IBM Tivoli Common Reporting, for report creation.

## Installing and starting Agent Builder

---

Before you install IBM Agent Builder, ensure that your system meets the prerequisites. Then use the installation wizard or the silent installation procedure to install Agent Builder.

**Tip:** For information about installing or modifying an *agent*, see [“Installing an agent”](#) on page 1604.

## Prerequisites for installing and running Agent Builder

To install and run Agent Builder, your system must meet certain requirements.

To install the Agent Builder, ensure that you have:

- A system with a minimum of 1 GB of free disk space. Agents that you develop will require additional disk space.
- A supported operating system. Agent Builder can run on the following operating systems:
  -  Windows
  -  Linux (x86 64-bit only)
-  If you are using the Linux operating system, you must install the `libstdc++.so.5` library. You can install the following packages that provide this library:
  - On Red Hat Enterprise Linux, `compat-libstdc++-33`
  - On SUSE Enterprise Linux, `libstdc++-33`

**Windows** On a Windows system, you must be able to run Agent Builder as a user with Administrator permissions. These permissions ensure that Agent Builder has an environment consistent with the agents that are developed with it.

**Linux** On a Linux system, you can run Agent Builder as root or as an ordinary user. However, if you run it as an ordinary user, testing of agents will be limited and in some cases might not be available.

## Detailed system requirements for Agent Builder

Use the Software Product Compatibility Reports to view the detailed system requirements for Agent Builder.

Access the [Software Product Compatibility Reports](#) website. Search for the IBM Agent Builder product name.

## Installing Agent Builder

You can use the installation wizard or the silent installation procedure to install Agent Builder.

**Tip:** Before you install Agent Builder, uninstall any previous versions. For more information about uninstalling, see ([“Uninstalling Agent Builder” on page 1394](#)). None of your existing agent information is lost when you uninstall.

## Using the installation wizard to install Agent Builder

You can use the installation wizard to install IBM Agent Builder.

### Before you begin

Ensure that your system meets the prerequisites. For information about prerequisites, see [“Prerequisites for installing and running Agent Builder” on page 1390](#)

### Procedure

1. If you are not signed in to [IBM Marketplace](#), sign in with your IBMid and password and go to **Products and services**.

The **Products and services** page is available to active subscribers. If you have any issues, go to the [Cloud Application Performance Management Forum](#) or to [Marketplace support](#).

2. Download the Agent Builder installation archive file:
  - a) In the Cloud APM subscription box, click **Manage > Downloads**.
  - b) Select **Multi-Platform** as the operating system.
  - c) Select the IBM Agent Builder package.
  - d) Click **Download** and save `IBM_Agent_Builder_Install.tar` to your system.
3. Extract the installation archive file.
4. Use the following command in the extracted image directory to start the installation:

- **Windows** `setup.bat`
- **Linux** **UNIX** `./setup.sh`

**Important:** Run the installation program with the same user ID that you intend to run the Agent Builder with.

5. When the **IBM Agent Builder** window opens, select your language, and click **OK**.
6. On the **Introduction** page, click **Next**.
7. On the **Software License Agreement** page, click **I accept the terms in the license agreement**, and click **Next**.
8. On the **Choose Install Folder** page, click one of the following options:

- **Next** to install Agent Builder to the directory specified in the **Where Would You Like to Install?** field.
- **Restore Default Folder** to install the Agent Builder in a default directory.
- **Choose** to select a different directory.

**Note:** The directory name that you choose must not contain the following characters:

!  
#  
%  
;

If it includes any of these characters, Agent Builder might not start.

9. On the **Pre-Installation Summary** page, click **Install**.
10. On the **Installing IBM Agent Builder** page, wait for the **Install Complete** page to open, then click **Done**.

## Results

**Windows** After the Agent Builder is installed, an option is added to the Start menu and an Agent Builder icon is added to your desktop. The installation log files are in *install\_dir* \IBM\_Agent\_Builder\_InstallLog.xml.

**Linux** **UNIX** After the Agent Builder is installed, the Agent Builder executable file is named *Install\_Location/agentbuilder*. The installation log files are in *install\_dir* /IBM\_Agent\_Builder\_InstallLog.xml.

## Silent installation

You can install Agent Builder by using a silent installation method. This method does not require a graphical environment and can be easily replicated on several hosts.

## About this task

The silent installation options file, *installer.properties*, is included in the installation image at the root of the installation directory. You must modify this file to meet your needs, and then run the silent installer. You can copy this file to other hosts and quickly install Agent Builder on all of them.

## Procedure

1. If you are not signed in to [IBM Marketplace](#), sign in with your IBMid and password and go to **Products and services**.  
The **Products and services** page is available to active subscribers. If you have any issues, go to the [Cloud Application Performance Management Forum](#) or to [Marketplace support](#).
2. Download the Agent Builder installation archive file:
  - a) In the Cloud APM subscription box, click **Manage > Downloads**.
  - b) Select **Multi-Platform** as the operating system.
  - c) Select the IBM Agent Builder package.
  - d) Click **Download** and save *IBM\_Agent\_Builder\_Install.tar* to your system.
3. Extract the installation archive file.
4. Create a copy of the *installer.properties* file, which is located in the installation image directory.
5. Edit the new file to suit your needs. An example of the contents of this file is:

```
# -----
# IBM Agent Builder
#
# (C) Copyright IBM Corporation 2009. All rights reserved.
```

```

#
# Sample response file for silent install
#
# To use this file, use the following command:
#
# Windows:
#   setup.bat -i silent -f <path>\installer.properties
#
# Linux or AIX:
#   setup.sh -i silent -f <path>/installer.properties
#
# Where
#   <path> is a fully-qualified path to the installer.properties
#   file (including the drive letter or UNC path name on Windows).
#   <path> cannot contain spaces.
# -----

# -----
# This property indicates that the license has been accepted
# -----
# LICENSE_ACCEPTED=FALSE

# -----
# This property specifies the install directory
#
# On Windows, the default is:
#   C:\Program Files (x86)\IBM\AgentBuilder
#
# On Linux, the default is:
#   /opt/ibm/AgentBuilder
# -----
#USER_INSTALL_DIR=C:\Program Files (x86)\IBM\AgentBuilder
#USER_INSTALL_DIR=/opt/ibm/AgentBuilder

```

6. Start the silent installation by running the following command in the extracted installation image directory:

**Windows** `setup.bat -i silent -f path/installer.properties`

**Linux** **UNIX** `./setup.sh -i silent -f path/installer.properties`

Where *path* is the fully-qualified path to the `installer.properties` file (including the drive letter or UNC path name on Windows). The path cannot contain spaces.

## Starting Agent Builder

After installing Agent Builder, you can start it.

### Procedure

- Start the Agent Builder by using one of the following methods
  - **Windows** On Windows systems:
    - From a command-line type: `Install_Location\agentbuilder.exe`.
    - Select **Start > All Programs > IBM > Agent Builder**.
    - Click the **Agent Builder desktop icon**.
  - **Linux** On Linux systems, start the following executable file: `INSTALL_DIR/agentbuilder`

**Note:** When you run the Agent Builder, it prompts you for the location of your workspace directory. The files that create your agents are saved in that directory. You can designate any directory as your workspace.

## Setting the default browser in Agent Builder

**Linux** On Linux systems, you might need to set the Agent Builder default browser so that help panels are displayed.

### Procedure

1. Select **Window > Preferences** to open the **Preferences** window.
2. Select and expand the **General** node.
3. Select **Web Browser**.
4. Select **Use external web browser**.
5. Select the browser that you want to use.
6. Optional: To add a web browser, complete the following steps
  - a) Click **New**.
  - b) In the **Name** field, enter a descriptive name for the browser.
  - c) In the **Location** field, enter the full path to the browser executable file .
  - d) Click **OK**.
7. Click **OK**.

## Setting the default Time Stamping Authority in Agent Builder

You can set the Time Stamping Authority for JAR files in the Agent Builder **Preferences** window. If the default Time Stamping Authority signing certificate expires, by setting a new authority, you can continue to verify JAR files.

### Procedure

1. Select **Window > Preferences** to open the **Preferences** window.
2. Select and expand the **IBM Agent Builder** node.
3. Select **Jar Signing**.
4. Select **Add time stamp to signed JAR files**.
5. Enter the URL of the Time Stamping Authority.
6. Click **OK**.

## Uninstalling Agent Builder

Depending on your operating system, you can use different procedures to uninstall Agent Builder.

### Procedure

- **Linux**  
On Linux systems, run the following command:
  - a) `INSTALL_DIR/uninstall/uninstaller`  
where `INSTALL_DIR` is the name of the directory where Agent Builder is installed.
- **Windows**  
On Windows 7, Windows Server 2008 R2, and later versions of Windows, complete the following steps:
  - a) Open Windows Programs and Features by selecting **Start > Control Panel > Programs > Programs and Features**.
  - b) Select **IBM Agent Builder** from the list of installed programs.
  - c) Click **Uninstall/Change**.
  - d) Click **Uninstall** on the **Uninstall IBM Agent Builder** page.

e) Click **Done** on the **Uninstall Complete** page.

**Tip:** On Windows 7 and Windows Server 2008 R2, you can also go to the **Windows Programs and Features** window by selecting **Start > Computer > Uninstall or change a program**. Then, continue from step “2” on page 1394.

- **Windows**  
On other Windows systems, complete the following steps:
  - a) From the Windows Control Panel, select **Add/Remove Programs**.
  - b) Click **IBM Agent Builder**.
  - c) Click **Change/Remove**.
- On all operating systems, you can also use the silent uninstallation method. Start the silent uninstallation by running the following command:
  - **Windows** On Windows systems, `INSTALL_DIR/uninstall/uninstaller.exe -i silent`
  - **Linux** On Linux systems, `INSTALL_DIR/uninstall/uninstaller -i silent`

## Silent uninstallation

You can use the silent uninstallation method to uninstall.

### Procedure

- Start the silent uninstallation by running the following command:

```
INSTALL_DIR/uninstall/uninstaller[.exe] -i silent
```

## Creating an agent

To start creating an agent in Agent Builder, use the new agent wizard. With this wizard you can set the basic agent configuration and create one data source. You can then work on the agent in Agent Builder to add more data sources and other options, including subnodes and navigator groups.

## Naming and configuring the agent

Use the **Agent** wizard to name your agent, set its version, supported operating systems, and other configuration settings.

### Procedure

1. Use one of the following ways to start the new agent wizard:
  - a) Click the  **Create New Agent** icon on the toolbar.
  - b) From the Main menu, select **File > New > Agent**.
  - c) From the Main menu, select **File > New > Other**. In the **Select a Wizard** page, double-click the **Agent Builder** folder, then double-click **Agent**.The **Agent** wizard opens.
2. Click **Next**.
3. In the **New Agent Project** page, set the name of the project in the **Project name** field. Agent Builder uses this name for the folder that contains the agent files. You can optionally change the following settings:
  - If you want to store the agent files in a different location, clear **Use default location** and click **Browse** to select the new directory in the **Location** field.
  - You can change how the Eclipse Navigator View displays resources by adding them to various working sets. For more information, see the Eclipse help. To add the agent to Eclipse working sets,

select **Add project to working sets** and click the **Select** button to add the sets to the **Working sets** field.

4. Click **Next**.

5. In the **General Information** page, configure the following settings:

- Type the copyright statement that you want to use for your new agents in the **Copyright** field. This statement must meet your legal requirements for copyrights. This copyright statement is inserted into all files that are generated for the agent; you can edit it later.
- Select the operating systems for which you want your agent to be built.

**Important:** If you want to run a full test of the agent inside Agent Builder (for instructions, see [“Full agent testing”](#) on page 1599), ensure that:

- If you are running Agent Builder on Windows, the 32-bit version of the operating system is installed.
- If you are running Agent Builder on Linux, the 64-bit version of the operating system is installed.

**Important:** In some rare cases, you might need to install your agent on a 64-bit system where only a 32-bit operating system agent is installed. In this case, ensure that the 64-bit version of the operating system is not selected and the 32-bit version is selected.

**Important:** 64-bit Windows Server 2003 R2 and earlier Windows systems are not supported by the agents created using Agent Builder.

6. Click **Next**.

7. In the **Agent Information** page, configure the following settings:

- Set the service name for the agent in the **Service name** field. The name is displayed in the **Manage Tivoli Monitoring Services** window in an IBM Tivoli Monitoring environment and in the **Manage Monitoring Services** utility and Threshold editor in an IBM Cloud Application Performance Management. On Windows systems, it is also the name of the Windows service that runs the agent. The full service name always starts with `Monitoring Agent for`. You enter the remaining part of the name, which normally describes the service that this agent monitors. The name can contain letters, numbers, spaces, and underscores.
- Set a three-character product code for the agent in the **Product code** field. A product code is required for both IBM Tivoli Monitoring and IBM Cloud Application Performance Management. A range of product codes is reserved for use with the Agent Builder. The permitted values are K00-K99, K{0-2}{A-Z}, and K{4-9}{A-Z}.

**Important:** These values are for internal use only and are not intended for agents that are to be shared or sold outside your organization. If you are creating an agent to be shared with others, you must send a note to [toolkit@us.ibm.com](mailto:toolkit@us.ibm.com) to reserve a product code. The request for a product code must include a description of the agent to be built. A product code is then assigned, registered, and returned to you. When you receive the three-letter product code, you are told how to enable the Agent Builder to use the assigned product code.

- Set a string that uniquely identifies the organization that develops the agent in the **Company identifier** field (IBM is reserved). You can take it from the URL of your company; for example, if the company website is `mycompany.com`, use the text `mycompany`.
- Set a string that uniquely identifies the agent in the **Agent identifier** field. By default, Agent Builder sets the Agent identifier to be the same as the Product code.

**Important:** The combined length of the **Agent identifier** field and the **Company identifier** field cannot exceed 11 characters.

- Set the agent version in the **Version** field. The agent version contains three digits in the format `V.R.R`, where:

V = Version

R = Release

*R* = Release

For displaying in the monitoring environment, the *V.R.R* value is converted into the following format: 0*V*.*RR*.00.00

**Tip:** In the agent editor, a **patch level** field is available. The **patch level** field can be used when you release a fix for an agent, without updating the version.

- If you want your agent to support multiple instances, select the **Support multiple instances of this agent** check box. You can use multiple instances of an agent to monitor several instances of an application on the same host, or to use an agent installed on one host to monitor several software servers on different hosts. When you install an agent that support multiple instances, you can create and configure as many instances as necessary.

## What to do next

Click **Next** to define an initial data source for your agent. For more information, see [“Defining initial data sources” on page 1397](#)

## Defining initial data sources

When creating an agent, define the initial data that the agent is to monitor. You can add more data sources later in the agent editor.

### About this task

Define the data sources that your new agent is to monitor by using the **Agent Initial Data Source** page. For detailed instructions about creating data sources from various data providers, see [“Defining and testing data sources” on page 1441](#).

### Procedure

1. On the **Agent Initial Data Source** page, select one of the **Monitoring Data Categories** and one of the **Data Sources**.
2. Click **Next** The wizard guides you through the process of defining and configuring any of the data collection types that you specify.  
  
**Tip:** You can use this wizard to define a data source or to add a subnode or navigator group for organizing the agent. For more information about subnodes, see [“Using subnodes” on page 1561](#). For more information about navigator groups, which are used only for IBM Tivoli Monitoring, see [“Creating a navigator group” on page 1560](#).
3. If you defined a new data source that might return more than one data row, you are prompted to select key attributes. For more information, see [“Selecting key attributes” on page 1397](#).
4. After you define the first data source, the **Data Source Definition** window displays. To add another data source, select the agent, or a subnode or navigator group if one is present, and click the **Add to Selected** button.
5. To finish defining data sources, click **Finish**. Aent Builder creates the new agent and opens it in the agent editor.

## Selecting key attributes

When an attribute group returns more than one data row, you must select key attributes.

### About this task

When an attribute group can return more than one data row, each row represents an entity that is being monitored. Each time monitored data is sampled, the monitoring environment matches a row to the entity that is being monitored and to previous samples for that entity. This matching is done with key attributes. One or more attributes in the attribute group can be identified as key attributes. These key attributes,

when taken together, distinguish one monitored entity from another. The key attributes do not change from one sample to the next for the same monitored entity.

Rate and delta attributes are calculated by comparing the current sample to the previous sample. Identical key attributes ensure that the agent is comparing values for the same monitored entity. Similarly, the summarization and pruning agent summarizes samples that have identical key attributes. In addition, any attribute that is set as a key attribute can also be used as a "Display item" in a situation.

You specify the details about your new data source in the **Agent Initial Data Source** page. If the selected data source might return multiple data rows, Agent Builder can sometimes detect the key attributes. Otherwise, it prompts you to select key attributes.

## Procedure

- On the **Select key attributes** page, take one of the following steps:
  - Click one or more attributes from the list that are the key attributes for this entity. To select more than one attribute, hold down the Ctrl key.
  - If this attribute group returns only one row, select **Produces a single data row**. If this option is selected, no key attributes are necessary because only one monitored entity is ever reported in this attribute group.

## Using the Agent Editor to modify the agent

---

Use the Agent Editor to change, save, and commit a version of your agent.

You can create a new agent in Agent Builder; for more information, see [“Creating an agent” on page 1395](#). After creating an agent, you can modify it using the Agent Editor.

To open an agent that you created in Agent Builder in the Agent Editor, in the **Project Explorer** pane, find the name of the agent and expand it. Under the name of the agent, double-click **Agent Definition**. Alternatively, double-click the `itm_toolkit_agent.xml` filename.

The Agent Editor is a multi-page Eclipse editor that you can use to modify the properties of an existing agent. Each page in the editor corresponds to a specific function of the agent.

The list of available pages is shown in the Outline view under the **Agent Definition** node. You can easily switch to another page by clicking a node in the Outline view. If the Outline view is missing, or hidden behind another view, you can reset the Agent Definition perspective. Reset the perspective by selecting **Window > Reset Perspective**. Alternatively, right-click the **Agent Definition** tab and select **Reset** from the menu.

**Note:** For detailed information and procedures for creating an agent, see [“Creating an agent” on page 1395](#).

The following pages are included in the Agent Editor:

- [“Agent Information page” on page 1398](#)
- [Data Source Definition page](#)
- [Runtime Configuration Information page](#)
- [Agent XML Editor page \(itm\\_toolkit\\_agent.xml\)](#)

**Note:** When you view an Editor page, you can also switch to another page by clicking the tab for the page. Some pages show tabs only when they are selected in the Outline view. You can force a page to have a tab even when it is not selected. To force a page to have a tab, click the pin icon so that the pin in the icon points toward the page.

### Agent Information page

The **Agent Information** page is the main page of the Agent Editor.

The **Agent Information** page contains the following information:

- General agent information, including the agent service name and the product code. You can click **Advanced** to set different names for different use, but this setting is normally not needed.
- Agent Content information
  - **Default Operating Systems** link
  - **Self-Describing Agent** link
  - **Environment Variables** link
  - **Watchdog Information** link
  - **Cognos Information** link
  - **Data sources** link
  - **Runtime Configuration** link
  - **Resources** link
  - **Dashboards** link
- **Test Agent** link
- **Generate Agent Wizard** link
- **Commit Agent Version** link

## Configuring the time for transient error messages

Agent Editor wizards sometimes display transient error messages. A message is displayed for a short time (by default, 3 seconds) in the header of the wizard. You can configure the duration for which these messages are displayed. To change this setting:

1. Select **Window > Preferences** from the Agent Builder menu bar. The **Preferences** window opens.
2. Select **Agent Builder**.
3. Set the **Time (seconds) that transient error message are displayed** setting.
4. Click **OK**.

## Default operating systems

Use the **Default Operating Systems** page to change the operating systems for which your agent is built.

### Procedure

- To open the **Default Operating Systems** page, click **Default Operating Systems** in the **Agent Content** section of the **Agent Information** page or the **Default Operating Systems** node in the Outline View.
- In the **Default Operating Systems** page, select the operating systems that your agent must support.

When you generate an installation package for the agent, Agent Builder adds files for the selected operating systems to the package. Data sources that you add to your agent that are not specific to the Windows operating system are available on any of the selected operating systems. The operating systems on which any specific data source is available can be changed from this default selection. To change the Operating Systems available for a specific data source, use the **Operating Systems** pane of the **Data Source Definition** page. If default operating systems are not selected, operating systems must be selected for each specific data source on the **Data Source Definition** page.

**Important:** If you want to run a full test of the agent inside Agent Builder (for instructions, see [“Full agent testing”](#) on page 1599), ensure that:

- If you are running Agent Builder on Windows, the 32-bit version of the operating system is installed.
- If you are running Agent Builder on Linux, the 64-bit version of the operating system is installed.

**Important:** In some rare cases, you might need to install your agent on a 64-bit system where only a 32-bit operating system agent is installed. In this case, ensure that the 64-bit version of the operating system is not selected and the 32-bit version is selected.

## Self-Describing Agent

For the IBM Tivoli Monitoring environment, use the **Self-Describing Agent** page to specify whether the agent's support files are bundled with the agent. For the IBM Cloud Application Performance Management environment, you must leave Self-Describing Agent enabled.

### Procedure

- To open the **Self-Describing Agent** page, click **Self-Describing Agent** in the **Agent Content** section of the **Agent Information** page or the **Self-Describing Agent** node in the Outline View.

Self-description is enabled by default for all new agents that are created with Agent Builder 6.2.3 or later. If the agent is for the IBM Cloud Application Performance Management environment, self-description must be enabled.

When self-description is enabled for an agent, application support packages are included in the agent image. The inclusion enables the agent to seed the support files for the Tivoli Enterprise Monitoring Server, Tivoli Enterprise Portal Server, the Tivoli Enterprise Portal Browser. For more information about self-describing agents, see the *IBM Tivoli Monitoring Installation and Setup Guide* and the *IBM Tivoli Monitoring Administrator's Guide*. In an IBM Cloud Application Performance Management environment, self-description enables the agent to seed support files onto the Cloud APM server; the seeding is a required step in the environment.

**Note:** In a IBM Tivoli Monitoring environment, you must have Tivoli Monitoring version 6.2.3 or later installed for the self-describing agent feature to work, and self-description must be enabled in Tivoli Monitoring. By default self-description is turned off in Tivoli Monitoring.

**Note:** Selecting the **Enable self-description for this agent** check box does not prevent your agent from working on previous versions of Tivoli Monitoring.

## Environment variables

Use the **Environment Variables** page to view and modify environment variables that are available to your agent while it is running.

### Before you begin

For more information about the **Agent Editor** and **Agent Information** page, see [“Using the Agent Editor to modify the agent” on page 1398](#).

### About this task

The environment variables can be defined by you, for access inside a script, or predefined variables that cause the agent to behave in a certain way. See [“List of environment variables” on page 1401](#) for a list of predefined variables.

### Procedure

- To open the **Environment Variables** page, click **Environment Variables** in the **Agent Content** section of the **Agent Information** page. Alternatively, click **Environment Variables** node in the **Outline** view.
- In the **Environment Variables** page, click **Add** to add a new variable. Alternatively, to edit an existing variable, select it and click **Edit**.
- In the **Environment Variable Information** window, set the following values:
  - In the **Name** field, type a variable name or select a predefined name from the list.
  - In the **Value** field, type a value for the variable if you want to set a variable for the agent. If you do not enter a value, the agent propagates a value for the existing variable.
  - In the **Description** field, type a description of the variable, or keep the existing description of a predefined variable.

a) Click **OK**.

The new variable is listed in the table on the **Agent Information** page.

## List of environment variables

Use environment variables to control the behavior of the agent at run time.

Environment variables can be built into the agent by using the **Environment Variables** page. On Windows systems, environment variables are defined in the agent KXXENV file. On UNIX and Linux systems, these variables can be defined in the agent \$CANDLEHOME/config/XX.ini file, where XX is the two-character product code. The agent must be restarted for the new settings to take effect.

**Note:** Environment variables are not set correctly on a remote system that runs C Shell. Use a different shell if you want to use environment variables.

| Table 295. Environment variable descriptions including their default values and valid value ranges |   |   |   |
|--|---|---|---|
| Environment variable   | Default value                                 | Valid values  | Description   |
| CDP_DP_REFRESH_INTERVAL  | 60 if subnodes are defined, otherwise not set | Any positive integer (such as 3600 for a 1-hour interval)   | The interval, in seconds, at which attribute groups are updated in the background. If this variable is not set or is set to 0, background updates are disabled.<br>Use this variable to tune behavior so that the data is fresh enough without causing undue load on the application from which data is being collected. If a thread pool is configured (see variable CDP_DP_THREAD_POOL_SIZE), then the attribute groups can be refreshed in parallel. If there is no thread pool, the updates happen serially, which can take a long time. Logically equivalent to a thread pool size of 1.   |
| CDP_ATTRIBUTE_GROUP_REFRESH_INTERVAL   | Not Applicable                                | Any positive integer (such as 600 for a 10-minute interval) | Override the interval, in seconds, at which a particular attribute group is updated in the background when the agent is updating data in the background because CDP_DP_REFRESH_INTERVAL was set. This variable works in the same way as CDP_DP_REFRESH_INTERVAL except it targets only the specified attribute group.<br>The attribute group name in the variable name must be in uppercase, even if the actual attribute group name is not. If the CDP_DP_REFRESH_INTERVAL environment variable has not been set, the attribute group override does not take effect. You can simulate background collection for a subset of attribute groups by using a large value for CDP_DP_REFRESH_INTERVAL, such as 86400 for once a day. |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable          | Default value                                 | Valid values                            | Description  |
|-------------------------------|---|---|--|
| CDP_DP_THREAD_POOL_SIZE       | 15 if subnodes are defined, otherwise not set | Any non-negative integer                | <p>The number of threads that are created to run background data collections at an interval that is defined by CDP_DP_REFRESH_INTERVAL. If this variable is not set or is set to 0, there is no thread pool.</p> <p>If CDP_DP_THREAD_POOL_SIZE is set to a value greater than 1 and CDP_DP_REFRESH_INTERVAL is set to 0, the value of CDP_DP_THREAD_POOL_SIZE is ignored and data collection happens on demand.</p> <p>The Thread Pool Status attribute group shows how the thread pool is running. Use the Thread Pool Status to adjust the thread pool size and refresh interval for best results. By default, the query for this attribute group is not displayed on the agent Navigator tree. You might not remember to include the query in a custom workspace for the agent. However, you can easily view it by assigning the Thread Pool Status query to a base agent level workspace view.</p> |
| CDP_DP_CACHE_TTL              | 55  | Any integer greater than or equal to 1. | Data that is collected for an attribute group is cached for this number of seconds. Multiple requests for the same data in this time interval receive a cached copy of the data. This value applies to all attribute groups in the agent.  |
| CDP_ATTRIBUTE_GROUP_CACHE_TTL | Value of CDP_DP_CACHE_TTL                     | Any integer greater than or equal to 1. | Data that is collected for the particular specified attribute group is cached for this number of seconds. Multiple requests for the same data in this time interval receive a cached copy of the data. This value overrides CDP_DP_CACHE_TTL for the specified group. The attribute group name in the variable name must be in uppercase, even if the actual attribute group name is not.  |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable                        | Default value                                | Valid values                                     | Description  |
|---|--|--|--|
| CDP_DP_IMPATIENT_COLLECTOR_TIMEOUT          | 5 if subnodes are defined, otherwise not set | Any positive integer                             | The number of seconds to wait for a data collection before a timeout and cached data is returned, even if the cached data is stale. (Cached data is stale if older than CDP_DP_CACHE_TTL seconds). If this variable is not set, the agent waits until the data collection completes. The wait at times can make the Tivoli Enterprise Portal timeout and give up waiting. If no thread pool is configured, this variable is ignored and data collection is done synchronously. |
| CDP_JDBC_MAX_ROWS                           | 1000   | Any positive integer                             | The maximum number of rows of data that the JDBC data provider returns. A result set that contains more than this number of rows is processed only up to this maximum value. Queries can be developed to prevent too much data from being returned to IBM Tivoli Monitoring.   |
| CDP_NT_EVENT_LOG_GET_ALL_ENTRIES_FIRST_TIME | NO   | YES, NO  | If set to YES, the agent sends an event for every event in the Windows event log. If set to NO, only new events in the Windows event log are sent.   |
| CDP_NT_EVENT_LOG_CACHE_TIMEOUT              | 3600   | Any integer greater than or equal to 300.        | The number of seconds Windows Event log events are cached by the agent. All cached events are returned when the event log attribute group is queried.<br><br><b>Note:</b> This variable is no longer used. Use the CDP_PURE_EVENT_CACHE_SIZE variable.   |
| CDP_PURE_EVENT_CACHE_SIZE                   | 100  | Any positive integer greater than or equal to 1. | Maximum number of events to cache for a log file data source that is configured to process new records, for the Windows Event Log attribute group. And also for JMX monitors and notifications. Each new record in the log causes an event to be sent. This environment variable defines how many events are remembered in a cache by the agent. The cached values are returned when the attribute group is queried.   |
| CDP_DP_ACTION_TIMEOUT                       | 20 seconds                                   | Any positive integer greater than or equal to 1. | The number of seconds to wait for a Take Action that is being handled by the agent to complete.  |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable              | Default value                                 | Valid values                                      | Description   |
|-----------------------------------|---|---|---|
| CDP_DP_SCRIPT_TIMEOUT             | 30 seconds                                    | Any positive integer greater than or equal to 10. | The number of seconds to wait for the program started by a script-based attribute group to complete.  |
| CDP_DP_PING_TIMEOUT               | 30 seconds                                    | Any positive integer greater than or equal to 10. | The number of seconds to wait for the program started by a command return code to complete.<br><b>Note:</b> This variable is not related to the ICMP ping data provider.  |
| CDP_SNMP_MAX_RETRIES              | 2   | Any positive integer                              | The number of times to try sending the SNMP request again. The total number of requests that are sent to the SNMP agent is this value plus one if no responses are received.  |
| CDP_SNMP_RESPONSE_TIMEOUT         | 2 seconds                                     | Any positive integer                              | The number of seconds to wait for each SNMP request to timeout. Each row in an attribute group is a separate request. This timeout value is the number of seconds to wait for a response before you try again. The total timeout for a single row of data is $(\text{CDP\_SNMP\_MAX\_RETRIES} + 1) * \text{CDP\_SNMP\_RESPONSE\_TIMEOUT}$ . The total default timeout value is $(2+1) * 2 = 6$ seconds. |
| CDP_DP_HOSTNAME                   | Name of the first installed network interface | An IP address or host name                        | Sets the preferred host name (network interface) on a multiple interface system. Use this environment variable if the agent binds its listening ports to a non-default network interface address. Used by the SNMP data provider.<br><br>For Socket data sources, this variable applies if CDP_DP_ALLOW_REMOTE is also set.   |
| CDP_SNMP_ALLOW_DECREASING_OIDS    | NO  | YES, NO   | If set to YES, the SNMP data providers do not check whether returned OIDs are increasing. Set to YES with caution because the monitored agent might have problems that this check would normally catch.   |
| KUMP_DP_COPY_MODE_SAMPLE_INTERVAL | 60  | Wait time in seconds                              | For a log file data provider, specifies how long to wait before it rereads the contents of a file when the agent is defined to <b>Process all records when the file is sampled</b> . The time is specified in seconds.  |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable               | Default value | Valid values                               | Description  |
|------------------------------------|---------------|--|--|
| KUMP_MAXPROCESS                    | 100%          | 5-100%                                     | For a log file data provider, specifies the maximum processor usage to use to process file data. Values range from 5 to 100 percent. The default is 100 percent.   |
| KUMP_DP_SAMPLE_FACTOR              | 5             | Any non-negative integer                   | For a log file data provider, sets the sampling factor when you select <b>Process all records when the file is sampled</b> on the Agent Builder. This wait time ensures that patterns that span multiple records are written before scans are logged for the pattern.  |
| KUMP_DP_EVENT                      | 5             | Any non-negative integer                   | For a log file data provider, sets the sampling frequency for Event data, in seconds.  |
| KUMP_DP_FILE_EXIST_WAIT            | YES           | YES, NO                                    | For a log file data provider, specifies that the file monitoring thread continues to run if it detects that the monitored file is absent or empty. The thread waits for the file to exist, rechecks every few seconds, and starts or restarts monitoring when the file becomes available.  |
| KUMP_DP_FILE_SWITCH_CHECK_INTERVAL | 600           | Any non-negative integer                   | The frequency in seconds that the log file Data Provider searches for a different monitoring file to switch to when dynamic file name support is enabled.  |
| KUMP_DP_FILE_ROW_PAUSE_INCREMENT   | None          | Any non-negative integer                   | For a log file data provider, specifies how many file records are read before the file monitoring thread pauses. The pause is so that previous updates can be processed. Use this environment variable only if the monitored file receives high-volume bursts of new records and you are concerned that some record updates might be lost. |
| CDP_COLLECTION_TIMEOUT             | 60 seconds    | Any positive integer                       | The number of seconds that the agent waits for a response from a data collector that was started in another process. JMX, JDBC, HTTP, and SOAP data collectors are examples.   |
| CDP_SSH_TEMP_DIRECTORY             | . (period)    | Any valid path string on the remote system | For an SSH enabled Script data provider, specifies a location on the remote system. The script files that are provided with the agent are to be uploaded to this location. A relative location is relative to the user's home directory. The default of . (period) denotes the user's home directory.                                      |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable             | Default value  | Valid values   | Description   |
|----------------------------------|----------------|--|---|
| CDP_SSH_DEL_COMMAND              | rm -Rf         | Any valid delete command string on the remote system                               | For an SSH enabled Script data provider, specifies the command to start to delete the uploaded script files that are provided with the agent.   |
| CDP_SNMP_SEND_DELAY_FACTOR       | 0 milliseconds | Any positive integer   | The initial SNMP send is delayed from 0 to the number of milliseconds specified. This variable is only enabled if the thread pool is also enabled. The delay does not apply to all sends, only to the first send made by an attribute group. This variable is useful if the device that is being monitored can sometimes fail to respond correctly if it receives multiple requests at the same time. |
| CDP_ICMP_PING_REFRESH_INTERVAL   | 60 seconds     | Any integer greater than or equal to 1   | The systems in a device list file are pinged at this interval. If the pings use too much time, there is always a delay of at least CDP_PING_MIN_INTERVAL_DELAY seconds before the pings begin again. Data is refreshed no more frequently than this setting. Data can be refreshed less frequently based on the number of entries in the device list file and the time it takes to receive responses. |
| CDP_ICMP_PING_MIN_INTERVAL_DELAY | 30 seconds     | Any integer greater than or equal to 1 and less than the CDP Ping refresh interval | After the devices in a device list file are pinged, the next ping refresh interval does not begin until at least this number of seconds elapses.  |
| CDP_ICMP_PING_BURST              | 10             | Any integer greater than or equal to 0   | The number of pings that are sent before the agents pauses for the amount of time that is specified by the CDP_ICMP_PING_BURST_DELAY variable. A value of 0 disables this function.   |
| CDP_ICMP_PING_BURST_DELAY        | 10             | Any integer greater than or equal to 0   | The amount of time in milliseconds to wait after a set number of pings are sent as defined by the CDP_ICMP_PING_BURST variable. A value of 0 disables this function.  |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable                   | Default value     | Valid values   | Description   |
|--|-------------------|--|---|
| CDP_ICMP_PING_TIMEOUT                  | 2000 milliseconds | Any integer greater than or equal to 1               | The number of milliseconds to wait for a ping response. This setting applies to each ping attempt that is made. Ping attempts are made 3 times for each host. If no response is received from any of the 3 attempts, the total time waited for a reply is CDP_ICMP_PING_TIMEOUT multiplied by 3. By default, this value is 6000 milliseconds. Changing the value for CDP_ICMP_PING_TIMEOUT causes the default TIMEOUT enumeration for the Current Response Time attribute to no longer apply. Change the TIMEOUT enumeration to the new value of CDP_ICMP_PING_TIMEOUT multiplied by 3. |
| CDP_JDBC_CONNECTIONLESS                | false             | true, false  | If set to true, JDBC connections are closed after each data collection attempt. That is, all attribute groups attempt to create their own connection each time data is collected. Connections are not reused if this variable is enabled. If set to false, one connection to the database is made and that connection is shared among the attribute groups.   |
| CDP_SSH_EXCLUDED_ENVIRONMENT_VARIABLES | None              | A comma-separated list of environment variable names | For an SSH enabled Script data provider, specifies the set of local environment variables that must not be set in the environment of the remote system.   |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable                                | Default value   | Valid values                        | Description  |
|---|---|-------------------------------------|--|
| CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME                   | 0 seconds   | 0, 1, or any integer greater than 1 | <p>If set to 0, and CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS is not set to 1 or a greater integer, does not process events that are generated while the agent is shut down. 0 is the default.</p> <p>If set to 1, and CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS is not set to an integer greater than 1, processes all events that are generated while the agent is shut down.</p> <p>If set greater than 1, and CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS is not set greater than 1, processes events that are generated within that value in seconds of the current computer time. For example, if the value is set to 300, at startup, the agent processes all events that are generated within 300 seconds of the current time.</p> <p>Where a value greater than 1 is entered for both CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME and CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS variables, either that time interval of events or that number of events is processed. Which variable is chosen depends on which is matched first.</p> |
| CDP_DP_EVENT_LOG_Windows_Event_Log_MAX_BACKLOG_TIME | 0 seconds (Do not process missed events while the agent is shut down) | 0, 1, or any integer greater than 1 | If set to  |

Table 295. Environment variable descriptions including their default values and valid value ranges (continued)

| Environment variable                                  | Default value  | Valid values                                | Description  |
|---|--|---|--|
| CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS                   | 0 events   | 0, 1, or any integer greater than 1         | <p>If set to 0, and CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME variable is not set to 1 or a greater integer, does not process events that are generated while the agent is shut down. 0 is the default.</p> <p>If set to 1, and the CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME variable is not set to an integer greater than 1, processes all events that are generated while the agent is shut down.</p> <p>If set greater than 1, and CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME is not set greater than 1, processes at most that number of events that are generated while the agent is shut down. For example, if the value is set to 200, then at startup of the agent the 200 events that generated directly before startup are processed.</p> <p>Where a value greater than 1 is entered for both CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS and CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME, either that number of events or that time interval of events is processed. Which variable is chosen depends on which is matched first.</p> |
| CDP_DP_EVENT_LOG_Windows_Event_Log_MAX_BACKLOG_EVENTS | 0 events (Do not process missed events while the agent is shut down) | 0 or any integer greater than or equal to 1 | If set to  |
| CDP_HTTP_READ_TIMEOUT                                 | 10   | Any positive integer                        | The number of seconds to wait for a reply to the HTTP request.   |
| CDP_JAT_THREAD_POOL_SIZE                              | 15   | Any positive integer                        | The number of threads that are used by the Java providers for handling data collection requests. JMX, JDBC, HTTP, and SOAP data providers are the providers that can benefit from this thread pool.  |
| CDP_HTML_OBJECTS_THREAD_POOL_SIZE                     | 10   | Any positive integer                        | The number of threads that are used to download page objects that are found in URLs monitored with the HTTP data provider.   |

| Table 295. Environment variable descriptions including their default values and valid value ranges (continued) |               |                      |   |
|--|---------------|----------------------|---|
| Environment variable   | Default value | Valid values         | Description   |
| CDP_HTTP_SOAP_MAX_ROWS   | 500           | Any positive integer | The maximum number of rows that are returned by the HTTP SOAP data provider.  |
| CDP_DP_ALLOW_REMOTE  | NO            | NO, YES              | If set to Yes, the agent allows remote socket connections. If set to No, the agent allows only socket connections from the local host. No is the default. |
| CDP_DP_INITIAL_COLLECTION_DELAY  | varies        | Any positive integer | The number of seconds, after the agent starts, until the thread pool begins its scheduled data collections.   |

## Watchdog information

Use the **Watchdog Information** page to specify configuration information for the Agent Watchdog.

### About this task

To open the **Watchdog Information** page, click **Watchdog Information** in the **Agent Content** section of the **Agent Information** page. You can also select the **Watchdog Information** node in the Outline View.

You can specify the following configuration information for the Agent Watchdog:

- **Monitor this agent by default**

Select this check box to put the agent under management by Agent Management Services when the agent is installed. The agent is monitored for unhealthy behavior or abnormal termination and is restarted by a watchdog.

- **Check frequency (seconds)**

How often the watchdog checks the agent process for unhealthy behavior or abnormal termination. The default is every 180 seconds.

- **Maximum number of restarts**

Number of times the Watchdog restarts the agent because of unhealthy behavior or abnormal termination in a 24-hour period before it alerts the administrator of the problem. The period starts at midnight each day. So, the first period from when the agent is started might be "short."

A restart occurs if the agent goes down for any reason. The Watchdog also stops and restarts the agent if the agent becomes unresponsive or unhealthy, for example, if the memory threshold is crossed. The default is four restarts in a 24-hour period, where the period is measured from midnight to 11:59 p.m. At midnight, the daily restart count for the agent returns to 0 automatically.

- **Memory Threshold Information**

Size of the agent process (in megabytes) to which the agent can grow before its watchdog deems it unhealthy. There is a separate value for Windows, Linux, and UNIX. If the agent process grows beyond the threshold, the watchdog stops the process and restarts it. There are no defaults for these properties. If no value is specified, the Watchdog does not monitor the process size. The metric uses the working set size on Windows, and the user memory on UNIX and Linux.

If the Watchdog stops the agent, and the maximum number of restarts is reached, the Watchdog sends an alert that the agent exceeded its restart count, and stops doing auto-restarts. The Watchdog still reports whether the agent is up or down assuming it is started in another manner such as through the Tivoli Enterprise Portal.

You must manually restart the agent by using the AMS Start Agent Take Action command so the restart count does not get reset.

The count gets reset in one of the following ways (the Watchdog continues to work and report status, but does not do auto-restarts):

- The clock strikes midnight.
- The user uses the AMS Start Agent Take Action command, which has an input parameter called **resetRestartCount**. If you enter a value of 1 (meaning "true" or "yes"), the daily restart count resets back to 0.

For more information, see the following sections in the *IBM Tivoli Monitoring Administrator's Guide*:

- For Tivoli System Monitor Agents  
*Configuring Agent Management Services on Tivoli System Monitor Agents*
- For Tivoli Enterprise Monitoring Agents  
*Installing and configuring Tivoli Agent Management Services*

## Cognos information

Use the **Cognos Information** page to specify the information that is used when a Cognos data model is generated for your agent. This information is used only for the IBM Tivoli Monitoring environment.

### Procedure

1. To open the **Cognos Information** page, click **Cognos Information** in the **Agent Content** section of the **Agent Information** page or the **Cognos Information** node in the Outline View.
2. In the **Data Source** field, enter the name of the data source that connects Tivoli Common Reporting to the IBM Tivoli Data Warehouse.

The default value is TDW.

3. In the **Schema** field, enter the name of the database schema that is used for the Tivoli Data Warehouse, which is used to fully qualify table names in Cognos reports.

The default value is ITMUSER. This value can be changed in Framework Manager when the generated Cognos model is loaded into Framework Manager.

The **Add this attribute group to a reporting category** check box in the **Data Source Definition** page determines where in the Cognos model the attribute group is placed. If not selected, the attribute group is placed in the extended attributes folder in the Cognos model. If selected, the attribute group is placed in the selected subfolder (availability or performance) in the Key Metrics folder. For more information about the data source fields, see [Table 296 on page 1416](#).

### What to do next

You can use the Cognos data model to create Tivoli Common Reporting reports for your agent, see [“Cognos data model generation” on page 1690](#).

## Generate Agent wizard link

When you finish creating or editing the new agent, use the Generate Agent wizard to prepare the installation.

### Procedure

- When you finish creating or editing the new agent, on the **Agent Editor Agent Information** page, click the **Generate Agent Wizard** link.

With the Generate Agent wizard, you can:

- Generate the agent files with a Tivoli Monitoring installation on the local system. For instructions, see [“Installing an agent locally” on page 1604](#).

- Create a package so the agent can be installed on other systems. For instructions, see [“Creating the agent package”](#) on page 1606.

## The Data Source Definition page

Use the **Data Source Definition** page to manipulate data sources.

### About this task

The **Data Source Definition** page lists the data sources that are configured for the agent. When you select a data source or attribute in the tree, the page is updated to display the properties for the selected object. Use the fields to modify the properties for the data source or attribute selected.

**Note:** For detailed instructions about creating data sources from various data providers, see [“Defining and testing data sources”](#) on page 1441.

### Procedure

- To open the **Data Source Definition** page, click **Data Sources** in the **Agent Content** section of the **Agent Information** page or the **Data Sources** node in the **Outline** view.
- You can add more data sources by clicking **Add to Selected** or right-clicking in the navigation tree and selecting one of the options.
- You can remove data sources and attributes by right-clicking on them and selecting **Remove**.
- You can add, modify, and remove attributes. For instructions, see [“Editing data source and attribute properties”](#) on page 1415

## Copying data sources by using the Data Source Definition page

Use the **Data Source Definition** page to copy data sources.

### Before you begin

Go to the **Data Source Definition** page. For more information, see [“The Data Source Definition page”](#) on page 1412

### About this task

Data sources that result in attribute groups can be copied to the clipboard and pasted back to this agent or another agent. Data sources that do not result in attribute groups are Availability and Windows Event Log data sources.

### Procedure

1. Select the attribute groups that you want to copy.
2. Cut or copy the attribute group by using one of the following methods:
  - Click **Edit > Cut > Edit > Copy** from the menu bar.
  - Right-click one of the selected items and click **Cut** or **Copy** from the menu.
  - Use one of the operating system or Eclipse key strokes that calls the cut or copy action. For example, on Windows systems, pressing **Ctrl-C** calls the copy action.

To remove data sources from their existing location and place them in the clipboard, use **Cut**. To leave data sources in place and copy them to the clipboard, use **Copy**.

3. Select the parent of an attribute group (the agent, a subnode, or a navigator group) or select an existing attribute group.
4. Paste the selection by using one of the following choices:
  - Select **Edit > Paste** from the menu bar.

- Right-click the node where you want to paste the selection in the tree, and click **Paste** on the menu.
- Use one of the operating system or Eclipse key strokes that calls the paste action. For example, on Windows systems, pressing **Ctrl-V** calls the paste action.

## Results

The attribute groups from the clipboard are placed in the selected parent. Alternatively, if an attribute group is selected, the attribute groups are placed in the parent of the selected attribute group.

If there is a name conflict with another attribute group while pasting, the pasted attribute group name is changed slightly to avoid the conflict.

## Runtime Configuration Information page

The **Runtime Configuration Information** page displays the configurable variables in the agent. You can set values for the variables when you install the agent on a monitored host.

These values are made available to command return codes and scripts through the environment. To open the **Runtime Configuration Information** page, click **Runtime Configuration** in the **Agent Content** section of the **Agent Information** page or the **Runtime Configuration** node in the Outline View. The Agent Builder automatically constructs the name of the environment variable from the product code and the label.

You can add and change the configuration properties and provide default values by using the **Runtime Configuration Information** page.

## Agent XML Editor page

The **Agent XML Editor** page displays the XML for the agent definition.

The agent definition XML includes the information that is displayed in all other parts of Agent Builder. If you change the XML, the information displayed in Agent Builder reflects the change.

**Attention:** Do not make any changes in the XML. Such changes can cause errors that might prevent you from generating the agent or negatively affect the functioning of the agent.

## Saving your edits and changes

Changes that you make with the editor are not stored until you save them.

### Procedure

- Perform a save in one of the following ways:
  - Select **File > Save**, selecting the save (diskette) icon.
  - Press **Ctrl+S**

When you save, a validation occurs to ensure that the information is complete. If problems occur, information about the error is displayed in the Eclipse **Problems** view. If this view is not visible, select **Window > Show View > Problems**. If you attempt to generate an agent that has errors, an error message is displayed.

**Note:** You must correct all errors and save the changes before you can generate and install the agent.

## Committing a version of the agent

Commit your agent when you are certain you are finished developing this version of the agent and you are ready to deliver it.

### About this task

IBM Tivoli Monitoring systems require that new versions of an agent include all of the information that is contained in the previous versions of that agent that were used in the monitoring environment. Including

all information from previous versions is necessary so workspaces, situations, and queries continue to work if the new agent is installed on some monitored hosts, but the old one remains on the others.

After you complete developing and testing an agent, you must commit the agent as the final version for a certain version number. Agent Builder ensures that no information is removed after you commit the agent. Subsequent builds of the agent have a new version number.

There is a limit of 1024 versions.

**Remember:** If you make changes to an agent that is to be tested and run in an IBM Cloud Application Performance Management environment, you must change the agent version.

## Procedure

1. Open the **Agent Editor** window, **Agent Information** page.
2. In the **Commit Agent Version** area, click **commit this level**.
3. Back up the committed agent or check it into your version control system.

## What to do next

After you commit an agent, any additional changes to the agent are part of a new version. You must enter the new version number before the additional changes can be saved. Any changes to the new version must not break compatibility with previous versions of the agent.

After you commit the agent, you cannot complete these actions on objects that existed before the agent was committed:

- Delete attributes from an attribute group.
- Delete attribute groups.
- Reorder existing attributes in an attribute group.
- Reorganize existing attribute groups (by using Navigator items).
- Move attribute groups or navigator groups into or out of subnodes.
- Rename attribute groups.
- Rename attributes.
- Change data types of existing attributes.
- Change a subnode name or type if it contains an attribute group that existed before the agent was committed.
- Change a company identifier or agent identifier for the agent.
- Change the product code of the agent. For more information, see ([“Changing the product code” on page 1415](#)).

You can complete the following actions after you commit the agent:

- Add new attributes to existing attribute groups.
- Add new attribute groups.
- Reorder new attributes.
- Organize new attribute groups by using navigator items.
- Create new subnode types.
- Add new queries.
- Add new situations.
- Add new workspaces.

## Setting a new version number for your agent

To save changes to a committed agent, you must enter a new version number.

### Procedure

1. Open the **Agent Editor** window, **Agent Information** page.
2. Enter a version, fix path, or patch level that is higher than current level after the Version prompt.
3. Make the edits your agent.

**Tip:** If you commit an agent and forget to change the agent version, you are prompted for the new version when you save any of your changes.

## Changing the product code

If you change the product code, you have an agent that is incompatible with any previous version of the agent. Any records of previous commit actions are lost and you are developing a new agent.

Any files, situations, Take Action commands, or workspaces that you exported from IBM Tivoli Monitoring and imported into the agent are deleted from the agent.

If you try to change the product code of an agent that was committed, Agent Builder displays a warning and asks if you want to continue.

When you click **Yes** in the **Agent Product Code** window you are warned that the contents of the agent support files are no longer valid. You are also warned that the files will be removed next time the agent is saved.

## Editing data source and attribute properties

---

When you add data sources to your agent, Agent Builder creates corresponding data sets. You can edit the data sets and attributes in them to provide the necessary monitoring information.

### Procedure

To edit or remove information from a data set (attribute group):

1. In the **Agent Content** area of the **Agent Information** page click **Data Sources**.

The **Data Source Definition** page opens.

2. Select the data set (attribute group).

The attribute group information area of the page is updated to display the properties for the selected data set.

**Note:** Alternatively, if you are on the last page of the **Agent** wizard, you can double-click the data source to open the **Attribute Group Information** window. This window has the same information as the attribute group information area of the **Data Source Definition** page.

(Table 296 on page 1416) describes the field information that is applicable to all of the data sources. Use the fields to modify the properties for the data source or attribute selected.

Table 296. Fields for editing data sources

| Field name  | Description   | Acceptable values and examples  |
|---|---|---|
| <b>Attribute group name</b>                             | Name of the data source as it is displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console | Acceptable values: Descriptive string less than or equal to 32 characters long. It must be unique within the agent. The first character must be a letter and remaining characters can be letters, numbers, or underscores. An underscore is displayed as a space. Do not use spaces or special characters.            |
| <b>Help text</b>  | Help text for the data source   | Acceptable values: String up to 256 characters long.  |
| <b>Produces a single data row</b>                       | The data source returns 1 row of data. Editable in all sampled data sources.  | Example: If you are monitoring physical system memory, choose a single row. A system typically manages all of its memory in a single pool; so only one row of data can be returned.   |
| <b>Can produce more than one data row</b>               | The data source can return any number of rows of data. Editable in all sampled data sources.  | Example: If you are monitoring disk drives, choose multiple rows because there can be more than one disk in a system. For keys, choose the attributes that distinguish a disk from another. For a disk, the key attribute is disk number, drive letter, volume label, or whatever is appropriate in your environment. |
| <b>Produces Events</b>                                  | The data source returns event-based data, 1 row of data per event.  | Example: An SNMP event-based data source sends notifications (traps) as performance thresholds are crossed.<br><br><b>Note:</b> Not all data sources can produce events.  |
| <b>Add this attribute group to a reporting category</b> | The category in the generated Cognos model to which the attributes in this attribute group are assigned.                                  | Select the check box to place the attribute group in the selected subfolder (Availability or Performance) in the Key Metrics folder. If the check box is not selected, the attribute group is placed in the <b>Extended Metrics</b> folder in the Cognos data model.  |
| <b>Metric Category</b>                                  | The category to which the attributes in this attribute group are assigned.  | Select either <b>Performance</b> or <b>Availability</b> .   |

**Note:**

- a. The **Produce a single data row** and **Can produce more than one data row** fields do not affect data for an event data source.
- b. For more about sampled and event data types, see [“Data types” on page 1436](#).
- c. For information about the fields for a specific data source, see the relevant data provider information in [“Defining and testing data sources” on page 1441](#).

## Creating, modifying, and deleting attributes

You can create, modify, or delete attributes in a data set (attribute group).

To work with attributes, open the **Data Source Definition** page. For more information, see [“The Data Source Definition page” on page 1412](#).

### Creating attributes

You can add new attributes to a data set.

#### Procedure

1. Right-click the data source and select **Add Attribute** on the menu.  
The **Attribute Information** page is displayed.  
**Note:** The page that is displayed depends on the data source for the attribute.
2. Specify your choices for the new attribute on the **Attribute Information** page.  
See [“Fields and options for defining attributes” on page 1420](#) for information about the fields and options.
3. To add more attributes, select **Add additional attributes** and click **Next**.
4. When finished adding attributes, click **Finish**.

### Copying attributes

You can copy attributes from the **Data Source Definition** page.

#### Procedure

1. In the Agent Editor, **Data Source Definition** page, right-click the attribute that you want to copy, and click **Copy Attribute**.
2. In the **Copy Attribute** window, type the name of the new attribute in the **Name** field, and click **OK**.

### Editing attributes

You can edit and change attribute information by using the **Data Source Definition** page.

#### Procedure

1. Select the attribute that you want to edit.  
The **Attribute Information** pane of the page is updated to show the properties for the selected attribute.
2. Specify your choices for the new attribute information.  
**Note:** On the last page of the **Agent** wizard (the **Data Source Definition** page), you can double-click the attribute to open the **Attribute Information** window. That window contains the same information as the Attribute Information pane of the **Data Source Definition** page.

## Creating derived attributes

You can create an attribute that derives its value from other attributes instead of directly from the data source.

### About this task

In the derived attribute, you can perform operations on the values of the source attributes. For example, you can perform basic arithmetic operations on numeric attributes or string concatenation on string attributes.

The basic expression syntax that is used for derived expressions contains functions. These functions provide a more complicated manipulation of data that includes short-term aggregation, conversion from string to integer, and accessing configuration properties and environment variables. In addition, an editor helps you visualize the expression as it is being built.

### Procedure

1. On the **Data Source Definition** page, right-click the data source and click **Add Attribute**.
2. On the **Attribute Information** page, type an Attribute name and Help text.
3. Select **Derived from other attribute values**.
4. In the **Formula** field, type the formula text or click **Edit** to enter the formula with a graphical editor.  
See “[Formula operators and functions](#)” on [page 1430](#) for information about the operators and functions that can be used in the formula.

**Note:** When you click **Edit**, the Formula Editor opens. See “[Editing derived attributes](#)” on [page 1419](#) for information about editing derived attributes.

5. Optional: Select or clear the **Interval specific calculations** check box to determine which two attribute sample values are used when the function is calculated.  
Use this option when your formula uses the `rate` or `delta` functions. For more information about **Interval specific calculations**, see “[Interval specific calculations](#)” on [page 1418](#). For more information about `rate` and `delta` functions, see “[Formula operators and functions](#)” on [page 1430](#).
6. In the **Attribute type** area, click the type of attribute.
7. Click **OK**.  
The **Data Source Definition** page is displayed again with the data source listed in it as before.
8. Click **Finish**.

**Important:** If you create a derived attribute that references another derived attribute, ensure that the referenced attribute is listed earlier than the new attribute. If an attribute references another derived attribute that is located later in the list, the agent is unable to display the value for this attribute. If you create such an attribute, Agent Builder displays a warning.

### *Interval specific calculations*

You can choose **Interval specific calculations** when you define a derived attribute that is based on the `rate` or `delta` functions.

You select **Interval specific calculations** on the **Derived Attribute Details** tab of the **Attribute Information** page. For more information, see “[Creating derived attributes](#)” on [page 1418](#).

When you use the **Interval specific calculations** selection, it is important to understand the concept of a delta or difference between attribute values. The delta is the difference between the most recent value of the attribute and a previous value of the attribute. The delta is returned directly by the `delta` function and is used by the `rate` function to calculate a result.

The `delta` or `rate` function must always have the `last` function as its only argument. The `last` function specifies which values of an attribute are used to determine the delta. If **Interval specific calculations** is not selected, the previous value that is used is always the second-most-recent value. If **Interval specific**

**calculations** is selected, the previous value that is used is the value whose age (relative to the most recent value) is equal to the collection interval of the requester.

For example, suppose CDP\_DP\_REFRESH\_INTERVAL is set to 120 seconds and attribute A has the following sampled values:

| Time                         | Sampled value |
|------------------------------|---------------|
| current                      | 2800          |
| 2 minutes (120 seconds) ago  | 2600          |
| 4 minutes (240 seconds) ago  | 2499          |
| 6 minutes (360 seconds) ago  | 1500          |
| 8 minutes (480 seconds) ago  | 1200          |
| 10 minutes (600 seconds) ago | 1000          |

When **Interval specific calculations** is not selected, the delta function always returns 200, the difference between the two most recent values, 2800 - 2600. The same value is returned whether the value is displayed on the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console, used in a situation, or a historical collection.

When **Interval specific calculations** is selected, the delta function returns a value that depends on the collection interval of the requester.

If a derived attribute with the delta function is used in a situation with a 4-minute collection interval, the value that is returned by the delta function is 301, the difference between the most recent value and the value obtained 4 minutes before that, 2800 - 2499.

If a derived attribute with the rate function is used in a situation with a 10-minute (600-second) collection interval, the value that is returned by the rate function is 3, the difference between the most recent value and the value obtained 10 minutes before that, divided by the number of seconds in the interval (2800 - 1000) / 600.

**Note:** The Tivoli Enterprise Portal has no inherent collection interval, so delta and rate calculations for Tivoli Enterprise Portal requests always use the most recent and second most recent attribute values, the same result whether **Interval specific calculations** is selected or not.

For delta or rate to work correctly with **Interval specific calculations**,

- The agent must collect data periodically in the background, and not on demand (CDP\_DP\_THREAD\_POOL\_SIZE must be greater than 0).
- Every situation or historical collection interval in which the attribute is used must be a multiple of the background refresh interval (CDP\_DP\_REFRESH\_INTERVAL).
- The count (the second argument of the last function) must be large enough to accommodate the largest collection interval from a situation or historical collection. For example, if the agent must support 10-minute (600 second) historical collection and CDP\_DP\_REFRESH\_INTERVAL is 120 seconds, the count must be at least 6,  $1 + (600 / 120)$ . A count value of 6 ensures that the last function returns the newest sample and samples up to 600 seconds old.

**Note:** If these conditions are not met, input values are likely invalid and a result of 0 is returned.

## Editing derived attributes

Use the Formula Editor to edit derived attributes.

The Formula Editor is available on the **Attribute Information** page for a derived attribute, as described in “Creating derived attributes” on page 1418. For more information about the Formula Editor, see “Formula Editor” on page 1425

## Removing attributes

You can remove one or several attributes from a data set using the **Data Source Definition** page.

### Procedure

- To remove an attribute or attributes, right-click the attribute or attributes and select **Remove** from the menu that is displayed.

**Note:** You cannot remove an attribute that is used by a derived attribute. You must first remove the reference by the derived attribute to the attribute you are removing.

## Fields and options for defining attributes

Description of the field information and options for the **Attribute Information** page that are applicable to all of the data sources

For information about the specific field information for each of the data sources, see the relevant documentation for each data source.

| Table 297. Fields and options for defining attributes |  |  |
|---|--|--|
| Field names/options                                   | Description  | Acceptable values  |
| <b>Attribute name</b>                                 | Name of the attribute as it is displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console  | String with the following characters: <ul style="list-style-type: none"><li>• A-Z</li><li>• _</li><li>• a-z</li><li>• 0-9</li></ul> <b>Note:</b> The name must start with A-Z or a-z.<br><br>The attribute name has a limit of 63 characters and the attribute group name has a limit of 63 characters |
| <b>Help text</b>                                      | Help text for the attribute  | String   |
| <b>Hidden - can only be used in derived attribute</b> | If selected, the attribute is not displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console. See note in the last row.  | Not applicable   |
| <b>Derived from other attribute values</b>            | Attribute value is to be calculated from values of other attributes  | Not applicable   |
| <b>Key Attribute</b>                                  | Attribute is a key in the table. Check whether this attribute helps to uniquely define the object that is being reported on.<br><br>If the data is warehoused and summarized, the key attributes are used to roll up data in the summary tables. | This option is not available for Perfmon attributes.   |

Table 297. Fields and options for defining attributes (continued)

| Field names/options   | Description  | Acceptable values   |
|---|--|---|
| <b>Attribute Information</b> pane   | <p>The contents of this tab depend on the type of data source to which this attribute belongs. See information in the chapter for the data source you want to monitor for more details.</p> <p>For a derived attribute, In the <b>Formula</b> field, enter a formula to calculate the value of the attribute that is based on other attributes or constants. You can type the formula in the <b>Formula</b> field or click <b>Edit</b> to use the graphical formula editor. See ("<a href="#">Formula Editor</a>" on page 1425).</p> |   |
| <b>Attribute type</b>   | <p>Describes how the attribute is displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console. There are 3 types:</p> <ul style="list-style-type: none"> <li>• String</li> <li>• Numeric</li> <li>• Time stamp</li> </ul> <p><a href="#">"Attribute types" on page 1421</a> contains more information about the attribute types.</p>  | <p><a href="#">Table 298 on page 1422</a> contains descriptions of the numeric attribute type values.</p>   |
| <b>Enumerations</b>   | <p>Can be a numeric with scale zero or string value.</p>   | <p>Add your enumerations to the table by using the procedure in ("<a href="#">Specifying an enumeration for an attribute</a>" on page 1424).</p> <p>The enumeration name is displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console when the corresponding Value is received in the attribute from the agent.</p> <p>This attribute is used for a set of specific values with identified meanings (for example, 1=UP, 2=DOWN).</p> |
| <p><b>Note:</b> In cases where the attribute is used in calculations with other attributes, there are reasons not to display the base value. For instance, a number that represents a byte count wraps so quickly that it is of little use.</p> |  |   |

## Attribute types

There are three attribute types

The three types of attributes are:

- String
- Numeric
- Time stamp

## String attributes

When you select **String**, use the **Maximum size** field to specify the maximum length of the string in bytes. The default size is 64 bytes.

A string value can contain any UTF-8 character. The maximum size is the total length of the buffer that is allocated to contain the string in bytes. Some non-ASCII UTF-8 characters take more than 1 byte, so you must account for this space when you select a maximum size. Data aggregation in the warehouse displays the latest value that is collected during the period.

## Numeric

When you specify **Numeric**, you can set a number of options. See [Table 298 on page 1422](#) for information about these options.

## Time stamp

A Time stamp attribute is a string attribute with a format that conforms to the CYYMMDDHHMMSSmmm format (where C=1 for the 21st century). All 16 characters must be used for scripts or socket clients. When displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console, a time stamp attribute type is displayed in the correct format for the locale.

When you use the browse feature for WMI, the Agent Builder automatically marks attributes whose CIM type is CIM\_DATETIME as time stamps. The data provider automatically converts WMI attributes to this format.

## Numeric aspects of attributes

Descriptions of the size, purpose, scale, and range aspects of attributes.

When you specify a numeric attribute, you must specify the size, purpose, scale, and range of the attribute. For more information, see [Table 298 on page 1422](#).

| Table 298. Numeric attribute options |                    |   |
|--------------------------------------|--------------------|---|
| Numeric aspects                      | Options and fields | Description   |
| Size                                 | 32 bits            | The value of 32-bit numbers can range from -2147483648 to 2147483647 (roughly -2,000,000,000 to 2,000,000,000).                             |
|                                      | 64 bits            | The value of 64-bit numbers can range from -9223372036854775808 to 9223372036854775807 (roughly $-9 \times 10^{18}$ to $9 \times 10^{18}$ ) |

Table 298. Numeric attribute options (continued)

| <b>Numeric aspects</b> | <b>Options and fields</b> | <b>Description</b>  |
|------------------------|---------------------------|---|
| <b>Purpose</b>         | <b>Gauge</b>              | Integer values where the raw values returned are larger or smaller than previous values. Negative values are supported. This type is the default type for integers. Data aggregation in the warehouse produces minimum, maximum, and average values.  |
|                        | <b>Counter</b>            | <p>A positive integer value that contains raw values that generally increase over time. Data aggregation in the warehouse displays the total, high, low, and latest delta values. In the following example of Delta-based calculations, detailed data values in one hour are 9, 15, 12, 20, 22, and delta-based processing has the following rules:</p> <ul style="list-style-type: none"> <li>• If the current value is greater than or equal to the previous value, the output equals the previous value minus the current value</li> <li>• If the current value is less than the previous value, the output equals the current value</li> <li>• Because 15 is greater than 9, the output equals 6</li> <li>• Because 12 is less than 15, the output equals 12</li> <li>• Because 20 is greater than 12, the output equals 8</li> <li>• Because 22 is greater than 20, the output equals 2</li> <li>• The TOT_ value is 28, which is the total of outputs</li> <li>• The LOW_ value is 2, which is the lowest of outputs</li> <li>• The HI_ value is 12, which is the highest of outputs</li> </ul> |
|                        | <b>Property</b>           | A property of the object that does not frequently change. Data aggregation in the warehouse displays the latest value that is collected during the period.  |
|                        | <b>Delta</b>              | An integer value that represents the difference between the current value and the previous value for this attribute. Because this attribute is represented as a gauge in the warehouse, data aggregation in the warehouse produces minimum, maximum, and average values.  |
|                        | <b>Percent change</b>     | An integer value that represents the percent change between the current value and the previous value. This type is calculated as: $((\text{new} - \text{old}) * 100) / \text{old}$ . Because this type is represented as a gauge in the warehouse, data aggregation in the warehouse produces minimum, maximum, and average values.   |
|                        | <b>Rate of change</b>     | An integer value that represents the difference between the current value and the previous value, which is divided by the number of seconds between the samples. It converts a value (such as bytes) to the value per second (bytes per second). Because this type is represented as a gauge in the warehouse, data aggregation in the warehouse produces minimum, maximum, and average values.   |

Table 298. Numeric attribute options (continued)

| Numeric aspects | Options and fields               | Description  |
|-----------------|----------------------------------|--|
| <b>Scale</b>    | <b>Decimal adjustment</b>        | Scale determines how many decimal places are in the number. Each decimal place reduces the range that is mentioned earlier by a factor of 10. For example, a decimal adjustment of 2 shows two decimal places, and in a 32-bit number the allowable range becomes -21474836.48 to 21474836.47.<br><br>When a non-zero decimal adjustment is specified, the number is manipulated internally as a floating point number. Therefore, the precision of large 64-bit numbers might be reduced. |
| <b>Range</b>    | <b>Minimum</b><br><b>Maximum</b> | Range gives the expected range of the value. If no minimum or maximum ranges are given, the maximum values that are described earlier are used. The range is used to produce a more useful initial view in some graphical Tivoli Monitoring workspace views.   |
| <b>Units</b>    |                                  | Unit of measurement for a numeric attribute.   |

## Specifying an enumeration for an attribute

Specify a value enumeration by using the **Attribute Information** page.

### About this task

Specifying an enumeration for an attribute involves a short procedure. When a value is encountered that has a defined enumeration, the enumeration name is displayed in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console instead of the value.

### Procedure

1. In the **Attribute Information** page **Attribute type** area, click **Numeric**.
2. In the **Enumerations** area, click an enumeration, and click **Add**.  
The **Enumeration Definition** window is displayed.
3. Type the name and value of the enumeration in the fields in the window.
4. Click **OK**.

You can then add more enumerations.

## Specifying severity for an attribute used as a status indicator

In an IBM Cloud Application Performance Management environment, a summary dashboard must display a status. You must use an attribute to provide the status value. For this attribute, you must specify values that denote specific status severity.

### About this task

The attribute that is used for status indication must be numeric. Select this attribute in the **Dashboard Setup** wizard; for instructions about using this wizard, see [“Preparing the agent for Cloud APM” on page 1590](#).

You can specify values for the attribute that correspond to the Normal, Warning, and Critical severity. Any other value denotes an "Unknown" severity status; you can also define some values as "Not defined" explicitly, and the "Unknown" status user interfaces displayed for these values.

## Procedure

1. Select the attribute that you want to edit.  
The Attribute Information pane of the page is updated to show the properties for the selected attribute.
2. In the Attribute Information pane, click the **Severity** tab.
3. Select the necessary severity (Normal, Warning, Critical, and Not defined) and click **Edit**.
4. Select **Range** or **Single number**, enter the range of values or the single numeric value, and click **Ok**.
5. Optional: If you need to add another value for the same severity, for example; both 2 and 25 denote warning, click **Add**, select the severity, enter the value, and click **OK**.

## Filtering attribute groups

You can create a filter to limit the data that is returned from an attribute group that returns sampled data.

### Before you begin

If the attribute group exists, open the **Data Source Definition** page. For more information, see [“The Data Source Definition page” on page 1412](#).

If you want to create an attribute group, follow the steps in [“Defining initial data sources” on page 1397](#) and click **Advanced** in the initial data source information page.

## Procedure

1. Use one of the following steps to begin creating the filter:
  - If you are creating an attribute group, click **Advanced** in the initial data source information page.
  - If the attribute group exists, select the attribute group in the **Data Source Definition** page and click **Advanced** in the **Data Source Definition** page.
2. In the **Advanced Data Source Properties** page, enter a selection formula. The selection formula that you enter must evaluate to a Boolean result, true, or false.  
In the **Advanced Data Source Properties** page, you can click **Edit** to enter or modify the formula by using the Formula Editor. For more information about the Formula Editor, see [“Formula Editor” on page 1425](#).
3. When you finish entering the filter selection formula, click **OK** until you return to the **Data Source Definition** page.  
When the filter is created, the agent uses the filter to evaluate each row of data. When the filter evaluates to *true* for a row of data, the data is sent to IBM Tivoli Monitoring or IBM Cloud Application Performance Management. When the filter evaluates to *false*, the row of data is not sent and is discarded.

## What to do next

You can validate that the filter is working as intended by using the test function for the attribute group. For more information about attribute group testing, see [“Attribute group testing” on page 1596](#)

## Formula Editor

Use the Formula Editor to create and change formulas in Agent Builder.

The Formula Editor, which is a graphical tool, is displayed when you do one of the following tasks:

1. Creating or editing derived attributes, see [“Creating derived attributes” on page 1418](#) and [“Editing derived attributes” on page 1419](#)
2. Creating Filtered Attribute groups, see [“Creating a filtered attribute group” on page 1559](#)
3. Filtering data from attribute groups, see [“Filtering attribute groups” on page 1425](#)

**Attention:**

- When you create derived attributes, the formula that you create must result in a data type that matches the type of the attribute. For example, if the derived attribute type is a number, the formula you create must evaluate to a numeric result.
- When you create filtered attribute groups or filter data from attribute groups, the formula that you create must result in a Boolean value, "true" or "false".

**Note:** In the following views, the Formula Editor is shown creating formulae for derived attributes. The views are identical when you use the Formula Editor with filtered attribute groups or to filter data from attribute groups. The views show the heading **Derived Formula Editor** or **Filter Formula Editor** depending on use.

When the Formula Editor is displayed, the current formula is loaded into the editor. If a formula does not exist, you can enter one by typing directly into the formula space in the **Formula Editor** window. Alternatively you can click **Insert** to begin entering a formula by using the editor menu options. The editor contains two views of the formula in the default window, and an option for a third view:

**Component view (default)**

The components of the edited formula are shown in the **operand** areas and **Operator** field. The operator and its two operands can be edited by using the selection menus.

**Formula view (default)**

The complete formula is in the formula field in the window. You can edit the formula by typing in this box.

**Formula hierarchy tree view (option)**

The formula hierarchy tree is displayed by selecting the **Show formula hierarchy** check box. The state of the check box is remembered in subsequent invocations of the Formula Editor.

## Changing the Formula Editor component view

Change the component view in the Formula Editor.

### About this task

The component that is shown in the component view can be changed in the following ways:

### Procedure

- Move the cursor in the formula text.
- Select a different node in the formula hierarchy tree.
- Select **Up one Level** or one of the Edit buttons.

### Component types

You can use the Formula Editor to edit the current component and any operands or function arguments of that component. Some components can appear differently in the Formula Editor when selected.

***Formula Editor Attribute component***

Use the attribute component in the Formula Editor to select and manipulate attributes in formulae.

### About this task

You can select an attribute from a list of attributes for the attribute group in the component view of the Formula Editor.

### Procedure

1. To work with a specific attribute, select that attribute from the list and click **Edit**

The **Edit the Selected Attribute** window is displayed.

2. You can manipulate the selected attribute in the following ways:

- You can replace the attribute with a string or number by selecting **String** or **Number**. The attribute list is replaced by an entry field and the contents are no longer compared to the list of valid attribute names.
- You can replace the attribute with a function by clicking **Function**. Parentheses are added after the name and the list now contains valid function names to choose from.
- You can type an attribute name instead of selecting one. Typing a name is useful if you did not yet define all of the attributes in this attribute group.
  - A warning is displayed if there is no attribute with the name that was entered.
  - An error is displayed if characters are entered that cannot be part of an attribute name.
  - The **OK** button is disabled until the warning or error is corrected.
- Attributes are not filtered based on type. If an attribute (or any value) of the wrong type is selected or entered, a warning message is displayed.

### ***Formula Editor Literal components***

Use the string and number components in the Formula Editor to manipulate literals in formulae.

### **About this task**

A literal is any value that is entered directly in the formula that does not come from an attribute value or from a function. A literal value can be either a string or a number.

### **Procedure**

- You can replace a literal string or number with an attribute by clicking **Attribute**. A valid attribute name must be selected or entered without quotation marks.
- You can replace a literal string or number with a function by clicking **Function**. Parentheses are added after the name and the selection list contains valid function names to choose from.
  - A warning is displayed if a number is entered where a string is expected or vice versa.
  - If **Number** is selected, an error is displayed if the content of the field is not a number. **OK** is disabled until the error is corrected.

### ***Formula Editor Operator component***

Use the operator component in the Formula Editor to manipulate operators in formulae.

### **About this task**

An operator component shows an operator and its operands.

### **Procedure**

- In the Formula Editor component view select the operator from the **Operator** list, between the two operands. The (%) operator multiplies the first operand by 100, and then divides by the second operand.
- Select the operator (+ - \* / or %).
  - The **Left operand** section of the page is before the operator.
  - The **Right operand** section is after the operator.
  - Simple operands (attributes and literals) can be edited without having to change the selected component to the operand as described in [“Formula Editor Attribute component” on page 1426](#) and [“Formula Editor Literal components” on page 1427](#).

- Complex operands, which consist of other operators or functions, can be edited by clicking **Edit**. This action highlights the operand component instead of the entire operator.

### **Formula Editor Conditional expression component**

The conditional expression component shows a condition, a value to return if the condition is true, and a value to return if the condition is false.

- The expression in the **Condition** section must evaluate to true or false. Operators (**=**), (**!=**), (**<**), (**<=**), (**>**), (**>=**), (**&&**), (**||**), (**!**) are available to form expressions that return true or false.
- Simple operands (attributes and literals) can be edited without having to change the selected component to the operand as described in [“Formula Editor Attribute component” on page 1426](#) and [“Formula Editor Literal components” on page 1427](#).
- Complex operands, which consist of other operators or functions, can be edited by clicking **Edit**. This action highlights the operand component instead of the entire conditional expression.
- See [“Formula Editor common options” on page 1428](#) for information about using the following options: **Insert**, **Remove**, **Up one Level**, and **Edit**.

#### **Related concepts**

[“Formula Editor” on page 1425](#)

Use the Formula Editor to create and change formulas in Agent Builder.

### **Formula Editor Function component**

Use the function component in the Formula Editor to select and manipulate function components in formulae.

#### **About this task**

The function component shows the function and its arguments.

#### **Procedure**

- To work with the functions Select the **Function name** from the list in the Formula Editor.
  - The description of the selected function is shown after the function.
  - **Function argument** sections are shown after the function name. The appropriate number of arguments for the selected function are shown. A description specific to the function selected is shown.
  - Simple arguments (attributes and literals) can be edited without having to change the selected component to the operand as described in [“Formula Editor Attribute component” on page 1426](#) and [“Formula Editor Literal components” on page 1427](#).
  - Complex arguments, which consist of operators or other functions, can be edited by clicking **Edit**. This action highlights the argument component instead of the entire function.
- For functions that take a variable number of arguments, add arguments by clicking **Insert** or remove arguments by clicking **Remove** in addition to the actions described in [“Formula Editor common options” on page 1428](#).
- For the `getenv` function, a configuration property can be chosen by clicking **Insert**. If you select the Configuration property choice, the **Configuration Properties** window is displayed.

### **Formula Editor common options**

You can use some options in all views in the Formula Editor

The Formula Editor common options are:

- **Insert**
- **Remove**

- **Up one Level**
- **Edit**

## Insert

**Insert** inserts an operator or a function before the component. The component is demoted to one of the operator operands or one of the function arguments. For example, if you click **Insert** before the `sqrt(attr2)` function, you are asked what you want to insert and the following choices are displayed:

- **An operator with `sqrt(attr2)` as one of the operator's operands**
- **A function with `sqrt(attr2)` as the function's first argument**
- **A conditional expression with `sqrt(attr2)` as the true or false values**

If you click **Insert** before the `getenv` function, you are asked what you want to insert and the following choices are displayed:

- **Configuration property:** use this option to retrieve the value of a configuration property that you have set up for the agent, or else of any environment variable (for example, `JAVA_HOME`) on the host running the agent.
- **An operator with `attr2` as one of the operator's operands**
- **A function with `attr2` as the function's first argument**
- **A conditional expression `attr2` as the true or false values**

## Remove

**Remove** is available only for operators and functions, and is the inverse of **Insert**. When you click **Remove**, you are asked what is to replace the removed operator or function. For example, **Remove** before the `sqrt(attr2)` function shows the following choices:

- **The current argument 1, `attr2`**
- **A new string, number, or attribute reference**

Select **A new string, number, or attribute reference** to discard the entire tree after the point that is being removed and replace it with a new attribute or literal value.

Click **The current argument** to promote the selected operand or argument to replace the removed operator or function. You can click subsequent choices if there are more arguments or operands. Any other operands or arguments are discarded.

## Up one Level

Click **Up one Level** to move up in the tree.

## Edit

Click **Edit**, before a complex operand or argument, to make it the component to be edited.

Click **Up One Level** after you click **Edit** to restore the current component to what it was before you clicked **Edit**.

## Formula Editor - Formula errors

Correcting formula errors in the **Formula Editor**

The component view is different when there is no formula or the entered formula cannot be parsed. It does not display a formula tree. Instead, it displays an error message.

You can correct a formula with parsing errors by typing directly in the formula field, or by replacing it with a new formula by clicking **Insert**. In this case, **Insert** presents the following choices:

- **An attribute**

- **A string**
- **A number**
- **An operator**
- **A conditional expression**
- **A function**

#### Related concepts

[“Formula Editor” on page 1425](#)

Use the Formula Editor to create and change formulas in Agent Builder.

## Formula operators and functions

A reference (including examples) of formula operators and functions that are used in the formula editor.

A derived attribute value is the result of evaluating an expression that is based on constants and other attribute values in the same data source. The expression grammar is the normal mathematical expression - operand operator operand with parentheses used for grouping. Numeric attributes can be combined with other numeric attributes or constants by using the normal mathematical operators: + - \* /, and %, which multiplies the **Left operand** by 100 and divides by the **Right operand**. String attributes can be combined with other string attributes or constants with +. You can also use the following described functions. Functions are entered in the format: `function_name(argument_1, argument_2, argument_3)`.

An attribute is represented by its name (the same name you see in the **Data Sources** Information tree). Integer constants are specified as numbers. String constants are surrounded by quotation marks.

You can use the following functions in a formula:

#### **abs**

Returns the absolute value of a number

#### **atof**

Converts a string to a floating point value

#### **atoi**

Converts a string to an integer value. It operates in the same way the normal **C atoi** works: it stops at the first non-decimal character.

#### **average**

Returns a single value that is the average of a set of values. The set of values comes from the arguments of the function. Several individual values can be given (for example attribute names or constants), each in a separate argument. Alternatively the last function can be the only argument to this function (to calculate the average of the most recent values of an attribute).

Examples of this function in use are:

```
average (Attr_A, AttrB, Attr_C)
```

```
average (last (Attr_A, 10))
```

#### **ceiling**

Returns the least integer that is not less than the argument.

For example, where `attribute_a = 12.4`, `ceiling(attribute_a)` returns the value 13. And, where `attribute_a = -12.4`, `ceiling(attribute_a)` returns the value -12.

#### **delta**

The difference between the most recent value of an attribute and a previously collected value of that attribute. The single argument to delta must be the last function, which obtains the current and previous values of an attribute. A normal use might look like:

```
delta (last(OtherAttribute, 2))
```

For more information about which attribute values from the last function are used to calculate the delta, see [“Interval specific calculations” on page 1418](#). This function is applicable only for derived attributes, not for attribute group filters.

### **floor**

Returns the greatest integer that is not greater than the argument.

For example, where `attribute_a = 12.4`, `floor(attribute_a)` returns the value 12. And, where `attribute_a = -12.4`, `floor(attribute_a)` returns the value -13.

### **getenv**

Returns the value of the provided environment or "configuration variable".

### **ipAddressToName**

Converts an IP address to a host name. This function requires one argument, an IP address string in dotted decimal notation. If the address cannot be resolved, then the IP address is returned.

### **itoa**

Converts an integer into a string. This function is most useful when you want to concatenate a numeric value onto a string. The derived string + function takes only two string arguments.

### **last**

Returns a list of values for use by the `min`, `max`, `average`, `stddev`, `rate` and `delta` functions. It takes two arguments: the attribute to collect and the number of values to use in the calculation. If the required attribute is an integral value in a string attribute, the first argument can contain the `atoi` function, such as `atoi(numericalStringAttribute)`. The second argument must be a number. It can either be hardcoded as a constant or it can be the result of an `atoi(getenv("ENV_VAR"))` expression. It cannot reference an attribute value.

Examples of this function in use are:

```
average (last (Attr_A, 10))
```

```
last (Attribute_A, ${K01_NUM_COLLECTIONS})
```

**Restriction:** You can use the `last` function only once in a specific formula.

### **matches**

Returns a Boolean, true, or false, indicating whether a regular expression matches a value. It takes two arguments, string source and a regular expression whose result the string is compared to. This function is useful for filtering attribute groups.

### **max**

Returns a single value that is the maximum of a set of values. The set of values comes from the arguments of the function. Several individual values can be given (for example attribute names or constants), each in a separate argument. Alternatively the last function can be the only argument to this function (to calculate the maximum of the most recent values of an attribute).

### **min**

Returns a single value that is the minimum of a set of values. The set of values comes from the arguments of the function. Several individual values can be given (for example attribute names or constants), each in a separate argument. Alternatively the last function can be the only argument to this function (to calculate the minimum of the most recent values of an attribute).

### **nameToIpAddress**

Converts a host name to an IP address. This function requires one argument, a host name string. If the address cannot be resolved, then the host name is returned.

### **NetWareTimeToTivoliTimestamp**

Converts a Novell NetWare hexadecimal time value to a Tivoli Monitoring time stamp. This function requires one argument, a special NetWare hexadecimal time value. The attribute type is timestamp.

## rate

The rate of change (per second) between the most recent value of an attribute and a previously collected value of that attribute. The single argument to rate must be the last function, which obtains the current and previous values of an attribute. A normal use might look like:

```
rate (last(OtherAttribute, 2))
```

For more information about which attribute values from the last function are used to calculate the rate, see [“Interval specific calculations” on page 1418](#). This function is applicable only for derived attributes, not for attribute group filters.

## replaceFirst

Replaces the first occurrence of a substring that matches a regular expression with a replacement string. This function takes three arguments. First: the input string. Second: the regular expression which is used to match a substring in the input string. Third: the replacement string. See [“ICU regular expressions” on page 1705](#) for details on the regular expressions and substitution values that are allowed in the replacement string.

## replaceAll

Replaces all occurrences of substrings that match a regular expression with a replacement string. This function takes three arguments. First: the input string. Second: the regular expression which is used to match a substring in the input string. Third: the replacement string. See [“ICU regular expressions” on page 1705](#) for details on the regular expressions and substitution values that are allowed in the replacement string.

## round

Mathematically Rounds the number to the nearest whole number.

## sqrt

Returns the square-root of a number

## stddev

Returns a single value that is the standard deviation of a set of values. The set of values comes from the arguments of the function. Several individual values can be given (for example attribute names or constants), each in a separate argument. Alternatively the last function can be the only argument to this function (to calculate the standard deviation of the most recent values of an attribute).

