

# Triple-Supply Power Management IC for Powering FPGAs and DSPs

# **FEATURES**

- Two 95% Efficient, 3A Buck Controllers and One 300mA LDO
- Tested and Endorsed by Xilinx for Powering the Spartan<sup>™</sup>-3, Spartan-3E and Spartan-3L FPGAs
- Adjustable (1.2V to 6.5V for Bucks, 1.0V to 6.5V for LDO) Output Voltages on All Channels
- Input Voltage Range: 2.2V to 6.5V
- Independent Soft-Start for Each Supply
- Independent Enable for Each Supply for Flexible Sequencing
- LDO Stable with 2.2µF Ceramic Output Cap
- Small, Low-Profile 4.5mm x 3.5mm x 0.9mm QFN Package

# **APPLICATIONS**

- FPGA/DSP/ASIC Supplies
- Set-Top Boxes
- DSL Modems

Æλ

• Plasma TV Display Panels

# DESCRIPTION

The TPS75003 is a complete power management solution for FPGA, DSP and other multi-supply applications. The device has been tested with and meets all of the Xilinx Spartan-3, Spartan-3E and Spartan-3L start-up profile requirements, including monotonic voltage ramp and minimum voltage rail rise time. Independent Enables for each output allow sequencing to minimize demand on the power supply at start-up. Soft-start on each supply limits inrush current during start-up. Two integrated buck controllers allow efficient, cost-effective voltage conversion for both low and high current supplies such as core and I/O. A 300mA LDO is integrated to provide an auxiliary rail such as  $V_{\mbox{\tiny CCAUX}}$  on the Xilinx Spartan-3 FPGA. All three supply voltages are offered in user-programmable options for maximum flexibility.

The TPS75003 is fully specified from -40°C to +85°C and is offered in a QFN package, yielding a highly compact total solution size with high power dissipation capability.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

Spartan is a trademark of Xilinx, Inc. All trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

TERMINAL		DESCRIPTION				
NAME	RHL	DESCRIPTION				
DGND	6, 15, PAD	Ground connection for BUCK1 and BUCK2 converters. Pins 6 and 15 should be connected to the back side exposed pad by a short metal trace as shown in the <i>PCB Layout</i> section of this data sheet.				
AGND	18	Ground connection for LDO.				
IN1	13	Input supply to BUCK1.				
IN2	8	Input supply to BUCK2.				
IN3	20	Input supply to LDO.				
EN1	17	Driving the enable pin (ENx) high turns on BUCK1 regulator. Driving this pin low puts it into shutdown mode, reducing operating current. The enable pin does not trigger on fast negative going transients.				
EN2	4	Same as EN1 but for BUCK2 controller.				
EN3	3	Same as EN1 but for LDO.				
SS1	16	Connecting a capacitor between this pin and ground increases start-up time of the BUCK1 regulator by slowing the ramp-up of current limit. This high-impedance pin is noise-sensitive; careful layout is important. See <i>Typical Characteristics, Applications</i> and <i>PCB Layout</i> sections for details.				
SS2	5	Same as SS1 but for BUCK2 regulator.				
SS3	19	Connecting a capacitor from this pin to ground slows the start-up time of the LDO reference, therby slowing output voltage ramp-up. See <i>Applications</i> section for details.				
IS1	12	Current sense input for BUCK1 regulator. The voltage difference between this pin and IN1 is compared to an internal reference to set current limit. For a robust output start-up ramp, careful layout and bypassing are required. See <i>Applications</i> section for details.				
IS2	9	Same as IS1 but compared to IN2 and used for BUCK2 controller.				
SW1	14	Gate drive pin for external BUCK1 P-channel MOSFET.				
SW2	7	Same as SW1 but for BUCK2 controller.				
FB1	11	Feedback pin. Used to set the output voltage of BUCK1 regulator.				
FB2	10	Same as FB1 but for BUCK2 controller.				
FB3	2	Same as FB1 but for LDO.				
OUT3	1	Regulated LDO output. A small ceramic capacitor ( $\geq 2.2\mu$ F) is needed from this pin to ground to ensure stability.

