

## LM4880 Boomer® Audio Power Amplifier Series

### Dual 250 mW Audio Power Amplifier with Shutdown Mode

#### General Description

The LM4880 is a dual audio power amplifier capable of delivering typically 250mW per channel of continuous average power to an 8Ω load with 0.1% THD+N using a 5V power supply.

Boomer audio power amplifiers were designed specifically to provide high quality output power with a minimal amount of external components using surface mount packaging.

Since the LM4880 does not require bootstrap capacitors or snubber networks, it is optimally suited for low-power portable systems.

The LM4880 features an externally controlled, low-power consumption shutdown mode, as well as an internal thermal shutdown protection mechanism.

The unity-gain stable LM4880 can be configured by external gain-setting resistors.

#### Key Specifications

- THD+N at 1kHz at 200mW continuous average output power into 8Ω: 0.1% (max)

- THD+N at 1kHz at 85mW continuous average output power into 32Ω: 0.1% (typ)
- Output power at 10% THD+N at 1kHz into 8Ω: 325mW (typ)
- Shutdown current: 0.7μA (typ)
- 2.7V to 5.5V supply voltage range

#### Features

- No bootstrap capacitors or snubber circuits are necessary
- Small Outline (SO) and DIP packaging
- Unity-gain stable
- External gain configuration capability

#### Applications

- Headphone Amplifier
- Personal Computers
- CD-ROM Players

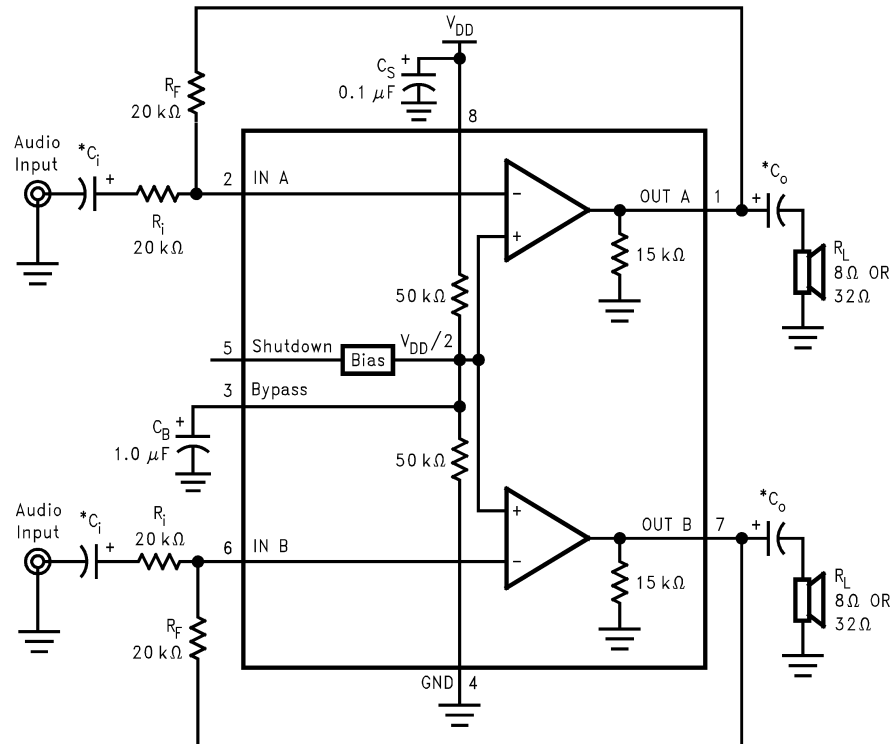

#### Connection Diagram

## External Components Description (Figure 1)

Components		Functional Description
1.	$R_i$	Inverting input resistance which sets the closed-loop gain in conjunction with $R_F$ . This resistor also forms a high pass filter with $C_i$ at $f_c = 1/(2\pi R_i C_i)$ .
2.	$C_i$	Input coupling capacitor which blocks the DC voltage at the amplifier's input terminals. Also creates a high pass filter with $R_i$ at $f_c = 1/(2\pi R_i C_i)$ . Refer to the section, <b>Proper Selection of External Components</b> , for an explanation of how to determine the value of $C_i$ .
3.	$R_F$	Feedback resistance which sets closed-loop gain in conjunction with $R_i$ .
4.	$C_S$	Supply bypass capacitor which provides power supply filtering. Refer to the <b>Application Information</b> section for proper placement and selection of the supply bypass capacitor.
5.	$C_B$	Bypass pin capacitor which provides half-supply filtering. Refer to the section, <b>Proper Selection of External Components</b> , for information concerning proper placement and selection of $C_B$ .
6.	$C_o$	Output coupling capacitor which blocks the DC voltage at the amplifier's output. Forms a high pass filter with $R_L$ at $f_o = 1/(2\pi R_L C_o)$ .

