

Features

- Read Access Time - 120 ns
- Word-wide or Byte-wide Configurable
- Dual Voltage Range Operation
 - Unregulated Battery Power Supply Range, 2.7V to 3.6V
 - or Standard 5V \pm 10% Supply Range
- 8-Megabit Flash and Mask ROM Compatible
- Low Power CMOS Operation
 - 20 μ A Maximum Standby
 - 10 mA Max. Active at 5 MHz for V_{CC} = 3.6V
- JEDEC Standard Packages
 - 44-Lead PLCC
 - 44-Lead SOIC (SOP)
 - 48-Lead TSOP (12 mm x 20 mm)
- High Reliability CMOS Technology
 - 2,000 ESD Protection
 - 200 mA Latchup Immunity
- Rapid™ Programming Algorithm - 50 μ s/word (typical)
- CMOS and TTL Compatible Inputs and Outputs
 - JEDEC Standard for LVTTTL and LVBO
- Integrated Product Identification Code
- Commercial and Industrial Temperature Ranges

Description

The AT27BV800 is a high performance low-power, low-voltage 8,388,608-bit one time programmable read only memory (OTP EPROM) organized as either 512K by 16 or 1024K by 8 bits. It requires only one supply in the range of 2.7 to 3.6V in normal read

mode operation. The x16 organization makes this part ideal for portable and hand held 16- and 32-bit microprocessor based systems using either regulated or unregulated battery power.

Atmel's innovative design techniques provide fast speeds that rival 5V parts while keeping the low power consumption of a 3V supply. At $V_{CC} = 2.7V$, any word can be accessed in less than 120ns. With a typical power dissipation of only 10 mW at 5mHZ and $V_{CC} = 3V$, the AT27BV800 consumes less than one fifth the power of a standard 5V EPROM.

Standby mode supply current is typically less than 1 mA at 3V. The AT27BV800 simplifies system design and stretches battery lifetime even further by eliminating the need for power supply regulation.

The AT27BV800 can be organized as either word-wide or byte-wide. The organization is selected via the \overline{BYTE}/V_{PP} pin. When \overline{BYTE}/V_{PP} is asserted high (V_{IH}), the word-wide organization is selected and the O15/A-1 pin is used for O15 data output. When \overline{BYTE}/V_{PP} is asserted low (V_{IL}), the byte wide organization is selected and the O15/A-1 pin is used for the address pin A-1. When the AT27BV800 is logically regarded as x16 (word-wide), but read in the byte-wide mode, then with $A-1=V_{IL}$ the lower eight bits of the 16 bit word are selected with $A-1=V_{IH}$ the upper 8 bits of the 16-bit word are selected.

The AT27BV800 is available in industry standard JEDEC-approved one-time programmable (OTP) PLCC, SOIC (SOP), and TSOP packages. The device features two-line control (\overline{CE} , \overline{OE}) to eliminate bus contention in high-speed systems.

With high density 512K word or 1024K-bit storage capability, the AT27BV800 allows firmware to be stored reliably and to be accessed by the system without the delays of mass storage media.

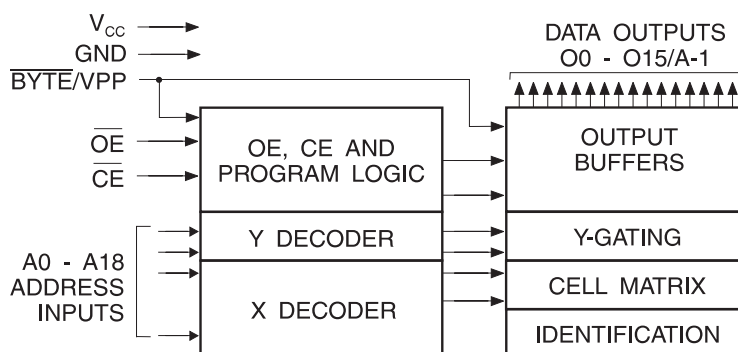

The AT27BV800 operating with V_{CC} at 3.0V produces TTL level outputs that are compatible with standard TTL logic devices operating at $V_{CC} = 5V$. At $V_{CC} = 2.7V$, the part is compatible with JEDEC approved low voltage battery operation (LVBO) interface specifications. The device is also capable of standard 5-volt operation making it ideally suited for dual supply range systems or card products that are pluggable in both 3-volt and 5-volt hosts.

Atmel's AT27BV800 has additional features that ensure high quality and efficient production use. The Rapid™ Programming Algorithm reduces the time required to program the part and guarantees reliable programming. Programming time is typically only 50µs/word. The Integrated Product Identification Code electronically identifies the device and manufacturer. This feature is used by industry standard programming equipment to select the proper programming equipment and voltages. The AT27BV800 programs exactly the same way as a standard 5V AT27C800 and uses the same programming equipment.

System Considerations

Switching between active and standby conditions via the Chip Enable pin may produce transient voltage excursions. Unless accommodated by the system design, these transients may exceed data sheet limits, resulting in device non-conformance. At a minimum, a 0.1 µF high frequency, low inherent inductance, ceramic capacitor should be utilized for each device. This capacitor should be connected between the V_{CC} and Ground terminals of the device, as close to the device as possible. Additionally, to stabilize the supply voltage level on printed circuit boards with large EPROM arrays, a 4.7 µF bulk electrolytic capacitor should be utilized, again connected between the V_{CC} and Ground terminals. This capacitor should be positioned as close as possible to the point where the power supply is connected to the array.

Storage Temperature	-65°C to +150°C
Voltage on Any Pin with with Respect to Ground	-2.0V to +7.0V ⁽¹⁾
Voltage on A9 with Respect to Ground	-2.0V to +14.0V ⁽¹⁾
V _{PP} Supply Voltage with Respect to Ground	-2.0V to +14.0V ⁽¹⁾

***NOTICE:** Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Note: 1. Minimum voltage is -0.6V DC which may undershoot to -2.0V for pulses of less than 20 ns. Maximum output pin voltage is V_{CC} + 0.75V DC which may overshoot to + 7.0V for pulses of less than 20 ns.

- Notes:**
1. X can be V_{IL} or V_{IH}.
 2. Read, output disable, and standby modes require, 2.7V ≤ V_{CC} ≤ 3.6V, or 4.5V ≤ V_{CC} ≤ 5.5V.
 3. Refer to the programming characteristics tables in this data sheet.
 4. V_H = 12.0 ± 0.5V.
 5. Two identifier words may be selected. All Ai inputs are held low (V_{IL}) except A9, which is set to V_H, and A0, which is toggled low (V_{IL}) to select the Manufacturer's Identification word and high (V_{IH}) to select the Device Code word.
 6. Standby V_{CC} current (I_{SB}) is specified with V_{PP} = V_{CC}. V_{CC} > V_{PP} will cause a slight increase in I_{SB}.

Rapid Programming Algorithm

A 50 μs $\overline{\text{CE}}$ pulse width is used to program. The address is set to the first location. V_{CC} is raised to 6.5V and $\overline{\text{BYTE}}/\text{VPP}$ is raised to 13.0V. Each address is first programmed with one 50 μs $\overline{\text{CE}}$ pulse without verification. Then a verification/reprogramming loop is executed for each address. In the event a word fails to pass verification, up to 10 successive 50 μs pulses are applied with a verification after each

pulse. If the word fails to verify after 10 pulses have been applied, the part is considered failed. After the word verifies properly, the next address is selected until all have been checked. V_{PP} is then lowered to 5.0V and V_{CC} to 5.0V. All words are read again and compared with the original data to determine if the device passes or fails.