## StringToTivoliTimestamp

Converts a date and time string to a Tivoli Monitoring time stamp. This function requires two arguments. The first argument is a free-form string representation of the time stamp. The second argument is a format string that identifies how to parse the free-form string representation of a time stamp. (Table 299 on page 1432) describes the valid format parameters. The attribute type is timestamp.

| Table 299. Valid format parameters for StringToTivoliTimestamp |   |                        |                         |
|--|---|------------------------|-------------------------|
| Symbol   | Meaning   | Format                 | Example                 |
| y  | Year  | yy<br>yyyy             | 96<br>1996              |
| M  | Month<br><b>Note:</b> Only English month strings are supported. | M or MM<br>MMM<br>MMMM | 09<br>Sept<br>September |
| d  | day   | d<br>dd                | 2<br>02                 |

| Table 299. Valid format parameters for StringToTivoliTimestamp (continued) |   |  |                       |
|--|---|--|-----------------------|
| Symbol   | Meaning   | Format   | Example               |
| E  | Day of week<br><b>Note:</b> Only English day-of-week strings are supported. | EE<br>EEE<br>EEEE  | Sa<br>Sat<br>Saturday |
| h  | Hour in AM or PM (1-12)   | hh   | 07                    |
| H  | Hour in day (0-23)  | HH   | 00                    |
| m  | Minute in hour  | mm   | 04                    |
| s  | Second in minute  | ss   | 05                    |
| S  | Millisecond   | S<br>SS<br>SSS   | 2<br>24<br>245        |
| a  | AM or PM marker   | a or aa  | am                    |
| Any other ASCII character  | skip this character   | - (hyphen)<br>(space)<br>(forward slash)<br>: (colon)<br>* (asterisk)<br>, (comma) |                       |

Table 300 on page 1433 provides examples of string representations of time stamps and the format strings that are used to parse them.

| Table 300. StringToTivoliTimestamp examples. A table listing and explaining a few examples of string representations of time stamps. |                            |
|--|----------------------------|
| String representation of the time stamp  | Format string              |
| 96.07.10 at 15:08:56   | yy.MM.dd ** HH:mm:ss       |
| Wed, August 10, 2010 12:08 pm  | EEE, MMMM dd, yyyy hh:mm a |
| Thu 21/01/2010 14:10:33.17   | EEE dd/MM/yyyy HH:mm:ss.SS |

## sum

Returns a single value that is the sum of a set of values. The set of values comes from the arguments of the function. Several individual values can be given (for example attribute names or constants), each in a separate argument. Alternatively the last function can be the only argument to this function (to calculate the sum of the most recent values of an attribute).

## TivoliLogTimeToTivoliTimestamp

Converts a Tivoli log file time stamp to a Tivoli Monitoring time stamp. This function requires one argument, the string time stamp from a Tivoli log file. The attribute type is timestamp.

**tokenize**

One token of a tokenized string. This function requires three arguments. The first argument is a string to be split into tokens. The second argument gives one or more characters in the string that separate one token from another. Any occurrence of any of the characters from this argument is used to identify and separate tokens in the first argument. The third argument is the index of the token to return as a result of this function. The first token is index 0, the second token is index 1, and so on. This argument can also be the string LAST to return the last token.

**UTCtoGMT**

Converts Coordinated Universal Time to a GMT Tivoli Monitoring time stamp. This function requires one argument, the integer time\_t value. The attribute type is timestamp.

**UTCtoLocalTime**

Converts Coordinated Universal Time to a local Tivoli Monitoring time stamp. This function requires one argument, the integer time\_t value. The attribute type is timestamp.

The following functions take no arguments and return a number.

**count**

Keeps a counter that starts at 1 the first time it is called, and increments by 1 each subsequent time it is called. If you use it in an expression that also uses last, it matches the number of elements that are stored by last(), but only until last() reaches its maximum. At that point, last() starts deleting the oldest value for each new one, thus staying at the same number of total values, while count() keeps increasing forever.

**cumulativeSum**

Returns the sum of argument values of duplicate events that are represented by a flow control summary event. Or returns the argument if it is a single event from a data source. It takes a single numeric argument. This function applies only to event attribute groups with event filtering and summarization turned on.

**eventThreshold**

Returns the threshold value that is configured for the attribute group which generated the event. A number, with three enumerations:

- SEND\_ALL (-3)
- SEND\_FIRST (-2)
- SEND\_NONE (-1)

The number in parentheses is the raw value. However, the Agent Builder defines the enumerations so by default the text version is visible on the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console. If you specify an actual numeric threshold and not one of the three pre-defined choices, that number is returned by this function. The value is an integer > 0. This function applies only to event attribute groups with event filtering and summarization turned on.

**isSummaryEvent**

Returns 0 if it is a single event from a data source, or 1 if the event is a flow control summary event. The displayed values are Event and Summary Event if you use the default attribute for the function. If you create the attribute manually, the displayed values are 0 and 1, unless you define the names as enumerations. This function applies only to event attribute groups with event filtering and summarization turned on.

**occurrenceCount**

The number of matching events that are represented by a flow control summary event, or 1 if it is a single event from a data source. (A flow control summary event includes the first event). This function applies only to event attribute groups with event filtering and summarization turned on.

**summaryInterval**

Returns the summary interval that is configured for the attribute group which generated the event, in seconds. This function applies only to event attribute groups with event filtering and summarization turned on.

## Examples

Examples of the use of formula operators and functions to create derived and filtered attributes

### Example 1 - Derived Attributes

If you have a data source that defines the following attribute type:

| Name         | String  |
|--------------|---------|
| xBytes       | Numeric |
| yBytes       | Numeric |
| Virtual_Size | Numeric |

You can define:

- An attribute `totalBytes` to be the sum of `xBytes` and `yBytes`. You enter the formula `xBytes + yBytes`.
- An attribute `yPercent` to be a percentage of the total bytes, which is `yBytes`, can be defined as `yBytes % (xBytes + yBytes)` or `yBytes % totalBytes`.

### Example 2 - Derived Attributes

This formula returns the maximum of the recently collected values for the `Virtual_Size` attribute. The number of samples that are collected is the value of the configuration variable, `K4P_COLLECTIONS_PER_HISTORY_INTERVAL` (accessed through `getenv`), converted to a number (through `atoi`):

```
max(last(Virtual_Size,atoi(getenv("K4P_COLLECTIONS_PER_HISTORY_INTERVAL"))))
```

### Example 3 - Derived Attributes

This formula returns the square-root of the sum of the squares of the `xBytes` and `yBytes` attribute values:

```
sqrt(xBytes * xBytes + yBytes * yBytes)
```

### Example 4 - Derived Attributes

This formula returns the average of the `xBytes` attribute from the 20 most recent samples of the attribute group. If fewer than 20 samples are collected since the agent was started, it returns the average of the `xBytes` attribute from all samples:

```
average(last(xBytes,20))
```

### Example 5 - Filtered Attributes

You have a data source that returns:

| Name   | Type | Size | Used | Free |
|--------|------|------|------|------|
| Memory | MEM  | 8    | 4    | 4    |
| Disk1  | DISK | 300  | 200  | 100  |
| Disk2  | DISK | 500  | 100  | 400  |

You are only interested in the disk usage. The solution is to create a filter to limit the data that is returned. To limit the returned data, you create a simple filter that returns a Boolean, true, or false value, as follows

Disk Filter:

```
Type=="DISK"
```

Now when the filter `Type=="DISK"` is true, the attribute group returns only disk usage data, for example:

| Name  | Type | Size | Used | Free |
|-------|------|------|------|------|
| Disk1 | DISK | 300  | 200  | 100  |
| Disk2 | DISK | 500  | 100  | 400  |

### Example 6 - Filtered Attributes

You have a data source that returns:

| Name   | Size | Used | Free |
|--------|------|------|------|
| Memory | 8    | 4    | 4    |
| Disk1  | 300  | 200  | 100  |
| Disk2  | 500  | 100  | 400  |

The data that is returned is similar to the previous example, however, there is not a `Type` attribute present this time. Here you can use the `matches` function to find any data rows with a name attribute value that matches "Disk" followed by a number.

Disk Filter:

```
matches(Name, "Disk[0-9]*")
```

Now when the filter matches the string "Disk" followed by a number in attribute `Name`, only the disk usage data rows are returned:

| Name  | Size | Used | Free |
|-------|------|------|------|
| Disk1 | 300  | 200  | 100  |
| Disk2 | 500  | 100  | 400  |

## Specifying operating systems

When you define data sources that are not available on all operating systems that the agent supports, you must specify the operating systems where the data source runs.

### About this task

By default, the data source provides data on all of the operating systems that are defined at the agent level, as described in [“Default operating systems” on page 1399](#). You can change the operating systems for each data source.

### Procedure

1. To open the Operating Systems section, click **Operating Systems** in the **Data Source Information** page when you add a data source.
2. Select the operating systems on which the data source is to operate.  
Select individual operating systems, all operating systems, all operating systems of a specific type, or the agent default operating systems.

## Configuring and Tuning data collection

When an Agent Builder agent is created, you can configure and tune its data collection to achieve the best results.

How you configure and tune your agent can be different for different Agent Builder agents and even between attribute groups in a single agent. Agent Builder agents can include two types of data and they support two basic methods of data collection for the most common type of data.

### Data types

An agent collects two types of data:

1. Most Tivoli Monitoring attribute groups represent snapshots of data. Someone asks for the data and it is returned. Agents use this type of data to represent configuration, performance, status, and other information where a one time collection of a set of data makes sense. This data is called *sampled data*.
2. Some Tivoli Monitoring data represents events. In this case, an event happens and the agent must forward data to Tivoli Monitoring. Examples of events are SNMP Traps, Windows Event Log entries, and new records that are written to a log file. For simplicity, these types of data are grouped and referred to as *event data*.

## ***Sampled data***

When sampled data is required, a request is sent to the agent for a specific attribute group. The request might be initiated by clicking a workspace in the Tivoli Enterprise Portal. Other things that might initiate a request are a situation that is running, a data collection for the Warehouse, or a SOAP request. When the agent receives the request, the agent returns the current data for that attribute group. Tivoli Enterprise Portal requests target a specific attribute group in a particular Managed System Name (MSN). Situations and historical requests are more interesting, especially in an agent which includes subnodes. When a situation needs data for an attribute group in a subnode, the agent receives one request with a list of the targeted subnodes. The agent must respond with all the data for the requested attribute group for all of the subnodes before Tivoli Monitoring can work on the next request.

The most straightforward way for an agent to satisfy a request is to collect data every time it receives a request from Tivoli Monitoring. Agent Builder agents do not collect data every time. Data is not collected every time because it often takes time or uses resources to collect data. And in many cases the same data is requested many times in a short period. For example, a user might define several situations that run at the same interval on an attribute group and the situations can signal several different conditions. Each of these situations results in a request to the agent, but you might prefer each of the situations to see the same data. It is likely that as each situation sees the same data, more consistent results are obtained, minimizing the demand for system resources by the monitoring agent.

The agent developer can configure agents to optimize data collection by choosing to run the collection in one of the following two modes:

1. **On-demand collection:** The agent collects data when it receives a request and returns that data.
2. **Scheduled collection:** The agent runs data collection in the background on scheduled intervals and returns the most recently collected data when it receives a request.

The agent uses a short-term cache in both of these modes. If another request for data is received while the cache is valid, the agent returns data from the cache without collecting new data for each request. Using data from the cache solves the problem that is caused by multiple concurrent situations (and other types of) requests. The amount of time the data remains valid, the scheduled collection interval, the number of threads that are used for collection and whether the agent runs in on demand or scheduled mode are all defined by environment variables. Using the environment variables, you can tune each agent for the best operation in its environment.

See the following examples that illustrate how the agent works in both modes:

- **Agent 1 (*on-demand* collection):** A simple agent that collects a small amount of data that is normally accessed only by situations or on an infrequent basis in the Tivoli Enterprise Portal. Data collection is reasonably fast, but it can use up computing and networking resources. This agent is normally defined to run on demand. If no situations are running or no one clicks the Tivoli Enterprise Portal, the agent does nothing. When data is needed, it is collected and returned. The data is placed into the short-term cache so that further requests at about the same time return the same data. This type of collection is likely the most efficient way for this agent to run because it collects data only when someone actually needs it.
- **Agent 2 (*scheduled* collection):** A complex agent that includes subnodes and collects data from multiple copies of the monitored resource. Many copies of the resource can be managed by one agent. It is normal to run situations on the data on a relatively frequent basis to monitor the status and performance of the monitored resource. This agent is defined to run a *scheduled* collection. One reason for running a *scheduled* collection is the way that situations are evaluated by Tivoli Monitoring agents. Because situations are running on the attribute groups in the subnodes, the agent receives one request

for the data from all of the subnodes simultaneously. The agent cannot respond to other requests until all of the data is returned for a situation. If the agent collected all of the data when the request arrived, the agent would freeze when you click one of its workspaces in the Tivoli Enterprise Portal. To avoid freezing the agent, the agent builder automatically defines all subnode agents to run as scheduled collection. The agent developer tunes the number of threads and refresh interval to collect the data at a reasonable interval for the data type. For example, the refresh interval can be one time a minute, or one time every 5 minutes.

### *Environment variables*

An agent determines which mode to use and how the scheduled data collection runs based on the values of a set of environment variables. These environment variables can be set in the definition of the agent on the **Environment Variables** panel. Each environment variable is listed in the menu along with the default values. The environment variables can also be set or modified for an installed agent by editing the agent's environment (env) file on Windows or initialization (ini) file on UNIX. The environment variables that control data collections for sampled attribute groups are:

- CDP\_DP\_CACHE\_TTL=<validity period for the cached data - default value 55 seconds>
- CDP\_DP\_THREAD\_POOL\_SIZE=<number of threads to use for concurrent collection - default value 15 for subnode agents>
- CDP\_DP\_REFRESH\_INTERVAL=<number of seconds between collections - default value 60 seconds for subnode agents>
- CDP\_DP\_IMPATIENT\_COLLECTOR\_TIMEOUT=<amount of time to wait for new data after validity period expires - default value 5 seconds>

The most important of these variables are CDP\_DP\_CACHE\_TTL, CDP\_DP\_REFRESH\_INTERVAL, and CDP\_DP\_THREAD\_POOL\_SIZE.

If CDP\_DP\_THREAD\_POOL\_SIZE has a value greater than or equal to 1 or the agent includes subnodes, the agent operates in *scheduled* collection mode. If CDP\_DP\_THREAD\_POOL\_SIZE is not set or is 0, the agent runs in *on-demand* collection mode.

If the agent is running in *scheduled* mode, then the agent automatically collects all attribute groups every CDP\_DP\_REFRESH\_INTERVAL seconds. It uses a set of background threads to do the collection. The number of threads is set by using CDP\_DP\_THREAD\_POOL\_SIZE. The correct value for the CDP\_DP\_THREAD\_POOL\_SIZE varies based on what the agent is doing. For example:

- If the agent is collecting data from remote systems by using SNMP, it is best to have CDP\_DP\_THREAD\_POOL\_SIZE similar to the number of remote systems monitored. By setting the pool size similar to the number of monitored remote systems, the agent collects data in parallel, but limits the concurrent load on the remote systems. SNMP daemons tend to throw away requests when they get busy. Discarding requests forces the agent into a try-again mode and it ends up taking more time and more resources to collect the data.
- If the agent includes a number of attribute groups that take a long time to collect, use enough threads so that long data collections can run in parallel. You can probably add a few more for the rest of the attribute groups. Use threads in this way if the target resource can handle it. Examples of when attribute groups can take a long time to collect are if the script runs for a long time, or a JDBC query takes a long time.

Running an agent with a larger thread pool causes the agent to use more memory (primarily for the stack that is allocated for each thread). It does not however increase the processor usage of the process or increase the actual working set size of the process noticeably. The agent is more efficient with the correct thread pool size for the workload. The thread pool size can be tuned to provide the wanted behavior for a particular agent in a particular environment.

When data is collected, it is placed in the internal cache. This cache is used to satisfy further requests until new data is collected. The validity period for the cache is controlled by CDP\_DP\_CACHE\_TTL. By default the validity period is set to 55 seconds. When an agent is running in scheduled mode, it is best to set the validity period to the same value as CDP\_DP\_REFRESH\_INTERVAL. Set it slightly larger if data

collection can take a long time. When set the validity period in this way, the data is considered valid until its next scheduled collection.

The final variable is `CDP_DP_IMPATIENT_COLLECTOR_TIMEOUT`. This variable comes into play only when `CDP_DP_CACHE_TTL` expires before new data is collected. When the cache expires before new data is collected, the agent schedules another collection for the data immediately. It then waits for this collection to complete up to `CDP_DP_IMPATIENT_COLLECTOR_TIMEOUT` seconds. If the new collection completes, the cache is updated and fresh data is returned. If the new collection does not complete, the existing data is returned. The agent does not clear the cache when `CDP_DP_CACHE_TTL` completes to prevent a problem that is seen with the Universal Agent. The Universal Agent always clears its data cache when the validity period ends. If the Universal Agent clears its data cache before the next collection completes, it has an empty cache for that attribute group and returns no data until the collection completes. Returning no data becomes a problem when situations are running. Any situation that runs after the cache cleared but before the next collection completes sees no data and any of the situations that fire are cleared. The result is floods of events that fire and clear just because data collection is a little slow. The Agent Builder agents do not cause this problem. If the 'old' data causes a situation to fire generally the same data leaves that situation in the same state. After the next collection completes, the situation gets the new data and it either fires or clears based on valid data.

### *Attribute groups*

Agent Builder agents include two attribute groups that you can use to inspect the operation of data collection and to tune the agent for your environment. The attribute groups are Performance Object Status and Thread Pool Status. When these attribute groups are used to tune data collection performance, the most useful data is:

- **Performance Object Status, Average Collection Duration** attribute. This attribute shows you how long each attribute group is taking to collect data. Often a small percentage of the attribute groups in an agent represents most of the processor usage or time that is used by the agent. You might be able to optimize the collection for one or more of these attribute groups. Or you can modify the collection interval for one or more groups, if you do not need some data to be as up-to-date as other data. For more information, see ([“Examples and advanced tuning” on page 1440](#)).
- **Performance Object Status, Intervals Skipped** attribute. This attribute shows you how many times the agent tried to schedule a new collection for the attribute group and it found that the previous collection was still on the queue, waiting to be run, or already running. In a normally behaved agent this attribute value is zero for all attribute groups. If this number starts growing, you tune the data collection, by adding threads, lengthening the interval between collections, or optimizing the collection.
- **Thread Pool Status, Thread Pool Avg Active Threads** attribute. You can compare this value to the Thread Pool Size attribute group to see how well your thread pool is being used. Allocating a thread pool size of 100 threads when the average number of active threads is 5 is probably just wasting memory.
- **Thread Pool Status, Thread Pool Avg Job wait** and **Thread Pool Avg Queue Length** attributes. These attributes represent the time an average data collection spends waiting on the queue to be processed by a thread and the average number of collections on the queue. Because of the way this data is collected, even an idle system indicates that at least an average of one job is waiting on the queue. A larger number of waiting jobs or a large average wait time indicates that collections are being starved. You can consider adding threads, lengthening the interval between collections or optimizing the collection for one or more attribute groups.

### **Event data**

Agent Builder agents can expose several types of event data. Some behavior is common for all event data. The agent receives each new event as a separate row of data. When a row of event data is received, it is sent immediately to Tivoli Monitoring for processing, and added to an internal cache in the agent. Situations and historical collection are performed by Tivoli Monitoring when each row is sent to Tivoli Monitoring. The cache is used to satisfy Tivoli Enterprise Portal or SOAP requests for the data. The agent can use the cache to perform duplicate detection, filtering, and summarization if defined for the attribute group. The size of the event cache for each attribute group is set by `CDP_PURE_EVENT_CACHE_SIZE`. This cache contains the most recent `CDP_PURE_EVENT_CACHE_SIZE` events with the most recent event

returned first. There are separate caches for each event attribute group. When the cache for an attribute group fills, the oldest event is dropped from the list.

The Agent Builder agent can expose events for:

- Windows Event Log entries
- SNMP Traps or Informs
- Records added to log files
- JMX MBean notifications
- JMX monitors
- Events from a Java API provider or socket provider.
- Joined attribute groups (where one of the data sources is an event data source)

These events are handled in the most appropriate way for each of the sources. SNMP Traps and Informs, JMX notifications and events from the Java API and socket providers are received asynchronously and forwarded to Tivoli Monitoring immediately. There is no requirement tune these collectors. The agent subscribes to receive Windows Event Log entries from the operating system by using the Windows Event Log API. If the agent is using the older Event Logging API, it polls the system for new events by using the thread pool settings. For joined attribute groups where one of the data sources is an event data source, there is no tuning to apply to the joined attribute group. Though the joined attribute group does benefit from any tuning applied to the event source group.

File monitoring is more complicated. The agent must monitor the existence of the files and when new records are added to the files. The agent can be configured to monitor files by using patterns for the file name or a static name. As the set of files that matches the patterns can change over time, the agent checks for new or changed files every KUMP\_DP\_FILE\_SWITCH\_CHECK\_INTERVAL seconds. This global environment variable governs all file monitoring in an agent instance. When the agent determines the appropriate files to monitor, it must determine when the files change. On Windows systems, the agent uses Operating System APIs to listen for these changes. The agent is informed when the files are updated and processes them immediately. On UNIX systems, the agent checks for file changes every KUMP\_DP\_EVENT seconds. This global environment variable governs all file monitoring in an agent instance. When the agent notices that a file changed, it processes all of the new data in the file and then waits for the next change.

## ***Examples and advanced tuning***

### **Example**

Environment variables that are used for more advanced tuning are defined at the agent level. You set the following variables one time and they apply to the all of the attribute groups in the agent:

- CDP\_DP\_CACHE\_TTL
- CDP\_DP\_IMPATIENT\_COLLECTOR\_TIMEOUT
- KUMP\_DP\_FILE\_SWITCH\_CHECK\_INTERVAL
- KUMP\_DP\_EVENT

You can make the following variables apply to individual attribute groups. They still have a global setting that applies to all other attribute groups in the agent:

- CDP\_DP\_REFRESH\_INTERVAL
- CDP\_PURE\_EVENT\_CACHE\_SIZE

If you defined an agent to include the following six attribute groups:

- EventDataOne
- EventDataTwo
- EventDataThree
- SampledDataOne

- SampledDataTwo
- SampledDataThree

You might set the following default variables:

- CDP\_DP\_CACHE\_TTL=55
- CDP\_DP\_IMPATIENT\_COLLECTOR\_TIMEOUT=2
- CDP\_DP\_REFRESH\_INTERVAL=60
- CDP\_PURE\_EVENT\_CACHE\_SIZE=100

As a result, all of the attribute groups which contain sampled data (SampledDataOne, SampledDataTwo, and SampledDataThree) would be collected every 60 seconds. Each of the event attribute groups (EventDataOne, EventDataTwo, and EventDataThree) would store the last 100 events in their cache.

These settings might work perfectly, or there might be reasons that you must control the settings at a more granular level. For example, what if EventDataOne generally receives 10 times as many events as EventDataTwo and EventDataThree? To further complicate things, there really is a link between EventDataOne and EventDataTwo. When one event is received for EventDataTwo, there are always multiple events for EventDataOne and users want to correlate these events. There is not a single correct setting for the cache size. It would be nice to be able to have EventDataOne store a larger number of events and EventDataTwo store a smaller number. You can achieve this storage by setting CDP\_PURE\_EVENT\_CACHE\_SIZE to the size that makes sense for most of the event attribute groups, 100 seems good. Then, you can set CDP\_EVENTDATAONE\_PURE\_EVENT\_CACHE\_SIZE to 1000. That way all of the corresponding events are visible in the Tivoli Enterprise Portal.

The same thing can be done with CDP\_DP\_REFRESH\_INTERVAL. Set a default value that works for the largest number of attribute groups in the agent. Then set CDP\_*attribute group name*\_REFRESH\_INTERVAL for the attribute groups which must be collected differently. To optimize collection, set the default CDP\_DP\_REFRESH\_INTERVAL to match the CDP\_DP\_CACHE\_TTL value. CDP\_DP\_CACHE\_TTL is a global value so if set to a value less than a refresh interval, unexpected collections might occur.

## Defining and testing data sources

---

Agent Builder supports a number of data providers. You can create data sources from each data provider. The procedure for creating and testing data sources is different for each data provider.

For most data providers, when you create a data source, a data set (attribute group) is added to the agent. The data set contains the information that is gathered by this data source.

A data source with a Process, Windows service, or Program return code data provider uses the special Availability data set. Only one Availability data set can be created in an agent. It contains the information that is gathered by all data sources with a Process, Windows Service, or Program Return Code data provider in this agent.

All Windows log data sources in an agent or subnode place event information into one Event Log data set.

### Setting up a data source for IBM Cloud Pak for Multicloud Management

In IBM Cloud Pak for Multicloud Management, you can use data from all data sets in the thresholds that you create. For data to be visible in the IBM Cloud Pak console, you must model the data as one or more resources.

These agent resources should group subsets of the data so that each resource represents a logical entity in the application, system, or network environment. Each resource can contain any subset of the information contained in any number of data sources. Each resource definition should include one data source with at least one attribute that can be used to identify the resource. If the data source is single-row, the agent creates one resource. If the data source is multi-row, the agent creates a resource for each unique set of values. A resource can include an event data source as additional data. All of the data selected when the resource is defined is displayed in a table in the IBM Cloud Pak console. You can choose to plot a subset of the data in a line graph by specifying a *units* value for the attribute.

For more information, see [“Preparing the agent for Cloud Pak for Multicloud Management” on page 1593](#).

## Setting up a data source for IBM Cloud Application Performance Management

In Cloud APM, you can use data from all data sets in the Details dashboard and to set up thresholds using the threshold manager. If you want to use information from a data set in the summary dashboard for the agent or subnode, including the status indicator, as well as for resource information (service name, address, and port), the data set must produce only one row.

For most data providers, you can select **Produces a single data row** in the data set configuration. If the gathered information would include more than one row, you can click **Advanced** to set up a filter that ensures the correct row is produced (for instructions, see [“Filtering attribute groups” on page 1425](#)). You can test your data source to ensure that the gathered information produces the row that you need.

For some data providers, the data set must produce multiple rows. Also, the process, Windows service, and command return code data sources place data into a single Availability data set, which produces multiple rows. In such cases, you must create a filtered data set that produces one row. For instructions about creating a filtered data set (attribute group), see [“Creating a filtered attribute group” on page 1559](#).

Some other data providers produce event data; a row is included for every new event. Do not use these data providers for summary or resource information in Cloud APM.

The following data providers must produce a data set with multiple rows:

- Process (uses the Availability data set)
- Windows service (uses the Availability data set)
- Program return code (uses the Availability data set)
- For some data types, SNMP and JMX
- Depending on the application, Socket and Java API

The following data providers produce event data:

- SNMP event
- Log file
- AIX binary log
- Windows event log
- Depending on the application, Socket and Java API

One of the attributes of the data set must provide a status value. Cloud APM uses this value for the overall status indicator. If the row does not include an attribute that can be used as a status indicator, you can create a derived attribute to calculate the status. You must configure the status severity values; for instructions, see [“Specifying severity for an attribute used as a status indicator” on page 1424](#).

## Monitoring a process

You can define a data source that monitors a process or several processes which run on a server. The processes must run on the same host as the agent. For every process, the data source adds a row to the Availability data set.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **A process** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **A process**.
3. Click **Next**.
4. On the **Process Monitor** page, in the **Process information** area, provide the display name and process name. You can type the process name manually or obtain it by clicking **Browse**. Clicking **Browse** shows a list of processes that are currently running on the local system or on a remote system.

You can further discriminate processes by selecting the **Use argument match** and **Match full command line** options. For example, if multiple instances of the same processes are running on the system, one instance can be distinguished from another by using these options.

| Table 301. Fields on the <b>Process Monitor</b> page. A table listing the fields in the <b>Process Monitor</b> page and their descriptions |   |                            |
|--|---|----------------------------|
| Field name   | Description   | Acceptable values          |
| <b>Display name</b>  | Descriptive name for the component of the application that is implemented by the process as it is shown in the Tivoli Enterprise Portal or in the IBM Cloud Application Performance Management console      | Descriptive string         |
| <b>Process name</b>  | Name of the process that is being monitored   | Valid executable file name |
| <b>Use argument match</b>  | Select if you want to match on the process arguments.   | On or Off                  |
| <b>Argument</b>  | Argument string on which to match. Argument matching looks for the provided string as a substring of the arguments. Matching is successful if you provide any part of the arguments as the input string.    | String                     |
| <b>Match full command line</b>   | Specify the entire name of the executable file that might include the path  | On or Off                  |
| <b>Command line</b>  | Matches the provided string against the fully qualified command name that is used to start the process. Command arguments are not included. Fully qualified means the path to the command must be included. | String                     |
| <b>Operating systems</b>   | Select the operating systems on which this process runs   | Any selection              |

5. If you click **Browse**, the **Process Browser** window opens. This window initially contains detailed information about each process on the Agent Builder system. The information includes the ID, the process name, and the full command line for the process. Select one or more processes or work with the list in the **Process Browser** window by using one or more of the following actions:
  - a) To sort the list of processes, click the column heading.
  - b) To refresh the information in the window, click the **Refresh** (lightening bolt) icon.
  - c) To search for specific processes, click the **Search** (binoculars) icon.  
You can enter a search phrase and select options section to search by process identifier, name, and command line.
  - d) To view processes on a different system, select a previously defined system from the **Connection Name** list. Or click **Add** to enter the system information for a new system.

For more information, see “Defining connections for process browsing” on page 1445. You can load processes from more than one system at a time, and switch between connections while processes are loading for one or more connections.

**Note:** When you browse remote systems, the command-line details are available only when you browse through a Tivoli Enterprise Portal Server.

In the following example, after you select `svchost.exe`, it is shown in the **Process name** field on the **Process Monitor** page (Figure 31 on page 1444).

Figure 31. Process Monitor page example

6. Complete the **Process Monitor** page by using the information in (Table 301 on page 1443).

**Note:** If the process you described in this monitor is applicable to only some of the operating systems that your application runs on, you might want to create one or more process monitors with the same display name to cover the other operating systems. Add the process monitors one at a time. Ensure that the display name is the same for each monitor, but that the process name can be found on the operating systems that are selected.

7. Do one of the following steps:

- If you are using the **Agent** wizard, click **Next**.
- Click **Finish** to save the data source and open the Agent Editor.

## What to do next

If you want to use the data from this data source in the summary dashboard for IBM Cloud Application Performance Management, you must create a filtered data set (attribute group) based on the Availability data set and configure it as providing a single row. Use the NAME field to select the row for your process.

You can use the Status field for status; DOWN means that the process is not running, while UP means it is running. In the new filtered attribute group, select the Status field and specify the severity values for it.

If several copies of the process are running, several rows with this process name are present in the Availability data set, and all of them include the UP status. Your filtered data set must be configured to return one row, so any of these rows might be returned, but the Status value is valid in any case.

For instructions, see:

- [“Creating a filtered attribute group” on page 1559](#)
- [“Specifying severity for an attribute used as a status indicator” on page 1424](#)
- [“Preparing the agent for Cloud APM” on page 1590](#)

## Defining connections for process browsing

When you define a process data source, you can view and select processes from other systems. However, when the agent runs, it monitors processes that run on the same system as the agent.

### About this task

You must have credentials for the other systems or they must be monitored by a Tivoli Monitoring operating system agent.

### Procedure

1. To define a connection, click **Add** in the **Process Browser** window.

You can select either a connection type (Secure Shell (SSH), Windows, or Tivoli Enterprise Portal Server Managed System) or select an existing connection to use as a template.

To add a Managed System connection, you require a Tivoli Enterprise Server host name, Tivoli Monitoring user name, and password. You also require the managed system name of the remote connection. When a managed system is selected, the table lists the process on the remote system.

**Note:** The OS agent must be running on the system you are attempting to browse. The agent must also be connected to a running Tivoli Enterprise Monitoring Server and Tivoli Enterprise Portal Server.

To add Secure Shell (SSH) or Windows connections, you require a host name, user name, and password.

2. When you add a connection, you can select the connection from the **Connection Name** list in the **Process Browser** window.

If all the fields required to make the connection are not saved (for example, the password), the **Connection Properties** window for that connection opens. Enter the missing information. For Tivoli Enterprise Portal Server Managed System connections, you must connect to the Tivoli Enterprise Portal Server before you can enter a managed system.

3. Enter your user name and password, and then click the **Refresh** (lightening bolt) icon to connect before you select the managed system.

## What to do next

To delete a connection, select the connection and click **Edit** to open the **Connection Properties** window. Select the **Remove this connection** check box and click **OK**.

## Monitoring a Windows service

You can define a data source that monitors a service or several services which run on a Windows system. The services must run on the same host as the agent. For every service, the data source adds a row to the Availability data set.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **A process** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **A Windows service**.
3. Click **Next**.
4. On the **Service Monitor** page, in the **Display name** field, type a description. In the **Service name** field, provide the name of the service application. You can type it manually or click **Browse** to view a list of services that are currently running on the local system or on a remote system.

If you click **Browse**, the **Service Browser** window opens. This window initially contains detailed information about each service on the Agent Builder system. The information includes the service name, the display name, the state, and the description for the service.

**Note:** Local services are not shown when Agent Builder is not running on a Windows system. A remote Windows system must be defined or selected, see ([“Defining connections for service browsing” on page 1447](#)).

**Note:** The service description is not available when you are browsing through the Tivoli Enterprise Portal Server or from a UNIX or Linux system.

5. Select one or more services or do one or more of the following steps to work with the list in the **Service Browser** window:
  - To sort the list of services, click the column heading.
  - To refresh the information in the window, click the **Refresh** (lightening bolt) icon.
  - To search for a service, click the **Search** (binoculars) icon to open the **Service Search** window. You can search by the service name, display name, and description.
  - To view services on a different system, select a previously defined system from the **Connection Name** list or click **Add** to enter the system information. For more information, see ([“Defining connections for service browsing” on page 1447](#)). You can load services from more than one system at a time, and switch between connections while services are loading for one or more connections.
6. After selecting or entering the name of the service, complete one of the following steps:
  - If you are using the **Agent** wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor.

### What to do next

If you want to use the data from this data source in the summary dashboard for IBM Cloud Application Performance Management, you must create a filtered data set (attribute group) based on the Availability data set and configure it as providing a single row. Use the NAME field to select the row for your process.

In the new filtered attribute group, select the Functionality\_Test\_Status field and specify the severity values for it.

For instructions, see:

- [“Creating a filtered attribute group” on page 1559](#)
- [“Specifying severity for an attribute used as a status indicator” on page 1424](#)
- [“Preparing the agent for Cloud APM” on page 1590](#)

## Defining connections for service browsing

In addition to selecting services from the system where Agent Builder is running, you can select services from other Windows systems.

### About this task

To select services from other Windows systems, you define a connection to the remote system. You must have credentials for the systems or they must be monitored by a Tivoli Monitoring operating system agent.

### Procedure

1. To define a connection, click **Add** in the **Service Browser** window.

The **Select Connection Type** window opens. To add a Managed System connection, you require a Tivoli Enterprise Server host name, Tivoli Monitoring user name and password, and the managed system name. When a managed system is selected, the table lists the service on the remote system.

**Note:** The OS agent must be running on the system you are attempting to browse and also connected to a running Tivoli Enterprise Monitoring Server and Tivoli Enterprise Portal Server.

You require a host name, user name, and password to add a Windows connection.

2. Select a connection type (Windows, or Tivoli Enterprise Portal Server Managed System) or select an existing connection to use as a template.

The **Connection Properties** window opens.

3. Complete the Connection Properties.

4. Click **Finish**

5. When you add a connection, you can select the connection from the **Connection Name** list in the **Service Browser** window.

If the fields necessary to make the connection are not saved (for example, the password), the **Connection Properties** window opens and you can enter the missing information.

- a) For Tivoli Enterprise Portal Server Managed System connections, you must connect to the Tivoli Enterprise Portal Server before you can enter a managed system. Enter your user name and password, and then click the **Refresh** (lightening bolt) icon to connect before you select the managed system.

6. To delete a connection, follow these steps:

- a) Select the connection in the **Service Browser** window.
- b) Click **Edit** to open the **Connection Properties** window.
- c) Select the **Remove this connection** check box.
- d) Click **OK**.

## Monitoring data from Windows Management Instrumentation (WMI)

You can define a data source to collect data from Windows Management Instrumentation (WMI) on the system where the agent runs or on a remote system. A data source monitors a single WMI class and places all values from this class into the data set that it produces. If the class provides several instances, the data set has multiple rows; you can filter by instance name to ensure the data set has one row.

### Before you begin

If your agent collects data from a remote system by using Windows Management Instrumentation (WMI), it requires permissions to access WMI data on the remote system. The agent can access WMI data on a remote system when you provide credentials of an account with permissions to access WMI data on the system. The Administrator account has the required permissions. In the procedure that follows you can either provide the Administrator credentials or the credentials of another user with the required permissions. For more information about creating a user account with permissions to browse WMI data, see [“Creating a user with Windows Management Instrumentation \(WMI\) permissions” on page 1582](#).

To collect metrics through the Windows APIs, the agent must be hosted on a Windows operating system. Remote registry administration must be enabled on the remote systems.

## Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **WMI**.
3. Click **Next**.
4. On the **Windows Management Instrumentation (WMI) Information** page, complete one of the following steps:
  - Type a name for the WMI namespace and a name for the WMI class name in the fields. Then go to step “9” on page 1448
  - Click **Browse** to see all of the WMI classes on the system.

To browse a remote system, select a system from the list (if one is defined). Alternatively click **Add** to add the host name of a Windows system. Provide the credentials of a user account with permissions to access WMI data on the remote system, or provide Administrator credentials for the remote system. The page is updated with the information for the remote system. Browsing is available only when the Agent Builder is run on a Windows system, and can browse only Windows systems.

5. Click the plus sign (+) next to a class to expand the class and show the attributes.
6. From the list, select the class with its associated attributes that you want to specify, and click **OK**.

**Note:** You can click the **Search** (binoculars) icon to find your selection in the list. Type a phrase in the **Search phrase** field; specify your preference by clicking either the **Search by name**, **Search by class description**, or **Search by class properties** fields; and click **OK**. If you find the item for which you are searching, select it and click **OK**.

The **WMI Information** page of the wizard opens again, showing the selected WMI class information.

7. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see “Testing WMI attribute groups” on page 1449
8. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see “Filtering attribute groups” on page 1425
9. Click **Next**.

**Note:** If you typed the WMI Namespace and WMI class name manually you are brought to the **Attribute Information** page, where you can complete attribute information. On the **Attribute Information** page, you can select **Add additional attributes** if you want to add more attributes. Click **Finish** to complete.

10. On the **Select key attributes** page, select key attributes or indicate that this data source produces only one data row. For more information, see “Selecting key attributes” on page 1397).
11. Do one of the following steps:
  - If you are using the **Agent** wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor.
12. You can add attributes and supply the information for them. For more information, see “Creating attributes” on page 1417.

In addition to fields that are applicable to all data sources (Table 297 on page 1420), the **Attribute Information** page for the WMI data source has the following field:

### **Metric name**

Property name from the class you want to collect

13. If you want to set global options for the data source, click **Global Options**.

Select the **Include remote Windows configuration properties** check box if you want to include this option, and click **OK**.

For information about Windows remote connection configuration for Windows data sources, see [“Configuring a Windows remote connection” on page 1581](#)).

## Testing WMI attribute groups

If you are running Agent Builder on a Windows system, you can test a WMI attribute group within Agent Builder.

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **WMI Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#).

After you click **Test** in one of the previous two steps, the **WMI Test** window is displayed.

2. Optional: Before you start testing, you can set environment variables and configuration properties. For more information, see [“Attribute group testing” on page 1596](#)).

3. Click **Start Agent**.

A window indicates that the Agent is starting.

4. To simulate a monitoring environment request for agent data, click **Collect Data**.

The agent queries WMI for data. The **WMI Test** window collects and displays any data in the agent's cache since it was last started.

5. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the **Data Collection Status** window is described in [“Performance Object Status node” on page 1638](#)).

6. Stop the agent by clicking **Stop Agent**.

7. Click **OK** or **Cancel** to exit the **WMI Test** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring a Windows Performance Monitor (Perfmon)

You can define a data source to collect data from Windows Performance Monitor (Perfmon). A data source monitors a Perfmon object. The counters in the object are placed in attributes in the resulting data set. If the class provides several instances, the data set has multiple rows; you can filter by instance name to ensure the data set has one row.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **Perfmon**.
3. Click **Next**.
4. On the **Perfmon Information** page, complete one of the following steps:
  - Type the name of the object in the **Object Name** field, and click **Next** to define the first attribute in the attribute group.

**Note:** If you type the name for the Windows Performance Monitor object, it must be the English name.

- Click **Browse** to view the list of Perfmon objects.

When the Performance Monitor (Perfmon) Object Browser window initially opens, the window populates with the information from the local system. To browse a remote system, select a system from the list (if one is defined), or click **Add** to add the host name of a Windows system. Provide an Administrator ID and password. The window updates with the information for the remote system. Browsing is available only when Agent Builder is running on a Windows system, and can browse only Windows systems. For example, you cannot add the host name of a Linux or Solaris system to do a remote browse.

- When you click an object name, the available counters in that object are shown in the window.
  - To sort the Windows Performance Monitor objects or counters, click the column heading.
  - To refresh the information in the window, click **Refresh**.
  - To search for specific objects or counters click the **Search** (binoculars) icon to open the **Performance Monitor Search** window. You can search object names, counter names, or both. The search operation does a substring match and is not case-sensitive.
  - Select an object and click **OK**.
  - The **Perfmon Information** page opens with the name of the selected object in the **Object Name** field.

- If you want to set global options for the data source, click **Global Options**

Select the **Include remote Windows configuration properties** check box if you want to include this option, and click **OK**.

For information about Windows remote connection configuration for Windows data sources, see [“Configuring a Windows remote connection” on page 1581](#).

5. If the Windows Performance Monitor object selected returns multiple instances and you want to filter the results that are based on the instance name:
  - a) Select the **Filter by Perfmon Instance Name** check box on the **Perfmon Information** page.
  - b) In the **Perfmon Instance Name** field, type the name of the instance to be filtered, or click **Browse** to list the instances available.
  - c) To browse a remote system, either select one from the list, or click **Add** to add the host name of a Windows system. After you select a host, provide an Administrator ID and password. The table is updated with the list of instances on the remote system.

**Note:** You can also filter by attribute group, see step [“9” on page 1450](#)

6. If the selected Windows Performance Monitor Object is to return multiple instances, and you want the instance name to be returned, select **Return Instance Name** on the **Perfmon Information** page. Checking this option adds an attribute to the data source that is not shown in the list of attributes. This attribute contains the instance name.

**Note:** If you browsed for the selected object, and that object is defined as having multiple instances, this check box is selected automatically.

7. If you did not check the option to return the instance name, the Select key attributes page opens. On the Select key attributes page, select key attributes or indicate that this data source produces only one data row. For more information, see [“Selecting key attributes” on page 1397](#).
8. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing Perfmon attribute groups” on page 1451](#)
9. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**.

For more information about filtering data from an attribute group, see step [“Filtering attribute groups” on page 1425](#)

**Note:** You can also filter by instance name, see [“5” on page 1450](#)

10. Do one of the following steps:

- If you are using the New Agent wizard, click **Next**.
- Click **Finish** to save the data source and open the Agent Editor.

The **Agent Editor Data Source Definition** page shows a list that contains the object and information about the object.

11. You can add attributes and supply the information for them. For more information, see ([“Creating attributes” on page 1417](#)).

In addition to the fields applicable to all data sources, the **Perfmon Attribute Information** page for the data source has the following field:

**Metric name**

Name of the counter for the specific object.

## What to do next

For information about Windows remote connection configuration for Perfmon data sources, see [“Configuring a Windows remote connection” on page 1581](#).

## Testing Perfmon attribute groups

If you are running Agent Builder on a Windows system, you can test the Perfmon attribute group that you created.

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **Perfmon Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#).

After you click **Test** in one of the previous two steps, the **Perfmon Test** window is displayed.

2. Optional: Before you start testing, you can set environment variables and configuration properties. For more information, see [“Attribute group testing” on page 1596](#).

3. Click **Start Agent**. A window indicates that the Agent is starting.

4. To simulate a request from the monitoring environment for agent data, click **Collect Data**.

The agent queries Performance Monitor for data. The **Perfmon Test** window collects and shows any data in the agent's cache since it was last started.

**Note:** You might not see useful data for all attributes until you click **Collect Data** a second time. The reason is that some Performance Monitor attributes return delta values, and a previous value is required to calculate a delta value.

5. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and shown by the **Data Collection Status** window is described in [“Performance Object Status node” on page 1638](#).

6. Stop the agent by clicking **Stop Agent**.

7. Click **OK** or **Cancel** to exit the **Perfmon Test** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring data from a Simple Network Management Protocol (SNMP) server

You can define a data source to monitor an SNMP server. A data source monitors all data from a single SNMP object identifier (OID) and a single host. If you select an element of the OID registration tree under which other objects are registered, a data set is created for each distinct set of scalar or table values. If an object returns scalar data, the data set has a single row. If an object returns tabular data, the data set has multiple rows.

### About this task

Simple Network Management Protocol V1, V2C (note that the version is V2C and not just V2), and V3 are supported by agents.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **SNMP**.
3. Click **Next**.
4. On the Simple Network Management Protocol (SNMP) Information page, type the display name or click **Browse** to see all of the objects on the system.

After you define the data source, you can add an attribute. The OIDs for these attributes can be long and difficult to type correctly. Using the Browse option is an easy way to input the correct OID.

**Note:** The browser does not browse the live system, it reads definitions, Management Information Bases (MIBs).

**Note:** Clicking the **Refresh** icon clears the in-memory version of the parsed MIB files and reparses the files in the workspace cache. The cache is in the following location: *workspace\_directory* \.metadata\.plugins\ com.ibm.tivoli.monitoring.agentkit\mibs

Where:

#### **workspace\_directory**

Identifies the workspace directory that you specified when you initially ran the Agent Builder, see ([“Starting Agent Builder” on page 1393](#)).

- a) If the MIB that defines the wanted object is not loaded, click **Manage Custom MIBs** to open the Manage Custom MIBs dialog.
- b) Click **Add** to browse to the MIB file to add. To delete a MIB from the cache, select it and click **Remove**.
- c) Click **OK** to update the cache.

If there are any errors when the MIBs are parsed, the Manage Custom MIBs dialog remains open. This dialog gives you the opportunity to add or remove MIBs to eliminate the errors.

Clicking **Cancel** returns the MIB cache to the state it was in when the dialog was opened.

Agent Builder includes a set of MIBs:

- hostmib.mib
- rfc1213.mib
- rfc1243.mib
- rfc1253.mib
- rfc1271.mib
- rfc1286.mib
- rfc1289.mib

- rfc1315.mib
- rfc1316.mib
- rfc1381.mib
- rfc1382.mib
- rfc1443.mib
- rfc1461.mib
- rfc1471.mib
- rfc1493.mib
- rfc1512.mib
- rfc1513.mib
- rfc1516.mib
- rfc1525.mib
- rfc1573a.mib
- rfc1595.mib
- rfc1650.mib
- rfc1657.mib

- rfc3411.mib

All of these MIBs are standard, IETF defined MIBs. The MIBs are included because they represent common definitions that can be useful in monitoring. Also, many of the MIBs are necessary so that custom MIBs can resolve the symbols that they import.

d) Select an object from the list.

Click the plus sign (+) next to an object to expand and show the levels.

e) From the list, select the object that you want to specify and click **OK**.

The new data source is then listed on the **Data Source Definition** page.

**Note:** If you select an object that defines other objects (objects that are nested underneath the first object), all of these objects are turned into data sources. If you select a high-level object, many data sources are added.

5. On the **Simple Network Management Protocol Information** page, select the operating systems.
6. Optional: You can test the data source or sources by clicking **Test** on the **Simple Network Management Protocol Information** page.  
For more information about testing, see [“Testing SNMP attribute groups” on page 1455](#)
7. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
8. Click **Next**.
9. On the **Attribute Information** page, specify the information for the attribute.
10. Do one of the following steps:
  - If you are using the New Agent wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor.
11. For more information about adding attributes and supplying the information for them, see [“Creating attributes” on page 1417](#).

In addition to fields that are applicable to all data sources, the **Attribute Information** page for the SNMP data source has the following fields:

**Metric name**

Arbitrary string

**Object identifier**

Full OID that is registered to the object, not including index values

## What to do next

You can use the runtime configuration of the agent to set the monitored host.

To enable Agent Builder to generate 64-bit data types and to handle the maximum value for 32-bit unsigned MIB properties, see [“SNMP MIB Parsing options” on page 1454](#).

## SNMP MIB errors

Dealing with errors in SNMP MIBs.

It is not unusual to find errors when you are adding SNMP MIBs. Click **Details>>** in the **Agent Builder Error** window to see what the MIB error is.

One of the most common errors is missing definitions that are defined in other MIBs. You can import several MIBs simultaneously to resolve this problem, or you can incrementally add MIBs until all of the missing definitions are resolved. Agent Builder can use any definitions that are resolved. So you can choose to ignore an error that affects only that part of the MIB that you do not plan to use. The order of the MIBs does not matter because they are all loaded, and then the references are resolved.

## SNMP MIB Parsing options

Set your preferences for SNMP MIB parsing

### Procedure

1. In the Agent Builder, select **Window > Preferences** to open the **Preferences** window.
2. In the navigation pane, expand **IBM Agent Builder**.

3. Click **MIB Parsing** to open the **MIB Parsing** window.

The MIB parser that is used by Agent Builder uses the grammar that is defined by ASN.1 to parse the MIBs. Some MIBs do not follow the grammar correctly. The parser can relax certain rules to accommodate the most common errors. By relaxing these rules, you can parse non-conforming MIBs.

**Allow types to start with lowercase letters**

Allows types that people write in MIBs, such as values

**Allow numeric named numbers**

Allows numbers that start with uppercase letters

**Allow underscore in value name**

Allows underscore characters

**Allow values to begin with uppercase letters**

Allows values that start with uppercase letters

**Ignore duplicate MIBs**

Turns off warning for duplicate MIB modules

4. Optional: Selecting the **Create 64-bit attributes for 32 bit unsigned MIB properties** check box, enables the Agent Builder to generate 64-bit data types to handle the maximum value for 32-bit unsigned MIB properties. Selecting this option does not change any existing agent field definitions. You must browse to the MIB file to create new data sources for these properties.
5. When you are finished editing the preferences, click **OK**.

## Testing SNMP attribute groups

You can test the SNMP attribute group that you created within Agent Builder.

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **Simple Network Management Protocol Information** page.

**Note:**

If the SNMP object selected contains more than one attribute group, you are prompted to select the attribute group to test.

- After agent creation, select an attribute group on the **Agent Editor Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398

After you click **Test** in one of the previous two steps, the SNMP Test settings window opens.

2. Select an existing connection from **Connection name** or click **Add** and you are prompted to select a connection type. Alternatively select an existing connection to use as a template, by using the **Create Connection Wizard**
3. After you select a connection type or an existing connection, click **Next** to complete the SNMP connection properties. When complete click **Finish** to return to the SNMP Test settings window.
4. Optional: Before you start testing, you can set environment variables and configuration properties. For more information, see [\(“Attribute group testing” on page 1596\)](#).
5. Click **Start Agent**. A window indicates that the Agent is starting.
6. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**. The agent queries the configured SNMP connection for data.
7. The **Test Settings** window collects and shows any data in the agent's cache since it was last started.
8. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and shown by the **Data Collection Status** window is described in [“Performance Object Status node”](#) on page 1638

9. Stop the agent by clicking **Stop Agent**.
10. Click **OK** or **Cancel** to exit the **Test Settings** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring events from Simple Network Management Protocol event senders

You can define a data source to collect data from SNMP Trap and Inform events. You must set the port in the agent runtime configuration and configure the servers to send event to the agent host on this port. All the monitored events are placed as rows in a data set.

### About this task

Simple Network Management Protocol (SNMP) V1, V2C (note that this version name is V2C and not just V2), and V3 are supported by agents. SNMP Traps and Informs can be received and processed by the agent. Data that is received by this provider is passed to the monitoring environment as events.

For more information about the attribute groups for SNMP events, see ([“SNMP Event attribute groups” on page 1664](#)).

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **SNMP Events**.
3. Click **Next**.
4. In the **Simple Network Management Protocol Event Information** window, do one of the following steps:
  - Click **All Events** to create an attribute group that sends an event for any received SNMP event.
  - Click **Generic Events** to create an attribute group that sends an event for any received generic SNMP event that matches any of the selected generic event types.
  - Click **Custom Events** to create one or more attribute groups that send events for enterprise-specific SNMP events. Click **Browse** to choose the events to be monitored.

In the **Simple Network Management Protocol (SNMP) Management Information Base (MIB) Browser** window, the events in the selection pane are organized by the MIB module in which they were defined. Expand an SNMP object to show the events in that MIB module. In the list, click the object that you want to specify and click **OK**.

Select the **Include attributes that show information defined in the trap configuration file** check box if you have a trap configuration file that contains static data for your traps. For more information about the SNMP trap configuration file, see ([“SNMP trap configuration” on page 1717](#)).

Select the **Include variable binding (VarBind) data attribute** check box if you want to include an attribute with all of the variable binding (VarBind) data that is received in the trap protocol data unit (PDU). For more information about this attribute, see the attribute definition ([“SNMP Event attribute groups” on page 1664](#)).

#### Note:

- a. The browser does not browse the live system; it reads definitions and, Management Information Bases (MIBs). The list of MIBs included with Agent Builder is defined in [“Monitoring data from a Simple Network Management Protocol \(SNMP\) server” on page 1452](#). MIBs loaded by either SNMP data provider are available in both.
- b. If you select a MIB module or individual events, all the events in that module are converted to separate data sources. One attribute is added for each of the variables that are defined in the

event. If you want all the events for the selected modules or traps to arrive in a single event source, select the **Collect events in a single attribute group** check box. If you select individual traps and the **Collect events in a single attribute group** flag is selected, one attribute is added for each of the variables that are defined in each of the events (duplicate variables are ignored). If you select a module, variable attributes are not added.

- c. If you want to type your own filter, use the following syntax:

The value of the OID (object identifier) element is used to determine which traps to process for this attribute group.

- **Trap matching:** The OID attribute of the `global_snmp_event_settings_for_group` element can be a comma-delimited list of tokens. A single token has the following syntax:

```
[enterpriseOID][-specificType]
```

- **Example:** "1.2.3.5.1.4,1.2.3.4.5.6.7.8.9-0" The first token matches any trap with an enterprise OID of 1.2.3.5.1.4. The second token matches any trap with an enterprise of 1.2.3.4.5.6.7.8.9 and specific of 0. Because the tokens are listed together in one attribute group, an event received that matches either is processed by that attribute group.
- d. Every event that is received is processed only by the first attribute group that matches the received event. Subnode attribute groups are processed first, and then the base attribute groups are processed. The agent developer must ensure that the groups are defined in a way so that events are received in the expected attribute group.
5. In the **SNMP Event Information** window, select the **Subnode Host matching** check box to match events to subnodes. If the SNMP event attribute group is part of a subnode, you can select the **Subnode Host Matching** check box to control whether the event must come from the SNMP agent that is monitored.

For example: You have an agent to monitor routers, where each subnode instance represents a specific router. You develop an agent to collect data from a router with the SNMP data collector. You also define an attribute group to receive SNMP events sent by that router. Each router instance includes the same data that is defined for the event filter. Therefore, you need another way to make sure that events from your router are shown in the attribute group for that router.

When subnode host-matching is selected, an event that is sent by the router is compared to the host defined for the SNMP data collector. If the host in use by the SNMP data collector is the same host that sent the received event, the subnode instance processes the SNMP event. Otherwise, the event is passed to the next subnode instance. Address-matching applies only to subnodes. No address-matching is done by the SNMP event attribute groups in the base agent. For the address-matching to work, the subnode definition must contain at least one SNMP attribute group. The SNMP host that is used by SNMP for that subnode instance is the host that is used for matching.

If the **Subnode Host Matching** check box is clear, your subnode instances do not do this extra comparison. You must allow the user to configure a different OID filter for each subnode in this case. Otherwise, you do not need to include SNMP event attribute groups in the subnode definition.

6. In the **SNMP Event Information** window, select the operating systems.
7. Optional: You can click **Test** in the **SNMP Event Information** window to start and test your agent. For more information, see [“Testing SNMP event attribute groups” on page 1460](#)
8. Optional:

In the **SNMP Event Information** window, click **Advanced** to select **Event Filtering and Summarization Options**. For more information, see [“Event filtering and summarization” on page 1623](#).

- a) When you finish selecting **Event Filtering and Summarization Options**, return to the **SNMP Event Information** window. If you previously selected **Custom Events** in the **SNMP Event Information** window, click **Next**, to select key attributes, otherwise skip the next step.
- b) On the Select key attributes page, click one or more key attributes for the attribute group, or click **Produces a single data row**.

9. Click **Next**, or click **Finish** if you are using the new agent wizard to save the agent and open the Agent Editor.
- 10.

### **What to do next**

For information about adding further attributes, see ([“Creating attributes” on page 1417](#)).

### **SNMP Event Configuration properties**

Certain configuration properties are automatically created when an SNMP Event attribute group is added to the agent

After a data source is added, the configuration is displayed on the **Runtime Configuration Information** page of the Agent Editor. For example, [Figure 32 on page 1459](#) shows the configuration sections and some configuration properties that are automatically created when an SNMP Event attribute group is added to the agent.

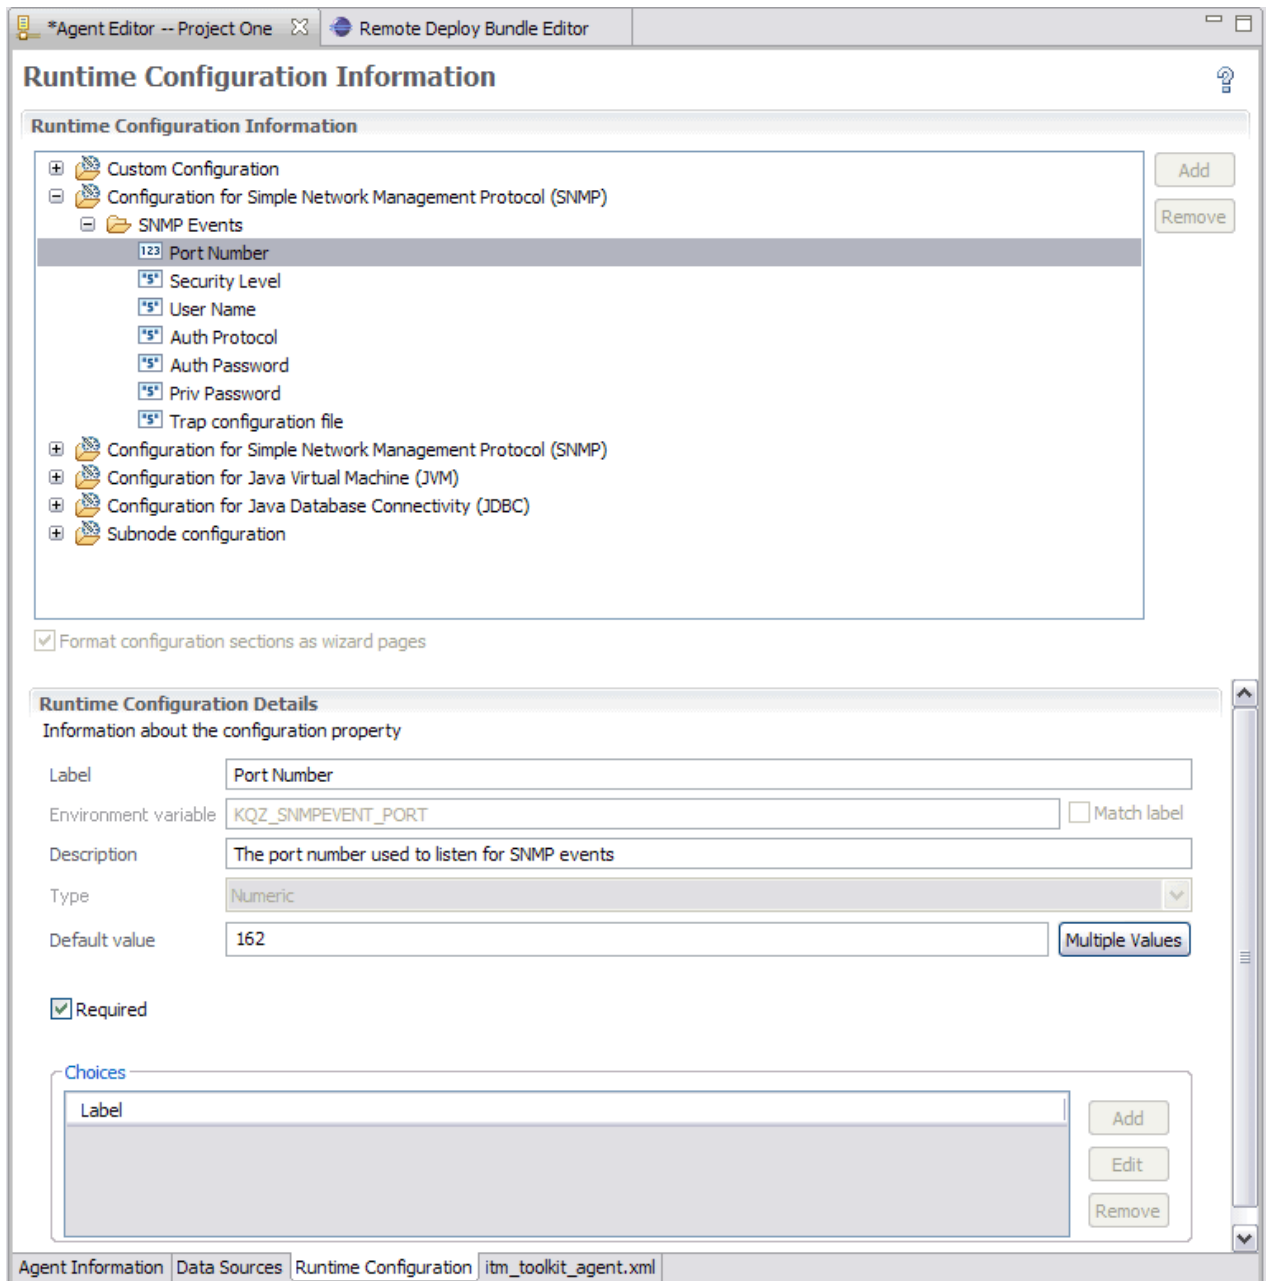

Figure 32. Runtime Configuration page

The labels, descriptions, and default values of predefined configuration properties can be changed, but variable names and types cannot be changed. The SNMP Events configuration section contains the following properties:

| Table 302. SNMP Events configuration properties |                                    |          |   |
|---|------------------------------------|----------|---|
| Name  | Valid values                       | Required | Description   |
| Port Number                                     | positive integer                   | Yes      | Required port number that is used for listening to events |
| Security Level                                  | noAuthNoPriv, authNoPriv, authPriv | No       | SNMP V3 security level                                    |
| User Name                                       | String                             | No       | SNMP V3 user name   |

| Table 302. SNMP Events configuration properties (continued) |                                  |          |  |
|---|----------------------------------|----------|--|
| Name  | Valid values                     | Required | Description  |
| <b>Auth Protocol</b>  | MD5 or SHA                       | No       | SNMP V3 authentication protocol  |
| <b>Auth Password</b>  | String                           | No       | SNMP V3 authentication password  |
| <b>Priv Password</b>  | String                           | No       | SNMP V3 privacy password   |
| <b>Trap configuration file</b>                              | File name that includes the path | No       | Location of the trap configuration file. If the file is not located by using this configuration property, an attempt is made to find a trapcnfg file in the agent bin directory. |

No configuration is required for V1 or V2C events. All V1 or V2C events are processed regardless of the source or community name specified. The only supported privacy protocol is DES, so there is no option to specify the privacy protocol. The SNMP V3 configuration options are not required (each can be optionally specified). If you want to specify them, you must specify the appropriate values for the security level you select.

## Testing SNMP event attribute groups

You can test the SNMP event attribute group that you created, within Agent Builder.

### Before you begin

To test the SNMP event attribute group, use a test program, or application to generate SNMP events.

### Procedure

1. You can start the Testing procedure in the following ways:
  - During agent creation click **Test** in the **SNMP Event Information** window.
  - After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398

After you click **Test** in one of the previous two steps, the **Test Event Setting** window opens.

2. Optional: Before you start testing, you can set environment variables and configuration properties. For more information, see [“Attribute group testing”](#) on page 1596. For more about SNMP Event configuration properties, see [“SNMP Event Configuration properties”](#) on page 1458.
3. Click **Start Agent**. A window indicates that the Agent is starting.

When the agent starts, it listens for SNMP events according to its configuration.

**Note:** The agent that starts is a simplified version that includes the one attribute group you are testing.

4. To test your agent's data collection you generate SNMP events that match the agents configuration. You can do this using an application or an event generator.

When the agent receives SNMP events that match its configuration, it adds the events to its internal cache.

5. To simulate a request from the monitoring environment for agent data, click **Collect Data**.

The **Test Event Settings** window collects and shows any events in the agent's cache since it was last started. An example data collection is shown in [Figure 33 on page 1461](#)

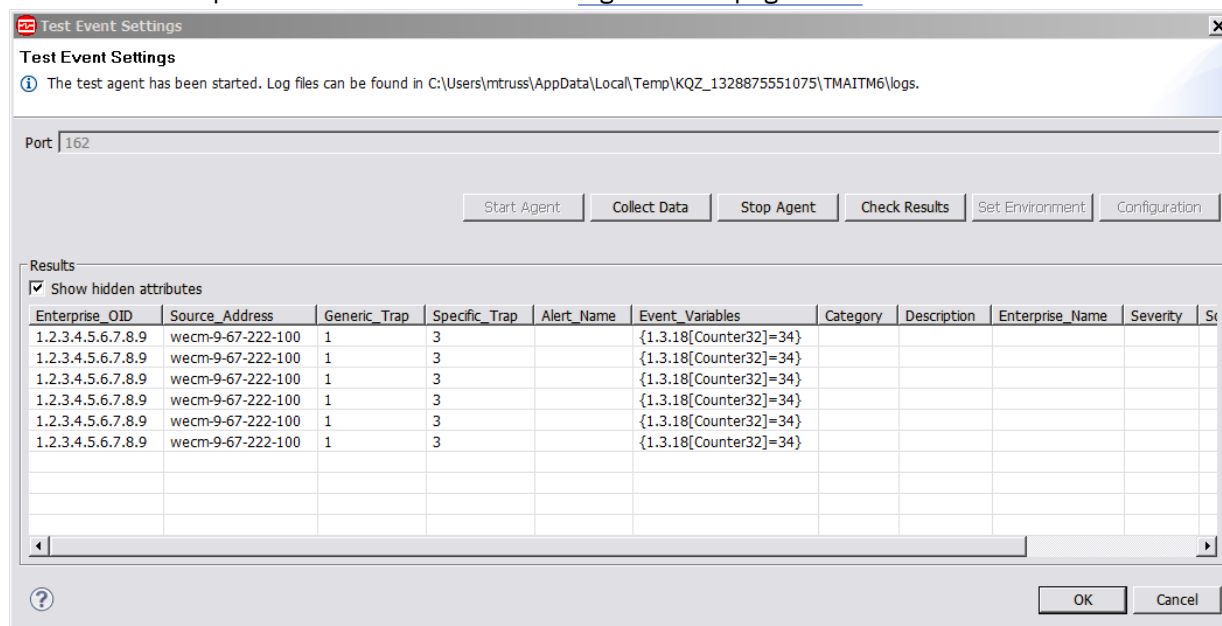

Figure 33. **Test Event Settings** window that shows collected SNMP event data

- Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. An example is shown in [\(Figure 34 on page 1461\)](#). The data that is collected and shown by the **Data Collection Status** window is described in [“Performance Object Status node” on page 1638](#)

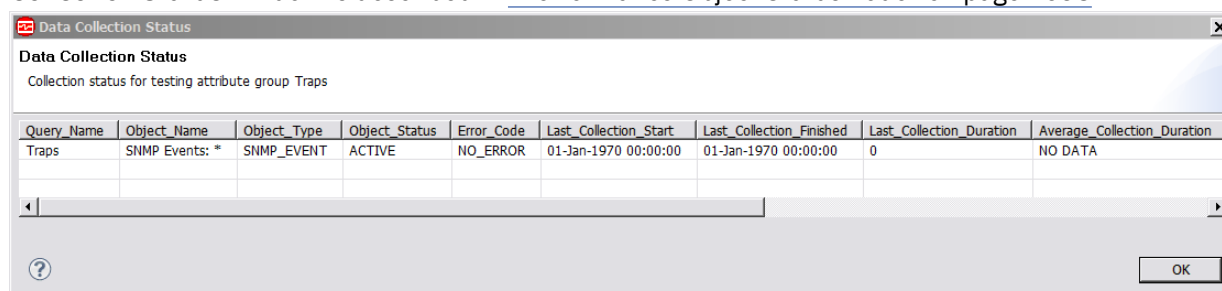

Figure 34. **Data Collection Status** window

- Stop the agent by clicking **Stop Agent**.
- Click **OK** or **Cancel** to exit the **Test Event Settings** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring Java Management Extensions (JMX) MBeans

You can define a data source to collect data from JMX MBeans. Data from every monitored MBean is placed into a data set. Depending on the MBean, the data set can produce a single row or multiple rows.

### About this task

Each JMX data source that you define must identify either a single MBean (single instance) or a certain type of MBean (multiple instances). You must know the Object Name of the MBean or an Object Name pattern for a MBean type that contains the data you want to collect. Use an Object Name pattern to identify only a set of similar MBeans. The set of MBeans that matches the pattern must all provide the

data that you want to see in the monitoring table. A typical Object Name pattern looks like `*:j2eeType=Servlet,*`. This Object Name Pattern matches all MBeans that have a j2eeType of servlet. You can expect any MBean matching that pattern to have a similar set of exposed attributes and operations that can be added to your data source. A data source that uses that pattern collects data from each MBean matching that pattern. The attributes that you define for this data source must be available for any MBean matching the Object Name pattern of the data source.

Java Version 5 or later is supported.

## Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **JMX**.
3. Click **Next**.
4. On the **JMX Information** page, click **Browse** to see all of the JMX MBeans on the MBean server.

After you define the data source, you can use the browse function to pre-populate your attribute list. You can then add to, remove from, or modify the attributes that the browser inserted. The names for these attributes can be long and difficult to type correctly. Using the Browse option is an easy way to input the correct name.

**Note:** You can manually create JMX data sources by specifying an Object Name and clicking **Next** without using the browser. Manually creating JMX data sources creates two data sources. An event data source that contains predefined attributes for JMX notifications is created. Also, a collection data source is defined containing one attribute that you must specify in the wizard.

### MBean pattern

Shows the MBean pattern.

### Global JMX Options

Shows the level of support.

Support is provided for the following JMX servers:

- Java 5 operating system MBean Server. Connection is made by using the JSR-160 connector. Notifications and monitors are supported.
  - WebSphere Application Server, version 6 and later. Connectors are provided for both SOAP and RMI protocols. JMX Monitors are not supported because MBeans cannot be created by a remote agent.
  - WebSphere Community Edition and other Apache Geronimo-based application servers. Connection is made through standard JSR-160 connectors. JMX notifications and monitors are supported in versions 1.1 and later.
  - JBoss Application Server, version 4.0 and earlier.
  - JBoss Application Server, JSR-160 connection.
  - WebLogic Server, version 9 and newer. Connector is provided for T3 protocol.
5. The first time that you run the JMX browser, there are no items in the **MBean server** scroll down menu. To add connections, click the **Add** button.  
Use the **Edit** button to modify or delete the connection that you already defined and selected in the scroll down menu. The connection definitions are stored in the workspace, so that, when you create a connection, it is remembered. Complete the following steps to create a connection. If you already have a connection, skip to the next step.
    - a) To create a connection to an MBean Server, click **Add** to add a connection or to edit an existing connection.  
The **Java Management Extensions (JMX) Browser** window is shown when no connections are defined.
    - b) After you click **Add** to add a connection, the **Select Connection Type** page opens.

- c) Use the MBean Server Connection wizard to connect to an MBean server. The new connections that are listed on the page are selections that you can make to create connection. You can use the list of existing connections to create a new connection using an existing connection as a template. Select one of the new connection types and click **Next** to begin creating a connection.
- d) After you select a connection type, you might be asked to select a more specific type of connection. Two templates that are based on the **Standard JMX Connections (JSR-160)** connection type are shown. Select the template that is most appropriate for your MBean server and click **Next**.

**Create Connection Wizard**

**Connection Properties**  
Edit the connection properties and press Finish.

Connection name: JBoss JSR-160

JMX user ID:

JMX password:

☒ Save the password in the Agent Builder workspace

JMX service URL: service:jmx:remoting-jmx://localhost:9999

Java class path information

JMX base paths: C:\jboss-eap-6.3.01\jboss-eap-6.3

JMX class path: bin\client\jboss-client.jar

JMX JAR directories:

Browser Java Runtime Environment

Java location: C:\Program Files (x86)\IBM\Java70\jre

☒ Set as agent configuration defaults

Figure 35. JMX connection properties

The **Connection Properties** page (Figure 35 on page 1463) contains the details on how to connect to an MBean server. You must complete the page with details about your MBean server.

**Important:** If your data source connects to a remote WebSphere Application Server, ensure that WebSphere Application Server is also installed on the host that is running Agent Builder and set

the **Java location** setting to the Java runtime environment that the local WebSphere Application Server uses.

- e) Select the **Save the password in the Agent Builder workspace** check box if you want to save the password for this connection.
- f) Optional: Select **Set as agent configuration defaults** if you want the defaults for JMX to be copied from these connection properties.  
For example, in Figure 35 on page 1463 the default **JMX base path** is C:\jboss-eap-6.3.01\jboss-eap-6.3, the **JMX service URL** is service:jmx:remoting-jmx://localhost:9999 and the **Java location** is C:\Program Files\IBM\Java70\jre
  - i) After you specify the properties that are required to connect, click **Test Connection** to ensure that the connection can be established. If the connection is not successful, correct the necessary properties.
  - ii) When the connection is successful, click **Finish** to return to the browser that uses the connection you configured.

The Java class path information in the **Connection Properties** page contains three fields. These fields must be completed as necessary to connect to an MBean server that requires Java classes that are not included in the Java runtime environment. Normally, the MBean server you want to connect to must be installed on the same system as the Agent Builder. In this case, specify the directory where the application that contains the MBean server was installed as the **JMX base paths** field. The **JMX Jar Directories** field then lists the directories relative to the Base Paths directory that contain the JAR files that are required to connect to the MBean server. The **JMX class path** field can be used to include specific JAR files. The JAR files that are listed in the **JMX JAR Directories** field are not required to be listed separately in the **JMX class path** field.

Any of the fields can contain more than one reference; separate the entries by a semicolon. These values are the same values that are required when you configure the agent. For more information, see (“JMX configuration” on page 1469).

6. After you select a connection, the JMX Browser downloads information about the MBeans from the JMX server. This information is shown in the following four areas of the **JMX Browser** window (Figure 36 on page 1465):

Directions for screens that begin with Java Management Extensions (JMX) Browser window to **Runtime Configuration** tab of the Agent Editor: From the **JMX Information** page, select **Browse**. From the browser (JMX Browser with no connection-selected), select **Add**. From the **JMX Connection Selection** page select **JBoss**, then select **Next**. From the **JMX Connection Properties** page, customize two Connection Properties: JBoss provider URL: jnp://wapwin3.tivlab.raleigh.ibm.com:1099/ and **JBoss Jar Directories**: The full path to the directory that contains the following JAR files: jbossall-client.jar, jboss-jmx.jar, jboss-jsr77-client.jar, jboss-management.jar. Select **Finish**. This configuration sets up your JBoss connection so you can get similar screens as shown here.

Figure 36. Java Management Extensions (JMX) Browser window

- **MBean Key Properties** area: This area is a collection of every unique Object Name key that is found from all the MBeans on the server. The **[Domain]** entry is special because it is not really a key. However, the **[Domain]** entry is treated as an implied key for the value of the MBean domain. Select an item from this list, and the MBeans that contain that key property are found. The list of values of the key property are shown in the **Selected Key Property Values** list. When you check a key property, it is included in the Object Name pattern for the data source.
- **Selected Key Property Values** area: This area shows the values of the currently selected MBean Key Property from all MBeans. Selecting one of these values checks the MBean key property. The selection also updates the Object Name Pattern shown in the message field with the MBean key property name and value.
- A table lists all MBeans matching the Object Name Pattern: As you select Key Properties and Values from the MBean Key Properties and Selected Key Property Values lists, you see the Object Name Pattern update. You also see the list of MBeans in this table change to reflect the list of MBeans that match the pattern you selected. If you have a pattern that is not matching any MBeans, you can

clear entries in the MBean Key Properties list. You clear entries by clicking the check box next to a key that is being used by your pattern and removing the check mark. Also, you can manually edit the pattern to find the MBeans you are looking for. The pattern `*:*` selects all MBeans.

You can use this table to browse the MBeans from the server and decide which ones contain the data you want to monitor. To help browse a potentially large number of MBeans, you can sort by any key attribute (from the menu or by clicking a column header). You can also show any key attribute in any column by selecting **Show Key Property** from the menu. When you see a key property value in the table that identifies MBeans you want to monitor, right-click on that value and choose **Select only MBeans with Key Property** from the menu.

- A table that contains details for a selected MBean: The JMX Browser shows you information about a single MBean. To see details for an MBean, you select the MBean from the table that shows the list of MBeans matching the current filter. The key information about the MBean is the list of Attributes, Operations, and Notifications it defines.

To create a data source from the JMX Browser, use the four panels that were described earlier to build an Object Name Pattern. Build the Object Name Pattern to match a set of MBeans that each contains the monitoring data you want to collect. For instance, if you wanted to monitor data from all of the `ThreadPool` MBeans, use the following steps:

- a) Select **type** from the **MBean Key Properties** panel. Selecting **type** causes the values in the **Selected Key Properties Values** to be updated to list all unique values from the type key of any MBean.
  - b) Select **ThreadPool** from the list of values for the type key. After you select **ThreadPool**, the type key property name is selected in the **MBean Key Properties** panel and the Object Name Pattern is updated to `*:type=ThreadPool,*`. The list of MBeans is also updated to show only the MBeans that match this pattern.
  - c) Select one of the MBeans from the MBean list to see the attributes, operations, and notifications available for the MBean. If your MBean list contains more MBeans than you want to monitor, you must continue this procedure of selecting key properties and values. Continue until you have the Object Name Pattern that identifies the set of MBeans you want to monitor. You can also open a menu in the MBean list to update the Object Pattern with key property values shown in the table.
7. When the object name pattern is correct, select an MBean from the table.

All attributes of the selected MBean are the initial attributes in the new JMX data source. Some attributes might not contain data. After the JMX data source is created, review the attributes and remove any that are not significant. If the selected MBean has no attributes, you are warned that the data source is created with no attributes. If the selected MBean contains notifications, an Event data source is also created to receive notifications from the MBeans.

**Important:** For every MBean attribute, Agent Builder creates an attribute in the new data set. For a numeric MBean attribute, Agent Builder creates a numeric attribute. For any object types, including `String`, Agent Builder creates a string attribute containing a string representation of the value. If an object from an MBean attribute is of the `javax.management.openmbean.CompositeData` type, and the Agent Builder browser can read the object itself, it creates several attributes, one for each object embedded in the `CompositeData` object. To include values internal to an object other than a `CompositeData` object (fields or method return values), you need to create an attribute that has a more complex metric name, as described in [“Specific fields for Java Management Extensions \(JMX\) MBeans” on page 1476](#).

8. Click **Finish** in the filled on JMX Information page.

Data sources are created based on the MBean that was selected in the previous step. If no MBean was selected, an attribute group with no attributes is created. A warning is shown, giving you a chance to select an MBean. The notification data source has the word, **Event**, at the beginning of the data source name to distinguish it from the data source that shows attributes.

9. To change other JMX options for the agent, click **Global JMX Options**. With these options, you can:
- a) Choose whether JMX monitors are supported by this agent. If you want JMX monitor attribute groups and Take Action commands to be created, select **Include JMX monitor attribute groups and take actions**

See the next section for a description of JMX monitors.

- b) Select the types of MBean servers your agent connects to when it is deployed.

There are several vendor-specific types of servers that are listed, along with a generic JSR-160-Compliant Server for standards-based servers. You can select as many as needed, but you must select only server types that support the MBeans that are being monitored. You must select at least one. If you select more than one, at agent configuration time you are prompted to specify which type of server you want to connect to.

10. Click **OK** after you select the wanted option.
11. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing JMX attribute groups” on page 1479](#)
12. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
13. Click **Next**.
14. On the **Select key attributes** page, select key attributes or indicate that this data source produces only one data row. For more information, see [“Selecting key attributes” on page 1397](#).
15. Click **Next**.

The **JMX Agent-Wide Options** window shows the types of application servers that the Agent Builder supports. If you previously selected **Set as agent configuration defaults** on the **Connection Properties** page, the type of application server that you browsed to is automatically selected.

16. In the **JMX Agent-Wide Options** window ([Figure 37 on page 1468](#)), select any other types of application servers to which you want your agent to be able to connect.

**Note:** In the example shown, choosing **JBoss Application Server JSR-160 connection** is the same as choosing **JSR-160-Compliant Server** except that different default values are supplied.

Figure 37. JMX Agent-Wide Options window

17. Do one of the following steps:

- If you are using the New Agent wizard, click **Next**.
- Click **Finish** to save the data source and open the Agent Editor.

18. If you want to change the types of application servers to which you can connect after the agent is created, click **Global JMX Options** in the **JMX Data Source Information** area.

19. In the **JMX Agent-Wide Options** window, change any selections that you want.

20. Click **OK**.

21. To view the configuration sections and properties that were automatically generated, click the **Runtime Configuration** tab of the Agent Editor.

The default value of the JBoss `base_paths` property has the value that was entered in the JMX browser.

## What to do next

For more information about the attribute groups for JMX events, see [“JMX Event attribute groups” on page 1666](#),

## JMX configuration

When you define a JMX data source in your agent, some configuration properties are created for you.

JMX runtime configuration is unique because it provides you with some control over how much configuration is displayed. The JMX client for the agent can connect to several different types of application servers. However, it is not necessary to support all of those types of application servers in any one agent. You can determine which types of application servers to support, and unnecessary configuration sections are not included in the agent.

In most cases, an agent is designed to monitor one JMX application server type. When you create the JMX data source, you can use the JMX Browser. When you use the JMX Browser, the JMX server configuration options that are used to browse the MBean server are added to your agent automatically. To change the types of application servers to which you can connect after the agent is created, click **Global JMX Options** in the **JMX Information** area. In the **JMX Agent-Wide Options** page, change any selections that you want.

You can design a generic agent that monitors more than one type of JMX application server. In this case, more than one JMX server configuration choice can be selected on the **JMX Agent-Wide Options** page. When more than one type of JMX connection is supported, the runtime configuration prompts you for the connection type that are used for that agent instance.

**Note:** An instance of an agent can connect only to one type of JMX application server. Subnodes can be used to connect to different JMX application servers of the same type within an agent instance. To connect to more than one type of JMX application server, you must configure at least one agent instance for each JMX application server type.

You can view, add, and change the configuration properties by using the Agent Editor. For instructions, see [“Changing configuration properties by using the Agent Editor” on page 1581](#). If a JMX data source is defined in a subnode, you are also able to specify Subnode Configuration Overrides. For instructions, see [“Subnode configuration” on page 1568](#).

If you define a JMX data source in your agent, the agent must use Java to connect to the JMX application server. Java configuration properties are added to the agent automatically.

The following Java configuration properties are specific to the agent runtime configuration:

### Java Home

Fully qualified path that points to the Java installation directory

Configure the agent to use the same JVM that the application you are monitoring uses, particularly for the WebLogic Server and WebSphere Application Server.

### JVM Arguments

Specifies an optional list of arguments to the Java virtual machine.

### Trace Level

Defines the amount of information to write to the Java trace file. The default is to write-only Error data to the log file.

**Note:** Agent Builder does not require these properties because it uses its own JVM and logging, which is configured through the JLog plug-in.

If you define a JMX data source in your agent, the following required, common configuration fields are added to the agent automatically:

### Connection

The type of connection to the MBean server

### User ID

User ID that is used to authenticate with the MBean server.

### Password

Password for the user ID.

### Base paths

Directories that are searched for JAR files that are named in **Class path**, or directories that are named in **JAR directories**, that are not fully qualified. Directory names are separated by a semi-colon ( ; ) on Windows, and by a semi-colon ( ; ) or colon ( : ) on UNIX systems.

### Class path

Explicitly named JAR files to be searched by the agent. Any that are not fully qualified are appended to each of the Base Paths until the JAR file is found.

### JAR directories

Directories that are searched for JAR files. Directory names are separated by a semi-colon ( ; ) on Windows, and by a semi-colon ( ; ) or colon ( : ) on UNIX systems. The JAR files in these directories are not required to be explicitly identified; they are found because they are in one of these directories. Subdirectories of these directories are not searched. Any directory names that are not fully qualified are appended to each of the Base Paths until the directory is found.

**Note:** For remote monitoring, the JAR files and all of their dependent JAR files must be installed locally on the computer where the agent is running. These JAR files are the files that are required to connect to the application that is being monitored. These JAR files must be configured in **JAR directories**, and in **Base paths** and **Class path**. In addition, locally install a supported JVM for the application you are monitoring and specify the path in the **Java Home configuration** field.

### Examples:

- For WebLogic 10, the class path is `server/lib/wlclient.jar;server/lib/wljmxclient.jar`. The base path points to the WebLogic application server directory where the `server/lib` directory is located.
- For WebSphere, the base path points to the location where the WebSphere Application Server is installed. Multiple base paths are listed in this example to provide a default for Windows and UNIX. The class path lists the JAR files relative to the base path. The relative value `lib` for the **JAR directories** field causes all JAR files in this directory under the base path to be loaded.
  - **Base paths:** `C:\Program Files\IBM\WebSphere\AppServer;/opt/IBM/WebSphere/AppServer`
  - **Class path:** `runtimes/com.ibm.ws.admin.client_6.1.0.jar;plugins/com.ibm.ws.security.crypto_6.1.0.jar`
  - **JAR directories:** `lib`

Depending on which JMX server types are selected in the JMX Agent-Wide Options page, some or all of the following configuration properties are added. Default values are provided by the Agent Builder, and can be modified:

### JSR-160 Compliant Server connection-specific configuration properties:

#### JMX Service URL

JMX Services URL to connect to for monitoring.

### WebSphere Application Server version 6.0 and later connection-specific configuration properties:

#### Host name

Host name of the system where the application server you are monitoring is located. For local monitoring, the name is the local system name. For remote monitoring, the name is the host name of the system where the application server is located.