## Application Information

### SHUTDOWN FUNCTION

In order to reduce power consumption while not in use, the LM4880 contains a shutdown pin to externally turn off the amplifier's bias circuitry. This shutdown feature turns the amplifier off when a logic high is placed on the shutdown pin. The trigger point between a logic low and logic high level is typically half supply. It is best to switch between ground and the supply to provide maximum device performance. By switching the shutdown pin to  $V_{DD}$ , the LM4880 supply current draw will be minimized in idle mode. While the device will be disabled with shutdown pin voltages less than  $V_{DD}$ , the idle current may be greater than the typical value of 0.7  $\mu A$ . In either case, the shutdown pin should be tied to a definite voltage because leaving the pin floating may result in an unwanted shutdown condition.

In many applications, a microcontroller or microprocessor output is used to control the shutdown circuitry which provides a quick, smooth transition into shutdown. Another solution is to use a single-pole, single-throw switch in conjunction with an external pull-up resistor. When the switch is closed, the shutdown pin is connected to ground and enables the amplifier. If the switch is open, then the external pull-up resistor will disable the LM4880. This scheme guarantees that the shutdown pin will not float which will prevent unwanted state changes.

### POWER DISSIPATION

Power dissipation is a major concern when using any power amplifier and must be thoroughly understood to ensure a successful design. Equation (1) states the maximum power dissipation point for a single-ended amplifier operating at a given supply voltage and driving a specified output load.

$$P_{DMAX} = (V_{DD})^2 / (2\pi^2 R_L) \quad (1)$$

Since the LM4880 has two operational amplifiers in one package, the maximum internal power dissipation point is twice that of the number which results from Equation (1). Even with the large internal power dissipation, the LM4880 does not require heat sinking over a large range of ambient temperatures. From Equation (1), assuming a 5V power supply and an 8 $\Omega$  load, the maximum power dissipation point is 158 mW per amplifier. Thus the maximum package

dissipation point is 317 mW. The maximum power dissipation point obtained must not be greater than the power dissipation that results from Equation (2):

$$P_{DMAX} = (T_{JMAX} - T_A) / \theta_{JA} \quad (2)$$

For the LM4880 surface mount package,  $\theta_{JA} = 170^\circ C/W$  and  $T_{JMAX} = 150^\circ C$ . Depending on the ambient temperature,  $T_A$ , of the system surroundings, Equation (2) can be used to find the maximum internal power dissipation supported by the IC packaging. If the result of Equation (1) is greater than that of Equation (2), then either the supply voltage must be decreased, the load impedance increased, or the ambient temperature reduced. For the typical application of a 5V power supply, with an 8 $\Omega$  load, the maximum ambient temperature possible without violating the maximum junction temperature is approximately 96 $^\circ C$  provided that device operation is around the maximum power dissipation point. Power dissipation is a function of output power and thus, if typical operation is not around the maximum power dissipation point, the ambient temperature may be increased accordingly. Refer to the **Typical Performance Characteristics** curves for power dissipation information for lower output powers.

### POWER SUPPLY BYPASSING

As with any power amplifier, proper supply bypassing is critical for low noise performance and high power supply rejection. The capacitor location on both the bypass and power supply pins should be as close to the device as possible. As displayed in the **Typical Performance Characteristics** section, the effect of a larger half supply bypass capacitor is improved low frequency PSRR due to increased half-supply stability. Typical applications employ a 5V regulator with 10  $\mu F$  and a 0.1  $\mu F$  bypass capacitors which aid in supply stability, but do not eliminate the need for bypassing the supply nodes of the LM4880. The selection of bypass capacitors, especially  $C_B$ , is thus dependant upon desired low frequency PSRR, click and pop performance as explained in the section, **Proper Selection of External Components** section, system cost, and size constraints.

