

Password Access Security Supervisor

4K

X76F041

4 x 128 x 8 Bit

PASS™ SecureFlash

FEATURES

- 64-Bit Password Security
- Three Password Modes
 - Secure Read Access
 - Secure Write Access
 - Secure Configuration Access
- Programmable Configuration
 - Read, Write and Configuration Access Passwords
 - Multiple Array Access/Functionality
 - Retry Register/Counter
- 8 Byte Sector Write
- (4) 1K Memory Arrays
- ISO Response to Reset
- Low Power CMOS
 - 50µA Standby Current
 - 3mA Active Current
- 1.8V to 3.6V or 5V “Univolt” Read and Program Power Supply Versions
- High Reliability
 - Endurance: 100,000 Cycles
 - Data Retention: 100 Years
 - ESD Protection: 2000V on All Pins

DESCRIPTION

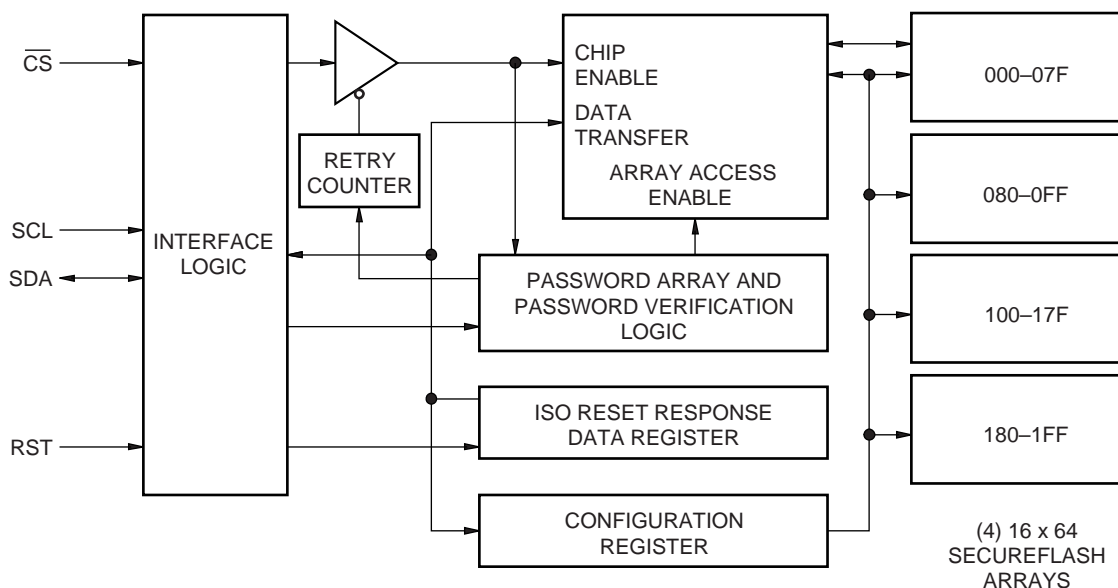

The X76F041 is a password access security supervisor device, containing four 128 x 8 bit SecureFlash arrays. Access can be controlled by three 64-bit programmable passwords, one for read operations, one for write operations and one for device configuration.

The X76F041 features a serial interface and software protocol allowing operation on a simple two wire bus. The bus signals are a clock input (SCL) and a bidirectional data input and output (SDA). Access to the device is controlled through a chip select input (CS), allowing any number of devices to share the same bus.

The X76F041 also features a synchronous response to reset; providing an automatic output of a pre-configured 32-bit data stream conforming to the ISO standard for memory cards.

The X76F041 utilizes Xicor's proprietary Direct Write™ cell, providing a minimum endurance of 100,000 cycles per sector and a minimum data retention of 100 years.

X76F041

PIN DESCRIPTION

Serial Data Input/Output (SDA)

SDA is a true three state serial data input/output pin. During a read cycle, data is shifted out on this pin. During a write cycle, data is shifted in on this pin. In all other cases this pin is in a high impedance state.

Serial Clock (SCL)

The Serial Clock controls the serial bus timing for data input and output.