#### Port

Port number to use on the host name to be monitored.

#### Connector protocol

Connector protocol to be used by the monitoring connection. RMI and SOAP are supported.

#### Profile name

Name of the profile to use for configuring the connection.

## **JBoss Application Server (non JSR-160) connection-specific configuration properties:**

### **JNDI Name**

JNDI Name that is used to look up the MBean server.

### **Provider URL**

JMX Services provider URL to connect to for monitoring.

## **WebLogic Server connection-specific configuration properties:**

### **Service URL**

JMX Services provider URL to connect to for monitoring that includes the JNDI name.

**Note:** If WebSphere administrative security is enabled, you must make sure that client login prompts are disabled in the appropriate client connection properties files. For RMI connections, to prevent clients from prompting the user, you must modify the *com.ibm.CORBA.loginSource* property in the *sas.client.props* file in the profile properties directory of your WebSphere Application Server. For a SOAP connection, you must modify the *com.ibm.SOAP.loginSource* property in the *soap.client.props* file in the same directory. In both cases, the *loginSource* property must be set to not contain a value.

You can view, add, and change the configuration properties by using the Agent Editor. See (“Changing configuration properties by using the Agent Editor” on page 1581). If a Windows data source is defined in a subnode, you can also specify Subnode Configuration Overrides. See [“Subnode configuration” on page 1568](#).

## **JMX notifications**

In addition to providing monitoring data when requested, some MBeans also provide notifications.

A notification is an object that is generated by an MBean that is passed to registered listeners when an event occurs.

Agents that are built by the Agent Builder can define attribute groups that contain values from notifications rather than MBeans.

When the agent is started, a `notification listener` is registered with each MBean that matches the MBean pattern of the attribute group. The attribute group then displays one row per notification received. Each column contains one item of data from the notification. The data wanted from the notification is defined by a column value similar to the way column data is defined for MBeans.

For non-event based attribute groups, data is collected when needed. For event-based attribute groups, the agent maintains a cache of the last 100 events received. These events are used to respond to requests from the Tivoli Enterprise Portal. The events are forwarded immediately for analysis by situations and warehousing.

## **JMX monitors**

In addition to providing monitoring data when requested, some MBeans also provide monitors.

The JMX Provider supports the ability for an agent to create JMX Monitors. A JMX Monitor is an MBean that the JMX agent creates on the JMX Server. It monitors the value of an attribute of another MBean and sends a notification when that value meets some criteria. Thresholds are defined that enable the Monitor to report on specific attribute values.

Not all application servers support the creation of monitors from a JMX client, which is true for current releases of WebSphere Application Server. JMX Monitors and Take Action commands can be included in your agent by selecting **Include JMX monitor attribute groups and take actions** under **Global JMX Options**.

Any MBean that reports on an attribute of another MBean can be considered a monitor. In practice, JMX defines three concrete monitor classes, which are the types of monitors that are created. The following concrete monitor types are created:

- String monitor – watches a string attribute, reports equality, or inequality of that string.

- Gauge monitor – watches a variable numeric attribute, reports up or down movement beyond threshold values.
- Counter monitor – watches an increasing numeric attribute, reports when it reaches a threshold value or increases by a certain amount.

The following attribute groups might be automatically added to the agent to collect or represent JMX Monitor notifications:

- **Registered Monitors**

This attribute group displays all of the JMX Monitors that are added by the user.

- **Counter Notifications**

This attribute group reports all notifications that are received from Counter Monitors.

- **Gauge Notifications**

This attribute group reports all notification received from Gauge Monitors.

- **String Notifications**

This attribute group reports all notifications that are received from String Monitors.

### ***Take Action commands for JMX monitors***

A monitor is created by running a Take Action command.

Three Take Action commands are defined, one to create each type of monitor, and a fourth Take Action is defined to delete an existing monitor. A 256-character limit applies to Take Action commands.

The monitor attribute groups are a part of every JMX agent that is built, including all agents that are built by the Agent Builder. The four Take Action commands are available to all agents, though they cannot be used unless it is a JMX agent.

#### *JMX Add String Metric Watcher*

Use this Take Action command to create a monitor to watch a string attribute.

## **Parameters**

### **MBean pattern**

All MBeans matching this pattern are monitored by this monitor.

### **Observed attribute**

Name of the MBean string attribute that is being watched.

### **Notify match**

True if a notification is to be sent when the monitored string matches a reference value, false if not (defaults to false).

### **Notify differ**

True if a notification is to be sent when the monitored string does not match the reference value, false if not (defaults to true)

### **Reference value**

String to compare with the observed attribute.

A default means that the argument is not specified.

## **Example: Request a notification when a service is stopped**

```
STRING_METRIC_WATCHER [*:type=Service,*] [StateString] [true] [false] [Stopped]
```

Where:

### **\*:type=Service,\***

MBean pattern: Monitors any MBean with a key property named type whose value is Service.

## StateString

Observed attribute: A string attribute that is common to all MBeans of type=Service.

### true

Notify match: You want a notification to be sent to your agent when the StateString attribute matches your reference value of Stopped.

### false

Notify differ: You do not want to be notified when the Service attribute does not match Stopped.

### Stopped

Reference value: When the StateString attribute changes to the value Stopped, a notification is sent.

## JMX Add Gauge Metric Watcher

Use this Take Action command to create a monitor to watch a gauge attribute.

## Parameters

### MBean pattern

All MBeans matching this pattern are monitored by this monitor.

### Observed attribute

Name of the MBean string attribute that is being watched.

### Difference mode

True if the value monitored is the difference between the actual current and previous values of the attribute. False if the value monitored is the actual current value of the attribute (defaults to false).

### Notify high

True if a notification is to be sent when an increasing monitored value crosses the high threshold, false if not (defaults to true).

### Notify low

True if a notification is to be sent when a decreasing monitored value crosses the low threshold, false if not (defaults to true).

### High threshold

Value that the observed attribute is expected to stay under.

### Low threshold

Value that the observed attribute is expected to stay over.

## Example: Request a notification when free memory goes under 10 Mb

```
GAUGE_METRIC_WATCHER [ServerInfo] [FreeMemory] [false] [false] [true] [30000000] [10000000]
```

Where:

### \*:type=ServerInfo

MBean pattern: Monitors any MBean whose name has a single key property named type whose value is ServerInfo.

### FreeMemory

Observed attribute: Numeric attribute that fluctuates up or down, this one indicating the amount of free memory in the application server.

### false

Difference mode: Monitors the actual attribute value, not the difference between one observation and another.

### false

Notify high: Notification is not sent when free memory goes up.

### true

Notify low: Notification is not sent when the free memory becomes too low.

### 30000000

High threshold: Even though you are not concerned with passing a high threshold, you need a reasonable high threshold value. A second low threshold notification does not occur until the attribute value hits or passes the high threshold.

### 10000000

Low threshold: Low threshold value that you want to be notified about.

#### *JMX Add Counter Metric Watcher*

Use this Take Action command to create a monitor to watch a counter attribute.

## Parameters

### MBean pattern

All MBeans matching this pattern are monitored by this monitor.

### Observed attribute

Name of the MBean string attribute that is being watched.

### Initial threshold

Value that the observed attribute is compared.

### Offset

Value added to the threshold after the threshold is exceeded to create a changed threshold.

### Modulus

Maximum value of counter after which it rolls over to 0.

### Difference mode

True if the value monitored is the difference between the actual current and previous values of the attribute. False if the value monitored is the actual current value of the attribute (defaults to false). This mode effectively turns on rate-of-change monitoring.

### Granularity period

Frequency with which measurements are taken (defaults to 20 seconds). Most important if difference mode is true

## Example: Request a notification when any server has three or more errors

```
COUNTER_METRIC_WATCHER [*:j2eeType=Servlet,*] [errorCount] [3] [4] [] [diff] [gran]
```

Where:

### **\*:j2eeType=Servlet,\***

MBean pattern: Monitors any J2EE servlet MBean whose name has a single key property named type whose value is ServerInfo

### **errorCount**

Observed attribute: Increasing numeric attribute, this one indicating the number of errors of the servlet.

### **3**

Initial threshold: You want to be notified when errorCount meets or exceeds 3.

### **4**

Offset: When you get a notification for three errors, 4 is to the previous threshold of 3 to make a new threshold of 7. A second notification will be sent after errorCount reaches 7; a third at 11; a fourth at 15, and so on. Zero or none is not valid because it expects the counter to always increase and not increasing the offset would not make sense for a counter.

### **Modulus:**

errorCount has no architected maximum value, so use an unreasonably high value.

### **false**

Difference mode: You are concerned with absolute error counts. Difference is true if you are interested in the rate that errorCount was increasing.

Granularity period: Not set, so take the default granularity period of 20 seconds. Granularity period is available for all monitor types. However, it is shown with a counter monitor so that a meaningful rate of change (with difference mode=true) can be determined.

#### *JMX Delete Metric Watcher*

Use this Take Action to delete a monitor.

## Parameter

### Number

Monitor number as shown in the REGISTERED\_MONITORS table

## Example: Delete monitor number 2

```
DELETE_WATCHER [2]
```

Where:

**2=**

Number of monitor to be deleted.

## JMX operations

In addition to providing monitoring data when requested, some MBeans also provide operations.

Agents that have JMX data sources include the JMX\_INVOKE Take Action command that you can use to run JMX operations against the server you are monitoring.

## Take Action command syntax

The action has the following syntax:

```
JMX_INVOKE [MBean pattern] [Operation name] [Argument 1] [Argument 2]  
[Argument 3] [Argument 4]
```

Where:

### MBean pattern

MBean query that selects the MBeans on which the operation runs. If the pattern matches more than one MBean, the operation runs on each of the matched MBeans.

### Operation name

Name of the MBean operation to run.

### Argument 1, Argument 2, Argument 3, Argument 4

Optional arguments that can be provided to the MBean operation. Arguments must be a simple data type such as a string or an integer.

The JMX invoke Take Action command returns success if the operation is successfully run. If the operation returns a value, that value is written to the JMX data provider log file.

## Example: Start an operation to reset a counter

This action runs the resetPeakThreadCount operation on the Threading MBeans:

```
JMX_INVOKE [*:type=Threading,*] [resetPeakThreadCount] [] [] [] []
```

Where:

### \*:type=Threading,\*

MBean Pattern: This pattern matches all MBeans that have a type of Threading.

### resetPeakThreadCount

Operation name: The operation that is run on every MBean that matches the pattern.

□ □ □ □

Argument 1, 2, 3, 4: The arguments are not needed for this operation. They are specified only to comply with the syntax of the action.

### Example: Start an action with an argument

This action runs the `getThreadCpuTime` operation on the Threading MBeans. The result is logged to the JMX data provider trace file.

```
JMX_INVOKE [*:type=Threading,*] [getThreadCpuTime] [1] [] [] []
```

Where:

#### **\*:type=Threading,\***

MBean Pattern: This pattern matches all MBeans that have a type of Threading

#### **getThreadCpuTime**

Operation name: The operation that is run on every MBean that matches the pattern.

**1**

Argument 1: The thread id that is being queried.

□ □ □

Argument 2, 3, 4: These arguments are not needed for this operation. They are specified as empty arguments to comply with the Take Action command syntax.

### Running the JMX\_INVOKE Take Action command

The agent developer cannot expect the user to run the JMX\_INVOKE Take Action command. Instead, more actions must be developed that run the JMX\_INVOKE Take Action. If possible in these actions, hide the details such as the operation name and the MBean pattern from the user.

### Starting and stopping JMX monitors

JMX monitors are persistent across starts and stops of the agent and the JMX server.

If the agent detects that the JMX server was recycled, it reregisters the monitors. If the agent is recycled, monitors are reregistered. The monitor definitions are stored in a file that is named `default_instanceName.monitors` where *instanceName* is the agent instance name or default if it is a single instance agent. This file is in the following directory (note that *xx* denotes the two character product code):

- Windows systems: `TMAITM6/kxx/config`
- UNIX and Linux systems: `architecture/xx/config` (see [“New files on your system”](#) on page 1611 for information about determining the architecture value)

If the agent is restarted, it uses the monitor definitions file to restore the monitors.

### Specific fields for Java Management Extensions (JMX) MBeans

The syntax of the metric name for a JMX Attribute group must follow certain rules when specified on the **Attribute Information** window.

The syntax of the metric name for a JMX Attribute group consists of tokens that are separated by a period. The tokens form primary values and optionally secondary values:

- **Primary value:** a value that is obtained directly from the MBean or Notification in a specific row of the table. Primary values from an MBean are obtained either from an MBean attribute or from the invocation of an MBean operation (method call). Primary values from a Notification are obtained from a field or invocation of a method on the Notification object. Primary values can be primitive types, or can be Java objects.
- **Secondary value:** a value that is obtained by further processing a primary value or other secondary value. Secondary values are processed internally to the engine and do not involve calls to the JMX server. If the primary (or other secondary value) is a Java object, a secondary value is the result of

fetching a public field from that object. A secondary value can also be the result of a method call on that object. Such secondary values are obtained by using Java introspection of the primary (or other secondary) Java object. If the primary (or other secondary) value is a Java String in the form of an MBean name, the secondary value can be the domain. The secondary value can also be any of the properties that make up the MBean name.

The following syntax describes the format for the **Metric name** field:

```
Metric Name    =    PrimaryValue [ .SecondaryValue ]
PrimaryValue   =    Attribute.attributeName |
                    Method.methodName |
                    Domain |
                    Property.propertyName |
                    Field.fieldName |
                    Name
SecondaryValue =    Field.fieldName |
                    Method.methodName |
                    Domain |
                    Property.propertyName |
                    Explode |
                    ElementCount
```

```
propertyName   =    the name of a key property in an MBean ObjectName
attributeName   =    the name of an MBean attribute
methodName      =    a zero-argument operation of an MBean or a zero-argument method
of a Notification or other Java object.
methodName(argument) = A single-argument operation of an MBean or a
single-argument method of a Notification or other Java object. The
argument will be passed to the method as a string.
fieldName       =    the name of a public instance variable in a Notification or
other Java object
notificationMethod =    the name of a public zero-argument method of a
Notification object
```

By including only a primary value in the metric name definition, the data that is collected can be any of the following items:

- MBean domain
- MBean string value
- Key property from the MBean name
- Numeric or string attribute value on an MBean attribute (including the full name of another MBean). A numeric or string return value from an operation of a MBean.
- Value of a numeric or string public instance variable in a Notification object
- Numeric or string return value from an operation of a Notification.

By adding a secondary value to the definition of a metric, you can drill down into the primary value of a Java object. Also, you can start a public method or fetch a public instance variable.

By adding a secondary value to another secondary value in the definition of the metric, you can drill down into a secondary value object. You can continue as deeply as objects are nested inside an MBean or a Notification.

Tokens that make up primary and secondary values are either keywords or names. In most cases, a keyword token is followed by a name token. The following table shows some examples:

| Metric name sample     | Attribute group type | Description of the data returned                              |
|------------------------|----------------------|---|
| Domain                 | MBean                | The domain portion of the MBean (the part before the colon).  |
| Name                   | MBean                | The full string representation of the MBean.                  |
| Attribute.serverVendor | MBean                | MBean attribute serverVendor.                                 |
| Method.getHeapSize     | MBean                | The value that is returned by the getHeapSize() on the MBean. |

| Metric name sample | Attribute group type | Description of the data returned                        |
|--------------------|----------------------|---|
| Property.j2eeType  | MBean                | The value of j2eeType is extracted from the MBean name. |
| Field.Message      | Event (Notification) | The <b>Message</b> field in a notification.             |

The keywords `Attribute`, `Method`, and `Field` can return Java objects which contain other data. You can run operations on those objects by appending secondary value definitions. More examples:

| Metric name sample  | Attribute group type | Description of the data returned   |
|---|----------------------|--|
| Attribute.deployedObject.Method.getName                           | MBean                | Takes the <code>deployedObject</code> attribute from the MBean and gets the result of the <code>getName()</code> method.   |
| Attribute.eventProvider.Method.getException.Method.getDescription | MBean                | Goes 3 deep: an attribute named <code>eventProvider</code> is presumed to be an object which has a <code>getException()</code> method. This method returns an object with a <code>getDescription()</code> method. That method is called and the return value is put in the column.   |
| Attribute.HeapMemoryUsage.Method.get(used)                        | MBean                | Takes the <code>HeapMemoryUsage</code> attribute from the MBean and gets the result of the <code>get(String value)</code> method. The string that is used is passed to the method as the argument. Only 1 argument can be provided and it must be a literal string value.<br><br>Shows how you can collect data from an open MBean composite data structure. |

`Domain` and `Property` can be used as keywords in secondary values if the previous value returned a String in the format of an MBean name. For example:

| Metric name sample                 | Attribute group type | Description of the data returned   |
|------------------------------------|----------------------|--|
| Attribute.jdbcDriver.Property.name | MBean                | The attribute <code>jdbcDriver</code> returns an MBean name, and the key property, <code>name</code> , is extracted from the MBean name. |
| Attribute.jdbcDriver.Domain        | MBean                | The attribute <code>jdbcDriver</code> returns an MBean name, and the domain is extracted from the MBean name.                            |

The `ElementCount` and `Explode` keywords run operations on arrays or collections of data.

- `ElementCount` – returns the number of elements in an array.
- `Explode` – explodes a row into several rows, one new row for each element of an array.

Examples of each of the keywords:

| Metric name sample   | Attribute group type | Description of the data returned   |
|--|----------------------|--|
| Attribute.deployedObjects.ElementCount                           | MBean                | The MBean attribute deployedObjects is an array, and this column contains the number of elements in the array.   |
| Attribute.deployedObjects.Explode.MBean.Property.j2eeType        | MBean                | Causes the table to have 1 row for each element in deployed objects. This column contains the j2eeType of the deployed Object.   |
| Attribute.SystemProperties.Method.values.Explode.Method.get(key) | MBean                | Causes you to get one new row for each entry in an open MBean tabular data structure. Each tabular data structure contains a composite data structure with an item named key, which is returned. |

## Testing JMX attribute groups

You can test the JMX attribute group that you created within Agent Builder.

### Procedure

1. You can start the Testing procedure in the following ways:
  - During agent creation click **Test** on the **JMX Information** page.
  - After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test** . For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398.

After you click **Test** in one of the previous two steps, the **JMX Test** window is displayed

2. Select a connection from the list available under **Connection Name** or alternatively click **Add** to add a connection and follow the procedure that is detailed under [“Monitoring Java Management Extensions \(JMX\) MBeans”](#) on page 1461.
3. Optional: Before you start testing, you can set environment variables, configuration properties, and Java information.  
For more information, see [“Attribute group testing”](#) on page 1596. For more about JMX configuration, see [“JMX configuration”](#) on page 1469.
4. Click **Start Agent**.  
A window indicates that the Agent is starting.
5. Click **Collect Data** to simulate a request from Tivoli Enterprise Portal or SOAP for agent data.  
The agent monitors the JMX Server for data. The **JMX Test** window collects and shows any data in the agent's cache since it was last started.
6. Optional: Click **Check Results** if the returned data is not as you expected.  
The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the Data collection Status window is described in [“Performance Object Status node”](#) on page 1638
7. Stop the agent by clicking **Stop Agent**.
8. Click **OK** or **Cancel** to exit the **JMX Test** window. Clicking **OK** saves any changes that you made.

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring data from a Common Information Model (CIM)

You can define a data source to receive data from a Common Information Model (CIM) data source. A data source monitors a single CIM class and places all values from this class into the data set that it produces. If the class provides several instances, the data set has multiple rows; you can filter by instance name to ensure the data set has one row.

### About this task

This task describes the steps to configure a Common Information Model (CIM) data source.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **CIM**.
3. Click **Next**.
4. On the **Common Information Model (CIM) Information** page **CIM information** area, make one of the following choices:
  - Complete the **Namespace** and **CIM class name** fields for the data that you want to collect.
  - Click **Browse** to browse a CIM repository on a specific system.

The **Common Information Model (CIM) Class Browser** window is displayed. This browser connects to a CIM server and provides you with information about the classes that exist on that server.

To browse a remote system, select a system from the **Hostname** list (if one is defined). Alternatively click **Add** to add the host name of the system where the CIM server is located.

The syntax for specifying the host name is `http[s]://hostname:port`. If you provide the host name only, the Common Information Model (CIM) Class Browser connects by using a default URL of `http://hostname:5988`.

If you provide a protocol without specifying a port, 5988 is used as the default for `http` or 5989 as the default for `https`.

If you provide a port without specifying a protocol, `http` is used with the port provided.

Provide a user ID and password for an account with read permission to the objects in the namespace that you want to browse. The window is updated with the information for the remote system.

Agent Builder attempts to discover the namespaces available on the CIM Server. The discovered namespaces are displayed in the **Namespace** list. However, the Agent Builder might not be able to discover all namespaces that are available on the server. If you want to browse a namespace that is not listed in the **Namespace** list, click the plus (+) icon next to the **Namespace** list. Enter the name of the namespace in the field and click **OK**. If the namespace is present on the CIM server, the classes that are defined in the namespace are listed. The namespaces you type are saved and put into the **Namespace** list the next time you browse that particular CIM server.

When you select a namespace from the **Namespace** list, the Agent Builder collects all of the class information for that particular namespace. Then, the Agent Builder caches this information so you can switch between namespaces quickly. If you want to force the Agent Builder to recollect the class information for a particular namespace, select the namespace and click **Connect**. Clicking **Connect** deletes any cached information, and causes the Agent Builder to recollect the class information.

You can click the **Search** (binoculars) icon to find your selection in the list. Type a phrase in the **Search phrase** field; specify your preference by clicking either the **Search by name** or **Search by**

**class properties** fields; and click **OK**. If you find the item for which you are searching, select it and click **OK**.

5. On the Common Information Model (CIM) Information page, **Operating systems** area, select the operating systems on which the collection is to take place.
6. If you typed the Namespace and CIM class name in the **CIM information** area, do the following steps:
  - a) Click **Next** to display the **Attribute Information** page and define the first attribute in the attribute group.
  - b) Specify the information about the **Attribute Information** page, and click **Finish**.
7. If you browsed the CIM information, the Select key attributes page is displayed. On the Select key attributes page, select key attributes or indicate that this data source produces only one data row. For more information, see ([“Selecting key attributes” on page 1397](#)).
8. If you browsed to the CIM information, click **Finish**.
9. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing CIM attribute groups” on page 1482](#)
10. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
11. Do one of the following steps:
  - a) If you are using the **Agent** wizard, click **Next**.
  - b) Click **Finish** to save the data source and open the Agent Editor.

## CIM configuration

Details about CIM configuration properties.

If you define a CIM data source in your agent, CIM configuration properties are added to the agent automatically. You can view, add, and change the configuration properties by using the Agent Editor. For instructions, see [“Changing configuration properties by using the Agent Editor” on page 1581](#)). If a CIM data source is defined in a subnode, specify Subnode Configuration Overrides. For instructions, see [“Subnode configuration” on page 1568](#).

The following connection-specific configuration properties are on the CIM configuration page:

### **CIM Local or Remote**

Local or remote authentication to the CIM server. Local/Remote Default value is Remote

### **CIM user ID**

The user ID used to access the CIM server

### **CIM password**

The password to access the CIM server

### **CIM host name**

The host name to be accessed for CIM data

### **CIM over SSL**

Use SSL for communication with the CIM server. The options are Yes and No. The default value is No.

### **CIM port number**

The port number that is used for communication that is not secure.

### **CIM SSL port number**

The port number that is used for secure communication. The default value is 5989. (The default value for Solaris 8 is normally different.)

## Testing CIM attribute groups

You can test the CIM attribute group that you created, within Agent Builder.

### Procedure

1. Start the Testing procedure in the following ways:
  - During agent creation click **Test** on the **CIM Information** page.
  - After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#)

After you click **Test** in one of the previous two steps, the **Test Settings** window is displayed

2. Optional: Set environment variables and configuration properties before you start testing.  
For more information, see [“Attribute group testing” on page 1596](#).
3. Select or add a **Host name**.  
For more about adding a **Host name**, see [“Monitoring data from a Common Information Model \(CIM\)” on page 1480](#)
4. Click **Start Agent**.  
A window opens indicating that the Agent is starting.
5. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**.  
The agent queries the CIM Server for data. The **Test Settings** window collects and shows any data in the agent's cache since it was last started.
6. Optional: Click **Check Results** if the returned data is not as you expected.  
The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the **Data Collection Status** window is described in [“Performance Object Status node” on page 1638](#)
7. Stop the agent by clicking **Stop Agent**.
8. Click **OK** or **Cancel** to exit the **Test Settings** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring a log file

You can define a data source to receive data from a text log file. The agent periodically parses the lines that are added the log file, and produces event information based on these lines. You can configure the way in which the agent parses the log into events. You can also configure the agent to filter and summarize the data. The resulting events are placed in a data set.

### Before you begin

**Note:** The agent monitors log files that are in the same locale and code page that the agent runs in.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Logged Data** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **A Log File**.
3. Click **Next**.
4. On the **Log File Information** page, type the name of the log file you want to monitor in the **Log File Information** area.  
The file name must be fully qualified.

- a) Optional: Part of the log file name can come from a runtime configuration property. To create a log file name, click **Insert Configuration Property** and select a configuration property.
  - b) Optional: The file can also be a dynamic file name. For more information, see ([“Dynamic file name support” on page 1714](#)).
5. In the **Field Identification** area, click one of the following options:
- Fixed number of characters**  
When selected, limits the number of characters.
- With this option, each attribute is assigned the maximum number of characters it can hold from the log file. For example, if there are three attributes A, B, and C (in that order), and each attribute is a String of maximum length 20. Then, the first 20 bytes of the log record go into A, the second 20 into B, and the next 20 into C.
- Tab separator**  
When selected, you can use tab separators.
- Space separator**  
When selected, multiple concurrent spaces can be used as a single separator.
- Separator Text**  
When selected, type in separator text.
- Begin and End Text**  
When selected, type in both Begin and End text.
- XML in element**  
When selected, type the name of the XML element to use as the record, or click **Browse** to define the element.
- If you clicked **Browse**, the **XML Browser** window is displayed. If you use the browse function, the Agent Builder identifies all possible attributes of the record by looking at the child tags and their attributes.
- Note:** Unless you click **Advanced** and fill out the information in that window, the following assumptions are made about information that you complete:
- Only one log file at a time is monitored.
  - Each line of the log file contains all the fields necessary to fill the attributes to be defined.
- For more information about log file parsing and separators, see ([“Log file parsing and separators” on page 1490](#)).
6. Optional: Click **Advanced** on the **Log File Information** page to do the following by using the **Advanced Data Source Properties** page:
- Monitor more than one file, or monitor files with different names on different operating systems or monitor files with names that match regular expressions.
  - Draw a set of fields from more than one line in the log file.
  - Choose **Event Filtering and Summarization Options**.
  - Produce output summary information. This summary produces an additional attribute group at each interval. For more information about this attribute group, see [“Log File Summary” on page 1649](#). This function is deprecated by the options available in the Event Information tab.
- a) To monitor more than one log file, click **Add** and type the name.  
If more than one file is listed, a unique label must be entered for each file. The label can be displayed as an attribute to indicate which file generated the record. It must not contain spaces.
  - b) Optional: To select the operating systems on which each log file is to be monitored, follow these steps:
    - i) Click in the **Operating systems** column for the log file.
    - ii) Click **Edit**.
    - iii) In the **Operating Systems** window, select the operating systems.

- iv) Click **OK** to save your changes and return to the **Advanced Data Source Properties** page.
- c) Optional: Select **File names match regular expression** if the file name you are providing is a regular expression that is used to find the file instead of being a file name.
- For more information, see [“ICU regular expressions”](#) on page 1705. If you do not check this box, the name must be an actual file name. Alternatively it must be a pattern that follows the rules for file name patterns that are described in [“Dynamic file name syntax”](#) on page 1714.
- d) Optional: Select **One directory element matches regular expression** to match one subdirectory of the file name path with a regular expression.
- You can select this option only if you also selected **File names match regular expression** in the previous step.
- If regular expression meta characters are used in the path name, the meta characters can be used in only one subdirectory of the path. For example, you can specify `/var/log/[0-9\.*]*/mylog.*` to have meta characters in one subdirectory. The `[0-9\.*]*` results in matching any subdirectory of `/var/log` that consists solely of numbers and dots (`.`). The `mylog.*` results in matching any file names in those `/var/log` subdirectories that begin with `mylog` and are followed by zero or more characters.
- Because some operating systems use the backslash (`\`) as a directory separator it can be confused with a regular expression escape meta character. Because of this confusion forward slashes must always be used to indicate directories. For example, Windows files that are specified as `C:\temp\mylog.*` might mean the `\t` is a shorthand tab character. Therefore, always use forward slashes (`/`) on all operating systems for directory separators. The `C:/temp/mylog.*` example represents all files in the `C:/temp` directory that start with `mylog`.
- e) In the **When multiple files match** list, select one of the following options:
- **The file with the highest numerical value in the file name**
  - **The biggest file**
  - **The most recently-updated file**
  - **The most recently-created file**
  - **All files that match**
- Note:** When you select **All files that match**, the agent identifies all files in the directory that match the dynamic file name pattern. The agent monitors updates to all of the files in parallel. Data from all files is intermingled during the data collection process. Its best to add an attribute by selecting **Log file name** in **Record Field Information** to correlate log messages to the log files that contain the log messages. Ensure that all files that match the dynamic file name pattern can be split into attributes in a consistent manner. If the log files selected cannot be coherently parsed, then its best to select **Entire record** in **Record Field Information** to define a single attribute. For more information about specifying **Record Field Information** for attributes, see step ([“8”](#) on page 1486).
- f) Choose how the file is processed.
- With **Process all records when the file is sampled**, you can process all records in the entire file every time the defined sampling interval for the log monitor expires. The default interval is 60 seconds. This interval can be modified by using the `KUMP_DP_COPY_MODE_SAMPLE_INTERVAL` environment variable (specifying a value in seconds). The same records are reported every time unless they are removed from the file. With this selection, event data is not produced when new records are written to the file. With **Process new records appended to the file**, you can process new records that are appended to the file while the agent is running. An event record is produced for every record added to the file. If the file is replaced (first record changes in any way), the file is processed and an event is produced for each record in the file.
- Note:** If appending records to an XML log file, the append records must contain a complete set of elements that are defined within the XML element you selected as **Field Identification**.
- g) If you chose to process new records that are appended to the file, you can also choose how new records are detected.

With **Detect new records when record count increases**, new records can be detected when the number of records in the file increases, whether the size of the file changes. This feature is useful when an entire log file is pre-allocated before any records are written to the file. This option can be selected for files that are not pre-allocated, but it is less efficient than monitoring the size of the file. With **Detect new records when the file size increases**, you can determine when a new entry is appended to a file in the typical way. There might be a brief delay in recognizing that a monitored file is replaced.

- h) If you selected **Detect new records when the file size increases**, you can also choose how to process a file that exists when the monitoring agent starts.

**Ignore existing records** disables event production for any record in the file at the time agent starts. **Process \_\_\_ existing records from the file** specifies production of an event for a fixed number of records from the end of the file at the time the agent starts. **Process records not previously processed by the agent**: Specifies for restart data to be maintained by the monitoring agent so the agent knows which records were processed the last time that it ran. Events are produced for any records that are appended to the file since the last time the agent was running. This option involves a little extra processing each time a record is added to the file.

- i) If you selected **Process records not previously processed by the agent**, you can choose what to do when the agent starts and apparently the existing file was replaced.

**Process all records if the file has been replaced**: If information about the monitored file and the restart data information do not match, events are produced for all records in the file. Examples of mismatches include: The file name is different, the file creation-time is different, the file-size decreased, the file last modification time is earlier than before. **Do not process records if the file has been replaced**: If the information about the monitored file and the restart data information do not match, disables processing of existing records in the file.

- j) Click the **Record Identification** tab to interpret multiple lines in the log file as a single logical record.

**Note**: If you select **XML in element** as the field identification on the **Log File Information** page, the **Record Identification** tab does not display.

- **Single line** interprets each line as a single logical record.
- **Separator line** you can enter a sequence of characters that identifies a line that separates one record from another.

**Note**: The separator line is not part of the previous or the next record.

- **Rule** identifies a maximum number of lines that make up a record and optionally a sequence of characters that indicate the beginning or end of a record. With **Rule**, you can specify the following properties:
  - **Maximum non-blank line** defines the maximum number of non-blank lines that can be processed by a rule.
  - **Type of rule**: Can be one of:
    - **No text comparison** (The Maximum lines per record indicates a single logical record).
    - **Identify the beginning of record** (Marks the start of the single logical record).
    - **Identify the end of record** (Marks the end of the single logical record).
  - **Offset**: Specifies the location within a line where the Comparison String must occur.
  - **Comparison Test**: Can either be **Equals**, requiring a character sequence match at the specific offset, or **Does not equal**, indicating a particular character sequence does not occur at the specific offset.
  - **Comparison String** defines the character sequence to be compared.
- **Regular Expression** identify a pattern that is used to indicate the beginning or end of a record. By using **Regular Expression**, you can specify the following properties:
  - **Comparison String** defines the character sequence to be matched.

OR

- Beginning or end of record:
    - **Identify the beginning of record** marks the start of the single logical record.
    - **Identify the end of record** marks the end of the single logical record.
  - k) If you did select **Process all records when the file is sampled** earlier, click the **Filter Expression** tab. By clicking **Filter Expression** you can filter the data that is returned as rows based on the values of one or more attributes, configuration variables or both.  
 If you selected **Process new records appended to the file** earlier you cannot create a filter expression. For more information about filtering data from an attribute group, see ([“Filtering attribute groups”](#) on page 1425).
  - l) If you selected **Process new records appended to the file** earlier, click the **Event Information** tab to select **Event Filtering and Summarization Options**.  
 For more information, see ([“Event filtering and summarization”](#) on page 1623).
- Note:** The Summary tab can be present if the agent was created with an earlier version of Agent Builder. The summary tab is now deprecated by the Event Information tab
7. Optional: Click **Test Log File Settings** on the **Log File Information** page to start and test the data source. . Click **Test Log File Settings** after you select the options for the log source. When you test the log file data source and supply log file content, Agent Builder creates the attributes in the group automatically, based on the results of parsing the log. For more information about testing, see [“Testing log file attribute groups”](#) on page 1491.
  8. Use the following steps if you did not use the test function earlier and you typed the log file name in the **Log File Information** area of the **Log File Information** page:
    - a) Click **Next** to display the **Attribute Information** page and define the first attribute in the attribute group.
    - b) Specify the information, on the **Attribute Information** page, and click **Finish**.

**Note:** When a log file attribute group is added to an agent at the default minimum Tivoli Monitoring version (6.2.1) or later, a Log File Status attribute group is included. For more information about the Log File Status attribute group, see ([“Log File Status attribute group”](#) on page 1680).

Along with the fields applicable to all data sources, the **Attribute Information** page for the log file data source has some additional fields in the **Record Field Information** area.

The **Record Field Information** fields are:

#### **Next field**

Shows the next field after parsing, by using the delimiters from the attribute group (or special delimiters for this attribute from the Advanced dialog).

#### **Remainder of record**

Shows the rest of the record after previous attributes are parsed. This attribute is the last attribute, except for possibly the log file name or log file label.

#### **Entire record**

Shows the entire record, which can be the only attribute, except for possibly the log file name or log file label.

#### **Log file name**

Shows the name of the log file.

#### **Log file label**

Shows the label that is assigned to the file on the advanced panel.

**Note:** Use the **Derived Attribute Details** tab only if you want a derived attribute, and not an attribute directly from the log file.

9. Click **Advanced** in the **Record Field Information** area to display the **Advanced Log File Attribute Information** page.
  - a) In the **Attribute Filters** section, specify the criteria for data to be included or excluded.

Filtering attributes can enhance the performance of your solution by reducing the amount of data processed. Click one or more of the attribute filters:

- **Inclusive** indicates that the attribute filter set is an acceptance filter, meaning that if the filter succeeds, the record passes the filter, and is output.
- **Exclusive** indicates that the attribute filter set is a rejection filter, meaning that if the attribute filter succeeds, the record is rejected, and is not output.
- **Match all filters** indicates that all filters defined to the filter must match the attribute record in order for the filter to succeed.
- **Match any Filter** indicates that if any of the filters that are defined to the filter match the attribute record, the filter succeeds.

b) Use **Add**, **Edit**, and **Remove** to define the individual filters for an attribute filter set.

c) To add a filter, follow these steps:

i) Click **Add**, and complete the options in the **Add Filter** window as follows:

a) The **Filter criteria** section defines the base characteristics of the filter, including the following properties:

- **Starting offset** defines the position in the attribute string where the comparison is to begin.
- **Comparison string** defines the pattern string against which the attribute is defined.  
Type a string, pattern, or regular expression that is used by the agent to filter the data read from the file. The records that match the filter pattern are eliminated from the records that are returned to the monitoring environment, or are the only records returned. The result depends on whether you choose for the filter to be inclusive or exclusive.
- **Match entire value** checks for an exact occurrence of the comparison string in the attribute string. Checking starts from the starting offset position.
- **Match any part of value** checks for the comparison string anywhere in the attribute string. Checking starts from the starting offset position.

b) **The comparison string is a regular expression** indicates that the comparison string is a regular expression pattern that can be applied against the attribute string.

Regular expression-filtering support is provided by using the International Components for Unicode (ICU) libraries to check whether the attribute value examined matches the specified pattern.

To effectively use regular expression support, you must be familiar with the specifics of how ICU implements regular-expressions. This implementation is not identical to how regular expression support is implemented in Perl, grep, sed, Java regular expressions, and other implementations. See [“ICU regular expressions” on page 1705](#) for guidance on creating regular expression filters.

c) **Define an override filter** indicates that you want to provide a more specific filter comparison that overrides the base characteristics previously defined. This additional comparison string is used to reverse the filter result. When the filter is **Inclusive**, the override acts as an exclusion qualifier for the filter expression. When the filter is **Exclusive**, the override acts as an inclusion qualifier for the filter expression. (For more about **Inclusive** and **Exclusive**, see step “9” on [page 1486](#), and the examples that follow). The override filter has the following properties:

- **Starting offset** defines the position in the attribute string where the comparison is to begin.
- **Comparison string** defines the pattern string against which the attribute is matched.

Type a regular expression that is used by the agent to filter the data read from the file. The records that match the filter pattern are eliminated from the records that are returned to

the monitoring environment, or are the only records returned. The result depends on whether you choose for the filter to be inclusive or exclusive.

- d) **Replacement value** can be used to alter the raw attribute string with a new value. See [“ICU regular expressions”](#) on page 1705 for more details about special characters that can be used.
- e) **Replace first occurrence** replaces the first occurrence that is matched by the comparison string with new text.
- f) **Replace all occurrences** replaces all occurrences that are matched by the comparison string with new text.

ii) Click **OK**.

**Add Filter**

Enter the information needed for a new attribute filter

**Filter criteria**

Starting offset: 0

Comparison string: ^([a-z]\*) is ([a-z]\*) as ([0-9]\*)\$

☐ Match entire value

☒ Match any part of value

☒ The comparison string is a regular expression

☐ Define an override filter

Starting offset:

Comparison string:

☒ Replacement value

Replacement value: \$3 is not as \$2 as \$1

☒ Replace first occurrence

☐ Replace all occurrences

?

OK Cancel

Figure 38. **Add Filter** example 1

If the attribute string is `abc is easy as 123`, then the replaced string that is displayed in the Tivoli Enterprise Portal or IBM Cloud Application Performance Management console as `123 is not as easy as abc`.

Figure 39. **Add Filter** example 2

If the attribute string is Unrecoverable Error reading from disk, and the filter is **Inclusive**, then the attribute is displayed in the Tivoli Enterprise Portal or IBM Cloud Application Performance Management console. If the attribute string is No Errors Found during weekly backup and the filter is **Inclusive**, then the attribute is not displayed.

- d) In the **Field Identification** section of the **Advanced Log File Attribute Information** page, specify how to override the attribute group field delimiters for this one attribute only. Click one of the attribute filters, and complete the required fields for the option:
  - **Number of characters:** Enter the limit for the number of characters.
  - **Tab separator** specifies the use of tab separators.
  - **Separator Text:** Enter the separator text that you want to use.
  - **Begin and End Text** Enter both **Begin** text and **End** text.
- e) In the **Summary** section of the **Advanced Log File Attribute Information** page, click the **Include attribute in summary attribute group** check box to add the attribute to the summary attribute group.  
This attribute group is produced when a user turns on log attribute summarization.
- f) Click **OK**.

10. If you used the test function in step (“7” on page 1486), the **Select key attributes** page is displayed. On the **Select key attributes** page, select key attributes or indicate that this data source produces only one data row.

For more information, see (“Selecting key attributes” on page 1397).

11. Do one of the following steps:

- If you are using the New Agent wizard, click **Next**.
- Click **Finish** to save the data source and open the Agent Editor.

**Note:** When a log file attribute group is added to an agent with the default minimum Tivoli Monitoring version (6.2.1) or later, a Log File Status attribute group is included. For more information about the Log File Status attribute group, see (“Log File Status attribute group” on page 1680).

## Log file parsing and separators

You can change the default separator that is used to separate one or more attributes in a log file record.

When you create a log file attribute group, a separator is by default assigned. The default separator is a tab. The separator is used by the agent to parse and delimit the data for each attribute in the data row. You can change the default attribute separator to be:

- A fixed number of characters
- A space
- A different character or characters
- A specific beginning and end text
- An XML element.

You change the default separator that is used for all attributes in the group in the following ways:

1. When you are creating the attribute group, on the **Log File Information** page.
2. After you create the attribute group, by opening the **Agent Editor > Data Sources** tab, selecting the attribute group and choosing a separator in the **Field Identification** area.

You can also optionally assign specific separators to one or more individual attributes. You can assign specific separators for individual attributes to use:

- A fixed number of characters.
- A tab separator
- A space separator
- A different character or characters
- A specific beginning and end text.

You change the separator that is used for individual attributes in the following ways:

1. By selecting **Advanced** on the **Attribute Information** page when you are creating an attribute.
2. By opening the **Agent Editor > Data Sources** tab, selecting the attribute and selecting **Advanced** on the **Log File Attribute Information** tab.

## Example 1 - Simple log file output

Some log file records have clear and regular separators, for example:

```
one,two,three
```

Here the “,” character is a clear and regular separator between the three pieces of data on the row. In this case, select **Separator Text** and specify “,” as the default separator for the attribute group. There is no need to change or define other separators.

Defining this separator for a log file that contains the data row that is shown earlier in this example is shown in the following output:

| Results  |             |             |  |
|--|-------------|-------------|--|
| <input checked="" type="checkbox"/> Show hidden attributes |             |             |  |
| Attribute_1  | Attribute_2 | Attribute_3 |  |
| one  | two         | three       |  |
|  |             |             |  |
|  |             |             |  |

Figure 40. Example attribute value output when Agent parses a simple log file data row.

## Example 2 - Complex log file output

Some log files can contain data rows that have irregular or changing separators, for example:

```
one,two,three,[four]12:42,five
```

In this example an assignment of separators to attribute definitions that you can use is:

1. In the previous example you set the default separator to " , ". This separator is used for all attributes unless you over-ride it with a specific separator. In this example the default separator of " , " is correct to use again for the first three attributes in the row.
2. For the fourth attribute, assume the string between the " [" and " ] " is a value that you want to extract. In this case when you define the fourth attribute, you assign a separator type **Begin and End Text** with begin and end text values of " [" and " ] ".
3. For the fifth attribute, assume that you want to extract the values between the " ] " and " : " characters. In this case when you define the fifth attribute, you assign separator type **Separator Text** set to " : ".
4. For the sixth attribute, your default attribute group separator " , " is fine again.
5. For the seventh attribute, you do not need to specify a separator as it is the last attribute.

Defining these separators on a log file that contains the data row that is shown earlier in this example is shown in the following output:

| Results  |             |             |             |             |             |             |  |
|--|-------------|-------------|-------------|-------------|-------------|-------------|--|
| <input checked="" type="checkbox"/> Show hidden attributes |             |             |             |             |             |             |  |
| Attribute_1  | Attribute_2 | Attribute_3 | Attribute_4 | Attribute_5 | Attribute_6 | Attribute_7 |  |
| one  | two         | three       | four        | 12          | 42          | five        |  |
|  |             |             |             |             |             |             |  |
|  |             |             |             |             |             |             |  |

Figure 41. Example attribute value output when Agent parses a complex log file data row.

The procedure to define the attribute separators is described under step [“5” on page 1483](#) of [“Monitoring a log file” on page 1482](#).

## Testing log file attribute groups

You can use Agent Builder to test the log file data set (attribute group) that you created. If no attributes are defined for the group, the testing process defines them automatically.

### Before you begin

If any attributes are already defined for this data set and you want to define attributes automatically during testing, use the agent editor to remove all the existing attributes from the data set. For instructions, see [“Removing attributes” on page 1420](#).

## Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test Log File Settings** on the **Log File Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test Log File Settings**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398.

After you click **Test Log File Settings** in one of the previous two steps, the **Parse Log** window opens.

2. Select the source of the log data for testing:

- **Use attribute group settings:** use the file name and location specified in the data source. By default, the data source processes only the information that is added to the log file after the testing process is started. You can use this option if the log file is being updated in real time.
- **Specify a sample file:** provide a sample log file. With this setting, the testing procedure parses the entire contents of the log file. With this option, you can test the data source and create the attributes for it immediately, based on an existing sample. Specify the path and name of the file in the **Log file name** field or use the **Browse** button to select the file.

3. Optional: Before you start testing, you can set environment variables and configuration properties.

For more information, see [\(“Attribute group testing” on page 1596\)](#).

4. Click **Start Agent**.

A window opens indicating that the Agent is starting. When the agent starts, it monitors the configured log file for new records

5. To test your agent's data collection, generate new records in the monitored log file.

When new records are added to the log file, the agent parses them according to its configuration and updates the corresponding attribute values in its cache.

6. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**.

The **Parse Log** window collects and shows any new attribute values in the agent's cache since it was last started. An example data collection is shown in [Figure 42 on page 1492](#)

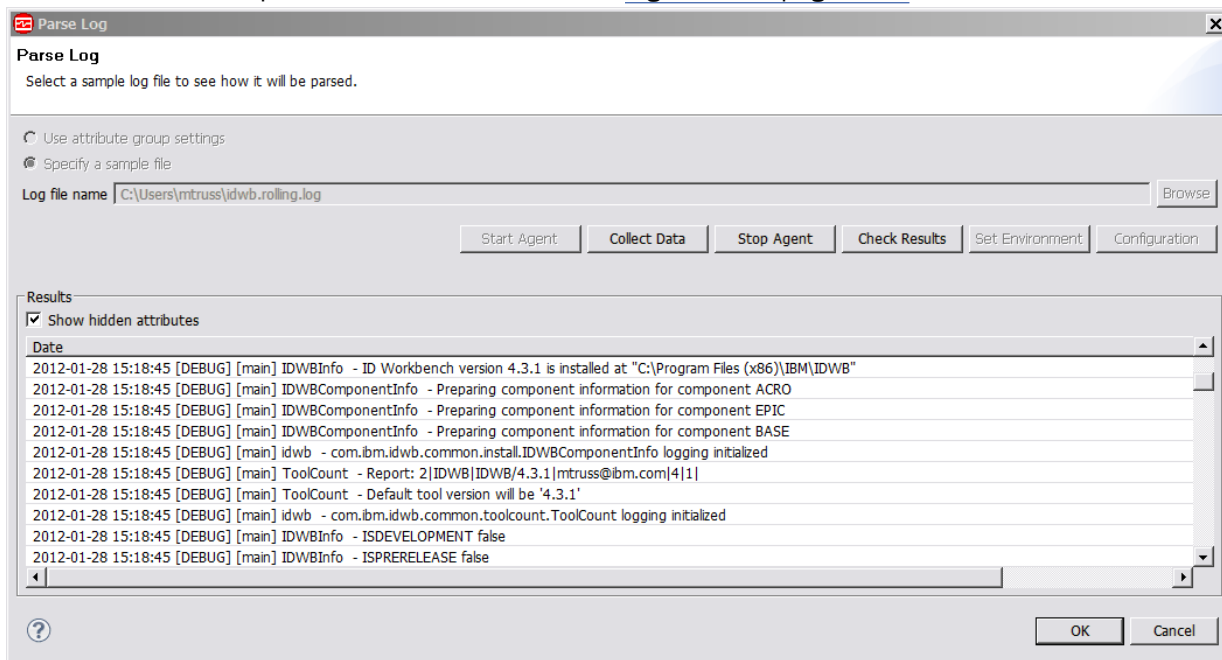

Figure 42. Parse Log window that shows parsed log file attribute values

7. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and shown by the Data collection Status window is described in [“Performance Object Status node”](#) on page 1638

8. The agent can be stopped by clicking **Stop Agent**.
9. Click **OK** or **Cancel** to exit the **Parse Log** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring an AIX Binary Log

You can define a data source to monitor AIX binary error logs through the `errpt` command. You can also configure it to filter and summarize the data. The resulting events are placed in a data set.

### About this task

Log Monitoring supports the monitoring of AIX binary error logs through the `errpt` command. The `errpt` command generates an error report from entries in an error log. It includes flags for selecting errors that match specific criteria. This support for the monitoring of AIX binary error logs through the `errpt` command is modeled on the support for the same function in the Tivoli Monitoring UNIX Logs Agent (product code `ku1` or `u1`).

When you supply the Agent Builder with an **errpt** command string, it processes the events that result from running this command. Agent Builder enforces the same constraints on this command that the Monitoring Agent for UNIX Logs does. In particular, you must use the **-c** (concurrent mode) option so that the command runs continuously, and you cannot use the **-t** option or the following options that result in detailed output: **-a**, **-A**, or **-g**.

An Agent Builder agent that monitors the AIX **errpt** command automatically includes the same information as a Monitoring Agent for UNIX Logs does. For more information about the attribute groups for AIX binary error logs, see [“AIX Binary Log attribute group” on page 1651](#).

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Logged data** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **AIX Binary Log**.
3. Click **Next**.
4. On the **Binary Log Information** page, enter an `errpt` command.

The default value is:

```
errpt -c -smddhmmmyy
```

The agent searches for the 'mmddhmmmyy' string and replaces it with the actual date and time on startup. Only the first occurrence of the string is replaced.

You can supply your own `errpt` command but Agent Builder enforces the same constraints on this command that the Monitoring Agent for UNIX Logs does. In particular, you must use the **-c** (concurrent mode) option so that the command runs continuously, and you cannot use the **-t** option or the following options that result in detailed output: **-a**, **-A**, or **-g**.

5. (Optional) Click **Advanced** to select filtering and summarization options for events. For more information, see [“Controlling duplicate events” on page 1623](#).
6. Do one of the following steps:
  - If you are using the **Agent** wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor.

### Related reference

[“AIX Binary Log attribute group” on page 1651](#)

The AIX Binary Log attribute group displays events from the AIX Binary Log as selected by the provided `errpt` command string.

## Monitoring a Windows Event Log

You can define a data source to collect data from a Windows event log. You can configure it to filter the data. The resulting events are placed in the Event Log data set.

### About this task

You can collect data from the Windows event log by using the type, source, or ID of events. You use these parameters to filter the log events that the Windows system gathered. The agent compares each new event in the monitored event log against the specified filter. If the event matches one of the event types, event sources, and event IDs specified in the filter, it passes.

For example, if the Event log filter is for the Application log, specify **Error** as the event type. This choice matches all events that are logged to the Application log with an event type value of `error`. If you add the **Diskeeper** and **Symantec AntiVirus** event sources, the agent matches all error events from either of these sources. You can add specific event IDs to refine the filter further. No direct association exists between the event type, event source, and event ID. If one of the values for each matches an event, the event matches.

By default, only events that are generated after the agent starts are processed. However, you can enable the agent when it restarts to process log events that are generated while the agent is shut down. For more information about enabling the agent to process events generated while the agent is shut down, see step “6” on page 1494.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Logged Data** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **Windows Event Log**.
3. Click **Next**.
4. On the **Windows Event Log** page, select the name from one of the logs in the **Windows Event Log name** list, or type a name for the event log.

The list is constructed from the set of logs on the current system, for example:

Application  
Security  
System

5. In the **Windows Event Log** page, specify whether you want to filter the results by using one or more of the following mechanisms:
  - [“Filtering by event type” on page 1495](#)
  - [“Filtering by event source” on page 1496](#)
  - [“Filtering by event identifier” on page 1496](#)

**Note:** You must select at least one of these filter criteria.

6. To process log events that are generated while the agent is shut down, on an agent restart, click **Offline Event Settings** on the **Windows Event Log** page.

The **Windows Event Log Bookmark Settings** window opens.

7. Select one of the following bookmarking options:

**Note:** These options apply to all Windows event logs being monitored.

- **Do not collect any offline events:** Events that are generated while the agent is shut down are not processed. This option is the default option.

- **Collect all offline objects:** All events that are generated while the agent is shut down are processed.
- **Specify custom collection settings:** You can enter a value to throttle the processing of old events that are based on a time value, or number of events, or both. By using this option, you ensure that the monitoring environment is not overloaded with events when the agent starts.

For example, if 100 is entered in **The maximum number of events to collect** field and 30 is entered in the **Restrict collection based on a time interval (in seconds)** field. The number of events that are processed is either the last 100 events that are generated before the agent starts, or any event that is generated within 30 seconds of agent start. Which result depends on the variable that is matched first.

When you enter a value for the maximum number of events to collect, the `CDP_DP_EVENT_LOG_MAX_BACKLOG_EVENTS` environment variable is added. When you enter a value to restrict collection that is based on a time interval, the `CDP_DP_EVENT_LOG_MAX_BACKLOG_TIME` environment variable is added. When either or both of these variables are added, the `eventlogname_productcode_instancename_subnodename.rst` file is created containing the last event record that is processed for the event log. This file is in the `%CANDLE_HOME%\tmaitm6\logs` directory and is used when the agent is restarted to process old events that are generated while the agent was shut down.

8. If you want to set global options for the data source, click **Global Options** on the **Windows Event Log** page

The **Global Windows Data Source Options** window opens.

9. Select the **Include remote Windows configuration properties** check box if you want to include this option, and click **OK**.

For information about Windows remote connection configuration for Windows data sources, see [“Configuring a Windows remote connection” on page 1581](#).

10. After you specify the filter and click **OK**, on the **Windows Event Log** page, do one of the following steps:
  - If you are using the **Agent** wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor. The name of the new Windows Event Log is shown on the **Agent Editor Data Source Definition** page.

## What to do next

For information about Windows remote connection configuration for Windows Event Log data sources, see [“Configuring a Windows remote connection” on page 1581](#).

## Filtering by event type

Filter Windows Event Log results by event type

### Procedure

1. In the **Windows Event Log** page, select **Filter by event type**.
2. Select one or more of the following Event types:
  - **Information**
  - **Warning**
  - **Error**
  - **Success Audit**
  - **Failure Audit**
3. Click **Finish** to complete.

## Filtering by event source

Filter Windows Event Log results by event source

### Procedure

1. Select **Filter by event source** and click **Add** in the **Event sources** area of the **Windows Event Log** page.

The **Event Source** window opens.

2. Make one of the following choices.

- Type the event source name and click **OK**.
- Click Browse **Browse** to find and select an event source from a list and click **OK**.

The name that you selected is shown in the **Event Source** window.

#### **Note:**

- a. To sort the list of event sources, click the column heading.
- b. To refresh the information in the window, click the **Refresh** icon.
- c. To search for specific event sources, click the **Search** (binoculars) icon.

3. Click **OK** to see the new event source filter in the Event sources list in the **Windows Event Log** window.

## Filtering by event identifier

For the Windows Event Log data source, you can filter events by event identifier.

### About this task

To filter by event identifier, use the following procedure:

### Procedure

1. Select **Filter by event identifier** and click **Add** in the **Event identifiers** area of the **Windows Event Log** window.

The **Event Identifier** window is displayed.

2. If you know that you want to monitor specific events from an application, specify the numbers of the event as the application defines it. Type an integer as the event identifier and click **OK**.

The new numeric event identifier filter is displayed in the Event identifiers list in the **Windows Event Log**.

**Note:** Each event identifier must be defined individually.

3. If you want to modify a Windows event log, select it and click **Edit**.
4. If you want to delete a Windows event log, select it and click **Remove**.
5. You can add more event logs to the list, or click **Finish**.

## Monitoring a command return code

You can define a data source to monitor an application or system by using a *command return code*. The agent runs the command, collects the return code, and adds the result to the Availability data set.

### About this task

A user-created script, executable file, query, or system command can return a code. A command return code is an application-specific mechanism for determining whether the application or monitored system is available. The agent runs the specified command and determines the state of the application or monitored system by examining the return code.

The command must present a unique return code for each descriptive state. The command must also define a message to be used by the agent for each of these return codes. The command can use environment and configuration variables within the user created script, executable file, query, or system command. The command must not use environment or configuration variables on the command-line invocation of the command, with only the following exceptions available: *AGENT\_BIN\_DIR*, *AGENT\_ETC\_DIR*, *AGENT\_LIB\_DIR*, *CANDLE\_HOME*, and *CANDLEHOME*.

## Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, select **Command or script** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **A command return code**.
3. Click **Next**.
4. On the **Command Return Code** page, **Command return code information** area, type the display name.
5. Use the following substeps to define and describe command lines that you want your command return code to use.

**Note:** Define a command for each operating system that is supported by the agent. Commands can be shared, but the total set of operating systems for all of the commands must equal the set of agent supported operating systems.

- a) Click **Add** in the **Commands** area of the **Command Return Code** window to open the **Command Information** window.
- b) Type a command line and select an operating system from the list in the **Operating Systems** area of the **Command Information** window.

**Note:**

- i) For a Windows command, you must type the full name of the command. For example, `command_to_run.bat` and not just `command_to_run`.
  - ii) Place quotation marks around the name so that it is not parsed by the command interpreter. For example, type `"this is a test.bat"` argument and not `this is a test.bat` argument.
  - iii) You can click a command and click **Edit** to modify it, or click **Remove** to delete it.
- c) Click **Add** in the **Return Codes** area of the **Command Information** window.
  - d) Select a return code type from the list that is shown in the **Return Code Definition** window

You can assign the following states to the test return codes:

- `ALREADY_RUNNING`
- `DEPENDENT_NOT_RUNNING`
- `GENERAL_ERROR`
- `NOT_RUNNING`
- `OK`
- `PREREQ_NOT_RUNNING`
- `WARNING`

- e) Type a numeric value for the return code type that you selected.

The return code value is an integer that specifies a defined return code for the command return code. For portability between operating systems, use a return code value of 0 - 255. For a command that runs only on Windows, the return code value can be -2147483648 - 2147483647.

- f) Define a message for each return code so that the message and code can be shown together. Click **Browse** to set up the message text.

The message window lists messages that are defined in the agent. The **Messages** (list) window opens.

**Note:**

- i) You can select text that was entered previously by selecting it in the list of message texts instead of clicking **Browse**. Then, continue to Step 5k.
- ii) Until you define messages, the list remains blank. You can use **Edit** to alter a defined message and **Remove** to delete one or more messages that you defined.

- g) In the **Messages** (list) window, click **Add**

The **Message Definition** window opens.

**Note:** The message identifier is automatically generated for you.

- h) Enter some text that describes the meaning of the new message in the **Message text** field.

- i) Click **OK**.

The **Messages** (list) window opens showing the new message .

- j) To verify the message and make it permanent, select it in the list and click **OK**.

The new return code type, value, and text are shown in the **Return Code Definition** window.

- k) If you want this return code to be available to other commands on other operating systems for this command return code, select **Global return code applies to all commands**. If you want this return code to be available only to this command, leave **Local return code applies only to this command** selected.

- l) Click **OK** in the **Return Code Definition** window.

- m) Define at least two return codes before you leave the **Command Information** window. One return code to indicate no problems with the availability, another to indicate whether a problem occurred. If you want to add another return code, return to step c.

- n) Optional: In the **Command Information** window, **Command files** area, click **Add** if you want to select one or more scripts or executable files for the agent to run.

The file or files are copied into the project folder of the agent under *scripts/operating system*, where *operating system* is a variable that depends on what you selected in the **Operating Systems** area of the **Command Information** window. These files are also packaged and distributed with the agent. To edit the definition of an existing command file, or the original command file since copied into the project, select the file and click **Edit**. See ([“Editing a command file definition” on page 1500](#)).

- o) Click **OK** in the **Command Information** window.

**Note:** The command files table is where you define any external files that you want to include in the agent package. These files are copied into the project directory and packaged with the agent for distribution.

- 6. If you have other return codes that are not already defined, define and describe global return codes that your command return code can use.

- a) Click **Add** in the **Global return codes** area of the **Command Return Code** page.

**Note:** The return codes that are defined here are global. This means that the return codes are appropriate for all of the commands that are defined for the command return code. (They are not shared between command return codes). In addition, you can define return codes when you enter the command information. The return codes that are defined here can be global or local. Local return codes are only appropriate for this specific command. This hierarchy is useful if you have a return code that is the same across all operating systems. (For instance, a return code of 0 means that everything is functioning correctly. You can define it at the global level, and then all defined commands interpret 0 in this way.) If none of the other operating systems return a 5, you can define the return code of 5 only for the Windows command. If you define a return code at the local command level that is already defined at the global level, the command level is used. You can use this method to override return codes on specific operating systems. For instance, if on all UNIX operating systems, a return code of 2 means one thing, but, on Windows, it means something

different. You can define a return code of 2 at the global level as expected by the UNIX operating systems. Then, in the command for Windows, you can redefine return code 2 for the meaning on Windows.

- b) Select a return code type from the list that is shown in the **Return Code Definition** window.

You can assign the following states to the test return codes:

- ALREADY\_RUNNING
- DEPENDENT\_NOT\_RUNNING
- GENERAL\_ERROR
- NOT\_RUNNING
- OK
- PREREQ\_NOT\_RUNNING
- WARNING

- c) Type a numeric value for the return code type that you selected. The return code value is an integer that specifies a defined return code for the command return code.

- d) Click **Browse** to set up the message text and its associated meaning. You must define a message for each return code so that the message and code are shown together.

The **Messages** window lists messages that are defined in the agent.

**Note:**

- i) Until you define messages, the list remains blank. You can use **Edit** to alter a defined message and **Remove** to delete one or more messages you defined.
  - ii) You can select text that was entered previously by selecting it in the **Message text** list instead of clicking **Browse**. Then, continue to Step 6h.
- e) In the **Messages** (list) window, click **Add** to see a **Message Definition** window, where you can type text that describes the meaning of the new message.
- f) Click **OK**.
- g) The **Messages** (list) window opens with the new message. To verify the message and make it permanent, select it in the list and click **OK**.
- h) When the new text, type, and value are shown in the **Return Code Definition** window, click **OK**.
- i) On the Command Return code page, when you finish defining the return codes and commands for all supported operating systems, do one of the following steps:
- If you are using the New Agent wizard, click **Next** or click **Finish** to save the data source and open the Agent Editor.
  - If you are using the New Agent Component wizard, click **Finish** to return to the Agent Editor.

## What to do next

If you want to use the data from this data source in the summary dashboard for IBM Cloud Application Performance Management, you must create a filtered data set (attribute group) based on the Availability data set and configure it as providing a single row. Use the NAME field to select the row for your process.

In the new filtered attribute group, select the Status field and specify the severity values for it.

For instructions, see:

- [“Creating a filtered attribute group” on page 1559](#)
- [“Specifying severity for an attribute used as a status indicator” on page 1424](#)
- [“Preparing the agent for Cloud APM” on page 1590](#)

## Editing a command file definition

You can change the command file that is imported into the project, or import changes to the existing command file into the project.

### Procedure

1. Select the file in the **Command files** area of the **Command Information window**.
2. Click **Edit** to open the **Import Command File** window.

From the **Import Command File** window, you can get the status of the command file. You can also change the location of the original source file, and recopy the source file into the agent.

3. Choose one of the following steps:

- Click **OK** to schedule a copy of the file to occur the next time that the agent is saved.
- Click **Copy Immediately** to copy the file without first saving the agent.

**Note:** The **Copy Immediately** option is not available when you access the **Import Command File** window from the New Agent wizard.

### File Separation & Consolidation

You can use the Separate and Consolidate functions to move files in and out of operating system-specific folders in the agent.

When a file is first added to the agent, a single copy is added in the `scripts/all_windows` folder, the `scripts/all_unix` folder, or the `scripts/common` folder. The `scripts/common` folder is used if the file is used on both Windows and UNIX.

To place different copies of the file on different operating systems (for example, a binary executable file), click **Edit** and click **Separate**. The file is removed from the common folder and copied into operating system-specific folders. Then, you can replace individual copies of the file with ones appropriate for specific operating systems.

**Note:** Java resource files must remain in the `scripts/common` folder. You cannot click **Separate** to make separate copies of Java resource files for individual operating systems.

If you separated the files into operating-system-folders, you can use **Consolidate** to move them back into a common folder. If you created the agent in an Agent Builder version that did not support common folders, use **Consolidate** to move them back into a common folder. If any of the copies of the file differ from one another, you are prompted to select the file to use as the common file. All other copies are discarded.

## Monitor output from a script

You can define a data source to collect data from a script or external program. Use it when application data is not available through a standard management interface or when you need to provide a summary of multi-row data in a single row. The agent runs the script and collects its output. Each line in the script output is parsed into a row of the resulting data set.

Data can be collected from either a local or remote system. The output of the script or program must contain only values for each attribute within the attribute group. To return multiple rows of data, the data for each row must be separated by a line break. The attributes in each row of data are separated by the separators you define. For more information about separators, see [“Script parsing and separators” on page 1501](#)

The command can use environment and configuration variables within the user-created script, executable file, query, or system command. The command cannot use environment or configuration variables on the command-line invocation of the command, with only the following exceptions available: `AGENT_BIN_DIR`, `AGENT_ETC_DIR`, `AGENT_LIB_DIR`, `CANDLE_HOME`, and `CANDLEHOME`.

The agent monitors script output that is written by using the same locale and code page that the agent runs in.

## Collecting script data from a remote system

To collect script or program data from a remote system, Agent Builder uses a Secure Shell (SSH)

To collect data from a remote system, Agent Builder creates a Secure Shell (SSH) session and starts the script or external program on the remote system. The agent establishes and logs on to an SSH session. The agent then uploads the scripts to the remote system, starts the script or external program, and retrieves the output. The agent can be configured to keep the session open or reestablish the session for each invocation. If the session is kept open, the script can be reused or uploaded for each invocation. By default, a single SSH session is used and the scripts are reused for each invocation.

Agent Builder supports use of only SSH Protocol Version 2 with Rivest, Shamir, and Adleman (RSA) or Digital Signature Algorithm (DSA) keys. The agent is either authenticated by user name and password, or by public key authentication. The generation and distribution of the public keys is an administrative task that must be done outside of the agent and Agent Builder.

To run a Take Action command that is written against a Secure Shell (SSH) enabled script data provider on the remote system, see [“SSEXEC action” on page 1721](#).

**Restriction:** If your agent was built with an Agent Builder version before 6.3 and it has a script data provider that uses SSH, the provider fails when run with IBM Tivoli Monitoring version 6.3 or later. To resolve this issue, rebuild the agent with the current version of Agent Builder.

The restriction is because IBM Tivoli Monitoring version 6.3 uses a newer version of the Global Secure Toolkit (GSKit) API. You must rebuild the agent with Agent Builder 6.3 or later to run it with IBM Tivoli Monitoring version 6.3 or later. If you build the agent with Agent Builder 6.3, it can also run with earlier versions of IBM Tivoli Monitoring.

## Script parsing and separators

You can change and assign specific script separators to one or more attributes.

When you create a script attribute group, a single character text separator is by default assigned. The default separator is ";". The separator is used by the agent to parse and delimit the data for each attribute in the data row. You can change the default separator to use a different character. You can also assign specific separators to one or more individual attributes.

You can assign specific separators for individual attributes that:

- Take a fixed number of bytes from the output.
- Separate one attribute from the next with a custom separator, which can be more than one character.
- Delimit an attribute value with a string at the beginning and end of the value.
- Return the rest of the text as the attribute value (whether it contains embedded separators or not).

You can use one or more of these separators to extract attribute values from the data rows.

### Example 1 - Simple script output

Some scripts can output data rows with clear and regular separators, for example:

```
Row One;1;2  
Row Two;3;4  
Row Three;5;6
```

Here the ";" character is a clear and regular separator between the three pieces of data on each row. In this case, the default separator is fine, so there is no need to change or define other separators. It is not difficult to imagine a similar script output where the separator is a different character, as in the following example.

```
Row One-1-2  
Row Two-3-4  
Row Three-5-6
```

In this example the separator is changed from a ";" character to a "-" character. In this case when you define the attributes, change the default separator to use the "-" character.

## Example 2 - Complex script output

Some scripts can output data rows that have irregular or changing separators, for example:

```
Row One;1;2;[option]Hour:MIN;fourtabby The end;4
Row Two;3;4;[required]12:30;fourvery tabby the tail;5
Row Three;5;6;[out]March:12;fourline up the rest of the story;6
```

In this example an assignment of separators to attribute definitions that you can use is:

1. Initially the default separator ";" is fine for the first three attributes in each data row. In this case, you assign the separator type **Separator Text** set to ";" when you define each attribute, this setting is the default one.
2. For the fourth attribute, assume the string between the "[" and "]" is a value that you want to extract. In this case when you define the fourth attribute, you assign a separator type **Begin and End Text** with begin and end text values of "[" and "]".
3. For the fifth attribute, assume that you want to extract the values between the ":" and ":" characters. In this case when you define the fifth attribute, you assign separator type **Separator Text** set to ":".
4. For the sixth attribute, the default separator ";" is fine again, accept the default.
5. For the seventh attribute, you would like to extract the string in the next four characters "four". There is not a clear separator at the end of this string. You can assign a number of characters to define the separation from the next attribute. You assign a separator type **Number of characters**, and specify four characters as the length.
6. For the eighth attribute you would like to extract the strings tabby, very tabby and line up. In this case, you can assume that all of these strings are followed by a tab character. In this case, you assign a separator of type **Tab separator**.
7. For the ninth attribute, you revert again to the default separator type to extract the remaining text to this attribute.
8. For the 10th attribute, you specify **Remainder of record** to assign the remainder of the data row to this attribute

Defining these separators on a script that outputs the data rows that are shown earlier in this example is shown in the following output:

| Results  |             |             |             |             |             |             |             |                       |                                    |
|--|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-----------------------|------------------------------------|
| <input checked="" type="checkbox"/> Show hidden attributes |             |             |             |             |             |             |             |                       |                                    |
| Attribute_1  | Attribute_2 | Attribute_3 | Attribute_4 | Attribute_5 | Attribute_6 | Attribute_7 | Attribute_8 | Attribute_9           | Attribute_10 (Remainder of record) |
| Row One  | 1           | 2           | option      | Hour        | MIN         | four        | tabby       | The end               | 4                                  |
| Row Two  | 3           | 4           | required    | 12          | 30          | four        | very tabby  | the tail              | 5                                  |
| Row Three  | 5           | 6           | out         | March       | 12          | four        | line up     | the rest of the story | 6                                  |
|  |             |             |             |             |             |             |             |                       |                                    |
|  |             |             |             |             |             |             |             |                       |                                    |

Figure 43. Example attribute value output when Agent parses complex script output.

The procedure to define the attribute separators is described under step "10" on page 1505 of "Steps for monitoring output from a script" on page 1502.

## Steps for monitoring output from a script

Configure your agent to receive data from a script data source.

### Before you begin

See "Monitor output from a script" on page 1500

## About this task

Use the following procedure to monitor output from a script:

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, select the option **Command or script** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **Output from a script**.
3. Click **Next**.
4. On the **Command List** page, click **Add** to display a **Command Information** window.

**Note:** Selecting the **Enable data collection using SSH** check box enables SSH for this attribute group. If this check box is not selected, the attribute group runs locally.

**Note:** If a command exists that can be run on the operating system on which the Agent Builder is running, the **Test** option is enabled. You can use **Test** to test a command that you defined.

5. In the **Command Information** area in the **Command Information** window, type a command name with the necessary arguments in the **Command** field, and a separator in the **Separator** field.

**Note:**

- a. Scripts in Windows are frequently started without specifying the .bat or .cmd extension on the command line. For remote execution, a shell environment must be installed and you must specify the .bat or .cmd in the script data source command for the script to run. Cygwin is an example of a shell environment that is available for Windows. Linux, Red Hat, and AIX. To verify that a shell environment exists, SSH or log on to the remote host and enter the command:

```
PATH=$PATH:. <command>
```

If the command runs, then a shell environment exists.

- b. Use quotation marks around the name so that it is not parsed by the command interpreter. For example, this is a test.bat argument becomes:

```
"this is a test.bat" argument
```

- c. Environment variables and configuration variables can be used in the user-provided script, but cannot be part of the command line that starts the script. The following variables are exceptions to this rule:

**AGENT\_BIN\_DIR**

The directory where the agent places binary files or scripts

**AGENT\_ETC\_DIR**

The directory where the agent places configuration files

**AGENT\_LIB\_DIR**

The directory where the agent places shared libraries or dynamic-link libraries

**CANDLEHOME**

The Linux or UNIX Tivoli Monitoring installation directory

**CANDLE\_HOME**

The Windows Tivoli Monitoring installation directory

- d. If the SSH data collection option is being used, the command line is run relative to the user's home directory on the remote system. If you are uploading scripts or executables to the remote system, they are copied to the location specified in the agent's environment variable `CDP_SSH_TEMP_DIRECTORY`. The location defaults to the user's home directory on the remote system. On some systems, you might need to define the command line with a relative path, such as `./Script.sh`.

6. In the **Operating Systems** area, select one or more operating systems. When you collect data from a remote system by using SSH, Operating Systems is a property of the system on which the agent is

installed. It is not the Operating System of the remote system. It is advised that you select the **All operating systems** check box when you use the SSH data collection features.

7. Optional: If one or more user-defined files are necessary to run the command, click **Add** in the Command files area to specify the files from your system.

The files are copied into the project folder of the agent under `scripts/operating system`, where `operating system` is a variable that depends on what you selected in the **Command Information** window. These files are also packaged and distributed with the agent. If you want to edit the definition of a command file you already added, or changed the contents of, select the file and click **Edit**. See [“Editing a command file definition” on page 1500](#).

8. Click **OK**. The **Command List** page is displayed.

9. To test the command, use the following steps:

- a) Click **Test** to open the command information and display the **Test Command** window. To test the script on a remote system, select a system from the **Connection name** list or click **Add** to add the host name of a system.
- b) Use the **Test Command** window to change the command, default separator, and attribute separators, and to view how these changes affect the data that is returned.
  - i) Type the command and separator in the fields if they are not already entered.

**Note:** You can specify other separators by using the **Attribute Information** window at attribute creation time or by using the Agent Editor to modify an existing attribute. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#) and for more information about manipulating data source and attributes, see [“Editing data source and attribute properties” on page 1415](#)

- ii) Before you start testing, you can set environment variables and configuration properties. For more information, see [“Attribute group testing” on page 1596](#).
- iii) Click **OK** to return to the **Test Settings** window.
- iv) Click **Start Agent**. A window indicates that the Agent is starting.
- v) To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**. The Agent Builder runs your command. If you specified a remote system, provide a user ID and password. Even if the return code is not 0, the Agent Builder parses the results of the command in the same way the agent does.
- vi) The **Test Settings** window collects and displays any data in the agent's cache since it was last started. The initial names of the attributes are **Attribute\_1**, **Attribute\_2**, and so on; however, you can modify the properties of the attributes by clicking the appropriate column heading.
- vii) Click **Check Results** to view the return code from the command, the unparsed data, and any error messages that were returned.
- viii) The agent can be stopped by clicking **Stop Agent**.
- ix) Click **OK** to return to the **Command Information** window.

If you change the command or the separator, the appropriate command is updated to reflect those changes.

If this window was opened when you created the script data source, the attributes were added to the new script data source.

If this window was opened from an existing script data source, then any changes to the attributes are made to the script data source. Any additional attributes are added, but any extra attributes are not removed. These options affect only the attributes that are parsed from the script output. Any derived attributes are not affected. If any of these attributes become invalid based on the attributes they reference, you can update or remove derived attributes manually. The derived attribute formula is displayed and not the actual result value.

**Note:** If the attribute group exists, to start a test, complete the following procedure

- a. Select the attribute group on the **Agent Editor Data Sources Definition** page.

- b. Select the script to be tested from the Command List
  - c. Click **Test** and follow the procedure at step “9” on page 1504
10. If you skipped testing the command in step (“9” on page 1504), use the following steps:
- a) On the **Command List** page with the completed command information, click **Next**.
  - b) On the **Attribute Information** page, complete the attribute name and type information by using (Table 297 on page 1420). Select **Add additional attributes** to add further attributes
  - c) On the **Attribute Information** page, use the **Script Attribute Information** tab to choose a specific data separator for this attribute.
- The standard separator ; is selected by default. You can choose a number of other separators such as a string, a number of characters, a tab, or a space. You can also choose to use a different string separator for the beginning and end of the data. Finally, you can also choose **Remainder of record** to assign the remainder of the record to the attribute. For more information about script parsing and separators, see “Script parsing and separators” on page 1501.
11. Do one of the following steps:
- If you are using the **Agent** wizard, click **Next**.
  - Click **Finish** to save the data source and open the Agent Editor.
12. You can add attributes and supply the information for them. For more information, see “Creating attributes” on page 1417.

In addition to the fields applicable to all data sources (described in “Fields and options for defining attributes” on page 1420), the **Data Sources Definition** page for the Script data source has the following options:

**Command List**

Provides access to the commands and scripts to start during data collection.

**Add**

Allows the user to add a command to be started by this attribute group.

**Edit**

Allows the user to edit an existing command entry.

**Remove**

Allows the user to delete an existing command entry.

**Test**

Allows the user to access the test environment for this attribute group.

**Enable data collection using SSH**

Selecting this check box enables SSH for this attribute group. If this check box is not selected, the attribute group runs locally.

For information about SSH remote connection configuration for script data sources, see “Configuring a Secure Shell (SSH) remote connection” on page 1584.

## Monitoring data from Java Database Connectivity (JDBC)

You can define a data source to receive data from a JDBC database. The agent runs an SQL query to collect data from the database. Each column that is returned by the query is an attribute in the resulting data set.

### About this task

The JDBC data provider supports the following database servers:

- IBM DB2 9.x and 8.x
- Microsoft SQL Server 2008, 2005, and 2000
- Oracle database 11g and 10g

Agent Builder does not include the JDBC drivers for these databases. The JDBC drivers are a set of JAR files that are provided by the vendor that are necessary to establish a JDBC connection to the database. For convenience, here are links to where those drivers can be downloaded:

- IBM DB2: JDBC drivers are included with the database server installation in a subdirectory named `java` located under the main DB2 installation directory.
- Microsoft SQL Server website at [www.microsoft.com](http://www.microsoft.com)
- Oracle database: [Oracle Database JDBC](http://www.oracle.com/technetwork/database/features/jdbc/index.html) (<http://www.oracle.com/technetwork/database/features/jdbc/index.html>)

**Note:** An important thing to remember is that the JDBC data provider can remotely monitor your Database servers. A Java runtime environment and JDBC driver JAR files for the database server you are connecting to must be on the system where the agent runs.

The following versions of Java are supported:

- Oracle Corporation Java Version 5 or later
- IBM Corporation Java Version 5 or later

## Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **JDBC**.
3. Click **Next**.
4. On the **JDBC Information** area in the **JDBC Information** page, click **Browse** to connect to a database and build your SQL Query.

Use the JDBC Browser to connect to a database and view its tables so you can build an SQL query that collects the data you need. When you select a table and columns, a query is generated for you and attributes are added for each of the columns returned by the query. You can modify and test the query that is generated to make sure the data that is returned is what you need.

**Note:** You can also manually create the JDBC data source without clicking **Browse**. If you want to manually create the data source, specify the query and click **Next**. You must define an attribute for each column returned by the query, in the order that the columns are returned.

With the JDBC data provider, you can run SQL queries and stored procedures against a database to collect monitoring data. When you specify an SQL query to collect data, you can include a where clause in your SQL statement to filter the data that is returned. The SQL statement can also join data from multiple tables. In addition to SQL select statements, the JDBC data provider can run stored procedures. For information about running stored procedures, see [“Stored procedures” on page 1511](#).

5. The first time the Browser opens, the Java Database Connectivity (JDBC) Browser window indicates that no connections are selected. You must add a connection. Click **Add** and follow the [Steps to add a connection](#).

If you already defined a connection, that connection is used and you can proceed to Step [“6” on page 1507](#).

**Note:** The **Status** field shows the status of the current connection.

Use the following steps to add a connection:

- a) On the **JDBC Connections** page, click **JDBC Connection**, and click **Next**.
- b) On the **Connection Properties** page, complete the fields as follows:

### Connection Name

Name of the JDBC connection. Type a unique name for this connection. You use this name to reference the connection in the browser.

**Database Type**

Type of database. Select the database product to which you are connecting. For example, to connect to the IBM DB2 database, select **DB2**.

**User Name**

Must be defined with at least read access to the database, but does not have to be the database administrator

**Password**

Must be defined with at least read access to the database, but does not have to be the database administrator

**Host name**

Host name on which the database server is running. With JDBC, you can monitor remote databases so you are not restricted to monitoring databases on the local system.

**Port**

Port on the host name on which the database server is listening.

**Database**

Name of the database to which to connect.

**Jar Directory**

Directory containing the JDBC JAR files used to connect to the database. Type the path name, or click **Browse** to locate the directory.

- c) Optional: Select the **Save the password in the Agent Builder workspace** check box if you want to save the password for this connection.
  - d) Optional: Select the **Set as agent configuration defaults** check box if you want the defaults for this application server type to be copied from these properties.  
If you are building the agent on a system that is similar to your monitored systems, it is advisable to check this box. If you do not check this box, the user who configures the agent sees an empty field. The user must then determine the values for all of the information without default values.
  - e) Click **Test Connection** to create a connection to the database that uses the configuration parameters you specified.  
A message on the **Connection Properties** page indicates whether the connection succeeds.
  - f) When you have a working connection, click **Finish**.
6. In the **Java Database Connectivity (JDBC) Browser** window, a connection is made to the configured database. The tables that are contained in the database are shown in the **Database Tables** area. Select a database table to see the columns that are contained in that table in the **Columns in the selected table** area.

**Note:**

- a. Click the binoculars icon to search for a table in the **Database Tables** list.
- b. All tables are shown by default. You can filter the tables that are shown by selecting a different filter option. The available filter options are shown in [Table 303 on page 1507](#).

| <i>Table 303. Filter options</i> |                          |
|----------------------------------|--------------------------|
| Filter option                    | Description              |
| <b>All</b>                       | Show all tables          |
| <b>User</b>                      | Show only user tables    |
| <b>System</b>                    | Show only system tables  |
| <b>View</b>                      | Show only database views |

**Note:** If you want to retrieve specific columns, select only these columns. If you select the table, Agent Builder automatically builds a query that gathers all of the columns from the table and creates attributes for all the columns that are currently in the table.

You can select columns in the following ways:

- Select the table and get the default query for all columns.
  - Select columns to get only those columns.
7. Optional: Modify the enumeration values that are set for Error, Missing data, and No value in the **Attribute Information** page.  
Modify the values to avoid any overlap with legitimate values that might be returned from database table columns.
  8. Optional: Click **Test** on the **Java Database Connectivity (JDBC) Browser** window to test and modify the SQL statement.  
The **Run the SQL statement** window opens.
    - a) Enter or modify the SQL statement in the **SQL statement** field.
    - b) Click **Run** to run the SQL statement.  
The results are displayed in the **Results** area. Continue to modify and test the statement until you are satisfied with the data that is returned.
    - c) Click **OK** to save the statement, create the correct attributes, and return to the **JDBC Information** window.
  9. Optional: Click **Test** on the **JDBC Information** window to test the attribute group in a more realistic agent environment. For more information about testing JDBC attribute groups, see [“Testing JDBC attribute groups” on page 1512](#). If you change the JDBC statement during this test, you must also adjust the attributes so that there is one attribute per column returned by the JDBC statement, in the correct order.
  10. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#).
  11. On the **JDBC Information** page, **Operating Systems** section, select the operating systems, and click **Next**. See [“Specifying operating systems” on page 1436](#) for information about which operating systems to select.  
**Note:** Click **Insert Configuration Property** to select a property to insert. For more information, see [\(“Customizing agent configuration” on page 1578\)](#).
  12. On the **Select key attributes** page, select key attributes or indicate that this data source produces only one data row. For more information, see [“Selecting key attributes” on page 1397](#).
  13. If you want to test a data source that you previously defined, in the Agent Editor window, select the **Data Sources** tab and select a JDBC data source. In the **JDBC Attribute Group Information** area, click **Test**. For more information about testing, see [“Testing JDBC attribute groups” on page 1512](#).
  14. If you want to view the configuration sections that were automatically generated, click the **Insert Configuration Property** tab of the Agent Editor.  
You can change the labels or default values for these properties to match the defaults that the user sees when they initially configure the agent.
  15. Optional: Complete the **Attribute Information** page; for details, see [“Fields and options for defining attributes” on page 1420](#). Do this step if you chose to manually create the JDBC data source without clicking Browse in step [“4” on page 1506](#).

The Agent Builder JDBC data source supports collecting data from most SQL types. The information in [Table 304 on page 1509](#) describes the type of attribute that is created by the JDBC Browser when it detects a column of one of these types. These data types are the supported types for use with a monitoring agent.

| Table 304. Supported SQL data types for use with a monitoring agent |  |
|---|--|
| SQL data type   | IBM Tivoli Monitoring attribute that is created  |
| BIGINT  | This data type is a 64-bit gauge value in IBM Tivoli Monitoring. If you select IBM Tivoli Monitoring V6.2 compatibility, it is a 32-bit gauge.   |
| DECIMALDOUBLEFLOATNUMERICREAL                                       | These SQL Types are created as 64-bit gauge attributes in IBM Tivoli Monitoring. If the database metadata contains a scale value, that value is used; otherwise, the scale is set to 1. If you select IBM Tivoli Monitoring V6.2 compatibility, the attribute is a 32-bit gauge. |
| BITINTEGERSMALLINTTINYINT   | The following SQL types are created as 32-bit gauge attributes in IBM Tivoli Monitoring.   |
| BOOLEAN   | This value is a 32-bit gauge in IBM Tivoli Monitoring with enumerations for TRUE and FALSE.  |
| TIMESTAMP   | Data in columns of this type are converted to a 16-byte IBM Tivoli Monitoring time stamp attribute.  |
| TIMEDATECHARLONGVARCHARVARCHAR                                      | These SQL types are all treated as string attributes by the browser. The column size is used as the attribute size up to 256, which is the default string attribute size for the JDBC browser.   |

**Note:** If you collect data from a data type that is not listed, a string attribute is used by default. The agent also tries to collect the data from the database as a string.