### AUTOMATIC SHUTDOWN CIRCUIT

As shown in Figure 2, the LM4880 can be set up to automatically shutdown when a load is not connected. This circuit is based upon a single control pin common in many headphone jacks. This control pin forms a normally closed

## Application Information (Continued)

switch with one of the output pins. The output of this circuit (the voltage on pin 5 of the LM4880) has two states based on the state of the switch. When the switch is open, signifying that headphones are inserted, the LM4880 should be enabled. When the switch is closed, the LM4880 should be off to minimize power consumption.

The operation of this circuit is rather simple. With the switch closed,  $R_p$  and  $R_o$  form a resistor divider which produces a gate voltage of less than 5 mV. This gate voltage keeps the NMOS inverter off and  $R_{sd}$  pulls the shutdown pin of the LM4880 to the supply voltage. This places the LM4880 in shutdown mode which reduces the supply current to 0.7  $\mu$ A typically. When the switch is open, the opposite condition is produced. Resistor  $R_p$  pulls the gate of the NMOS high which turns on the inverter and produces a logic low signal on the shutdown pin of the LM4880. This state enables the LM4880 and places the amplifier in its normal mode of operation.

This type of circuit is clearly valuable in portable products where battery life is critical, but is also beneficial for power conscious designs such as "Green PC's".

### AUTOMATIC SWITCHING CIRCUIT

A circuit closely related to the **Automatic Shutdown Circuit** is the **Automatic Switching Circuit** of *Figure 3*. The **Automatic Switching Circuit** utilizes both the input and output of the NMOS inverter to toggle the states of two different audio power amplifiers. The LM4880 is used to drive stereo single ended loads, while the LM4861 drives bridged internal speakers.

In this application, the LM4880 and LM4861 are never on at the same time. When the switch inside the headphone jack is open, the LM4880 is enabled and the LM4861 is disabled since the NMOS inverter is on. If a headphone jack is not present, it is assumed that the internal speakers should be on and thus the voltage on the LM4861 shutdown pin is low and the voltage at the LM4880 pin is high. This results in the LM4880 being shutdown and the LM4861 being enabled.

Only one channel of this circuit is shown in *Figure 3* to keep the drawing simple but the typical application would a LM4880 driving a stereo external headphone jack and two LM4861's driving the internal stereo speakers. If only one internal speaker is required, a single LM4861 can be used as a summer to mix the left and right inputs into a single mono channel.

### PROPER SELECTION OF EXTERNAL COMPONENTS

Selection of external components when using integrated power amplifiers is critical to optimize device and system performance. While the LM4880 is tolerant of external component combinations, care must be exercised when choosing component values.

The LM4880 is unity-gain stable which gives a designer maximum system flexibility. The LM4880 should be used in low gain configurations to minimize THD + N values, and maximize the signal to noise ratio. Low gain configurations require large input signals to obtain a given output power. Input signals equal to or greater than 1 Vrms are available from sources such as audio codecs. Please refer to the section, **Audio Power Amplifier Design**, for a more complete explanation of proper gain selection.

Besides gain, one of the major design considerations is the closed-loop bandwidth of the amplifier. To a large extent, the

bandwidth is dictated by the choice of external components shown in *Figure 1*. Both the input coupling capacitor,  $C_i$ , and the output coupling capacitor,  $C_o$ , form first order high pass filters which limit low frequency response. These values should be chosen based on needed frequency response for a few distinct reasons.

### Selection of Input and Output Capacitor Size

Large input and output capacitors are both expensive and space hungry for portable designs. Clearly a certain sized capacitor is needed to couple in low frequencies without severe attenuation. But in many cases the transducers used in portable systems, whether internal or external, have little ability to reproduce signals below 100 Hz–150 Hz. Thus using large input and output capacitors may not increase system performance.

In addition to system cost and size, click and pop performance is effected by the size of the input coupling capacitor,  $C_i$ . A larger input coupling capacitor requires more charge to reach its quiescent DC voltage (normally  $1/2 V_{DD}$ ). This charge comes from the output via the feedback and is apt to create pops upon device enable. Thus, by minimizing the capacitor size based on necessary low frequency response, turn-on pops can be minimized.