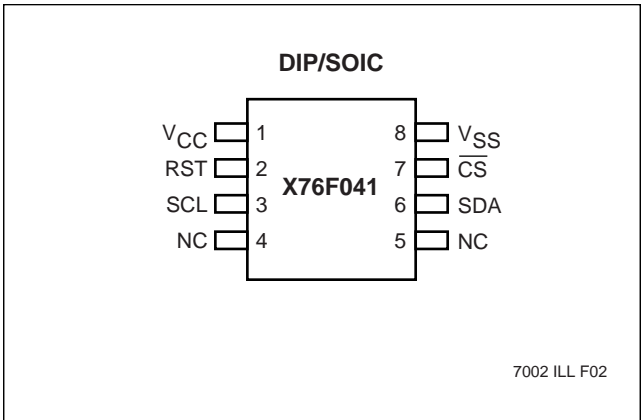

Chip Select (\overline{CS})

When \overline{CS} is HIGH, the X76F041 is deselected and the SDA pin is at high impedance and unless an internal write operation is underway the X76F041 will be in the standby power mode. \overline{CS} LOW enables the X76F041, placing it in the active power mode.

Reset (RST)

RST is a device reset pin. When RST is pulsed HIGH while \overline{CS} is LOW the X76F041 will output 32 bits of fixed data which conforms to the ISO standard for "synchronous response to reset". \overline{CS} must remain LOW and the part must not be in a write cycle for the response to reset to occur. If at any time during the response to reset \overline{CS} goes HIGH, the response to reset will be aborted and the part will return to the standby mode.

PIN CONFIGURATION

Symbol	Description
\overline{CS}	Chip Select Input
SDA	Serial Data Input/Output
RST	Reset Input
SCL	Serial Clock Input
V _{SS}	Ground
V _{CC}	Supply Voltage
NC	No Connect

7002 FRM T01

X76F041

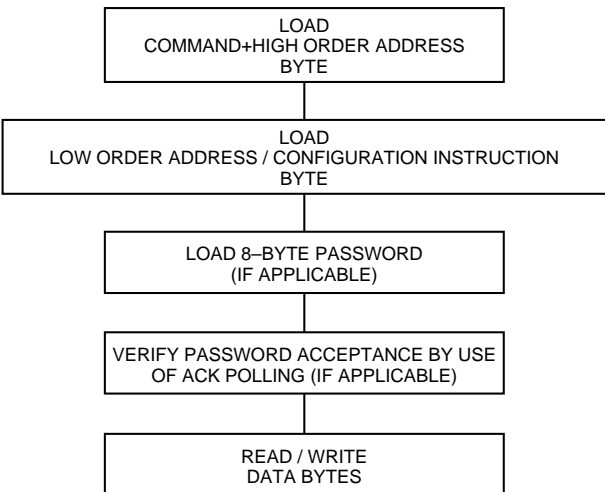

DEVICE OPERATION

There are three primary modes of operation for the X76F041; READ, WRITE and CONFIGURATION. The READ and WRITE modes may be performed with or without an 8-byte password. The CONFIGURATION mode always requires an 8-byte password.

The basic method of communication is established by first enabling the device (\overline{CS} LOW), generating a start condition and then transmitting a command and address field followed by the correct password (if configured to require a password). All parts will be shipped from the factory in the non-password mode. The user must perform an ACK Polling routine to determine the validity of the password and start the data transfer (see Acknowledge Polling). Only after the correct password is accepted and an ACK Polling has been performed can the data transfer occur.

To ensure correct communication, RST must remain LOW under all conditions except when initiating a "Response to Reset sequence".

Figure 1. X76F041 Device Operation

7002 ILL F03

Data is transferred in 8-bit segments, with each transfer being followed by an ACK, generated by the receiving device.

If the X76F041 is in a nonvolatile write cycle a "no ACK" (SDA HIGH) response will be issued in response to loading of the command + high order address byte. If a stop condition is issued prior to the nonvolatile write cycle the write operation will be terminated and the part will reset and enter into a standby mode.

The basic sequence is illustrated in Figure 1.

After each transaction is completed, the X76F041 will reset and enter into a standby mode. This will also be the response if an attempt is made to access any limited array.

Password Registers

The three passwords, Read, Write and Configuration are stored in three 64 bit Write Only registers as illustrated in figure 2.

Figure 2. Password Registers

7002 ILL F04

Device Configuration

Five 8-Bit configuration registers are used to configure the X76F041. These are shown in figure 3.

Figure 3. Configuration Registers

7002 ILL F04B

X76F041

Array Control

The four 1K arrays, are each programmable to different levels of access and functionality. Each array can be programmed to require or not require the read/write passwords. The functional options are:

- Read and Write Access.
- Read access with all write operations locked out.
- Read access and program only (writing a “1” to a “0”). If an attempt to change a “0” to a “1” occurs the X76F041 will reset, issue a “no ACK” and enter the standby power mode.
- No read or write access to the memory. Access only through use of the configuration password.

8-Bit Configuration Register

Unauthorized Access Bits (UA1, UA2):

1 0

Access is forbidden if retry register equals the retry counter (provided that the retry counter is enabled) and no further access of any kind will be allowed.