# **APPLICATION INFORMATION**

The TPS75003 is an integrated power management IC designed specifically to power DSPs and FPGAs such as the Xilinx Spartan-3, Spartan-3E and Spartan-3L. Two non-synchronous buck controllers can be configured to supply up to 3A for both CORE and I/O rails. A low dropout linear regulator powers auxiliary rails up to 300mA. All channels have independent enable and soft-start, allowing control of inrush current and output voltage ramp time as required by the application.

Figure 1 shows a typical application circuit for powering the Xilinx Spartan-3 FPGA. Table 1 through Table 4 show component values that have been tested for use with 2A and 3A load currents. Other similar external components can be substituted as desired; however, in all cases the circuits that are used should be tested for compliance to application requirements.

## Table 4. Capacitors Tested with the TPS75003

# **OPERATION (BUCK CONTROLLERS)**

Channels 1 and 2 contain two identical non-synchronous buck controllers that use minimum on-time/minimum off-time hysteretic control. (Refer to Figure 1.) For clarity, BUCK1 is used throughout the discussion of device operation. When  $V_{OUT1}$  is below its target, an external PMOS (Q1) is turned on for at least the minimum on-time, increasing current through the inductor (L1) until  $V_{OUT1}$  reaches its target value or the current limit (set by R1) is reached. Once either of these conditions is met, the PMOS is switched off for at least the minimum off-time of the device. After the minimum off-time has passed, the output voltage is monitored and the switch is turned on again when necessary.

When output current is low, the buck controllers operate in discontinuous mode. In this mode, each switching cycle begins at zero inductor current, rises to a maximum value, then falls back to zero current. When current reaches zero on the falling edge, ringing occurs at the resonant frequency of the inductor and stray switch node capacitance. This is normal operation; it does not affect circuit performance, and can be minimized if desired by using an RC snubber and/or a resistor in series with the gate of the PMOS, as shown in Figure 22.

Figure 22. RC Snubber and Series Gate Resistor Used to Minimize Ringing

At higher output currents, the TPS75003 operates in continuous mode. In continuous mode, there is no ringing at the switch node and  $V_{OUT}$  is equal to  $V_{IN}$  times the duty cycle of the switching waveform.

When  $V_{IN}$  approaches or falls below  $V_{OUT}$ , the buck controllers operate in 100% duty cycle mode, fully turning on the external PMOS to allow regulation at lower dropout than would otherwise be possible.

#### **Enable (Buck Controllers)**

The enable pins (EN1 and EN2) for the buck controllers are active high. When the enable pin is driven low and input voltage is present at IN1 or IN2, an on-chip FET is turned on to discharge the soft-start pin SS1 or SS2, respectively. If the soft-start feature is being used, enable should be driven high at least 10 $\mu$ s after V<sub>IN</sub> is applied to ensure this discharge cycle occurs.

## **UVLO (Buck Controllers)**

An under-voltage lockout circuit is present to prevent turning on the external PMOS (Q1 or Q2) until a reliable operating voltage is reached on the appropriate regulator (IN1 or IN2). This prevents the buck controllers from mis-operation at low input voltages.

#### **Current Limit (Buck Controllers)**

An external resistor (R1 or R2) is used to set the current limit for the external PMOS transistor (Q1 or Q2). These resistors are connected between IN1 and IS1 (or IN2 and IS2) to provide a reference voltage across these pins that is proportional to the current flowing through the PMOS transistor. This reference voltage is compared to an internal reference to determine if an over-current condition exists. When current limit is exceeded, the external PMOS is turned off for the minimum off-time. Current limit detection is disabled for 10ns any time the PMOS is turned on to avoid triggering on switching noise. In 100% duty cycle mode, current limit is always enabled. Current limit is calculated using the  $V_{IS1}$  or  $V_{IS2}$  specification in the *Electrical Characteristics* section, shown in Equation 1:

$$I_{\text{LIMIT}} = \frac{V_{\text{IS1,2}}}{R_{1,2}} \tag{1}$$

The current limit resistor must be appropriately rated for the dissipated power determined by its RMS current calculated by Equation 2:

$$I_{\text{RMS}} = I_{\text{OUT}} \sqrt{D} = I_{\text{OUT}} \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}}}$$

$$\mathsf{P}_{\mathsf{DISS}} = \left(\mathsf{I}_{\mathsf{RMS}}\right)^2 \cdot \mathsf{R}$$

(2)

For low-cost applications the  $I_{S1,2}$  pin can be connected to the drain of the PMOS, using  $R_{DS,ON}$  instead of R1 or R2 to set current limit. Variations in the PMOS  $R_{DS,ON}$  must be taken into account to ensure that current limit will protect external components such as the inductor, the diode, and the switch itself from damage as a result of over-current.