Modify the enumeration values that are set for Error, Missing data, and No value in the **Attribute Information** page, if required. Modify the values to avoid any overlap with legitimate values that might be returned from database table columns.

## JDBC configuration

When you define a JDBC data source in your agent, some configuration properties are created for you.

If you define a JDBC data source in your agent, the agent must use Java to connect to the JDBC database server. Java configuration properties are added to the agent automatically. The following Java configuration properties are specific to the agent runtime configuration:

- *Java Home:* A fully qualified path that points to the Java installation directory
- *JVM Arguments:* Use this parameter to specify an optional list of arguments to the Java virtual machine.
- *Trace Level:* This parameter defines the amount of information to write to the Java trace log file. The default is to write only Error data to the log file.

**Note:** Agent Builder does not require the Java properties because it uses its own JVM and logging, which are configured through the JLog plug-in.

If you define a JDBC data source in your agent, the following required, common configuration fields are added to the agent automatically:

- *JDBC database type:* Type of database to which you are connecting, IBM DB2, Microsoft SQL Server, or Oracle Database Server.
- *JDBC user name:* User name that is used to authenticate with the database server.

- *JDBC password*: Password that is used to authenticate with the database server.
- *Base paths*: List of directories that are searched for JAR files that are named in the *Class Path* field, or directories that are named in the *JAR directories* field, that are not fully qualified. Directory names are separated by a semi-colon ( ; ) on Windows, and by a semi-colon ( ; ) or colon ( : ) on UNIX systems.
- *Class path*: Explicitly named JAR files to be searched by the agent. Any files that are not fully qualified are appended to each of the Base Paths until the JAR file is found.
- *JAR directories*: List of directories that are searched for JAR files. Directory names are separated by a semi-colon ( ; ) on Windows, and by a semi-colon ( ; ) or colon ( : ) on UNIX systems. The JAR files in these directories do not have to be explicitly identified; they are found because they are in one of these directories. Subdirectories of these directories are not searched. Any directories that are not fully qualified are appended to each of the Base Paths until the directory is found.

The runtime configuration also requires that you specify some additional details to connect to the database. You can choose how to specify the remaining configuration items, either as a JDBC URL or as basic configuration properties (the default):

- URL configuration option
  - JDBC connection URL: Vendor-specific connection URL that provides details on which host the database is located and the port number to which to connect. The URL format typically looks as follows:

```
jdbc:identifier://server:port/database
```

see the JDBC driver vendor documentation for the different URL formats.

- JDBC Basic Properties option (default)

JDBC server name: Host name that the database server is running on.

JDBC database name: Name of the database on the host where the connection is made.

JDBC port number: Port number on which the database server is listening.

**Note:** With the JDBC data provider, you can monitor multiple database types in the same agent by using subnodes. To monitor in this way, you must carefully define the Subnode Configuration Overrides. If you monitor multiple database types, the following configuration settings are likely to be different:

- JDBC database type
- JDBC user name
- JDBC password

If you are using the basic configuration option, you must also define overrides for the following properties on the **Subnode Configuration Overrides** page:

- JDBC server name
- JDBC port number
- JDBC database name

To define the configuration overrides for your subnode, see [“Using subnodes” on page 1561](#) for more details about accessing the **Subnode Configuration Overrides** page. When you configure the agent at run time, all of these properties must be configured for each new subnode instance that is created.

In addition to configuration overrides, your agent must also point to JDBC drivers for each database type that you plan to connect to from your subnodes. The *JAR directories* parameter is the most convenient way to point to your JDBC drivers. List the directories that contain the JDBC drivers by using a semicolon to separate each directory. For example, if you are connecting to DB2 and Oracle databases with the agent, you must specify a *JAR directories* value similar to this example: C:\Program Files\IBM\SQLLIB\java;C:\oracle\jdbc.

## Stored procedures

Example SQL and DB2 stored procedures that you can use with the JDBC data provider.

The JDBC data provider can process the result sets returned by a stored procedure. String or integer input parameters can be passed to the stored procedure. The following syntax runs a stored procedure:

```
call[:index] procedureName [argument] ...
```

Where:

### index

An optional integer that specifies which result set is to be used by the data provider. This parameter is useful when the stored procedure returns multiple result sets and you want to collect only the values from one of the result sets. If an index is not specified, data from each result set is collected and returned.

### procedureName

The name of the stored procedure that is to be run by the JDBC data provider.

### argument

An input argument to the stored procedure. Multiple arguments must be separated by a space. If the argument contains a space character, enclose the entire argument in double quotation marks. If the argument can be parsed as an integer, it is passed to the stored procedure as an integer argument. Any argument that is enclosed in double quotation marks is passed as a string argument.

## SQL Server Samples

### call sp\_helpdb

Runs the procedure `call sp_helpdb` which requires no arguments. Data from all returned result sets are included in the data that is returned by the data provider.

### call:2 sp\_helpdb master

Runs the procedure `sp_helpdb` with the `master` argument. This argument is a string input argument. Only data from the second result set that is returned by the stored procedure is included in the data that is returned by the data provider.

When the index is not specified, data from all returned results sets is collected. You must ensure that the data returned in these cases is compatible with the attributes you define. Agent Builder creates attributes from the first returned result set, and any further result sets are expected to be compatible with the first one.

## DB2 stored procedure

Here is a sample DB2 function that is written in SQL. This function demonstrates how to return results that can be processed by the Agent Builder JDBC data provider:

```
-- Run this script as follows:
-- db2 -td# -vf db2sample.sql

-- Procedure to demonstrate how to return a query from
-- a DB2 stored procedure, which can then be used by
-- an Agent Builder JDBC provider. The stored procedure
-- returns the following columns:
-- Name                Description                Data Type
-- current_timestamp    The current system time    timestamp
-- lock_timeout          The lock timeout            numeric scale 0
-- user                 The user for the session    String 128 characters long
DROP procedure db2sample#

CREATE PROCEDURE db2sample()
  RESULT SETS 1
  LANGUAGE SQL
  BEGIN ATOMIC

  -- Define the SQL for the query
  DECLARE c1 CURSOR WITH HOLD WITH RETURN FOR
  SELECT CURRENT TIMESTAMP as current_timestamp,
```

```

CURRENT LOCK TIMEOUT as lock_timeout, CURRENT USER as user
FROM sysibm.sysdummy1;

-- Issue the query and return the data
OPEN c1;
END#

```

This function can be called from Agent Builder by using the same syntax that is defined for other stored procedures. In this case, you define `call db2sample` as your JDBC statement to run this stored procedure.

## Oracle stored procedures

Oracle stored procedures do not return result sets. Instead, you must write a function that returns an Oracle reference cursor. Here is a sample Oracle function that is written in PL/SQL that demonstrates how to return results that can be processed by the Agent Builder JDBC data provider:

```

CREATE OR REPLACE FUNCTION ITMTEST
RETURN SYS_REFCURSOR
IS
    v_rc SYS_REFCURSOR;
BEGIN
    OPEN v_rc FOR SELECT * FROM ALL_CLUSTERS;
    RETURN v_rc;
END;

```

This function can be called from Agent Builder by using the same syntax that is defined for other stored procedures. In this case, you define `call ITMTEST` as your JDBC statement to run this stored procedure. Because the Oracle function must return a cursor reference, only one result set can be processed by Oracle functions. This means that the index option is not supported for Oracle because there is no way to return multiple result sets.

## Testing JDBC attribute groups

You can test the JDBC attribute group that you created, within Agent Builder.

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **JDBC Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#).

After you click **Test** in one of the previous two steps, the **Test JDBC Statement** window is displayed.

2. Optional: Before you start testing, you can set environment variables, configuration properties, and Java information.

For more information, see [“Attribute group testing” on page 1596](#). For more about JDBC configuration properties, see [\(“JDBC configuration” on page 1509\)](#).

3. Click **Start Agent**.

A window indicates that the Agent is starting.

4. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**.

The agent queries the database with the specified SQL query. The **Test JDBC Statement** window collects and shows any data in the agent's cache since it was last started.

**Note:** The order of the returned data is significant; for example, the data value in the first returned column is always assigned to the first attribute. If you change the JDBC statement, you must add, remove, or reorder the attributes to match the columns returned by the statement.

5. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the Data collection Status window is described in [“Performance Object Status node” on page 1638](#)

6. Stop the agent by clicking **Stop Agent**.
7. Click **OK** or **Cancel** to exit the **Test JDBC Statement** window. Clicking **OK** saves any changes that you made.

#### Related concepts

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring system availability by using Ping

You can define a data source to test a list of network devices by using the Internet Control Message Protocol (ICMP) echo ping. The host name or IP address of the devices you want to test are listed in one or more device list files. A separate Ping configuration file specifies the path to each device list file. Then, the name of the Ping configuration file is set in the agent runtime configuration. The results include the status of each network device.

### Before you begin

Create device list files and a ping configuration file (see [“Configuration files” on page 1513](#)).

### About this task

Part of network management involves the ability to determine whether systems respond to an Internet Control Message Protocol (ICMP) ping. Use this data source to monitor basic online or offline status for a set of servers or other critical devices in your environment. Monitoring with ping is simple and low-overhead. To monitor a list of devices, add the Ping data collector to your agent.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Network management data** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **Ping**.
3. Click **Next**.
4. In the **Operating Systems** area in the **Ping Information** window, select the operating systems.
5. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing Ping attribute groups” on page 1515](#)
6. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
7. Do one of the following steps:
  - a) If you are using the **Agent** wizard, click **Next**.
  - b) Click **Finish** to save the data source and open the Agent Editor.
8. For more information about adding attributes, see [\(“Creating attributes” on page 1417\)](#).

### Results

For more information about the attribute group for Ping, see [“Ping attribute group” on page 1667](#).

## Configuration files

You provide the agent with the list of devices to ping by using configuration files.

The agent requires two types of configuration files.

## Device list file

Includes a list of devices to ping. If you have many devices, you can divide them across multiple device list files. The agent starts a separate thread for each device list file and cycles through the files in parallel. It cycles through each file every 60 seconds or every 30 seconds plus the time it takes to ping the list, whichever is longer.

The syntax of the device list file is as follows:

```
LISTNAME=list_name  
device_name or host_name  
device_name or host_name  
device_name or host_name device_name or host_name
```

Where *list\_name* is a description for the devices in that file. If no list name is defined, the name of the device list file is used. The list name does not need to be the first entry in the file. However, if the file has multiple list name definitions, the last definition is used.

There is no limit to the number of devices you can include in a device list file. However, including too many entries defeats the purpose of having a targeted list of critical devices and increases the overall workload. It might be more difficult to retrieve the status of each device within the 60-second monitoring interval.

At the start of each cycle, the agent checks the last modification time of the device list file. If the last modification time of the file is more recent than the last time the agent read the file, the agent rereads the file without requiring a restart.

## Ping configuration file

Specifies the location of each device list file. Use the fully qualified path or a path relative to the location of the ping configuration file. The ping configuration file is passed as a runtime configuration parameter to the agent.

## Example

In the following example, devices are divided into two files.  
The /data/retailList.txt file contains the following entries:

```
LISTNAME=Retail  
frontend.mycompany.com  
productdb.mycompany.com
```

The /data/manufacturingList.txt file contains the following entries:

```
LISTNAME=Manufacturing systems  
manufloor.mycompany.com  
stats.supplier.com
```

The ping file, /data/pinglists.txt, contains the following entries:

```
/data/retailList.txt  
/data/manufacturingList.txt
```

## Network Management configuration property

After a ping data source is added, the configuration is displayed on the **Runtime Configuration Information** page of the Agent Editor.

The **Network Management** configuration section of the **Runtime Configuration Information** page contains the following property:

Table 305. Network Management configuration properties

| Name                    | Valid values   | Required  | Description   |
|-------------------------|----------------|---|---|
| Ping configuration file | Path to a file | No. If this file is not provided, the KUMSLIST file is used from the agent bin directory. | The path to the file that contains a list of files, each containing a list of hosts to monitor by using ICMP pings. |

## Testing Ping attribute groups

You can test the Ping attribute group that you created within Agent Builder.

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **Ping Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398.

After you click **Test** in one of the previous two steps, the **Test Settings** window opens.

2. Optional: Before you start testing, you can set environment variables and configuration properties. For more information, see [“Attribute group testing”](#) on page 1596.
3. Click **Browse** to select a Ping configuration file. For more about Ping configuration files, see [“Configuration files”](#) on page 1513
4. Click **Start Agent**. A window indicates that the Agent is starting.
5. To simulate a request from the monitoring environment for agent data, click **Collect Data**. The agent pings the devices that are specified in the device list file, which is referenced from the Ping configuration file.
6. The **Test Settings** window collects and shows any data in the agent's cache since it was last started.
7. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and shown by the Data collection Status window is described in [“Performance Object Status node”](#) on page 1638.

8. Stop the agent by clicking **Stop Agent**.
9. Click **OK** or **Cancel** to exit the **Test Settings** window. Clicking **OK** saves any changes that you made.

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring HTTP availability and response time

You can configure a data source to monitor the availability and response time of selected URLs. Use a configuration file to define a list of URLs. Set the name of the file in the agent runtime configuration. In IBM Tivoli Monitoring, you can also use Take Action commands to add and remove monitored URLs. The status for each URL is added as a line in the resulting data set.

### About this task

For each URL you monitor, the results provide general information about the HTTP response to the HTTP request. The results include whether it can be retrieved, how long it takes to retrieve, and the size of the response. If the response content is HTML, information is also provided about the page objects within the URL.

You can monitor URLs that use the HTTP, HTTPS, FTP, and file protocols. You specify the URLs to monitor in the HTTP URLs file, or through Take Action options.

**Important:** At the time of release, Take Action commands are not available in an IBM Cloud Application Performance Management environment. They are available only in a Tivoli Monitoring environment.

This data source requires a Java runtime environment. The following versions of Java are supported:

- Oracle Corporation Java Version 5 or later
- IBM Corporation Java Version 5 or later

Use the following procedure to create an attribute group to monitor a list of URLs:

## Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **HTTP**.
3. Click **Next**.
4. On the **HTTP Information** page, select one or more operating systems in the **Operating Systems** area.
5. Optional: Click **Test** to test this attribute group. For more information about testing, see [“Testing HTTP attribute groups” on page 1522](#)
6. Optional: Click **Advanced** to create a filter to limit the data that is returned by this attribute group. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
7. Do one of the following steps:
  - a) If you are using the **Agent** wizard, click **Next**.
  - b) Click **Finish** to save the data source and open the Agent Editor.

## Results

The HTTP data source creates two attribute groups: Managed URLs and URL Objects. You can add, modify, or delete attributes.

### Related tasks

[“Creating attributes” on page 1417](#)

You can add new attributes to a data set.

### Related reference

[“HTTP attribute groups” on page 1670](#)

The two HTTP attribute groups, Managed URLs and URL Objects, are used to receive information from URLs and the objects within these URLs.

## HTTP tables

Reference information about the default HTTP attribute groups.

The two attribute groups that are created by the HTTP data source are:

### Managed URLs

The Managed URLs table provides availability and response time data about each URL being monitored.

### URL Objects

The URL Objects table contains a separate URL entry for each embedded object. For example, the .gif and .jpg files that might be used in the website that is listed in the Managed URL report.

For information about the syntax that is used in the Managed URLs and URL Objects tables, see [\(“Specific fields for HTTP attributes” on page 1517\)](#).

When you want to monitor the response time and availability of specific objects within a website, review the contents of the URL Objects table. The URL Objects table monitors a specific list of objects that are detected in downloaded HTML files. The following table lists the HTML elements that are searched for objects to monitor and the attributes within these elements that reference the objects:

| <i>Table 306. HTML elements searched for objects to monitor</i> |   |
|---|---|
| HTML element  | Attribute containing object to be monitored |
| img   | src   |
| script  | src   |
| embed   | src   |
| object  | codebase or data                            |
| body  | background                                  |
| input   | src   |

In the following example HTML extract, the object that is monitored is the image that is referenced by the src attribute of the `img` element.

```

```

A full URL to the image is calculated based on the URL to the source document.

**Note:** If you do not want to monitor objects that are found in a web page, in the URL Monitoring configuration section, set the **Page object collection** property to **No**.

## Specific fields for HTTP attributes

In the **Attribute information** page, there are two fields for HTTP attributes that define how data is collected from the URL. The **Attribute Type** field can be any value from a list that controls the information about the URL that is returned. Some attribute types require a value in the **Type Value** field.

The following table describes all of the attribute types for the Managed URLs attribute group, and the type value when one is required:

| <i>Table 307. HTTP Attribute Information - Managed URLs</i> |   |  |   |   |
|---|---|--|---|---|
| Attribute type  | Description   | Type value   | Data type that is returned  | Differences with FTP and file protocols |
| XPath Query   | Runs an XPath query on the content that is returned from a URL connection. The query must be written to return data useful for an attribute, not a list of nodes. | The XPath query to run against the content that is obtained from a URL connection. | The data that is returned can be a string, a numeric, or a timestamp value. If the data is in the XML DateTime format, you can specify timestamp as the attribute type. The agent converts the value to a Candle Timestamp. | None                                    |

Table 307. HTTP Attribute Information - Managed URLs (continued)

| Attribute type   | Description  | Type value                      | Data type that is returned       | Differences with FTP and file protocols  |
|------------------|--|---------------------------------|----------------------------------|--|
| Response Time    | The amount of time in milliseconds that it took to download the content from the requested URL.  | None                            | Integer (number of milliseconds) | None   |
| Response Message | The HTTP response message that is returned by the server.  | None                            | String                           | The response message applies only if the URL uses the HTTP or HTTPS protocols.                                   |
| Response Code    | The HTTP response code that is returned by the server.   | None                            | Integer                          | The response code applies only if the URL uses the HTTP or HTTPS protocols. It is always 0 for file or FTP URLs. |
| Response Length  | The size of the content in bytes that is downloaded from the requested URL   | None                            | Integer (size in bytes)          | None   |
| Response Header  | The response header can be used to retrieve a value from one of the URL response header fields. The argument specifies which field is requested.   | The response header to collect. | String                           | Generally FTP and file protocols do not have any headers that can be collected.                                  |
| Request URL      | The connection is made to this URL. All of the response keywords provide information about the connection to this URL. The XPath Query can be used to obtain information that is obtained from the content that is returned by accessing this URL. | None                            | String                           | None   |

*Table 307. HTTP Attribute Information - Managed URLs (continued)*

| <b>Attribute type</b> | <b>Description</b>  | <b>Type value</b> | <b>Data type that is returned</b> | <b>Differences with FTP and file protocols</b> |
|-----------------------|---|-------------------|-----------------------------------|--|
| Page Objects          | The number of objects that are discovered on the monitored HTML page that are monitored by the URL Objects attribute group. | None              | Integer                           | None   |
| Total Object Size     | The total size of the objects that is monitored in the URL Objects attribute group for this web page.                       | None              | Integer (in bytes)                | None   |
| Alias                 | The user specified alias for this URL.  | None              | String                            | None   |
| User                  | The user specified data for this URL.   | None              | String                            | None   |

The following table describes the attribute types for the URL Objects attribute group:

*Table 308. HTTP Attribute Information - URL Objects*

| <b>Attribute type</b> | <b>Description</b>  | <b>Type value</b> | <b>Data type that is returned</b> | <b>Differences with FTP and file protocols</b> |
|-----------------------|---|-------------------|-----------------------------------|--|
| URL                   | The URL that is monitored in the Managed URLs table.                          | None              | String                            | None   |
| Object Name           | The URL for the object that is monitored within the <b>HTML</b> page.         | None              | String                            | None   |
| Object Size           | The size in bytes of the content that is downloaded from the Object Name URL. | None              | Numeric                           | None   |
| Object Response Time  | The time in milliseconds it took to download the page object.                 | None              | Numeric                           | None   |

## Monitoring a URL

You can start monitoring any URL by including it in the URLs file or by using the HTTP URL Add Take Action option.

## URLs file

The URLs file specified in configuration can be in any directory. If this file does not exist or is empty, then you can start URL monitoring by using Take Actions. For more information, see [“Take Action option” on page 1520](#). If you already have a Tivoli Universal Agent that uses the Tivoli Universal Agent HTTP Data Provider, you can reuse the KUMPURLS file. When you are configuring the agent, point to your KUMPURLS file.

The following table provides examples of how URLs are entered in the URLs file, depending on the method by which they were added.

| Table 309. URLs file entries   |  |
|--|--|
| URLs   | Added by   |
| <code>www.bbc.co.uk<br/>http://weather.com<br/>www.ibm.com</code>                  | Manually adding entries to the file. If no protocol is specified, as in the <code>www.ibm.com</code> example, http is assumed. |
| <code>ftp://userid:password@ftpserver/<br/>index.html</code>                       | Manually added by using File Transfer Protocol (FTP)   |
| <code>http://www.ibm.com USER=ibm ALIAS=ibm</code>                                 | Using the HTTP URL Add Take Action   |
| <code>file:/tmp/samples.html USER=samples \<br/>ALIAS=samples</code>               | Using a HTTP URL Add Take Action that uses FTP   |
| <code>http://google.com INTERVAL=60 CACHE=50 \<br/>USER=google ALIAS=search</code> | Example from the Tivoli Universal Agent KUMPURLS file  |

When you directly edit the URLs file, your changes are implemented when the agent does its next data collection.

## Take Action option

You can also specify URLs to monitor through a Take Action option that is called HTTP URL Add.

**Restriction:** This option is not available in the current release of IBM Cloud Application Performance Management, because you can not start Take Action commands manually.

When this option is selected, a window is displayed where you can specify the following parameters:

### URL

A required parameter that represents the URL itself. You can type this parameter with or without the `http://` or `https://` prefix.

### Alias

An optional parameter that you can specify to associate a more meaningful name to a URL. No spaces are allowed in this parameter. If this parameter is not completed, the Alias Name defaults to blank.

### User\_Data

An optional parameter that you can specify to enter data about the URL. If this parameter is not completed, the `User_Data` defaults to `INITCNFG`.

After you complete the information and close the window, assign the HTTP URL Add action to the destination managed system that is associated with the agent. Monitoring begins immediately for the new URL. The URL is also added to the URLs file so that it continues to be monitored across agent restarts.

A corresponding Take Action option is named HTTP URL Remove. Use the HTTP URL Remove action to immediately stop monitoring for a particular URL. The removed URL is also deleted from the URLs file. The **HTTP URL Remove** window requests only the URL and `User_Data` values. The URL and `User_Data` values must match the values that are seen in the Tivoli Enterprise Portal or the Remove action fails. For

example, if you omitted the `http://` from the URL field of the Add action, you must include it in the URL field of the Remove action. If you did not specify `User_Data`, you must specify `INITCNFG` as seen in the Tivoli Enterprise Portal.

If a URL is added manually to the URLs file, you can delete it with the Take Action. If you delete with the Take Action, you must specify the values as seen in the Tivoli Enterprise Portal. For example, if you added `www.ibm.com` to your URLs file, the Tivoli Enterprise Portal displays `http://www.ibm.com` as the URL and `INITCNFG` as the `User_Data`. To remove the URL with the Take Action, you must use the values that are seen in the Tivoli Enterprise Portal.

After you complete the information and close the window, assign the HTTP URL Remove action to the destination managed system that is associated with the agent.

## Monitor `https://` URLs

The HTTP data source can monitor only secure `https://` URLs that do not require scripted access or interactive prompting.

If the `https://` URL can be retrieved with a standard HTTP Get call, then it can be monitored.

## Proxy server

If the system where the agent is running requires a proxy to access the SOAP data provider, you must specify proxy server configuration properties.

For more information, see [“Proxy Server configuration” on page 1521](#).

## HTTP configuration

Reference information about HTTP configuration.

After an HTTP data source is added, the configuration is displayed on the **Runtime Configuration** page of the Agent Editor. Configuration sections are added for URL Monitoring, for Proxy Server authentication, and for Java.

## URL Monitoring configuration

The URL Monitoring configuration section contains the following properties:

| Table 310. URL Monitoring configuration properties |                                      |          |  |
|--|--------------------------------------|----------|--|
| Name   | Valid values                         | Required | Description  |
| HTTP URLs file                                     | Path to a file                       | Yes      | The path to the file that contains a list of URLs.                                   |
| Page Object Collection                             | Yes, No<br>The default value is Yes. | No       | Whether to download objects that are found in a web page and collect data from them. |

## Proxy Server configuration

The Proxy Server configuration section contains the following properties:

| Table 311. Proxy Server configuration properties |              |          |  |
|--|--------------|----------|--|
| Name   | Valid values | Required | Description  |
| Proxy Hostname                                   | String       | No       | The proxy host name to be used for HTTP connections. |

| Table 311. Proxy Server configuration properties (continued) |  |          |   |
|--|--|----------|---|
| Name   | Valid values                                 | Required | Description                               |
| Proxy User Name  | String                                       | No       | The user name for the proxy server.       |
| Proxy Port   | Positive integer<br>The default value is 80. | No       | The HTTP port number of the proxy server. |
| Proxy Password   | Password                                     | No       | The password for the proxy server.        |

**Note:** If the **Proxy Hostname** property is blank, no proxy is used.

## Java configuration

If you define an HTTP data source in your agent, the agent must use Java to connect to the HTTP server. Java configuration properties are added to the agent automatically. The following Java configuration properties are specific to the agent runtime configuration. The Agent Builder does not require the Java properties because it uses its own JVM and logging, which are configured through the JLog plug-in):

| Table 312. Java configuration properties |  |          |   |
|--|--|----------|---|
| Name                                     | Valid values                           | Required | Description   |
| Java Home                                | Fully qualified path to a directory    | No       | A fully qualified path that points to the Java installation directory.                  |
| Trace Level                              | Choice<br>(The default value is Error) | Yes      | Use this property to specify the trace level that is used by the Java providers.        |
| JVM Arguments                            | String                                 | No       | Use this property to specify an optional list of arguments to the Java virtual machine. |

## Testing HTTP attribute groups

You can test the HTTP attribute group that you created, within Agent Builder.

### Procedure

1. Start the Testing procedure in the following ways:
  - During agent creation click **Test** on the **HTTP Information** page.
  - After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398

After you click **Test** in one of the previous two steps, the **HTTP Test** window is displayed.

2. Click **Browse** to select the HTTP URLs file. For more information about URLs files, see [“URLs file”](#) on page 1520.
3. Optional: Set environment variables, configuration properties, and Java information before you start testing.

For more information, see [“Attribute group testing”](#) on page 1596. For more information about HTTP configuration, see [“HTTP configuration”](#) on page 1521.

4. Click **Start Agent**.

A window indicates that the Agent is starting.

5. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**.

The agent monitors the URLs defined in the HTTP URLs file. The **HTTP Test** window displays any data that is returned.

6. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the Data collection Status window is described in [“Performance Object Status node” on page 1638](#)

7. Stop the agent by clicking **Stop Agent**.

8. Click **OK** or **Cancel** to exit the **HTTP Test** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring data from a SOAP or other HTTP data source

You can define a data source to receive data from an HTTP server (for example, using the SOAP protocol). The data source sends an HTTP request to an URL and parses the response (in XML, HTML, or JSON formats) into the attributes of the resulting data set. You can select the data that is retrieved from the request.

### About this task

By using the SOAP data source, you can specify an HTTP URL and send a GET, POST, or PUT request. For POST or PUT requests, you can specify the associated POST data. An XML, HTML, or JSON response is retrieved and parsed, and the data is exposed to the monitoring environment in attributes. You can define the attributes as all of the values within a particular element. Or you can define custom XPath values to specify how to populate individual attributes. You can also combine the two mechanisms.

Use the following procedure to collect and parse XML, HTML, or JSON responses from a URL:

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Data from a server** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **SOAP**.
3. Click **Next**.
4. On the **SOAP Information** page, enter a URL.

The default value is:

```
http://${KQZ_HTTP_SERVER_NAME}:${KQZ_HTTP_PORT_NUMBER}
```

**Note:** You can use a configuration variable or multiple configuration variables that resolve to a URL. Click **Insert Configuration Property** to select a property to insert. For more information, see [“Customizing agent configuration” on page 1578](#).

5. Select a request type. The default request type is Get. For Post and Put requests, enter the data to be processed.

**Note:** For Post and Put requests, the **Insert Configuration Property** is enabled. Click **Insert Configuration Property** to include a configuration variable in the data to be processed. For more information, see [“Customizing agent configuration” on page 1578](#).

6. Click **Browse**

**Note:** If after you enter a URL and select a request type, you do not want to use the SOAP browser to build the definition, enter a **Row Selection XPath**. You enter the **Row Selection XPath** in the **SOAP Information** window. Next, define all of the attributes for the attribute group.

7. In the **SOAP Browser** window, do the following steps:

- a) Enter a URL and select a request type if you did not already do so.
- b) Click **Configuration** to set any configuration properties that are referenced in the URL or other fields.
- c) Click **Connect** to obtain data from the SOAP provider.

When you connect to the URL, a list of XML elements for this URL is shown in a Document Object Model (DOM) tree. An HTML or JSON response is converted to XML and displayed as a DOM tree. For details about conversion of a JSON response to XML, see [“XML representation of JSON data” on page 1526](#). In the WebSphere Application Server example in (Figure 44 on page 1524), the following URL was entered:

```
http://nc053011.tivlab.raleigh.ibm.com:9080/wasPerfTool/servlet/perfservlet?module= \threadPoolModule
```

The PerformanceMonitor XML element is shown. This element is the top-level XML element in the XML document that is returned by the SOAP provider.

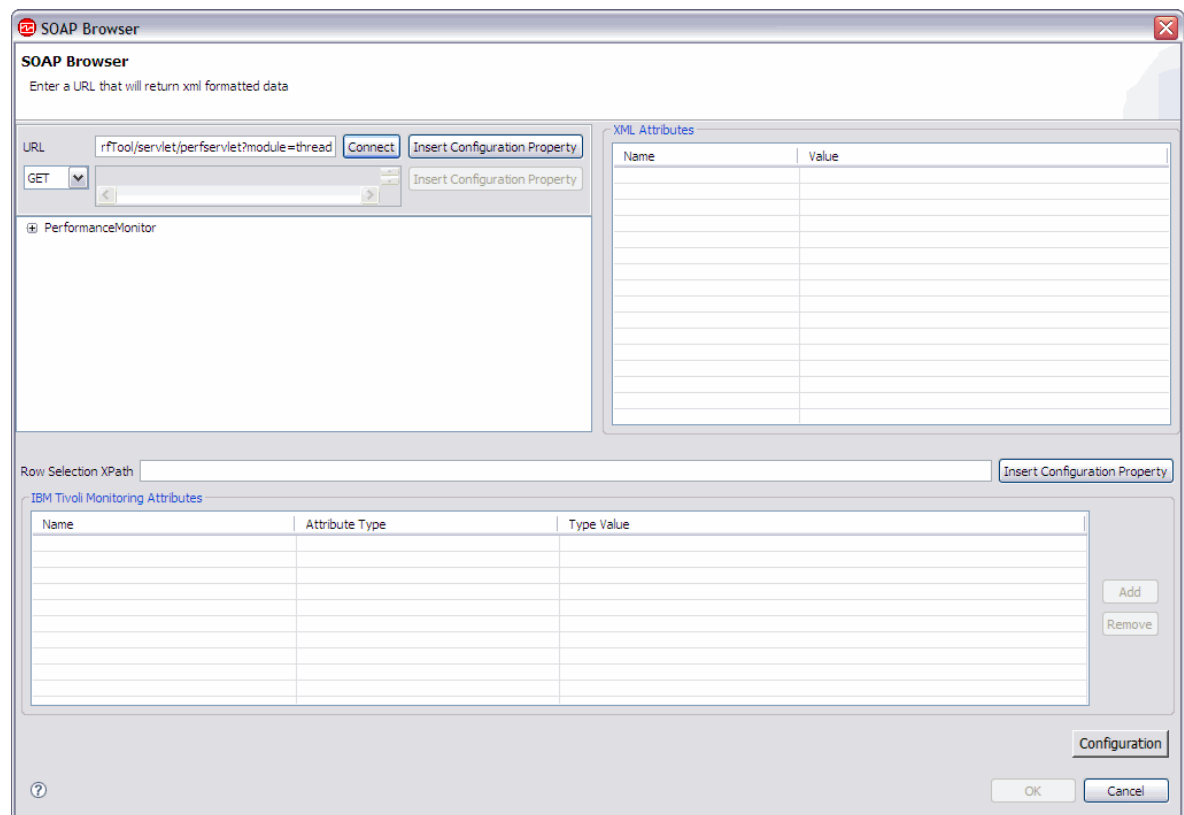

Figure 44. **SOAP Browser** window

- d) In the DOM tree, find and select the XML node that you want to set as the **Row Selection XPath**. In the WebSphere Application Server example in (Figure 45 on page 1525), the PerformanceMonitor/Node/Server/Stat/Stat/Stat node is selected. This node represents a row of data in the attribute group. When you select a node in the DOM tree and click **Add**, you get all of the attributes and elements defined on that node of the tree. (You click **Add** in the **Agent Attributes** area).

When a node is selected, the **XML Attributes** area shows any XML attributes defined for the selected node. Select an XML attribute and click **Add** to include this attribute in the list of Agent Attributes.

**Note:** If more than one row of data is expected, the XPath must map to a node set. Where the Row Selection XPath returns a node that is set with only one item, the attribute group contains only one row.

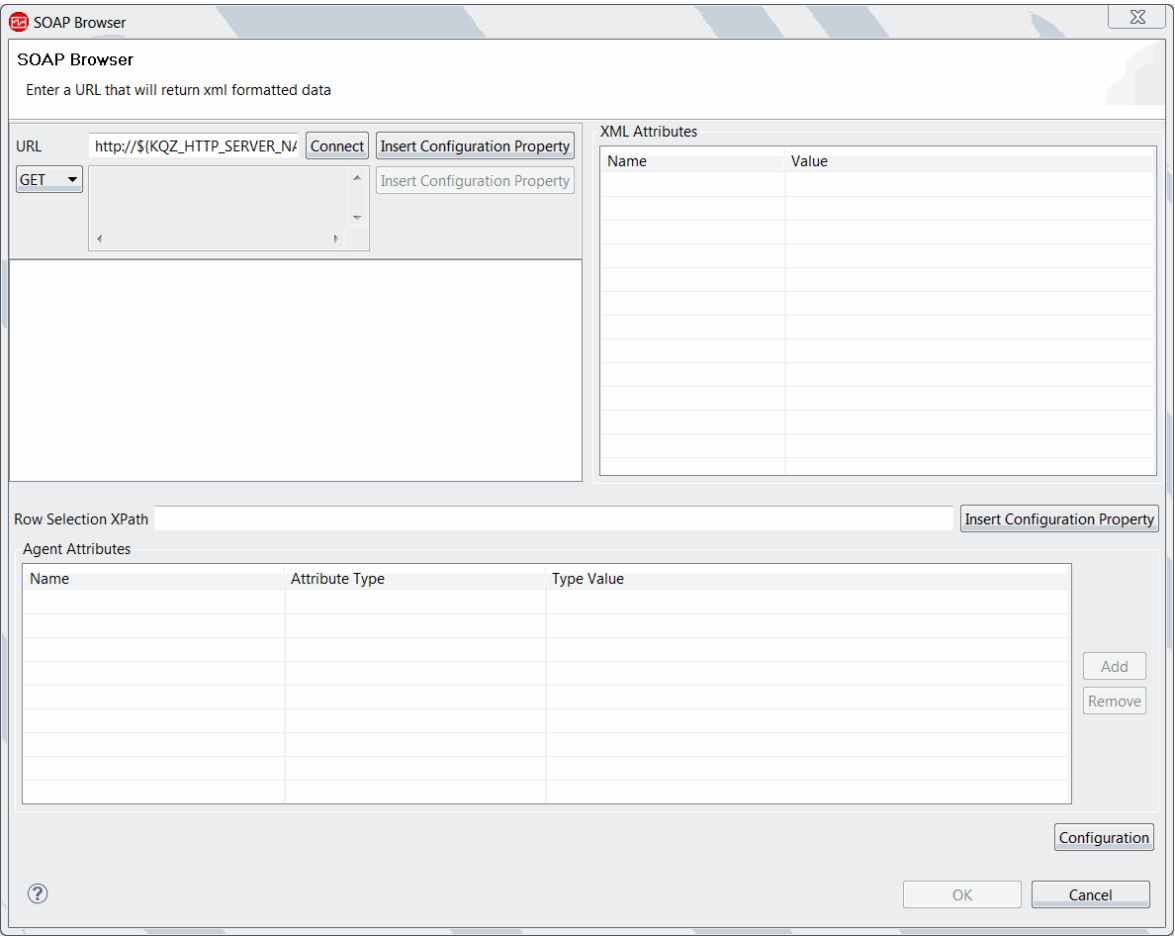

Figure 45. **SOAP Browser** window

e) Click **Add** in the Agent Attributes area.

The list of agent attributes is shown and the **Row Selection XPath** field is filled.

The XPath for each agent attribute is used to map XML nodes or elements to agent attributes. In the WebSphere Application Server example in theFigure 46 on page 1526, the first attribute in the list of agent attributes, Stat, is not of use and would be removed.

You can edit the name and XPath for an agent attribute in the **Type Value** field. For more information about using XPaths, see [“XPath options” on page 1528](#)

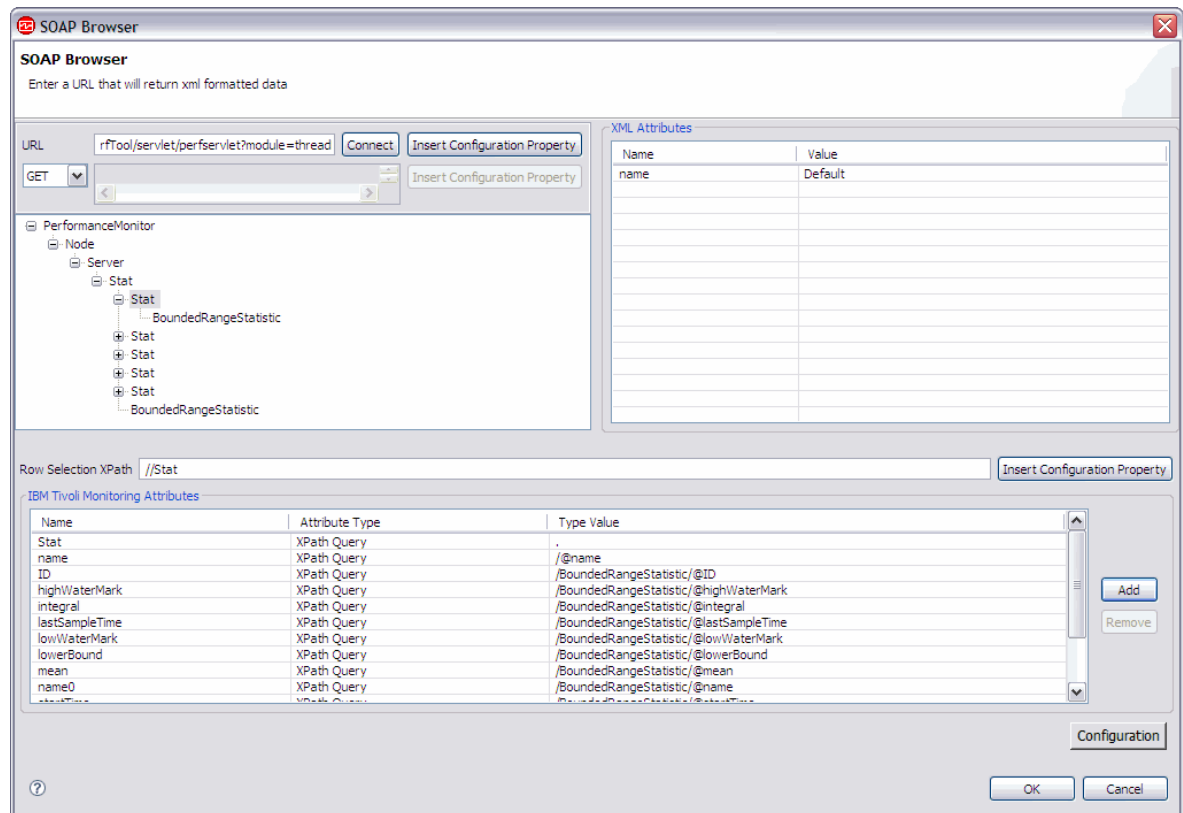

Figure 46. **SOAP Browser** window

- f) In the **SOAP Browser** window, click **OK** to save your changes and return to the **SOAP Information** window.
8. In the **SOAP Information** window, click **Next**.
9. If you did not use **Browse** earlier and you entered the **URL** and **Row Selection XPath** in the **SOAP Information** window, the **Attribute Information** page is shown. Specify the information for the first attribute on the **Attribute Information** page, and click **Finish**. You can then specify more attributes by using the Agent Editor. For more information about creating attributes, see ([“Creating attributes” on page 1417](#)).
10. If you used the **Browse** function in step “6” on page 1523, the **Select key attributes** page is shown. On the **Select key attributes** page, select key attributes or indicate that this data source produces only one data row. For more information, see [“Selecting key attributes” on page 1397](#).
11. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing SOAP attribute groups” on page 1530](#)
12. Optional: You can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
13. Do one of the following steps:
  - a) If you are using the **Agent** wizard, click **Next**.
  - b) Click **Finish** to save the data source and open the Agent Editor.

## XML representation of JSON data

If the HTTP request returns JSON data, the data provider converts the data to XML.

The data provider converts the name of a JSON attribute to the element name. For a JSON attribute of a simple type, it converts the value to text data within the element. Embedded JSON objects are converted to embedded XML elements. Any subordinate attributes are converted to subordinate elements.

The root XML element is JSON\_document.

If a JSON attribute name contains characters that are invalid in an element name, the data provider modifies it to produce a valid element name. The data provider also adds a JSON\_name attribute to the element. The value of the attribute is the original JSON attribute name.

For every element of a JSON array, the data provider creates a JSON\_xxx\_array\_element XML element, where xxx is the name of the array. The value of the array element is converted into text within the XML element. A JSON\_index attribute is added to each XML element; the value of the attribute is the index of the array element within the array.

The data provider adds the following attributes to every element:

- JSON\_level: the level of the node within the JSON file. The root of the tree, represented by the JSON\_document tag, is level 1.
- JSON\_type: the type of the JSON node (object, array, string, or number).

## Specific fields for SOAP attributes

In the **Attribute Information** window, there are two fields for SOAP attributes that define how data is collected from the SOAP response.

The **Attribute Type** field can be any value from a list that controls the information about the response that is returned. Some attribute types require a value in the **Type Value** field. The default attribute type is XPath Query, which runs an XPath query against the SOAP server response content. The type value is the XPath query that is run. The following table describes all of the attribute types and the type value when one is required:

| Table 313. SOAP Attribute Information |   |  |  |   |
|---------------------------------------|---|--|--|---|
| Attribute type                        | Description   | Type value   | Returned data type   | Differences with FTP and file protocols |
| XPath Query                           | Runs an XPath query on the content that is returned from a URL connection. The query must be written to return data useful for an attribute, not a list of nodes. | The XPath query to run against the content that is obtained from a URL connection. If a row selection query was defined, this XPath query must be relative to the row selection query. | The data that is returned can be a string, a numeric, or a timestamp value. The Agent Builder browser for SOAP generally detects the correct data type for the attribute from the data that is being browsed. If the data is in XML DateTime format, you can specify timestamp as the attribute type and the agent converts the value to a Candle Timestamp. | None                                    |
| Response Time                         | The amount of time in milliseconds that it took to download the content from the requested URL.   | None   | Integer (number of milliseconds)   | None                                    |

Table 313. SOAP Attribute Information (continued)

| Attribute type   | Description   | Type value                            | Returned data type      | Differences with FTP and file protocols  |
|------------------|---|---------------------------------------|-------------------------|--|
| Response Message | The HTTP response message that is returned by the server.   | None                                  | String                  | The response message applies only if the URL uses the HTTP or HTTPS protocols.                                   |
| Response Code    | The HTTP response code that is returned by the server.  | None                                  | Integer                 | The response code applies only if the URL uses the HTTP or HTTPS protocols. It is always 0 for file or FTP URLs. |
| Response Length  | The size of the content in bytes that was downloaded from the requested URL   | None                                  | Integer (size in bytes) | None   |
| Response Header  | The response header can be used to retrieve a value from one of the URL response header fields. The argument specifies which field is requested.  | The response header field to collect. | String                  | Generally FTP and file protocols do not have any headers that can be collected.                                  |
| Request URL      | The connection was made to this URL. All of the response keywords provide information about the connection to this URL. The XPath Query can be used to obtain information that is obtained from the content that is returned by accessing this URL. | None                                  | String                  | None   |

## XPath options

Using XML Path Language, you can select nodes from an XML document. A few of the possible uses of XPaths for the SOAP data sources include:

- Using predicates in the XPath to identify the XML elements that correspond to rows of data in the IBM Tivoli Monitoring attribute group. You can use predicates in the XPath that maps XML elements or attributes to Tivoli Monitoring attributes, as in the following example:

```
Stat[@name="URLs"]/CountStatistic[@name="URIRequestCount"]/@count
```

Where there are multiple location steps in the XPath, each location step can contain one or more predicates. The predicates can be complex and contain boolean values or formula operators. For example:

```
//PerformanceMonitor/Node/Server[@name="server1"]/Stat/Stat/Stat[@name="Servlets"]/Stat
```

- Including node set functions in the XPath, if a row contains multiple XML elements of the same type. And if the position of an XML element in the node list determines the Tivoli Monitoring attribute the element maps to. Examples of node set functions are, `position()`, `first()`, `last()`, and `count()`.
- Doing simple data transformation, such as substring. If you specify the following substring:

```
substring(myXMLElement,1,3)
```

the XPath returns the first three characters of the XML element, myXMLElement.

You can specify elements outside the context of the Row Selection XPath by using two periods, ( `..` ), as in the following example:

```
../OrganizationDescription/OrganizationIdentifier
```

## SOAP configuration

After a SOAP data source is added, the configuration is displayed on the **Runtime Configuration** page of the Agent Editor.

Configuration sections are added for HTTP Server, for Proxy Server, and for Java. For information about Proxy server configuration, see ([“Proxy Server configuration” on page 1521](#)). For information about Java configuration, see [“Java configuration” on page 1522](#).

## HTTP Server

The HTTP Server configuration section contains the following properties:

| Table 314. HTTP Server configuration properties |  |          |  |
|---|--|----------|--|
| Name  | Valid values                               | Required | Description  |
| <b>HTTP user name</b>                           | String                                     | No       | The HTTP user  |
| <b>HTTP password</b>                            | Password                                   | No       | The HTTP server password                                 |
| <b>HTTP server name</b>                         | String<br>(The default value is localhost) | No       | The host or IP address of the HTTP server                |
| <b>HTTP port number</b>                         | Numeric<br>(The default value is 80)       | No       | The host or IP address of the HTTP server                |
| <b>Certificate validation enabled</b>           | True, False<br>(The default value is True) | Yes      | Disabling certificate validation is potentially insecure |
| <b>HTTP trust store file</b>                    | Path to a file                             | No       | The HTTP trust store file                                |

Table 314. HTTP Server configuration properties (continued)

| Name                             | Valid values                  | Required | Description                   |
|----------------------------------|-------------------------------|----------|-------------------------------|
| <b>HTTP trust store password</b> | The HTTP trust store password | No       | The HTTP trust store password |

## Proxy server

If the system where the agent is running requires a proxy to access the SOAP data provider, you must specify proxy server configuration properties. For more information, see [“Proxy Server configuration”](#) on page 1521.

## Testing SOAP attribute groups

You can test the SOAP attribute group that you created, within Agent Builder

### Procedure

1. You can start the Testing procedure in the following ways:

- During agent creation click **Test** on the **SOAP Information** page.
- After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398

After you click **Test** in one of the previous two steps, the **Test SOAP Collection** window is displayed.

2. Optional: Before you start testing, you can set environment variables, configuration properties, and Java information.

For more information, see [“Attribute group testing”](#) on page 1596. For more information about SOAP configuration, see [“SOAP configuration”](#) on page 1529.

3. Change the URL, Row Selection XPath, and request type.
4. Click **Start Agent**.

A window indicates that the Agent is starting.

5. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**. This action populates the Results table and you can preview how the data is parsed and shown in columns in the Tivoli Enterprise Portal.

In the Results area, you can change the attribute definitions and reload the data to see how your changes affect the attribute group. You can right-click in a column results area to display options to edit the attribute. The attribute edit options are:

- **Edit Attribute**
- **Hide Attribute**
- **Insert Attribute Before**
- **Insert Attribute After**
- **Remove**
- **Remove Subsequent Attributes**
- **Remove All**

6. Optional: Click **Check Results** if the returned data is not as you expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and shown by the **Data Collection Status** window is described in [“Performance Object Status node”](#) on page 1638.

7. Stop the agent by clicking **Stop Agent**.

- Click **OK** or **Cancel** to exit the **Test SOAP Collection** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Monitoring data by using a socket

You can define a data source to collect data from an external application by using a TCP socket. The application must initiate the TCP connection to the agent and send data in a structured XML format. Depending on the application, the data source can produce a data set with a single row, multiple rows, or event data.

### About this task

Use the socket data source to provide data to the agent from an external application, running on the same system as the agent. The external application can send data to the agent anytime it wants to. For example, you can develop a command-line interface that allows a user to post data to an attribute group when it is run. Another option is to modify a monitored application to send updates to the agent. The agent does not start or stop the application that is sending data to the socket; this action is controlled by the user.

There are some limitations with the socket data source:

- By default only connections to the local host (127.0.0.1) are possible. For more information about configuring your agent to accept connections from a remote host, see [“Remote socket port connection” on page 1539](#).
- There is no mechanism in the socket API for the client to determine what subnodes are available. The client can send data for a specific subnode, but it must already know the subnode name.

Use the following procedure to create an attribute group to collect data by using a Transmission Control Protocol socket (TCP) socket.

### Procedure

- On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Custom programs** in the **Monitoring Data Categories** area.
- In the **Data Sources** area, click **Socket**.
- Click **Next**.
- On the **Socket Information** page, enter an Attribute group name.
- Enter a help text for the attribute group.
- Select whether the attribute group **Produces a single data row**, **Can produce more than one data row**, or **Produces events**. For more information, see [“Sending data” on page 1533](#).
- In the Socket Information section, select a **Code page**. For more information, see [“Character sets” on page 1536](#).
- Optional: Click **Advanced** to modify the advanced properties for the attribute group. The **Advanced** option is active when you select that the attribute group **Can produce more than one data row**, or **Produces events**.
- Click **Next**.
- On the **Attribute Information** page, specify the first attribute for the attribute group. For more information about creating attributes, see [“Creating attributes” on page 1417](#).
- Click **Next**.
- Optional: On the **Global Socket Data Source Information** page, **Error Codes** section, you can define the error codes that the socket client can send when it cannot collect data. For more information, see [“Sending errors instead of data” on page 1534](#)). To define an error code, use the following steps:

- a) In the **Error Codes** section, click **Add**. An error code has a limit of 256 characters. Only ASCII letters, digits, and underscores are allowed. No spaces are allowed.
  - b) In the **Socket Error Code Definition** window, enter a display value that is shown in the **Performance Object Status** attribute group.
  - c) Enter an internal value. The internal value must be an integer from 1,000 to 2,147,483,647.
  - d) You must define a message text for each error. You can use message text that was entered previously by selecting it from the list. Click **OK** to return to the **Global Socket Data Source Information** page. The message text is used in the agent log file.  
If no suitable message text is available, click **Browse** to set up the message text. The Messages (list) window opens. The message window lists messages that are defined in the agent. Until you define messages, the list remains blank. You can use **Edit** to alter a defined message and **Remove** to delete one or more messages that you defined.
  - e) In the Messages (list) window, click **Add** to see a **Message Definition** window. In the **Message Definition** window type, the text that describes the meaning of the new message and select the message type.  
**Note:** The message identifier is automatically generated for you.
  - f) Click **OK**.
  - g) The Messages (list) window opens, with the new message. To verify the message and return to the **Global Socket Data Source Information** page, click **OK**.
13. Optional: In the **Supplemental Files** section of the **Global Socket Data Source Information** page, you can add files that are packaged with the agent. These files are copied to the agent system when the agent is installed.

The **File Type** column describes how each file is expected to be used. Three possible uses are described in the following table:

| <i>Table 315. File types for supplemental files</i> |  |
|---|--|
| <b>File Type</b>                                    | <b>Description</b>   |
| Executable  | Select this option if you want to include an executable file with the agent. The agent does not use these files. |
| Library   | Select this option if you to include a library with the agent. The agent does not use these files.               |
| Java resource                                       | Select this option to include Java resources with the agent. The agent does not use these files.                 |

For information about where the Supplemental Files are installed with your agent, see ([“New files on your system” on page 1611](#)).

Click **Edit** to edit the imported file. For more information, see ([“Editing a command file definition” on page 1500](#)).

14. Optional: You can test this attribute group by clicking **Test**. For more information about testing, see [“Testing socket attribute groups” on page 1540](#)
15. Optional: If the data source is sampled, you can create a filter to limit the data that is returned by this attribute group by clicking **Advanced**. The data source is sampled when you did not select "Produces events" on the **Socket Information** page. For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#)
16. Do one of the following steps:
  - a) If you are using the **Agent** wizard, click **Next**.
  - b) Click **Finish** to save the data source and open the Agent Editor.

Select the operating systems on which the agent listens to data from socket clients in the **Operating Systems** section of the **Socket Provider Settings** page. To open the page, click **Socket Provider Settings** in the outline view or click **Global Settings** in the Agent Editor on any socket attribute group page.

**Note:** Error codes and supplemental files can be updated in the **Error Codes** and **Supplemental Files** sections of the **Socket Provider Settings** page.

## Sending socket information to the agent

When your agent contains one or more socket attribute groups, the agent opens a socket and listens for data from clients.

The application that sends socket data to the agent connects to a port that is defined in the agent. The port is either the value that is set by an agent configuration property or an ephemeral port that is allocated automatically by TCP/IP. For more information about socket ports and configuration, see [“Socket configuration” on page 1538](#).

The data that is received must follow a structured XML format. The following XML information flows are possible by using the socket data source:

- Send one or more rows of data to the agent for a sampled attribute group
- Send a row of data to the agent for an attribute group that Produces events
- Send an error code to the agent instead of data.
- Send a task prefix registration to the agent
- Receive a task request from the agent
- Send a task response to the agent

## Sending data

An attribute group is defined to receive sampled data or event data. When you create the attribute group, you specify an option that indicates whether the data to be received:

- Produces a single data row
- Produce more than one data row
- Produces events

If you select **Produces a single data row** or **Can produce more than one data row**, that is a sampled attribute group. If you select **Produces events**, then your attribute group sends an event to the monitoring environment each time that a row is received.

When you view sampled data in the Tivoli Enterprise Portal or IBM Cloud Application Performance Management console, you see the latest set of collected rows. The data that is displayed for an event attribute group is the contents of a local cache that is maintained by the agent. For event data, the agent adds the new entry to the cache until the size is reached when the oldest one is deleted. For sampled data, the agent replaces the contents of the cache every time you send data.

If you select **Produces events** or **Produces a single data row**, you must send only one row of data to the agent for that attribute group in each message. You can send as many events as you want, send each event in a separate message.

Normally sampled data is collected by the agent on request, but the socket client provides updated samples on its own schedule. You can update a sampled attribute group (single row or multiple row) as often as you require. When the data is requested by Tivoli Monitoring or IBM Cloud Application Performance Management, the agent provides the latest data.

If there are missing rows of data for the socket attribute group in the Tivoli Enterprise Portal or IBM Cloud Application Performance Management console, check the errors in the log file. Also, if the data in the attribute group is not as expected, check the errors in the log file. The socket data source attempts to process whatever it can from the input. For example, if the client sends three well-formed rows and one that is not valid (for example, malformed XML), you see:

- Three rows of data in the attribute group
- An error is logged for the malformed row in the agent's log file
- Since valid rows were returned, the Performance Object Status shows a status of NO\_ERROR

For both event and sampled data, the data is sent to the agent as a single XML data flow from the socket client. Data that is sent from a socket client must always be terminated with a newline character: '\n'. The agent reads data until it sees the newline character and then an attempt is made to process what was received. Any data received that cannot be processed is discarded. The following is a sample of how you would send two rows of data to the agent for an attribute group named abc:

```
<socketData><attrGroup name="abc"><in><a v="1"/><a v="no"/><a v="5"/></in><in> \
<a v="3"/><a v="yes"/><a v="5"/></in></attrGroup></socketData>\n
```

This sample sends two rows of data to the agent where each row contains three attributes. The order of the attributes is important and must follow the order that is defined in your attribute group. The only exception to this is that the derived attributes must be skipped, regardless of where they are in your attribute group.

If the attribute group is defined in a subnode, then the subnode instance ID must be identified when data is sent to the agent. The subnode instance ID is identified by using the subnode attribute in the socketData element. A convention must be adopted for configuring subnode instance IDs for use by the socket client since the client cannot query instance IDs or configuration properties. Data sent to a subnode which is not configured is ignored.

Here is a sample:

```
<socketData subnode="app1"><attrGroup name="abc"><in><a v="1"/><a v="no"/><a v="5"/>
</in><in> \<a v="3"/><a v="yes"/><a v="5"/></in></attrGroup></socketData>\n
```

In this sample, the data is sent to the subnode with an instance ID equal to "app1". "app1" is not the managed system name, but the instance identifier that is specified when the subnode instance is configured.

The following XML elements make up the socket data:

#### **socketData**

The root element. It has one optional attribute that is called subnode that specifies the subnode instance ID.

#### **attrGroup**

This element identifies the attribute group that the socket data is for. The name attribute is required and is used to specify the attribute group name.

#### **in**

This element is required to identify a new row of data. All of the attribute values for a row of data must be children of the same in element.

#### **a**

The a element identifies an attribute value. The v attribute is required and is used to specify the attribute value.

## **Sending errors instead of data**

Sometimes the application that posts socket data might not be able to collect the data necessary for an attribute group. In this case, instead of sending data to the agent, an error code can be returned. The error code gives you a way to tell the monitoring environment about your problem. An example error is:

```
<socketData><attrGroup name="abc"/><error rc="1000"/></attrGroup></socketData>\n
```

The error code must be defined in the agent in a list that is common to all of the socket attribute groups. When the agent receives an error code, the defined error message is logged in the agent log file. In addition, the attribute group named Performance Object Status has an Error Code attribute is updated with the Error Code Type. The Error Code Type is defined for the error code you send.

For the previous example, you must define the Error Code Value of 1000 in the agent. See the following sample error code definition:

| Table 316. Sample error code |                 |                                |
|------------------------------|-----------------|--------------------------------|
| Error Code Value             | Error Code Type | Message                        |
| 1000                         | APP_NOT_RUNNING | The application is not running |

When the error code is sent, a message similar to the following is logged in the agent log file:

```
(4D7FA153.0000-5:customproviderserver.cpp,1799,"processRC") Received error code 1000  
from client. \Message: K1C0001E The application is not running
```

If you select Performance Object Status query from the Tivoli Enterprise Portal, the **Error Code** column for the row **abc** attribute group shows the value APP\_NOT\_RUNNING in that table.

Sending an error to a sampled attribute group clears any data that was previously received for that attribute group. Sending data to the attribute group causes the error code to no longer be displayed in the Performance Object Status attribute group. You can also send an error code of 0 to clear the error code from that table.

Sending an error to an attribute group that produces events does not clear the cache of events that were previously sent.

## Handling take action requests

The socket client can register to receive take action requests from the agent when the action command matches a certain prefix. Any action that does not match is handled by the agent. The prefix must not conflict with actions that the agent is expected to handle, so use the agent product code as the prefix. Take actions provided with the Agent Builder are named after the data source that the take action uses. For example, the JMX\_INVOKE take action operates on the JMX data source. Another example is the SSHEXEC take action which uses the SSH script data provider. Since these actions do not use the product code, the product code is a safe prefix to use as the take action prefix.

The socket client must be long running and leave the socket open. It must send a registration request for the prefix and listen for requests from the socket. The agent ensures that a timeout does not occur on the socket of a long-running client, even if no data is flowing. The following is a sample registration request:

```
<taskPrefix value="K42"/>\n
```

In this sample, any take action command that is received by the agent that begins with "K42" is forwarded to the socket client that initiated the registration. The following shows a sample take action request that the socket client might receive:

```
<taskRequest id="1"><task command="K42 refresh" user="sysadmin"/></taskRequest>\n
```

The `id` is a unique identifier that the agent uses to track requests that are sent to clients. When the socket client responds to the task, it must provide this identifier in the `id` attribute of the `taskResponse` element.

The socket client must process the action and send a response. A sample response is:

```
<taskResponse id="1" rc="1"/>\n
```

If the action completes successfully, an `rc` attribute value of 0 is returned. The value of `rc` must be an integer, where any value other than 0 is considered a failure. The task return code value is logged to the agent log file and shown in the Take Action Status query that is included with the agent. The dialog that is displayed on the Tivoli Enterprise Portal after an action is run does not show the return code. That dialog indicates whether the take action command returned success or failure. The agent log or Take Action Status query must be viewed to determine the actual return code if a failure occurred.

It is the agent developer's responsibility to document, create, and import any actions that are supported by the socket clients that are used with an agent. If users send unsupported actions to the socket client, the client must be developed to handle those scenarios in an appropriate manner. If users define more actions that start with the registered prefix, they are passed to the client. The client must be developed to handle those scenarios in an appropriate manner.

There is a timeout that controls how long the agent waits for a response from the socket client. The setting is an environment variable that is defined in the agent that called CDP\_DP\_ACTION\_TIMEOUT and the default value is 20 seconds.

**Note:** The error code messages that are defined for socket data source attribute groups are not used for take actions. You can return the same return code values. However, the agent does not log the message that is defined or affect the Error Code field in the Performance Object Status attribute group.

## Encoding of socket data

The socket client encodes data that is sent to the agent.

It is important to be aware of how your socket client is encoding data that is being sent to the agent.

## Special characters

Data sent to the agent must not contain any newline characters except at the end of each event or data sample. Newline characters that occur inside of attribute values must be replaced with a different character or encoded as shown in (Table 317 on page 1536). You must also be careful not to break the XML syntax with your attribute values. The following table shows the characters that occur in the attribute values that you encode:

| Table 317. Characters to encode in attribute values |        |
|---|--------|
| Character   | Header |
| &   | &amp;  |
| <   | &lt;   |
| >   | &gt;   |
| "   | &quot; |
| '   | &apos; |
| \n  | &#10;  |

**Note:** The agent uses the newline character to separate responses received from a client. Unexpected newline characters prevent data from being parsed correctly.

The agent does not contain a full-featured XML parser so you must not use special encoding for characters not in (Table 317 on page 1536). For example, do not encode &#162; or &cent; in place of a cent sign ¢.

## Character sets

In addition to encoding special characters, the agent must know what code page was used to encode your data. Define each socket attribute group to indicate whether you are sending the data to the agent as **UTF-8** data or as **Local code page**. Be aware of how your client is sending data. If you use a client that is written in Java, specify **UTF-8** as the encoding on the writer you use to send data to the agent. Specify **UTF-8** as the **Code Page** for your attribute group. **Local code page** means the local code page of the agent. If the data is sent over a remote socket, it must conform to the local code page of the agent or use UTF-8.

## Numeric Data

Be aware of how you are formatting your numeric attribute values. The numeric values that you send to the agent must not contain any special characters. One example is the thousands separator character. Other examples are currency symbols or characters that describe the units of the value. If the agent encounters a problem when it is parsing numeric data, it logs an error that indicates the issue. The Performance Object Status Error Code is not set when an attribute fails to parse. The following is an example error message from the agent log:

```
(4D3F1FD6.0021-9:utilities.cpp,205,"parseNumericString") Invalid characters :00:04 \
found getting numeric value from 00:00:04, returning 0.000000
```

**Note:** For information about how a time stamp attribute must be formatted, see ([“Time stamp” on page 1422](#)).

## Socket errors

Errors are written to the agent log file for problems that occur with data received from a socket client.

Other errors that are logged are take actions that return a value other than 0. Error values that are sent by the socket client are logged along with the message associated with the error code.

The Performance Object Status for the attribute group is set when the socket client sends an error return code to the agent. Some other values can be seen in addition to the ones defined by the agent. The following table describes other “Error Code” values you are likely to encounter with socket attribute groups:

| Table 318. Performance Object Status values |   |
|---|---|
| Error Code                                  | Description   |
| NO_ERROR                                    | No error occurred. Indicates that there are no problems with the attribute group. Problems with a row of sampled data do not cause the state to change from NO_ERROR. You must validate the number of rows that are shown and the attribute values even when you see NO_ERROR as the error code.                        |
| NO_INSTANCES_RETURNED                       | A socket client sent no rows of data for a sampled attribute group. Not an error. It indicates that there are no instances of the resources that are being monitored by this attribute group.   |
| XML_PARSE_ERROR                             | The agent failed to parse data that is received from the client. See the agent log for more details.  |
| OBJECT_CURRENTLY_UNAVAILABLE                | The client sent the agent an error code that was not defined in the global list of error codes.   |
| GENERAL_ERROR                               | <p>A problem occurred collecting data from the client, usually because the client did not reply to the request within the timeout interval. See the agent trace log for more details.</p> <p>The client can also specify GENERAL_ERROR as an error code, but it is better if a more detailed error code is defined.</p> |

## Socket configuration

After you add a socket data source to your agent, you can configure the agent to accept data from a specified socket port.

### About this task

After you add a Socket data source, the configuration is displayed on the **Runtime Configuration** page of the Agent Editor. The Socket configuration section contains the following property:

| Table 319. Socket configuration property |   |          |  |
|--|---|----------|--|
| Name                                     | Valid values  | Required | Description  |
| <b>Port number</b>                       | 0 or any positive integer<br>The default value is 0 | Yes      | The port that the agent uses to listen on for data from socket clients. A value of 0 indicates that an ephemeral port is to be used. |

The agent writes the value of the port that is being used to a file. Socket clients that run on the agent computer can later read this file to determine which port to connect to. The file that the port is written to is named *kxx\_instanceName\_cps.properties*, where: *kxx* is the three character product code of the agent and *instanceName* is the agent instance name for a multiple instance agent. If the agent is not a multiple instance agent, this part of the name is not included so the file name is *kxx\_cp.properties*.

In Windows, the file is written to the %CANDLE\_HOME%\TMAITM6 directory for 32-bit installations or %CANDLE\_HOME%\TMAITM6\_x64 for 64-bit installations. In UNIX, the file is written to /tmp.

### Procedure

- Optional: Set the environment variable CDP\_DP\_HOSTNAME to the host name or IP address of your network interface, if your system has multiple interfaces:
  - Go to the Agent Editor **Agent Information** view and select **Environment Variables**.
  - Click **Add** and select CDP\_DP\_HOSTNAME from the list of environment variables by using the Name field.
  - Set the host name or IP address in the Value field.
- Start your agent.

When the agent is started, it binds to the interface that is defined by the CDP\_DP\_HOSTNAME environment variable. If CDP\_DP\_HOSTNAME is not set, the agent binds to the default host name.

If you want the agent to bind to a defined port instead of an ephemeral port, you can set the configuration property **Port Number** (CP\_PORT).

To set the port number configuration property, use the following steps:

- Go to the Agent Editor **Runtime Configuration** view.
- In the **Runtime Configuration Information** pane select **Configuration for Socket > Socket > Port Number**
- Enter a port number value in **Default value**.  
If you do not enter a value, a value of 0 is used. A value of 0 indicates that an ephemeral port is used.

## Remote socket port connection

You can configure your agent to accept data from a remote socket port. The agent must run on a system that has a network interface connection to a remote system.

### Procedure

1. Set the value of the environment variable CDP\_DP\_ALLOW\_REMOTE to YES by completing the following steps.
  - a) Go to the Agent Editor **Agent Information** page and select **Environment Variables**.
  - b) Click **Add** and select CDP\_DP\_ALLOW\_REMOTE from the list of environment variables by using the **Name** field.
  - c) Set the **Value** field to YES.
2. Follow the procedure that is detailed in [“Socket configuration” on page 1538](#).

#### Restriction:

- The data that is sent between the socket application and the agent:
  - Must conform to the XML syntax defined for a socket data provider. For more information, see [“Encoding of socket data” on page 1536](#).
  - Must be encoded in UTF-8.
  - Is sent in clear text (unencrypted). If the data contains sensitive information, the communication must be secured through an SSH tunnel or other mechanism outside the agent.
- The agent processes data that is received from any remote hosts, so the environment must be secured with appropriate firewall or network traffic filters.

### Results

You can run code that implements a socket data provider on any system which can connect to the system where the agent is running.

### Sample script for socket

This samples script demonstrates how a socket client might be written.

#### Perl sample

The following sample Perl script connects to a socket and sends data. This sample was written for an agent that runs on UNIX, with the product code k00 and an attribute group called SocketData.

```
#!/usr/bin/perl -w
# SocketTest.pl
# A simple Agent Builder Socket client using IO::Socket
#-----

use strict;
use IO::Socket;

# Initialize socket connection to the agent
#-----
my $host = '127.0.0.1';
my $port = 0;
# This sample is for an agent with the k00 product code. The product code is
# used in the following line to find the file containing the port number to use.
open PORTFILE, "/tmp/k00_cps.properties" || die "Port file not found $!\n";
while (<PORTFILE>) {
    if (/^CP_PORT=([0-9]+)/) {
        $port = $1;
    }
}

if ($port == 0) {
    die "Could not find port to use to connect to agent.\n";
}
```

```

my $sock = new IO::Socket::INET( PeerAddr => $host, PeerPort => $port,
    Proto => 'tcp'); $sock or die "no socket :$!";

# The following call sends 2 rows of data to the agent. Each row contains 1
# String attribute and 3 numeric attributes.
syswrite $sock, "<socketData><attrGroup name=\"SocketData\"><in><a v=\"A message
from perl\"/> \<a v=\"1\"/><a v=\"2\"/><a v=\"123\"/></in><in><a v=\"More from
perl\"/><a v=\"456\"/> \<a v=\"123\"/><a v=\"789\"/></in></attrGroup>
</socketData>\n";

close $sock;

```

## Testing socket attribute groups

You can test the socket attribute group that you created, within Agent Builder.

### Before you begin

To test the attribute group, you need a socket client to send data. An example socket client that is written with perl script can be seen at [“Sample script for socket” on page 1539](#)

**Restriction:** Unlike most other attribute groups, you cannot test the socket attribute group while it is being created. You can test the attribute group when you complete its creation.

### Procedure

1. Select an attribute group on the Agent Editor **Data Source Definition** page after agent creation and click **Test**. For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#).

After you click **Test** in one of the previous two steps, the **Test Socket Client** window is displayed.

2. Optional: Set environment variables and configuration properties before you start testing.

For more information, see [“Attribute group testing” on page 1596](#).

3. Click **Start Agent**. A window indicates that the Agent is starting.
4. When the agent starts, it listens for socket data according to its configuration.
5. To test your agent's data collection, you now generate socket data that matches the agents configuration.

You can generate socket data by using a socket client.

When the agent receives socket data that matches its configuration, it adds the data to its internal cache.

6. To simulate a request from Tivoli Enterprise Portal for agent data, click **Collect Data**.

The **Test Socket Client** window collects and displays any data in the agent's cache since it was last started.

7. Click **Check Results** if something does not seem to be working as expected.

The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the Data collection Status window is described in [“Performance Object Status node” on page 1638](#)

8. Stop the agent by clicking **Stop Agent**.
9. Click **OK** or **Cancel** to exit the **Test Socket Client** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Use the Java API to monitor data

You can define a data source to use the Java API to interact with a long-running application on the Java platform. The agent starts the application at startup and interacts with it periodically. When you build the agent, Agent Builder creates the source code for the application. You must customize the code to gather the correct data. Depending on the code, the data source can produce multiple data set that can contain a single row, multiple rows, or event data.

### About this task

Use the Java API data source and the Java programming language to collect data that cannot be collected by using other Agent Builder data sources. The agent starts the Java application and sends a shutdown request when it is time to shutdown. The Java application must exit only when it is requested to do so.

An agent that contains Java API attribute groups interfaces with the Java application process. The Java application uses the Java Provider Client API to interface with the agent. For information about the API, see the [Javadoc](#) on the Tivoli Monitoring Knowledge Center. Using the Java API you can:

- Connect to the agent process and register for attribute groups that are supported by the Java application
- Receive and reply to a request for sampled data
- Send data asynchronously for an attribute group that produces events
- Send an error for an attribute group where data collection is failing
- Support attribute groups in subnodes with configured subnode instances
- Receive and reply to a "Take Action" request

Use the following procedure to create an attribute group which collects data in a Java application and sends it using the Java API. The procedure shows how to create a sample Java application to use as a starting point for your Java application.

### Procedure

1. On the **Agent Initial Data Source** page or the **Data Source Location** page, click **Custom programs** in the **Monitoring Data Categories** area.
2. In the **Data Sources** area, click **Java API**.
3. Click **Next**.
4. On the **Java API Information** page, enter an Attribute group name.
5. Enter a help text for the attribute group.
6. Select whether the attribute group **Produces a single data row**, **Can produce more than one data row**, or **Produces events**. This choice affects the sample Java application that is created at the end of the wizard. For more information, see [“Sending data” on page 1533](#).
7. Optional: Click **Advanced** to modify the advanced properties for the attribute group. **Advanced** is available when you select that the attribute group **Can produce more than one data row**, or **Produces events**.
8. Click **Next**.
9. On the **Attribute Information** page, specify the first attribute for the attribute group. For more information about creating attributes, see [“Creating attributes” on page 1417](#).
10. Select **Add additional attributes** and click **Next** to add other attributes to the agent. References to the attributes are incorporated into the sample Java application that is created at the end of the wizard.
11. Click **Next**.
12. On the **Global Java API Data Source Information** page, enter a Class name and a JAR file name.

The class name is a fully qualified class name whose main method is called when Java is started. The sample Java application is created with the main Java method in this class.

The JAR file is the archive that contains the Java classes that comprise the Java application. The JAR file is packaged and installed with the agent.

13. Optional: Define the error codes that the Java application can send, on the **Global Java API Data Source Information** page, **Error Codes** section. These error codes are sent by the Java application when it cannot collect data.

**Restriction:** An error code has a limit of 256 characters. Only ASCII letters, digits, and underscores are allowed. No spaces are allowed.

- a) Click **Add** in the Error Codes section.
- b) In the **Java API Error Code Definition** window, enter a display value.
- c) Enter an internal value. The internal value must be an integer from 1,000 to 2,147,483,647.
- d) Define a message text for each error. You can use message text that was entered previously by selecting it from the list. Click **OK** to return to the **Global Java API Data Source Information** page.

The message is logged in the agent log file.

- e) If no suitable message text is available, click **Browse** to set up the message text.  
The Messages (list) window is displayed. The message window lists messages that are defined in the agent. Until you define messages, the list remains blank. You can use **Edit** to alter a defined message and **Remove** to delete one or more messages that you defined.
- f) In the Messages (list) window, click **Add** to see a **Message Definition** window. In the **Message Definition** window, you can type the text that describes the meaning of the new message and select the message type.

**Note:** The message identifier is automatically generated for you.

- g) Click **OK**.
  - h) The Messages (list) window is displayed with the new message. To verify the message and return to the **Global Java API Data Source Information** page, click **OK**.
14. Optional: In the **Supplemental Files** section of the **Global Java API Data Source Information** page, you can add files that are packaged with the agent and copied to the agent system on agent installation. The Java provider client API JAR file is not listed here; it is automatically copied to the agent system. The **File Type** column describes how each file is expected to be used. Three possible uses are described in the following table (Table 320 on page 1542). Click **Edit** to edit the imported file. For more information, see ([“Editing a command file definition”](#) on page 1500).

| Table 320. File types for supplemental files |   |
|--|---|
| File type                                    | Description   |
| Executable                                   | Select this option if you want to include an executable file with the agent. The agent does not use this file, but it is in the path for the Java application to use. |
| Library                                      | Select this option if you to include a library with the agent. The agent does not use this file, but it is in the library path for the Java application to use.       |
| Java resource                                | Select this option to include Java resources with the agent. The agent does not use this file, but it is in the class path for the Java application to use.           |

**Note:** When a Java resource supplemental file is added to the Agent Builder, the file is automatically added to the project class path. The Java compiler uses the supplemental file to resolve any references that your code has, to classes in the resource.

For information about where the Supplemental Files are installed with your agent, see ([“New files on your system” on page 1611](#)).

15. Optional: Create a filter to limit the data that is returned by this attribute group, if the data is sampled. Create a filter by clicking **Advanced**.

**Note:** The data is sampled if you did not select **Produces events** on the **Java API Information** page.

For more information about filtering data from an attribute group, see [“Filtering attribute groups” on page 1425](#).

16. Optional: Add configuration properties to the subnode.

If you are adding this data source to a subnode, the **Subnode Configuration Overrides** page is shown so you can add configuration properties to the subnode. At least one configuration property is needed under the subnode for the sample Java application to be created. At least one configuration property is needed because the sample uses a configuration property to distinguish one subnode instance from another.

17. Do one of the following steps:

- a) If you are using the **Agent** wizard, click **Next**. Complete the wizard as required.
- b) Otherwise, click **Finish** to save the data source and open the Agent Editor. Then, in the main menu, select **File > Save**.

At this point, Agent Builder creates the source code for the monitoring application. The code is located in the `src` subdirectory of the project directory. Edit this code to create your monitoring application.

## What to do next

Select the correct operating systems on the **Java API Settings** page. Make this selection if this attribute group and the Java application, run on operating systems different from the operating systems that are defined for the agent. To open the page, click **Java API Settings** in the outline view or click **Global Settings** in the Agent Editor on any Java API attribute group page.

**Note:** Error codes and supplemental files can be updated later in the **Error Codes** and **Supplemental Files** sections of the **Java API Settings** page.

## Running the Java application

Information about the initialization of the Java application and its dependencies

### Initializing the Java application

The agent starts the Java application while the agent is starting and initializing. Configuration settings are used to control which Java run time is used to start the process. Java virtual machine arguments and the Java logging level can also be specified in the configuration. For more information about Java API configuration, see [“Java API configuration” on page 1552](#). The Java process inherits the environment variables that are defined for the agent. Runtime configuration settings are also placed in the environment and can be queried by using API calls.

The Java application must be a long-running process. It must not terminate unless it receives a shutdown request from the API. If the Java application does terminate after it is registered with the agent, the agent will attempt to restart the Java application up to three times. If data collection is successfully resumed, this restart count is reset. The agent logs an error when a Java application terminates and when a restart is initiated.

**Note:** If the Java application terminates before attribute group registration is completed, no restart is attempted.

## Dependencies

A Java application must use a Java runtime environment. The following versions of Java are supported:

- Oracle Corporation Java Version 5 or later
- IBM Corporation Java Version 5 or later

Java must already be installed on the agent system when the agent is configured and started. The JAR file that contains the API used to communicate with the agent is included with the agent runtime and included in the classpath of the JVM. Any additional JAR files that are needed by your Java application must be defined as Supplemental Files to the Java API attribute groups. Any supplemental files that have a *File Type* of *Java resource* are automatically added to the base classpath of the Java application, along with the Java API JAR file.

Any JAR files that are necessary for the runtime operation of the Java application that are not included with the agent, must be included in the *Classpath for external jars* configuration setting.

## Generated sample Java application

A reference that describes the code the Agent Builder generates and the code you must add or replace for the resources you want to monitor.

When you create an agent with one or more Java API data sources, the Agent Builder generates Java application source code. The code is generated in the agent project and follows the structure of your agent. You must add your own Java code to the generated application. Your code collects data for sampled attribute groups, handles events to be posted to event-based attribute groups, reports errors if problems are encountered, and runs tasks. The generated application supplies the agent with data, but it is sample data, to be replaced with data obtained from the resources you want to monitor.

A sample agent is assumed that has the following characteristics:

- Product code: K91
- Java API Main class: `agent.client.MainClass`
- Agent data source structure as shown in (Figure 47 on page 1544):

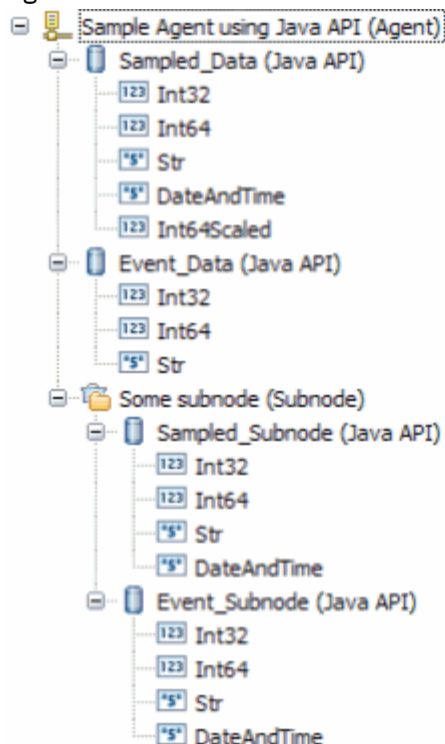

Figure 47. Sample agent structure

- *Some subnode* configuration property: `K91_INSTANCE_KEY`

## Class structure

The generated Java application separates, to a great degree, code that interfaces with the agent from code that interfaces with the resources you are monitoring. It contains files that you modify, and files that you do not modify.

The following Java classes are created by the Agent Builder:

### **MainClass (agent.client package)**

The class that you specified on the **Global Java API Data Source Information** page. This class contains a main method and a method that handles *take action* requests. This class inherits from the helper class described next. You must modify this class to interface with resources you want to monitor and the actions you want to take.

### **MainClassBase (agent.client package)**

A helper class which initializes the connection to the server, registers attribute groups, and waits for requests from the server. Do not modify this class.

### **Sampled\_Data, Sampled\_Subnode, Event\_Data, and Event\_Subnode classes (agent.client.attributeGroups package)**

There is one class for each Java API attribute group which handles data collection requests for the attribute group or generates events for the attribute group. These classes each inherit from one of the helper classes described next. You must modify these classes to gather data from the resources you want to monitor.

### **Sampled\_DataBase, Sampled\_SubnodeBase, Event\_DataBase, and Event\_SubnodeBase classes (agent.client.attributeGroups package)**

Helper classes, one for each Java API attribute group, which define the structure of the attributes of the group in an internal class. Do not modify these classes.

### **ICustomAttributeGroup interface (agent.client.attributeGroups package)**

An interface that defines public methods in each attribute group class. Do not modify this interface.

The classes which you can modify are never overwritten by the Agent Builder. The Agent Builder creates them only if they do not exist.

The helper classes and the interface are overwritten each time the Agent Builder is saved. As you modify and save the agent, the helper classes are updated to reflect any structural changes to the Java API attribute groups. The interface and helper classes contain a warning in the header that reminds you not to modify the file.

## Initialization and cleanup

The main method in MainClass is called when the agent is started. It creates a MainClass instance and then enters the long-running method to receive and handle agent requests.

Most of the initialization and cleanup code must be added to MainClass. In the constructor, add initialization that is needed to create or access your resources. You might want to open connections to remote resources, create handles, or initialize data structures.

Before the agent terminates, the stopDataCollection method is called. If you want to close connections or cleanup before the Java application ends, add that code to the stopDataCollection method.

If initialization is needed only for a particular attribute group, that initialization can be added to the constructor of the attribute group class. Similarly, if any cleanup is needed only for a particular attribute group, that cleanup code can be added to the stopDataCollection method of the attribute group.

Any code in the Java application can use the logger object to write log entries. (The main helper class creates a protected logger object in its constructor. The attribute group helper objects create a protected reference to that logger in their constructors). The logger object uses the Java trace log utility. Errors and detailed trace information can be obtained from the trace log that is created by the logger. The trace information is important for troubleshooting problems with the provider.

When `stopDataCollection` is called, if you pass the cleanup work to another thread, wait for that thread to finish before you return from the `stopDataCollection` method. Otherwise, the cleanup work can be abruptly terminated when the process ends because the main thread completed.

One of the agent configuration settings is for the Java trace level. The following table shows the values that you can set in the `JAVA_TRACE_LEVEL` configuration property. If the API created the logger for you, the table shows the Level that is used by the logger.

| <i>Table 321. Java trace level options</i> |                          |   |
|--|--------------------------|---|
| Configured trace level                     | Java logging trace level | Description   |
| Off  | OFF                      | No logging is done.   |
| Error                                      | SEVERE                   | Trace problems that occurred in the Java application.                               |
| Warning                                    | WARNING                  | Trace errors and potential errors.  |
| Information                                | INFORMATION              | Trace important information about the Java application.                             |
| Minimum Debug                              | FINE                     | Trace high-level details necessary to analyze the behavior of the Java application. |
| Medium Debug                               | FINER                    | Trace details about the program flow of the Java application.                       |
| Maximum Debug                              | FINEST                   | Trace all details about the Java application.                                       |
| All  | ALL                      | Trace all messages.   |

The name of the log file that is created by the Java application in this example is `k91_trace0.log`. If the agent is a multiple instance agent, the instance name is included in the log file name.

**Note:** Do not write messages to standard error or to standard out. On Windows systems, these messages are lost. On UNIX and Linux systems, this data is written to a file that does not wrap.

## Collecting sampled attribute group data

The class for a sampled attribute group (one that collects one or more data rows) contains a `collectData` method, for example, `Sampled_Data.collectData`. This method is called whenever data is requested by the agent.

The helper class of the attribute group defines an inner class that is called `Attributes`. This class has one field for each attribute that is defined in your attribute group. Derived attributes are not included since they are calculated by the agent. The data types of attribute fields are Java equivalents to the Tivoli Monitoring attribute types, as shown in (Table 322 on page 1546).

| <i>Table 322. The data types of attribute fields and their IBM Tivoli Monitoring attribute type equivalents</i> |                              |
|---|------------------------------|
| Tivoli Monitoring type  | Data type of attribute field |
| String  | String                       |
| Numeric, 32 bit, no decimal adjustment  | int                          |
| Numeric, 64 bit, no decimal adjustment  | long                         |
| Numeric, non-zero decimal adjustment  | double                       |
| Time stamp  | Calendar                     |

The `collectData` method must:

1. Collect the appropriate data from the resource that is being monitored.
2. Create an `Attributes` object.
3. Add the data to the fields of the `Attributes` object.
4. Call the `Attributes.setAttributeValues` method to copy the data to an internal buffer.
5. Repeat steps 1 - 4 as necessary for each data row. (You can skip steps 1 - 4 altogether and return no rows. In this case, the Error Code column of the Performance Object Status table has a value of `NO_INSTANCES_RETURNED`. For more information about error codes, see [“Error codes” on page 1549](#)).
6. Call `AgentConnection.sendData` to send the data to the agent, or call `sendError` to discard data that is copied from calls to `setAttributeValues` and send an error code instead.

