

# AN2426 Application note

Auxiliary power supply with VIPer53EDIP

## 1 Introduction

This document describes the reference design of the 25W Switch Mode Power Supply which is dedicated to industrial or white goods applications. The board accepts wide range input voltages (90 to 265Vrms) and delivers 2 or 3 output voltages depending on the version. Two types of power supply are available: negative output or positive output voltage. The actual version depends the way the components are assembled on the secondary side and on the configuration of jumpers. On the primary side, the PCB and transformer are the same for both versions. More information is available in *Chapter 3*. The Switch mode power supply is based on the VIPer53E. The VIPer53E combines in the same package an enhanced current mode PWM controller with a high voltage MDMesh Power Mosfet. High efficiency and low standby consumption are the main characteristics of this board. Such features, coupled with minimal part requirements and global low cost in addition to, makes it an ideal solution for powering industrial or consumer equipment, meeting worldwide standards.

## 2 Main characteristics

The main characteristics of the SMPS are listed below:

- Input voltage: Vin: 90-265Vrms
- Frequency 45-66Hz
- Output voltages are given in *Table 1*, and 2:
- Standby consumption: <1 Watt
- Short circuit protection: on all outputs with auto-restart at short removal
- EMI according to:EN55022 Class B.

#### Table 1. Output voltages, positive version

V <sub>OUT</sub>	I <sub>OUT</sub>	P <sub>MAX</sub>	Stability
3.3V	100mA	330mW	2%
5V	ЗA	15W	5%
12V	0.8A	9.6W	15%
P <sub>OUT</sub> = 24.93W			

#### Table 2. Output voltages, negative version

V <sub>OUT</sub>	I <sub>OUT</sub>	P <sub>MAX</sub>	Stability
-5V	3A	15W	5%
-12V	0.8A	9.6W	15%
P <sub>OUT</sub> = 24.6W			

## 3 Circuit description

The converter topology of this SMPS is the fly-back, working in continuous and discontinuous conduction mode. The core of this design is the primary controller VIPer53EDIP, integrating the controller and a Power Mosfet in a single, standard DIP-8 package. The device integrates all the functions needed to control and protect a power supply, giving a modern, compact and cheap solution to SMPS designs. If an SMT mounting is required, a PowerSO-10 version is also available (VIPer53ESP).

The operating frequency of the circuit (~60kHz) has been chosen in order to obtain a compromise between the transformer size and the input filter complexity. Frequency modulation has been implemented on the input of VIPer53E to reduce electromagnetic interferences on the SMPS. Thus, the EMI input filter can be a simple LC-filter consists of CMC and two X2 capacitors, for differential and common mode noise. The input of SMPS is protected against inrush peak current by an NTC. In case any catastrophic failures a standard 5 x 20mm fuse disconnects the SMPS from mains. The transformer reflected voltage is ~73V, which provides enough room for the leakage inductance voltage spike and leaves enough margin of reliability. The D4 diode and the D5 transil, clamp the leakage inductance voltage spike, assuring reliable operation of the Viper53EDIP.

The transformer is manufactured by TDK, and designed according to the safety standard EN60950. It has two secondary windings, which provide 5 and 12V or -5 and -12V, and an additional winding which provides the supply voltage for the VIPer53EDIP.

This power supply can generate positive or negative output voltages depending on the configuration of the jumpers. Jumpers J1, J2, J5 and J7 have to be assembled for the positive version of the power supply, whilst jumpers J3, J4, J6 and J8 have to be assembled for the negative version. It is also mandatory to change polarity of the output electrolytic capacitors: C9, C10, C11, C13 and C14. Diode D6 is found on the secondary side of the positive power supply, whilst diode D7 is found on the negative side. The polarization of the diode D8 has to be also changed. The positive power supply can generate a voltage of 3.3V from the linear regulator U4.

The output rectifiers have been chosen in accordance with the maximum reverse voltage and their power dissipation. The 5V and –5V rectifier is a Schottky barrier, type STPS1045D0. It is assembled in an axial TO220 package. The 12V and –12V rectifier is a Schottky barrier, type STPS2H100. It is assembled in an SMD package. This rectifier has low forward voltage drop, therefore it improves efficiency as it has a lower power dissipation in comparison with a standard type. A small LC filter has been added on both outputs in order to filter the high frequency ripple without increasing the output capacitors size or quality. Output voltage regulation is performed by secondary feedback, which monitors the 5V output. The feedback network is a classical one, which uses a TL431 and optocoupler. It assures the required insulation between the primary and secondary sides. The optotransistor drives the COMP pin of the Viper53EDIP, directly. Capacitor C6 and resistor R4 are parts of the compensation loop filtering the high frequency noise.