#### **Short-Circuit Protection (Buck Controllers)**

In an overload condition, the current rating of the external components (PMOS, diode, and inductor) can be exceeded. To help guard against this, the TPS75003 increases its minimum off-time when the voltage at the feedback pin is lower than the reference voltage. When the output is shorted ( $V_{FB}$  is zero), minimum off-time is increased to approximately 4 $\mu$ s. The increase in off-time is proportional to the difference between the voltage at the feedback pin and the internal reference.

#### Soft-Start (Buck Controllers)

The buck controllers each have independent soft-start capability to limit inrush during start-up and to meet timing requirements of the Xilinx Spartan-3 FPGA. Limiting inrush current by using soft-start, or by staggering the turn-on of power rails, also guards against voltage drops at the input source due to its output impedance. Refer to the soft-start circuitry shown in Figure 23 and the soft-start timing diagram shown in Figure 24. BUCK 1 will be discussed in this section; it is identical to BUCK2. Note that pins SS1 and SS2 are very high-impedance and cannot be probed using a typical oscilloscope setup. When input voltage is applied at IN1 and EN1 is driven low, any charge on the SS pin is discharged by an on-chip pull-down transistor. When EN1 is driven high, an on-chip current source starts charging the external soft-start capacitor  $C_{\rm SS1}$ . The voltage on the capacitor is compared to the voltage across the sense resistor goes above the reference voltage, then the external PMOS is shut off for the minimum off-time. This implementation provides a cycle-by-cycle current limit and allows the user to program the soft-start time over a wide range for most applications. For detailed information on choosing  $C_{\rm SS1}$  and  $C_{\rm SS2}$ , see the section, *Selecting the Soft-Start Cap*.

#### Input Capacitor C<sub>IN1</sub>, C<sub>IN2</sub> Selection (Buck Controllers)

TEXAS TRUMENTS www.ti.com

It is good analog design practice to place input capacitors near the inputs of the device in order to ensure a low impedance input supply.  $10\mu$ F to  $22\mu$ F of capacitance for each buck converter is adequate for most applications, and should be placed within 100mils (0.001in) of the IN1 and IN2 pins to minimize the effects of pulsed current switching noise on the soft-start circuitry during the first ~1V of output voltage ramp. Low ESR capacitors also help to minimize noise on the supply line. The minimum value of capacitance can be estimated using Equation 3:

$$C_{IN}, MIN = \frac{(1/2)L \times (\Delta I_{L})^{2}}{V_{(RIPPLE)} \times V_{IN}} \approx \frac{(1/2)L \times (0.3 \times I_{OUT})^{2}}{V_{(RIPPLE)} \times V_{IN}}$$
(3)

15

Note that the capacitors must be able to handle the RMS current in continuous conduction mode, which can be calculated using Equation 4:

$$I_{\text{C,IN(RMS)}} \approx I_{\text{OUT}} \sqrt{\left(\frac{V_{\text{OUT}}}{V_{\text{IN},\text{MIN}}}\right)}$$

(4)

IEXAS TRUMENTS www.ti.com

#### Inductor Value Selection (Buck Controllers)

The inductor is chosen based on inductance value and maximum current rating. Larger inductors reduce current ripple (and therefore, output voltage ripple) but are physically larger and more expensive. Inductors with lower DC resistance typically improve efficiency, but also have higher cost and larger physical size. The buck converters work well with inductor values between  $4.7\mu$ H and  $47\mu$ H in most applications. When selecting an inductor, the current rating should exceed the current limit set by R<sub>IS</sub> or R<sub>DS,ON</sub> (see *Current Limit* section). To determine the minimum inductor size, first determine if the device will operate in minimum on-time or minimum off-time mode. The device will operate in minimum on-time mode if Equation 5 is satisfied:

$$V_{\rm IN} - V_{\rm OUT} - I_{\rm OUT} \times r_{\rm DS(on)} - R_{\rm L} \times I_{\rm OUT} \ge \frac{t_{\rm (OFF,min)} \times (V_{\rm OUT} + V_{\rm SCHOTTKY} + R_{\rm L} \times I_{\rm OUT})}{t_{\rm ON,MIN}}$$
(5)

where  $R_L$  = the inductor's DC resistance.