You must collect the data from your resource (Step 1), replacing the sample data that is used in the generated application.

To populate the `Attributes` object, you can pass the data in using the `Attributes` constructor (as is done in the generated application). Alternatively use the zero-argument constructor to create an `Attributes` object and then assign the fields of the attributes object to the attribute values you collected. Fields have the same name as the attributes, though they start with a lowercase letter.

## Collecting sampled data for a subnode

If a sampled attribute group is in a subnode, there are presumably multiple resources that you are monitoring (a different one for each subnode). You must determine which resource to collect data from. There must be one or more configuration properties that identify which resource is being monitored.

For this example, it is assumed that one configuration property, `K91_INSTANCE_KEY`, contains a value that identifies the resource from which data must be collected.

Use the following steps to find the correct resource:

1. Get the instance ID of all configured subnodes by calling `AgentConnection.getConfiguredSubnodeInstanceIDs`. Each subnode that is configured has a unique instance ID.
2. For each instance ID, get the `K91_INSTANCE_KEY` configuration property by calling `AgentConnection.getSubnodeConfigurationProperty`.
3. Find the resource that is represented by the value in `K91_INSTANCE_KEY`.

These steps might be done in the `collectData` method before the series of steps that are detailed in [“Collecting sampled attribute group data” on page 1546](#)).

Alternatively, you might want to do these steps in the attribute group class constructor and establish a direct mapping from instance ID to resource. An example attribute group class constructor is the `Sampled_Subnode` constructor. This procedure also gives you the opportunity to create handles or open connections that might be used through the life of the agent. Creating handles or open connections can make access to your resources more efficient.

The generated code creates sample resource objects of type `MonitoredEntity` in the constructor, and adds them to a `configurationLookup` map. You must remove the `MonitoredEntity` inner class, and replace the `MonitoredEntity` objects with objects that access your own resources. If you choose to do the entire lookup procedure in the `collectData` method, you can remove the `configurationLookup` map from the class.

If you choose to use the constructor, to map the subnode instance ID to your resource, the steps in the `collectData` method are:

1. Retrieve the instance ID of the subnode from the request parameter, by calling `Request.getSubnodeInstanceID`.
2. Retrieve the resource object from the map that is created in the constructor.
3. Perform the series of steps that are detailed in [“Collecting sampled attribute group data” on page 1546](#) to send data to the agent.

An arbitrary subnode property is chosen in the Agent Builder example, in this case `K91_INSTANCE_KEY`. If not the correct property, or more than one property is needed to identify the correct resource, you must choose the properties to identify the resource.

## **Sending events**

For attribute groups that generate events, there is no periodic call to a `collectData` method. Events are sent by your application as your resource posts them.

As an example of producing events, the generated code for an event-based attribute group creates and starts a thread which runs from an internal class named `SampleEventClass`. The event-based attribute group that is used in the example is the `Event_Data` class. The thread periodically wakes up and sends an event. If you want to periodically poll your resource for events, you can use the structure of the `Event_Data` class as it was generated:

1. From the `Event_Data` constructor, create and start a thread.
2. In the run method of the thread, loop until the agent terminates.
3. Sleep for a time before you check for events. You might want to change the polling interval of 5000 milliseconds to a number that makes sense for your agent.
4. Determine whether one or more events occurred. The generated application does not check, but always posts a single event.
5. For each event that must be posted, get the event data to be posted.
6. Create and populate the `Attributes` object (like the `collectData` method did for a sampled attribute group).
7. Call the `Attributes.sendEventData` method. Events consist of a single row, so only a single event can be sent at a time.

Alternatively, if you are working with a Java API that reports events from its own thread, you can initialize that thread in the `Event_Data` constructor. You can also register your own event-handling object with the event-handling mechanism of your resource. In your event handler, use the following steps:

1. Get the event data to be posted.
2. Create and populate the `Attributes` object.
3. Call the `Attributes.sendEventData` method.

In this case, you do not have to create your own thread in the `Event_Data` class nor would you need the `SampleEventClass` class.

## **Sending events in a subnode**

When an event is detected for a subnode attribute group, the Java application must post the event to the correct subnode.

For this example, it is assumed that one configuration property, `K91_INSTANCE_KEY`, contains a value that identifies an instance of a resource which can produce events. It is also assumed that the value of the `K91_INSTANCE_KEY` property is retrieved along with data to be posted in the event. To do retrieve the property and data, the Java application does the following steps:

1. Gets the event data to be posted, along with the “instance key”.
2. Creates and populates the `Attributes` object.
3. Gets a list of all configured subnode instance IDs by calling `AgentConnection.getConfiguredSubnodeInstanceIDs`.
4. For each subnode instance, fetches the value of `K91_INSTANCE_KEY` by calling `AgentConnection.getSubnodeConfigurationProperty`.
5. When the value of `K91_INSTANCE_KEY` is found which matches the value that is obtained with the event data, remembers the corresponding subnode instance ID.
6. Calls `Attributes.sendSubnodeEventData`, passing the remembered subnode instance ID.

The generated application does not do the lookup described in steps 4 and 5, but instead posts an event to the attribute group of every subnode. This behavior is probably not the correct one for a production agent.

## Take action commands

Take action commands are defined either in the Tivoli Enterprise Portal or by using the `tacmd createaction` command. The actions can be imported into the agent's Agent Builder project so that they are created when the agent is installed. For more information about importing take action commands, see (["Importing application support files" on page 1621](#)).

The generated Java application registers for any actions that begin with the product code of the agent, for example, K91Refresh. This registration is done in the main helper class (`MainClassBase`) from the `registerActionPrefix` method. If you want to register other prefixes, or not register for actions at all, override the `registerActionPrefix` in (`MainClassBase`).

When the agent wants to run an action which starts with a prefix that your agent registered, the `MainClass.takeAction` method is called. You add code to call `Request.getAction()`, do the appropriate action, and then call `AgentConnection.sendActionResultCode` to send the return code from your action. A return code of 0 means the action is successful, any other return code means the action failed.

## Handling exceptions

The `collectData` and `takeAction` methods can throw any Java exception, so you can allow your collection code to throw exceptions without catching them. The `handleException` method (for `collectData`) or `handleActionException` method (for `takeAction`) is called when the helper class gets the exception.

For `collectData` exceptions, you must call `AgentConnection.sendError` when an exception occurs or when there is a problem in data collection. The generated application passes an error code of `GENERAL_ERROR`. However, you must replace this error code with one defined by your agent that best describes the problem that was encountered. For more information about adding error codes, see Step (["13" on page 1542](#)).

For `takeAction` exceptions, you must call `AgentConnection.sendActionResultCode` with a non-zero return code.

Some of the `AgentConnection` methods throw exceptions that are derived from `com.ibm.tivoli.monitoring.agentFactory.customProvider.CpciException`. The `handleException` method is not called if a `CpciException` is thrown during the collecting of data as the helper class handles the exception.

**Note:** If you choose to catch your exceptions inside the `collectData` method rather than using the `handleException` method, ensure any `CpciException` is rethrown. You ensure `CpciException` is rethrown so it can be handled by the base class.

## Error codes

A typical response to an exception or other resource error is to send an error code to the agent by calling the `AgentConnection.sendError` method. An error for an event-based attribute group can be sent at any time. An error for a sampled attribute group can be sent only in response to a collect data request, and in place of a `sendData` call.

If you send an error to the agent, the following happens:

1. An error message is logged in the agent trace log. This error message includes the error code and the message that is defined for that error code.
2. There is a Performance Object Status query that can be viewed to obtain status information about your attribute groups. The Error Code column is set to the Error Code type defined for the error you sent. The error status clears after data is successfully received by the agent for the attribute group. If you

reply to a collect data request with a sendData call but you included no data rows, you get NO\_INSTANCES\_RETURNED in the Error Code column.

The following table describes some error codes that are internal to the agent that you can expect to see in certain situations:

| Table 323. Internal error codes for the agent |  |
|---|--|
| Error Code                                    | Description  |
| NO_ERROR                                      | There are no problems with the attribute group currently.  |
| NO_INSTANCES_RETURNED                         | The Java application responded to a data collection request but provided no data. Not providing data is not an error. It generally indicates that there are no instances of the resource that are being monitored by the attribute group.  |
| OBJECT_NOT_FOUND                              | The agent tried to collect data for an attribute group that is not registered through the client API. This error can mean that the application failed to start or did not initiate the attribute group registration when the agent tried to collect data.  |
| OBJECT_CURRENTLY_UNAVAILABLE                  | The application sent the agent an error code that is not defined in the global list of error codes.  |
| GENERAL_ERROR                                 | <p>A problem occurred collecting data from the application, usually because the application did not reply to the request within the timeout interval. See the agent trace log for more details.</p> <p>The application can also specify GENERAL_ERROR as an error code, but it is better if a more detailed error code is defined.</p> |

## Changes to the agent

Certain changes to the agent require you to make corresponding changes to the Java application. If the structural changes are complex, you can delete any or all of the Java source files before you save the agent. You can also delete the files if you want to start over without the customizations you made,

The following table describes required modifications to the Java application source files after certain changes are made in the Agent Builder when the agent is saved.

| Table 324. Changes to an agent that require modifications to the Java source |  |   |
|--|--|---|
| Agent change   | What Agent Builder does  | Manual changes that are needed in the Java source   |
| Change of the main class package name  | <ul style="list-style-type: none"><li>Generates all classes in the new package structure.</li><li>Removes all helper classes from the old package.</li></ul> | <ul style="list-style-type: none"><li>Port main and attribute group class content from the classes in the old package to the classes in the new package.</li><li>Remove the classes from the old package after migration is complete.</li></ul> |

Table 324. Changes to an agent that require modifications to the Java source (continued)

| Agent change  | What Agent Builder does  | Manual changes that are needed in the Java source   |
|---|--|---|
| Change of the main class name                           | <ul style="list-style-type: none"> <li>Creates new main classes.</li> <li>Removes old main helper class.</li> </ul>  | <ul style="list-style-type: none"> <li>Port main class content to the new class.</li> <li>Update references to the class name from the attribute group classes.</li> </ul>  |
| Addition of a Java API attribute group                  | <ul style="list-style-type: none"> <li>Creates classes for the new attribute group.</li> <li>Adds registration for the new attribute group in the main helper class.</li> </ul>                    | Overwrite sample code with custom logic in the attribute group class.   |
| Removal of a Java API attribute group                   | Removes registration from the main helper class.   | <ul style="list-style-type: none"> <li>Remove the attribute group class or port customized logic to some other class.</li> <li>Remove the attribute group helper class.</li> </ul>  |
| Renaming of a Java API attribute group                  | <ul style="list-style-type: none"> <li>Creates classes for the new name of the attribute group.</li> <li>Updates registration for the renamed attribute group in the main helper class.</li> </ul> | <ul style="list-style-type: none"> <li>Port customized logic in the attribute group class with the old name to the attribute group class with the new name.</li> <li>Remove the attribute group class with the old name.</li> <li>Remove the attribute group helper class with the old name.</li> </ul> |
| Addition of an attribute to a Java API attribute group  | Updates the Attributes inner class in the attribute group helper class.  | Collect data for the new attribute in the attribute group class.  |
| Removal of an attribute from a Java API attribute group | Updates the Attributes class in the attribute group helper class.  | Remove data collection for the former attribute in the attribute group class.   |
| Renaming of an attribute in a Java API attribute group  | Updates the attribute name in the Attributes class in the attribute group helper class.  | Update any references to the attribute name in the Attributes class (often there are no references because the Attributes constructor, with positional arguments, is used).   |
| Reordering of attributes in a Java API attribute group  | Updates the attribute order in the Attributes class in the attribute group helper class.   | Update the argument order in any calls to the Attributes constructor.   |

Some of the changes that are mentioned in the previous table can be streamlined if you use the Eclipse Refactor - Rename action. Use this action on all the affected names (including helper class names) before you save the changed agent.

## Use of the Java API

The Java API is used throughout the generated Java application to communicate with the agent. Often your only direct interaction with the Java API is to modify a parameter of an existing method call. For example, changing a posted error code from `GENERAL_ERROR` to an error code defined in your agent.

If you want to do more extensive coding with the Java API, you can view Javadoc from the Eclipse text editor. You can view Javadoc while you edit the Java code by doing the following steps:

1. Highlight a package, class, or method name from the API.
2. Press **F1** to open the Eclipse Help view.
3. Select the Javadoc link.

You can also see a brief description from the Javadoc by hovering over a class or method name. Javadoc for the API can also be found on the Tivoli Monitoring Knowledge Center, see [Javadoc](#).

The classes for the Java API are in `cpci.jar`. The `cpci.jar` file is automatically added to the Java Build Path of the project when an agent which contains a Java API attribute group is created. The file is also added when an agent that contains a Java API attribute group is imported. The file is also added when a Java API attribute group is added to an existing agent. The `cpci.jar` is also automatically packaged with each agent that contains a Java API attribute group and added to the CLASSPATH of the Java application.

## Java API configuration

When you define a Java API data source in your agent, some configuration properties are created for you.

If you define a Java API data source in your agent, the agent must use Java to connect to the Java API server. Java configuration properties are added to the agent automatically. The following Java configuration properties are specific to the agent runtime configuration:

| Table 325. Java configuration properties |                                     |          |   |
|--|-------------------------------------|----------|---|
| Name                                     | Valid values                        | Required | Description   |
| Java home                                | Fully qualified path to a directory | No       | A fully qualified path that points to the Java installation directory.  |
| Java trace level                         | Choice                              | Yes      | Use this property to specify the trace level that is used by the Java providers.  |
| JVM arguments                            | String                              | No       | Use this property to specify an optional list of arguments to the Java virtual machine.                                 |
| Class path for external jars             | String                              | No       | Path containing any JAR files that are not included with the agent, but are necessary for the runtime client operation. |

These configuration variables are available on the **Runtime Configuration Information** page of the Agent Editor under **Configuration for Java Virtual Machine (JVM)**, and **Configuration for Java API**.

## Testing Java application attribute groups

You can test the Java application attribute group that you created, within Agent Builder.

### Before you begin

**Restriction:** Unlike most other attribute groups, you cannot test the Java application attribute group while it is being created. You can test the attribute group when it is added to the agent and the agent is saved. Saving the agent causes the Java code to be generated for the attribute group.

### Procedure

1. Select an attribute group on the **Agent Editor Data Source Definition** page after agent creation and click **Test**.

For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent” on page 1398](#)

After you click **Test** in one of the previous two steps, the **Test Java Client** window is displayed.

2. Optional: Set environment variables, configuration properties, and Java information before you start testing. For more information, see [“Attribute group testing” on page 1596](#). For more about default Java runtime configuration properties, see [“Java API configuration” on page 1552](#).
3. Click **Start Agent**. A window indicates that the Agent is starting.
4. To simulate a request from Tivoli Enterprise Portal or SOAP for agent data, click **Collect Data**.  
The agent monitors the Java Client for data. The **Test Java Client** window displays any data that is returned.
5. Optional: Click **Check Results** if the returned data is not as you expected.  
The **Data Collection Status** window opens and shows you more information about the data. The data that is collected and displayed by the Data collection Status window is described in [“Performance Object Status node” on page 1638](#)
6. Stop the agent by clicking **Stop Agent**.
7. Click **OK** or **Cancel** to exit the **Test Java Client** window. Clicking **OK** saves any changes that you made.

### Related concepts

[“Testing your agent in Agent Builder” on page 1595](#)

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

## Creating data sets from existing sources

---

When at least one data set exists, you can create a new data set using data from an existing data set.

The option to create a new data set is available on the **Agent Initial Data Source** page and on the **Data Source Location** page. You can create a data set by using existing data sources in the following ways:

1. Joining data from two existing data sets (attribute groups). For more information, see [“Joining two attribute groups” on page 1554](#).
2. Filtering data from an existing data set (attribute group). For more information, see [“Creating a filtered attribute group” on page 1559](#).

**Tip:** The option to join two data sets is available only after two or more data sets are created.

# Joining two attribute groups

Create an attribute group from two other attribute groups.

## About this task

Joining attribute groups is most useful when the agent collects data from two different types of data sources. For example, the agent might collect data WMI and PerfMon, or SNMP and script data sources. Each set of attributes might be more useful when used together in one Tivoli Enterprise Portal view.

For example, assume that your attribute groups are defined as follows:

```
First_Attribute_Group
  index integer
  trafficRate integer
  errorCount integer
```

```
Second_Attribute_Group
  index2 integer
  name string
  traffic string
```

One definition provides you with counters (like Perfmon) and the other provides you with identification information. Neither attribute group is useful to you by itself. However, if you can combine both attribute groups by using the index to match the appropriate rows from each, you have a more useful attribute group. You can use the combined attribute group to display the name, type, and metrics together.

This same mechanism can be used to add tags to information collected through normal attribute groups. The information can then be more easily correlated in an event system when a problem is detected. For example, a company wants to manage all its servers by collecting common data and by using common situations to monitor the health of the servers. It also wants to be able to identify the servers with more information that tells it what application is running on a particular server. It wants to have control of the values that are used on each server, but it does not want to create different agents for each application. It can accomplish this control by creating an additional attribute group in its single agent as follows:

```
Application_Information
  application_type integer
  application_name string
  application_group string
```

This attribute group would be defined as a script attribute group that gathers its values from agent configuration. You can specify different values for each agent instance and use one agent to manage all of their systems. This attribute group would then be joined to all the source attribute groups where this application information might be needed. The information is then available in the Tivoli Enterprise Portal, situations, events, and warehoused data.

When you join two attribute groups, a third attribute group is created. This attribute group contains all the attributes that are contained within the source attribute groups.

The results of a join operation vary depending on the number of rows that each source attribute group supports. If both attribute groups are defined to return only a single row of data, then the resulting joined attribute group has one row of data. The single row contains all attributes from both source attribute groups.

| Table 326. source attribute group one (single row) |            |            |
|--|------------|------------|
| Attribute1   | Attribute2 | Attribute3 |
| 16   | some text  | 35         |

| Table 327. source attribute group 2 (single row) |            |            |            |
|--|------------|------------|------------|
| Attribute4                                       | Attribute5 | Attribute6 | Attribute7 |
| 5001   | more data  | 56         | 35         |

| Table 328. Resulting join |            |            |            |            |            |            |
|---------------------------|------------|------------|------------|------------|------------|------------|
| Attribute1                | Attribute2 | Attribute3 | Attribute4 | Attribute5 | Attribute6 | Attribute7 |
| 16                        | some text  | 35         | 5001       | more data  | 56         | 35         |

Suppose that one source attribute group is defined to return only one row (single-row) while the other can return more than one row (multi-row). The resulting joined attribute group contains the same number of rows as the multi-row source attribute group. The data from the single-row attribute group is added to each row of the multi-row attribute group.

| Table 329. source attribute group one (single row) |            |            |
|--|------------|------------|
| Attribute1   | Attribute2 | Attribute3 |
| 16   | some text  | 35         |

| Table 330. source attribute group two (more than one row) |            |            |            |
|---|------------|------------|------------|
| Attribute4  | Attribute5 | Attribute6 | Attribute7 |
| user1   | path1      | 56         | 35         |
| user2   | path2      | 27         | 54         |
| user3   | path3      | 44         | 32         |

| Table 331. Resulting join |            |            |            |            |            |            |
|---------------------------|------------|------------|------------|------------|------------|------------|
| Attribute1                | Attribute2 | Attribute3 | Attribute4 | Attribute5 | Attribute6 | Attribute7 |
| 16                        | some text  | 35         | user1      | path1      | 56         | 35         |
| 16                        | some text  | 35         | user2      | path2      | 27         | 54         |
| 16                        | some text  | 35         | user3      | path3      | 44         | 32         |

Finally, assume that both source attribute groups are defined to return more than one row. You must identify an attribute from each of the source attribute groups on which to join. The resulting attribute group contains data rows where the attribute value in the first attribute group matches the attribute value from the second attribute group.

| Table 332. source attribute group one (more than 1 row) |                |            |
|---|----------------|------------|
| Attribute1  | Attribute2     | Attribute3 |
| 16  | some text      | 35         |
| 27  | more text      | 54         |
| 39  | another string | 66         |

| Table 333. source attribute group 2 (more than 1 row) |            |            |            |
|---|------------|------------|------------|
| Attribute4  | Attribute5 | Attribute6 | Attribute7 |
| user1   | path1      | 56         | 35         |

| Table 333. source attribute group 2 (more than 1 row) (continued) |            |            |            |
|---|------------|------------|------------|
| Attribute4  | Attribute5 | Attribute6 | Attribute7 |
| user2   | path2      | 27         | 54         |
| user3   | path3      | 44         | 32         |

| Table 334. Resulting join (joining on Attribute3 and Attribute7) |            |            |            |            |            |            |
|--|------------|------------|------------|------------|------------|------------|
| Attribute1   | Attribute2 | Attribute3 | Attribute4 | Attribute5 | Attribute6 | Attribute7 |
| 16   | some text  | 35         | user1      | path1      | 56         | 35         |
| 27   | more text  | 54         | user2      | path2      | 27         | 54         |

With Agent Builder, you can also join user-defined attribute groups to the Availability attribute group if there are any availability filters defined in your agent. For more information about the data that is contained in the Availability attribute group, see ([“Availability node” on page 1633](#)).

You can create this type of attribute group by accessing the menu on the data sources tree by right-clicking and then selecting **Join Attribute Groups**.

## Procedure

1. On the **Data Source Definition** page, right-click one of the attribute groups you would like to join and select **Join Attribute Groups**.

This option is only visible if there are at least two attribute groups defined. Having an availability filter defined counts as having an attribute group defined.

The **Attribute Group Information** page is displayed.

Figure 48. **Attribute Group Information** pageAttribute Group Information window

2. In the **Join Information** area, select the two attribute groups you would like to join. Select the attribute groups by choosing from the groups available in the **Attribute Group One** and **Attribute Group Two** lists.

For each attribute group, either **Produces a single data row** or **Can produce more than one data row** is selected for you. This selection is locked and depends on how the source attribute groups were originally defined.

**Note:** There are restrictions on which attribute groups can be joined:

- You cannot join an attribute group in one subnode type to an attribute group in another subnode type.
- You can join only an event attribute group to a single row non-event attribute group.
- a) Select the attribute that you want to join on for each attribute group when both attribute groups show **Can produce more than one data row**, under **Attribute to join on**.

The **Attribute group name** and **Help** fields are filled for you using information from the chosen attribute groups. If you want to, you can change these entries.

3. Click **OK**.

## Results

The joined attribute group that you created is added to the **Attribute Group Information** area of the **Data Source Definition** page

## Manipulating attributes in joined attribute groups

Using attributes in joined attribute groups can impose rules on how those attributes are manipulated.

### Deleting an attribute group

An attribute group cannot be deleted if it is referenced in a joined attribute group unless the joined attribute group is also being deleted.

### Deleting an attribute

An attribute cannot be deleted if its parent attribute group is referenced in a joined attribute group and one of these statements is true:

- The attribute is defined as a join attribute in the joined attribute group.
- The attribute is used in any derived attribute in the joined attribute group.

Joined attributes cannot be deleted. Only derived attributes, if any are added, can be deleted from the joined attribute group.

### Reordering attributes

The order of the joined attributes is fixed by the order of the source attributes. The joined attribute list cannot be reordered. Only derived attributes, if any, can be reordered.

When the version of an agent, is committed, source, and derived attributes cannot be reordered or removed. Attributes added in a new version of the agent, whether source or derived attributes, will come after all committed attributes. For more information, see [“Committing a version of the agent” on page 1413](#).

### Adding an attribute

New joined attributes cannot be explicitly added. Only derived attributes can be explicitly created.

## Removing availability filters

The last availability filter cannot be removed if the Availability attribute group is referenced in a joined attribute group.

## Joined attributes

Manipulate information that relates to joined attributes

### Procedure

- Change the attribute name and help text of the joined attribute can be changed so that they are different from the source attribute:
  - a) Select the attribute in the joined attribute group in the **Attribute Group Information** pane of the **Data Source Definition** page.
  - b) Enter the new name and help text.
- The joined attribute can be shown or not shown on the Tivoli Enterprise Portal by selecting or clearing the **Display attribute in the Tivoli Enterprise Portal** check box. The check box is in the **Joined Attribute Information** section of the **Data Source Definition** page. This choice is irrespective of whether the source attribute is shown on the Tivoli(r) Enterprise Portal.
- Any attribute or combination of attributes (that are shown on the Tivoli Enterprise Portal) can be marked as key attributes by selecting the **Key attribute** check box. This choice is independent of whether the attributes are key attributes in the source attribute groups. The choice is also independent of whether the source attributes are shown on the Tivoli(r) Enterprise Portal.
- Attribute type information for joined attributes is taken from the source attributes and cannot be changed in the joined attribute. In the **Joined Attribute Group Information** section of the agent editor (Figure 49 on page 1558), click **Locate source attribute** to go to the source attribute.

Enumerations

Figure 49. Locating source attribute information

Any changes to the source attribute groups are reflected in the joined attributes. If the source attribute groups change, those attributes are automatically updated under the joined attribute group. This automatic update also occurs if a different attribute group is set as the source attribute group. Changes to a source attribute type are copied to the joined attribute. Changes to a source attribute name or help text are copied to the joined attribute. However, such source attribute changes are not copied after you change the name or help text of a joined attribute.

## Creating a filtered attribute group

Create a filtered attribute group (data set) by filtering rows of data from an existing attribute group. If an existing data set returns multiple rows, you can create a filtered group returning one row for use with IBM Cloud Application Performance Management.

### About this task

A filtered attribute group has the same columns as the source attribute group, but can exclude some of the rows. It uses a selection formula to determine which rows to include.

To provide status and summary information for Cloud APM, you need to use a data set that returns a single row. For details, see [“Preparing the agent for Cloud APM” on page 1590](#). If the source information is in a data set that returns multiple rows, you can create a filtered attribute group that returns a single row.

For example, the process, Windows service, and command return code data sources provide information as rows in the single Availability data set. You can create a filtered attribute group, using the NAME field in the selection formula. The group includes status for the necessary application. Define it as returning one row. Then you can use this attribute group as the summary data set for Cloud APM.

A filtered attribute group is also useful when a base data source query returns data that you prefer to divide into separate groups. Examples of such data sources are Windows Performance Monitor, SNMP and WMI.

For example, assume that a data source can return the following data:

| Name   | Type | Size | Used | Free |
|--------|------|------|------|------|
| Memory | MEM  | 8    | 4    | 4    |
| Disk1  | DISK | 300  | 200  | 100  |
| Disk2  | DISK | 500  | 100  | 400  |

This is a table that reports on the storage that exists on the system and it includes both memory and disk space. You might prefer to break down the table into memory and disk as separate tables. You can break down the table by creating two base attribute groups. Each of these base attribute groups collects the same data and filters out the rows you do not want. However, that is not the most efficient way to do things. Instead, you define one base attribute group that returns both the memory and disk usage data together. Next, define two filtered attribute groups. Each uses the same base table as its source. One includes a filter where Type=="MEM" and the other includes a filter where Type=="DISK".

In the example, for the filtered attribute group where Type=="MEM", the returned data is:

| Name   | Type | Size | Used | Free |
|--------|------|------|------|------|
| Memory | MEM  | 8    | 4    | 4    |

and where Type=="DISK", the returned data is:

| Name  | Type | Size | Used | Free |
|-------|------|------|------|------|
| Disk1 | DISK | 300  | 200  | 100  |
| Disk2 | DISK | 500  | 100  | 400  |

**Note:** Attributes groups whose data is event-based cannot be used to create filtered attribute groups. Only attribute groups whose data is sampled can be used.

### Procedure

1. Click **Existing data sources** in the **Monitoring Data Categories** area on the **Agent Initial Data Source** page or the **Data Source Location** page

#### Note:

- You reach the **Agent Initial Data Source** page by using the new agent wizard. For more information, see [“Creating an agent” on page 1395](#).

- You can reach the **Data Source Location** page by right-clicking an agent in the **Data Source Definition** page of the **Agent Editor** and selecting **Add Data Source**.
2. Select **Filter an attribute group's data rows** in the **Data Sources** area.
  3. Click **Next**  
The **Filter Information** page is displayed.
  4. Select a **Source attribute group** from the list.
  5. Enter a **Selection formula** to filter the data from the attribute group you selected.  
For example, in the **Filter Information** page that is shown earlier, the selection formula filters data rows where the Type attribute is equal to "DISK". Data rows whose Type attribute does not match "DISK" are discarded. The selection formula that you enter must evaluate to a Boolean result, true, or false.
- Note:** In the **Filter Information** page, you can click **Edit** to enter or modify the formula by using the Formula Editor. For more information about the Formula Editor, see [“Formula Editor”](#) on page 1425.
6. Click **Next**.
  7. Select **Produces a single data row** or **Can produce more than one data row**.
    - a) If you selected **Can produce more than one data row**, select a key attribute or attributes from the list.
  8. Click **Finish**.

## Creating a navigator group

---

In an IBM Tivoli Monitoring environment, use Navigator groups to group several related data sources (attribute groups) together so that workspaces can be created that show views that combine the data sources. You can create a navigator group while you create an agent by using the New Agent wizard at the base agent level. You can also create a navigator group while you define a subnode by using the New Agent Component wizard.

### About this task

For example, you might be able to collect file system data from more than one data source. It can be useful to create one workspace that shows views of all file system data from those different data sources.

Navigator groups are also a good way to hide data sources on the Tivoli Enterprise Portal. You might decide that metrics collected from two data sources are most useful if the data sources are joined to create a new combined data source. You want to see only the combined data in the Joined data source. You can create a navigator group that contains all three data sources and create a workspace that contains views to display only the combined data source. The two original data sources are effectively hidden from view in the Tivoli Enterprise Portal. See [“Creating data sets from existing sources”](#) on page 1553 for information about joining data sources.

**Note:** When you group data sources in a navigator group, Tivoli Monitoring does not associate a query with the navigator group. It is assumed that you define a default workspace for the navigator group to display the data sources in a useful format.

A navigator group can be defined in the base agent or in a subnode. A navigator group cannot contain another Navigator group.

Navigator groups have no effect in an IBM Cloud Application Performance Management environment.

### Procedure

1. Take one of the following steps:
  - When creating a new agent using the **Agent** wizard, on the **Agent Initial Data Source** page, click **Data source groupings** in the **Monitoring Data Categories** area.
  - With an existing agent, take the following steps in the Agent Editor:

- a. Click the **Data Sources** tab to open the **Data Source Definition** page.
  - b. Select the agent and click **Add to selected**.
  - c. On the **Data Source Location** page, in the **Monitoring Data Categories** area, click **Data source groupings**.
2. In the **Data Sources** area, click **A navigator group**.
3. Click **Next**.
4. On the **Navigator Group Information** page, type the navigator group name and the text for the Help you want associated with the name, and click **Next**.
 

**Note:** Agent Builder automatically creates navigator groups in certain situations. The following navigator group name is reserved:

  - Availability
  -
5. On the **First Navigator Group Data Source** page, select the first source of monitoring data for the new navigator group. Click a category in the **Monitoring Data Categories** list and a data source in the **Data Sources** list. Then, click **Next**.
 

**Tip:** You can create the data source as usual. Alternatively, click **Existing data sources** and choose to move one or more data sources that you already created into the navigator group.
6. If you want to create a data source within a navigator group, on the **Data Source Definition** page, select the navigator group, and click **Add to Selected**.
7. If you want to move existing data sources into the navigator group, on the **Data Source Definition** page, select the navigator group, and click **Add to Selected** and on the **Navigator Group Data Source** page, select **Existing data sources**. In the **Currently Defined Data Sources** page, select the data sources.
8. If you want to remove a data source from a navigator group, do one of the following steps on the **Data Source Definition** page:
  - Select the data source, and drag it to the root of the data sources tree.
  - Select the data source, and clicking **Remove**.
9. If you want to create a navigator group, do one of the following steps on the **Data Source Definition** page:
  - Click **Add to Agent**.
  - Select a subnode and click **Add to Selected**.

## Using subnodes

---

You can use subnodes to monitor multiple application components from a single agent instance.

You can build a single agent that accomplishes the following tasks by using subnodes:

- Monitors each instance of a software server that is running on a system instead of having to use separate instances of the agent, one per software server instance.
- Monitors several different remote systems instead of having to use separate instances of the agent, one for each remote system.
- Monitors several different types of resources from one agent instead of having to build and deploy several different agents.
- In IBM Tivoli Monitoring, displays an additional level in the Tivoli Enterprise Portal physical Navigation tree that allows further grouping and customization. Moreover, you can define Managed System Groups for another level of granularity with situations.
- In IBM Cloud Application Performance Management, provides several different resources, displaying different summary and detail dashboards. Subnode resources can be displayed as peers or subcomponents of the agent resource. You can include these resources in applications independently.

You can create subnode types in Agent Builder. Each type must correspond to a different type of resource that an agent can monitor. Add data sources and data sets to the subnode type for a particular monitored resource.

When you deploy the agent on a monitored host and configure it, you can create one or more instances of each subnode type. Each instance of a subnode must correspond to an instance of a server, a remote system, or whatever resource the subnode type was designed to monitor. All subnode instances of a single subnode type have attribute groups and workspaces that have an identical form. However, each subnode instance has data that comes from the particular resource that is being monitored.

When you configure the agent on the monitored host, you can determine the number of subnode instances. Some configuration data can apply to the agent as a whole, but other configuration data applies to a single subnode instance. Configure each subnode instance differently from the other subnode instances so that they do not monitor the exact same resource and display the exact same data.

In an IBM Tivoli Monitoring environment, a subnode instance is displayed within the agent in the Navigation Physical view in the Tivoli Enterprise Portal. Workspaces display the data that is produced by a subnode instance and situations can be distributed to one or more instances of a subnode. A managed system list is automatically created that contains all instances of the subnode, just like the Managed System List that is created for an agent.

In an IBM Cloud Application Performance Management environment, you can display both agent and subnode instances as monitored resources. Each subnode instance becomes a separate resource. For details, see [“Subnodes in IBM Cloud Application Performance Management” on page 1567](#).

Because agents built with Agent Builder create the subnode instances that are based on configuration values, these subnodes have the same life span as the agent. There is still just one heartbeat that is done for the agent, not a separate heartbeat for each subnode. Therefore, by using subnodes you can significantly increase the potential scale of the monitoring environment. The alternative is to use multiple agent instances, which can limit the potential scale of the IBM Tivoli Monitoring or IBM Cloud Application Performance Management environment.

Adding or removing a subnode requires reconfiguring the agent. To reconfigure the agent, you need to stop and restart it, involving all subnodes. You can define the agent as a multi-instance agent; in this case, you can start and stop a single instance, and leave the other instances running.

Along with data sets in subnodes, an agent can define agent-level data sets that are located outside of a subnode.

In the Tivoli Enterprise Portal Navigator tree, a subnode type is displayed under the agent name, and subnode instances are displayed under a subnode type. Subnodes are identified by a Managed System Name (MSN) just like agents, for example `94:Hill:cmn`.

For example, in the Navigator tree in [Figure 50 on page 1563](#), **Watching Over Our Friends** is an agent with three resources (**Boarders**, **Common Areas**, and **Kennel Runs**) and two subnode types (**Common Area** and **Kennel Run**). Two of these resources have subnode types that are defined for them (**Common Area** and **Kennel Run**). A subnode is not required for the third resource (**Boarder**), which is represented by a single row in a table at the base agent level. The Common Area subnode type has three subnode instances: `94:Hill:cmn`, `94:Meadow:cmn`, and `94:Tree:cmn` representing three common areas in the kennel. The Kennel Run subnode type has four subnode instances: `94:system1:run`, `94:system2:run`, `94:system4:run`, and `94:system5:run` representing four kennel runs.

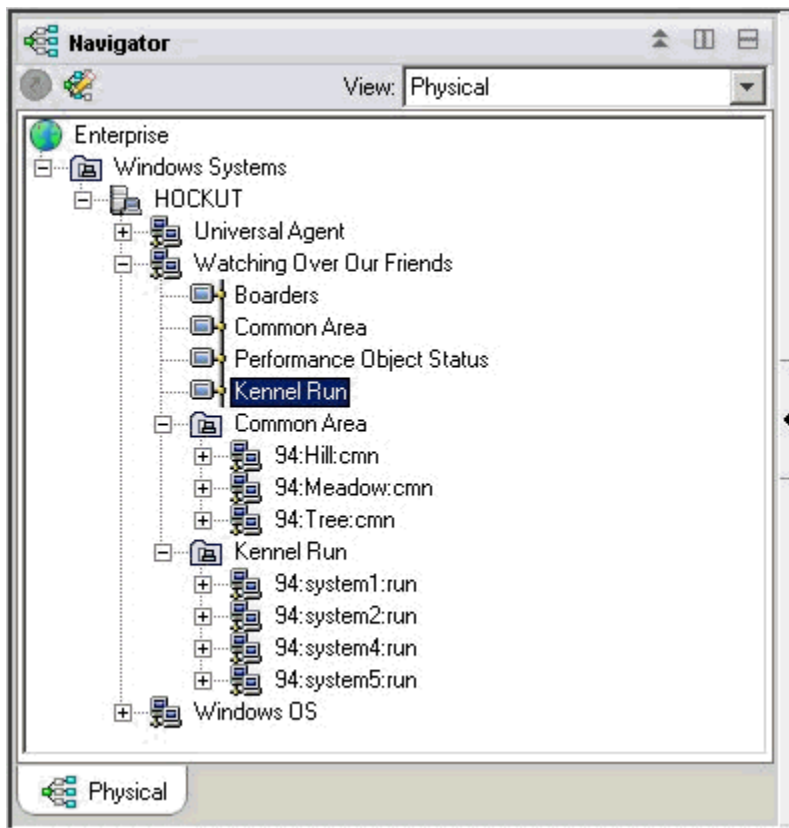

Figure 50. Subnodes in the Navigator tree

There are two ways that a single agent can use subnodes:

- The agent can have different subnodes of the same type.
- The agent can have subnodes of different types.

## Subnodes for the same data from different sources

You can use subnodes of the same type to represent multiple instances of a monitored resource type. Each subnode of the same type includes the same attribute groups and the correct values for the specific monitored resource instance. The number of subnodes varies based on agent configuration. The example in [Figure 51](#) on page 1564 shows the monitoring of different systems.

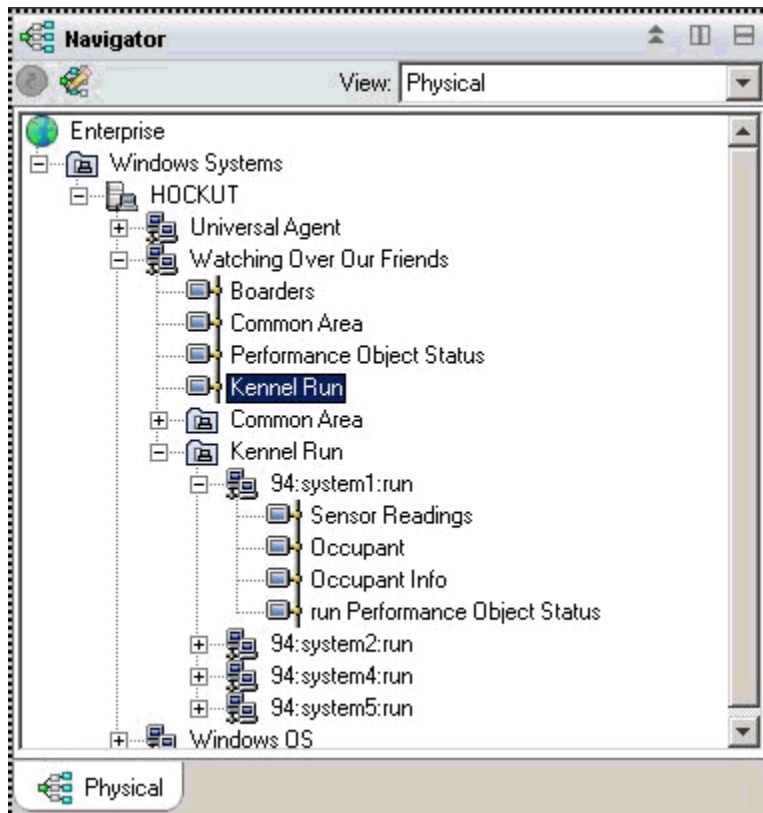

Figure 51. Subnodes monitoring different systems

## Subnodes for multiple types of data

When one agent monitors multiple types of monitored resources, you can create a subnode type for each of the resource types. Each subnode includes the information that is defined in that subnode type. The following example shows two subnode types. Each type is monitoring a different type of resource, with different types of data available for each resource:

- Common Area
- Kennel Run

The agent in [Figure 52 on page 1565](#) runs one copy of each subnode type. A particular agent might create any subset of the defined agents. Subnodes can be used to mimic Tivoli Monitoring V5 profiles.

Figure 52. Subnode types in Navigator tree

Both ways of using subnodes can be used in the same agent, where each type can have more than one subnode instance.

Figure 52 on page 1565 shows two types of subnodes that monitor two types of resources: Common Areas and Kennel Runs. In addition, there are several subnodes that are defined for each type. There are three subnodes of type Common Area; these subnodes have the following IDs: Meadow, Hill, and Tree. There are also four subnodes of type Kennel (each collecting data from a different system that is dedicated to a Kennel Run); these subnodes have the following IDs: system1, system2, system4, and system5.

**Note:** The first 24 characters of subnode IDs must be unique for all instances of the subnode type in the IBM Tivoli Monitoring installation.

## Data Providers in subnodes

A subnode can contain any mixture of data from the different data provider types. Most current Agent Builder data providers can be used in a subnode, including the following data providers:

- WMI
- Perfmon
- Windows Event Log
- SNMP
- SNMP Events
- JMX
- ICMP ping
- Script
- Log

- CIM
- JDBC
- HTTP
- SOAP
- Socket
- Java API

A subnode can also contain a joined attribute group that combines data from two other attribute groups from the same subnode or from agent-level attribute groups.

## Status of subnodes

There are two ways to determine status for a subnode agent. The first way is to look at the data that is displayed in the Performance Object Status attribute group. This attribute group displays the status for each of the other attribute groups at the same level in the agent. The Performance Object Status attribute group at the agent level displays the collection status for the other attribute groups at the agent level. The Performance Object Status attribute group in each subnode displays the collection status for the attribute groups in that subnode.

Agent Builder also creates one attribute group for each subnode type, which displays one row for each configured subnode of that type. In the example in (Figure 53 on page 1566), four subnodes are running to collect data.

The screenshot shows the IBM Tivoli Enterprise Console interface. The title bar reads 'K94:K941000 - HOCKUT - SYSADMIN'. The Navigator pane on the left shows a tree structure with 'HOCKUT' expanded, showing 'Universal Agent', 'Watching Over Our Friends', 'Boards', 'Common Area', 'Performance Object Status', 'Kernel Run', and 'Common Area'. The 'Kernel Run' subnode is selected, showing four instances: '94:system1:run', '94:system2:run', '94:system4:run', and '94:system5:run'. The main pane displays a 'Report' table with columns: Node, Timestamp, Subnode MSN, Subnode Affinity, Subnode Type, Subnode Resource Name, and Subnode Version. The table contains four rows of data for the selected subnode instances. The status bar at the bottom shows 'Hub Time: Fri, 05/16/2008 04:22 PM', 'Server Available', and 'K94:K941000 - HOCKUT - SYSADMIN'.

| Node      | Timestamp         | Subnode MSN    | Subnode Affinity | Subnode Type | Subnode Resource Name | Subnode Version |
|-----------|-------------------|----------------|------------------|--------------|-----------------------|-----------------|
| HOCKUT:94 | 05/16/08 16:21:22 | 94:system1:run | %dog.kennelrun   | run          | system1               | 06.02.00        |
| HOCKUT:94 | 05/16/08 16:21:22 | 94:system2:run | %dog.kennelrun   | run          | system2               | 06.02.00        |
| HOCKUT:94 | 05/16/08 16:21:22 | 94:system4:run | %dog.kennelrun   | run          | system4               | 06.02.00        |
| HOCKUT:94 | 05/16/08 16:21:22 | 94:system5:run | %dog.kennelrun   | run          | system5               | 06.02.00        |

Figure 53. Monitoring multiple subnode instances of the same subnode type

In the IBM Tivoli Monitoring environment, the **Performance Object Status** subnode contains data visible in the Navigator tree and can have situations that monitor the status of the other data collections.

In the IBM Cloud Application Performance Management environment, you can create thresholds to monitor **Performance Object Status** data.

The example in Figure 54 on page 1567 shows a case where the data collection failed (the script shell command was not found). Typically, any value other than NO\_ERROR indicates that there is a problem. For each of the data collectors that are defined in the subnode, there is one row in the table.

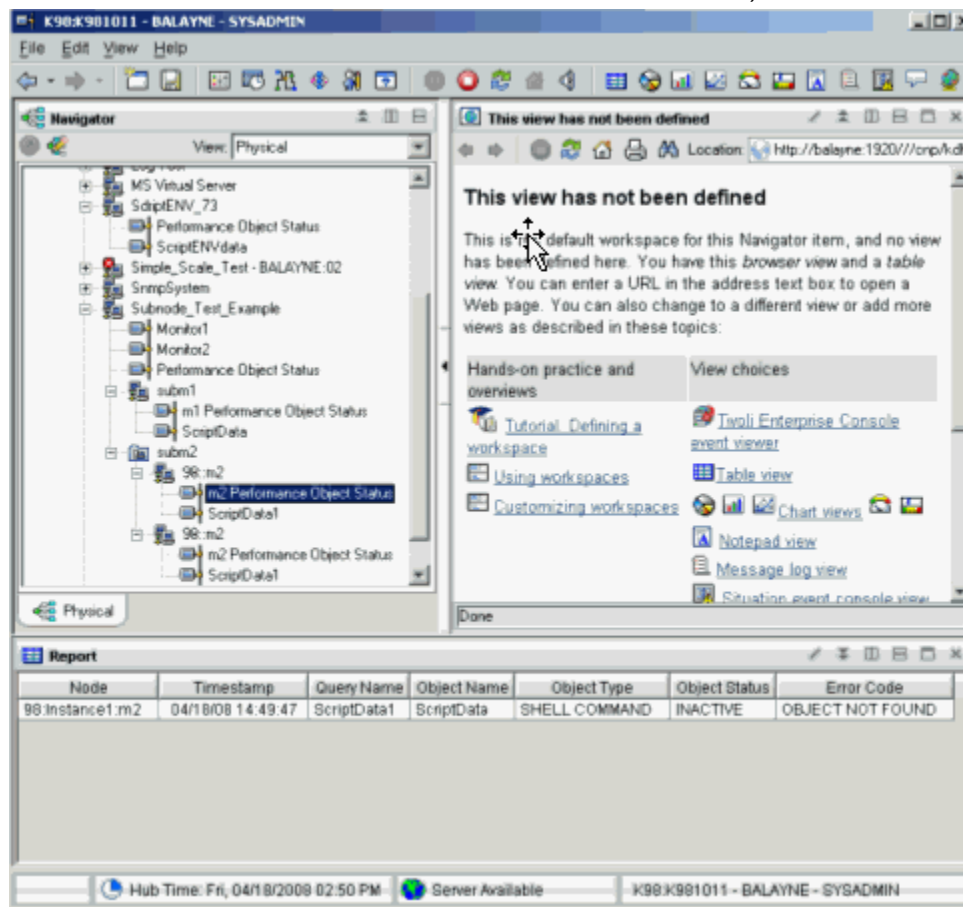

Figure 54. Example: data collection in a subnode

## Subnodes in IBM Cloud Application Performance Management

In IBM Cloud Application Performance Management, you can define either the agent instance or a subnode instance or both as monitored resources, and each resource corresponds to a summary dashboard.

Subnode dashboards can not display agent-level data. To display agent-level data in this environment, define a summary dashboard for the agent.

Depending on the settings you select, agent and subnode resources can appear at the same level, with no hierarchical distinction, or subnode resources can be listed as children to agent resources.

For instructions about configuring agent and subnode resources, see [“Preparing the agent for Cloud APM” on page 1590](#).

## Creating subnodes

You can create a subnode when creating or editing an agent.

### Procedure

1. Take one of the following steps:

- When creating a new agent using the **Agent** wizard, on the **Agent Initial Data Source** page, click **Data source groupings** in the **Monitoring Data Categories** area.
  - With an existing agent, take the following steps in the Agent Editor:
    - a. Click the **Data Sources** tab to open the **Data Source Definition** page.
    - b. Select the agent and click **Add to selected**.
    - c. On the **Data Source Location** page, in the **Monitoring Data Categories** area, click **Data source groupings**.
2. In the **Data Sources** area, click **A Subnode Definition**
  3. Click **Next**.
  4. Complete the **Subnode Information** page as follows to define the new subnode:
    - a) In the **Name** field, type the name of the subnode you are creating.
    - b) In the **Type** field, enter 1-3 characters (by using numbers, letters, or both) to identify the type of the subnode you are creating.
    - c) In the **Description** field, type a description for the subnode you are creating.
    - d) Click the **Show nodes attribute group for this type of subnode** check box to hide or display the availability attribute group. For more details about this attribute group, see [“Availability node” on page 1633](#).
    - e) Click **Next**.
  5. Complete the **Initial Subnode Data Source** page to select a data source as the first item in the new subnode. Click a category in the **Monitoring Data Categories** list and a data source in the **Data Sources** list. Then, click **Next**.
 

**Tip:** You can create the data source as usual. Alternatively, you can move one or more data sources that you already created into the navigator group. To move data sources, click **Existing data sources** and, in the **Currently Defined Data Sources** page, select the data sources.

**Important:** You can not include process, Windows service, or command return code data sources in a subnode. As a workaround, you can write a script that determines the necessary process or service information and use a script output data source.
  6. If your agent contains custom configuration properties or if the selected data source requires configuration, use the **Subnode Configuration Overrides** page to choose the configuration properties. In the **Subnode Configuration Overrides** page, choose the configuration properties that you want for the subnode at the agent level. Then, choose the configuration properties that you want to vary for each subnode.
 

Use **Move**, **Copy**, and **Remove** to specify the configuration properties as described in [“Configuring a subnode” on page 1569](#).
  7. Click **Next**.
 

The **Data Source Definition** page is displayed.

## Subnode configuration

When a subnode type is defined, a single configuration section is defined specifically for that subnode.

There are several ways that a subnode configuration section differs from other configuration sections:

- The set of properties in a subnode section can be duplicated, so there are multiple sets of properties. Each set of properties forms its own section. The layout of all sections is identical, but different values can be entered in each section.

In contrast, the properties in other sections (which are referred to as agent-level sections) are shown only one time during runtime configuration. They do not form subsections and cannot be duplicated or removed.

See [“Subnode configuration example” on page 1572](#) for GUI and command-line examples of configuring subnodes.

- For each copy of a subnode section that is created at runtime configuration, the agent creates a separate subnode instance. All of those subnode instances are of the same type.
- The property names in subnode sections can be duplicates of property names in agent-level sections. When duplicate names occur, the subnode property value overrides the agent-level property value.
- In IBM Tivoli Monitoring V6.2.1 and later, a subnode section can have default property values that apply to all instances of subnodes of that type. This feature makes it possible to have a three-level lookup of a single property value as follows:
  1. The agent obtains the property value from the subnode instance subsection.
  2. If no value is configured at the subnode instance level, the property value is obtained from the subnode default level.
  3. If no value is configured at either of those two levels, then the property value is obtained from an agent-level section.

See [“Subnode configuration example” on page 1572](#) for GUI and command-line examples of configuring subnodes.

## Configuring a subnode

Use the **Subnode Configuration Overrides** page to configure a subnode data source.

### Before you begin

Use the steps in [“Creating subnodes” on page 1567](#) to create a subnode.

### About this task

When you add a data source to a subnode, the **Subnode Configuration Overrides** page is presented if the data source requires configuration. It shows custom configuration properties and any other configuration properties that are applicable to the subnode type.

### Procedure

- In the **Subnode Configuration Overrides** window, choose the configuration properties that you want for the subnode at the agent level. Also, choose the configuration properties that you want to vary for each subnode.
- Use **Copy >>** to copy configuration properties so that they are both at the agent level and the subnode level.  
The agent looks for a value first at the subnode level, and if it does not find a value, it looks at the agent level. If a property at both levels is a required property, it is required only at the agent level, it is optional at the subnode level.
- Use **Move >>** to move properties from the agent level to the subnode level. **Move>>** is not available for properties that are required by an agent-level data source or by a subnode of a different type.
- Use **Remove** to remove one of the two lists. Properties can be removed only if they are listed at both the agent-level and the subnode level. This function cannot be used to remove a property completely.
- Use **<< Copy** to copy a property from the subnode level to the agent-level.
- Use **<< Move** to move a property from the subnode to the agent-level.

### What to do next

You can change the configuration for an existing subnode by using the Agent Editor.

## Subnode configuration overrides

Use Subnode Configuration Overrides to override agent configuration properties with subnode-specific properties.

The procedure in [“Configuring a subnode” on page 1569](#) describes how to manage subnode configuration for automatically generated properties. Managing custom configuration properties is similar. Any custom configuration properties that are defined are displayed in the **Subnode Configuration Overrides** window.

When you copy or move a custom property from the subnode level to the agent-level, you are prompted for the section to place the property in. You can select an existing custom section, or enter the name of a new custom section.

## Selecting subnode configuration properties

Without subnodes, all instances of a data source type share the configuration parameters. For example, all SNMP attribute groups connect to the same host by using the same community name. With subnodes, each instance of a subnode can connect to a different host if the `SNMP_HOST` property is placed at the subnode level.

Selecting properties to be overridden at the subnode level is an important consideration when you are developing an agent. If too many properties are selected, the subnode configuration section becomes cluttered and difficult to manage. If too few properties are selected, then the agent functions might be limited when someone wants to vary a property from one subnode to the next.

The following properties cannot be copied to the subnode level. (All attribute groups in all subnodes and in the base agent must use the same SNMP version and JMX connection type):

- SNMP version
- JMX MBean server connection type
- Java home
- Java trace level
- JVM arguments
- Class path for external JAR files
- Socket data source port number
- JMX or JDBC class path settings

## Advanced subnode configuration

Use advanced subnode configuration to override an agent configuration property in a subnode.

### About this task

There is an option in IBM Tivoli Monitoring V6.2.1 and later agents that you can enable to override properties from any agent-level configuration section in a subnode instance. On the **Subnode Configuration Overrides** page, there is a check box labeled **Allow any configuration property to be overridden in any subnode**. For more information, see ([“Subnode configuration overrides” on page 1570](#)). For this option to be enabled, you must select **6.2.1** as the **Minimum ITM version** when you name your agent ([“Naming and configuring the agent” on page 1395](#)). If you choose this option, each subnode instance can override any property from any agent-level configuration section. But this property can be overridden only from the GUI and not from the `itmcmd` command line.

### Procedure

The **Allow any configuration property to be overridden in any subnode** option causes an **Advanced** field that contains a list to be displayed on each subnode configuration panel. The initial selection in the **Advanced** field provides the brief directions: **Select a section to override values**.

- When you click the list, you see a list of all the non-subnode sections that contain configuration properties.
- Select a section.

The properties from that section are temporarily added to the subnode panel. The value of any property that you change is added to the set of properties that are defined for the subnode. A data source in the subnode looks for property values in the subnode before it looks in the agent-level sections. .

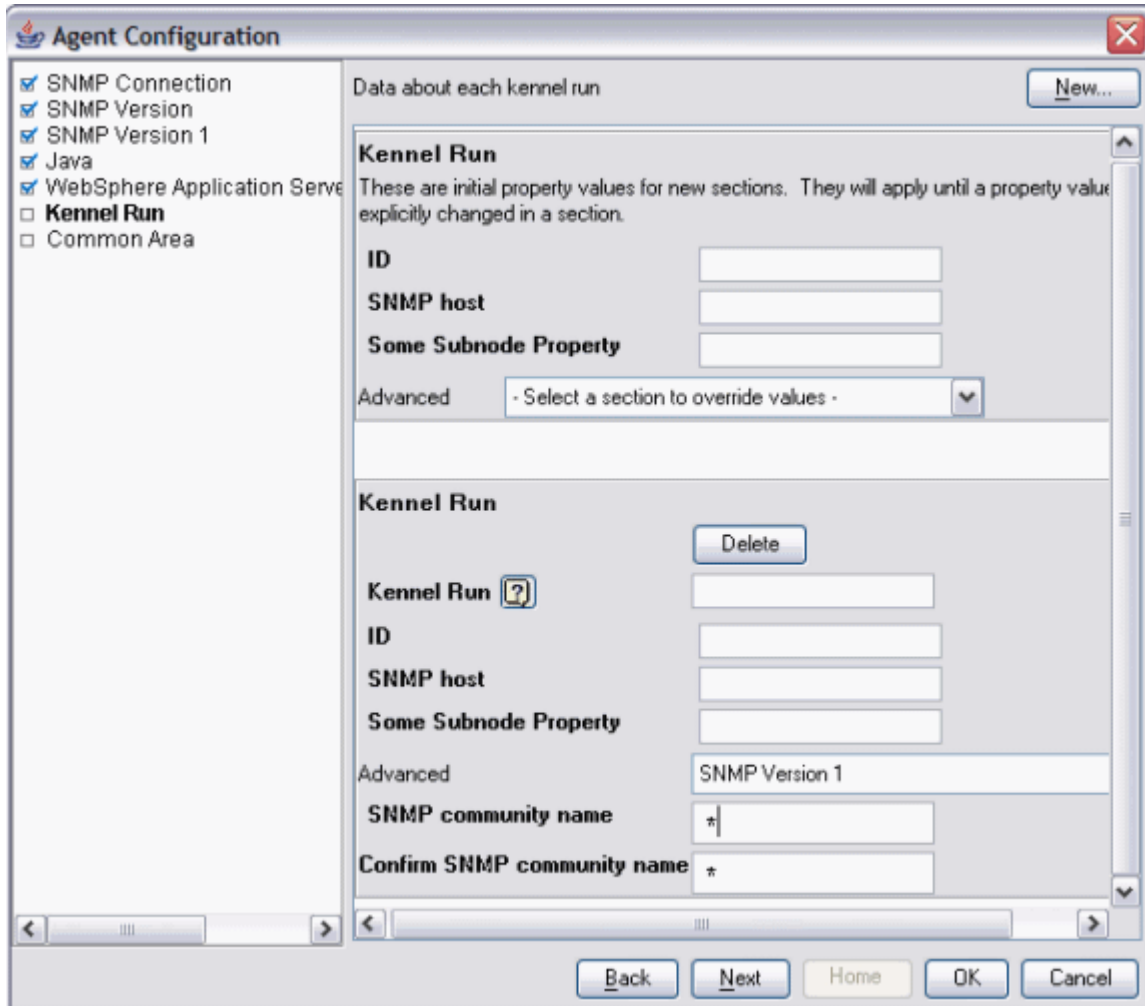

Figure 55. SNMP Version 1 Properties expanded

The following further information applies to overriding properties from agent-level sections:

- Properties that were copied to the subnode section are not shown when the agent-level section is selected in the **Advanced** list. For example, in Figure 55 on page 1571, **SNMP host** is not displayed after the **Advanced** list because it was copied to the subnode properties and is already displayed.
- Sections that contain no properties to override do not have a selection in the **Advanced** list.
- Overridden values that you enter for one section are retained even if you select a different section to display different properties.
- Select **Allow any configuration property to be overridden in any subnode** to enable this feature in your agent.

## Configuring a subnode from the command line

In the IBM Tivoli Monitoring environment, you can also configure a subnode by using the command line.

### Before you begin

For more information about subnode configuration, see [“Subnode configuration” on page 1568](#)

### About this task

#### Procedure

- To configure a subnode instance from the command line, use the following command:

```
tacmd configureSystem -m HOSTNAME:00 -p  
section_name:subnode_instance_id.property_name=value
```

Where:

**section\_name**

Same as the subnode type

**subnode\_instance\_id**

ID for the subnode that is defined during configuration.

**property\_name**

Name of the configuration property

**value**

Value for the property

### Subnode configuration example

How to configure a sample agent with one defined subnode.

#### Example:

This example shows how to configure a sample agent that has one subnode named Example Subnode of type exs and the following three configuration properties:

- Agent Cfg (actual property name is K00\_AGENT\_CFG) is defined only at the agent level.
- Subnode Cfg (actual property name is K00\_SUBNODE\_CFG) is defined only in the example subnode.
- Overridable Cfg (actual property name is K00\_OVERRIDABLE\_CFG) is defined at the agent level and was copied to the example subnode.

(Figure 56 on page 1573) shows these configuration properties on the **Runtime Configuration Information** page of the Agent Editor.

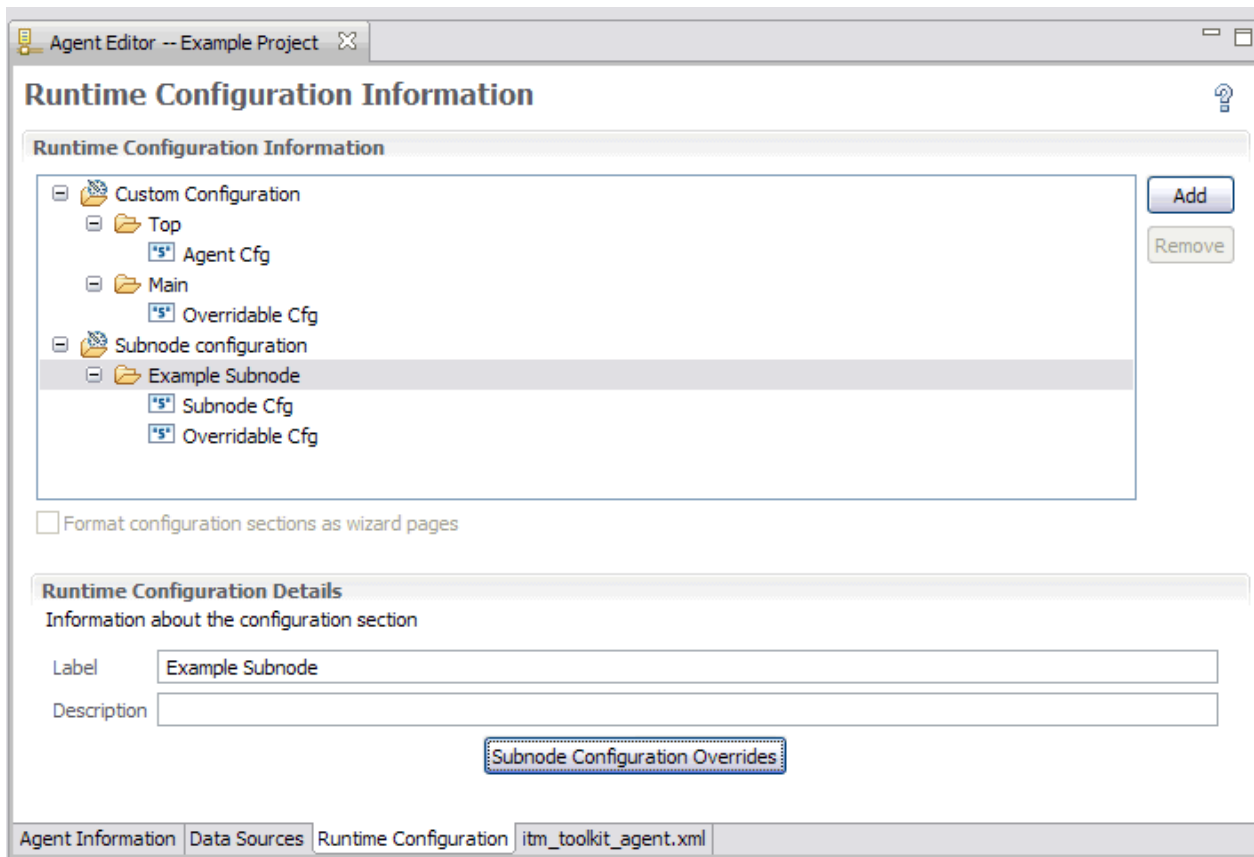

Figure 56. Configuration property definitions in the Agent Builder

When this example agent is configured, the first page that is displayed is the **Top** section, which contains the **Agent Cfg** property as shown in (Figure 57 on page 1574). Because this property is an agent-level property, it is shown one time during agent configuration. Any instance of the Example Subnode can see this property value, but all instances see the same value.

Figure 57. **Top** section with agent-level configuration for the **Agent Cfg** property

If you are configuring from the Tivoli Enterprise Monitoring Server command line, the **Agent Cfg** property can be set by using the following command:

```
tacmd configureSystem -m HOSTNAME:00 -p "TOP.K00_AGENT_CFG=a value"
```

The next section that is displayed is the **Main** section as shown in [Figure 58 on page 1575](#). It is also an agent-level section and contains the agent-level **Overridable Cfg** property. This property differs from the **Agent Cfg** property because this property was copied to the Example Subnode in the Agent Builder. This means that a default value for the property can be entered on the **Main** page. However, any Example Subnode instance can override the value that is entered here with a different value.

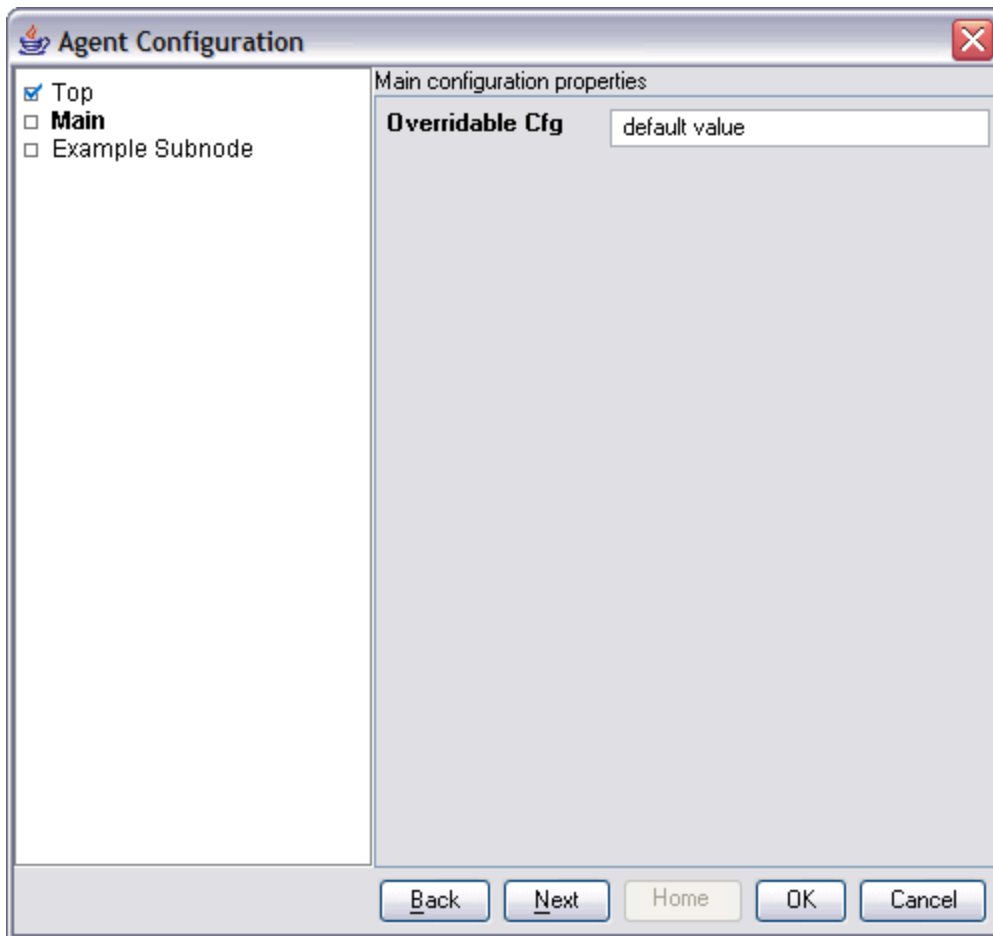

Figure 58. **Main** section with the agent-wide default value for the **Overridable Cfg** property

If you are configuring from the Tivoli Enterprise Monitoring Server command line, this property can be set by using the following command:

```
tacmd configureSystem -m HOSTNAME:00 -p "MAIN.K00_OVERRIDABLE_CFG=default value"
```

You can place both of these properties in the same agent-level section. You can decide how many custom agent-level sections to create and how to distribute custom properties among them.

The next section that is displayed is the **Example Subnode** section as shown in [Figure 59 on page 1576](#). Because this agent is being configured for the first time, there are no defined subnode instances and no subnode instance subsections are shown. The initial property values subsection is shown, although it is optional and some subnode types might not show it. Because the initial property values subsection is shown, default values can be entered for any of the configuration properties. The **Overridable Cfg** property already has a default value that was obtained from the agent-level property of the same name.

Figure 59. **Example Subnode** section page with no subnode

Subnode instances are defined by doing the following actions on the empty **Example Subnode** section page (Figure 60 on page 1577):

1. In the initial **Example Subnode** section, in the **Subnode Cfg** field, type the following default string for the property: `sub-default value`.
2. Click **New**. An **Example Subnode** subsection is displayed after the initial properties subsection.
3. In the **Example Subnode** field, type the following subnode instance ID: `do`.
4. Click **New**. A second **Example Subnode** subsection is shown after the first.
5. In the second **Example Subnode** field, type the following subnode instance ID: `re`.
6. In the **Subnode Cfg** field, type the following value for the **Subnode Cfg** property: `sc override`.
7. In the **Overridable Cfg** field, type the following value for the **Overridable Cfg** property: `oc override`.

Figure 60. **Example Subnode** section page with two subnode instances defined

The two new subsections cause the agent to create two subnode instances when it is started. Because the properties of the **do** subnode subsection were not changed, the default property values are used by that subnode instance. Since different values were entered for the properties in the **re** subsection, the **re** subnode instance uses those values that were typed.

You can set a default value from the Tivoli Enterprise Monitoring Server command line with the following command:

```
tacmd configureSystem -m HOSTNAME:00 -p "exs.K00_SUBNODE_CFG=sub-default value"
```

The format for setting subnode default values is exactly like the format for setting agent-level properties, except that the section name identifies a subnode section.

You can create the subnode instances from the Tivoli Enterprise Monitoring Server command line with the following command:

```
tacmd configureSystem -m HOSTNAME:00 -p "exs:do.K00_OVERRIDABLE_CFG=default value" \
  "exs:re.K00_SUBNODE_CFG=sc override" "exs:re.K00_OVERRIDABLE_CFG=oc override"
```

The subnode instance ID is inserted between the section name and property name. When you use the command line to create a subnode instance, at least one property must be specified, even if all the

properties use default values. Otherwise, default values are not required to be specified on the command line when you define subnode instances.

All of the agent configuration properties can be set in a single command. The following command is equivalent to all of the preceding individual commands:

```
tacmd configureSystem -m HOSTNAME:00 -p "TOP.K00_AGENT_CFG=a value" \  
"MAIN.K00_OVERRIDABLE_CFG=default value" \  
"exs.K00_SUBNODE_CFG=sub-default value" \  
"exs:do.K00_OVERRIDABLE_CFG=default value" \  
"exs:re.K00_SUBNODE_CFG=sc override" "exs:re.K00_OVERRIDABLE_CFG=oc override"
```

## Subnodes and Windows data sources

Choose to include Windows Remote Connection properties in the agent or not.

### About this task

If an agent has Windows data sources at the agent level and not in subnodes, including Windows Remote Connection configuration properties in the agent are optional. Windows data sources are Windows Event Log, Windows Management Instrumentation, Windows Performance Monitor. If configuration properties are not included, these data sources monitor the local Windows system by default and need no configuration. By default, no Windows data sources are included in any subnode.

To choose whether to include Windows Remote Connection properties in the agent, do the following steps:

### Procedure

1. On the **Windows Management Instrumentation (WMI) Information** page, click **Global Options** when data source properties are displayed. Select **Global Options** either while you are creating the data source or from the Agent Editor **Data Sources** page.
2. In the **Global Windows Data Source Options** window, select **Include Windows Remote Connection configuration** if you want to include these properties in the agent.

## Subnodes and Script data sources

Subnode instance configuration properties are accessed in subnode scripts just as they are in agent-level scripts.

Scripts have access to all agent-level configuration properties and all subnode instance configuration properties. If an agent-level property is overridden at the subnode level, the script has access only to the subnode level property value.

## Customizing agent configuration

---

Customize the configuration of process, log file, and script data sources.

### Before you begin

If you are adding SNMP, JMX, CIM, JDBC, HTTP, and SOAP data sources to your agent, configure these data sources as described in the following sections:

- [“Monitoring data from a Simple Network Management Protocol \(SNMP\) server” on page 1452](#)
- [“Monitoring Java Management Extensions \(JMX\) MBeans” on page 1461](#)
- [“Monitoring data from a Common Information Model \(CIM\)” on page 1480](#)
- [“Monitoring data from Java Database Connectivity \(JDBC\)” on page 1505](#)
- [“Monitoring HTTP availability and response time” on page 1515](#)
- [“Monitoring data from a SOAP or other HTTP data source” on page 1523](#)

## About this task

Use this task to customize the configuration of process, log file, and script data sources so an agent can access the application that it is monitoring.

All agents must be configured before they can be started. All agents must have basic configuration information such as the method of connecting to the Tivoli Enterprise Monitoring Server. Many times, an agent must have more configuration information so it has access to information specific to the system on which it is running. For example, if you must know the installation location of a software product, add configuration properties to prompt for this information. Another example of information you might prompt for is the user ID and password to access an interface,

Custom configuration is defined by the agent developer. It is not required for all agents, but can be used in the following areas of data collection:

- Matching an argument in a Process Monitor
- Matching the command line in a Process Monitor
- Forming a log file path or name
- Defining an environment variable in a script

**Note:** Certain data sources such as JMX and SNMP add this configuration automatically.

**Note:** When data source specific configuration is added automatically by the Agent Builder, this configuration is added in English only.

If during data source definition your agent requires system-specific information for an area of data collection, **Insert Property** or **Insert Configuration Property** is shown.

For example, when you create an attribute group that monitors a log file, **Insert Configuration Property** is shown.

## Procedure

1. Click **Insert Configuration Property** to display the **Configuration Properties** window,
2. In the **Configuration Properties** window, click a property, and click **Add**.

**Note:** Initially there are no configuration properties that are defined for the agent.

3. In the **Runtime Configuration Property** window, complete the following fields:

- a) In the **Section** area, complete the following fields:

**Label**

Text that describes the properties

**Description**

(optional) Description of the properties

- b) In the **Property** area, complete the following fields:

**Label**

Text that is displayed in the agent configuration panel that identifies the information you must enter.

**Environment variable**

The environment variable is displayed in the **Environment variable** field and is updated as you type in the label field. The Agent Builder automatically constructs the name of the environment variable from the product code and the label. If you want to change the environment variable independently from the label, you can clear **Match Label**.

**Description**

(optional) Description of the property that is being defined.

**Type**

Type of information that is collected, one of the following options:

**String**

For any alphabetic information that must be collected (for example, installation locations, user names, and host names).

**Password**

For any information that must be encrypted when stored. In addition to providing encryption of the data, the data that is typed into the text box is obscured by asterisks. In addition, you are required to type this information twice to validate the data.

**Numeric**

For any numeric information (for example, port numbers).

**Choice**

For a list of specific values. This option enables the Choices table. You can define specific values by clicking **Add**. The values that are entered are displayed in the agent configuration panel as a group of selections, you can make only one selection from the group.

**Read Only Text**

Displays text when you configure the agent, but no information is collected.

**Separator**

Displays a horizontal separator, but no information is collected.

**File Browser**

Collects a string, which is a file name. Click **Browse** to browse the file system for the wanted file.

**Default value**

(Optional) Specify the value that is shown in the configuration panel at run time when the agent is configured for the first time. If you want a default value for UNIX/Linux that is different from a default value for Windows, click **Multiple Values**.

In the **Configuration Property Default Values** window, specify the default values that you want for Windows systems and for UNIX and Linux systems.

**Note:** Support for multiple default values is a feature that is only supported in IBM Tivoli Monitoring V6.2.1 and higher. If your agent is compatible with IBM Tivoli Monitoring V6.2, a prompt warns you about this requirement and you can cancel or continue with V6.2.1 compatibility enabled.

**Required**

Check this field if the user must enter a value when the agent is configured. Clear this field if it is optional for the user to enter a value.

- c) To add a choice, click **Add**
- 4. In the **Configuration Property Value** window, complete the **Label** and **Value** fields.  
The Label is displayed as one of the choices. If this choice is taken, the value becomes the property value.
- 5. Click **OK**.  
The new configuration section and property are displayed in the **Configuration Properties** window under **Custom Configuration**.
- 6. Optional: To add another property to an existing section, select the section or an existing property in the section and click **Add**. You make the selection in the runtime configuration tree of the **Configuration Properties** window.
- 7. Complete the fields for the new property. (Complete the same fields as in step “3” on page 1579).
- 8. Click **OK**. The property that you most recently added is selected.
- 9. Keep the selection or select the property that you want to insert into the log file name.
- 10. Click **OK**. The property is inserted into the log file name.  
You can then continue through the wizard to complete defining your log file attribute group.

**Note:** Even though a configuration property is defined in the context of a log file name, it can be used in other locations. For instance, another location that accepts a configuration property is a script data source. This flexibility means that you can access the value for the configuration element **File Information** with the script variable `$K00_APPLICATION_LOG_FILE` if the product code is K00. You can also use the Windows batch file variable `%K00_APPLICATION_LOG_FILE%`.

## Changing configuration properties by using the Agent Editor

Use the Agent Editor to change configuration properties of your agent.

### About this task

This task provides information about viewing, adding, and changing configuration properties by using the Agent Editor.

### Procedure

1. Click the **Runtime Configuration** tab.
2. Select a configuration section, and click **Add**.

**Add** works just like it does in “Customizing agent configuration” on page 1578. There is no **Edit** selection because a configuration section or property is edited when it is selected.

3. Select a configuration property to display the **Runtime Configuration Details** area.
4. In the **Runtime Configuration Details** area, edit the fields to configure the property.

## Configuring a Windows remote connection

Information about Configuring a Windows remote connection

### About this task

Windows Management Instrumentation (WMI), Windows Performance Monitor (Perfmon), and Windows Event Log data sources can monitor data on the system where the agent is installed. These data sources can also monitor data on remote Windows systems. These three data source types are known as Windows data sources. If these Windows data sources are monitoring data remotely, they all share Windows Remote Connection configuration properties for the agent level where they are defined.

If you define a Windows data source in the base level of your agent, Windows Remote Connection configuration properties are not added to the agent automatically. They are not added to maintain compatibility with earlier versions of agents that might use the Windows data provider before remote monitoring was enabled. The Windows data source in your agent monitors data on the local Windows system where the agent is installed.

If you define a Windows data source in a subnode in your agent, Windows Remote Connection configuration properties are added to the agent automatically. The Windows data source must support Windows Remote Connection if it is in a subnode. You cannot clear the option until all windows data sources are removed from all subnodes in the agent. Each instance of a subnode might be configured to monitor a different remote Windows system. All Windows data sources in the subnode share Windows Remote Connection configuration properties.

To configure a base agent to remotely monitor a single remote Windows system, use the following procedure.

### Procedure

1. In the Agent Editor **Data Source Definition** window, click **Global Options**.  
The **Global Windows Data Source Options** window opens.
2. Select **Include Windows Remote Connection configuration**.
3. Click **OK**.

## Results

The following connection-specific configuration properties can be accessed from the Agent Editor **Runtime Configuration Information** page by selecting **Configuration for Windows remote access > Windows Remote Connection**

### Remote Windows host

Host name of remote Windows computer

### Remote Windows password

Password for remote Windows

### Remote Windows DOMAIN\user name

User name for the remote Windows host

## What to do next

You can view, add, and change the configuration properties by using the Agent Editor. For instructions, see [“Changing configuration properties by using the Agent Editor” on page 1581](#). If a Windows data source is defined in a subnode, you can also specify Subnode Configuration Overrides. For instructions, see [“Subnode configuration” on page 1568](#).

## Creating a user with Windows Management Instrumentation (WMI) permissions

You can add and configure a user on a Windows system with permissions to allow WMI browsing.

### About this task

If your agent collects data from a remote system by using Windows Management Instrumentation (WMI), it requires permissions to access WMI data on the remote system. The agent can access WMI data on a remote system when you provide credentials of an account with permissions to access WMI data on the system. The procedure applies to Windows 7, Windows 2008 Server and Windows Vista.

**Note:** Your agent can also access data on a remote Windows system by using Windows Performance Monitor (Perfmon), and Windows Event Log data sources. However, in the case of Windows Performance Monitor (Perfmon), and Windows Event Log data sources, you must provide Administrator credentials for the remote system.

### Procedure

1. Create a user account:
  - a. Go to Windows **Start > Administrative Tools > Computer Management**. The **Computer Management** window opens.
  - b. Expand **Local Users and Groups**.
  - c. Right-click the **Users** folder and select **New User**.
  - d. Complete the user details and click **Create** and **Close**.
2. Configure the group membership for the new user account:
  - a. In the **Computer Management** window, select the **Users** folder.
  - b. Right-click the new user account and select **Properties**.
  - c. Click the **Member Of** tab.
  - d. Click **Add**.
  - e. Click **Advanced**.
  - f. Click **Find Now**.
  - g. Select the following groups:

- Distributed COM Users
  - Performance Log Users
  - Remote Desktop Users
- Tip:** Press Ctrl and click to select multiple groups.
- h. Click **OK** until you return to the **Computer Management** window.
  - i. Select **File > Exit** to exit the **Computer Management** window.
3. Assign Distributed Component Object Model (DCOM) rights:
    - a. Go to Windows **Start > Administrative Tools > Component Services**. The **Component Services** window opens.
    - b. Expand **Component Services > Computers > My Computer**.
    - c. Right-click **My Computer** and select **Properties**. The **My Computer Properties** window opens.
    - d. Click the **COM security** tab.
    - e. In the **Access Permissions** area, click **Edit Limits**
    - f. In **Distributed COM Users**, verify that **Local Access** and **Remote Access** are selected.
    - g. Click **OK** to save settings.
    - h. In the **My Computer Properties** window, **Launch and Activation Permissions** area, click **Edit Limits**
    - i. In **Distributed COM Users**, verify that **Local Launch**, **Remote Launch**, **Local Activation**, and **Remote Activation** are selected.
    - j. Click **OK** to save settings and click **OK** again to close the **My Computer Properties** window.
    - k. Select **File > Exit** to exit the **Component Services** window.
  4. Configure the WMI namespace security assignments
    - a. Go to Windows **Start > Run....**
    - b. Enter `wmimgmt.msc` and click **OK**.
    - c. Right-click **WMI Control (Local)** and select **Properties**.
    - d. Click the **Security** tab.
    - e. Click **Security**.
    - f. Click **Add**.
    - g. Click **Advanced**.
    - h. Click **Find Now**.
    - i. Select the new user account, and click **OK** until you return to the **Security for Root** window.
    - j. Click **Advanced** and select the newly added user account.
    - k. Click **Edit**.
    - l. From the **Apply to:** menu selection, select **This namespace and subnamespaces**.
    - m. In **Execute Methods**, verify that **Enable Account**, **Remote Enable**, and **Read Security** are selected.
    - n. Click **OK** until you return to the **wmimgmt** window.
    - o. Select **File > Exit** to exit the **wmimgmt** window.

## What to do next

For more information about collecting WMI data from a remote system, see [“Monitoring data from Windows Management Instrumentation \(WMI\)” on page 1447](#).

# Configuring a Secure Shell (SSH) remote connection

Information about configuring an SSH remote connection

## About this task

Script data sources can monitor data on the system where the agent is installed and also on remote systems. If script data sources are monitoring data remotely, they all share SSH remote connection configuration properties for the agent level where they are defined. Earlier versions of an agent might use the script data provider before remote monitoring was enabled. To maintain compatibility with earlier versions of agents, SSH remote connection configuration properties are not automatically added to the agent. The script data source in your agent monitors data on the local system where the agent is installed.

If you define a Script data source in a subnode and you select **Enable data collection using SSH**, you can configure each subnode instance to monitor a different remote system. All script data sources in the subnode share SSH remote connection configuration properties.

If you want the agent to remotely monitor a remote system, use the following procedure.

## Procedure

In the Agent Editor **Data Source Definition** window for the script data source, select **Enable data collection using SSH**.

## Results

The following connection-specific configuration properties can be accessed from the **Agent Editor, Runtime Configuration Information** page by selecting **Configuration for Secure Shell (SSH) > SSH Remote Connection**

### Network address

The IP address or host name of the remote computer.

### SSH Port Number

The IP port number on which the SSH server is running. The default value is 22.

### Authentication Type

Type of authentication to use when you are logging on to the remote SSH server. You can choose Password or Public Key.

### Disconnect from the remote system after each collection interval

An option to determine whether the script data provider drops the login session to the remote system after it collects data. By default, the value is No.

### Remove script from the remote system after each collection interval

An option to delete the script from the remote system after each data collection interval. By default, the value is No.

If the Authentication Type is set to Password, the following configuration properties can be accessed from the **Agent Editor, Runtime Configuration Information** page by selecting **Configuration for Secure Shell (SSH) > Password**:

### Username

User name for the remote system

### Password

Password for the remote system

If Authentication Type is set to Public Key, the following configuration properties can be accessed from the **Agent Editor, Runtime Configuration Information** page by selecting **Configuration for Secure Shell (SSH) > Public Key**:

### Username

User name that is associated with the public key file

**Public Keyfile**

Public key file that is associated with the user

**Private Keyfile**

Private key file that is associated with the user

**Password**

Password that is used to unlock the private key file

**What to do next**

You can view, add, and change the configuration properties by using the Agent Editor. For instructions, see [“Changing configuration properties by using the Agent Editor” on page 1581](#). If the SSH Remote Connection configuration properties are included in a subnode, you can also specify Subnode Configuration Overrides. For instructions, see [“Subnode configuration” on page 1568](#).

