

Low Power, 5V μ P Reset - Active LOW, Push-Pull Output

General Description

The ASM1810 is a voltage supervisor with low-power, 5V μ P active LOW Reset, Push-Pull output. Maximum supply current over temperature is a low 20 μ A.

The ASM1810 generates an active LOW reset signal whenever the monitored supply is out of tolerance. A precision reference and comparator circuit monitor power supply (V_{CC}) level. Tolerance level options are 5%, 10% and 15%. When an out-of-tolerance condition is detected, an internal power-fail signal is generated which forces an active LOW reset signal. After V_{CC} returns to an in-tolerance condition, the reset signal remains active for 150ms to allow the power supply and system microprocessor to stabilize.

The ASM1810 is designed with a push-pull output stage and operates over the extended industrial temperature range. Devices are available in low cost TO-92 and compact surface mount SOT-23 packages.

Other low power products in this family include the ASM1811/12/15/16/17, ASM1233D and ASM1233M.

Key Features

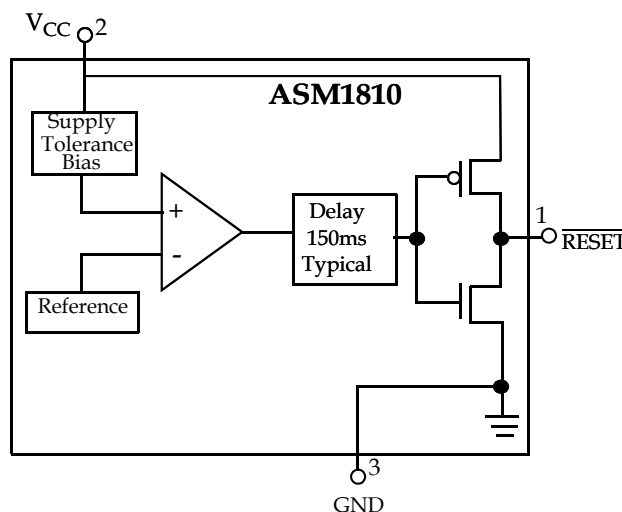

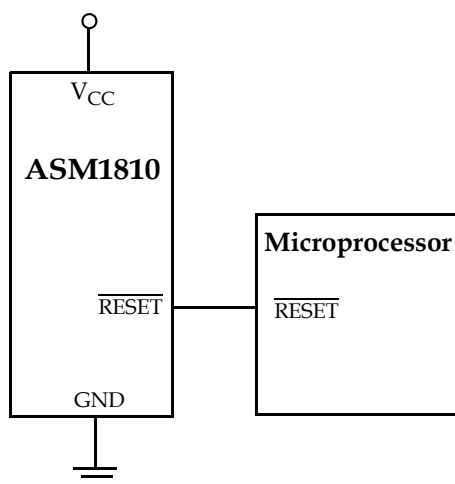

- Low Supply Current
• 20 μ A maximum (5.5 V)
- Automatically restarts a microprocessor after power failure
- 150ms reset delay after V_{CC} returns to an in-tolerance condition
- Active LOW power-up reset
- Precision temperature-compensated voltage reference and comparator
- Eliminates external components
- Low cost TO-92 and compact surface mount SOT-23 package
- Push-Pull output for minimum current drain
- Operating temperature -40°C to +85°C

Applications

- Set-top boxes
- Cellular phones
- PDAs
- Energy management systems
- Embedded control systems
- Printers
- Single board computers

Application Information

Operation - Power Monitor

The ASM1810 detects out-of-tolerance power supply conditions. It resets a processor during power-up, power-down and issues a reset to the system processor when the monitored power supply voltage is below the reset threshold. When an out-of-tolerance V_{CC} voltage is detected, the $\overline{\text{RESET}}$ signal is asserted. On power-up, $\overline{\text{RESET}}$ is kept active (LOW) for approximately 150ms after the power supply voltage has reached the selected tolerance. This allows the power supply and microprocessor to stabilize before $\overline{\text{RESET}}$ is released.

Figure 1: $\overline{\text{RESET}}$ Valid to 0V V_{CC}

Output Conditions

The ASM1810 active LOW reset signal is valid as long as V_{CC} remains above 1.2V. However the $\overline{\text{RESET}}$ output on the ASM1810 uses a push-pull drive stage that can maintain a valid output below 1.2V. To sink current with V_{CC} below 1.2V, a resistor can be connected from the reset pin ($\overline{\text{RESET}}$) to Ground (see Figure 1). This configuration will give a valid value on the $\overline{\text{RESET}}$ output with V_{CC} approaching 0V. During both power up and down, this configuration will draw current when the $\overline{\text{RESET}}$ is in the high state. A value of 100kΩ should be adequate to maintain a valid connection.