0 1, 0 0, 1 1

Only configuration operations are allowed if the retry register equals the retry counter (provided that the retry counter is enabled).

Retry Counter Reset Bit (RCR):

If the retry counter reset bit is a “1” then the retry counter will be reset following a correct password, provided the retry counter is enabled.

If the retry counter reset bit is a “0” then the retry counter will not be reset following a correct password, provided the retry counter is enabled.

Retry Counter Enable Bit (RCE):

If the Retry counter enable bit is a “1”, then the retry counter is enabled. An initial comparison between the retry register and retry counter determines whether the number of allowed incorrect password attempts has been reached. If not, the protocol continues and in case of a wrong password, the retry counter is incremented by one. If the password is correct then the retry counter will either be reset or unchanged, depending on the reset bit.

X76F041

The retry register must have a higher value than the retry counter for correct device operation. If the retry counter value is larger than the retry register and the retry counter is enabled, the device will wrap around allowing up to an additional 255 incorrect access attempts.

If the Retry counter enable bit is a "0", then the retry counter is disabled.

Retry Register/Counter

Both the retry register and retry counter are accessible in the configuration mode and may be programmed with a value of 0 to 255.

The difference between the retry register and the retry counter is the number of access attempts allowed, therefore the retry counter must be programmed to a smaller value than the retry register to prevent wrap around.

DEVICE PROTOCOL

The X76F041 supports a bidirectional bus oriented protocol. The protocol defines any device that sends data onto the bus as a transmitter, and the receiving device as the receiver. The device controlling the transfer is a master and the device being controlled is the slave. The master will always initiate data transfers, and provide the clock for both transmit and receive operations. Therefore, the X76F041 will be considered a slave in all applications.

Start Condition

All commands except for response to reset are preceded by the start condition, which is a HIGH to LOW transition of SDA when SCL is HIGH. The X76F041 continuously monitors the SDA and SCL lines for the start condition and will not respond to any command until this condition has been met.

Figure 4. Data Validity During Write

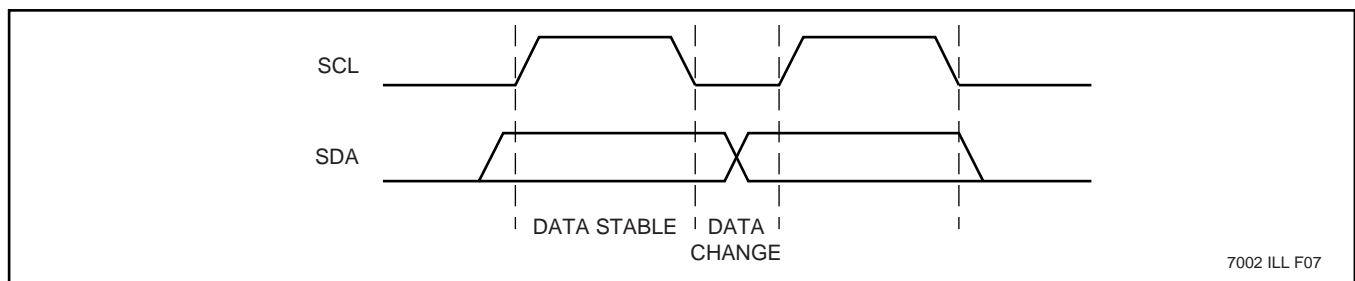

Figure 5. Definition of Start and Stop

NOTE: The part requires the SCL input to be LOW during non-active periods of operation. In other words, the SCL will need to be LOW prior to any START condition and LOW after a STOP condition. This is also reflected in the timing diagram.

X76F041

Stop Condition

All communications must be terminated by a stop condition, which is a LOW to HIGH transition of SDA when SCL is HIGH. A stop condition can only be issued after the transmitting device has released the bus.

Acknowledge

Acknowledge is a software convention used to indicate successful data transfer. The transmitting device, either master or slave, will release the bus after transmitting eight bits. During the ninth clock cycle the receiver will pull the SDA line LOW to acknowledge that it received the eight bits of data.