## Creating workspaces, Take Action commands, and situations

---

After installing an agent in an IBM Tivoli Monitoring environment, you can create workspaces, queries, Take Action commands, and situations for your monitoring solution.

The situations, workspaces, Take Action commands, and queries that you create can be included in the installation package. To have one installation image for situations, workspaces, and the agent itself, the situation, and workspace files must be in the same project as the agent. The Agent Builder provides a wizard to create the appropriate files in the agent project. For information about importing application support files, see [“Importing application support files” on page 1621](#).

### Creating situations, Take Action commands, and queries

Find information to help create situations, Take Action commands, and queries.

To create situations, Take Action commands, and queries, use the Tivoli Enterprise Portal and the embedded Situation editor. For detailed information about how to create situations, see the [Tivoli Enterprise Portal User's Guide](#). You can also use the help documentation that is installed with your Tivoli Enterprise Portal Server. An Agent Builder monitoring agent can recognize and perform special processing for a set of specific Take Action commands. For more information about these special Take Action commands, see [“Take Action commands reference” on page 1720](#).

Situations for system monitor agents are created differently from the Enterprise situations that are created with the Tivoli Enterprise Portal Situation editor or the **tacmd createSit** command. For system monitor agents, private situations are created in a local private situation configuration XML file for the agent. For information about creating situations for system monitor agents, see "Private situations" in the "Agent Autonomy" chapter of the *IBM Tivoli Monitoring Administrator's Guide*.

### Creating workspaces

Place the Tivoli Enterprise Portal in the Administrator mode to create workspaces that you can export and include in your solution.

**About this task**

Build the workspaces in the environment from which they are used. When you build workspaces, change the display settings on your computer to build workspaces at the minimum resolution that is normally used in your environment. Building workspaces at a greater resolution can create views that are too cluttered to be used reasonably at lesser resolutions.

To create workspaces that you can export and include in your solution, the Tivoli Enterprise Portal must be placed in the "Administrator" mode. To place the Tivoli Enterprise Portal in "Administrator" mode, use the following steps:

## Procedure

1. Go to the *ITM\_INSTALL/CNP* directory and open the *cnp.bat* file.

If you used the default installation, the directory is *C:\IBM\ITM\CNP*. In the *cnp.bat* file, you must update the *set \_CMD= %\_JAVA\_CMD%* line to include option *-Dcnp.candle.mode="\$\_KCJ\_\$"*.

If you want to create extensions on Linux or AIX systems, use the following path:

```
/opt/IBM/ITM/li263/cj/bin/cnp.sh
```

Where *li263* is the operating system on which the Tivoli Enterprise Portal is running.

The updated *set \_CMD= %\_JAVA\_CMD%* looks similar to the following example:

```
set _CMD= %_JAVA_CMD% -Dcnp.candle.mode="$_KCJ_$" -Xms64m -Xmx256m -showversion -noverify
-classpath %CPATH% -Dkjr.trace.mode=LOCAL -Dkjr.trace.file=C:\IBM\ITM\CNP\LOGS\kcjras1.log
-Dkjr.trace.params=ERROR -DORBTcpNoDelay=true -Dibm.stream.nio=true
-Dice.net.maxPersistentConnections=16 -Dice.net.persistentConnectionTimeout=1
-Dcnp.http.url.host=SKINANE -Dvbroker.agent.enableLocator=false -Dnv_inst_flag=%NV_INST_FLAG%
%Dnvwc.cwd=%NVWC_WORKING_DIR% -Dnvwc.java=%NVWC_JAVA% candle.fw.pres.CMWAplet
```

**Note:** The command is shown here on multiple lines for formatting reasons only.

2. Open a new Tivoli Enterprise Portal Client, and log in with the *sysadmin* user ID.
3. Set the "sysadmin" user ID in "Administrator" mode. In the Tivoli Enterprise Portal, select **Edit > Administer Users**. Select *sysadmin* and then under the **Permissions** tab, select **Workspace Administration**. Select the **Workspace Administration Mode** check box.

If you make the selection correctly, **\*ADMIN MODE\*** is displayed in the desktop title bar.

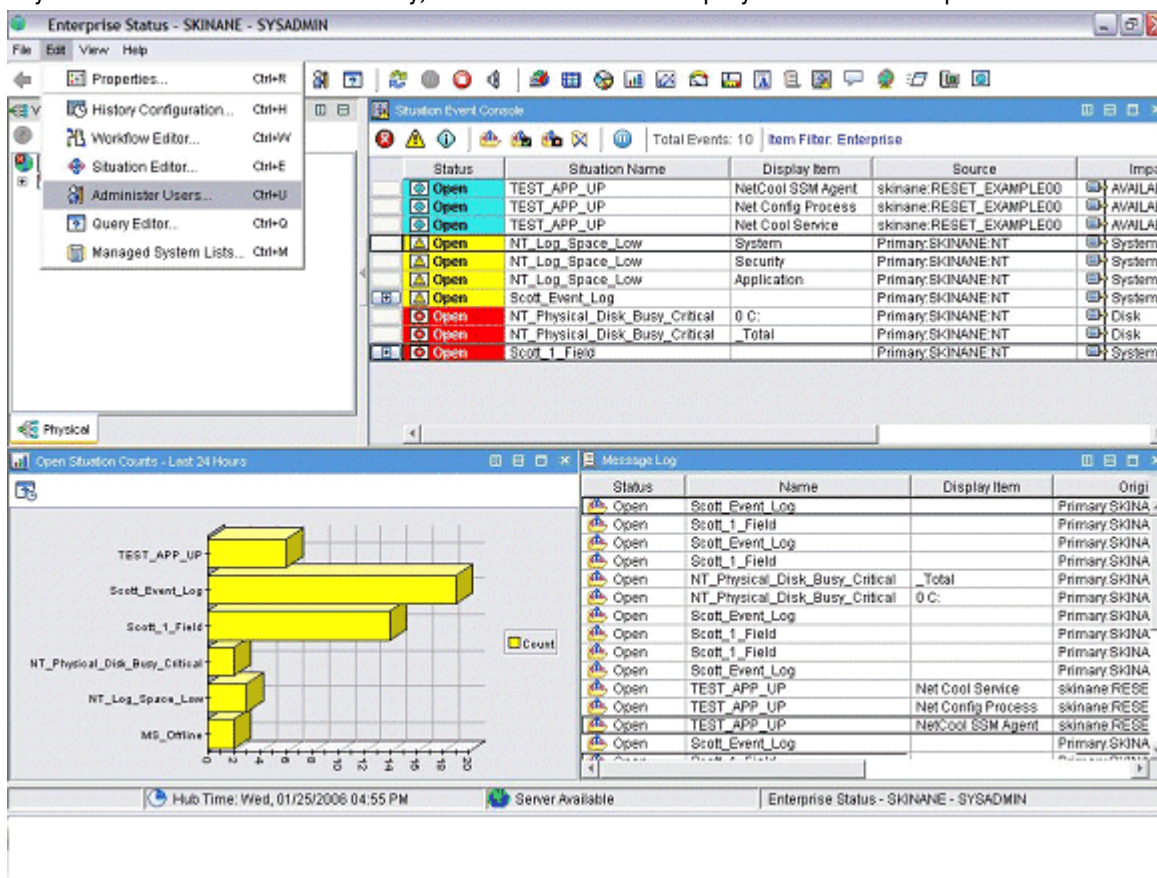

Figure 61. Setting the *sysadmin* user ID

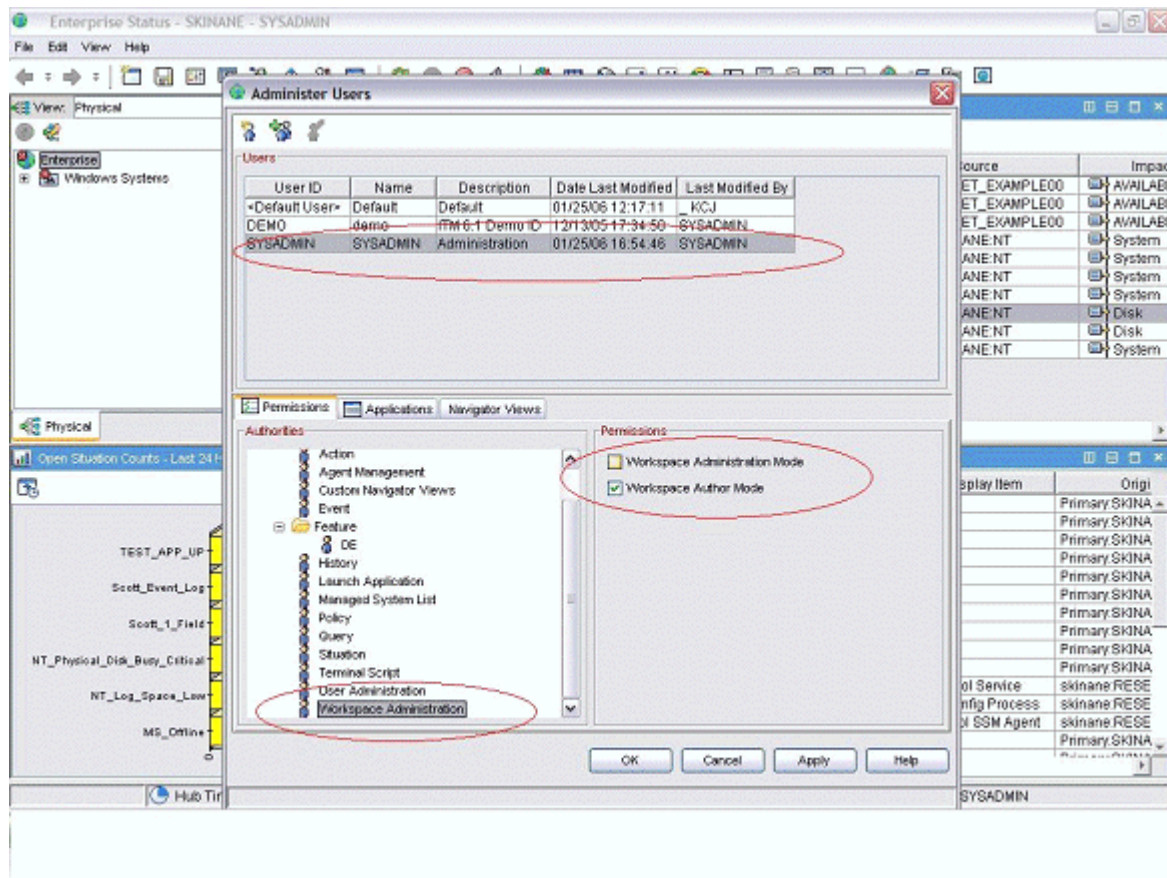

Figure 62. Setting the sysadmin user ID (continued)

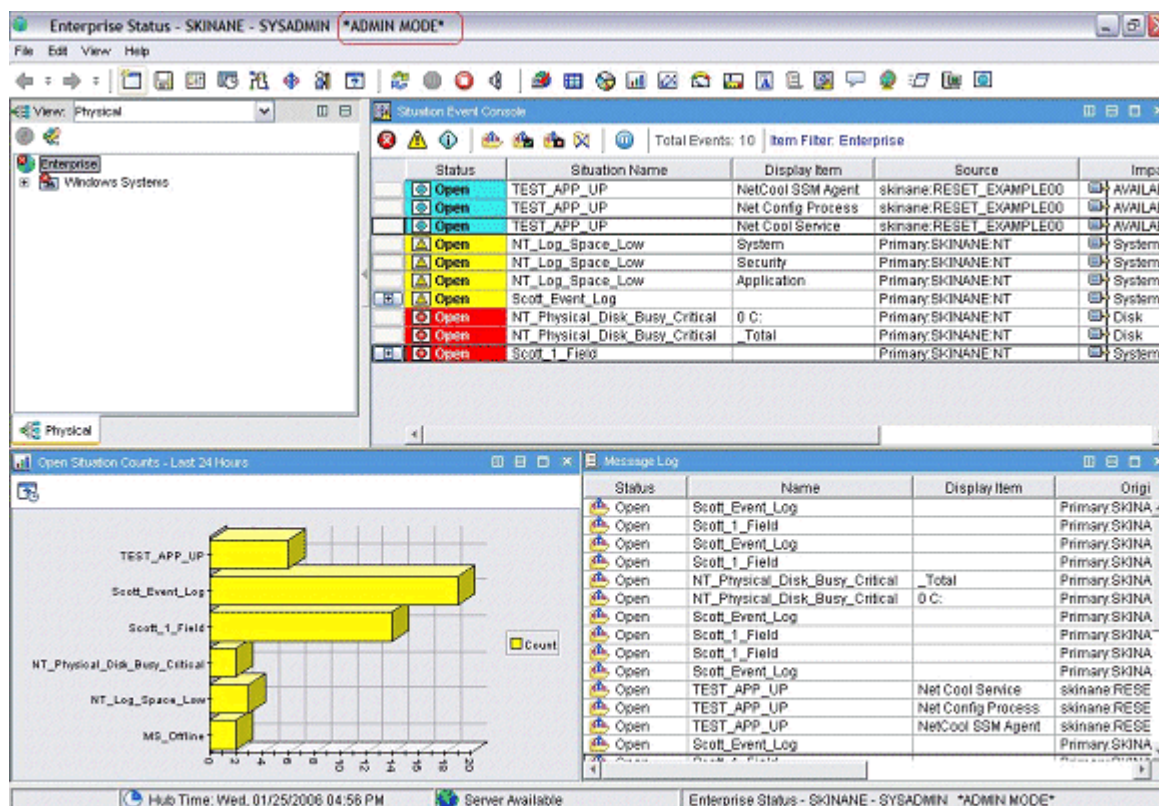

Figure 63. Setting the sysadmin user ID (continued)

## What to do next

After you are in "Administrator" mode as depicted in (Figure 63 on page 1588), you are now ready to create workspaces for your application. For information about how to customize and create workspaces, see the Tivoli Enterprise Portal User's Guide. Alternatively, use the help documentation that is installed with your Tivoli Enterprise Portal component.

If you want your workspaces to be "read-only" and to not be deleted by a customer, set the "not-editable" and "non-deletable" properties for each workspace. In the workspace properties, you must select the following properties:

- **Do not allow modifications**
- **Product-provided by IBM (mark as non-deletable)**

You can go to the properties by either viewing a workspace or clicking the icon with the controls on it. You can also go to one of the view property pages and then going to the workspace level in the properties tree. If you have more than one workspace for each navigator item, remember to set the properties for each workspace. As indicated in the following example screen capture:

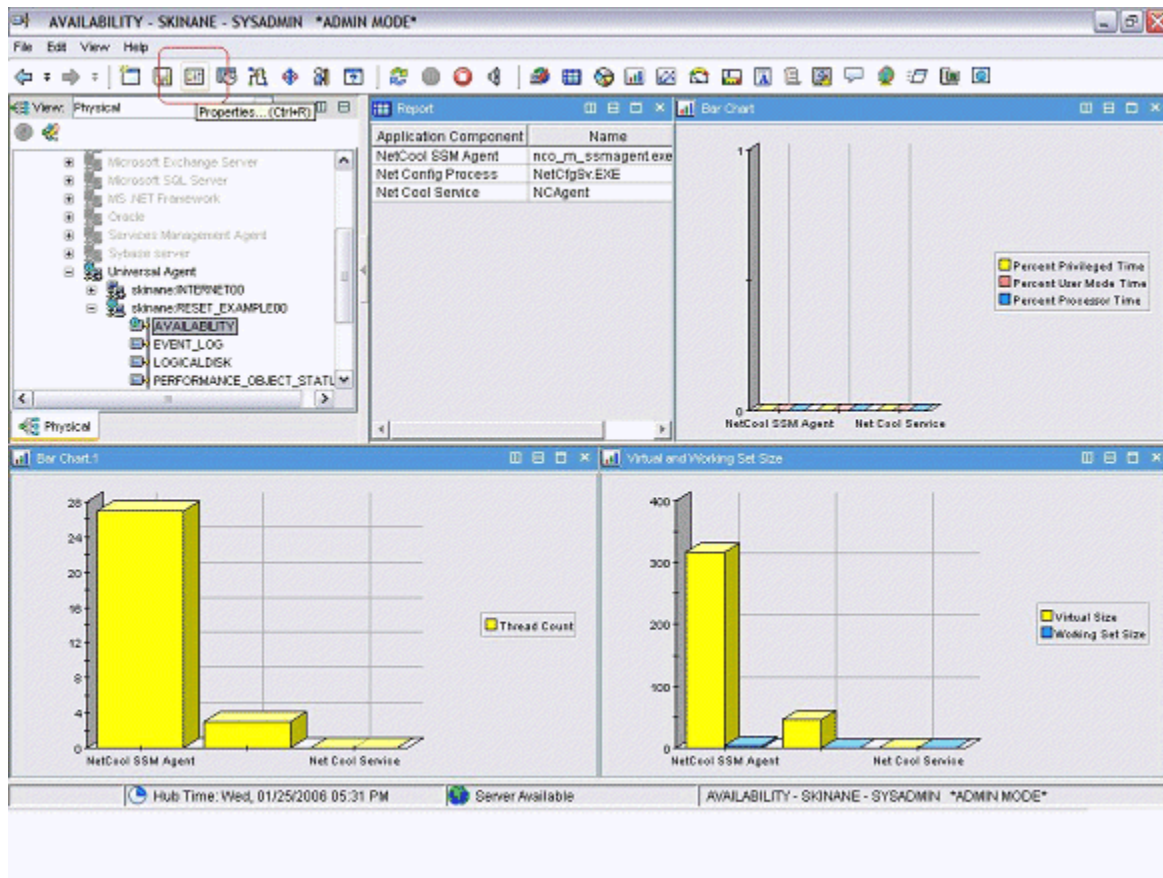

Figure 64. Setting workspace properties

Figure 65. Setting workspace properties (continued)

## Preparing the agent for Cloud APM

If you want to use your agent with IBM Cloud Application Performance Management, you need to prepare it using the **Dashboard Setup** wizard. This wizard configures the information that you can see in the summary and detail dashboards in Cloud APM. It also sets the resource information that Cloud APM requires for the agent.

### Before you begin

In order to prepare the agent for Cloud APM successfully, you need to ensure that the agent provides the following data:

- One or more data sets (attribute groups) that produce one row of data. You can use the attributes from these data sets to populate the summary dashboard.

**Important:** To include any information in the summary dashboard, you need to provide it in a data set that produces a single row of data. Some data sources create data sets that produce multiple rows of data; for example, the process, Windows service, and command return code data sources place data into the single Availability data set, which produces multiple rows. In such cases, you need to create a filtered data set producing one row in order to include the data in a summary dashboard. For instructions, see [“Creating a filtered attribute group”](#) on page 1559.

- A numeric attribute within one of these data sets that indicates the status of the monitored service (normal, warning, critical, or other similar status values). You must define status severity values for this attribute. For instructions about defining status severity values, see [“Specifying severity for an attribute used as a status indicator”](#) on page 1424.

- If the port number on which the monitored application provides service is fixed, you must know the port. If the port might change between different deployments, one of the data sets that produce one row of data must contain a numeric field that indicates the port.
- If the agent can be installed on a host to monitor a server that is running on a different host, a string attribute within one of these data sets that indicates the server IP address. If the agent always monitors the host where it is running, such an attribute is not required.

**Tip:** If an attribute that provides the host name is available, you can create a derived attribute for the IP address by using the `nameToIpAddress` function. For information about creating a derived attribute, see [“Creating derived attributes” on page 1418](#). For information about the function, see [“ipAddressToName” on page 1431](#).

If the agent has subnodes, these requirements apply to each subnode for which you want to create a dashboard.

## About this task

Cloud APM monitors *resources*. A resource corresponds to instance of the agent, or sometimes a subnode. To define a resource, you need to supply a resource type name, server name, IP address, and port number that apply to the monitored service.

Cloud APM displays a summary dashboard for every monitored resource. The summary dashboard includes a status indicator; with this indicator (usually green, yellow, or red for normal, warning, or critical status) the user can see the status of the resource at a glance. The same dashboard can contain a few other high-level health metrics.

On the summary dashboard, data is displayed as single items. Therefore, the data set with this data must produce only one row.

Optionally, a detail dashboard can be available for the agent. The user can click the summary dashboard to view the detail dashboard. The detail dashboard can display tables, so data from any data set can be used on this dashboard.

You must select the attributes that are displayed on the summary dashboard (including the status indicator) and on the detail dashboard.

**Important:** The data in the attributes that you select is automatically passed from the agent to the Cloud APM server every minute. Specifying too much data can lead to overloading of the network, the server, or the monitored host. Select the required attributes only. For example, if a joined data set or a derived attribute must be displayed, do not specify the source attributes as well.

**Important:** No data other than these attributes is passed to Cloud APM. You cannot view or use other data in Cloud APM, except for thresholds, which are monitored at the agent level. If you use other data in thresholds, you might not be able to view the threshold status in the Cloud APM console.

## Procedure

1. From the **Agent Information** view, click the **Dashboards** link.
2. Under **Dashboard Components**, select **Show agent components in the dashboard**.

**Tip:** Alternatively, if you are creating an agent for use exclusively with IBM Tivoli Monitoring, you can select **No dashboard presence for this agent**. In this case, do not complete the subsequent steps of this procedure. You can not install such an agent in a Cloud APM environment.

3. Click the **Dashboard Setup Wizard** link.
4. If the agent has subnodes, define the arrangements of agent and subnode resources in Cloud APM:
  - Select **Base agent instances** to display the base agent (data outside of subnodes) as a resource.
  - For every subnode, select **Subnode "name" instances** to display this subnode as a resource.
  - Optionally, for any of the selected subnodes, select **Show as child of agent**. In this case, the subnode resource is displayed as a child under the agent resource in lists in the Cloud APM console.

Cloud APM displays a summary and detail dashboard for each of the components you selected.

**Important:** If you run the wizard again and unselect an agent or subnode, the resources for the agent or subnode are not removed automatically. To remove the resources, expand **Resources** in the Outline view, select the resources to be deleted, and press the Delete key on the keyboard.

5. In the **Attribute Selection - Status** page, select the attribute that indicates the status of the monitored service. Numeric attributes from groups that return a single data row are available.

**Tip:** Alternatively, if you do not want to display status in the dashboard, unselect **Provide status for this agent**.

6. In the same page, you can select whether you want to display additional data in the summary and detail dashboards:
  - To display additional high-level health metrics in the summary dashboard, ensure the **Select additional attributes to display in this agent's summary information** box is selected. Otherwise, clear the box.
  - To display additional data in the detail dashboard, ensure the **Select additional attributes to display in this agent's detail information** box is selected. Otherwise, clear the box. (Typically, select this box, as a detail dashboard is required to display enough data to make a monitoring agent meaningful).

Click **Next**.

7. If you selected **Select additional attributes to display in this agent's summary information**, in the **Attribute Selection - Summary** page, select up to four additional attributes to include in the summary dashboard. Attributes from groups that return a single data row are available. Click **Next**.
8. If you selected **Select additional attributes to display in this agent's detail information**, in the **Attribute Selection - Details** page, select the attributes to include in the detail dashboard. All attributes in the agent are available; to avoid performance issues, include as few attributes as possible. Click **Next**.
9. In the **Resource Type** page, enter the server type that you are monitoring, for example, Email server or SampleCo Database Server. Click **Next**.
10. In the **Attribute Selection - Software Server Name** page, enter a fixed software server name in the **Fixed Name** field or select an attribute from your agent that gives the software server name. This name is displayed to the user for this particular monitored instance, for example, the name of the JBoss application server instance. Click **Next**.

**Important:** Do not run two or more monitoring agents, agent instances, or subnodes with the same software server name on the same monitored host. If your agent has instances or subnodes, ensure that a unique software server name is generated for every instance or subnode. If two different agents produce the same software server name, do not install them on the same monitored host.

11. In the **Attribute Selection - IP address** page, select an attribute from your agent that specifies the IP address (not host name) of the primary interface connection that the monitored server or application uses. For example, the HTTP connection for an HTTP server or the database client connection for a database server. Alternatively, select **Use the agent's IP address** to use the address of the host where the agent runs. Click **Next**.
12. In the **Attribute Selection - Port** page, enter the port on which the monitored application provides service or select a numeric attribute from your agent that specifies this port. Click **Finish**.
13. If you selected both an agent and a subnode or more than one subnode as resources, click **Next** to enter dashboard and resource information for the next component (agent or subnode). If the **Next** button is disabled, you entered the information for all necessary components; click **Finish** to complete the wizard.

## Results

When you install the agent on a monitored host, you can view the summary and detail dashboards in the **Status Overview** tab.

**Important:** There can be a delay of up to 30 minutes between installation of the agent and availability of the dashboards, especially if this is the first time that this agent type and version is installed in your environment.

Click the summary dashboard for the agent to view the detail dashboard. By default, all information in the detail dashboard is displayed as tables.

You can use the **Attribute Details** tab to configure custom display of this information as tables and charts.

## Preparing the agent for Cloud Pak for Multicloud Management

---

If you want to use your agent with IBM Cloud Pak for Multicloud Management, you need to prepare it using the **Resource wizard**. The Resource wizard creates a resource definition. You can also establish relationships between defined resources using the **Relationship wizard**.

### Defining resources

Use the Resource wizard to create or modify resource definitions for your agent so that you can see their monitoring data in the Resources dashboard on the Cloud Pak console.

#### Before you begin

The resource definition process reads the agent definition and allows you to build resources. But if you then edit the agent definition to add an attribute, rename an attribute, add an attribute group, or delete either one, these changes are not automatically reflected in the resource definition. For this reason, ensure that you have the correct data before you run the Resource wizard.

#### About this task

Resources are defined by resource types, and when the agent runs it will create resource instances that are displayed in the console. Resource types define a set of properties and metrics that provide the identity and metrics related to a managed resource.

Use the Resource wizard to create or edit a resource definition for the agent. The resource definition then automatically generates the widgets for the Resources dashboard. In the Resource wizard, you define an attribute group; this attribute group provides the data for the basic widgets in the Resources dashboard. Optionally, you can also add components; components are extra tables of data that appears in the Resources dashboard below the Events timeline widget. You can add as many component tables as you need.

When you run the Resource wizard, the following widgets are created and displayed in the IBM Cloud Pak for Multicloud Management Resources dashboard:

- Events timeline
- Line graphs that display data for the "important" metrics (see step [“5” on page 1594](#) for a description)
- Tabular display of the metrics in the main resource attribute group
- Optional (s) for each component created
- Related resources widget

In addition, if you have a status attribute in the attribute group that defines a resource, a threshold is automatically created in the Cloud Pak console.

### Procedure

Complete these steps to define or edit a resource for the agent:

1. Select **Agent Definition>Resources**, the **Introduction** window is displayed, click **Next**.
2. In the **Resource Information** window, select **Add new Resource**, click **Next**.
3. In the **Attribute Group Selection** window, select an attribute grouping. At a minimum, the attribute grouping needs to identify the resource.

4. In the **Resource Information** window, enter a name and description for the resource. The name that you enter corresponds to the name you see in the Resources types list in the Resources dashboard. The description also appears in the resource list in the Resource tab. You can use any characters for name or description.
5. In the **Attributes** window, you can assign different characteristics to your attributes.
  - **Not Available:** Use this to eliminate the attribute completely from both the Resources dashboard and the Threshold manager.
  - **Not uploaded to the server, available for threshold calculation:** Use this to indicate that the attribute data isn't uploaded by default. Use this if you don't want this attribute to be displayed in the Resources dashboard, but you do want to be able to create thresholds against it in the Threshold manager.
  - **Metric describes the state of the resource instance at a given time.** Use this to assign a string as a metric. Usually all strings are properties and all numbers are metrics (unless you earlier explicitly specified otherwise in the Attribute editor, for more information, search for 'purpose' in table 1 in the [“Numeric aspects of attributes” on page 1422](#) topic.
  - **Property describes the resource instance:** Use this to assign a numeric as a property. By default all the strings are properties and all the numbers are metrics.
  - **Display Name:** By default the display name and key property is the node name. This is indicated with "D" in the **Opt** column. When node name is the display name, you see the origin node name from IBM Tivoli Monitoring displayed in the selection lists in the Resources dashboard. If there is an attribute that is more suited to being the display name, select Display name for that attribute.
  - **Important:** This indicates that a metric is represented in a line chart in the Resources dashboard. The label and grouping for the line chart is based on the unit that you specified when you defined the attribute. For more information, see [“Numeric aspects of attributes” on page 1422](#). It is recommended indicating 1 - 4 metrics as important.
6. If you want more tables to present extra data in the resource, add a component, you add one component for each table you want to add to a resource. In the **Component selection** window, select **Add a new component**. Click **Next**.
7. In the **Component Information** window, enter a name and description for the component. The name that you enter corresponds to the name that is given to the table in the Resources dashboard. You can use any characters for name or description. Click **Next**.
8. Repeat step [“3” on page 1593](#) and [“5” on page 1594](#). Click **Finish**.

## Results

You can now view the Resource dashboard in the Cloud Pak console. Representations of your resource definition are presented in these Resource dashboard widgets:

- Events timeline
- Line graphs that display data for the "important" metrics (see step [“5” on page 1594](#) for a description)
- Tabular display of the metrics in the main resource attribute group
- Optional (s) for each component created
- Related resources widget

## Building resource relationships

After you have created your resource definitions, you can create a relationship between two resources using the **Relationship wizard**.

### About this task

The Relationship wizard guides you through setting up a resource relationship for enriching the interaction and display of data in the Resource dashboard between two resources. For example, you can set up a

relationship for an application resource that runs on the Operating system (the target resource). You can then see the linkage in the Resource dashboard when the operating system is slow or fails, and how it affects the application.

## Procedure

Complete these steps to create or edit a resource relationship:

1. Select **Agent Definition > Relationship** to open the **Introduction** window, and then click **Next**.
2. In the **Relationship Selection** window that displays, choose to add or modify a relationship:
  - To define a new relationship, click **Add a new relationship**, and click **Next**.
  - To edit an existing relationship, select it from the list, click **Modify selected relationship**, and click **Next**.
3. Create or edit the resource relationship definition:
  - a) For **Source resource**, select the main resource.
  - b) For **Relationship type**, select the option that describes the relationship: is a federation of, runs on (and depends on), is a member of, defines, has been assigned to, manages, or uses.
  - c) For **Target resource**, select the target resource.
  - d) If you selected a source resource or target resource that is a *single-instance* resource (does not specify keys), click **Finish**.
  - e) If you selected a source and target that are both *multi-instance* resources, click **Next**, and select which resource properties to use to match the related resources.  
You can add multiple properties if you want multiple key attributes that match.

**Note:** To define a relationship to an *operating system*, select by selecting the check box for **Relationship is with the operating system the agent is running on**.

## Results

You can observe the relationship in the Resource dashboard for your agent in the Cloud Pak console.

## Data Definition Designer

---

For information about the Data Definition Designer, see [The Data Definition Designer guide](#).

## Testing your agent in Agent Builder

---

After you use Agent Builder to create an agent, you can test the agent in Agent Builder.

Test the agent to ensure that the monitoring data you are expecting is the data that is being displayed. By testing your agent, you can learn to modify or tweak settings in the agent to ensure that the data displayed is beneficial and accurate.

You can test your agent in Agent Builder by using the following methods:

1. Begin by using the attribute group test function of Agent Builder to test individual attribute groups one at a time. For more information, see [“Attribute group testing” on page 1596](#).
2. After you complete attribute group testing, you can use the agent test function of Agent Builder to test all attribute groups in your agent together. For more information, see [“Full agent testing” on page 1599](#).

**Important:** When testing your agent in Agent Builder, you can see the following special values for numeric attributes:

- -1: a general error
- -2: missing data
- -3: no value (for example, NULL was returned by a database)

## Attribute group testing

You can use attribute group testing to test the attributes groups of the agent you created with Agent Builder, one attribute group at a time. You can test many attribute groups before you complete the attribute group definition. For example, you can initiate testing from the **IBM Tivoli Monitoring Agent Wizard** when you are defining the attribute groups of a new agent. You can also initiate testing from the **IBM Tivoli Monitoring Agent Component Wizard** when you are adding attribute groups to an existing agent.

### Before you begin

Before you start testing an attribute group, you can optionally:

- Set attribute group testing preferences. For more information, see [“Attribute group testing - preferences”](#) on page 1597.
- Set environment variables, configuration properties, and where applicable Java information. For more information, see [“Attribute group testing - configuration”](#) on page 1598.

### About this task

Agent Builder supports an attribute group test function for most data sources

### Procedure

- Start the Testing procedure in the following ways:
  1. During agent or attribute group creation click **Test** on the relevant data source Information page.
  2. After agent creation, select an attribute group on the Agent Editor **Data Source Definition** page and click **Test** . For more information about the Agent Editor, see [“Using the Agent Editor to modify the agent”](#) on page 1398.

After you click **Test** in one of the previous two steps, the Attribute group Test window is displayed. This window is different for different data sources,

Agent Builder supports an attribute group test function for most data sources.

For more information about the test procedures for specific attribute groups, see the following Testing sections:

- Windows Management Instrumentation (WMI), for more about the WMI test procedure, see [“Testing WMI attribute groups”](#) on page 1449
- Windows Performance Monitor (Perfmon), for more about the Perfmon test procedure, see [“Testing Perfmon attribute groups”](#) on page 1451
- Simple Network Management Protocol (SNMP), for more about the SNMP testing, see [“Testing SNMP attribute groups”](#) on page 1455
- Simple Network Management Protocol (SNMP) event sender, for more about the SNMP event test procedure, see [“Testing SNMP event attribute groups”](#) on page 1460
- Java Management Extensions (JMX), for more about the JMX test procedure, see [“Testing JMX attribute groups”](#) on page 1479
- Common Information Model (CIM), for more about the CIM test procedure, see [“Testing CIM attribute groups”](#) on page 1482
- Log file, for more about the log file test procedure, see [“Testing log file attribute groups”](#) on page 1491
- Script, for more about the script test procedure, see [“Steps for monitoring output from a script”](#) on page 1502
- Java Database Connectivity (JDBC), for more about the JDBC test procedure, see [“Testing JDBC attribute groups”](#) on page 1512

- Internet Control Message Protocol (ICMP) ping, for more about the ICMP test procedure, see [“Testing Ping attribute groups” on page 1515](#)
- Hypertext Transfer Protocol (HTTP) Availability, for more about the HTTP test procedure, see [“Testing HTTP attribute groups” on page 1522](#)
- SOAP, for more about the SOAP test procedure, see [“Testing SOAP attribute groups” on page 1530](#)
- Transmission Control Protocol socket (TCP) socket, for more about the socket test procedure, see [“Testing socket attribute groups” on page 1540](#)
- Java application programming interface (API), for more about the Java API test procedure, see [“Testing Java application attribute groups” on page 1553](#)

Some data sources do not have an attribute group test function, for example:

- When you can use the Agent Builder browser to view live data on a system. For example, you can view the processes that are currently running on the system (processes). Other examples are when you can view the services that are installed on the system (windows services) and the Windows Event Logs that are present.
- There is little or no customization that you can do in the agent (AIX Binary Log, command return code).
- Joined and Filtered attribute groups cannot be tested by using the attribute group test function because these groups are based on multiple attribute groups.

**Note:**

1. Use the full agent test to test data sources that cannot be tested by using the attribute group test function. For more information about the full agent test, see [“Full agent testing” on page 1599](#).
  2. When you test data sources, after you click **Collect Data**, data might not be displayed at all or might not be current after the first click. In such cases, click **Collect Data** a second time to display current data.
- Debugging:

Each data source that is tested has a test directory that is created for it by Agent Builder. This directory is used for the test runtime environment of the data source. Log files that relate to tests run on the data source are stored under this directory. The log files can be useful to help debug issues that are found during testing.

**Note:**

1. The location of the test log file is shown as a status message in the **Test** window after you click **Start Agent** and also after you click **Stop Agent**.
2. All test data source directories are deleted when the Agent Builder is shut down.

## Attribute group testing - preferences

Set preferences before you test an attribute group.

### About this task

Before you start testing an attribute group, you can optionally set some preferences that determine how attributes are treated during testing.

### Procedure

1. Select **Window > Preferences** from the Agent Builder menu bar.  
The **Preferences** window opens.
2. Select **Agent Builder**.

The preferences that are associated with testing attribute groups are shown:

### Show data types changed dialog when testing

When selected, Agent Builder suggests changes to the data type of an attribute. Agent Builder suggests changes when the data type of an attribute does not match the data that is returned by a test for that attribute. For example, if the string length defined for an attribute is too short to hold a value that is returned by a test. In this example, Agent builder suggests redefining the attribute to have a longer string length. When this option is cleared, Agent Builder does not check or suggest data types during testing. This option is selected by default.

### Maximum script or log attributes created

The value that is entered in this field determines the maximum number of attributes that Agent Builder parses during the initial test of a log file or script attribute group. The default value is 25.

3. When you are finished setting your preferences, click **OK** to save your settings and close the **Preferences** window.

If you want to restore the default settings, click **Restore Defaults** before you click **OK**

## Attribute group testing - configuration

Set environment variables, configuration properties, and Java information before you test an attribute group.

### About this task

Before you start testing an attribute group, you can optionally set environment variables, configuration properties, and where applicable Java information from the data source Test window. The Java information is a subset of the configuration data. Some environment variables have special values that are set by default for attribute group testing. For more information about environment variables with special values for attribute group testing, see [“Test Environment variables” on page 1603](#).

### Procedure

1. Optional: Click **Set Environment** from the data source **Test** window.  
The **Environment Variables** window opens. When populated, the **Environment Variables** window lists all of the environment variables that are used during the running of the test. The initial view of the Environment variable window contains any existing environment variables that are defined in your agent. It also contains any environment variables that you added from previous tests of this agent.
  - a) Click **Add** or **Edit** to add or edit individual variables.
  - b) Click **Remove** to remove individual variables, or **Restore Default** to restore default variables and remove all others.
  - c) Click **OK** to save your changes and return to the **Test** window.
2. Optional: Click **Configuration** from the data source **Test** window. The **Runtime Configuration** window opens.
  - a) Click **Edit Agent Configuration** to add a configuration property or to edit existing agent configuration properties by using the **Configuration Properties** window.
  - b) Select a configuration property and click **Edit** to edit an existing configuration property that relates to the attribute group you are testing.
  - c) Select a configuration property and click **Restore Default** to restore a configuration property to its default value.

**Important:** If a JMX data source connects to a remote WebSphere Application Server, ensure that a local WebSphere Application Server is installed and that the Java location is set to the JRE that this server uses. For details about setting up the connection, see [“Monitoring Java Management Extensions \(JMX\) MBeans” on page 1461](#).

3. Click **OK** to save your changes and return to the **Test** window.
4. **Note:** You can set Java information for following types of attribute groups:
  - Java Management Extensions (JMX)

- Java Database Connectivity (JDBC)
- Hypertext Transfer Protocol (HTTP) Availability
- SOAP
- Java application programming interface (API)

The Java information is a subset of the configuration data described in step “2” on page 1598

Optional: Click **Java Information** from the data source **Test** window.

The **Java Information** window opens.

- Enter Java Information.  
For example, Browse to or type the location of the Java Runtime Environment (JRE), select a **Java trace level**, or enter **JVM arguments**
- Click **OK** to save your changes and return to the **Test** window.

## Full agent testing

Use full agent testing to test all attribute groups of your agent together. You can also use full agent testing to test data sources that cannot be tested by using the attribute group test function.

### About this task

You can use full agent testing to run the agent in the same way it runs in IBM Tivoli Monitoring without needing an IBM Tivoli Monitoring installation.

**Important:** On Windows systems, If you want to run a full test of the agent inside Agent Builder (see “Full agent testing” on page 1599), ensure that the 32-bit version of the operating system on which you are running the Agent Builder, that is, 32-bit Windows, is selected in the Agent Information window. On Linux systems, the 64-bit version must be selected.

### Procedure

- Open the **Agent Test** perspective:
  - In the agent editor, open the **Agent Information** tab.
  - Click **Test the agent**.

Figure 66. **Test Agent** section of the **Agent Editor**, **Agent Information** page.

Alternatively, from the Agent Builder menu select **Window > Open Perspective > Other**, select **Agent Test** and click **OK**

The **Agent Test** perspective opens (Figure 68 on page 1601). The **Agent Test** view shows agents that you have opened in the agent editor; you can test any of these agents. An **Attribute Group Test** view is also displayed; this view is initially empty. The **Attribute Group Test** view shows data that is collected from a selected attribute group when the agent is running.

**Tip:** If no agents are being edited, the **Agent Test** perspective is empty. To populate the view, go to the **IBM Tivoli Monitoring** perspective and open an agent in the **Agent Editor**. When an agent is opened in the **Agent Editor** return to the **Agent Test** perspective to test the agent.

- Optional: Configure environment variables and configuration properties before you start the test.

You can access the **Environment Variables** and **Runtime Configuration** windows in two ways from the **Agent Test** view:

- Right-click the agent in the **Agent Test** view to open a selection menu. You can select **Set Environment** from the menu to open the **Environment Variables** window. You can select **Configuration** from the menu to open the **Runtime Configuration** window.

- Click the view menu icon  on the **Agent Test** view toolbar to access the **Set Environment** and **Configuration** menu items as in the previous choice.

For more information about using the **Environment Variables** and **Runtime Configuration** windows, see [“Attribute group testing”](#) on page 1596.

**Important:**

- The agent is populated automatically with the last set of configuration that relates to each tested attribute group.
- Some environment variables can have different default values for attribute group testing and for full agent testing. For more information about environment variables with special values for attribute group testing, see [“Test Environment variables”](#) on page 1603).
- If a JMX data source connects to a remote WebSphere Application Server, ensure that a local WebSphere Application Server is installed and that the Java location is set to the JRE that this server uses. For details about setting up the connection, see [“Monitoring Java Management Extensions \(JMX\) MBeans”](#) on page 1461.
- In a Java API, JDBC, JMX, HTTP, or SOAP data source, you can use the **Java > JVM arguments** setting to control agent trace logging. Set the following value:

```
-DJAVA_TRACE_MAX_FILES=files -DJAVA_TRACE_MAX_FILE_SIZE=size
```

where *files* is the maximum amount of trace log files that are kept (the default value is 4) and *size* is the maximum log file size in kilobytes (the default value is 5000). For example, you can set the following value:

```
-DJAVA_TRACE_MAX_FILES=7 -DJAVA_TRACE_MAX_FILE_SIZE=100
```

In this case, the agent writes 100 kilobytes into the first log file, then switches to the second log file, and so on. After writing seven log files of 100 kilobytes each, it overwrites the first log file.

- If your agent has subnodes, in an installed version you can set different configuration values for different subnodes and separately for the base agent attribute groups. However, in full agent testing configuration you can only set every configuration value once; the setting applies to the base agent and any subnodes. You can only test one instance of every subnode.
- In the **Agent Test** view, select the agent that you want to test and click the  **Start Agent** icon.

A window indicates that the agent is starting. When the agent starts, its attributes groups are shown as children of the agent in the **Agent Test** view. The attribute groups are indicated by the attribute group icon .

The status attribute groups that give information about the agent (**Performance Object Status**, **Thread Pool Status** and **Take Action Status**) are also shown as children of the agent in the **Agent Test** view. The status attribute groups are indicated by the  information icon.

You can start and run more than one agent at the same time.

The  **Stop Agent** icon becomes available when the agent is started.

If your agent has subnodes or navigator groups, they are shown as nodes in the **Agent Test** view. Subnode definitions are shown under the agent. A subnode instance node is shown under the subnode definition node. Attribute groups and navigator groups are shown under the subnode instance node. For example:

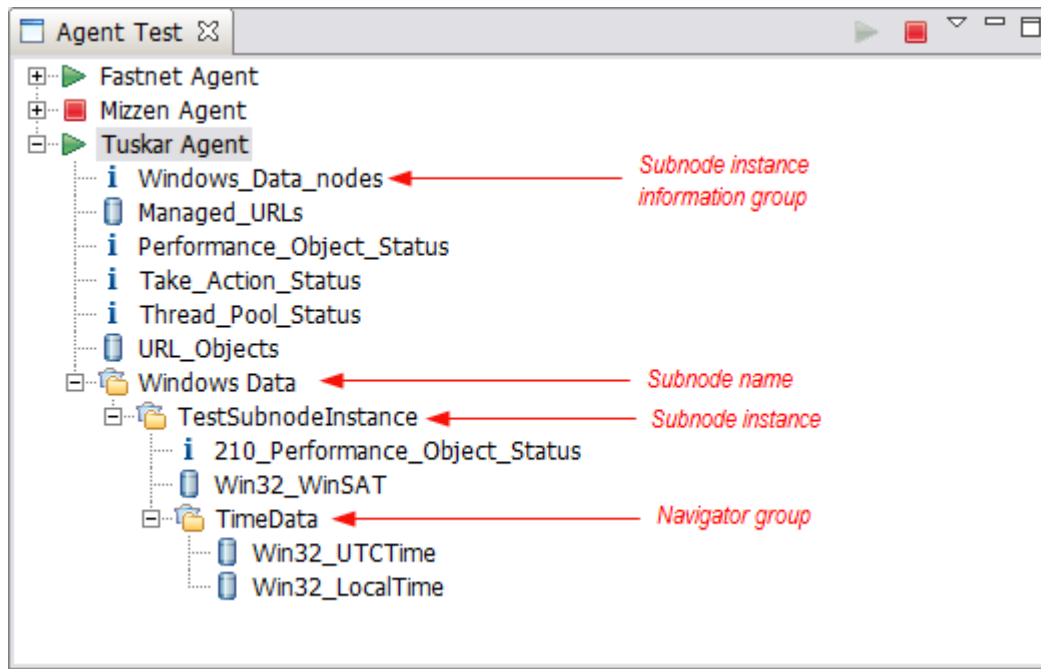

Figure 67. **Agent Test** view with example subnode and navigator group highlighted.

You can right-click on any of the nodes in the **Agent Test** view to access menu selections like **Edit** and **Stop Agent**. **Edit** opens the **Data Source Definition** for the selected node in the **Agent Editor**.

**Note:** Changes that you make with the **Agent Editor** are not visible in the running agent until you stop and restart the agent.

4. In the **Agent Test** view, select the first attribute group that you want to test.

When you select an attribute group, a data collection begins for the selected attribute group. If the collection takes some time, a window indicates that the data collection is in progress. When the data collection is complete the collected data is displayed in the **Attribute Group Test** view, for example:

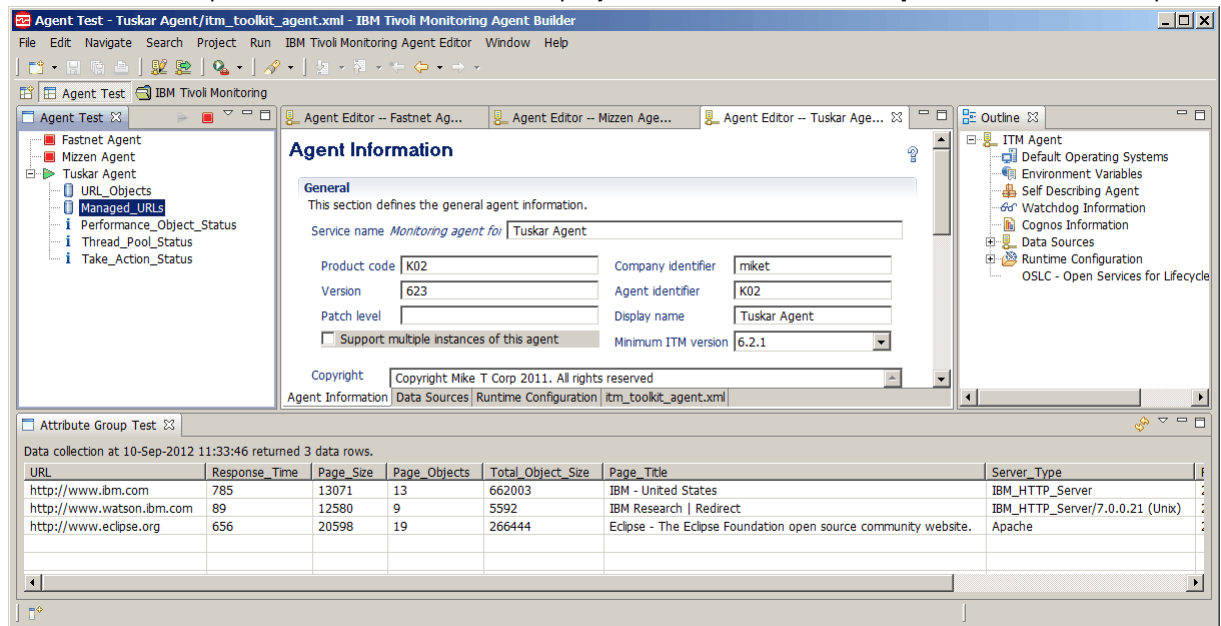

Figure 68. **Agent Test** perspective

If no data is displayed, a message 0 data rows returned is shown in the **Attribute Group Test** view. There are several reasons why the agent might not return data. These reasons include:

- There is no data
- Incorrect definition
- Incorrect configuration

You can check the reason why no data is returned by looking at the value of the **Error\_Code** in the **Performance Object Status** attribute group. For more information about viewing the **Performance Object Status** attribute group, see step “9” on page 1602

To collect data for another attribute group in the running agent, select the required attribute group.

When you select an attribute group in the **Agent Test** view, the corresponding attribute group is displayed in the **Agent Editor** view.

5. Optional: Run a second data collection, after the initial data collection, for certain attribute group types, to get useful data values.

To run a data collection, click the collect data icon  in the **Attribute Group Test** view.

If the collection takes some time, a window indicates that a data collection is in progress. When the data collection is complete, the newly collected data is displayed in the **Attribute Group Test** view.

6. Optional: Click an attribute column heading in the **Attribute Group Test** view to open the **Attribute Information** in the **Agent Editor Data Source Definition** tab. You can also access the same **Attribute Information** by right-clicking on any data cell in the table and choosing **Edit** from the menu.

You can edit properties of the attribute in the normal way. Changes that you make are not visible in the running agent until you stop and restart the agent.

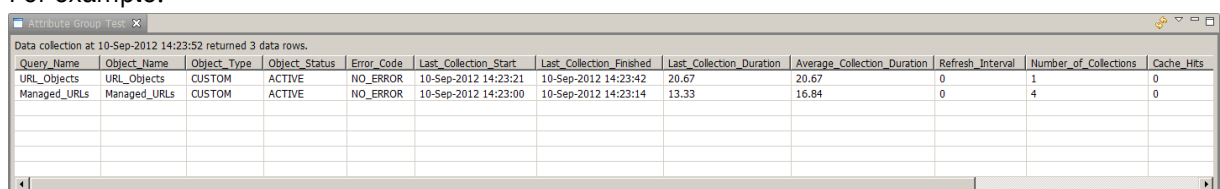

7. Optional: Open multiple **Attribute Group Test** views at the same time.

To open an additional **Attribute Group Test** view, click the view menu icon  on the **Attribute Group Test** view toolbar and then select **Open view for attribute group**.

**Note:** When an additional **Attribute Group Test** view is opened, it displays the same attribute information as the original **Attribute Group Test** view. You can then select another attribute group in the **Agent Test** view to display different attribute group information in the original **Attribute Group Test** view. The first time another **Attribute Group Test** view is opened, it opens in the same location as the original view but with its own tab. If you want to see the two views simultaneously, you can drag the tab to another location in the workspace.

8. Optional: Select the subnode instance information attribute group, if your agent has subnodes, to see how the subnodes are listed in your agent (Figure 67 on page 1601). Selecting the subnode instance information attribute group shows subnode instance information in the **Attribute Group Test** view (for all online subnodes of the selected type).
9. Optional: To see more information about the operation of the agent, you can select the **Performance Object Status** and **Thread Pool Status** attribute groups in the **Agent Test** view. These status attribute groups are indicated by the information icon . Select these groups to see status information about earlier data collections for your attribute groups.

For example:

| Query Name   | Object Name  | Object Type | Object Status | Error Code | Last Collection Start | Last Collection Finished | Last Collection Duration | Average Collection Duration | Refresh Interval | Number of Collections | Cache Hits |
|--------------|--------------|-------------|---------------|------------|-----------------------|--------------------------|--------------------------|-----------------------------|------------------|-----------------------|------------|
| URL_Objects  | URL_Objects  | CUSTOM      | ACTIVE        | NO_ERROR   | 10-Sep-2012 14:23:21  | 10-Sep-2012 14:23:42     | 20.67                    | 20.67                       | 0                | 1                     | 0          |
| Managed_URLs | Managed_URLs | CUSTOM      | ACTIVE        | NO_ERROR   | 10-Sep-2012 14:23:00  | 10-Sep-2012 14:23:14     | 13.33                    | 16.84                       | 0                | 4                     | 0          |

Figure 69. The **Attribute Group Test** view that shows more information (Performance Object Status) about data collections for the **Managed\_URLs** and **Managed\_Nodes** attribute groups

10. When you are finished testing your agent, click the stop agent icon 

## Test Environment variables

Use these environment variables to control the behavior of the agent during testing.

Environment variables are dynamic named values that determine how the agent runs. For attribute group test, some agent environment variables are set to special values. The special values are used so that the agent responds in a way that suits the testing of a single attribute group. For full agent test special values are not used and instead the default values are used. The default values mean that the agent behaves as it normally would, which is more appropriate to full agent testing.

The environment variables that have special values for attribute group testing are summarized in the following table. For more information about all agent environment variables, see ([“List of environment variables” on page 1401](#)). For more information about setting environment variables, see ([“Environment variables” on page 1400](#)).

| Table 335. Environment variables |                                 |                            |   |
|----------------------------------|---------------------------------|----------------------------|---|
| Environment variable             | Default value (full agent test) | Attribute group test value | Reason for changed value for attribute group test   |
| CDP_DP_INITIAL_COLLECTION_DELAY  | varies                          | 1                          | This value applies to an agent with a thread pool. This value is the time in seconds that the thread pool waits before the initial data collection request is sent to a data provider.<br><br><b>Note:</b> If CDP_DP_INITIAL_COLLECTION_DELAY is not set, the thread pool waits for a time that is specified by CDP_DP_REFRESH_INTERVAL or CDP_ATTRIBUTE_GROUP_REFRESH_INTERVAL. This wait time is the same time the thread pool waits between data collections, and might be too long to wait for the first data collection. |
| CDP_DP_CACHE_TTL                 | 55                              | 1                          | When set to 1 a Collect Data request is much more likely to cause the data provider to collect data immediately. Otherwise it might return cached data that is up to 60 seconds old.  |

## Installing your agent into a monitoring infrastructure for testing and use

After you test your agent in Agent Builder, you can install the agent into an existing IBM Tivoli Monitoring, IBM Cloud Application Performance Management or IBM Cloud Pak for Multicloud Management environment for further testing and for use.

Installing and testing your agent in a monitoring infrastructure has the following benefits:

- You can configure and test multiple instances of an agent that run simultaneously.
- You can configure and test multiple instances of subnodes that run simultaneously.
- In a Tivoli Monitoring environment, you can build workspaces, situations, actions, and queries in the Tivoli Enterprise Portal.

**Important:** Deploy initial versions of your agent into a test version of the monitoring infrastructure. On Tivoli Monitoring, use a separate monitoring server and portal server. On Cloud APM, use a test cloud account or a separate test deployment of the on-premises monitoring server. Deploy the final version of your agent on a production infrastructure.

If you deploy a version of the agent on the production monitoring infrastructure and then change any data sets in the agent, the new version might conflict with the older version on the server. In this case it might be impossible to use any version of the agent.

## Installing an agent

There are two methods for installing the agents that you create with Agent Builder.

1. To test your agent with a monitoring infrastructure that is running on the same system as the Agent Builder, you can install the agent into the local Tivoli Monitoring or Cloud APM installation.
2. To test or use the agent with a Tivoli Monitoring or Cloud APM system that is not running on the same system as the Agent Builder, you can generate a compressed file (*agent package*) that you can transfer to the other systems and deploy.

### Note:

1. With Tivoli Monitoring, after you install an agent, you can see performance metrics in the Tivoli Enterprise Portal tables. For support of situations or workspaces, see [“Importing application support files” on page 1621](#).
2. With Tivoli Monitoring, after you install the agent, you can use the Tivoli Enterprise Portal to verify the data from the agent. For more information, see [“Changes in the Tivoli Enterprise Portal” on page 1615](#). If after you view the data in the Tivoli Enterprise Portal, you want to modify the agent, see [“Using the Agent Editor to modify the agent” on page 1398](#).
3. For an agent that supports Linux or UNIX, generate the installer image on a Linux or UNIX system because a Linux or UNIX system creates the files with the appropriate permissions.

## Installing an agent locally

Install the agent into a monitoring environment on the local system where Agent Builder is running.

### About this task

Complete the following steps to install your agent into a monitoring environment on the local system:

1. Click the `itm_toolkit_agent.xml` file from the Project Explorer navigation tree of Agent Builder by using one of the following methods:
  - a. Right-click the `itm_toolkit_agent.xml` file and select **IBM > Generate Agent**.
  - b. Select the `itm_toolkit_agent.xml` file and select the  **Generate Agent** icon on the toolbar.
  - c. Double-click the `itm_toolkit_agent.xml` file and select **Agent Editor > Generate Agent**.
2. In the **Generate Agent Wizard** window, in the **Install the Agent Locally** section, enter the installation directory for the monitoring infrastructure. The Agent Builder completes the value that is found in the `CANDLE_HOME` environment variable. If this variable is not set, the default value for Windows, `C:\IBM\ITM`, is displayed.

The check boxes are enabled as follows:

#### Install the agent

Enabled if the Agent Builder detects an appropriate Tivoli Enterprise Monitoring Agent or a IBM Cloud APM agent in the specified location. An appropriate agent is one that supports the local operating system and is the correct minimum version.

#### Install the TEMS support

Enabled in a Tivoli Monitoring environment if the Agent Builder detects a Tivoli Enterprise Monitoring Server in the specified location.

#### Install the TEPS support

Enabled in a Tivoli Monitoring environment if the Agent Builder detects a Tivoli Enterprise Portal Server in the specified location.

3. Select the components to install (agent, Tivoli Enterprise Monitoring Server support, Tivoli Enterprise Portal Server support).
4. In a Tivoli Monitoring environment, if the Tivoli Enterprise Monitoring Server or Tivoli Enterprise Portal Server is installed on the local computer and you are installing the support files for these servers, you can choose whether to restart the servers.

In this case, the **Restart TEMS without credentials** and **Restart TEPS** check boxes are active in the **Install the Agent Locally** section of the Generate Agent wizard. You can clear the check boxes to install the support without recycling the servers.

When you clear the **Restart TEMS without credentials** check box, you are prompted for the Tivoli Enterprise Monitoring Server user ID and password. Enter these details and click **Logon**. If you are running Tivoli Monitoring with security off, enter "sysadmin" for the user ID, leave the password blank, and click **Logon**.

Alternatively, to continue without entering credentials, click **Logon** without specifying a user ID and password or click **Cancel**. If you complete these steps, the Tivoli Enterprise Monitoring Server is recycled.

**Important:** To install support files without recycling the Tivoli Enterprise Monitoring Server, ensure that the Tivoli Enterprise Monitoring Server is running.

5. Select the agent components to generate. You can select **Base Agent**, **Cognos Reporting**, or both.
6. In a IBM Cloud APM environment, you can provide security signing for self-describing agents. Click **Edit all jar signing preferences**. You can add a time stamp to signed JAR files and specify the time stamping authority. Specify details about your Java Keystore File.

**Note:** You must create the Java Keystore File by using Java tools. For example, to generate a private key and certificate with a corresponding public key in a Java Keystore File, you can run this command:

```
ab_install_path/jre/bin/keytool -genkeypair -keystore keystore_file_path -storepass key_store_password -alias key_store_alias -dname "CN=common_name, OU=organizational_unit, L=city_or_locality, ST=state_or_province, C=country" -keypass key_password
```

Where:

- *ab\_install\_path* is the location where Agent Builder is installed
- *keystore\_file\_path* is the path where an existing JKS keystore is located, or where one is created
- *key\_store\_password* is the password that is needed to access any items in this keystore
- *key\_store\_alias* is a name that identifies this key within the keystore (defaults to "mykey")
- *key\_password* the password that is needed to access this particular key (defaults to *key\_store\_password*)

The certificate must be included in the keystore for the server.

7. When you complete the **JAR Signing** details, click **OK**.
8. Click **Finish**.
9. Configure and start the agent. For more information, see [“Configuring and starting the agent in an IBM Tivoli Monitoring environment”](#) on page 1608 or [“Configuring the agent”](#) on page 1609 and [“Starting and stopping the agent”](#) on page 1611 in a IBM Cloud APM environment.

For Tivoli Monitoring v6.2 FP1 or later, you can install the Tivoli Enterprise Monitoring Server and Tivoli Enterprise Portal Server support without restarting the servers. In this case, the **Restart TEMS without credentials** and **Restart TEPS** check boxes are active in the **Install the Agent Locally** section of the Generate Agent wizard. You can clear the check boxes to install the support without recycling the servers. When you clear the **Restart TEMS without credentials** check box, you are prompted for the Tivoli Enterprise Monitoring Server user ID and password. Enter the Tivoli Enterprise Monitoring Server user ID and password and click **Logon**. If you are running Tivoli Monitoring with security off, enter "sysadmin" for the user ID, leave the password blank, and click **Logon**. You can also continue

without entering credentials (click **Logon** without specifying a user ID and password or click **Cancel**. Doing so causes the Tivoli Enterprise Monitoring Server to be recycled).

**Note:** The Tivoli Enterprise Monitoring Server must be running to install support files without recycling the Tivoli Enterprise Monitoring Server.

## Creating the agent package

You can use Agent Builder to create a compressed agent installation package.

### About this task

An agent package contains all the files necessary to run the agent, as well as the installation and configuration scripts. The package also includes support files for the monitoring environment.

You can use an agent package to install the agent into the IBM Tivoli Monitoring and IBM Cloud Application Performance Management environments.

### Procedure

1. Click the `itm_toolkit_agent.xml` file from the **Project Explorer** navigation tree of Agent Builder by using one of the following methods:
  - Right-click the `itm_toolkit_agent.xml` file and select **IBM > Generate Agent**.
  - Select the `itm_toolkit_agent.xml` file and select the  **Generate Agent** icon on the toolbar.
  - Double-click the `itm_toolkit_agent.xml` file and select **Agent Editor > Generate Agent**.
2. Enter the name of the directory where you want to place the output (a compressed package or expanded files) in the **Generate Agent Image** section.
3. Select the **Keep intermediate files** check box to keep the generated expanded files separate from the zip or tar file.
4. Select the **Create a ZIP file** check box to create a compressed file in the specified directory. The compressed zip file is named `smai-agent_name-version.zip` for Windows systems by default.
5. Select the **Create a TAR file** check box to create a tar file in the specified directory. The compressed tar file is named `smai-agent_name-version.tgz` for UNIX and Linux systems by default.
6. Select the agent components to generate. You can select **Base Agent**, **Cognos Reporting**, or both.

**Important:** For the IBM Cloud Application Performance Management environment, do not select **Cognos Reporting**, because the reports are currently not supported and including the reports increases the size of the package.

7. You can optionally provide security signing for agent application files. If you want to provide security signing, select **Sign self-describing support JAR**. Click **Edit all jar signing preferences**. You can add a timestamp to signed jar files and specify the time stamping authority. Specify details about your Java Keystore File.

**Important:** You can create the Java Keystore File by using Java tools. For example, to generate a private key and certificate with a corresponding public key in a Java Keystore File, you can run this command:

```
ab_install_path/jre/bin/keytool -genkeypair -keystore keystore_file_path -storepass key_store_password -alias key_store_alias -dname "CN=common_name, OU=organizational_unit, L=city_or_locality, ST=state_or_province, C=country" -keypass key_password
```

Where:

- `ab_install_path` is the location where Agent Builder is installed
- `keystore_file_path` is the path where an existing JKS key store resides, or where one will be created
- `key_store_password` is the password needed to access any items in this key store

- *key\_store\_alias* is a name identifying this key within the key store (defaults to "mykey")
- *key\_password* is the password needed to access this particular key (defaults to *key\_store\_password*)

Include this certificate in the server key store.

8. Click **Finish**.

## Installing the package in an IBM Tivoli Monitoring environment

To test or use the agent in the IBM Tivoli Monitoring environment, use the generated package to install the agent on the monitored systems, hub Monitoring Server systems, and Portal Server system.

### Before you begin

Before installing the agent on a monitored system, ensure that the Tivoli Monitoring operating system agent is present and working. For information about installing Tivoli Monitoring agents, see [Installing monitoring agents](#) in the Tivoli Monitoring Knowledge Center.

**Important:** To display agent information in the Tivoli Enterprise Portal, you must install the following components:

- The agent on all monitored systems
- Tivoli Enterprise Monitoring Server support files on the hub Tivoli Enterprise Monitoring Servers
- Tivoli Enterprise Portal Server support files on the Tivoli Enterprise Portal Server
- Tivoli Enterprise Portal support files on the Tivoli Enterprise Portal Server and, if applicable, any Tivoli Enterprise Portal desktop clients

### Procedure

1. Copy the compressed file, which is named *product\_code.zip* for Windows systems or *product\_code.tgz* for UNIX and Linux systems by default, onto the system where you want to install the agent.
2. Extract the file to a temporary location.

**Note:** **Linux** **UNIX** For UNIX and Linux systems, this temporary location must not be */tmp/product\_code*, where the product code is lowercase.

You can install the agent remotely by using the compressed file.

- **Linux** On a Linux system, use the following command to extract your *.tgz* file:

```
tar -xvzf filename
```

- **UNIX** On an AIX system, use the following command to extract your *.tgz* file:

```
gunzip filename
tar -xvf filename
```

3. Run the appropriate installation script.
  - To install the agent, Tivoli Enterprise Monitoring Server, Tivoli Enterprise Portal Server, and Tivoli Enterprise Portal support all at the same time:

```
InstallIra.bat/.sh itm_install_location [[-h Hub_TEMS_hostname] -u
HUB_TEMS_username -p Hub_TEMS_password]
```

- To install the agent without installing support files:

```
installIraAgent.bat/.sh itm_install_location
```

- To install the Tivoli Enterprise Monitoring Server support:

```
installIraAgentTEMS.bat/.sh itm_install_location [[-h Hub_TEMS_hostname] -u
HUB_TEMS_username -p Hub_TEMS_password]
```

- To install the Tivoli Enterprise Portal Server and Tivoli Enterprise Portal support:

```
installIraAgentTEPS.bat/.sh itm_install_location
```

The installation location, *itm\_install\_location* must be the first argument and is mandatory on all scripts: *installIra.bat/.sh*, *installIraAgent.bat/.sh*, *installIraAgentTEMS.bat/.sh*, and *installIraAgentTEPS.bat/.sh*. This is the location where Tivoli Monitoring components are installed on this system.

Other arguments are optional.

If you install Monitoring Server support files and do not provide a user ID is not provided, the Tivoli Enterprise Monitoring Server is recycled.

4. Configure and start the agent, see [“Configuring and starting the agent in an IBM Tivoli Monitoring environment”](#) on page 1608.

## What to do next

If you changed the layout of your agent in a way that causes navigator items to be moved or removed, restart the Tivoli Enterprise Portal Server and Tivoli Enterprise Portal. The restart ensures that your changes are correctly recognized.

## Configuring and starting the agent in an IBM Tivoli Monitoring environment

After installing an agent on a monitored system in the IBM Tivoli Monitoring, configure and start the agent.

### Procedure

1. Open the **Manage Tivoli Monitoring Service**.  
The new entry **Monitoring Agent for *agent\_name*** is displayed.
2. Right-click the entry and select **Configure Using Defaults**. Click **OK** to accept the defaults if you are prompted.

#### Important:

- a. On UNIX systems, the option to select is **Configure**.
- b. For multi-instance agents, when you are configuring, you are prompted for an instance name.

**Tip:** If your agent uses a JMX data source to connect to a remote WebSphere Application Server, ensure that WebSphere Application Server is also installed on the host that is running the agent and set the Java home setting to the Java runtime environment that the local WebSphere Application Server uses.

**Tip:** For a Java API, JDBC, JMX, HTTP, or SOAP data source, you can use the **Java > JVM arguments** setting to control agent trace logging. Set the following value in this setting:

```
-DJAVA_TRACE_MAX_FILES=files -DJAVA_TRACE_MAX_FILE_SIZE=size
```

where *files* is the maximum number of trace log files that are kept (the default value is 4) and *size* is the maximum log file size in kilobytes (the default value is 5000). For example, you can set the following value:

```
-DJAVA_TRACE_MAX_FILES=7 -DJAVA_TRACE_MAX_FILE_SIZE=100
```

In this case, the agent writes 100 kilobytes into the first log file, then switches to the second log file, and so on. After writing seven log files of 100 kilobytes each, it overwrites the first log file.

If you added runtime configuration elements to your agent, or if you selected a data source, then you are presented with configuration panels. You use these panels to collect the required information for your agent.

3. Right-click the agent entry and select **Start**
4. Open the Tivoli Enterprise Portal and go to the new agent.

## Installing and using an agent in an IBM Cloud Application Performance Management environment

To test or use the agent in the IBM Cloud Application Performance Management environment, use the generated package to install the agent on all monitored systems. In some cases, you need to configure the agent before it can be started. You can start and stop the agent as necessary.

### Installing the agent

Use the installation package prepared by Agent Builder to install the agent on all monitored systems.

### Before you begin

Ensure that an agent for IBM Cloud Application Performance Management, usually the operating system agent, is already present on the monitored system and working.

**Windows** On Windows systems, use an Administrator command line shell to install and configure agents. To start an Administrator shell, select **Command Prompt** from the Windows Programs menu, right-click, and click **Run as Administrator**.

### Procedure

1. Extract the package to a temporary directory and change to this directory.
2. Install the agent by using the following command, depending on your operating system:
  - **Windows** On Windows systems, `installIraAgent.bat agent_install_location`
  - **Linux** **UNIX** On Linux and UNIX systems, `./installIraAgent.sh agent_install_location`

Where *agent\_install\_location* is the installation location of the existing agent. The default location is:

- **Windows** On Windows systems, `C:\IBM\APM`
- **Linux** On Linux systems, `/opt/ibm/apm/agent`
- **AIX** On AIX systems, `/opt/ibm/apm/agent`

**Important:** If you have added any custom configuration properties in the **Runtime Configuration** window of the Agent Editor, if the agent supports multiple instances, or if the agent uses any predefined data source that needs configuration (for example, a user ID and password), you must configure the agent before it can start. If an agent does not require configuration, it starts automatically after installation.

### Configuring the agent

If you have added any custom configuration properties in the Runtime Configuration window of the Agent Editor, if the agent supports multiple instances, or if the agent uses any predefined data source that needs configuration (for example, a user ID and password), you must configure the agent before it can start.

### Before you begin

**Windows** On Windows systems, use an Administrator command line shell to install and configure agents. To start an Administrator shell, select **Command Prompt** from the Windows Programs menu, right-click, and click **Run as Administrator**.

## About this task

In the configuration process, you can:

- Set the instance name to create or change an instance, if the agent supports multiple instances.
- Set any configuration properties that are available for the agent.
- Create and configure subnodes, if the agent supports subnodes.

**Windows** On Windows systems, to set any configuration properties or create any subnodes, you must use the silent configuration procedure. A sample silent configuration response file is located in the *install\_dir*\samples directory and is named *agentname\_silent\_config.txt*. Create a copy of this file and set the configuration variables as necessary.

**Linux** **UNIX** On Linux and UNIX systems, you can optionally use the silent configuration procedure. Alternatively, you can use the interactive procedure. If you start the configuration command without a response file name, the configuration utility prompts you for the configuration values.

## Procedure

1. Change to the *install\_dir*/bin directory.
2. Run the following command to configure the agent:
  - If the agent does not support multiple instances:
    - **Windows** On Windows systems, *name-agent.bat config [response\_file]*
    - **Linux** **UNIX** On Linux and UNIX systems, *./name-agent.sh config [response\_file]*
  - If the agent supports multiple instances:
    - **Windows** On Windows systems, *name-agent.bat config instance\_name [response\_file]*
    - **Linux** **UNIX** On Linux and UNIX systems, *./name-agent.sh config instance\_name [response\_file]*

Where:

- *instance\_name* is the name of the instance. If an instance with this name does not exist, the instance is created. If the instance already exists, it is reconfigured. You must create at least one instance to use the agent.
- *response\_file* is the name of the silent configuration response file.

**Tip:** If your agent uses a JMX data source to connect to a remote WebSphere Application Server, ensure that WebSphere Application Server is also installed on the host that is running the agent and set the Java home setting to the Java runtime environment that the local WebSphere Application Server uses.

**Tip:** For a Java API, JDBC, JMX, HTTP, or SOAP data source, you can use the **Java > JVM arguments** setting to control agent trace logging. Set the following value in this setting:

```
-DJAVA_TRACE_MAX_FILES=files -DJAVA_TRACE_MAX_FILE_SIZE=size
```

where *files* is the maximum number of trace log files that are kept (the default value is 4) and *size* is the maximum log file size in kilobytes (the default value is 5000). For example, you can set the following value:

```
-DJAVA_TRACE_MAX_FILES=7 -DJAVA_TRACE_MAX_FILE_SIZE=100
```

In this case, the agent writes 100 kilobytes into the first log file, then switches to the second log file, and so on. After writing seven log files of 100 kilobytes each, it overwrites the first log file.

## Starting and stopping the agent

To monitor a system, ensure that the agent is started on the system. You can start and stop the agent at any time. If the agent supports multiple instances, you can start and stop every instance independently.

### Procedure

1. Change to the `install_dir/bin` directory.
2. Run the following command to start the agent:
  - If the agent does not support multiple instances:
    - **Windows** On Windows systems, `name-agent.bat start`
    - **Linux** **UNIX** On Linux and UNIX systems, `./name-agent.sh start`
  - If the agent supports multiple instances:
    - **Windows** On Windows systems, `name-agent.bat start instance_name`
    - **Linux** **UNIX** On Linux and UNIX systems, `./name-agent.sh start instance_name`
3. Run the following command to stop the agent:
  - If the agent does not support multiple instances:
    - **Windows** On Windows systems, `name-agent.bat stop`
    - **Linux** **UNIX** On Linux and UNIX systems, `./name-agent.sh stop`
  - If the agent supports multiple instances:
    - **Windows** On Windows systems, `name-agent.bat stop instance_name`
    - **Linux** **UNIX** On Linux and UNIX systems, `./name-agent.sh stop instance_name`

## Agent post-generation and installation results

Installation of an Agent Builder agent creates and changes certain files on your system. In an IBM Tivoli Monitoring environment, you can also see changes in the Tivoli Enterprise Portal.

### New files on your system

After you generate and install the agent that you created with Agent Builder, you can see the following new files on your agent system:

**Note:** xx denotes the two character product code.

#### Windows

##### Windows systems:

**TMAITM6\kxxagent.exe**

Agent binary

**TMAITM6\KxxENV**

Environment variable settings

**TMAITM6\Kxx.ref**

Agent provider configuration

**TMAITM6\SQLLIB\kxx.his**

SQL description of agent attribute information

**TMAITM6\SQLLIB\kxx.atr**

Agent attribute information

**TMAITM6\xx\_dd\_version.xmll**

Product description

**TMAITM6\xx\_dd.properties**

Product name

**TMAITM6\kxxcma.ini**

Agent service definition file

**TMAITM6\your\_files**

Supplemental files included from the Java API or Socket data sources with a file type of *executable* or *library*. Scripts included from the Script or Command return code data sources.

Linux

UNIX

**UNIX/Linux systems:****registry/xxarchitecture.ver**

Internal versions and prerequisites file

**architecture/xx/bin/xx\_dd\_version.xml**

Product description

**architecture/xx/bin/kxxagent**

Agent binary

**architecture/xx/bin/xx\_dd.properties**

Product name

**architecture/xx/work/kxx.ref**

Agent provider configuration

**architecture/xx/tables/ATTRLIB/kxx.atr**

Agent attribute information

**architecture/xx/hist/kxx.his**

SQL description of agent attribute information

**architecture/xx/bin/your\_files**

Supplemental files included from the Java API or Socket data sources with a file type of *executable*. Scripts included from the Script or Command return code data sources.

**architecture/xx/lib/your\_files**

Supplemental files included from the Java API or Socket data sources with a file type of Library.

**config/.xx.rc**

Internal setup file

**config/xx.environment**

Environment settings

**config/xx\_dd\_version.xml**

Product description

**config/xx\_dd.properties**

Product name

**config/.ConfigData/kxxenv**

Environment variable settings

**Note:** Run the following command to find out the architecture of the system:

```
cinfo -pxx
```

where xx is the two-character product code.

For example, for a Solaris 8 64-bit system that is running an agent with product code 19, here is the output:

```
# /opt/ibm/apm/agent/bin/cinfo -p 19

***** Fri Aug 17 11:23:58 EDT 2007 *****
User : root Group: other
Host name : guadalajara Installer Lvl:06.20.00.00
CandleHome: /opt/IBM/ITM
*****
```

```
Platform codes:
sol286 : Current machine
sol286 : Product (19)
tmaitm6/sol286 : CT Framework (ax)
```

The line in bold is the relevant one. The string before the colon, sol286, indicates the architecture in use for this agent. This string is different for different combinations of operating system and computer hardware type. The agent must be previously installed for this feature to work.

The following files are for Java-based data sources. These files are created only if the agent contains JMX, JDBC, HTTP, or SOAP data sources:

- cpci.jar
- jlog.jar
- common/jatlib-1.0.jar

The following files are for JMX runtime support. These files are created only if the agent contains JMX data sources:

- common/jmx-1.0.jar
- common/connectors/jboss/connJboss-1.0.jar
- common/connectors/jsr160/connJSR160-1.0.jar
- common/connectors/was/connWas-1.0.jar
- common/connectors/weblogic/connWeblogic-1.0.jar

The following file is for JDBC runtime support. These files are created only if the agent contains JDBC data sources:

- common/jdbc-1.0.jar

The following file is for HTTP or SOAP runtime support. These files are created only if the agent contains HTTP or SOAP data sources:

- http-1.0.jar

The following files are for the Java API runtime support. These files are created only if the agent contains a Java API data source:

- cpci.jar
- custom/*your JAR file* The name of this JAR file is specified in the **Global settings** of a Java API data source.
- custom/*your JAR file* Supplemental files with a file type of Java resource.

The same files exist on Windows, UNIX, and Linux systems for Java-based data sources, but they are in different directories:

- **Windows** Windows path: TMAITM6\kxx\jars
- **Linux** **UNIX** UNIX/Linux path: *architecture/xx/jars*

The following files are for log file monitoring runtime support. These files are created only if the agent contains log file data sources:

- **Windows** On Windows systems: TMAITM6\kxxudp.dll
- **Linux** On Solaris/Linux systems: *architecture/xx/lib/libkxxudp.so*
- On HP-UX systems: *architecture/xx/lib/libkxxudp.sl*
- **UNIX** On AIX systems: *architecture/xx/lib/libkxxudp.a*

The following files are for SSH script monitoring runtime support. These files are created only if the agent contains a script data source that is enabled for SSH collection:

- **Windows** On Windows systems: TMAITM6\kxxssh.dll

- **Linux** On Solaris/Linux systems: *architecture/xx/lib/libkxxxssh.so*
- On HP-UX systems: *architecture/xx/lib/libkxxxssh.sl*
- **UNIX** On AIX systems: *architecture/xx/lib/libkxxxssh.a*

## Changes in the Manage Tivoli Enterprise Monitoring Services window

After installing an agent in a IBM Tivoli Monitoring environment, you can see an entry for the agent in the **Manage Tivoli Enterprise Monitoring Services** window. The entry name is **Monitoring Agent for *agent\_name***.

**Important: Manage Tivoli Enterprise Monitoring Services** is not supported in the IBM Cloud Application Performance Management environment.

**Windows** On Windows systems, this entry contains a **Task/Subsystem** column that identifies whether your agent supports multiple instances:

- A single instance agent displays a new application in the **Manage Tivoli Enterprise Monitoring Services** window. The name of the application is **Monitoring Agent for *agent\_name***. A service is created for the agent (Figure 70 on page 1615). The **Task/Subsystem** column contains the value **Primary**.
- A multiple instance agent displays a new application template in the **Manage Tivoli Enterprise Monitoring Services** window. The name of the template is **Monitoring Agent for *agent\_name***. A service is not created for the agent until you create an instance of the agent from this template. The **Task/Subsystem** column contains the value **Template** to indicate that this entry is a template that is used to create instances of the agent.

**Linux** **UNIX** On Linux and UNIX systems, the entry for the agent is the same whether your agent supports multiple instances or not.

**Note:** The following screens are for a Windows system. UNIX and Linux systems have similar screens.

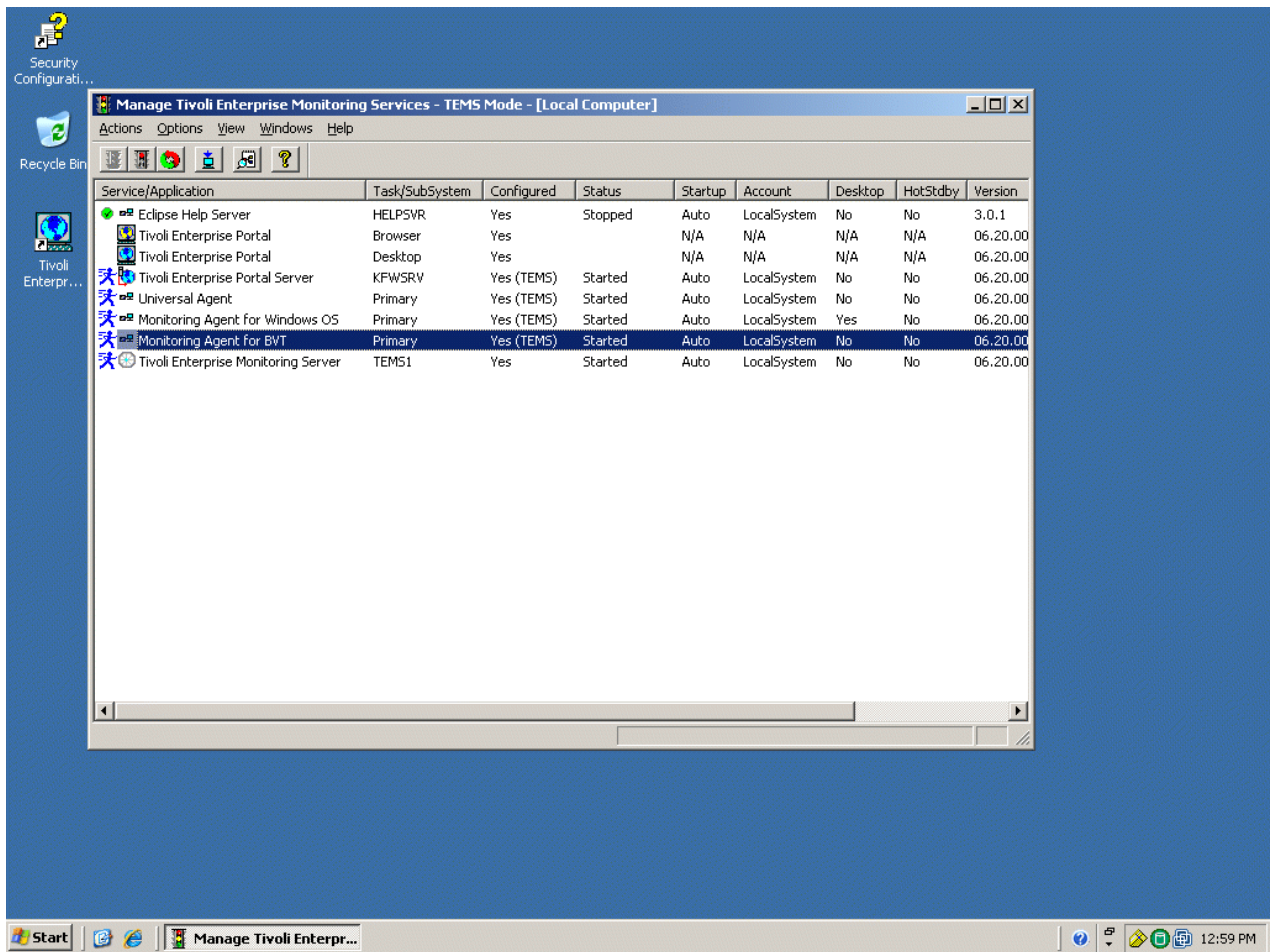

Figure 70. Manage Tivoli Enterprise Monitoring Services window

## Changes in the Tivoli Enterprise Portal

In an IBM Tivoli Monitoring environment, after you install and start the agent, click the green **Refresh** icon in Tivoli Enterprise Portal. Then you can view the new agent. You can see the following changes in the portal:

- A new subnode for the agent in the Tivoli Enterprise Portal physical view.
- Nodes for every navigator group and data source that you defined by using the Agent Builder (Figure 71 on page 1616).

**Note:** For each navigator item, you must define a default query.

Figure 71. Nodes for attribute groups in the new agent.

- If your agent contains subnodes, an expandable node is present for each subnode that is defined in your agent. The following nodes are shown under the expandable node:
  - xxx performance object status, where xxx is the three-letter subnode type
  - Nodes for every Navigator group and data source that you defined in the subnode
  - xxx event log node if you have event logs
  - xxx JMX monitors node if you have JMX and you included JMX monitors
- The following automatic node:
  - An availability node if your agent contains an availability data source (Figure 72 on page 1617)

**Note:** This node behaves differently depending on the contents of the agent. If the agent monitors only availability, the availability node represents the availability data source. If the agent monitors availability and performance, the availability node becomes the navigator item that represents the availability and performance object status data sources.