Minimum inductor size needed when operating in minimum on-time mode is given by Equation 6:

$$L_{MIN} = \frac{\left(V_{IN} - V_{OUT} - I_{OUT} \times r_{DS(on)} - R_{L} \times I_{OUT}\right) \times t_{ON, MIN}}{\Delta I}$$
(6)

Minimum inductor size needed when operating in minimum off-time mode is given by Equation 7:

$$L_{MIN} = \frac{(V_{OUT} + V_{SCHOTTKY} + R_L \times I_{OUT}) \times t_{OFF, MIN}}{\Delta I}$$
(7)

#### **External PMOS Transistor Selection (Buck Controllers)**

The external PMOS transistor is selected based on threshold voltage ( $V_T$ ), on-resistance ( $R_{DS,ON}$ ), gate capacitance ( $C_G$ ) and voltage rating. The PMOS  $V_T$  magnitude must be much lower than the lowest voltage at IN1 or IN2 that will be used. A  $V_T$  magnitude that is 0.5V less than the lowest input voltage is normally sufficient. The PMOS gate will see voltages from 0V to the maximum input voltage, so gate-to-source breakdown should be a few volts higher than the maximum input supply. The drain-to-source of the device will also see this full voltage swing, and should therefore be a few volts higher than the maximum input supply. The RMS current in the PMOS can be estimated by using Equation 8:

$$I_{\text{PMOS}(\text{RMS})} \approx I_{\text{OUT}} \sqrt{D} = I_{\text{OUT}} \sqrt{\frac{V_{\text{OUT}}}{V_{\text{IN}}}}$$
(8)

The power dissipated in the PMOS is comprised of both conduction and switching losses. Switching losses are typically insignificant. The conduction losses are a function of the RMS current and the  $R_{DS,ON}$  of the PMOS, and are calculated by Equation 9:

$$P_{(cond)} = \left(I_{OUT}\sqrt{D}\right)^{2} \times r_{DS(on)} \times \left(1 + TC \times \left[T_{J} - 25^{\circ}C\right]\right) \approx \left(I_{OUT}\sqrt{D}\right) \times r_{DS(on)}$$
(9)

#### **Diode Selection (Buck Controllers)**

The diode is off when the PMOS is on, and on when the PMOS is off. Since it will be turned on and off at a relatively high frequency, a Schottky diode is recommended for good performance. The peak current rating of the diode should exceed the peak current limit set by the sense resistor R<sub>IS1,2</sub>. A diode with low reverse leakage current and low forward voltage at operating current will optimize efficiency. Equation 10 calculates the estimated average power dissipation:

$$I_{\text{(diode)(RMS)}} \approx I_{\text{OUT}}(1-D) = I_{\text{OUT}}\left(1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}\right)$$
(10)

#### **Output Capacitor Selection (Buck Controllers)**

The output capacitor is selected based on output voltage ripple and transient response requirements. As a result of the nature of the hysteretic control loop, a minimum ESR of a few tens of m $\Omega$  should be maintained for good operation unless a feed-forward resistor is used. Low ESR bulk tantalum or PosCap capacitors work best in most applications. A 1.0µF ceramic capacitor can be used in parallel with this capacitor to filter higher frequency spikes. The output voltage ripple can be estimated by Equation 11:

$$\Delta V_{PP} = \Delta I \times \left[ ESR + \left( \frac{1}{8 \times C_{OUT} \times f} \right) \right] \approx 1.1 \Delta I \times ESR$$
(11)

To calculate the capacitance needed to achieve a given voltage ripple as a result of a load transient from zero output to full current, use Equation 12:

$$C_{OUT} = \frac{L \times \Delta I_{OUT}^{2}}{(V_{IN} - V_{OUT}) \times \Delta V}$$
(12)