7002 FRM T04

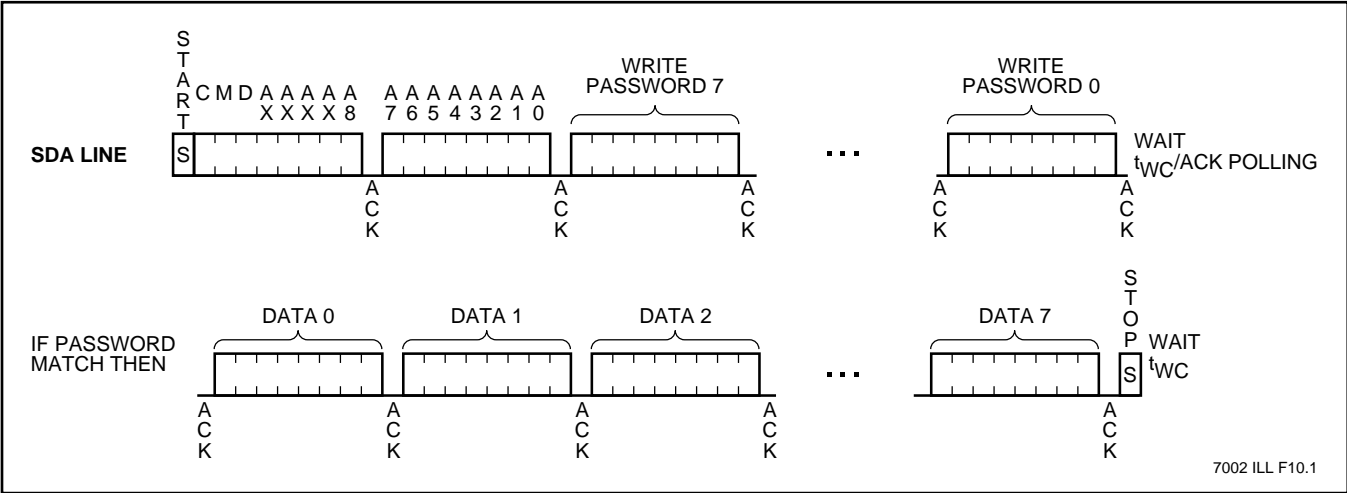

WRITE OPERATION

Sector Write

The Sector Write mode requires issuing the 3-bit write command followed by the address, password if required and then the data bytes transferred as illustrated in Figure 6. Eight bytes must be transferred. After the last byte to be transferred is acknowledged, a stop condition is issued, which starts the nonvolatile write cycle. If more than 8 bytes are transferred the data will wrap around and previous data will be overwritten. All data will be written to the same sector as defined by A₈–A₃.

Figure 6. Eight bytes must be transferred. After the last byte to be transferred is acknowledged, a stop condition is issued, which starts the nonvolatile write cycle. If more than 8 bytes are transferred the data will wrap around and previous data will be overwritten. All data will be written to the same sector as defined by A₈–A₃.

Figure 6. Sector Write

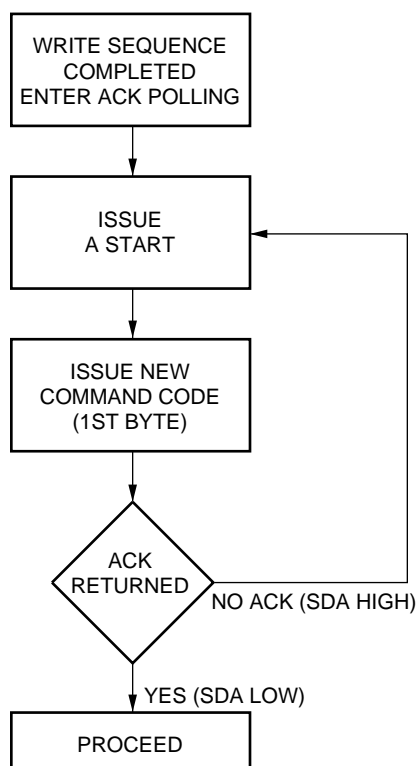

7002 ILL F10.1

X76F041

ACK Polling

Once a stop condition is issued to indicate the end of the host's write sequence, the X76F041 initiates the internal nonvolatile write cycle. In order to take advantage of the typical 5ms write cycle, ACK polling can be initiated immediately. This involves issuing the Start condition followed by the new command code of eight bits (1st byte of the protocol). If the X76F041 is still busy with the nonvolatile write operation, it will issue a "no ACK" in response. If the nonvolatile write operation has completed, an "ACK" will be returned and the host can then proceed with the rest of the protocol. Refer to the following flow:

ACK Polling Sequence

After a password sequence, there is always a nonvolatile write cycle. In order to continue the transaction, the X76F041 requires the master to perform an ACK polling with the specific code of C0h. As with regular acknowledge polling the user can either time out for 10ms, and then issue the ACK polling once, or continuously loop as described in the flow.

As with regular acknowledge polling, if the user chooses to loop, then as long as the nonvolatile write cycle is active, a no ACK will be issued in response to each polling cycle.