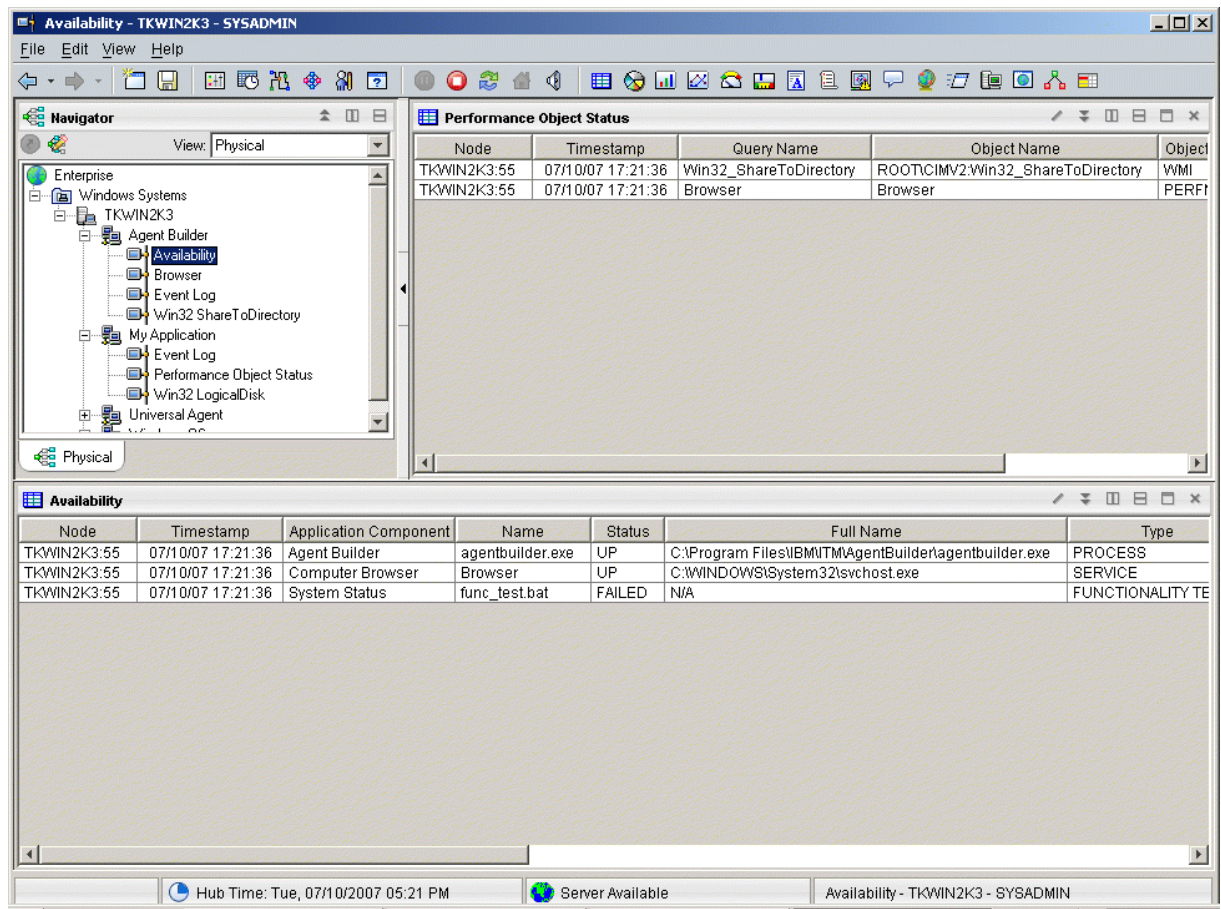

Figure 72. Availability node

- Performance Object Status, if the agent includes performance monitoring (not availability) data sources (Figure 73 on page 1618)

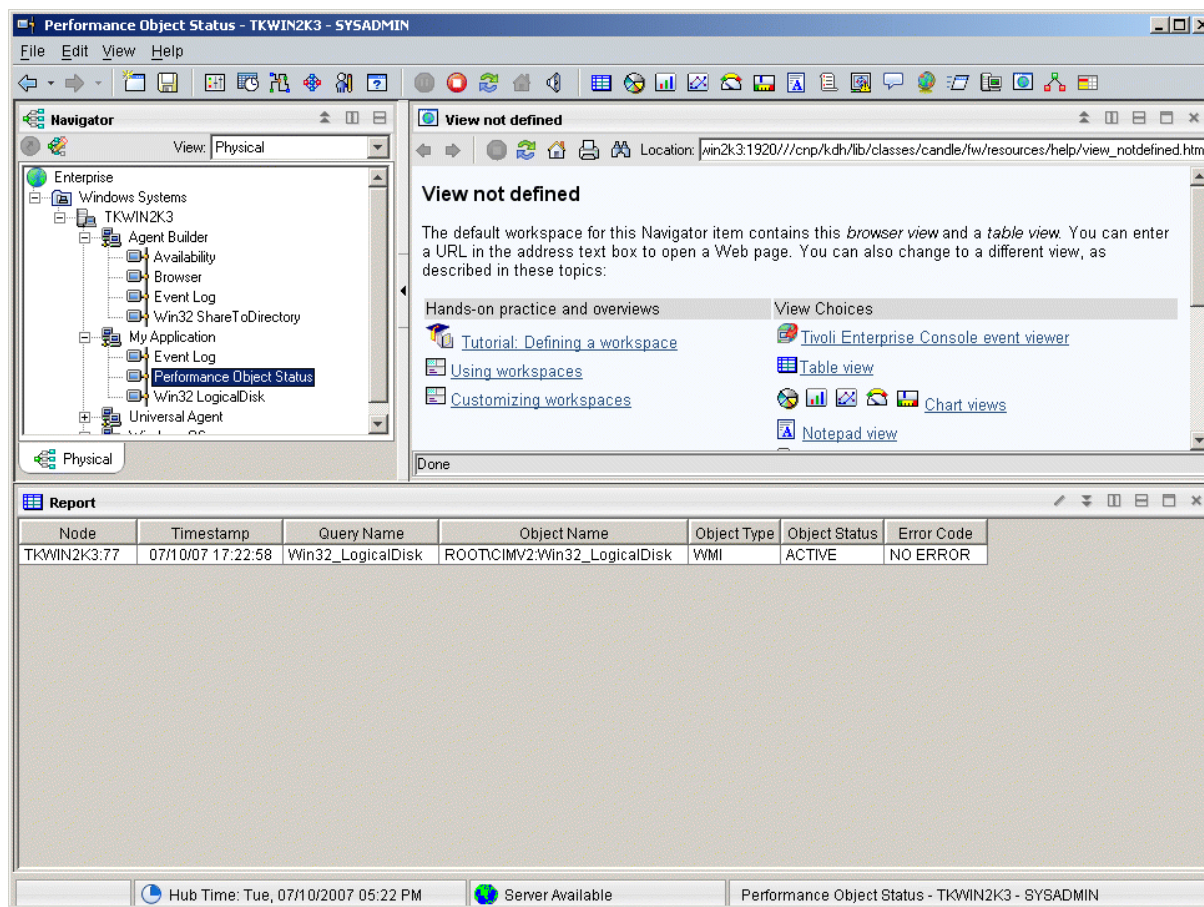

Figure 73. Performance Object Status node

- Event log, if the agent contains data sources producing log data (Figure 74 on page 1619)

Figure 74. Event log node

See [“Attributes reference” on page 1633](#) for descriptions of the attribute groups and attributes for Agent Builder.

## Uninstalling an agent

You can remove an agent that the Agent Builder generated from a monitored host.

### About this task

The uninstallation process uninstalls only the agent from the agent system. This process does not uninstall any other agent or any monitoring infrastructure.

In an IBM Tivoli Monitoring environment, you can use one of the following procedures to remove an agent that the Agent Builder generated:

- [“Removing a Tivoli Monitoring agent by using the Tivoli Enterprise Portal” on page 1620](#)
- [“Removing a Tivoli Monitoring agent without using the Tivoli Enterprise Portal” on page 1620](#)

After removing the agent using any of these procedures, clear it from the Tivoli Enterprise Portal using the following procedure: [“Clearing a Tivoli Monitoring agent from the Tivoli Enterprise Portal” on page 1620](#).

In an IBM Cloud Application Performance Management environment, use the following procedure: [“Uninstalling an IBM Cloud Application Performance Management agent” on page 1621](#).

## Removing a Tivoli Monitoring agent by using the Tivoli Enterprise Portal

In an IBM Tivoli Monitoring environment, you can use the Tivoli Enterprise Portal to remove an agent.

### Before you begin

Your operating system agent must be running in order to remove your created agent.

### Procedure

To use the Tivoli Enterprise Portal to remove an agent, complete the following step:

- In the Tivoli Enterprise Portal navigation tree, right-click the agent and select **Remove**.

## Removing a Tivoli Monitoring agent without using the Tivoli Enterprise Portal

If a Tivoli Enterprise Portal is not available in your IBM Tivoli Monitoring environment, you can use operating system scripts and commands to remove an agent.

### Procedure

To remove an agent that the Agent Builder generated from the target system without using a Tivoli Enterprise Portal, you can complete any of the following steps:

- **Windows**

On Windows systems, use the commands:

```
cd ITM_INSTALL/TMAITM6
kxx_uninstall.vbs ITM_INSTALL
```

where xx is the product code for the agent

- **Windows**

Alternatively, on Windows systems, you can use the `cscript.exe` command to run the uninstallation script. This command is the command-line interface parser for vbs scripts and does not display a window; instead, a message is displayed on the console:

```
cd ITM_INSTALL/TMAITM6
cscript.exe kxx_uninstall.vbs ITM_INSTALL
```

- **Linux**    **UNIX**

On Linux or UNIX systems, use the `uninstall.sh` file that is found in `ITM_INSTALL/bin`:

```
uninstall.sh [-f] [-i] [-h ITM_INSTALL] [product platformCode]
```

## Clearing a Tivoli Monitoring agent from the Tivoli Enterprise Portal

In an IBM Tivoli Monitoring environment, after you remove the agent, empty fields for information from the agent can remain in the Tivoli Enterprise Portal. To remove the fields, clear the agent from the Tivoli Enterprise Portal.

### Procedure

1. Ensure that your Tivoli Enterprise Monitoring Server and Tivoli Enterprise Portal Server are up and running.
2. Log on to your Tivoli Enterprise Portal client.
3. From the Tivoli Enterprise Portal client Physical Navigator view, right-click **Enterprise** and select **Workspace > Managed System Status**.  
The Managed System Status workspace is displayed.
4. Select all of the IBM Tivoli Managed Systems for your agent.

5. Right-click and select **Clear off-line entry**, which clears all of the entries from that table.

## Uninstalling an IBM Cloud Application Performance Management agent

You can uninstall your agent from any monitored system in an IBM Cloud Application Performance Management environment.

### Procedure

1. On the system where the agent is installed, start a command line and change to the `install_dir/bin` directory, where `install_dir` the installation directory of the monitoring agents.
2. To uninstall a specific monitoring agent, enter the agent script name and the uninstall option where `name` is the agent script name:
  - On Windows systems, `name-agent.bat uninstall`
  - On Linux or AIX systems, `./name-agent.sh uninstall`

## Importing application support files

---

If an agent is to be used in an IBM Tivoli Monitoring environment, custom situations, workspaces, Take Action commands, and queries can be included in the installation package.

### About this task

To have a single installation image for situations, workspaces, and the agent, the situation, and workspace files must be in the same project as the agent. The Agent Builder provides a wizard to create the appropriate files in the agent project.

Definitions that are associated with an agent can also be included in the installation package. The content of these definitions is different for an agent that is used in an enterprise monitoring environment and in a system monitor environment. An enterprise monitoring agent image can include custom situations, workspaces, Take Action commands and queries. A system monitor agent image can include private situations, trap definitions, and agent configuration information.

To have a single installation package that includes the appropriate definitions and the agent itself, the files must be in the same project as the agent. The Agent Builder provides a wizard to create the appropriate files for an enterprise monitoring installation. The files for a system monitor agent environment are created by using the process that is described in the *Agent Autonomy* chapter in the *IBM Tivoli Monitoring Administrator's Guide*. The resulting files are copied into the root of the Eclipse project for the agent.

## Exporting and importing files for Tivoli Enterprise Monitoring Agents

### About this task

After you create situations, workspaces, queries, and Take Action commands in the Tivoli Enterprise Portal, you can export and import them into another Tivoli Monitoring Version 6.2 environment. For more information about creating situations and workspaces, see ([“Creating workspaces, Take Action commands, and situations” on page 1585](#)). Use the following steps to extract the situations, workspaces, Take Action commands, and queries:

### Procedure

1. From the **Project Explorer** tab, right-click the agent project folder.
2. Select **IBM Corporation > Import Application Support Files**.
3. Enter the host name of the Tivoli Enterprise Portal Server.

4. Enter the user name and password for the Tivoli Monitoring environment you are connecting to and click **Finish**.
5. If you defined situations for your agent, a dialog box is presented that lists the situations that are defined for the agent.
6. Select the situations that you want to export from the list and click << to add them to the selected situations table and click **OK**.

The import might take a few moments. When the task completes, you see the SQL files in the appropriate folders in the agent project.

7. If you defined Take Action commands for your agent, a dialog presents the Take Action commands defined. Choose the Take Action commands that you want to export from the list and click >> to add them to the Selected Take Actions table and click **OK**.

The import might take a few moments. When the task completes, you see the SQL files in the appropriate folders in the agent project.

8. If you defined custom queries for your agent, a dialog presents the Queries defined. Select the queries that you want to export from the list and click << to add them to the Selected Queries table and click **OK**.

The import might take a few moments. When the task completes, you see the SQL files in the appropriate folders in the agent project. Workspaces are imported automatically.

### What to do next

Re-create your custom agent, install your agent on the monitored host, and install the Tivoli Enterprise Portal support.

## Exporting and importing files for Tivoli System Monitor Agents

### About this task

The system monitor agent definitions are contained in three types of files:

- Private situations are defined in a file named `xx_situations.xml`, where `xx` is the two-character product code
- Trap configuration information is defined in a file named `xx_trapcnfg.xml`, where `xx` is the two-character product code
- For agents that require configuration, the configuration is defined in one file for each instance of the agent. When the agent is a single instance agent, the file is named `xx.cfg`. When the agent is a multi-instance agent, there is a file present for each instance. The file names are `xx_instance name.cfg`, where `xx` is the two-character product code and `instance name` is the name of the agent instance.

### Procedure

- Create the files by using the process that is described in the *Agent Autonomy* chapter in the *IBM Tivoli Monitoring Administrator's Guide*. Copy the files into the root of the project directory manually, or use the Eclipse import function to select the files to be imported: **File > Import > General > File System**. These files are included in the agent image and installed by the installer.

When the agent is installed the installation:

- Copies the included files into the appropriate locations.
- Any private situations that are defined in the `pc_situations.xml` file that is run on the agent.
- The trap definitions that are defined in the `pc_trapcnfg.xml` are used to forward traps that are based on the situations.
- The agent is automatically configured and started if:
  - The agent is a single instance agent with no configuration defined as part of the agent.

- The agent is a single instance agent with configuration defined as part of the agent and the image includes a `pc.cfg` file.
- The agent is a multi-instance agent (all multi-instance agents require configuration): the installer starts one instance of the agent for each `pc_inst.cfg` file.

## Event filtering and summarization

---

An attribute group is defined to be *pure event* or *sampled*. Pure event attribute groups contain data rows that occur asynchronously. As each new row of data arrives, it is processed immediately by Tivoli Monitoring. Sampled attribute groups collect the current set of data rows each time the data is requested. The following attribute groups illustrate the difference:

- An `SNMPEvent` attribute group is created that represents all of the SNMP Traps and informs that are sent to the agent. Traps or informs arrive asynchronously as they are sent by the monitored systems. As each event arrives, it is passed to Tivoli Monitoring.
- A `Disk` attribute group is created to represent information about all of the disks on a system. The disk information is collected periodically. Each time disk information is collected, the agent returns a number of rows of data, one for each disk.

The difference between pure event and sampled attribute groups affects various aspects of Tivoli Monitoring. These aspects include: situations, warehouse data, and Tivoli Enterprise Portal views.

Each situation is assigned (or *distributed*) to one or more managed systems to be monitored for a specific condition of a set of conditions. When the determination of the event must be made based on observations that are made at specific intervals, the event is known as a *sampled event*. When the event is based on a spontaneous occurrence, the event is known as a *pure event*. Therefore, situations for sampled events have an interval that is associated with them, while situations for pure events do not. Another characteristic of sampled events is that the condition that caused the event can change, thus causing it to be no longer true. Pure events cannot change. Therefore, alerts that are raised for sampled events can change from true to false, while a pure event stays true when it occurs.

An example of a sampled event is `number of processes > 100`. An event becomes true when the number of processes exceeds 100 and later becomes false again when this count drops to 100 or less. A situation that monitors for `invalid logon attempt by user` is a pure event; the event occurs when an invalid logon attempt is detected, and does not become a False event. While you can create situations that are evaluated on a specific interval for sampled attribute groups, such evaluations are not possible for pure event attribute groups.

Similarly, for historical data, you can configure how frequently sampled data is collected. However, when you turn collection on for pure event data, you get each row as it happens.

The data that is displayed in the Tivoli Enterprise Portal for sampled data is the latest set of collected rows. The data that is displayed for pure event attribute groups is the contents of a local cache that is maintained by the agent. It does not necessarily match the data that is passed to Tivoli Monitoring for situation evaluation and historical collection.

## Controlling duplicate events

Use the event filtering and summarization options to control how duplicate events are sent to Tivoli Monitoring.

### Before you begin

For more information about event filtering and summarization, see [“Event filtering and summarization” on page 1623](#).

### About this task

The Agent Builder defines attribute groups that represent event data as *pure event* in Tivoli Monitoring. These attribute groups include log file, AIX Binary Log, SNMP events, and JMX notifications. These

attribute groups can produce multiple duplicate events. You can control how these duplicate events are sent to Tivoli Monitoring. You can activate these controls for log file, SNMP events, and JMX notifications attribute groups in the **Event Information** tab under **Advanced Data Source Properties** in the **Advanced** window.

Whether an event is treated as a duplicate of other events is determined by the key attributes, you define in the attribute group. A duplicate event occurs when the values for all key attributes in the event match the values for the same key attributes in an existing event. When event filtering and summarization is enabled, the attributes for the `isSummary`, `occurrenceCount`, `summaryInterval`, and `eventThreshold` functions are added automatically.

## Procedure

- In the **Event Filtering and Summarization Options** area, select one of the following options:
  - **No event filtering or summarization:** Sends all events without any event filtering or summarization. This option is the default option.
  - **Filter and summarize events:** Creates a summary record for each event with duplicates and each unique event that is based on the key attributes. Select also to choose the event filtering option. In the **Summarization Options** area, enter the summary interval. You can enter either a value in seconds or insert a configuration property.

The event filtering options are:

- **Only send summary events:** Sends only the summary records for the specified interval.
- **Send all events:** Sends all events and summary records.
- **Send first event:** For each event, sends only the first event that is received in the summary interval that is specified and no duplicate events. This option also sends the summary records.
- **Event threshold:** Sends an event to Tivoli Monitoring when the number of duplicate events that are received in the interval is evenly divisible by the threshold. For example, if you set the event threshold to 5 and you receive less than five duplicates (including the first event) in the interval, no event is sent to Tivoli Monitoring. If you receive 5, 6, 7, 8, or 9 duplicates, one event is sent. If you receive 10 duplicates, 2 events are sent. In the **Event threshold** field, you can enter a number or insert a configuration property. This option also sends the summary records.

## Viewing event filtering and summarization in the Tivoli Enterprise Portal

Examples of how data is treated depending on your event filtering and summarization choices.

The agent maintains a cache of the last events received. By default, this cache is 100 in size. If you enable agent event filtering and summarization, differences can occur between the number of events in the cache and the number sent to IBM Tivoli Monitoring. Additional events in the cache might not reach the designated threshold for sending. Or you might have fewer events in the cache if you selected the **Send all events** option. If the **Send all events** option is set, an event is sent each time a duplicate occurs. However, only one copy of the event is kept in the cache, and the occurrence count is incremented each time that the event occurs. To view the events that are sent to IBM Tivoli Monitoring, create a historical view. For information about creating historical views, see *Historical Reporting* in the [Tivoli Enterprise Portal User's Guide](#). You can compare this view with the real-time cache view in the Tivoli Enterprise Portal. You can also use situations to make the same comparison.

The following examples indicate how the same log data is treated depending on your choice, if any, of event filtering and summarization. The example agent was created to illustrate different behaviors. Each attribute group was defined to monitor the same log file. In each example, a historical view and a real-time (cache) view is shown. The names of the nodes in the Tivoli Enterprise Portal reflect the settings selected. By default, the historical view displays the newest events last. The default real-time view of the cache displays the newest events first. In these examples, the historical view shows the last 1 hour.

As new events arrive, you can see them in the cache view. As duplicates of an event arrive, the data is updated in the existing row. When a summary interval elapses, the existing events are converted to summary events and sent. New rows are then added for the next summary interval.

(Figure 75 on page 1625) shows the historical view and cache view if you did not enable event filtering or summarization. Both views display the same data, but in reverse order. To display the corresponding events, the historical view is scrolled down and the real time (cache) view is scrolled up.

The screenshot shows the 'log Old Way - localhost - SYSADMIN \*ADMIN MODE\*' window. The 'Navigator' pane on the left shows the tree structure with 'log Old Way' selected. The main area is divided into two panes: 'Historical View' and 'Cache View'.

Hub Time: Fri, 08/06/2010 02:22 PM Server Available log Old Way - localhost - SYSADMIN \*ADMIN MODE\*

Figure 75. Historical view and cache view when event filtering or summarization is not enabled

(Figure 76 on page 1626) shows the historical view and cache view if you selected the **Only send summary events** option in the **Event Information** tab. The summary events are displayed in both views, but the new events are only displayed in the real-time (cache) view.

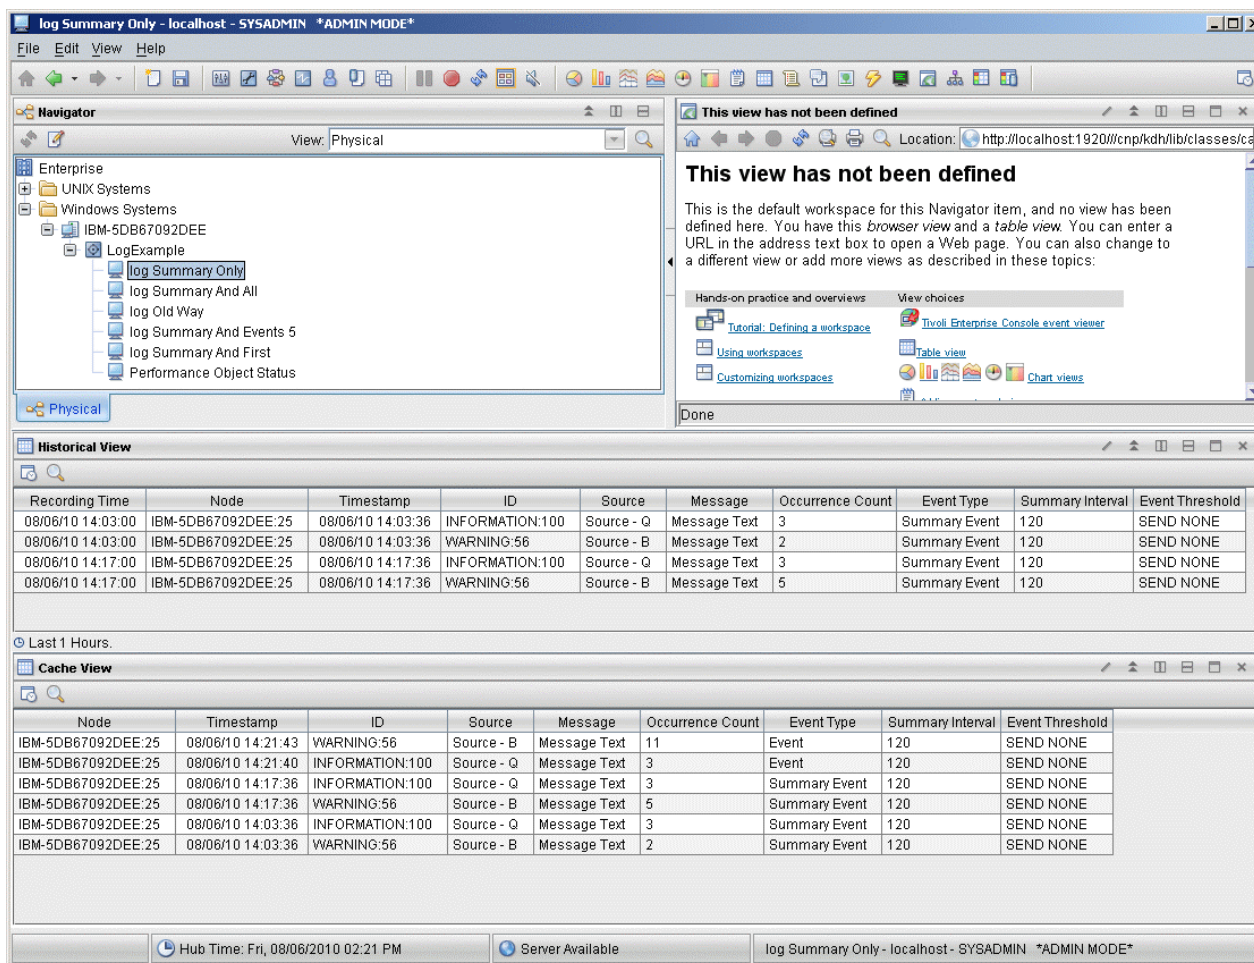

Figure 76. Historical view and cache view when **Only send summary events** is selected

(Figure 77 on page 1627) shows the historical view and cache view if you selected the **Send all events** option in the **Event Information** tab. All of the events are shown in both views, but you also see the summary events that are created at the end of each interval. The real-time view changes when the interval elapses. The existing events are converted into summary records and then the new events are added. The addition of the other two available event attributes that are used to display the summary interval (120 seconds in this example) and the **SEND ALL** threshold.

The screenshot shows the 'log Summary And All - localhost - SYSADMIN \*ADMIN MODE\*' window. The 'Physical' view is selected in the Navigator. The 'Historical View' is displayed, showing a table of events. The 'Cache View' is also displayed, showing a table of events. The status bar at the bottom indicates 'Hub Time: Fri, 08/06/2010 02:22 PM', 'Server Available', and 'log Summary And All - localhost - SYSADMIN \*ADMIN MODE\*'.

**Historical View Table:**

Figure 77. Historical view and cache view when **Send all events** is selected

(Figure 78 on page 1628) shows the historical view and cache view if you selected the **Send first event** option in the **Event Information** tab. The summary events are displayed in both views, but all the new events are only displayed in the real-time (cache) view. For each event, the historical view displays only the first event that is received in the interval and no duplicate events.

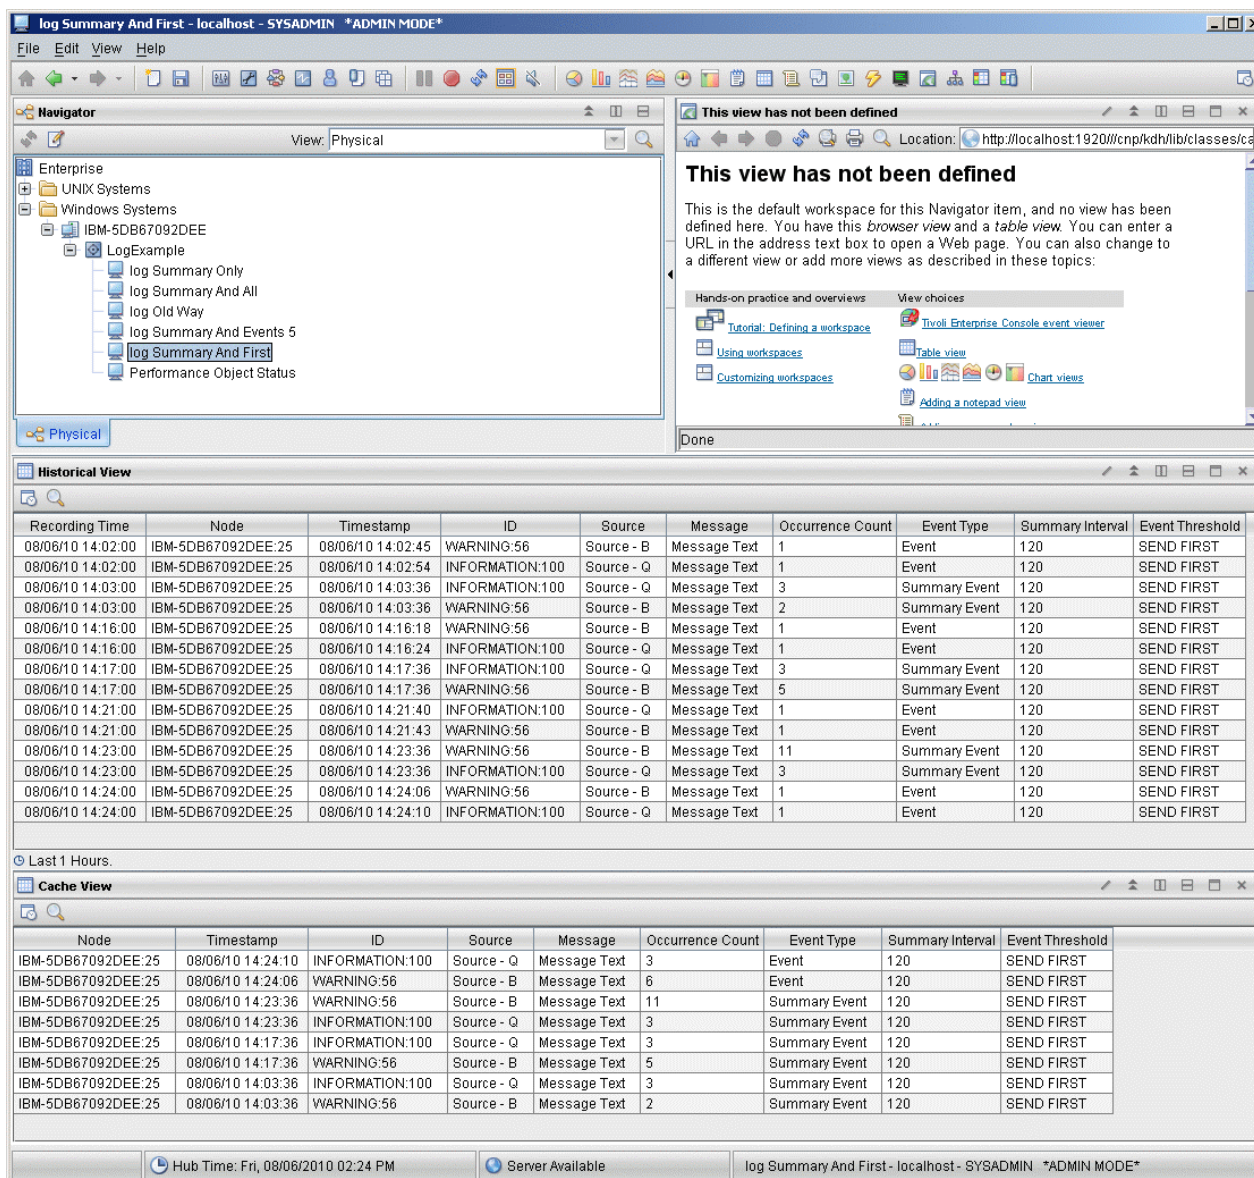

Figure 78. Historical view and cache view when **Send first event** is selected

(Figure 79 on page 1629) shows the historical view and cache view if you selected the **Event threshold** option and entered a value of 5. The summary events are displayed in both views, but all the new events are only displayed in the real-time (cache) view. In this example, a threshold of 5 is specified. The historical view displays an event only when five duplicates of an event (including the first event) are received in the interval. If less than 5 are received, no event is displayed. If 6, 7, 8, or 9 duplicates are received in the interval, one event is displayed. If 10 duplicates are received, 2 events are displayed.

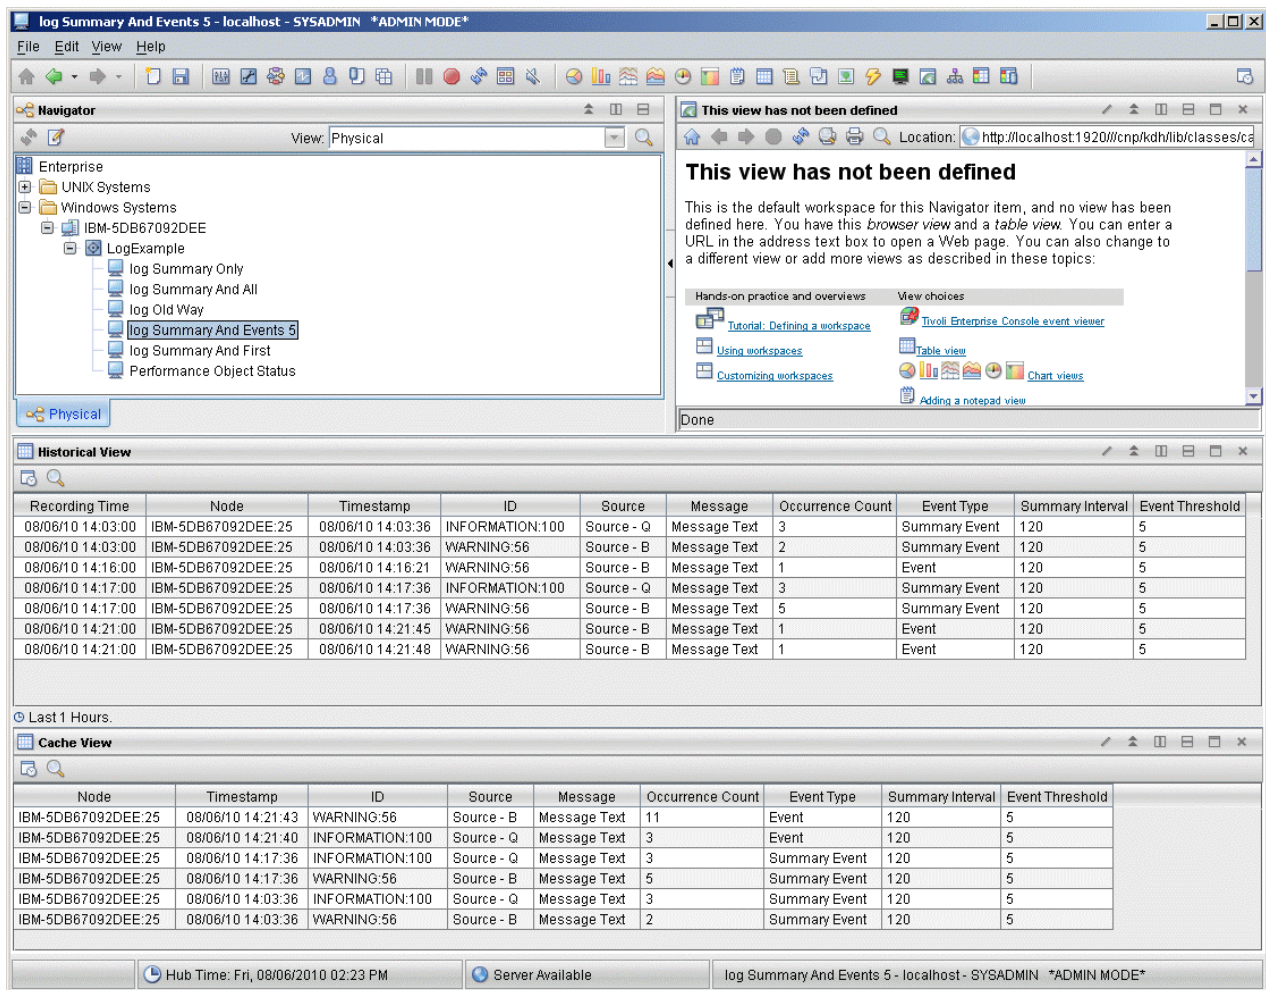

Figure 79. Historical view and cache view when **Event threshold** is selected

## Troubleshooting and support

Review the troubleshooting information for problems that you might experience with installing, configuring, or using IBM Agent Builder.

For help with troubleshooting issues while developing, installing, or using custom agents in the IBM Cloud Application Performance Management environment, see the [IBM Cloud Application Performance Management Troubleshooting Guide](#).

For logging and message reference information and for help with troubleshooting issues related to the IBM Tivoli Monitoring environment, see the [IBM Agent Builder Version 6.3.1 Troubleshooting Guide](#).

## Sharing project files

Share an IBM Tivoli Monitoring agent project with someone.

### Procedure

1. Obtain their files. You need the entire contents of the directory with the same name as the project in your workspace directory.

For example, if your workspace directory is `c:\Documents and Settings\User1\workspace` and you want to share your project named `TestProject`. You must make the directory `c:\Documents and Settings\User1\workspace\TestProject` and all of its contents accessible to your system.

2. Select **File > Import**.
3. Open **IBM Tivoli Monitoring**.
4. Select **IBM Tivoli Monitoring Agent** and click **Next**.
5. Type the full path to the agent xml file or click **Browse** to browse to the file.
6. Click **Finish**.

## Results

When the wizard completes, you see the new IBM Tivoli Monitoring agent project in your workspace.

## Share a Solution Installer Project

Share a Solution Installer Project with someone

### Procedure

1. Obtain their files. You must have the entire contents of the directory with the same name as the Solution Installer project in your workspace directory.  
For example, if your workspace directory is `c:\Documents and Settings\User1\workspace` and you want to share your Solution Installer project named `TestProject Installer`. You must make the directory `c:\Documents and Settings\User1\workspace\TestProject Installer` and all of its contents accessible to your system.
2. Click **File > Import**.
3. Open **General**.
4. Select **Existing Projects into Workspace**, and click **Next**.
5. Type the full path to the root directory of the Solution Installer project, or click **Browse** to browse to the root directory of the Solution Installer project. (In this example the `TestProject Installer` directory.) The Project in that directory is displayed in the Projects list and is selected by default.
6. Optional: Click **Copy projects into workspace**.
7. Click **Finish**.

## Command-line options

---

Commands available from the Agent Builder command-line interface (CLI).

The Tivoli Monitoring Agent Builder contains a command-line interface (CLI) that you can use to generate the Tivoli Monitoring Agent without starting the Eclipse graphical user interface (GUI). You can generate the agent as part of a build, for example:

On Windows systems, you can use a batch file in the following directory to access the CLI:

```
install_location\agenttoolkit.bat
```

On UNIX and Linux systems, you can use a script in the following directory to access the CLI:

```
install_location/agenttoolkit.sh
```

The commands that are described in this documentation are formatted for Windows systems, which use a backslash (\) for directory paths.

For UNIX® or Linux® systems, use the same commands as for Windows systems, but with the following changes:

- Use a forward slash (/) for directory paths instead of a backslash (\).

- Use the `agenttoolkit.sh` script instead of the `agenttoolkit.bat` script.

## Commands

Table 336 on page 1631 lists the name and purpose statement for each command option for the text command:

| Table 336. Command quick-reference table |   |
|--|---|
| Command                                  | Purpose   |
| <b><u>generatelocal</u></b>              | Loads and validates the <code>itm_toolkit_agent.xml</code> file and generates the files that run the Tivoli Monitoring Agent. The installation is into a local Tivoli Monitoring environment. |
| <b><u>generatemappingfile</u></b>        | Creates the mapping file for porting custom IBM Tivoli Monitoring v5.x resource models to IBM Tivoli Monitoring v6 agents.  |
| <b><u>generatezip</u></b>                | Generates a compressed file named <code>productcode.zip</code> or <code>productcode.tgz</code> .  |

The command descriptions that are referenced from the table describes how to run the commands by covering the following information:

### Purpose

Lists the purpose of the command.

### Format

Specifies the syntax that you type on the command line. The syntax contains the command name and a list of the parameters for the command. A definition of each parameter follows the command name.

### Examples

The example for the command contains a brief description of the example and an example of the syntax.

### Usage

Provides an explanation of the command and its purpose.

### Comments

Provides commands or text that can give you more information.

## Command - **generatelocal**

Use this command to load and validate XML and to generate files to run the Tivoli Monitoring Agent.

### Purpose

Loads and validates the `itm_toolkit_agent.xml` file and generates the files for running the Tivoli Monitoring Agent. The installation is into a local Tivoli Monitoring environment.

### Format

For Windows systems:

```
install_location\agenttoolkit.bat project_dir -generatelocal itm_install_dir
```

where:

#### ***install\_location***

Directory where the Agent Builder is installed

#### ***project\_dir***

Name of the directory that contains the `itm_toolkit_agent.xml` file

### ***itm\_install\_dir***

Location where Tivoli Monitoring is installed (for example c : \IBM\ITM)

### **Examples**

In the following example for Windows, the agent definition in C : \ABCAgent is validated and the files that are required to run ABCAgent are generated in C : \IBM\ITM:

```
install_location\agenttoolkit.bat C:\ABCAgent -generate local C:\IBM\ITM
```

## **Command - generatemappingfile**

Use this command to migrate custom IBM Tivoli Monitoring v5.x resource models to IBM Tivoli Monitoring v6 agents.

### **Purpose**

This command creates the mapping file for migrating custom IBM Tivoli Monitoring v5.x resource models to IBM Tivoli Monitoring v6 agents.

### **Format**

For Windows systems:

```
install_location\agenttoolkit.bat project_dir -generatemappingfile output_dir  
itm5_interp_list
```

Where:

#### ***install\_location***

Directory where the Agent Builder is installed

#### ***project\_dir***

Name of the directory that contains itm\_toolkit\_agent.xml

#### ***output\_dir***

Name of the directory where the mapping file is written

#### ***itm5\_interp\_list***

Comma-separated list of the ITM 5x operating systems on which the custom resource model ran. The following values are allowed:

- aix4-r1
- hpux10
- linux-ix86
- linux-ppc
- linux-s390
- os2-ix86
- os400
- solaris2
- solaris2-ix86
- w32-ix86

### **Examples**

For Windows systems

```
install_location\agenttoolkit.bat c:\ABCAgent -generatemappingfile c:\output  
linux-ix86,linux-ppc,linux-s390
```

# Command - generatezip

Use this command to load and validate XML and to generate a compressed file that can be used to install the agent on another system.

## Purpose

Loads and validates the `itm_toolkit_agent.xml` file and generates a compressed file named `productcode.zip` or `productcode.tgz`. The generated compressed file can be used to install the agent on another system. Depending on your environment, both file types can be generated.

## Format

For Windows systems:

```
install_location\agenttoolkit.bat project_dir -generatezip output_dir
```

Where:

***project\_dir***

Name of a directory that contains the `itm_toolkit_agent.xml` file

***output\_dir***

Name of a directory where the compressed file is written

## Examples

In the following example for Windows, the agent definition in `C:\ABCAGENT` is validated and a compressed file that contains the required files for running ABCAGENT is generated in `C:\Output`:

```
install_location\agenttoolkit.bat\ C:\ABCAGENT -generatezip C:\Output
```

# Attributes reference

Contains descriptions of the attributes for each attribute generated group included in the Agent Builder.

## Availability node

The Availability attribute group contains availability data for the application.

The table provides a common format for representing application availability, which includes relevant information for three aspects of an application: services (Windows only), processes, and command return codes.

The following list contains information about each attribute in the Availability attribute group:

**Node attribute - This attribute is a key attribute**

**Description**

The managed system name of the agent

**Type**

String

**Names**

**Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute**

**Description**

The local time at the agent when the data was collected

**Type**

Time

**Names****Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Application Component attribute - This attribute is a key attribute**

**Description**

The descriptive name of a part of the application

**Type**

String

**Names****Attribute name**

Application\_Component

**Column name**

COMPONENT

**Name attribute**

**Description**

The name of the process, service, or functional test. This name matches the executable name of the process, the service short name, or the name of the process that is used to test the application.

**Type**

String

**Names****Attribute name**

Name

**Column name**

NAME

**Status attribute**

**Description**

The status of the application component.

- For processes, the values are UP, DOWN, WARNING, or PROCESS\_DATA\_NOT\_AVAILABLE. PROCESS\_DATA\_NOT\_AVAILABLE is displayed for a process when the matching process is running but the resource use information cannot be collected for that process.
- For services, the values are UP, DOWN, or UNKNOWN. UNKNOWN is displayed when the service is not installed.
- For command return codes, the values are PASSED or FAILED.

**Type**

String

**Names****Attribute name**

Status

**Column name**

STATUS

**Full Name attribute****Description**

The full name of the process which includes information that is process-dependent. The name might include the full path if the process was started that way. The name can also include a partial path or even a path that is changed by the process.

**Type**

String

**Names****Attribute name**

Full\_Name

**Column name**

FULLNAME

**Type attribute****Description**

Identifies the type of the application component. Components are processes, services, or command return codes.

**Type**

Integer (gauge)

**Names****Attribute name**

Type

**Column name**

TYPE

**Virtual Size attribute****Description**

The virtual size (in MB) of the process

**Type**

Integer (gauge)

**Names****Attribute name**

Virtual\_Size

**Column name**

VIRTSIZE

**Page Faults Per Sec attribute****Description**

The rate of page faults for the process that is measured in faults per second. This value contains only valid data for processes.

**Type**

Integer (gauge)

**Names****Attribute name**

Page\_Faults\_Per\_Sec

**Column name**  
PAGEFAULTS

### **Working Set Size attribute**

**Description**  
The working set size of the process in MB. This value contains only valid data for processes.

**Type**  
Integer (gauge)

#### **Names**

**Attribute name**  
Working\_Set\_Size

**Column name**  
WORKSET

### **Thread Count attribute**

**Description**  
The number of threads that are currently allocated by this process. This value contains only valid data for processes.

**Type**  
Integer (gauge)

#### **Names**

**Attribute name**  
Thread\_Count

**Column name**  
THREADS

### **PID attribute**

**Description**  
The process id that is associated with the process. This value contains only valid data for processes.

**Type**  
Integer (gauge)

#### **Names**

**Attribute name**  
PID

**Column name**  
PID

### **Percent Privileged Time attribute**

**Description**  
The percentage of the available processor time that is being used by this process for privileged operation

**Type**  
Integer (gauge)

#### **Names**

**Attribute name**  
Percent\_Privileged\_Time

**Column name**  
PERCPRIV

## Percent User Mode Time attribute

### Description

The percentage of the available processor time that is being used by this process for user mode operation

### Type

Integer (gauge)

### Names

#### Attribute name

Percent\_User\_Mode\_Time

#### Column name

PERCUSER

## Percent Processor Time attribute

### Description

The percentage of the elapsed time that this process used the processor to run instructions

### Type

Integer (gauge)

### Names

#### Attribute name

Percent\_Processor\_Time

#### Column name

PERCPROC

## Command Line attribute

### Description

The program name and any arguments that are specified on the command line when the process was started. This attribute has the value N/A if you are running a Service or Functionality test.

### Type

String

### Names

#### Attribute name

Command\_Line

#### Column name

CMDLINE

## Functionality Test Status attribute

### Description

The return code of the functionality test. When the monitored application is running correctly, SUCCESS is returned. NOT\_RUNNING is returned when the application is not running correctly. N/A is returned when the row does not represent a functionality test.

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the numbers. The defined values are: N/A(1), SUCCESS (0), GENERAL\_ERROR (2), WARNING (3), NOT\_RUNNING (4), DEPENDENT\_NOT\_RUNNING (5), ALREADY\_RUNNING (6), PREREQ\_NOT\_RUNNING (7), TIMED\_OUT (8), DOESNT\_EXIST (9), UNKNOWN (10), DEPENDENT\_STILL\_RUNNING (11), or INSUFFICIENT\_USER\_AUTHORITY (12). Any other values display the numeric value in the Tivoli Enterprise Portal.

## Names

### Attribute name

Functionality\_Test\_Status

### Column name

FUNCSTATUS

## Functionality Test Message attribute

### Description

The text message that corresponds to the Functionality Test Status. This attribute is valid only for command return codes.

### Type

String

## Names

### Attribute name

Functionality\_Test\_Message

### Column name

FUNCMSG

## Performance Object Status node

Use the Performance Object Status attribute group to see the status of all of the attribute groups that make up the agent. Each of the attribute groups is represented by a row in this table or other type of view. The status of an attribute group reflects the result of the last data collection attempt, or data reception event, for the attribute group. When you check the status information, you can see whether the agent is operating correctly. When your agent does not collect data, but receives it (event data), attributes that relate to sampled data do not contain useful data. Only the first seven attributes that are listed are relevant for event data.

### Historical group

This attribute group is eligible for use with Tivoli Data Warehouse.

### Attribute descriptions

The following list contains information about each attribute in the Performance Object Status attribute group:

**Node attribute: This attribute is a key attribute.**

### Description

The managed system name of the agent.

### Type

String

### Warehouse name

NODE

## Timestamp attribute

### Description

The local time at the agent when the data was collected.

### Type

String

### Warehouse name

TIMESTAMP

**Query Name attribute: This attribute is a key attribute.**

**Description**

The name of the attribute group.

**Type**

String

**Warehouse name**

QUERY\_NAME or ATTRGRP

**Object Name attribute****Description**

The name of the performance object.

**Type**

String

**Warehouse name**

OBJECT\_NAME or OBJNAME

**Object Type attribute****Description**

The type of the performance object.

**Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- WMI (0)
- PERFMON (1)
- WMI ASSOCIATION GROUP (2)
- JMX (3)
- SNMP (4)
- SHELL COMMAND (5)
- JOINED GROUPS (6)
- CIMOM (7)
- CUSTOM (8)
- ROLLUP DATA (9)
- WMI REMOTE DATA (10)
- LOG FILE (11)
- JDBC (12)
- CONFIG DISCOVERY (13)
- NT EVENT LOG (14)
- FILTER (15)
- SNMP EVENT (16)
- PING (17)
- DIRECTOR DATA (18)
- DIRECTOR EVENT (19)
- SSH REMOTE SHELL COMMAND (20)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

**Warehouse name**

OBJECT\_TYPE or OBJTYPE

## Object Status attribute

### Description

The status of the performance object.

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- ACTIVE (0)
- INACTIVE (1)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

### Warehouse name

OBJECT\_STATUS or OBJSTTS

## Error Code attribute

### Description

The error code that is associated with the query.

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- NO ERROR (0)
- GENERAL ERROR (1)
- OBJECT NOT FOUND (2)
- COUNTER NOT FOUND (3)
- NAMESPACE ERROR (4)
- OBJECT CURRENTLY UNAVAILABLE (5)
- COM LIBRARY INIT FAILURE (6)
- SECURITY INIT FAILURE (7)
- PROXY SECURITY FAILURE (9)
- NO INSTANCES RETURNED (10)
- ASSOCIATOR QUERY FAILED (11)
- REFERENCE QUERY FAILED (12)
- NO RESPONSE RECEIVED (13)
- CANNOT FIND JOINED QUERY (14)
- CANNOT FIND JOIN ATTRIBUTE IN QUERY 1 RESULTS (15)
- CANNOT FIND JOIN ATTRIBUTE IN QUERY 2 RESULTS (16)
- QUERY 1 NOT A SINGLETON (17)
- QUERY 2 NOT A SINGLETON (18)
- NO INSTANCES RETURNED IN QUERY 1 (19)
- NO INSTANCES RETURNED IN QUERY 2 (20)
- CANNOT FIND ROLLUP QUERY (21)
- CANNOT FIND ROLLUP ATTRIBUTE (22)
- FILE OFFLINE (23)
- NO HOSTNAME (24)

- MISSING LIBRARY (25)
- ATTRIBUTE COUNT MISMATCH (26)
- ATTRIBUTE NAME MISMATCH (27)
- COMMON DATA PROVIDER NOT STARTED (28)
- CALLBACK REGISTRATION ERROR (29)
- MDL LOAD ERROR (30)
- AUTHENTICATION FAILED (31)
- CANNOT RESOLVE HOST NAME (32)
- SUBNODE UNAVAILABLE (33)
- SUBNODE NOT FOUND IN CONFIG (34)
- ATTRIBUTE ERROR (35)
- CLASSPATH ERROR (36)
- CONNECTION FAILURE (37)
- FILTER SYNTAX ERROR (38)
- FILE NAME MISSING (39)
- SQL QUERY ERROR (40)
- SQL FILTER QUERY ERROR (41)
- SQL DB QUERY ERROR (42)
- SQL DB FILTER QUERY ERROR (43)
- PORT OPEN FAILED (44)
- ACCESS DENIED (45)
- TIMEOUT (46)
- NOT IMPLEMENTED (47)
- REQUESTED A BAD VALUE (48)
- RESPONSE TOO BIG (49)
- GENERAL RESPONSE ERROR (50)
- SCRIPT NONZERO RETURN (51)
- SCRIPT NOT FOUND (52)
- SCRIPT LAUNCH ERROR (53)
- CONF FILE DOES NOT EXIST (54)
- CONF FILE ACCESS DENIED (55)
- INVALID CONF FILE (56)
- EIF INITIALIZATION FAILED (57)
- CANNOT OPEN FORMAT FILE (58)
- FORMAT FILE SYNTAX ERROR (59)
- REMOTE HOST UNAVAILABLE (60)
- EVENT LOG DOES NOT EXIST (61)
- PING FILE DOES NOT EXIST (62)
- NO PING DEVICE FILES (63)
- PING DEVICE LIST FILE MISSING (64)
- SNMP MISSING PASSWORD (65)
- DISABLED (66)
- URLS FILE NOT FOUND (67)

- XML PARSE ERROR (68)
- NOT INITIALIZED (69)
- ICMP SOCKETS FAILED (70)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

**Warehouse name**

ERROR\_CODE or ERRCODE

**Last Collection Start attribute**

**Description**

The most recent time a data collection of this group started.

**Type**

Time stamp with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- NOT COLLECTED (0691231190000000)
- NOT COLLECTED (0000000000000001)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

**Warehouse name**

LAST\_COLLECTION\_START or COLSTR

**Last Collection Finished attribute**

**Description**

The most recent time a data collection of this group finished.

**Type**

Time stamp with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- NOT COLLECTED (0691231190000000)
- NOT COLLECTED (0000000000000001)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

**Warehouse name**

LAST\_COLLECTION\_FINISHED or COLFINI

**Last Collection Duration attribute**

**Description**

The duration of the most recently completed data collection of this group in seconds.

**Type**

Real number (32-bit counter) with two decimal places of precision

**Warehouse name**

LAST\_COLLECTION\_DURATION or COLDURA

**Average Collection Duration attribute**

**Description**

The average duration of all data collections of this group in seconds.

**Type**

Real number (32-bit counter) with two decimal places of precision with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the values that are shown in parentheses. The following values are defined:

- NO DATA (-100)

Any other value is the value that is returned by the agent in the Tivoli Enterprise Portal.

**Warehouse name**

AVERAGE\_COLLECTION\_DURATION or COLAVGD

**Refresh Interval attribute**

**Description**

The interval at which this group is refreshed in seconds.

**Type**

Integer (32-bit counter)

**Warehouse name**

REFRESH\_INTERVAL or REFRINT

**Number of Collections attribute**

**Description**

The number of times this group is collected since agent start.

**Type**

Integer (32-bit counter)

**Warehouse name**

NUMBER\_OF\_COLLECTIONS or NUMCOLL

**Cache Hits attribute**

**Description**

The number of times an external data request for this group is satisfied from the cache.

**Type**

Integer (32-bit counter)

**Warehouse name**

CACHE\_HITS or CACHEHT

**Cache Misses attribute**

**Description**

The number of times an external data request for this group was not available in the cache.

**Type**

Integer (32-bit counter)

**Warehouse name**

CACHE\_MISSES or CACHEMS

**Cache Hit Percent attribute**

**Description**

The percentage of external data requests for this group that are satisfied from the cache.

**Type**

Real number (32-bit counter) with two decimal places of precision

**Warehouse name**

CACHE\_HIT\_PERCENT or CACHPCT

**Intervals Skipped attribute**

**Description**

The number of times a background data collection was skipped because the previous collection was still running when the next one was due to start.

**Type**

Integer (32-bit counter)

**Warehouse name**

INTERVALS\_SKIPPED or INTSKIP

## Thread Pool Status attribute group

The Thread Pool Status attribute group contains information that reflects the status of the internal thread pool that is used to collect data asynchronously.

The following comprises a list of the attributes for this attribute group. The name in bold text shows how the attribute is displayed in the Tivoli Enterprise Portal.

The following list contains information about each attribute in the Thread Pool Status attribute group:

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent

**Type**

String

**Names****Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute****Description**

The time that is collected from the agent system when the data row was built and sent from the agent to the Tivoli Enterprise Monitoring Server. Or stored for historical purposes. It represents the local time zone of the agent system.

**Type**

Time

**Names****Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Thread Pool Size attribute****Description**

The number of threads currently existing in the thread pool.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Size

**Column name**

THPSIZE

**Thread Pool Max Size attribute****Description**

The maximum number of threads that are allowed to exist in the thread pool.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Max\_Size

**Column name**

TPMAXSZ

**Thread Pool Active Threads attribute****Description**

The number of threads in the thread pool currently active doing work.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Active\_Threads

**Column name**

TPACTTH

**Thread Pool Avg Active Threads attribute****Description**

The average number of threads in the thread pool simultaneously active doing work.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Avg\_Active\_Threads

**Column name**

TPAVGAT

**Thread Pool Min Active Threads attribute****Description**

The minimum number of threads in the thread pool simultaneously active doing work.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Min\_Active\_Threads

**Column name**

TPMINAT

**Thread Pool Max Active Threads attribute**

**Description**

The peak number of threads in the thread pool simultaneously active doing work.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Max\_Active\_Threads

**Column name**

TPMAXAT

**Thread Pool Queue Length attribute****Description**

The number of jobs currently waiting in the thread pool queue.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Queue\_Length

**Column name**

TPQLGTH

**Thread Pool Avg Queue Length attribute****Description**

The average length of the thread pool queue during this run.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Avg\_Queue\_Length

**Column name**

TPAVGQL

**Thread Pool Min Queue Length attribute****Description**

The minimum length the thread pool queue reached.

**Type**

Integer

**Names****Attribute name**

Thread\_Pool\_Min\_Queue\_Length

**Column name**

TPMINQL

**Thread Pool Max Queue Length attribute****Description**

The peak length the thread pool queue reached.

**Type**

Integer

## Names

### Attribute name

Thread\_Pool\_Max\_Queue\_Length

### Column name

TPMAXQL

## Thread Pool Avg Job Wait attribute

### Description

The average time a job spends waiting on the thread pool queue.

### Type

Integer

## Names

### Attribute name

Thread\_Pool\_Avg\_Job\_Wait

### Column name

TPAVJBW

## Thread Pool Total Jobs attribute

### Description

The number of jobs that are completed by all threads in the pool since agent start.

### Type

Integer

## Names

### Attribute name

Thread\_Pool\_Total\_Jobs

### Column name

TPTJOBS

## Event log attribute node

The Event log attribute group contains any recent event log entries that pertain to the application.

By default, the agent displays only events that occur after the agent is started. Events are removed from the Event Log view 1 hour after they occur.

The following list contains information about each attribute in the Event Log attribute group:

### Node attribute - This attribute is a key attribute

### Description

The managed system name of the agent

### Type

String

## Names

### Attribute name

Node

### Column name

ORIGINNODE

## Log Name attribute

**Description**

The event log - Application, System, Security, or an application-specific log

**Type**

String

**Names****Attribute name**

Log\_Name

**Column name**

LOGNAME

**Event Source attribute****Description**

The event source that is defined by the application

**Type**

String

**Names****Attribute name**

Event\_Source

**Column name**

EVTSOURCE

**Event Type attribute****Description**

Event Type - Error(0), Warning(1), Informational(2), Audit\_Success(3), Audit\_Failure(4), Unknown(5)

**Type**

Integer

**Names****Attribute name**

Event\_Type

**Column name**

EVTTYPE

**Event ID attribute****Description**

The ID of the event

**Type**

Integer

**Names****Attribute name**

Event\_ID

**Column name**

EVTID

**Event Category attribute****Description**

The category of the event

**Type**

String

**Names****Attribute name**

Event\_Category

**Column name**

EVTCATEG

**Message attribute****Description**

The event message

**Type**

String

**Names****Attribute name**

Message

**Column name**

MESSAGE

**Time Generated attribute****Description**

The time the event was generated

**Type**

Time

**Names****Attribute name**

Time\_Generated

**Column name**

TIMESTAMP

## Log File Summary

The attributes of this attribute group are included in summary attribute groups when that option is selected in the advanced properties of the data source.

A Summary node is created for each Log File data source when **Include attribute in summary attribute group** is selected in the advanced properties of the data source. The name of the summary node is the name of the data source with Summary added to the end.

The following list contains information about each of the default attributes in the Log File Summary attribute group. These attributes are always included in summary attribute groups. If you select **Include attribute in summary attribute group**, see step “9” on page 1486 in (“Monitoring a log file” on page 1482), then the summary attribute group for that log attribute group also contains each of the attributes you selected. The values are a copy of the corresponding attribute in the log file attribute group.

All of the added attributes together become a key and the summary table includes one row per unique set of keys. The row indicates how many log records are received during the interval where all of the provided keys matched the value reported in the corresponding attributes.

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent

**Type**

String

**Names****Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute****Description**

The local time at the agent when the data was collected

**Type**

Time

**Names****Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Interval Unit attribute****Description**

The number of seconds between summary attribute generation

**Type**

Integer (gauge)

**Names****Attribute name**

\_Interval\_Unit

**Column name**

IU

**Interval attribute****Description**

Offset of the current interval within the next larger unit of time (for example, minutes within an hour)

**Type**

Integer (gauge)

**Names****Attribute name**

\_Interval

**Column name**

INV

**Occurrences attribute****Description**

The number of occurrences that are recorded during the interval

**Type**

Integer (gauge)

## **Names**

### **Attribute name**

\_Occurrences

### **Column name**

### **Attribute name**

\_Interval\_Unit\_Name

### **Column name**

IUN

## **AIX Binary Log attribute group**

The AIX Binary Log attribute group displays events from the AIX Binary Log as selected by the provided `errpt` command string.

The following list contains information about each attribute in the AIX Binary Log Attribute Group:

**Note:** The Agent Builder prevents removing, reordering, or changing the size of the Identifier, ErrptTimestamp, Type, Class, ResourceName, and Description attributes. The agent parses the data that comes back from an `errpt` command that is based on columns within the line of text. These columns are defined by the order and size of the Identifier, ErrptTimestamp, Type, Class, ResourceName, and Description attributes. Removing, reordering, or changing the size of these

attributes, changes the attribute that the various columns go into. The resulting row as seen in Tivoli Monitoring is then incorrect.

You can, however, rename these attributes.

#### **Node attribute - This attribute is a key attribute**

##### **Description**

The managed system name of the agent

##### **Type**

String

##### **Names**

###### **Attribute name**

Node

###### **Column name**

ORIGINNODE

#### **Identifier attribute - This attribute is a key attribute**

##### **Description**

The event identifier reported by errpt

##### **Type**

String

##### **Names**

###### **Attribute name**

Identifier

###### **Column name**

IDENTIFIER

#### **ErrptTimestamp attribute**

##### **Description**

The time the event is recorded as reported by errpt.

**Note:** This attribute is hidden at run time. This attribute contains a raw value. Other attributes that are derived from this attribute display the value in a more usable form. This attribute is available from within Agent Builder for that purpose, but by default it is not visible in the Tivoli Monitoring environment at run time. If you want to make it visible, select the attribute in the **Data Source Definition** page in the Agent Editor and select **Display attribute in the Tivoli Enterprise Portal**.

##### **Type**

String

##### **Names**

###### **Attribute name**

ErrptTimestamp

###### **Column name**

ERRPTTIMES

#### **Type**

##### **Description**

The single character event type reported by errpt, one of I(NFO), P(END/ERF/ERM), T(EMP), and U(NKN)

##### **Type**

String

## Names

### Attribute name

Type

### Column name

TYPE

**Class attribute - This attribute is a key attribute**

## Description

The event class reported by `errpt`, one of Hardware, Software, Operator, and Undertermined. These values are enumerated. The raw values for use with situations are H, S, O, and U.

## Type

String

## Names

### Attribute name

Class

### Column name

CLASS

## ResourceName

## Description

The resource name reported by `errpt`, identifies the origin of the error record

## Type

String

## Names

### Attribute name

ResourceName

### Column name

RESCOURCENA

## Description attribute

## Description

The description reported by `errpt`, typically a short text message that describes the nature of the error

## Type

String

## Names

### Attribute name

Description

### Column name

DESCRIPTIO

## LogFile attribute

## Description

The full name of the binary `errpt` log including the path.

**Note:** This attribute is hidden at run time. This attribute contains a raw value. Other attributes that are derived from this attribute display the value in a more useable form. This attribute is available from within Agent Builder for that purpose, but by default it is not visible in the Tivoli Monitoring

environment at run time. If you want to make it visible, select the attribute in the **Data Source Definition** page in the Agent Editor and select **Display attribute in the Tivoli Enterprise Portal**.

**Type**

String

**Names**

**Attribute name**

LogFile

**Column name**

LOGFILE

**System attribute**

**Description**

The host name of the system where the error was collected

**Type**

String

**Names**

**Attribute name**

System

**Column name**

SYSTEM

**LogName attribute**

**Description**

The base name of the binary `errpt` log from which the record was collected

**Type**

String

**Names**

**Attribute name**

LogName

**Column name**

LOGNAME

**LogPath attribute**

**Description**

The directory name that contains the binary `errpt` log from which the record was collected

**Type**

String

**Names**

**Attribute name**

LogPath

**Column name**

LOGPATH

**EntryTime attribute**

**Description**

The time the event is recorded as reported by `errpt` in Tivoli Timestamp format. This time is not necessarily identical to the time when the agent received the event, as recorded in the **Timestamp** field.

**Type**

Time stamp

**Names****Attribute name**

EntryTime

**Column name**

ENTRYTIME

## Monitor and Notification attribute groups

Definitions for the Monitor and Notification attribute groups.

The first 4 are specific to monitors and the last is for notifications (all are related to JMX).

Each one is listed with an indication whether it is event-based or not. For non-event based attribute groups, data is collected when needed. For event-based attribute groups, the agent maintains a cache of the last 100 events received. These events are used to respond to requests from the Tivoli Enterprise Portal. The events are forwarded immediately for analysis by situations and warehousing.

### Counter Notifications

The Counter Notifications attribute group is a non-event based attribute group that sends events that are received by all counter monitors.

The following list contains information about each attribute in the Counter Notifications attribute group:

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent

**Type**

String

**Names****Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute****Description**

The local time at the agent when the data was collected

**Type**

Time

**Names****Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Notification Type attribute****Description**

The type of notification received. Describes how the observed attribute of the MBean triggered the notification.

**Type**

String

**Names****Attribute name**

Notification\_Type

**Column name**

NOTIFICATI

**Monitor ID attribute****Description**

Monitor ID of the monitor who generated this notification

**Type**

Integer

**Names****Attribute name**

Monitor\_ID

**Column name**

MONITOR\_ID

**Observed MBean attribute****Description**

The MBean whose attribute is being monitored

**Type**

String

**Names****Attribute name**

Observed\_MBean

**Column name**

OBSERVED\_M

**Observed Attribute attribute****Description**

Name of the attribute that is monitored in the Observed MBean

**Type**

String

**Names****Attribute name**

Observed\_Attribute

**Column name**

OBSERVED\_A

**Threshold attribute****Description**

The current threshold of the monitor

**Type**

String

**Names****Attribute name**

Threshold

**Column name**

THRESHOLD

**Offset attribute****Description**

The value added to the threshold each time the attribute exceeds the threshold. This value forms a new threshold.

**Type**

String

**Names****Attribute name**

Offset

**Column name**

OFFSET

**Modulus attribute****Description**

The maximum value of the attribute. When it reaches this value, it rolls over and begins counting again from zero.

**Type**

Integer

**Names****Attribute name**

Modulus

**Column name**

MODULUS

**Counter Value attribute****Description**

Value of the counter that triggered the notification

**Type**

Integer

**Names****Attribute name**

Counter\_Value

**Column name**

COUNTER\_VA

**Notification Time Stamp attribute****Description**

Time that the notification was triggered

**Type**

Time

## **Names**

### **Attribute name**

Notification\_Time\_Stamp

### **Column name**

NOTIFICATO

## **Notification Message attribute**

### **Description**

The message in the notification

### **Type**

String

## **Names**

### **Attribute name**

Notification\_Message

### **Column name**

NOTIFICAT1

## **Gauge Notifications**

The Gauge Notifications attribute group is a non-event based attribute group that sends events that are received by all gauge monitors.

The following list contains information about each attribute in the Gauge Notifications attribute group:

### **Node attribute - This attribute is a key attribute**

### **Description**

The managed system name of the agent

### **Type**

String

## **Names**

### **Attribute name**

Node

### **Column name**

ORIGINNODE

## **Timestamp attribute**

### **Description**

The local time at the agent when the data was collected

### **Type**

Time

## **Names**

### **Attribute name**

Timestamp

### **Column name**

TIMESTAMP

## **Notification Type attribute**

### **Description**

The type of notification received. Describes how the observed attribute of the MBean triggered the notification.

**Type**

String

**Names****Attribute name**

Notification\_Type

**Column name**

NOTIFICATI

**Monitor ID attribute****Description**

Monitor ID of the monitor who generated this notification

**Type**

Integer

**Names****Attribute name**

Monitor\_ID

**Column name**

MONITOR\_ID

**Observed MBean attribute****Description**

The MBean whose attribute is being monitored

**Type**

String

**Names****Attribute name**

Observed\_MBean

**Column name**

OBSERVED\_M

**Observed Attribute attribute****Description**

Name of the attribute that is monitored in the Observed MBean

**Type**

String

**Names****Attribute name**

Observed\_Attribute

**Column name**

OBSERVED\_A

**Low Threshold attribute****Description**

The threshold that the monitor is watching for the observed attribute to cross

**Type**

String

**Names****Attribute name**

Low\_Threshold

**Column name**

LOW\_THRESH

**High Threshold attribute****Description**

The threshold that the monitor is watching for the observed attribute to cross

**Type**

String

**Names****Attribute name**

High\_Threshold

**Column name**

HIGH\_THRES

**Gauge Value attribute****Description**

Value of the gauge that triggered the notification

**Type**

String

**Names****Attribute name**

Gauge\_Value

**Column name**

MODULUSGAUGE\_VALU

**Notification Time Stamp attribute****Description**

Time that the notification was triggered

**Type**

Time

**Names****Attribute name**

Notification\_Time\_Stamp

**Column name**

NOTIFICATO

**Notification Message attribute****Description**

The message in the notification

**Type**

String

**Names****Attribute name**

Notification\_Message

**Column name**  
NOTIFICAT1

## Registered Monitors

The Registered Monitors attribute group is an event-based attribute group that shows a list of all JMX Monitors that are created by the agent.

The following list contains information about each attribute in the Registered Monitors attribute group:

### Node attribute - This attribute is a key attribute

**Description**

The managed system name of the agent

**Type**

String

**Names**

**Attribute name**

Node

**Column name**

ORIGINNODE

### Timestamp attribute

**Description**

The local time at the agent when the data was collected

**Type**

Time

**Names**

**Attribute name**

Timestamp

**Column name**

TIMESTAMP

### Monitor ID attribute - This attribute is a key attribute

**Description**

The unique integer identifier for a monitor

**Type**

Integer

**Names**

**Attribute name**

Monitor\_ID

**Column name**

MONITOR\_ID

### Monitor Parameters attribute

**Description**

The parameters that are used to create the monitor

**Type**

String

## **Names**

### **Attribute name**

Monitor\_Parameters

### **Column name**

MONITOR\_PA

## **Monitor Name attribute**

### **Description**

The JMX Object Name of the monitor MBean

### **Type**

String

## **Names**

### **Attribute name**

Monitor\_Name

### **Column name**

MONITOR\_NA

## **String Notifications**

The String Notifications attribute group is a non-event based attribute group that sends events that are received by all string monitors.

The following list contains information about each attribute in the String Notifications attribute group:

### **Node attribute - This attribute is a key attribute**

### **Description**

The managed system name of the agent

### **Type**

String

## **Names**

### **Attribute name**

Node

### **Column name**

ORIGINNODE

## **Timestamp attribute**

### **Description**

The local time at the agent when the data was collected

### **Type**

Time

## **Names**

### **Attribute name**

Timestamp

### **Column name**

TIMESTAMP

## **Notification Type attribute**

### **Description**

The type of notification received. Describes how the observed attribute of the MBean triggered the notification.

**Type**

String

**Names****Attribute name**

Notification\_Type

**Column name**

NOTIFICATI

**Monitor ID attribute - This attribute is a key attribute****Description**

The unique integer identifier for a monitor

**Type**

Integer

**Names****Attribute name**

Monitor\_ID

**Column name**

MONITOR\_ID

**Observed MBean attribute****Description**

The MBean whose attribute is being monitored

**Type**

String

**Names****Attribute name**

Observed\_MBean

**Column name**

OBSERVED\_M

**Observed Attribute attribute****Description**

Name of the attribute that is monitored in the Observed MBean

**Type**

String

**Names****Attribute name**

Observed\_Attribute

**Column name**

OBSERVED\_A

**Compare String attribute****Description**

The string that is used in the comparison operation

**Type**

String

## **Names**

### **Attribute name**

Compare\_String

### **Column name**

COMPARE\_ST

## **String Value attribute**

### **Description**

Value of the attribute that triggered the notification

### **Type**

String

## **Names**

### **Attribute name**

String\_Value

### **Column name**

STRING\_VAL

## **Notification Time Stamp attribute**

### **Description**

Time that the notification was triggered

### **Type**

Time

## **Names**

### **Attribute name**

Notification\_Time\_Stamp

### **Column name**

NOTIFICATO

## **Notification Message attribute**

### **Description**

The message in the notification

### **Type**

String

## **Names**

### **Attribute name**

Notification\_Message

### **Column name**

NOTIFICAT1

## **SNMP Event attribute groups**

SNMP event attribute groups are used to receive traps and informs. These attribute groups are event-based attribute groups

The following list contains information about each attribute in the SNMP Event Attribute Groups:

**Note:** You can change the default display name of these attributes. These display names are distinct from the internal ID for each attribute.

### **Enterprise\_OID**

The enterprise OID that generated the trap.

**Source\_Address**

Host name or IP address of the SNMP agent that sent the trap.

**Generic\_Trap**

Generic trap number that is extracted from the received trap. Possible values:

- 0 ColdStart
- 1 WarmStart
- 2 LinkDown
- 3 LinkUp
- 4 Authentication Failure
- 5 EGPNeighborLoss

**Specific\_Trap**

Enterprise-specific trap number that is extracted from the received trap. Applies only when Generic\_Trap = 6.

**Alert\_Name**

Trap name as specified in the definition in the trap configuration file.

**Category**

Trap category as specified in the definition in the trap configuration file.

**Description**

Trap description as specified in the definition in the trap configuration file. The maximum description length is 256 characters.

**Enterprise\_Name**

Trap Enterprise name as specified in the trap configuration file and determined through the trap object identifier.

**Source\_Status**

Status of the agent that originated the trap after the trap is sent as specified in the trap definition in the trap configuration file.

**Source\_Type**

Type of the agent that originated the trap as specified in the trap definition in the trap configuration file.

**Event\_Variables**

Variable binding (VarBind) data that is received in the trap protocol data unit (PDU). The string is constructed as:

```
{OID[type]=value}{OID[type]=value}{oid[type]=value}...
```

Where:

**oid**

MIB variable object identifier

**type**

SMI data type

**value**

Variable value

**{}**

Each triplet is surrounded by braces ({}).

**Note:** The attributes Alert Name, Category, Description, Enterprise\_Name, Source\_Status, and Source\_Type provide more information. In the **SNMP MIB Browser** window, select the **Include attributes that show information defined in the trap configuration file** check box to include these attributes.

## JMX Event attribute groups

JMX event attribute groups are used to receive notifications from an MBean server.

These attribute groups are non-event based attribute groups and are generated with the following attributes that can be edited by the agent developer.

The following list contains information about each attribute in the JMX Event Attribute Groups:

### **Node attribute - This attribute is a key attribute**

#### **Description**

The managed system name of the agent

#### **Type**

String

#### **Names**

##### **Attribute name**

Node

##### **Column name**

ORIGINNODE

### **Timestamp attribute**

#### **Description**

The local time at the agent when the data was collected

#### **Type**

Time

#### **Names**

##### **Attribute name**

Timestamp

##### **Column name**

TIMESTAMP

### **Type attribute**

#### **Description**

The notification type

#### **Type**

String

#### **Names**

##### **Attribute name**

Type

##### **Column name**

TYPE

### **Source attribute**

#### **Description**

The MBean that caused the notification to be sent

#### **Type**

String

#### **Names**

##### **Attribute name**

Source

**Column name**

SOURCE

**Sequence Number attribute****Description**

The sequence number from the notification object

**Type**

String

**Names****Attribute name**

Sequence\_Number

**Column name**

SEQUENCE\_N

**Message attribute****Description**

The notification message

**Type**

String

**Names****Attribute name**

Message

**Column name**

MESSAGE

**User Data attribute****Description**

The user data object from the notification

**Type**

String

**Names****Attribute name**

User\_Data

**Column name**

USER\_DATA

**Ping attribute group**

The Ping attribute group contains the results of ICMP pings that are sent to lists of devices.

The following list contains information about each attribute in the Ping Attribute Group:

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent.

**Type**

String

**Names****Attribute name**

Node

**Column name**  
ORIGINNODE

#### **Timestamp attribute**

**Description**

The time that is collected from the agent system when the data row was built and sent from the agent to the Tivoli Enterprise Monitoring Server. Or stored for historical purposes. It represents the local time zone of the agent system.

**Type**

Time

**Names**

**Attribute name**  
Timestamp

**Column name**  
TIMESTAMP

#### **Address attribute - This attribute is a key attribute**

**Description**

The IP address of the host that is monitored.

**Type**

String with enumerated value. The value UNKNOWN\_ADDRESS is displayed if the IP address is unknown. The warehouse and queries return 0.0.0.0 for this enumeration. Any other IP address values are displayed as is.

**Names**

**Attribute name**  
Address

**Column name**  
PNGADDR

#### **Device Entry attribute - This attribute is a key attribute**

**Description**

The entry in the device list file for this node.

**Type**

String

**Names**

**Attribute name**  
Device\_Entry

**Column name**  
PINGDEV

#### **Current Response Time attribute**

**Description**

The current network response time for ICMP requests for the managed node in milliseconds.

**Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the numbers. The defined values are TIMEOUT (-1) and SEND\_FAILURE (-2). Any other values show the numeric value.

## **Names**

### **Attribute name**

Current\_Response\_Time

### **Column name**

PINGRSTM

## **Name attribute**

### **Description**

The host name of the managed node. If the node address cannot be resolved through DNS, then the dotted decimal IP address is shown.

### **Type**

String with enumerated value. The value UNKNOWN\_HOSTNAME is displayed if the host name is unknown. The warehouse and queries return 0.0.0.0 for this enumeration. Any other host name values are displayed as is.

## **Names**

### **Attribute name**

Name

### **Column name**

PNGNAME

## **Node Description attribute**

### **Description**

The description of the managed node.

### **Type**

String

## **Names**

### **Attribute name**

Node\_Description

### **Column name**

PNGDESC

## **Node Status attribute**

### **Description**

The current operating status of the managed node.

### **Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the numbers. The defined values are INVALID(-2), UNKNOWN(-1), INACTIVE(0), and ACTIVE(1).

## **Names**

### **Attribute name**

Node\_Status

### **Column name**

PNGSTAT

## **Node Type attribute**

### **Description**

The type of the managed node. If the node is online, it is an IP Node. If it is offline, the type is Unknown.

**Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the numbers. The defined values are UNKNOWN (0) and IP NODE (1).

**Names****Attribute name**

Node\_Type

**Column name**

PNGTYPE

**Status Timestamp****Description**

The date and time the node was last checked.

**Type**

Time

**Names****Attribute name**

Status\_Timestamp

**Column name**

PNGTMSP

## HTTP attribute groups

The two HTTP attribute groups, Managed URLs and URL Objects, are used to receive information from URLs and the objects within these URLs.

For information about the syntax that is used in the Managed URLs and URL Objects tables, see ([“Specific fields for HTTP attributes” on page 1517](#)).

### Managed URLs

The following list contains information about each attribute in the Managed URL Attribute Group:

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent

**Type**

String

**Names****Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute****Description**

The local time at the agent when the data was collected

**Type**

Time

## **Names**

### **Attribute name**

Timestamp

### **Column name**

TIMESTAMP

## **URL attribute - This attribute is a key attribute**

### **Description**

The URL that is being monitored.

### **Type**

String

## **Names**

### **Attribute name**

URL

### **Column name**

HTTPURL

## **Response Time attribute**

### **Description**

The amount of time it took to download the response in milliseconds.

### **Type**

Integer with enumerated value. The string is displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the number. The defined value is TIMEOUT (-1).

## **Names**

### **Attribute name**

Response\_Time

### **Column name**

HTTPURL

## **Page Size attribute**

### **Description**

The size of the page that is returned by the HTTP request.

### **Type**

Integer with enumerated value. The string is displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the number. The defined value is NO\_RESPONSE\_RECEIVED (-1).

## **Names**

### **Attribute name**

Page\_Size

### **Column name**

PAGESZ

## **Page Objects attribute**

### **Description**

The total number of objects that are associated with the monitored page.

### **Type**

Integer with enumerated value. The string is displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the number. The defined value is NOT\_COLLECTED (-1).

## **Names**

### **Attribute name**

Page\_Objects

### **Column name**

PGOBJS

## **Total Object Size attribute**

### **Description**

The size of the page that is returned by the HTTP request.

### **Type**

Integer with enumerated value. The string is displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the number. The defined value is NOT\_COLLECTED (-1).

## **Names**

### **Attribute name**

Total\_Object\_Size

### **Column name**

TOTOSZ

## **Page Title attribute**

### **Description**

The page title of the received URL page.

### **Type**

String

## **Names**

### **Attribute name**

Page\_Title

### **Column name**

PAGETTL

## **Server Type attribute**

### **Description**

The type of server that is used at the target URL website.

### **Type**

String

## **Names**

### **Attribute name**

Server\_Type

### **Column name**

SRVTYP

## **Response Code attribute**

### **Description**

The response code of the HTTP request.

### **Type**

Integer with enumerated value. The string is displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the number. The defined value is NO\_RESPONSE\_RECEIVED (-1).

## **Names**

### **Attribute name**

Response\_Code

### **Column name**

CODE

## **Status attribute**

### **Description**

The current managed URL status (OK or status description).

### **Type**

String

## **Names**

### **Attribute name**

Status

### **Column name**

STATUS

## **URL Alias attribute**

### **Description**

The user-specified alias for the URL.

### **Type**

String

## **Names**

### **Attribute name**

URL\_Alias

### **Column name**

ALIAS

## **User Data attribute**

### **Description**

The user data that is specified with the URL.

### **Type**

String

## **Names**

### **Attribute name**

User\_Data

### **Column name**

USER

## **URL Objects**

The following list contains information about each attribute in the URL Objects Attribute Group:

### **Node attribute - This attribute is a key attribute**

### **Description**

The managed system name of the agent

### **Type**

String

## **Names**

### **Attribute name**

Node

### **Column name**

ORIGINNODE

## **Timestamp attribute**

### **Description**

The local time at the agent when the data was collected

### **Type**

Time

## **Names**

### **Attribute name**

Timestamp

### **Column name**

TIMESTAMP

## **URL attribute - This attribute is a key attribute**

### **Description**

The URL that is being monitored.

### **Type**

String

## **Names**

### **Attribute name**

URL

### **Column name**

HTTPURL

## **Object Name attribute**

### **Description**

The name of the page object within the target URL.

### **Type**

String

## **Names**

### **Attribute name**

Object\_Name

### **Column name**

ONAME

## **Object Size attribute**

### **Description**

The size (bytes) of the page object within the target URL.

### **Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the numbers. The defined values are NOT\_COLLECTED (-1), OBJECT\_NOT\_FOUND (-2). Any other values show the numeric value.

## Names

### Attribute name

Object\_Size

### Column name

SIZE

## Object Response Time attribute

### Description

The amount of time it took to download the object in milliseconds.

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The warehouse and queries return the numbers. The defined values are NOT\_COLLECTED (-1), NO\_RESPONSE\_RECEIVED (-2), STATUS\_CODE\_ERROR (-3). Any other values show the numeric value.

## Names

### Attribute name

Object\_Response\_Time

### Column name

ORTIME

## Discovery attribute groups

An attribute group that represents the set of subnode instances that are defined for a subnode type

When you create a subnode type, an attribute group is created that represents the set of subnode instances that are defined for that subnode type. Each of these attribute groups includes the same set of attributes.

The following list contains information about each attribute in a Discovery attribute group. The name in bold text shows how the attribute is displayed in the Tivoli Enterprise Portal:

### Node attribute - This attribute is a key attribute

### Description

The managed system name of the agent

### Type

String

## Names

### Attribute name

Node

### Column name

ORIGINNODE

## Timestamp attribute

### Description

The time from the agent system when the data row was built and sent to the Tivoli Enterprise Monitoring Server (or stored for historical purposes). It represents the local time zone of the agent system.

### Type

Time

## Names

### Attribute name

Timestamp

**Column name**  
TIMESTAMP

**Subnode MSN attribute**

**Description**  
The Managed System Name of the subnode agent.

**Type**  
String

**Names**

**Attribute name**  
Subnode\_MSN

**Column name**  
SN\_MSN

**Subnode Affinity attribute**

**Description**  
The affinity for the subnode agent.

**Type**  
String

**Names**

**Attribute name**  
Subnode\_Affinity

**Column name**  
SN\_AFFIN

**Subnode Type attribute**

**Description**  
The node type of this subnode.

**Type**  
String

**Names**

**Attribute name**  
Subnode\_Type

**Column name**  
SN\_TYPE

**Subnode Resource Name attribute**

**Description**  
The resource name of the subnode agent.

**Type**  
String

**Names**

**Attribute name**  
Subnode\_Resource\_Name

**Column name**  
SN\_RES

**Subnode Version attribute**

**Description**

The version of the subnode agent.

**Type****Names****Attribute name**

Subnode\_Version

**Column name**

SN\_VER

## Take Action Status attribute group

The Take Action Status attribute group contains the status of actions that the agent processed.

This attribute group is event-based and contains information about each attribute in the Take Action Status attribute group:

**Node attribute - This attribute is a key attribute****Description**

The managed system name of the agent.

**Type**

String

**Names****Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute****Description**

The time that is collected from the agent system, when the data row was built and sent from the agent to the Tivoli Enterprise Monitoring Server. Or stored for historical purposes. It represents the local time zone of the agent system.

**Type**

Time

**Names****Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Action Name attribute****Description**

The name of the action that was run

**Type**

String

**Names****Attribute name**

Action\_Name

**Column name**

TSKNAME

### Action Status attribute

#### Description

The status of the action.