Besides minimizing the input and output capacitor sizes, careful consideration should be paid to the bypass capacitor size. The bypass capacitor,  $C_B$ , is the most critical component to minimize turn-on pops since it determines how fast the LM4880 turns on. The slower the LM4880's outputs ramp to their quiescent DC voltage (nominally  $1/2 V_{DD}$ ), the smaller the turn-on pop. Choosing  $C_B$  equal to 1.0  $\mu$ F along with a small value of  $C_i$  (in the range of 0.1  $\mu$ F to 0.39  $\mu$ F), should produce a virtually clickless and popless shutdown function. While the device will function properly, (no oscillations or motorboating), with  $C_B$  equal to 0.1  $\mu$ F, the device will be much more susceptible to turn-on clicks and pops. Thus, a value of  $C_B$  equal to 1.0  $\mu$ F or larger is recommended in all but the most cost sensitive designs.

### AUDIO POWER AMPLIFIER DESIGN

#### Design a Dual 200 mW/8 $\Omega$ Audio Amplifier

Given:

Power Output: 200 mWrms Load Impedance: 8 $\Omega$   
Input Level: 1 Vrms (max) Input Impedance: 20 k $\Omega$   
Bandwidth: 100 Hz–20 kHz  $\pm$  0.50 dB

A designer must first determine the needed supply rail to obtain the specified output power. Calculating the required supply rail involves knowing two parameters,  $V_{opeak}$  and also the dropout voltage. As shown in the Typical Performance Curves, the dropout voltage is typically 0.5V.  $V_{opeak}$  can be determined from Equation (3).

$$V_{opeak} = \sqrt{(2R_L P_o)} \quad (3)$$

For 200 mW of output power into an 8 $\Omega$  load, the required  $V_{opeak}$  is 1.79V. Since this is a single supply application, the minimum supply voltage is twice the sum of  $V_{opeak}$  and  $V_{od}$ . Since 5V is a standard supply voltage in most applications, it is chosen for the supply rail. Extra supply voltage creates headroom that allows the LM4880 to reproduce peaks in excess of 200 mW without clipping the signal. At this time, the designer must make sure that the power supply choice along with the output impedance does not violate the conditions explained in the **Power Dissipation** section. Remem-

## Application Information (Continued)

ber that the maximum power dissipation value from Equation (1) must be multiplied by two since there are two independent amplifiers inside the package.

Once the power dissipation equations have been addressed, the required gain can be determined from Equation (4).

$$|A_V| \geq \sqrt{(P_o R_L) / (V_{IN})} = V_{orms} / V_{inrms} \quad (4)$$

$$A_V = -R_F / R_i \quad (5)$$

From Equation (4), the minimum gain is:  $A_V = -1.26$

Since the desired input impedance was 20 k $\Omega$ , and with a gain of -1.26, a value of 27 k $\Omega$  is designated for  $R_i$ , assuming 5% tolerance resistors. This combination results in a nominal gain of -1.35. The final design step is to address the bandwidth requirements which must be stated as a pair of -3 dB frequency points. Five times away from a -3 dB point is 0.17 dB down from passband response assuming a single pole roll-off. As stated in the **External Components** section,

both  $R_i$  in conjunction with  $C_i$ , and  $C_o$  with  $R_L$ , create first order high pass filters. Thus to obtain the desired frequency low response of 100 Hz within  $\pm 0.5$  dB, both poles must be taken into consideration. The combination of two single order filters at the same frequency forms a second order response. This results in a signal which is down 0.34 dB at five times away from the single order filter -3 dB point. Thus, a frequency of 20 Hz is used in the following equations to ensure that the response is better than 0.5 dB down at 100 Hz.

$$C_i \geq 1 / (2\pi * 20k\Omega * 20Hz) = 0.397 \mu F; \text{ use } 0.39 \mu F$$

$$C_o \geq 1 / (2\pi * 8\Omega * 20Hz) = 995 \mu F; \text{ use } 1000 \mu F$$

The high frequency pole is determined by the product of the desired high frequency pole,  $f_H$ , and the closed-loop gain,  $A_V$ . With a closed-loop gain magnitude of 1.35 and  $f_H = 100$  kHz, the resulting GBWP = 135 kHz which is much smaller than the LM4880 GBWP of 12.5 MHz. This figure displays that if a designer has a need to design an amplifier with a higher gain, the LM4880 can still be used without running into bandwidth limitations.