If only ceramic or other very low ESR output capacitor configurations are desired, additional voltage ripple must be passed to the feedback pin. This can be accomplished by using the application circuit in Figure 1. Resistor  $R_{1B}$  adds additional control signal to the feedback loop. This circuit works best with  $R_{1B} = 2$  to  $4 \times R_{1A}$ . If  $R_{1B}$  is too low, the output shows worse load regulation.  $R_{1A}$  and  $R_{1B}$  can be calculated using Equation 13:

R1 = 
$$\frac{1}{\frac{1}{R1_A} + \frac{1}{R1_B}}$$
 and R1<sub>B</sub> =  $\frac{1}{\frac{1}{R1} - \frac{1}{R1_A}}$  (13)

Use Equation 14 to calculate  $R1_A$  if  $R1_B = (4)(R1_A)$ :

$$\mathsf{R1}_{\mathsf{A}} = \frac{5}{4}\mathsf{R1} \tag{14}$$

#### **Output Voltage Ripple Effect on VOUT (Buck Controllers)**

Output voltage ripple causes V<sub>OUT</sub> to be higher or lower than the target value by half of the peak-to-peak voltage ripple. For minimum on-time, the ripple adds to the voltage; for minimum off-time, it subtracts from the voltage.

#### Soft-Start Capacitor Selection (Buck Controllers)

BUCK1 is discussed in this section; it is identical to BUCK2. Soft-start is implemented on the buck controllers by ramping current limit from 0 to its target value (set by R1) over a user-defined time. This time is set by the external soft-start cap connected to pin SS1. If SS1 is left open, a small on-chip capacitor will provide a current limit ramp time of approximately 250µs. Figure 25 shows the effects of R1 and SS1 on the current limit start-up ramp.

Figure 25. Effects of C<sub>SS1</sub> and R<sub>1</sub> on Current Ramp Limit

This soft-start current limit ramo can be used to provide inrush current control or output voltage ramp control. While the current limit ramp can be easily understood by looking at Figure 25, the output voltage ramp is a complex function of many variables. The dominant variables in this process are  $V_{OUT1}$ ,  $C_{SS1}$ ,  $I_{OUT1}$ , and  $R_1$ . Less important variables are  $V_{IN1}$  and  $L_1$ .

The best way to set a target start-up time is through bench measurement under target conditions, adjusting  $C_{SS1}$  to get the desired startup profile. To stay above a minimum start-up time, set the nominal start-up time to approximately five times the minimum. To stay below a maximum time, set the nominal start-up time at one-fifth of the maximum. Fastest start-up times occur at maximum  $V_{IN1}$ , with minimum  $V_{OUT1}$ ,  $L_1$ ,  $C_{OUT1}$ ,  $C_{SS1}$ , and  $I_{OUT1}$ . Slowest start-up times occur under opposite conditions.

Refer to Figure 10 to Figure 14 for characterization curves showing how the start-up profile is affected by these critical parameters.

#### **Output Voltage Setting Selection (Buck Controllers)**

Output voltage is set using two resistors as shown for Buck2 in Figure 1. Output voltage is then calculated using Equation 15:

$$V_{OUT} = V_{FB} \left( \frac{R_5}{R_6} + 1 \right)$$

where  $V_{FB} = 1.24V$ .

#### LDO OPERATION

The TPS75003 LDO uses a PMOS pass element and is offered in an adjustable version for ease of programming to any output voltage. When used to power  $V_{CC,AUX}$  it is set to 2.5V; it can optionally be set to other output voltages to power other circuitry. The LDO has integrated soft-start, independent enable, and short-circuit and thermal protection. The LDO can be used to power  $V_{CC,AUX}$  on the Xilinx Spartan-3 FPGA when 3.3V JTAG signals are used as described in Application Note SLVA159 (available for download from www.ti.com).

#### Input Capacitor Selection (LDO)

Although an input capacitor is not required, it is good analog design practice to connect a  $0.1\mu$ F to  $10\mu$ F low ESR capacitor across the input supply near the regulator. This capacitor counteracts reactive input sources and improves transient response, stability, and ripple rejection. A higher value capacitor may be needed if large, fast rise-time load transients are anticipated, or if the device is located far from its power source.