#### Type

Integer with enumerated values. The values are: OK (0), NOT\_APPLICABLE (1), GENERAL\_ERROR (2), WARNING (3), NOT\_RUNNING (4), DEPENDENT\_NOT\_RUNNING (5), ALREADY\_RUNNING (6), PREREQ\_NOT\_RUNNING (7), TIMED\_OUT (8), DOESNT\_EXIST (9), UNKNOWN (10), DEPENDENT\_STILL\_RUNNING (11), INSUFFICIENT\_USER\_AUTHORITY (12)

#### Names

##### Attribute name

Action\_Status

##### Column name

### Action Application Return Code attribute

#### Description

The return code of the application the action started.

#### Type

Integer

#### Names

##### Attribute name

Action\_App\_Return\_Code

##### Column name

TSKAPRC

### Action Message attribute

#### Description

The message that is associated with the return code of the action.

#### Type

String

#### Names

##### Attribute name

Action\_Message

##### Column name

TSKMSGE

### Action Instance attribute

#### Description

The instance that is associated with the output produced by running the action. If the action is a system command, the instance is the line number of the output of the command.

#### Type

String

#### Names

##### Attribute name

Action\_Instance

##### Column name

TSKINST

### Action Results attribute

#### Description

The output that is produced by running the action.

**Type**

String

**Names****Attribute name**

Action\_Results

**Column name**

TSKOUTP

**Action Command attribute****Description**

The command that was run by the action.

**Type**

String

**Names****Attribute name**

Action\_Command

**Column name**

TSKCMND

**Action Node attribute****Description**

The node where the action ran.

**Type**

String

**Names****Attribute name**

Action\_Node

**Column name**

TSKORGN

**Action Subnode attribute****Description**

The subnode where the action ran.

**Type**

String

**Names****Attribute name**

Action\_Subnode

**Column name**

TSKSBND

**Action ID attribute****Description**

The ID of the action.

**Type**

Integer

**Names****Attribute name**

Action\_ID

**Column name**

TSKID

## Action Type attribute

### Description

The type of the action.

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal, the warehouse, and queries return the numbers. The defined values are: UNKNOWN (0), AUTOMATION (1).

### Names

#### Attribute name

Action\_Type

#### Column name

TSKTYPE

## Action Owner attribute

### Description

The name of the situation or user that initiated the action.

### Type

String

### Names

#### Attribute name

Action\_Owner

#### Column name

TSKOWNR

## Log File Status attribute group

The Log File Status attribute group contains information that reflects the status of log files this agent is monitoring.

The Log File Status attribute group is included if you have a log attribute group and the agent is at the default minimum Tivoli Monitoring version of 6.2.1 or later. The Log File Status attribute group includes two attributes that are defined as 64-bit numbers so that they can handle large files. 64-bit numeric attribute support is provided by Tivoli Monitoring version 6.2.1 or later.

The following list contains information about each attribute in the Log File Status attribute group:

### Node attribute - This attribute is a key attribute

#### Description

The managed system name of the agent.

#### Type

String

#### Names

##### Attribute name

Node

##### Column name

ORIGINNODE

### Timestamp attribute

#### Description

The value is the time that is collected from the agent system, when the data row was built and sent from the agent to the Tivoli Enterprise Monitoring Server. Or stored for historical purposes. It represents the local time zone of the agent system.

#### Type

Time

## **Names**

### **Attribute name**

Timestamp

### **Column name**

TIMESTAMP

## **Table Name attribute - This attribute is a key attribute**

### **Description**

The name of the table in which this log is being monitored

### **Type**

String

## **Names**

### **Attribute name**

Table\_Name

### **Column name**

TBLNAME

## **File Name attribute - This attribute is a key attribute**

### **Description**

The name of the file that is being monitored

### **Type**

String

## **Names**

### **Attribute name**

File\_Name

### **Column name**

FILNAME

## **RegEx Pattern attribute - This attribute is a key attribute**

### **Description**

The regular expression pattern (if any) that caused this file to be monitored

### **Type**

String

## **Names**

### **Attribute name**

RegEx\_Pattern

### **Column name**

REPATRN

## **File Type attribute**

### **Description**

The type of this file (regular file or pipe)

### **Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The defined values are UNKNOWN(0), REGULAR FILE(1), PIPE(2)

## **Names**

### **Attribute name**

File\_Type

### **Column name**

FILTYPE

## File Status attribute

### Description

The status of the file that is being monitored

### Type

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. The defined values are: OK(0), PERMISSION DENIED(1), FILE DOES NOT EXIST(2), INTERRUPTED SYSTEM CALL(4), I/O ERROR(5), NO SUCH DEVICE(6), BAD FILE NUMBER(9), OUT OF MEMORY(12), ACCESS DENIED(13), RESOURCE BUSY(16), NOT A DIRECTORY(20), IS A DIRECTORY(21), INVALID ARGUMENT(22), FILE TABLE OVERFLOW(23), TOO MANY OPEN FILES(24), TEXT FILE BUSY(26), FILE TOO LARGE(27), NO SPACE LEFT ON DEVICE(28), ILLEGAL SEEK ON PIPE(29), READ-ONLY FILE SYSTEM(30), TOO MANY LINKS(31), BROKEN PIPE(32)

### Names

#### Attribute name

File\_Status

#### Column name

FILSTAT

## Num Records Matched attribute

### Description

The number of processed records from this log which matched one of the specified patterns

### Type

Integer

### Names

#### Attribute name

Num\_Records\_Matched

#### Column name

RECMTCH

## Num Records Not Matched attribute

### Description

The number of processed records sent to the UnmatchLog; did not match any patterns

### Type

Integer

### Names

#### Attribute name

Num\_Records\_Not\_Matched

#### Column name

RECUNMT

## Num Records Processed attribute

### Description

The number of records that are processed from this log since agent start (including ones that are not matches/events)

### Type

Integer

### Names

#### Attribute name

Num\_Records\_Processed

#### Column name

RECPROC

### Current File Position attribute

#### Description

The current position in bytes into the monitored file. Data up to this position is processed, data after this position is not processed. Not applicable to pipes.

#### Type

Integer

#### Names

##### Attribute name

Current\_File\_Position

##### Column name

OFFSET

### Current File Size attribute

#### Description

The current size of the monitored file. Not applicable to pipes.

#### Type

Integer

#### Names

##### Attribute name

Current\_File\_Size

##### Column name

FILESIZE

### Last Modification Time attribute

#### Description

The time when the monitored file was last written to. Not applicable to pipes.

#### Type

Timestamp

#### Names

##### Attribute name

Last\_Modification\_Time

##### Column name

LASTMOD

### Codepage attribute

#### Description

The language codepage of the monitored file

#### Type

String

#### Names

##### Attribute name

Codepage

##### Column name

CODEPG

## Log File RegEx Statistics attribute group

The Log File RegEx Statistics attribute group contains information that shows the statistics of the log file regular expression search expressions.

Regular expressions can be used to filter records or to define records. This attribute group shows information about both types. When the Result Type attribute contains either INCLUDE or EXCLUDE, the filter is used to filter records. If the Result Type attribute contains BEGIN or END, the filter is used to define

records. The CPU measurements are approximations that are based on the granularity of the data that is exposed by the operating system. These measurements can result in values of 0.00 when a regular expression takes a small time to evaluate. Use the CPU times to determine the relative cost of regular expressions and to optimize the behavior of specific regular expressions.

The Log File RegEx Statistics attribute group is included if you have a log attribute group and the agent is at Tivoli Monitoring version of 6.2.1 or later. The minimum Tivoli Monitoring Version is selected on the **Agent Information** page. For more information, see (“Naming and configuring the agent” on page 1395). The Log File RegEx Statistics attribute group includes attributes that are defined as 64-bit numbers so that they can handle long durations. Support for 64-bit numeric attributes is provided by Tivoli Monitoring version 6.2.1 or later.

The following list contains information about each attribute in the Log File RegEx Statistics attribute group:

**Node attribute - This attribute is a key attribute**

**Description**

The managed system name of the agent.

**Type**

String

**Names**

**Attribute name**

Node

**Column name**

ORIGINNODE

**Timestamp attribute**

**Description**

The local time at the agent when the data was collected.

**Type**

Time

**Names**

**Attribute name**

Timestamp

**Column name**

TIMESTAMP

**Table Name attribute - This attribute is a key attribute**

**Description**

The name of the log file attribute group.

**Type**

String

**Names**

**Attribute name**

Table\_Name

**Column name**

TBLNAME

**Attribute Name attribute - This attribute is a key attribute**

**Description**

The name of the attribute to which this filter is applied.

**Type**

String

## **Names**

### **Attribute name**

Attribute\_Name

### **Column name**

ATRNAME

## **Filter Number**

### **Description**

The sequence number, starting at zero, of the filter that is being used for the attribute.

### **Type**

Integer (Numeric Property)

## **Names**

### **Attribute name**

Filter\_Number

### **Column name**

FLTRNUM

## **Result Type attribute**

### **Description**

The result type can be INCLUDE or EXCLUDE to accept or reject the attribute if the filter matches.  
The result type can be BEGIN or END to specify the start or end of a record for multi-line records.

### **Type**

Integer with enumerated values. The strings are displayed in the Tivoli Enterprise Portal. If the filter is used to filter records, the defined values are INCLUDE (1) or EXCLUDE (2). If the filter is used to define records, the defined values are BEGIN (3) or END (4).

## **Names**

### **Attribute name**

Result\_Type

### **Column name**

RSTTYPE

## **Average Processor Time attribute**

### **Description**

The average number of processor seconds used to process the filter for this attribute. The average processor time is the total processor seconds divided by the filter count.

### **Type**

Integer (Gauge)

## **Names**

### **Attribute name**

Average\_Processor\_Time

### **Column name**

CPUTAVG

## **Processor Time attribute**

### **Description**

The total number of processor seconds used to process the filter for this attribute. The processor time is cumulative and is truncated, not rounded. Similar to the Linux `/proc/<pid>/task/thread/stat` file.

### **Type**

Integer (Counter)

## **Names**

### **Attribute name**

Processor\_Time

### **Column name**

CPUTIME

## **Max Processor Time attribute**

### **Description**

The maximum number of processor seconds used for a single filter processing. It is possible that the maximum is zero if the filter was never used or if each of the filter processing took less than 0.01 seconds.

### **Type**

Integer (Gauge)

## **Names**

### **Attribute name**

Max\_Processor\_Time

### **Column name**

CPUTMAX

## **Min Processor Time attribute**

### **Description**

The minimum number of processor seconds used for a single filter processing. It is possible that the minimum is zero if a filter processing took less than 0.01 seconds.

### **Type**

Integer (Gauge)

## **Names**

### **Attribute name**

Min\_Processor\_Time

### **Column name**

CPUTMIN

## **Filter Count attribute**

### **Description**

The number of times the filter is run. Used with the total processor time to compute the average processor time.

### **Type**

Integer (Counter)

## **Names**

### **Attribute name**

Filter\_Count

### **Column name**

COUNT

## **Filter Count Matched attribute**

### **Description**

The number of times the filter is run and the attribute matched.

### **Type**

Integer (Counter)

## **Names**

### **Attribute name**

Filter\_Count\_Matched

**Column name**

COUNTMA

**Filter Count Unmatched attribute****Description**

The number of times the filter is run and the attribute did not match.

**Type**

Integer (Counter)

**Names****Attribute name**

Filter\_Count\_Unmatched

**Column name**

COUNTUN

**RegEx Pattern attribute - This attribute is a key attribute****Description**

The regular expression that is used for the match.

**Type**

String

**Names****Attribute name**

RegEx\_Pattern

**Column name**

REGXPAT

**Last Matched Time attribute****Description**

The last time the filter was used and the result matched.

**Type**

Time

**Names****Attribute name**

Last\_Matched\_Time

**Column name**

LASTMAT

**Last Unmatched Time attribute****Description**

The last time the filter was used and the result was unmatched.

**Type**

Time

**Names****Attribute name**

Last\_Unmatched\_Time

**Column name**

LASTUMA

## Creating application support extensions for existing agents

---

For the IBM Tivoli Monitoring environment, you can build an installable package to distribute custom workspaces, situations, queries, and Take Action commands that you created, as an application support extension for an existing agent.

### Before you begin

For more information about how to create custom situations, workspaces, Take Action commands, and queries, see ([“Creating workspaces, Take Action commands, and situations” on page 1585](#)).

### About this task

**Important:** This task is not how you add application support to an agent that you are building. To add application support to an agent that you are building see ([“Importing application support files” on page 1621](#)).

### Procedure

1. From the Agent Builder, select **File > New > Other**.
2. Select **Agent Builder Application Support Extension** under **Agent Builder**.
3. Click **Next** to get to the welcome page for the **IBM Tivoli Monitoring Application Support Extension** wizard.
4. Click **Next** on the welcome page.
5. Enter a name for the project and click **Finish**

## Creating an Application Support Extension project

Create an Application Support Extension project by using Agent builder.

### Procedure

1. From the Agent Builder, select **File > New > Other**.
2. Select **Agent Builder Application Support Extension** under **Agent Builder**.
3. Click **Next** to get to the welcome page for the **IBM Tivoli Monitoring Application Support Extension Wizard**.
4. Click **Next** on the welcome page.
5. Enter a name for the project and click **Finish**

## Adding support files to a project

Add your support files to an Application Support Extension project

### Before you begin

Create an Application Support Extension project. For more information, see [“Creating an Application Support Extension project” on page 1688](#).

### Procedure

1. Right-click an Application Support Extension project and select **IBM Tivoli > Import Application Support Extensions**
2. In the **Import Information** window, select the name of the host where the Tivoli Enterprise Portal Server is located or click **Add** to add one.
3. In the **Application** field, enter the agent product code.
4. Enter the affinity of the agent for which you are creating custom application support.

The agent affinity is a Tivoli Monitoring internal identifier that associates workspaces, queries, and other items, with the agent. It must be unique in the Tivoli Monitoring installation. Click **Browse** to open the **Node Types** window and select this information from a list rather than typing it.

5. When you are satisfied with the import information, click **Finish**.
6. In the **Situations** window, select the situations that you want to import from the Available Situations list.  
Click << to add them to the Selected Situations list and click **OK**. A new folder is created under the project, and it contains the necessary files to install the workspaces, situations, and queries.
7. In the **Queries** window, select the queries that you want to import from the Available Queries list.  
Click << to add them to the Selected Queries list and click **OK**.
8. In the **Take Actions** window, Choose the Take Action commands that you want to import from the Available Take Actions list.  
Click << to add them to the Selected Take Actions list and click **OK**. The support files for the agent are put in the project under the appropriate folder.

## What to do next

You can repeat this process for as many different agents as you want. The Agent Builder creates a single installation image from all of the support files in the Application Support Extension project.

## Generating the Application Support Extension installation image

Generate an Application Support Extension installation image.

### Procedure

1. Right-click on the Application Support Extension project and select **IBM Tivoli > Create Application Support Extension Install Image**.
2. In the **Application Support Extension Information** window, enter the directory where the image is to be placed.
3. Your Application Support Extension must have its own product code. Enter the registered product code for your new agent. You can use one of the product codes that are reserved for use with the Agent Builder. The allowed values are K00-K99, K{0-2}{A-Z}, and K{4-9}{A-Z}.

**Note:** These values are for internal use only and are not intended for agents that are to be shared or sold. If you are creating an agent to be shared with others, you must send a note to toolkit@us.ibm.com to reserve a product code. The request for a product code must include a description of the agent to be built. A product code is then assigned, registered, and returned to you. When you receive the three-letter product code, you are told how to enable the Agent Builder to use the assigned product code.

4. Enter the name of the Application Support Extension.
5. Enter a description of the Application Support Extension.
6. Enter a version for the Application Support Extension in the VVRRMMFF format where vv = version number; rr = release number; mm = modification number (fix pack number); and ff = interim fix number.
7. Click **Finish**.

## Installing your Application Support Extension

Install your Application Support Extension

### Procedure

1. Transfer your image to your Tivoli Enterprise Monitoring Server and Tivoli Enterprise Portal Server servers.

2. To install the Tivoli Enterprise Monitoring Server support, run one of the following commands:

- On Windows: `installKXXTEMSSupport.bat`
- On UNIX: `installKXXTEMSSupport.sh`

The format for the command is as follows:

```
installKXXTEMSSupport[.bat | .sh] <ITM Install Directory> [-s tems_host]  
[-u tems_user] \[-p tems_password]
```

3. To install the Tivoli Enterprise Portal Server support, run one of the following commands:

- On Windows: `installKXXTEPSSupport.bat`
- On UNIX: `installKXXTEPSSupport.sh`

The format for the command is as follows:

```
installKXXTEPSSupport[.bat | .sh] <ITM Install Directory> [-r]
```

where `-r` indicates that the Tivoli Enterprise Portal Server must be restarted after installation

## Converting a Solution Install Project to an Application Support Extension project

Convert an existing **Solution Install Project** to an Application Support Extension project

### About this task

If you have an existing **Solution Install Project** that you want to convert to an Application Support Extension project, complete the following steps:

**Note:** In the **Solution Install Project** only Support files are migrated.

### Procedure

1. Right-click on the **Solution Install project** and select **IBM Tivoli > Convert Solution Install Project**.
2. Enter the name of a new Application Support Extension project or select an existing one from the list
3. Click **Finish**.

## Cognos data model generation

Agent Builder can generate a Cognos data model for each agent. Use the data model to import agent information into the Cognos Framework Manager for report creation.

This Cognos data model can be opened and viewed in the Framework Manager, which builds a model package to be published into Tivoli Common Reporting. The data model can also be customized or modified within the Framework Manager before publication.

When a report is created, Agent Builder also allows for a final report package to be imported into the Agent Builder project. This feature enables future agent projects to be generated with the reports that are already part of the agent package. The reports that are packaged as part of the agent installation image can be imported into Tivoli Common Reporting in your production environment.

**Note:** In this documentation, note the following convention:

- `Kxx` or `kxx` refers to the product code given to the agent, for example, `k99`.
- `dbType` refers to the database that is being used by the Tivoli Data Warehouse, for example, `DB2`.

## Prerequisites to generating a Cognos data model

Complete these tasks before you generate a Cognos data model

### About this task

#### Note:

- These steps must be completed only one time, as all future data models generated with Agent Builder will use this environment.
- It is advisable to create an isolated development environment for agent testing and report creation.

### Procedure

1. Install and configure a (“Tivoli Data Warehouse” on page 1691).
2. Create tables and Procedures in the Tivoli Data Warehouse.
  - a) “Create tables and Procedures in the Tivoli Data Warehouse” on page 1691.
  - b) “Populating the Tivoli Data Warehouse with the Tivoli Reporting and Analytics Model” on page 1693.
3. Install and configure (“Tivoli Common Reporting” on page 1694).
4. Install and configure the (“Framework Manager” on page 1694).

### Tivoli Data Warehouse

About Tivoli Data Warehouse.

To create reports, you need a Tivoli Data Warehouse, a Warehouse Proxy agent, and a Summarization and Pruning agent, to be installed and configured in your environment. For more information, see the *IBM Tivoli Monitoring Installation and Setup Guide*.

#### **Create tables and Procedures in the Tivoli Data Warehouse**

Create or alter the ManagedSystem Table and Stored Procedure in the Tivoli Data Warehouse

### About this task

The generated Cognos data model includes a ManagedSystem table which is used to define a ManagedSystem dimension. The ManagedSystem dimension allows reports to be created that can correlate managed systems. For example, if the agent is a subnode agent, the dimension can be used to determine the subnodes that exist for a specific agent instance.

The ManagedSystem table is not created by the Tivoli Data Warehouse. Therefore, when an agent is generated in Agent Builder, SQL scripts are generated for each database platform that will:

- Create the ManagedSystem table. Use this script if the table does not exist in the Tivoli Data Warehouse.
- Edit the ManagedSystem table. Use this script if the table exists in the Tivoli Data Warehouse. Other reporting products can create the ManagedSystem table, but they do not create it with all of the required columns.
- Create a stored procedure that populates the ManagedSystem table from tables in the Tivoli Data Warehouse.

Run these scripts one time only.

*Running DB2 Scripts to Create tables and Procedures in the Tivoli Data Warehouse*  
For a DB2 database, use these scripts to create tables in the Tivoli Data Warehouse

## Before you begin

The scripts for DB2 are in the following directory:

```
reports/db2/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

## Procedure

1. The generated scripts (`create_table.sql`, `alter_table.sql`, and `create_procedure.sql`) all use *itmuser* as the Tivoli Data Warehouse user ID. If *itmuser* is not the Tivoli Data Warehouse user ID in your environment, change all occurrences of *itmuser* to the correct user ID.
2. Connect to the Tivoli Data Warehouse as the Tivoli Data Warehouse User:

```
db2 connect to <Tivoli Data Warehouse alias name> user  
<Tivoli Data Warehouse user id> using <password>
```

3. Determine whether the ManagedSystem table exists:

```
db2 "select count(*) from sysibm.systables where name = 'MANAGEDSYSTEM'  
and creator=upper ('<Tivoli Data Warehouse user id>')"
```

4. Create or alter the table.

- If the query returns 1, the table exists. Run the alter script:

```
db2 -tvf alter_table.sql
```

- If the query returns 0, the table does not exist. Run the create script:

```
db2 -tvf create_table.sql
```

5. Run the script to create the stored procedure:

```
db2 -td@ -f create_procedure.sql
```

*Running Oracle Scripts to Create tables and Procedures in the Tivoli Data Warehouse*  
For an Oracle database, use these scripts to create tables in the Tivoli Data Warehouse

## Before you begin

The scripts for Oracle are in the following directory:

```
reports/oracle/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

## Procedure

1. The generated scripts (`create_table.sql`, `alter_table.sql`, and `create_procedure.sql`) all use *itmuser* as the Tivoli Data Warehouse user ID. If *itmuser* is not the Tivoli Data Warehouse user ID in your environment, change all occurrences of *itmuser* to the correct user ID.
2. Start sqlplus:

```
sqlplus <IBM Tivoli Monitoring user ID>/<password>@  
<Tivoli Data Warehouse SID>
```

3. Determine whether the ManagedSystem table exists:

```
select count(*) from user_tables where table_name = 'MANAGEDSYSTEM';
```

4. Create or alter the table.

- If the query returns 1, the table exists. Run the alter script:

```
@<path to alter_table.sql>;
```

- If the query returns 0, the table does not exist. Run the create script:

```
@<path to create_table.sql>;
```

5. Run the script to create the stored procedure:

```
@<path to create_procedure.sql>;
```

*Running SQL Server 2005 and 2008 Scripts to Create tables and Procedures in the Tivoli Data Warehouse*

## Before you begin

The scripts for SQL Server are in the following directory:

```
reports/mssql/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

## Procedure

1. The generated scripts (create\_table.sql, alter\_table.sql, and create\_procedure.sql) all use *itmuser* as the Tivoli Data Warehouse user ID. If *itmuser* is not the Tivoli Data Warehouse user ID in your environment, change all occurrences of *itmuser* to the correct user ID.
2. Determine whether the ManagedSystem table exists:

```
osql -S <Server> -U <Tivoli Data Warehouse user ID> -P <password> -d  
<Tivoli Data Warehouse database name> -Q "Select count(*)  
from INFORMATION_SCHEMA.TABLES where table_name = 'ManagedSystem'"
```

3. Create or alter the table.

- If the query returns 1, the table exists. Run the alter script:

```
osql -S <Server> -U <Tivoli Data Warehouse user ID> -P <password> -d  
<Tivoli Data Warehouse database name> -I -n -i <path to alter_table.sql>
```

- If the query returns 0, the table does not exist. Run the create script:

```
osql -S <Server> -U <Tivoli Data Warehouse user ID> -P <password> -d  
<Tivoli Data Warehouse database name> -I -n -i <path to create_table.sql>
```

4. Run the script to create the stored procedure:

```
osql -S <Server> -U <Tivoli Data Warehouse user ID> -P  
<password> -d <Tivoli Data Warehouse database name>  
-I -n -i <path to create_procedure.sql>
```

## Populating the Tivoli Data Warehouse with the Tivoli Reporting and Analytics Model

Use provided database scripts to populate the Tivoli Data Warehouse

## About this task

Tivoli Reporting and Analytics Model (TRAM) contains the base-set of knowledge that is common to all reporting packages. TRAM is installed by a set of scripts unique to each database. The necessary scripts for populating each supported database are included in the agent installation image, within the reports directory. Use the following procedure to create Tivoli Reporting and Analytics Model Common Dimensions in Tivoli Data Warehouse.

## Procedure

1. Browse to the Tivoli Reporting and Analytics Model database scripts.

2. Extract the agent package.

- On Windows systems, agent package is `kxx.zip`.
- On Linux and UNIX systems, agent package is `kxx.tgz`.

3. Go to the appropriate database scripts.

- DB2 scripts are in the Agent package at:

```
reports/db2/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

- Oracle scripts are in the Agent package at:

```
reports/oracle/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

- Microsoft SQL Server scripts are in the Agent package at:

```
reports/mssql/Kxx/reports/cognos_reports/itmKxx/db_scripts
```

4. Run the database scripts to generate the common dimensions within the Tivoli Data Warehouse. Each script set provides a readme file for usage instructions.

5. Verify that the scripts added the following tables to the Tivoli Data Warehouse:

```
"Computer System", WEEKDAY_LOOKUP, MONTH_LOOKUP, TIMEZONE_DIMENSION, TIME_DIMENSION
```

## Tivoli Common Reporting

Tivoli Common Reporting contains the Cognos Business Intelligence engine, which contains elements to assist with the creation of agent reports.

Tivoli Common Reporting must be installed and configured with a data source that connects to the Tivoli Data Warehouse.

## Installing Tivoli Common Reporting

You must install Tivoli Common Reporting. Versions 1.3, 2.1, 2.1.1 or later are supported. For information about installing Tivoli Common Reporting, see [Installing Tivoli Common Reporting](#).

## Configuring Tivoli Common Reporting

You must configure Tivoli Common Reporting. For information about configuring Tivoli Common Reporting, see [Configuring IBM Tivoli Common Reporting](#).

Create a data source between the Tivoli Data Warehouse and Tivoli Common Reporting. For more information, see [Configuring database connection](#). Click the appropriate database type. Note the name that is given to the data source. The default is **TDW**.

**Note:** The data source name must match the name in the **Data source** field of the **Cognos Information** page. For more information about the **Cognos Information** page, see [“Cognos information” on page 1411](#).

## Framework Manager

Framework Manager is an application that ships with the Tivoli Common Reporting application, but must be installed and configured separately.

Framework Manager is used to view and modify data models and to publish data models to Tivoli Common Reporting

## Installing Framework Manager

You must install Framework Manager. Versions 8.4, 8.4.1 or later are supported.

The Framework Manager ships with Tivoli Common Reporting, but must be manually installed. Tivoli Common Reporting 1.3 ships with Framework Manager 8.4. Tivoli Common Reporting 2.1 and 2.1.1 ships

with Framework Manager 8.4.1. For information about installing Framework Manager, see [Installing Framework Manager](#) in the *Tivoli Common Reporting User's Guide*.

## Configuring Framework Manager

You must configure Framework Manager. For information about configuring Framework Manager, see [Configuring Framework Manager](#) in the *Tivoli Common Reporting User's Guide*.

## Creating reports

Use the Framework Manager to publish the agent model, and Report Studio to begin creating reports.

### Before you begin

When the agent is completed, it must be installed into the Tivoli Monitoring environment. In addition, historical collection for the agent must be configured and the agent be run for at least one warehouse upload interval. Summarization must be configured, and the summarization setting choices that are made in Tivoli Monitoring must be identical to the summarization choices made in the Agent Builder. The Summarization and Pruning agent must run at least one time after the agent's data is uploaded to the warehouse.

1. Install, configure, and start your agent.
2. Create and distribute to the agent a historical collection for each attribute group you want to create a report for.

**Note:** The warehouse upload interval defaults to daily. However, you might want to shorten this interval.

For information about configuring historical collection, see [Managing historical data](#) in the *IBM Tivoli Monitoring Administrator's Guide*.

3. In Tivoli Monitoring, configure summarization for all of the attribute groups you created historical collections for in Step 2.

**Note:** When you configure historical collection and summarization, you must wait enough time for data to end up in the summary tables.

**Note:** By default, the Summarization and Pruning agent is configured to run one time a day at 2 a.m. You might want to change this setting. For example, you can configure it to run hourly. For information about configuring the Tivoli Data Warehouse, see [Setting up data warehousing](#) in the *IBM Tivoli Monitoring Installation and Setup Guide*.

### About this task

Generating an agent in Agent Builder creates an entire Framework Manager project, which includes the data model and the Framework Manager project file. Framework Manager can open the project file directly, which opens the data model for modification, customization, or publication.

### Procedure

**Note:** The generated data model for the agent contains all of the summary time dimensions for each attribute group: hourly, daily, weekly, monthly, quarterly, and yearly. The dimensions exist only in the Tivoli Data Warehouse for the agent if summarization and pruning is configured for the agent. And also if the dimensions are selected, and if the Summarization and Pruning agent, created, and populated the tables. Reports can be defined and published into Tivoli Common Reporting that use dimensions that do not exist. Such reports do not function until the summary tables are created by the Summarization and Pruning agent.

1. Open the Agent Data Model in Framework Manager:
  - a) Open the Framework Manager.
  - b) From the **Welcome** page, click **Open a project**.

**Tip:** If you are in Framework Manager, click **Open** from the **File** menu.

c) Browse to the Agent data model.

- For DB2:

```
reports/db2/Kxx/model/
```

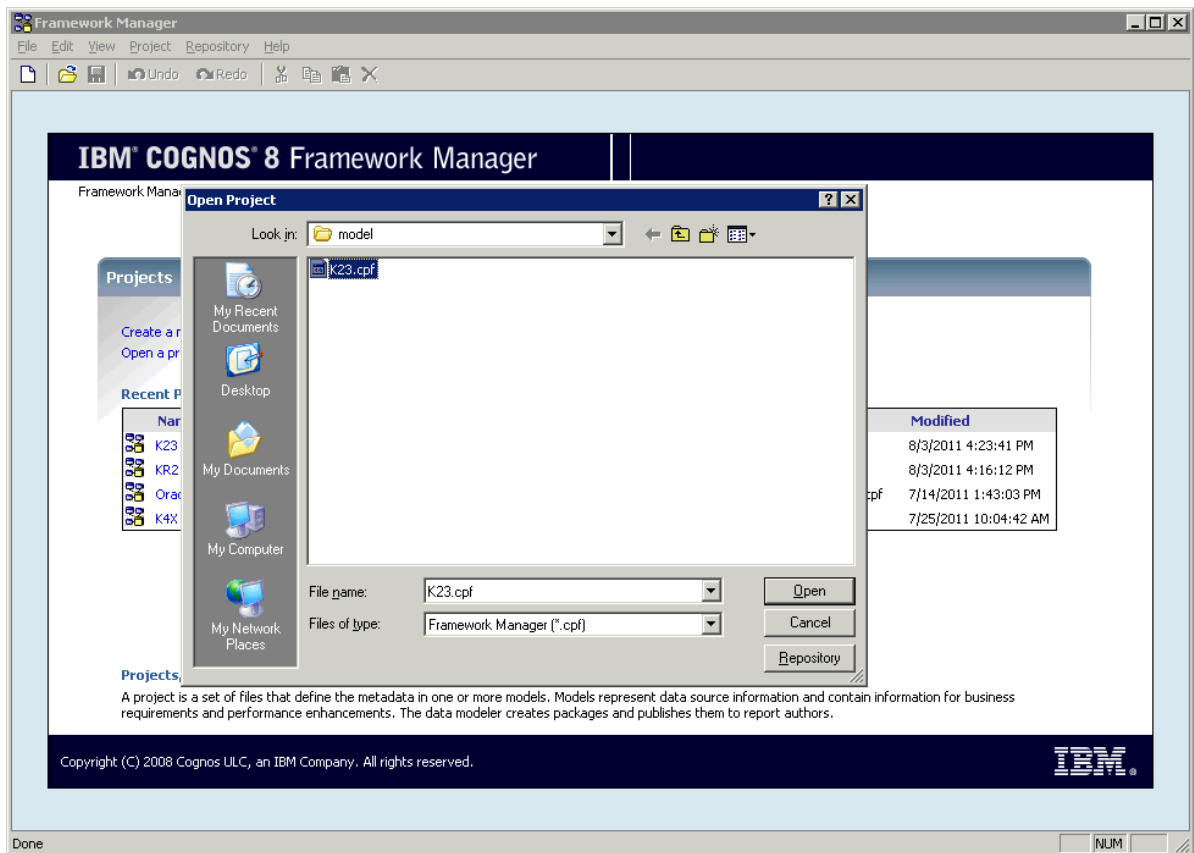

- For Oracle:

```
reports/oracle/Kxx/model/
```

- For Microsoft SQL Server:

```
reports/mssql/Kxx/model/
```

d) Select the agent project file, *Kxx.cpf*.

*Figure 80. Selecting agent project file*

**Note:** When an agent project is opened in Framework Manager, the agent name is listed under the Recent Projects.

2. Populate the Managed System Table. For more information, see [“Populating the ManagedSystem Table” on page 1700](#)
3. Use the Framework Manager to publish the Agent Model to Tivoli Common Reporting
  - a) Open the Framework Manager.
  - b) Open the Agent project.
  - c) Expand **Packages** in the navigation tree.
  - d) Right-click the agent package and select **Publish Packages**.

Figure 81. Selecting Publish Packages

4. Use Report Studio to create new reports or templates.
  - a) Log on to Tivoli Common Reporting.
  - b) Browse to Public Folders, expand **Reporting** in the navigation panel, and select **Common Reporting**.

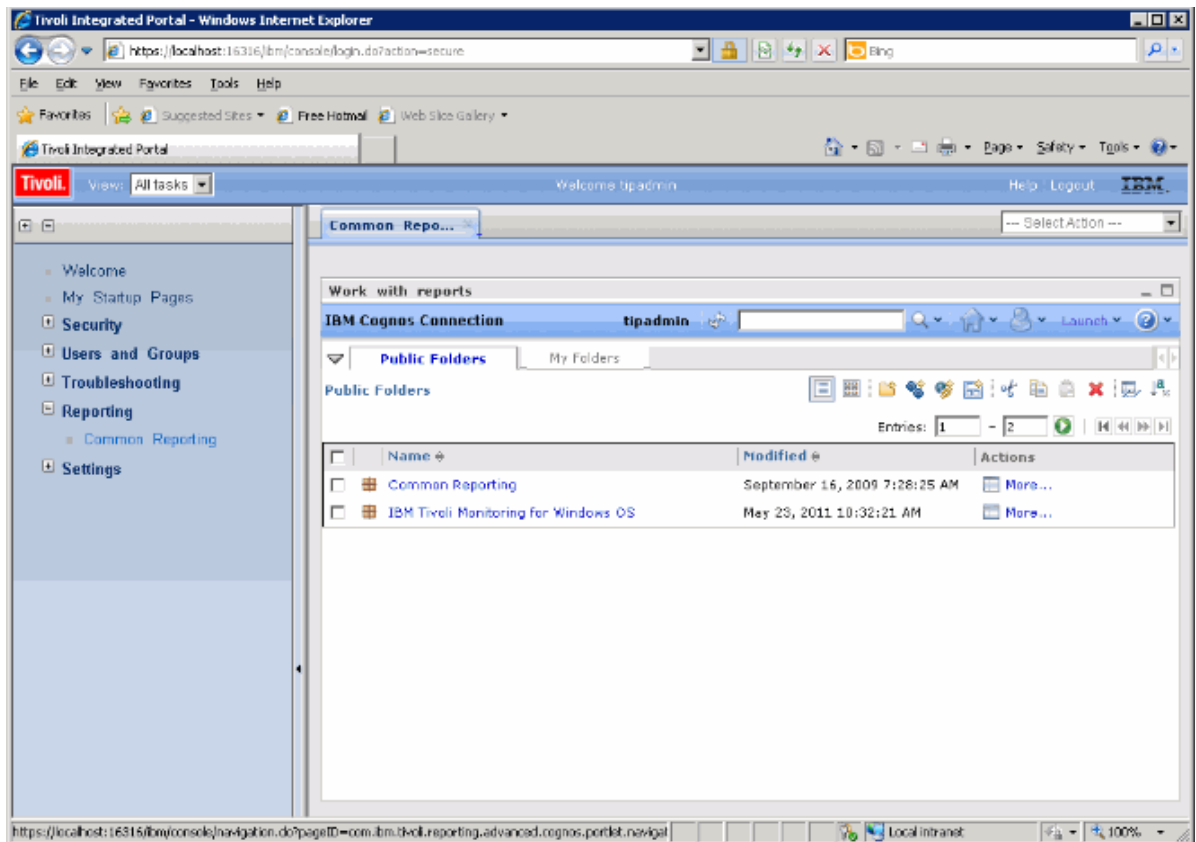

Figure 82. Selecting Common Reporting

- c) Select your Tivoli Monitoring agent from the list provided.
- d) Open the report creation tool, by clicking the Launch menu and selecting **Report Studio** or **Query Studio**.

Figure 83. Selecting Report Studio

## What to do next

You can use the Report Studio to create new reports or templates, or you can modify an existing report or template.

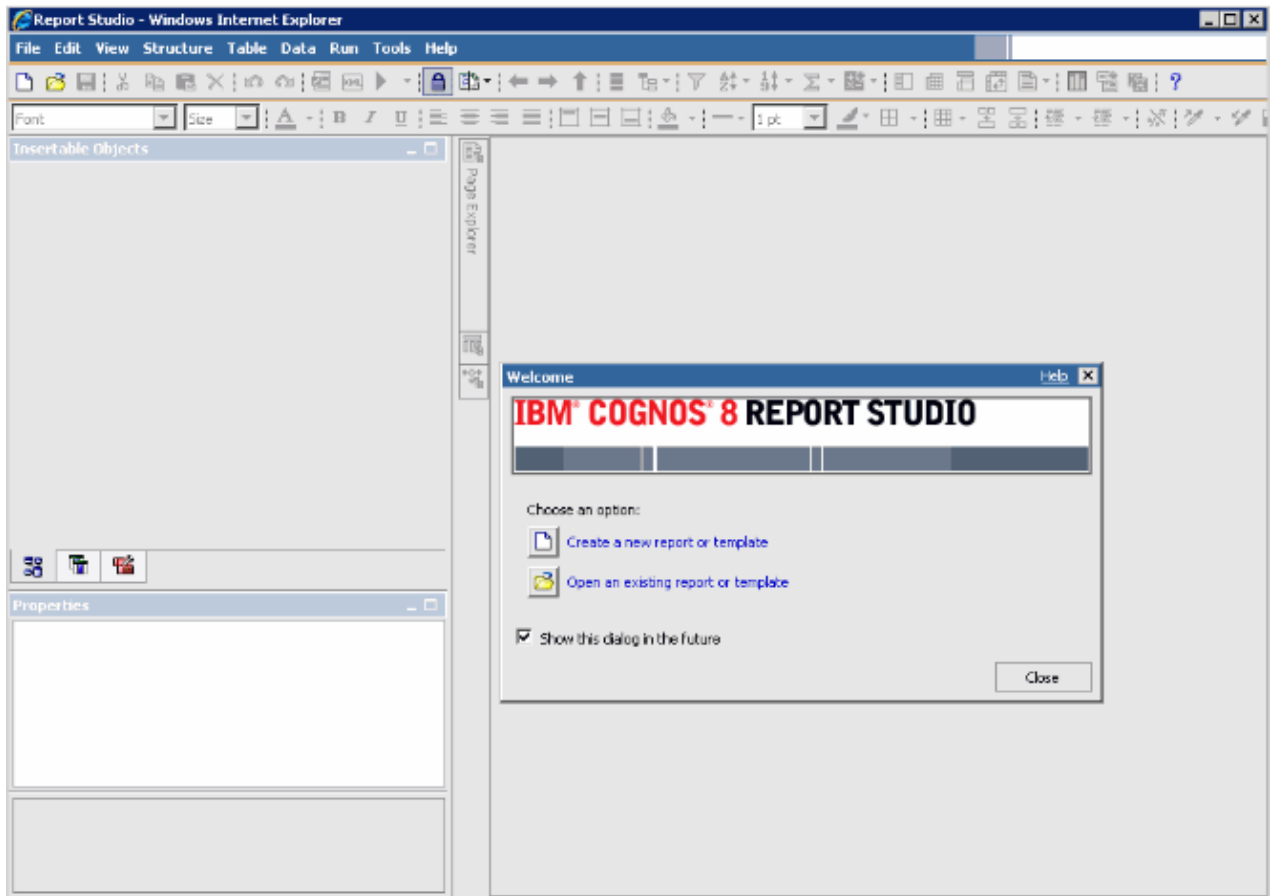

Figure 84. Report Studio

For more information, see the Tivoli Common Reporting topic collection on [IBM Knowledge Center](#).

## Populating the ManagedSystem Table

The ManagedSystem table is populated by using the `kqz_populate_msn` stored procedure.

For more information, see [“Running the DB2 stored procedure” on page 1702](#). This procedure must be run periodically so that the ManagedSystem table contains the current list of managed system names.

The stored procedure reads the following historical tables in the Tivoli Data Warehouse if they exist:

- The agent's Performance Object status table
- The agent's availability table. Agents that monitor processes or services have an availability table.
- The agent's discovery tables. Subnode agents create discovery tables.

Historical collection must be started on a particular set of attribute groups. A set of scripts is generated that creates and starts historical collection for these attribute groups. If you do not want to use the scripts, the list of attribute groups is listed in the comment header block of the script.

Sample scripts are created that show which tables must have historical collection enabled:

- `reports/configuretdw.sh`
- `reports/configuretdw.bat`

The following table describes the required arguments:

**Note:** You must specify either `-n` or `-m`, but not both.

| Table 337. Required arguments                       |  |
|---|--|
| Argument  | Description  |
| -h <i>candle_home</i>                               | The Tivoli Monitoring installation path.   |
| -u <i>teps_user</i>                                 | The Tivoli Enterprise Portal Server user to log in as when you create the historical collections.  |
| -n <i>tems_name</i>                                 | The Tivoli Enterprise Monitoring Server where the collections must be started. More than one Tivoli Enterprise Monitoring Server can be specified by using a space separated list. If you specify more than one Tivoli Enterprise Monitoring Server, put the list in quotation marks. For example, -n "tems1 tems2"                    |
| -m<br><i>managed_system_group_or_managed_system</i> | The managed system group or managed system name against which the collection must be started. More than one managed system group or managed system can be specified by using a space separated list. If you specify more than one managed system group or managed system, put the list in quotation marks. For example, -m "msg1 msg2" |

The following table describes the optional arguments:

| Table 338. Optional arguments            |   |
|--|---|
| Argument                                 | Description   |
| -s <i>teps_host</i>                      | The host name or IP address of the Tivoli Enterprise Portal Server. If not specified, the default is localhost.   |
| -p <i>teps_password</i>                  | The password for the Tivoli Enterprise Portal Server user that is specified with the -u option. If not specified, the script prompts for the password   |
| -c <i>historical_collection_interval</i> | The historical collection interval to use when you start the historical collections. If not specified, the default is 1h (1 hour). The valid values are: 15m, 30m, 1h, 12hor 1d, where m is minutes, h is hours and d is days.      |
| -i <i>pruning_interval</i>               | The pruning interval to use for the historical data. The historical data must be pruned so that the tables do not continue to grow in size. If not specified, the default is 2d(2 days). Use d for days, m for months, y for years. |

After historical collection is started, the `kqz_populate_msn` stored procedure must be run periodically. The stored procedure is run periodically so that the `ManagedSystem` table contains the most current list of managed systems in the Tivoli Monitoring environment.

## ***Running the DB2 stored procedure***

Run a stored procedure on DB2.

### **About this task**

Perform the following steps to run the stored procedure on DB2:

#### **Procedure**

1. Connect to the Tivoli Data Warehouse database as the warehouse user:

```
connect to <Tivoli Data Warehouse database alias> user  
<Tivoli Data Warehouse user id> using <password>
```

2. Run the stored procedure:

```
db2 "call <Tivoli Data Warehouse schema>.kqz_populate_msn  
( '<three letter product code for the agent>' )"
```

## ***Running the Oracle stored procedure***

Run a stored procedure on Oracle.

### **About this task**

Perform the following steps to run the stored procedure on Oracle:

#### **Procedure**

1. Start sqlplus:

```
sqlplus <Tivoli Data Warehouse user id>/<password>@  
<Oracle SID>
```

2. Run the stored procedure:

```
execute kqz_populate_msn('<three letter product code for the agent>');
```

## ***Running the stored procedure on SQL Server 2005 and 2008***

Run a stored procedure on SQL Server.

### **About this task**

Perform the following steps to run the stored procedure on SQL Server 2005 and 2008:

#### **Procedure**

Run the stored procedure:

```
osql -S <server> -U <Tivoli Data Warehouse id> -P  
<Tivoli Data Warehouse password> -d  
<Tivoli Data Warehouse database name> -Q "EXEC  
[<Tivoli Data Warehouse schema>].[kqz_populate_msn]  
@pv_productcode = N'<three letter product code>'"
```

## **Exporting reports and data models from Tivoli Common Reporting**

Export reports and data models from Tivoli Common Reporting.

#### **Procedure**

1. Log in to the Tivoli Common Reporting.

2. Go to Public Folders, and under **Reporting** in the navigation panel select **Common Reporting**.
3. In the Work with reports section, click the **Launch** menu and select **IBM Cognos Administration**.
4. Click the **Configuration** tab.
5. Click **Content Administration**.

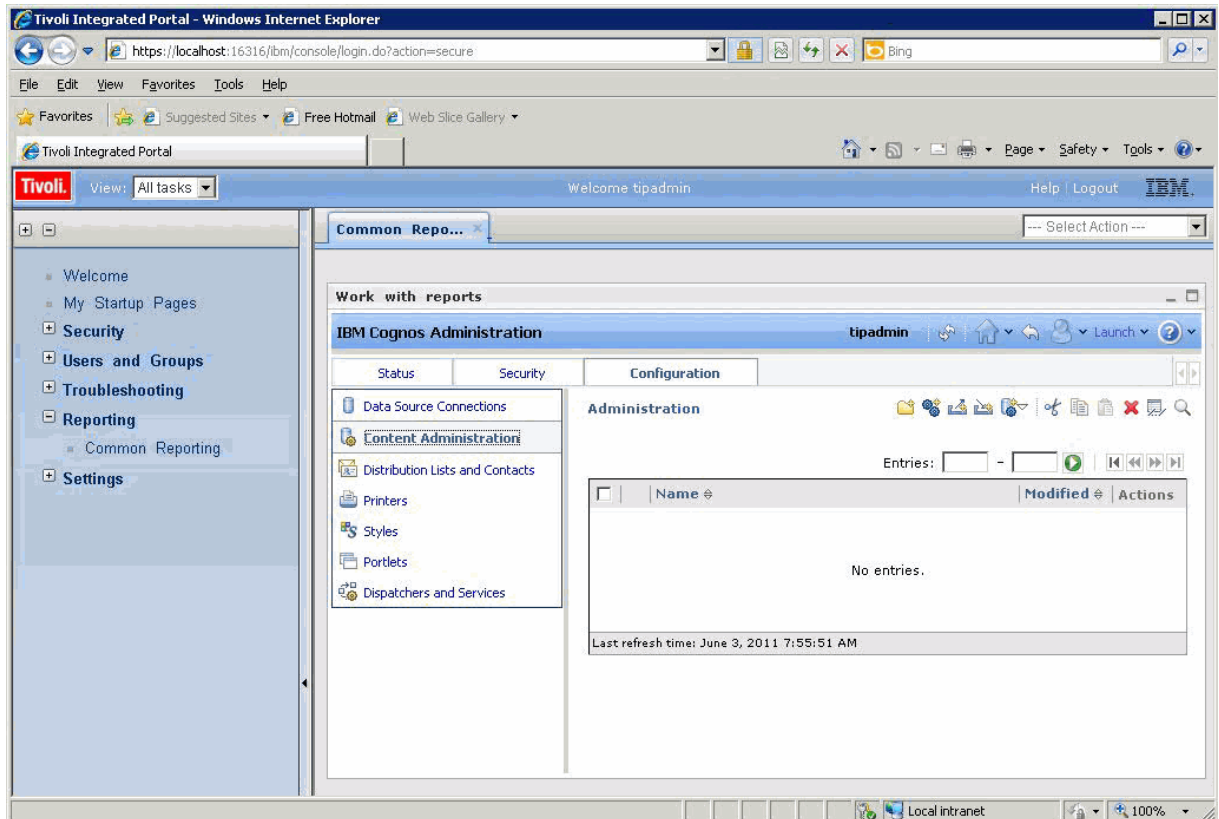

Figure 85. The Content Administration tab

6. Click the **New Export** icon to export a new package.
7. Name the package. Optionally, you can add a screen tip and description.
8. Select **Select public folders and directory content**.
9. In the Public Folders dialog, click the **Add** link.
10. Move your agent package to **Selected entries**.
11. On the last page of the wizard, select **Save Only**. When the wizard completes, the report package is listed on the Content Administration tab.
12. On the Content Administration tab, click the green arrow (Run) to create the compressed .zip file.

Figure 86. The Content Administration tab with agent package listed

## Results

The compressed .zip file that is created by the export process is placed in the deployment directory.

- The directory path for Tivoli Common Reporting version 1.3 is:

```
C:\IBM\tivoli\tip\products\tcr\Cognos\c8\deployment
```

- The directory path for Tivoli Common Reporting version 2.1 or later is:

```
C:\IBM\tivoli\tipv2Components\TCRComponent\cognos\deployment
```

## What to do next

For more information about exporting reports, see [Exporting Cognos report packages](#) in the *Tivoli Common Reporting User's Guide*.

## Importing reports into Agent Builder

When the report package is exported from Tivoli Common Reporting, it can be imported into the Agent Builder project. The report package can then be included in the agent installation image.

## Procedure

1. Right-click on the agent project in the Agent Builder.
2. Select **IBM > Import Report Package**.
3. In the **Import Report Package** window, select the **Database Type** on which the report package was created.
4. Enter the fully qualified path to the report package, or click **Browse** to select it.

5. Click **OK**.
6. The report package is now shown in the agent project under the `reports/dbtype` directory.  
**Note:** If you create report packages that are database-specific you must import each package into the Agent Builder.

## Installing reports from an agent package into Tivoli Common Reporting

Import a report package from your agent to Tivoli Common Reporting

### Procedure

1. Follow the steps in the wizard to import a new package from your agent image.  
In the agent image, the reports are found in: `reports/dbType/Kxx/reports/cognos_reports/itmKxx/packages`
2. Copy the reports compressed zip file into the Tivoli Common Reporting deployment directory.
  - The directory path for Tivoli Common Reporting version 1.3 is: `C:\IBM\tivoli\tip\products\tcr\Cognos\c8\deployment`
  - The directory path for Tivoli Common Reporting version 2.1 or later is: `C:\IBM\tivoli\tipv2Components\TCRComponent\cognos\deployment`
3. Log in to the Tivoli Common Reporting.
4. Go to Public Folders, and under **Reporting** in the navigation panel select **Common Reporting**.
5. In the Work with reports section, click the **Launch** menu and select **IBM Cognos Administration**.
6. Go to the **Configuration** tab, and open the **Content Administration** section.
7. Click **New Import** to create a package import.
8. Select the agent's reports package.
9. Select the public folders that you want to import.
10. Select save.
11. Click the green (run) arrow to import.

### Results

For more information, see [Logging in to the reporting interface](#) in the *Tivoli Common Reporting User's Guide*.

## ICU regular expressions

A description of the specifics of the ICU regular expression implementation.

This reference content is extracted from the *ICU User Guide*. The content describes the specifics of the ICU regular expression implementation. This information is essential if you are using the Agent Builder regular expression feature because different programming languages implement regular expressions in slightly different ways.

| Table 339. Regular expression metacharacters |  |
|--|--|
| Character                                    | Description  |
| \a   | Match a BELL, \u0007   |
| \A   | Match at the beginning of the input. Differs from ^ in that \A does not match after a new line within the input. |

Table 339. Regular expression metacharacters (continued)

| Character                  | Description  |
|----------------------------|--|
| \b, outside of a [Set]     | Match if the current position is a word boundary. Boundaries occur at the transitions between word (\w) and non-word (\W) characters, with combining marks ignored. For more information about word boundaries, see ICU Boundary Analysis. |
| \b, within a [Set]         | Match a BACKSPACE, \u0008.   |
| \B                         | Match if the current position is not a word boundary.  |
| \cX                        | Match a Ctr1-X character.  |
| \d                         | Match any character with the Unicode General Category of Nd (Number, Decimal Digit.)   |
| \D                         | Match any character that is not a decimal digit.   |
| \e                         | Match an ESCAPE, \u001B.   |
| \E                         | Terminates a \Q . . . \E quoted sequence.  |
| \f                         | Match a FORM FEED, \u000C.   |
| \G                         | Match if the current position is at the end of the previous match.   |
| \n                         | Match a LINE FEED, \u000A.   |
| \N{UNICODE CHARACTER NAME} | Match the named character.   |
| \p{UNICODE PROPERTY NAME}  | Match any character with the specified Unicode Property.   |
| \P{UNICODE PROPERTY NAME}  | Match any character not having the specified Unicode Property.   |
| \Q                         | Place quotation marks around all following characters until \E.  |
| \r                         | Match a CARRIAGE RETURN, \u000D.   |
| \s                         | Match a white space character. White space is defined as [\t\n\f\r\p{Z}].  |
| \S                         | Match a non-white space character.   |
| \t                         | Match a HORIZONTAL TABULATION, \u0009.   |
| \uhhhh                     | Match the character with the hex value hhhh.   |
| \Uhhhhhhhhh                | Match the character with the hex value hhhhhhhh. Exactly eight hex digits must be provided, even though the largest Unicode code point is \U0010ffff.  |
| \w                         | Match a word character. Word characters are [\p{Ll}\p{Lu}\p{Lt}\p{Lo}\p{Nd}].  |
| \W                         | Match a non-word character.  |
| \x{hhhh}                   | Match the character with hex value hhhh. From one to 6 hex digits can be supplied.   |

| Table 339. Regular expression metacharacters (continued) |  |
|--|--|
| Character  | Description  |
| \xhh   | Match the character with 2 digit hex value hh.   |
| \X   | Match a Grapheme Cluster.  |
| \Z   | Match if the current position is at the end of input, but before the final line terminator, if one exists.   |
| \z   | Match if the current position is at the end of input.  |
| \n   | Back Reference. Match whatever the nth capturing group matched. n must be a number > 1 and < total number of capture groups in the pattern.<br><br><b>Note:</b> Octal escapes, such as \012, are not supported in ICU regular expressions. |
| [pattern]  | Match any 1 character from the set. See UnicodeSet for a full description of what can appear in the pattern  |
| .  | Match any character.   |
| ^  | Match at the beginning of a line.  |
| \$   | Match at the end of a line.  |
| \  | Place quotation marks around the following character. Characters that must have surrounding quotation marks to be treated as literals are * ? + [ ( ) { } ^ \$   \ . /   |

| Table 340. Regular expression operators |  |
|---|--|
| Operator                                | Description  |
|   | Alternation. A   B matches either A or B.  |
| *                                       | Match 0 or more times. Match as many times as possible.                            |
| +                                       | Match 1 or more times. Match as many times as possible.                            |
| ?                                       | Match zero or 1 time. Prefer one.  |
| {n}                                     | Match exactly n times  |
| {n,}                                    | Match at least n times. Match as many times as possible.                           |
| {n,m}                                   | Match between n and m times. Match as many times as possible, but not more than m. |
| *?                                      | Match 0 or more times. Match as few times as possible.                             |
| +?                                      | Match 1 or more times. Match as few times as possible.                             |
| ??                                      | Match zero or 1 time. Prefer zero.   |
| {n}?                                    | Match exactly n times  |

Table 340. Regular expression operators (continued)

| Operator       | Description  |
|----------------|--|
| $\{n, \}?$     | Match at least n times, but no more than required for an overall pattern match   |
| $\{n, m\}?$    | Match between n and m times. Match as few times as possible, but not less than n.  |
| $\star$        | Match 0 or more times. Match as many times as possible when first encountered, do not retry with fewer even if overall match fails (Possessive Match)  |
| $++$           | Match 1 or more times. Possessive match.   |
| $?+$           | Match zero or 1 time. Possessive match.  |
| $\{n\}+$       | Match exactly n times  |
| $\{n, \}+$     | Match at least n times. Possessive Match.  |
| $\{n, m\}+$    | Match between n and m times. Possessive Match.   |
| $( \dots )$    | Capturing parentheses. Range of input that matched the parenthesized subexpression is available after the match.   |
| $(?: \dots )$  | Non-capturing parentheses. Groups the included pattern, but does not provide capturing of matching text. More efficient than capturing parentheses.  |
| $(?> \dots )$  | Atomic-match parentheses. First match of the parenthesized subexpression is the only one tried. If it does not lead to an overall pattern match, back up the search for a match to a position before the "(?>".  |
| $(?# \dots )$  | Free-format comment ( $?# \text{ comment } $ ).  |
| $(?= \dots )$  | Look-ahead assertion. True if the parenthesized pattern matches at the current input position, but does not advance the input position.  |
| $(?! \dots )$  | Negative look-ahead assertion. True if the parenthesized pattern does not match at the current input position. Does not advance the input position.  |
| $(?<= \dots )$ | Look-behind assertion. True if the parenthesized pattern matches text that precedes the current input position. The last character of the match is the input character just before the current position. Does not alter the input position. The length of possible strings that is matched by the look-behind pattern must not be unbounded (no $\star$ or $+$ operators.) |

| Table 340. Regular expression operators (continued) |  |
|---|--|
| Operator  | Description  |
| (?<!...)  | Negative Look-behind assertion. True if the parenthesized pattern does not match text that precedes preceding the current input position. The last character of the match is the input character just before the current position. Does not alter the input position. The length of possible strings that is matched by the look-behind pattern must not be unbounded (no * or + operators.) |
| (?ismx-ismx: ... )                                  | Flag settings. Evaluate the parenthesized expression with the specified flags enabled or disabled.   |
| (?ismx-ismx)  | Flag settings. Change the flag settings. Changes apply to the portion of the pattern that follows the setting. For example, (?i) changes to a not case-sensitive match.  |

## Replacement text

The replacement text for find-and-replace operations can contain references to capture-group text from the find. References are of the form \$n, where n is the number of the capture group.

| Table 341. Replacement text characters |  |
|--|--|
| Character                              | Description  |
| \$n                                    | The text of the positional capture group n is substituted for \$n. n must be >= 0, and not greater than the number of capture groups. A \$ not followed by a digit has no special meaning, and is displayed in the substitution text as itself, a \$.                                    |
| \                                      | Treat this character as a literal, suppressing any special meaning. Backslash escaping in substitution text is required only for '\$' and '\', but can be used on any other character without adverse effects.   |
| \$@n                                   | The text of capture group n is substituted for the regular expression that matched capture group n. n must be >= 0, and not greater than the number of capture groups. A \$@ not followed by a digit has no special meaning, and is displayed in the substitution text as itself, a \$@. |
| \$#n                                   | The text of the matched capture group n is substituted for \$#n. n must be >= 0, and not greater than the number of matched capture groups. A \$# not followed by a digit has no special meaning, and is displayed in the substitution text as itself, a \$#.                            |

## Flag options

The following flags control various aspects of regular expression matching. The flag values can be specified at the time that an expression is compiled into a `RegexPattern` object. Or, they can be specified within the pattern itself using the `(?ismx-ismx)` pattern options.

| Table 342. Flag options |                         |  |
|-------------------------|-------------------------|--|
| Flag (pattern)          | Flag (API constant)     | Description  |
| i                       | UREGEX_CASE_INSENSITIVE | If set, matching take place in a case-insensitive manner.  |
| x                       | UREGEX_COMMENTS         | If set, white space and <code>#</code> comments can be used within patterns.   |
| s                       | UREGEX_DOTALL           | If set, a <code>"."</code> in a pattern matches a line terminator in the input text. By default, it does not. A carriage-return / line-feed pair in text behaves as a single-line terminator, and matches a single <code>"."</code> in a RE pattern  |
| m                       | UREGEX_MULTILINE        | Control the behavior of <code>"^"</code> and <code>"\$"</code> in a pattern. By default these patterns match only at the start and end, respectively, of the input text. If this flag is set, <code>"^"</code> and <code>"\$"</code> also match at the start and end of each line within the input text. |

## Creating Non-agent file bundles

You can create file bundles that can be placed in the Tivoli Monitoring depot. These file bundles can then be deployed to target systems in your environment.

### About this task

With this function, you can remotely configure products for which there is no remote configuration option. To use this function, you place pre-populated configuration files into the depot and send them out to the wanted systems.

### Procedure

1. From the Agent Builder, select **File > New > Other**.
2. Under **Agent Builder**, select **Non-Agent Remote Deploy Bundle**.
3. Click **Next**.
4. In the **Project name** field, enter a name for your project.
5. Click **Next**.
6. Complete the information in the **Remote Deploy Bundle Information** window:
  - a) In the **Bundle identifier** field, type an identifier that is a unique alphanumeric string of 3 - 31 characters. This string can contain a hyphen. The string must start with a letter, but it cannot start with a K or a hyphen.
  - b) In the **Bundle description** field, type a description of the bundle.

- c) In the **Version** field, type a version for the bundle in the VVRRMMFFF format. Where vv= version number; rr= release number; mm= modification number (fix pack number); and fff = interim fix number.
7. In the **Operating Systems** area, select the operating systems to which the bundle can be deployed.
8. Click **Finish** to create a project in the workspace and open the **Remote Deploy Bundle Editor**.

## Remote Deploy Bundle Editor

The Remote Deploy Bundle Editor is used to generate commands to help deploy your file bundle.

The Remote Deploy Bundle Editor provides information about the bundle for a project.

The **Bundle Identification Information** section contains the following information:

### Bundle identifier

Unique ID for the bundle

### Bundle description

Description for the bundle

### Bundle version

Version of the bundle

### Build

Build identifier for the bundle. Enter a build number here. If no build number is specified, a number is generated from the date and time when the bundle is generated.

### Create copy commands for the files in the bundle check box

Click the check box to generate a set of default copy commands that run when the bundle is deployed. The files are copied to the location specified in the **Copy location** text box. The default location is *INSTALLDIR*. Specify this remote deployment variable from the command-line deployment by setting *KDY.INSTALLDIR=...*

The **Operating Systems** section shows the operating systems to which the bundle can be deployed.

The **Commands** section shows the commands to run when the bundle is deployed.

**Prerequisite Bundles** section shows the bundles that must be present for this bundle to work.

Use the Remote Deploy Bundle Editor to opt for a set of default copy commands that copy the files in your bundle to a set location. If this option is selected, then a copy command is generated for each file in your bundle project. The default copy location is *INSTALLDIR*. A special remote deployment variable that, if not set on the deployment command line, defaults to *CANDLEHOME*. To change the location that is specified by *INSTALLDIR*, specify the **KDY.INSTALLDIR** property when you run the **addSystem** command.

The same directory structure that is specified in your bundle project is replicated in *INSTALLDIR*. For example, if there is a folder named *config* in your bundle project with a file named *myprod.config*, then the generated copy command copies the file to *INSTALLDIR/config/myprod.config* when the bundle is deployed.

## Adding commands to the bundle

You can specify more commands to run during the deployment.

### About this task

You can specify more commands to run during the deployment by using the **Remote Deploy Bundle Editor**.

### Procedure

1. To specify more commands to run during the deployment, click **Add** in the **Commands** section of the **Remote Deploy Bundle Editor**.

2. In the **Command** window, select the type of command **Preinstall**, **Install**, **Post-Install**, or **Uninstall** and then specify the command to run.

You must specify the fully qualified path to the command you want to run. For convenience, remote deployment provides a set of predefined variables. To reference the variable for a command, surround the variable with vertical bars, for example, `|DEPLOYDIR|`. For more information about predefined variables for commands, see (Table 343 on page 1712).

| Table 343. Predefined Variables for Commands |   |
|--|---|
| Variable                                     | Description   |
| <i>DEPLOYDIR</i>                             | The temporary directory on the endpoint where the bundle is stored during the deployment. For instance, if you want to run <code>myscript.sh</code> , a script that is included in your bundle, you specify the following command: <code> DEPLOYDIR /myscript.sh</code> |
| <i>INSTALLDIR</i>                            | Either <i>CANDLEHOME</i> or the value of <i>KDY.INSTALLDIR</i> if specified on the <b>addSystem</b> command.  |
| <i>CANDLEHOME</i>                            | The Tivoli Monitoring installation directory.   |

3. Finally, select the **Operating Systems** on which the command is to run.

## Adding prerequisites to the bundle

Use the **Remote Deploy Bundle Editor** to specify prerequisites for the bundle.

### Procedure

1. To add a prerequisite, click **Add** in the **Prerequisite Bundles** section of the **Remote Deploy Bundle Editor, Bundle Information** page.
2. In the **New Prerequisite** window, enter the bundle identifier on which this bundle depends and the minimum version required.
3. Select the operating systems for which this prerequisite is required.
4. Click **OK** to complete and exit.

## Adding files to the bundle

Add files to a file bundle by using the **Remote Deploy Bundle Editor**.

### Procedure

1. To add files to the remote deployment bundle, do one of the following procedures:
  - In the Bundle Editor, click **Add files to the bundle**.
  - Right-click the project in the Navigator tree, then click **IBM Tivoli Monitoring Remote Deploy > Add Files to Bundle**

Both of these actions display the **Import Bundle Files** window:

2. Specify individual files or directories that contain files in **File Information** area.
3. Click **Finish**.

The files or directories that are specified are copied into the project directory. The directory structure in the project is maintained when you build the remote deployment bundle. If you want Agent Builder to generate default copy commands, ensure that the files are in the correct directory structure for deployment.

## Generating the bundle

Use Agent Builder to generate a bundle for remote deployment of an agent.

### Procedure

1. To generate the remote deployment bundle, use one of the following procedures to display the **Generate Final Remote Deploy Bundle** window
  - In the **Remote Deploy Bundle Editor**, click **generate the final Remote deploy bundle**.
  - Right-click the project in the Navigator tree, then click **IBM Tivoli Monitoring Remote Deploy > Generate Remote Deploy Bundle**
2. You can now generate the bundle in two ways:
  - If there is a Tivoli Enterprise Monitoring Server on the system where you are running the Agent Builder, click **Install the Remote Deploy bundle into a local TEMS depot**.

The Agent Builder attempts to determine the Tivoli Monitoring installation location and enter it into the **Directory** field. If *CANDLE\_HOME* is not set, the default location of C:\IBM\ITM or /opt/IBM/ITM is used. Ensure that the installation location is correct before you continue.

You must provide Tivoli Enterprise Monitoring Server login information to install the bundle.
  - To generate the bundle to a directory on your system, click **Generate the Remote Deploy bundle in a local directory**

After the process is complete, you must transfer this directory to a Tivoli Enterprise Monitoring Server system and use the `tacmd addbundles` command to add the bundle to the depot.

### What to do next

When you deploy the bundle, you must use the `tacmd addSystem` command. For example:

```
tacmd addsystem -t MONITORINGCOLLECTION -n Primary:ITMAGT:NT
```

Where `-t` (type) is the Product Code as returned by the `tacmd viewDepot` command:

```
>tacmd viewDepot
Product Code : MONITORINGCOLLECTION
Version : 010000003
Description : MonitoringCollectionScripts
Host Type : WINNT
Host Version : WINNT
Prerequisites:
```

**Note:** You cannot deploy remotely from the Tivoli Enterprise Portal Desktop or Browser. Deploy remotely from the Tivoli Enterprise Portal Desktop or Browser results in the KFWITM219E message.

See the Tivoli Monitoring documentation for more details.

## Creating deployable bundles for Tivoli Netcool/OMNIBus probes

You can use the Agent Builder to create package and configuration bundles that can be used to deploy Tivoli Netcool/OMNIBus probes to remote computers.

### About this task

To support the remote deployment of probes, you can also create Tivoli Netcool/OMNIBus bundles that can be deployed to the remote computers before you deploy the probes.

### Procedure

1. From the Agent Builder, select **File > New > Other**.

2. Under **IBM Tivoli OMNIBus Wizards**, select **Package Bundle**.
3. Click **Next**.

## What to do next

Next, use the **OMNIBus Install Bundle** wizard to create the bundles. For information about using this wizard, see the [Tivoli Netcool/OMNIBus documentation](#).

## Dynamic file name support

---

Use dynamic file name support to specify a file name pattern instead of an actual file name.

Some application programs create an output file name that is subject to change. The name changes based on specific criteria such as the current day, month, year, or a file name that includes an incrementing sequence number. In these cases, you can specify the file name pattern instead of the actual file name. There are two pattern formats that are recognized when you specify the file name pattern:

- Regular Expressions (preferred).
- IBM Tivoli Universal Agent dynamic file name syntax (deprecated).

### Regular expression file name patterns

To specify file name patterns, you can use regular expressions according to the International Components for Unicode (ICU) syntax that is documented in (“ICU regular expressions” on page 1705). To use this capability, you must select the **File names match regular expression** check box on the **Advanced Log File Attribute Group Information** page. When you specify regular expression patterns, you must also select an option from the **When Multiple Files Match** list on the **Advanced Log File Attribute Group Information** page to specify the guidelines for selecting the most current matching file.

**Note:** Regular expressions is the preferred method to specify file name patterns.

For more information about how to configure advanced log file attribute group properties, see (“Monitoring a log file” on page 1482), Step (“6” on page 1483). For example, if you specified a file name pattern:

```
d:\program files\logs\tivoli.*
```

This pattern searches for file names that start with `tivoli` in the `d:\program files\logs` directory. Regular expressions can be specified only for the file name portion, and not the path name.

### Dynamic file name syntax

With the dynamic file name syntax, only one file at a time can be monitored. The File Data Provider inspects all files in the designated path location, seeking files that match the defined pattern. The File Data Provider always monitors the most current matching file that is based on whichever matching file name has the highest number or date-time value. The appropriate file to monitor is determined by file name, instead of by file creation or other criteria.

Patterns can be specified for file names with any number of parts. For example, `Log{###}` matches on one-part file names such as `Log010` or `Log456`. In multi-part file names, pattern characters can be specified in any part of the file name or in multiple parts. For example, `aaa.bbb{???}.ccc` is a valid pattern, and `aaa.bbb{???}.ccc{###}` is also valid.

**Note:** Regular expressions rather than dynamic file name syntax is the preferred method to specify file name patterns, for more about regular expressions, see “Regular expression file name patterns” on page 1714

The following examples illustrate file name pattern specification:

**{#####}.abc**

Matches numeric file names of length 8 and the file extension *.abc*, such as 10252006.*abc* or 10262006.*abc*. File 10262006.*abc* is monitored because 10262006 is greater than 10252006.

**{#####}.\***

Matches numeric file names of length 8 and ignores the file extension. Examples include 20061025.*log*, 20061101.*log*, and 10252006.*abc*. File 20061101.*log* is monitored because 20061101 is the largest number.

**{#####??}.abc**

Matches numeric file names of length 8 and file extension *.abc*, and ignores the last two positions in the name portion. Examples include 02110199.*abc*, 02110200.*abc*, and 021101AZ.*abc*. File 02110200.*abc* is monitored because 021102 is the largest number.

**Console.{#####}**

Matches file names that contain *Console* in the name portion and a six-digit number in the extension portion. Examples include Console.000133, Console.000201, and Console.000134. File Console.000201 is monitored.

**IN{#####}.log**

Matches file names that start with IN followed by six numerals and the file extension *.log*. Examples include IN021001.*log*, IN021002.*log*, and IN021004.*log*. File IN021004.*log* is monitored.

**PS{###}FTP.txt**

Matches file names that start with PS followed by three numerals, followed by FTP, and the extension *.txt*. Examples include PS001FTP.*txt*, PS005FTP.*txt*, and PS010FTP.*txt*. File PS010FTP.*txt* is monitored.

Follow these guidelines to establish file name patterns:

- Use braces {} to enclose pattern characters in a file name. The presence of pattern characters inside braces indicates that a file name pattern is being used.
- Use an asterisk (\*) as a wildcard to ignore file extensions or any trailing characters in the file name. For example, Myapp{###}.log\* specifies that any file name that starts with Myapp, followed by three digits, and followed by *.log*, is a match, regardless of what comes after.

The asterisk must be specified after the curly braces ({} ) and cannot be used at the beginning of a file name. When you use the asterisk in a file name extension, the asterisk must be used by itself.

Examples of correct wildcard (\*) usage:

**err{??}.\***

**error{\${}}.\***

Examples of incorrect wildcard (\*) usage:

**error.20\***

No curly braces precede the asterisk (\*).

**error\*. {###}**

The asterisk is not used at the end of the file name.

**error.\***

No curly braces precede the asterisk (\*).

- If a specific file extension is defined, then only files with the same extension are considered.
- Use a number sign to indicate each numeric element of a file name.
- Use a question mark to exclude each element of the naming convention that does not serve as search criteria in determining the appropriate file name.
- Use a dollar sign (\$) to represent either any character or no character. For example, if you want to match on two files named Log and LogA, specify Log{\${}}. The dollar sign has several usage restrictions. When you use one or more dollar signs to prefix a file name as in {\$\$\$\$\$\_abc.*log*, the number of dollar signs must exactly match the number of characters in that position in the file name. Also, you cannot specify dollar signs in multiple locations in a file name pattern, for example, {\$\$\$}b{\$\$\$}.log

does not match `abc.log`. Given these dollar sign restrictions, use regular expression file name patterns if there are an indeterminate number of characters in the file names.

- The total number of number signs and question marks that are enclosed in braces is significant. It must match the portion of file name exactly. For example, the pattern `AA{####}` instructs the File Data Provider to look for files such as `AA0001`. File names, such as `AA001` or `AA00001`, are not considered.
- The exact file name pattern, the constant, and the numeric parts, must match the file name exactly. For example, the pattern `AA{###}` instructs the File Data Provider to check file `AA101`. File names, such as `XAA101`, `AA222X` and `AA55555`, are not considered.
- Use the reserved pattern string `{TIVOLILOGTIME}` to substitute for the hex timestamp and file sequence number in a Tivoli Monitoring agent or server log file. This pattern string is useful when you do self-monitoring of Tivoli Monitoring components. For example, if you want to monitor the latest monitoring server log in the `/opt/IBM/ITM/logsdirectory`, can specify a file name pattern:

```
/opt/IBM/ITM/logs/Host1_ms_{TIVOLILOGTIME}.log
```

If `Host1_ms_452053c0-01.log`, `Host1_ms_451f11f4-01.log`, `Host1_ms_45205946-01.log`, and `Host1_ms_451f11f4-02.log` are present in the `/logsdirectory`, the `Host1_ms_45205946-01.log` file is selected for monitoring.

To precisely specify a file name that consists of date components (year, month, and day), use the capital letters Y, M, and D. These letters must be specified within braces; otherwise they are treated as literal characters in the file name.

See the following examples:

**{YYYYMMDD}.log**

Specifies file names such as `20060930.log` or `20061015.log`.

**{MMDDYY}.log**

Specifies file names such as `101106.log` or `110106.log`.

**{DDMMYYYY}.log**

Specifies file names such as `01092006.log` or `15082006.log`.

**{DDMMYY}.log**

Specifies file names such as `24Jan07` or `13Sep06`.

**{MM-DD-YY}.log**

Specifies file names such as `11-02-06` or `04-29-07`. The ( - ) separator character is ignored in the date field and does not require a question mark pattern character to skip over it.

**MY{YYDDD}.log**

Specifies file names such as `MY06202.log`, `MY06010.log`, or `MY04350.log`.

Complex cases exist, where a date field is embedded within a longer file name, and the date patterns in the previous examples are not sufficient. For complex cases, create patterns that mix number signs and question marks and still perform numeric comparisons that select the most current file for monitoring. For example, the pattern `ABC{?####?##?##?##?##?##?}XYZ.TXT` can be used for file names such as `ABC 2006-04-20 11_22_33 XYZ.TXT`. In this example, you are interested in only the #- marked digits and question marks serve as placeholders that ignore other characters in the file name.

The File Data Provider periodically checks for new files that match the defined file pattern in the target path location. When a newer file that matches the pattern is detected, the File Data Provider automatically switches application monitoring to the new file. The File Data Provider searches for the best matching file when:

- The File Data Provider first starts.
- The currently monitored file no longer exists because of possible renaming or deleting.
- The existing file contents, changed because of possible rewriting.
- The check interval expired. The default interval is 10 minutes. You can change the interval to a longer or shorter interval value by specifying the environment variable

## SNMP trap configuration

Description of the configuration file that is used by the SNMP Data Provider to render trap information in a more easily readable form. The file is also used to assign categories, severities, status, and source IDs to traps.

Also contains instructions for modifying the default file or substituting your own configuration file.

### SNMP trap configuration file, `trapcnfg`

At startup, the SNMP Data Provider reads a configuration file named `trapcnfg`. One purpose of this file is to translate SNMP trap information into a more readable form. Another is to assign categories, severities, status, and source IDs to specific traps, since these categories are not defined by SNMP.

You can modify the `trapcnfg` file to suit your site-specific needs by adding new trap or enterprise definitions or changing the existing ones. You can also use your own configuration file.

### Use the HP OpenView `trapd.conf` file

The `trapcnfg` file is similar in format, but not identical, to the HP OpenView Network Node Manager trap configuration file `trapd.conf`. You can copy the OpenView file and reuse many of the definition statements if necessary.

### Types of records

`trapcnfg` contains three types of records or record blocks:

#### **comments**

Comment records begin with a number sign (#).

#### **enterprise definitions**

Enterprise definitions consist of two blank-delimited tokens, where the first token is a name and the second is an object identifier (OID) surrounded by curly brackets ({ }).

#### **trap definitions**

Trap definitions consist of eight blank-delimited tokens. Trap definitions are block records because each definition might consist of multiple records.

The first type is self-explanatory. (Figure 87 on page 1718) shows examples of the second and third types.

The first example in Figure 87 on page 1718 shows an enterprise definition record which defines enterprise OID 1.3.6.1.4.1.311.1.1.3.1.1 as being Microsoft Windows NT.

The second example shows a trap definition record that defines `trapName MSNTCOLD` as being associated with enterprise OID 1.3.6.1.4.1.311.1.1.3.1.1, generic trap number 0, and specific trap number 0. Notice that the severity is in decimal form whereas the category is in textual form. Severities are translated into their textual form before they are displayed. The next record in the type 3 record block is the short description, which the Agent Builder does not use. The Agent Builder uses the long description that is enclosed within the delimiters `SDESC` and `EDESC`.

### Example of record type 2

MS-Windows NT {1.3.6.1.4.1.311.1.1.3.1.1}

### Example of record type 3

MSNTCOLD {1.3.6.1.4.1.311.1.1.3.1.1} 0 0 A 1 0 "Status Events"

MSNT - agent up with possible changes (coldStart trap)

SDESC

A coldStart trap signifies that the sending protocol entity is reinitializing itself in such a way that the agents configuration or the protocol entity implementation may be altered.

EDESC

Figure 87. Examples of configuration record types 2 and 3

## Defaults for the trapcnfg file

Tables that list the defaults that are supported by the SNMP Data Provider.

## Supported categories

(Table 344 on page 1718) shows the categories that are supported by the Agent Builder.

| Table 344. Categories supported by the SNMP Data Provider |                         |
|---|-------------------------|
| Category  | Textual representation  |
| 0   | Threshold Events        |
| 1   | Network Topology Events |

*Table 344. Categories supported by the SNMP Data Provider (continued)*

| Category | Textual representation    |
|----------|---------------------------|
| 2        | Error Events              |
| 3        | Status Events             |
| 4        | Node Configuration Events |
| 5        | Application Alert Events  |
| 6        | All Category Events       |
| 7        | Log Only Events           |
| 8        | Map Events                |
| 9        | Ignore Events             |

(Table 345 on page 1719) lists the severities that are supported by the Agent Builder.

*Table 345. Severities supported by the SNMP Data Provider*

| Severity | Textual representation |
|----------|------------------------|
| 0        | Clear                  |
| 1        | Indeterminate          |
| 2        | Warning                |
| 3        | Minor Error            |
| 4        | Critical               |
| 5        | Major Error            |

## Supported statuses

(Table 346 on page 1719) shows the statuses that are defined in the Agent Builder configuration file.

*Table 346. Statuses supported by the SNMP Data Provider*

| Status | Textual representation |
|--------|------------------------|
| 0      | Unchanged              |
| 1      | Unknown                |
| 2      | Up                     |
| 3      | Marginal               |
| 4      | Down                   |
| 5      | Unmanaged              |
| 6      | Acknowledge            |
| 7      | User1                  |
| 8      | User2                  |

## Supported source IDs

(Table 347 on page 1720) lists the source IDs supported by trapcnfg.

Table 347. Source IDs supported by the SNMP Data Provider

| Source ID | Description            |
|-----------|------------------------|
| a         | Application            |
| A         | Agent                  |
| C         | Xnmcollect             |
| d         | Demo                   |
| D         | Data Collector         |
| E         | Nvevents               |
| I         | Ipmap                  |
| L         | LoadMIB                |
| m         | Shpmon                 |
| M         | IP topology            |
| n         | netmon related         |
| N         | netmon-generated traps |
| O         | OSI SA                 |
| P         | Non-IP traps           |

## Take Action commands reference

An overview of Take Action commands, references about Take Action commands, and descriptions of special Take Action commands.

### About Take Action commands

Take Action commands can be included in an Agent Builder monitoring agent. Take Action commands can be run from the portal client or included in a situation or a policy. When included in a situation, the command runs when the situation becomes true. A Take Action command in a situation is also known as reflex automation. When you enable a Take Action command in a situation, you automate a response to system conditions. For example, you can use a Take Action command to send a command to restart a process on the managed system. You can also use a Take Action command to send a text message to a cell phone.

Advanced automation uses policies to run actions, schedule work, and automate manual tasks. A policy comprises a series of automated steps that are called activities that are connected to create a workflow. After an activity is completed, the Tivoli Enterprise Portal receives return code feedback, and advanced automation logic responds with subsequent activities prescribed by the feedback.

A basic Take Action command displays the return code of the operation in a message box or a log file that is displayed after action completion. After you close this window, no further information is available for this action.

## More information about Take Action commands

For more information about working with Take Action commands, see the *Tivoli Enterprise Portal User's Guide*.

For a list and description of the Take Action commands for this monitoring agent, see ([“Special Take Action commands” on page 1721](#)). See also the information in that section for each individual command.

## Special Take Action commands

An Agent Builder monitoring agent can recognize and do special processing for a set of Take Action commands:

- SSEXEC

For more information about creating these commands and including them in an Agent Builder monitoring agent project, see ([“Creating workspaces, Take Action commands, and situations” on page 1585](#)).

## SSEXEC action

### Before you begin

For more information about Take Action commands, see ([“Take Action commands reference” on page 1720](#)).

### About this task

The SSEXEC action is recognized for a monitored application that has at least one SSH Script attribute group. It indicates that the command that follows the SSEXEC keyword is remotely started on the SSH target system. The command is started with the credentials and privileges of the user that is configured to monitor the SSH target system. The command is run on the remote system that is represented by the Managed System Name.

### Procedure

To include the Take Action command in a situation or workflow policy, use the following syntax for the system command:

```
SSEXEC [Command]
```

For example:

```
SSEXEC [ls &path]
```

**Note:** You can customize the command or portions of the command during invocation of the Take Action by using the Take Action arguments option with the *Command*.

**Note:** If the *Command* includes multiple arguments, then consider including the bracket parenthesis to enable invocation of the Take Action command with the **tacmd** command-line interface.

# Accessibility features

---

Accessibility features assist users who have a disability, such as restricted mobility or limited vision, to use information technology content successfully.

## Accessibility features

The web-based interface of IBM Cloud Application Performance Management is the Cloud APM console. The console includes the following major accessibility features:

- Enables users to use assistive technologies, such as screen-reader software and digital speech synthesizer, to hear what is displayed on the screen. Consult the product documentation of the assistive technology for details on using those technologies with this product.
- Enables users to operate specific or equivalent features using only the keyboard.
- Communicates all information independently of color.<sup>2</sup>

The Cloud APM console uses the latest W3C Standard, WAI-ARIA 1.0 (<http://www.w3.org/TR/wai-aria/>), to ensure compliance with US Section 508 (<http://www.access-board.gov/guidelines-and-standards/communications-and-it/about-the-section-508-standards/section-508-standards>), and Web Content Accessibility Guidelines (WCAG) 2.0 . To take advantage of accessibility features, use the latest release of your screen reader in combination with the latest web browser that is supported by this product.

The Cloud APM console online product documentation in IBM Knowledge Center is enabled for accessibility. The accessibility features of IBM Knowledge Center are described at [IBM Knowledge Center release notes](#) .

## Keyboard navigation

This product uses standard navigation keys.

## Interface information

The Cloud APM console web user interface does not rely on cascading style sheets to render content properly and to provide a usable experience. However, the product documentation does rely on cascading style sheets. IBM Knowledge Center provides an equivalent way for low-vision users to use their custom display settings, including high-contrast mode. You can control font size by using the device or browser settings.

The Cloud APM console web user interface includes WAI-ARIA navigational landmarks that you can use to quickly navigate to functional areas in the application.

The Cloud APM console user interface does not have content that flashes 2 - 55 times per second.

## Related accessibility information

In addition to standard IBM help desk and support websites, IBM has established a TTY telephone service for use by deaf or hard of hearing customers to access sales and support services:

TTY service 800-IBM-3383 (800-426-3383) (within North America)

## IBM and accessibility

For more information about the commitment that IBM has to accessibility, see [IBM Accessibility \(www.ibm.com/able\)](http://www.ibm.com/able).

---

<sup>2</sup> Exceptions include some **Agent Configuration** pages of the Performance Management console.

## Notices

---

This information was developed for products and services offered in the US. This material might be available from IBM in other languages. However, you may be required to own a copy of the product or product version in that language in order to access it.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

## Terms and conditions for product documentation

---

Permissions for the use of these publications are granted subject to the following terms and conditions.

### Applicability

These terms and conditions are in addition to any terms of use for the IBM website.

### Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

### Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

### Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the above instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

## IBM Online Privacy Statement

---

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth in the following paragraphs.

Depending upon the configurations deployed, this Software Offering may use session cookies that collect each user's user name for purposes of session management, authentication, and single sign-on configuration. These cookies can be disabled, but disabling them will also likely eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek

your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details> the section entitled "Cookies, Web Beacons and Other Technologies" and the "IBM Software Products and Software-as-a-Service Privacy Statement" at <http://www.ibm.com/software/info/product-privacy>.