The VIPer53EDIP is activated at start-up by an internal current source, charging capacitor C7 from the DC bus via the Drain pin. As a result of this circuit, the start-up time is short and independent from the mains voltage input. During normal operation the device is powered by the transformer via the LEB circuit (Q1, C8, D3 and R5) and the D2 diode. The LEB circuit filters leakage inductance spikes, i.e. it blanks the spike appearing at the leading edges of the voltage which are generated by the self-supply winding. These spikes, which are due to inductance leakage from the transformer, are the major cause of raised  $V_{CC}$ 

voltages at high load. This circuit also helps to keep the max  $V_{CC}$  voltage under control if the transformer has a high leakage inductance across the auxiliary.

The switching frequency is selected by resistor R3 and capacitor C4. Capacitor C5 provides a delay to the current protection intervention, the so called TOVL function.

*Figure 3*, *Figure 4* and *Figure 5* show the drain voltage and current at nominal mains voltage input during normal operation at full load. Clearly the current peak is below the maximum current peak defined in the VIPer53 datasheet. The drain voltage rise time is around 120ns. *Figure 3* shows the drain peak voltage at full load and maximum mains voltage input. The measured voltage of 564V, assures reliable operation of the Viper53 MOSFET with a good margin of the maximum break down voltage BV<sub>DSS</sub> (620V).

Figure 3. Drain voltage and current at V<sub>IN</sub> = 90VAC - 50Hz and full load

## 4 Cross regulation and stand by

The following tables show the output voltages for both positive and negative version of power supplies, in addition to the overall efficiency of the converter measured at different input voltages. All the output voltages have been measured on the output connector. It should be noted that the 5V output is regulated. The 12V output is influenced by load of 5V branch. If the 5V voltage branch is not loaded typically the voltage on the 12V branch fall rapidly down.

## 5 Functional checking

## 5.1 Stand by

The consumption reduction is requested at low load or stand by mode. This request is completely fulfill thanks burst mode of operation implemented in the VIPer53. When the VIPer53 detects a light load, it operates automatically in burst mode. VIPer53 monitors the voltage on pin 1 (Comp) and if this voltage remains lower than 0.5V the device stops switching cycles. It starts switching cycles again as soon as the voltage on pin 1 increases to greater than 0.5V. In this way, the output voltage is always under control and the device is ready to start. *Figure 9* shows power consumptions of positive and negative version of power supplies during stand-by. *Figure 10* shows the main waveforms in stand-by operation.

Figure 10. Device voltages in stand by operation

Ch1: VPIN5 (Drain) Ch3: VPIN2 (Osc) Ch2: VPIN1 (Comp) Ch4: VPIN7 (V<sub>DD</sub>)

## 5.2 Short-circuit tests

The VIPer53 contains two overload protections. The first one is undervoltage detection on the V<sub>DD</sub> pin. The second one depends on the voltage on the COMP pin connected to the optocoupler. This protection protects the power supply also against the feedback loop disconnection. When V<sub>COMP</sub> goes above 4.4 V, the capacitor connected on the TOVL pin begins to charge. When reaching typically 4 V (V<sub>OVLth</sub>), the internal mosfet driver is disabled and the device stops switching. This state is latched thanks to the regulation loop which maintains the COMP pin voltage above the V<sub>COMPovI</sub> threshold. Since the V<sub>DD</sub> pin doesn't receive any more energy from the auxiliary winding, its voltage drops down until it reaches V<sub>DDoff</sub> and the device is reset. If V<sub>COMP</sub> goes below the OVL threshold till the TOVL pin does not reach the V<sub>OVLth</sub> level, normal operation conditions are resumed. It is important to note that the maximum Peak Drain Current value to consider for design purposes is the I<sub>DMAX</sub>, also called Drain Current Capability. The I<sub>DMAX</sub> is the maximum Drain Current that does not trigger overload protection and defines the maximum power output that the power supply can deliver.

All tests have been performed at minimum, nominal and maximum input voltage. Short circuit tests have been also made for negative version of power supply and are shown in *Figure 11, Figure 12, Figure 13, Figure 14*, and *Figure 15*. Only the most significant positive power supply images are shown (figures *11* to *15*).

When a short occurs the controller enters hiccup mode, and works only for a short period as shown in figures 11 to 15. This behavior limits the average power dissipation of all devices, preventing dangerous overheating and catastrophic failure of the SMPS.