If the password that was inserted was correct, then an "ACK" will be returned once the nonvolatile write cycle is over, in response to the ACK polling cycle immediately following it.

If the password that was inserted was incorrect, then a "no ACK" will be returned even if the nonvolatile write cycle is over. Therefore, the user cannot be certain that the password is incorrect until the 10ms write cycle time has elapsed.

Figure 7. Acknowledge Polling

READ OPERATION

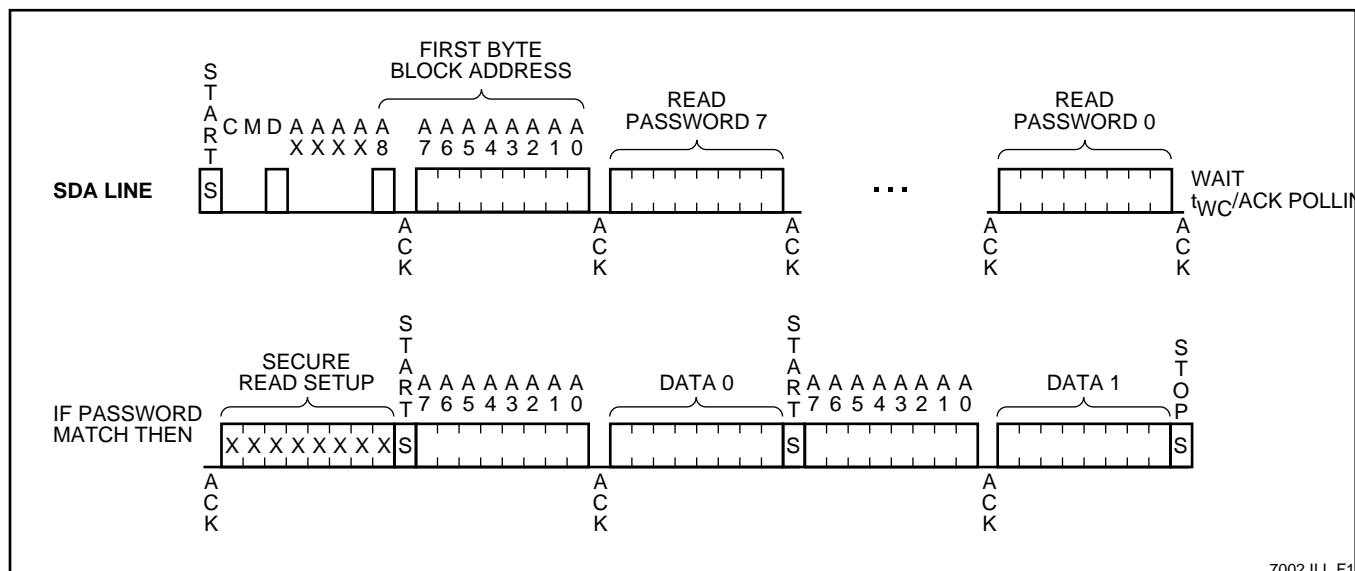

Random Read with Password

Random read with password operations are initiated with a START command followed by the read command and the address of the first byte of the block in which data is to be read:

Block 0 = 000h
Block 1 = 080h
Block 2 = 100h
Block 3 = 180h

This is followed by the eight byte read password sequence which includes the 10ms wait time and the password acknowledge polling sequence. If the password is accepted an "ACK" will be returned followed by eight bits of "secure read setup" which is to be ignored. At this point a START is issued followed by the address and data to be read within the original 1K block. See figure 8. Once the first byte has been read, another start can be issued followed by a new 8-bit address. Random reads are allowed only within the original 1K-bit block. To access another 1K-bit block, a stop must be issued followed by a new command/block address/password sequence.

Figure 8. Random Read with Password

7002 ILL E1

Random Read without Password

Random read operations without a password do not require the first byte block initiation address. To perform a random read without password, a START is followed by the read command plus address location of the byte to be read. This is followed by an “ACK” and the eight bits of data to be read. Other bytes within the same 1K-bit block may be read by issuing another START followed by a new 8-bit address as shown in figure 9.

Sequential Read

Once past the password acceptance sequence (when required) and “secure read setup”, the host can read sequentially within the originally addressed 1K-bit array. The data output is sequential, with the data from address n followed by the data from address n+1. The address counter for read operations increments the address, allowing the 1K memory contents to be serially read during one operation. At the end of the address space (address 127), the counter “rolls over” to address space 0 within the 1K Block and the X76F041 continues to output data for each acknowledge received. Refer to figure 10 for the address, acknowledge and data transfer sequence. An acknowledge must follow each 8-bit data transfer. After the last bit has been read, a stop condition is generated without a preceding acknowledge.