(15)

#### **Output Capacitor Selection (LDO)**

A 2.2µF or greater capacitor is required near the output of the device to ensure stability. The LDO is stable with any capacitor type, including ceramic. If improved transient response or ripple rejection is required, larger and/or lower ESR output capacitors can be used.

## Soft-Start (LDO)

The LDO uses an external soft-start capacitor,  $C_{SS3}$ , to provide an RC-ramped reference voltage to the control loop. (See the Functional Block Diagram.) This is a voltage-controlled soft-start, as compared to the current-controlled soft-start used by the buck controllers.

## Setting Output Voltage (LDO)

Output voltage is set using two resistors as shown in Figure 1. Output voltage is then calculated using Equation 16:

$$V_{OUT} = V_{FB} \left( \frac{R_3}{R_4} + 1 \right)$$
(16)

where  $V_{FB} = 0.507V$ .

#### Internal Current Limit (LDO)

The internal current limit of the LDO helps protect the regulator during fault conditions. When an over-current condition is detected, the output voltage will be reduced until the current falls to a level that will not damage the device. For good device reliability, the LDO should not operate at current limit.

#### Enable Pin (LDO)

The active high enable pin (EN3) can be used to put the device into shutdown mode. If shutdown and soft-start capability are not required, EN3 can be tied to IN3.

#### Dropout Voltage (LDO)

The LDO uses a PMOS transistor to achieve low dropout. When  $(V_{IN} - V_{OUT})$  is less than the dropout voltage  $(V_{DO})$ , the pass device is in its linear region of operation, and the input-output resistance is the R<sub>DS,ON</sub> of the pass transistor. In this region, the regulator is said to be out of regulation; ripple rejection, line regulation, and load regulation degrade as  $(V_{IN} - V_{OUT})$  falls much below 0.5V.

#### Transient Response (LDO)

The LDO does not have an on-chip pull-down circuit for output is over-voltage conditions. This feature permits applications that connect higher voltage sources such as an alternate power supply to the output. This design also results in an output overshoot of several percent if the load current quickly drops to zero. The amplitude of overshoot can be reduced by increasing  $C_{OUT}$ ; the duration of overshoot can be reduced by adding a load resistor.

#### Thermal Protection (LDO)

Thermal protection disables the output when the junction temperature,  $T_J$ , reaches unsafe levels. When the junction cools, the output is again enabled. Depending on power dissipation, thermal resistance, and ambient temperature, the thermal protection circuit may cycle on and off. This cycling limits the dissipation of the regulator, protecting it from damage. For good long term reliability, the device should not be continuously operated at or near thermal shutdown.

#### Power Dissipation (LDO)

The TPS75003 comes in a QFN-style package with an exposed lead frame on the package underside. The exposed lead frame is the primary path for removing heat and should be soldered to a PC board that is configured to remove the amount of power dissipated by the LDO, as calculated by Equation 17:

$$\mathsf{P}_{\mathsf{D}} = (\mathsf{V}_{\mathsf{IN3}} - \mathsf{V}_{\mathsf{OUT3}}) \times \mathsf{I}_{\mathsf{OUT3}}$$

(17)

Power dissipation can be minimized by using the lowest possible input voltage necessary to assure the required output voltage. The two buck converters do not contribute a significant amount of dissipated power. Using heavier copper will increase the overall effectiveness of removing heat from the device. The addition of plated through-holes to heat-dissipating layers will also improve the heatsink effectiveness.

#### **PCB Layout Considerations**

As with any switching regulators, careful attention must be paid to board layout. A typical application circuit and corresponding recommended printed circuit board (PCB) layout with emphasis on the most sensitive areas are shown in Figure 26 through Figure 28.

Note: Most sensitive areas are highlighted by bold lines.

Figure 26. Typical Application Circuit

# THERMAL PAD MECHANICAL DATA

## THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB), the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to a ground plane or special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, Quad Flatpack No-Lead Logic Packages, Texas Instruments Literature No. SCBA017. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTE: All linear dimensions are in millimeters

<sup>(1)</sup> The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS) or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