## 5.3 Start-up behavior at full load

The figures 17, 18, 19 and 20 display the rising slopes of output voltages. The measurements were perform at full load and for different input voltages (90VAC and 230VAC). As shown in figures 17 to 20, rising time is monotonic and it is almost constant over all the mains input ranges. No overshoot or abnormal behavior is apparent.

## 5.4 Wake-up time

The wake-up time is the time needed for the power supply to deliver the nominal output voltages once it has been plugged-in the mains. During wake up time the external capacitor on the V<sub>DD</sub> pin is charged at about 9mA. When V<sub>DDoff</sub> is reached, the charging current is reduced down to I<sub>DDch2</sub> which is about 0.6mA. This lower current leads to a slope change on the V<sub>DD</sub> rise.

Figures 21 to 24 show the wake up time of the power supply. It is clear that no overshoot, undershoot or loss of control occurs during the power supply wake up time.

Figure 21. Wake-up time, positive version of power supply at  $V_{IN}$  = 90VAC

Ch1: VPIN5 (Drain) Ch2: 5V level Ch3: 12V level Ch4: VPIN7 (V<sub>DD</sub>)

Ch1: VPIN5 (Drain) Ch2: -5V level Ch3: -12V level Ch4: VPIN7 (V<sub>DD</sub>)

## 5.5 Power down

Figures 25 to 28 present the output voltages at converter switch off. All voltages fall at the same time, because the converter doesn't deliver any more energy. However, the slopes are individually driven by the output capacitors and the output current.

Figure 25. Power down, positive version of power supply at  $V_{IN}$  = 90VAC

Ch1: VPIN5 (Drain) Ch2: VPIN7 (V\_{DD}) Ch3: 5V level Ch4: 12V level

Ch1: VPIN5 (Drain) Ch2: VPIN7 (V\_{DD}) Ch3: –5V level Ch4: –12V level

## 5.6 Overvoltage protection

The open-loop fault is a very dangerous, event which could happen as a result of feedback circuitry failure. If this occurs, the SMPS output voltages can rise causing the rectifiers and output capacitors to be overstressed, destroyed or even catch fire. However, this depends on the load of each output and the transformer coupling between the windings. The safety rules requests that the SMPS has to have suitable protection against such risks. The Viper53 has an integrated overvoltage comparator. The non inverting pin of the overvoltage comparator is connected to the  $V_{\text{DD}}$  pin. If the  $V_{\text{DD}}$  voltage reaches the  $V_{\text{DD}}$ ovp the Viper53EDIP stops operations.

The SMPS has been tested with opening the feedback loop. Measured data are shown in tables *11* and *12*.

# Table 11. Output voltages with open feedback loop - positive version of power supply

V <sub>IN</sub> 230VAC 50Hz	Stand by	Full load
3.3V	3.30V	3.28V
5.0V	8.29V	5.88V
12.0V	18.18V	13.71V

# Table 12. Output voltages with open feedback loop - negative version of power supply

V <sub>IN</sub> 230VAC 50Hz	Stand by	Full load
–5.0V	-8.47V	-6.06V
-12.0V	-18.35V	-14.22V

## 5.7 Output ripple voltage at full load

Figures 29 and 30 present the ripple voltage at switching frequency measured at 90VAC on the input. As shown, ripple voltage spikes are in line with power-supply specifications mainly thanks LC filters added on the outputs of positive and negative version of power supplies.

Figure 29. Ripple voltage at switching frequency, positive version of power supply

Ch2-5V level Ch3: -12V level

## 6 Conducted noise measurements

The following figures display the conducted noise measurements at full load when a mains voltage of 230VAC was applied on the input. The measurement was made in accordance with EN55022 CLASS B using Peak and Average detection. The diagrams clearly indicate a good margin of all measurements with respect to their limits.

Figure 31. Conducted noise measurements Phase A - positive version of power supply, peak detection

## 9 Transformer specification

- Application type: Consumer, Home Appliance
- Transformer type: Open
- Coil former: Vertical type 5 + 5 pins
- Maximum temperature rise: 45°C
- Maximum operating ambient temperature: 60°C
- Main insulation: Acc with EN60065.

## 9.1 Electrical characteristics:

- Converter topology: Flyback, CCM/DCM Mode
- Core type: EER28 PC40 or equivalent
- Typical operating frequency: 60kHz
- Primary inductance: 600µH ±10% at 10kHz 1V <sup>(a)</sup>
- Leakage inductance: 32µH MAX at 10kHz 1V <sup>(b)</sup>
- Maximum peak primary current: 1.4 Apk
- RMS primary current: 0.45 ARMS.

b. Measured between pins 1-3 with all secondary windings shorted.

a. Measured between pins 1-3