Figure 9. Random Read without Password

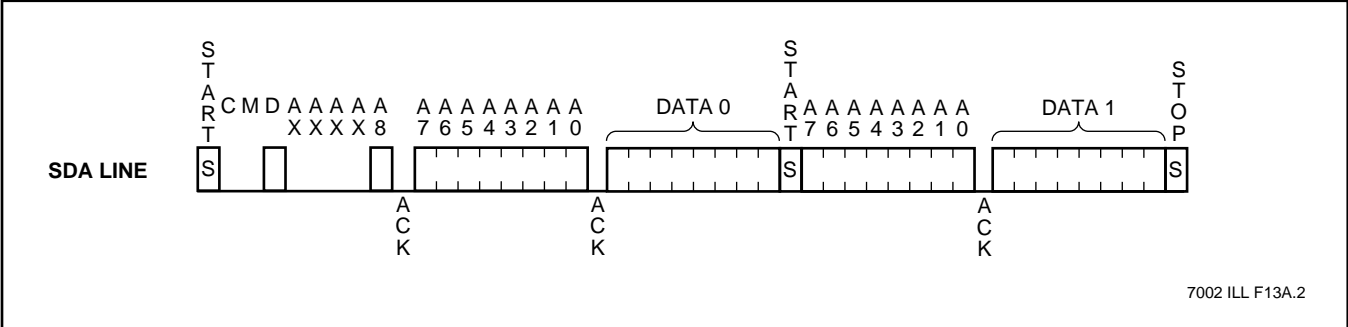

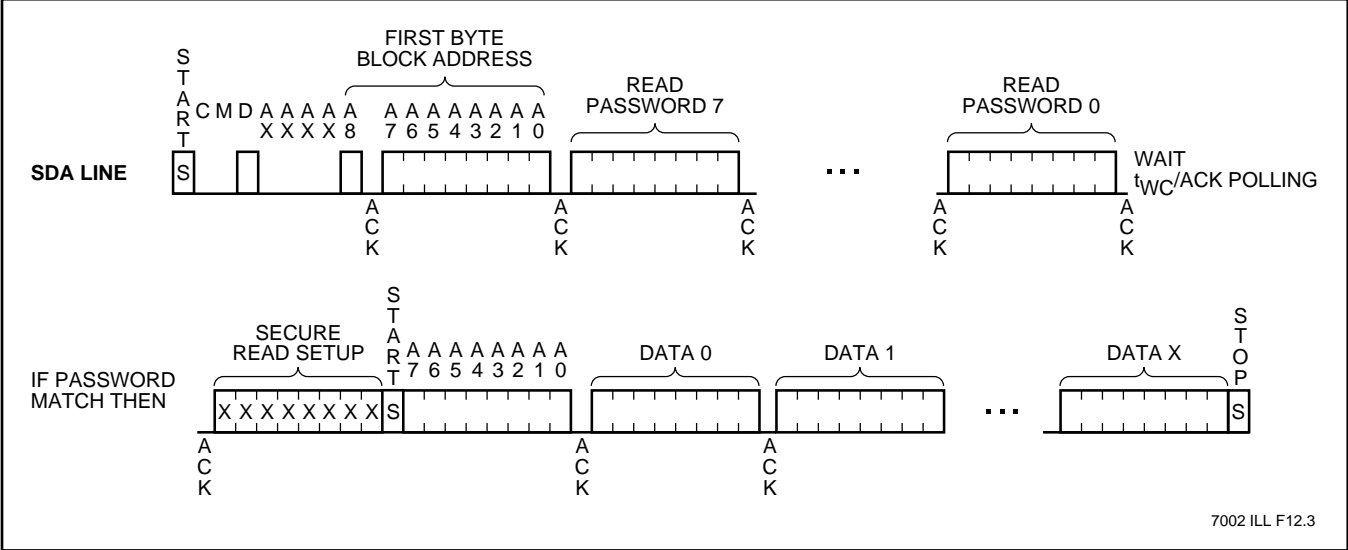

Figure 10. Sequential Read with Password

CONFIGURATION OPERATIONS

Configuration commands generally require the configuration password. The exception is that programming a new read/write password requires the old read/write password and not the configuration password. In most cases these operations will be performed by the equipment manufacturer or end distributor of the equipment or card.

Configuration Read/Write

Configuration read/write allows access to all of the non-volatile memory arrays regardless of the contents of the configuration registers. Access includes sector writes, random and sequential reads using the same format as normal reads and writes.

In general, the configuration read/write operation enables access to any memory location that may otherwise be limited. The configuration password, in this sense, is like a master key that can override the limits caused by the control partitioning of the arrays.

Figure 11. Configuration Write

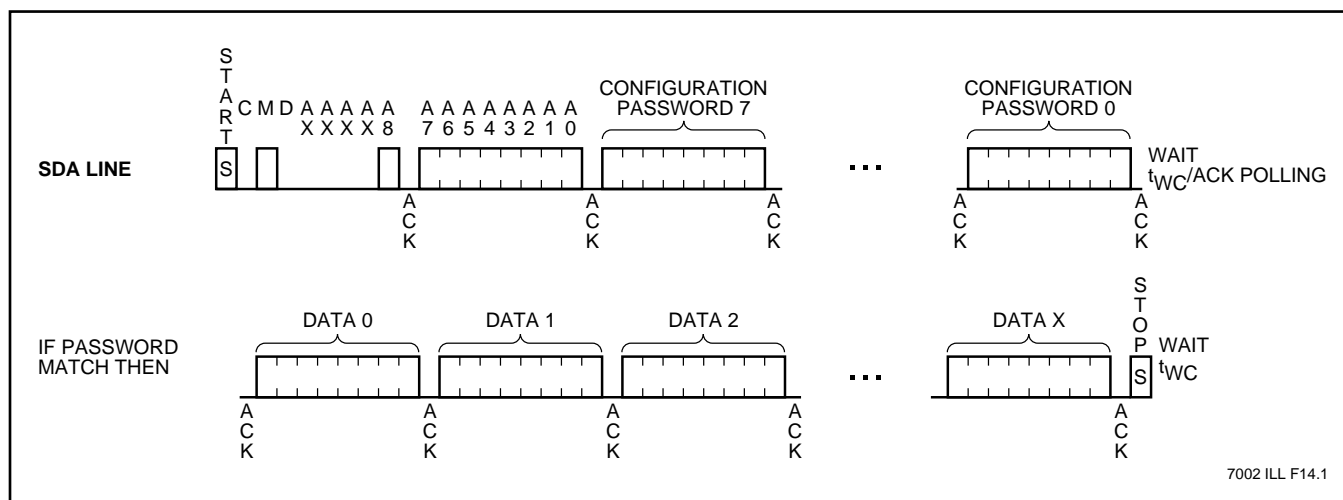

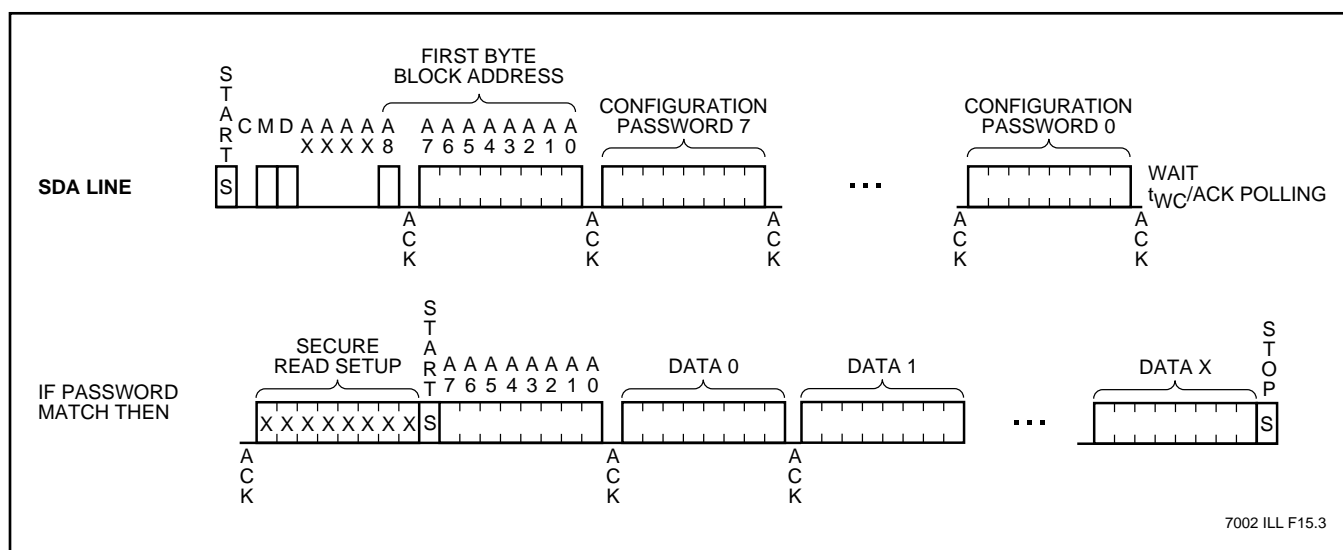

Figure 12. Configuration Sequential Read

Configuration of Passwords

The sequence in figure 14 will change (program) the write, read and configuration passwords. The programming of passwords is done twice prior to the nonvolatile write cycle in order to verify that the new password is consistent. After the eight bytes are entered in the second pass, a comparison takes place. A mismatch will cause the part to reset and enter into the standby mode and a “no ACK” will be issued.

There is no way to read the Read/Write/Configuration passwords.

Program Configuration Registers

This mode allows programming of the five configuration/control registers using the configuration password. The retry counter must be programmed with a value less than the retry register. If it is programmed with a value larger than the retry register there will be a wrap around.

Read Configuration Registers

This mode allows reading of the 5 configuration/control registers with the configuration password. It may be useful for monitoring purposes.

X76F041

Bus Timing⁽¹⁾ — SDA Driven by the Bus Master

Bus Timing⁽²⁾ — SDA Driven by the Slave

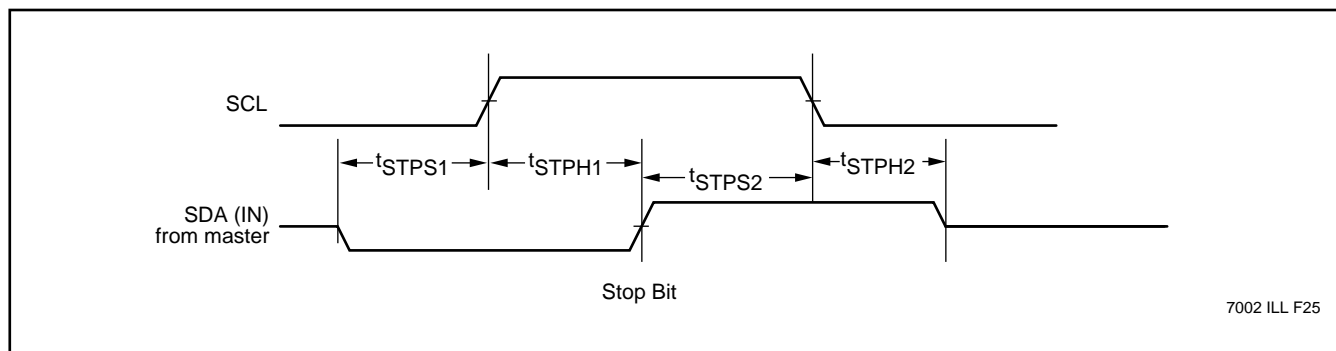

START Condition Timing

- NOTES:**
- (1) The master may issue a STOP condition at any given time in which it is driving the SDA line. In other words, when the part is sending ACK or data the master may NOT issue a STOP condition. The part will not respond to any such attempt which also causes bus contention. At any other time, a STOP condition will cause the part to reset and stop (enter a stand-by mode). Write operations will terminate prior to entering the stand-by mode.
 - (2) When the part drives the SDA line, it will tri-state the bus only after the last bit of the sequence. In other words, after the 8th bit of a byte that is read or after ACK between incoming bytes. In all other cases when the part drives the bus (between successive bits) it will continue to drive the bus also during the clock LOW periods.

ORDERING INFORMATION

LIMITED WARRANTY

Devices sold by Xicor, Inc. are covered by the warranty and patent indemnification provisions appearing in its Terms of Sale only. Xicor, Inc. makes no warranty, express, statutory, implied, or by description regarding the information set forth herein or regarding the freedom of the described devices from patent infringement. Xicor, Inc. makes no warranty of merchantability or fitness for any purpose. Xicor, Inc. reserves the right to discontinue production and change specifications and prices at any time and without notice.

Xicor, Inc. assumes no responsibility for the use of any circuitry other than circuitry embodied in a Xicor, Inc. product. No other circuits, patents, licenses are implied.

U.S. PATENTS

Xicor products are covered by one or more of the following U.S. Patents: 4,263,664; 4,274,012; 4,300,212; 4,314,265; 4,326,134; 4,393,481; 4,404,475; 4,450,402; 4,486,769; 4,488,060; 4,520,461; 4,533,846; 4,599,706; 4,617,652; 4,668,932; 4,752,912; 4,829, 482; 4,874, 967; 4,883, 976. Foreign patents and additional patents pending.

LIFE RELATED POLICY

In situations where semiconductor component failure may endanger life, system designers using this product should design the system with appropriate error detection and correction, redundancy and back-up features to prevent such an occurrence.

Xicor's products are not authorized for use in critical components in life support devices or systems.

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
